2. I have sent for a tested queen of last year's rearing, as there are no drones to fertilize the virgin queen. Shall I kill the virgin queen a couple of days before I introduce the new queen, or shall I kill her at the same time I introduce the new queen?
Iowa.

ANSWER.—1. In an ordinary case of superseding, preparations for the rearing of a queen are made while the old queen is doing duty, the old queen continuing to lay until the young queen emerges, and in some cases even longer, one or more queen-cells being constructed in the same manner as when preparations are made for swarming. As you relate the case, there seems to have been no brood in the hive at the time the young queen emerged, so all laying must have stopt with the laying of the egg from which the young queen was reared. This would hardly fall under the head of ordinary supersedeure.

2. It may be better to kill the queen a day or two before the introduction of the stranger, altho if introduced in the way instructions are generally given when the queen is sent, the bees being allowed to liberate the queen by eating thru the candy, there would be little risk in killing the virgin at the time the new queen is put in the hive.

Double-Deck Management—Controlling Swarming.

1. For the benefit of a whole host of readers of the American Bee Journal, will you not please give a detailed account of the management of an apiary on the "double-deck" plan? Also, how you manage to control swarming by placing the queen in a nucleus on the hive? MICH.

ANSWER.—It is by no means an easy thing to tell you about any management that is constantly changing, but I'll try to tell you what I do with two-story hives, which is not a very long story. I use 8-frame hives, and the great desideratum is to get colonies as strong as possible for white clover, which is the first, and about the only thing, upon which I depend for surplus, for I am not in a rich honey region. At no time is a queen allowed to be crowded for room. Whenever there is danger of that a second story is added. It may be added long before that. For the added story is always put underneath the story with the brood-nest, and it takes away none of the heat of the upper story to have another story under it. On the other hand it would

take away a great deal of heat from the brood-nest to have an empty hive placed over it.

This added under story is a nice place to put combs that have a little honey in them, always having a sharp eye on robbers; and wormy combs, or combs in danger of becoming wormy can hardly be in any safer place. When the colony becomes crowded above, it will of its own accord work its way down into the lower story. Sometimes, in order to hurry up matters, a comb of brood is taken from the upper story and put in the lower story, but such a thing is not advisable until there is brood in all the eight frames above. The comb so moved is taken from one side of the upper story, putting a frame from below in its place, thus leaving no gap to be filled above, for putting the comb below is all the spreading they ought to stand.

That's about all that's peculiar to the plan (and there's nothing very peculiar about that) up to the time of putting on supers. I have tried leaving strong colonies with two stories when putting on supers, and one poor season the only colony that workt in a super was a two-story colony, but in general I have not obtained good results by leaving the two stories. So one story is taken away, and a super put on within a few days after I see the very first stray clover blossom. This first blossom appears before the general bloom, and I can generally count that the bees will not begin to store until about 10 days later, and it is well to have a super on 3 or 4 days before it is needed for storing. The first super always has at least one bait-section, and at least that one section is promptly occupied.

At the time of putting on supers, the strongest colonies may have 12, 13, and in very rare cases even 16 frames with brood in them. Eight of the best of these frames are left, the others taken away, of course taking no bees with them. Any colonies that have less than 8 frames of brood are brought up to the 8, and whatever of surplus brood there may be is piled up on some of the weakest colonies, making them 4 or 5 stories high. These can then be used for increase or otherwise as desired. When the supers are taken off, a second story may be given, but in this case it is given above with an excluder between, so that it can be easily taken away before time for cellaring. If the colonies were to be wintered outdoors, very likely each one would have a second story put under upon removal of supers, and the two stories left till the time of putting on supers the next year.

The plan of managing swarms by "putting up" the queen over the hive is a good one where there is any one on hand to watch for swarms, and the queens are cleft, and is given in "A Year Among the Bees," as follows:

"When a swarm issues and returns, it is ready for treatment immediately; altho usually it is put down in my memorandum of work to be done, and the time set for it may be the next day or any time within 5 days, just as suits my convenience. The queen is caged at the time of swarming, and put in the vacant part of the brood-chamber—possibly in the upper part of a super—where the bees can care for her.

"Within the 5 days, I take off the super, and put most of the brood-combs into an empty hive. Indeed, I may take all the brood-combs, for I want in this hive all the combs the colony should have. In the hive left on the stand, I leave or put from one to three frames, generally two. These combs must be sure to have no queen-cells, and may be most safely taken from a young or weak colony having no inclination to swarm. The two combs are put in the south side of the hive, a division-board and dummy next to them, and the supers again put on. If I did not do so at the time of taking out the frames, I now shake off the bees from about half the frames, not being particular to shake them off clean. This hive is then put on the top of the supers, the queen let free on top of the frames, and the hive covered up. A plenty of bees will be left to care for the brood, the queen will commence laying, all thought of swarming is given up, and every queen-cell torn down by the bees. In perhaps two days I take a peep to see if the queen is laying, for it sometimes happens that at the time when I 'put up the queen,' as I call the operation I have just described, there is already a young queen just hatcht, and then the old queen is pretty sure to be destroyed. In this latter case I may remove the young queen and give them a laying one, or I may let the young queen remain.

"In 10 days from the time the swarm issued—sometimes 10 days from the time I 'put up the queen'—I put down the queen. If, by chance, a young queen is in the upper hive, I do not like to put her down until she commences laying and her wing is cleft, for fear of her taking out a swarm. It seems a foolish operation for them to

swarm when there is nothing in the hive from which a queen can be reared, but I have had it happen. The operation of putting down is very simple. I lift the hive off the top, place it on the ground, remove the supers, take the hive off the stand, place it on one side, put the hive containing the queen on the stand, and replace the supers. At the time I put up the queen I changed the number-tag, so as to keep the number always on the hive containing the queen.

"You will see that this leaves the queen full chance to lay from the minute she is uncaged, and at the time of putting down there will be as much brood as if the queen had remained in her usual place. Most of the bees, of course, adhered to the lower hive when the queen was put up, but by the time she is put down quite a force has hatched out, and these have marked the upper hive as their location. Upon this being taken away, the bees, as they return from the field, will settle upon the cover, where their hive was, and form a cluster there; finally an explorer will crawl down to the entrance of the hive below, and a line of march in that direction will be established immediately. In a day or two they will go straight to the proper entrance.

"We left, standing on the ground, the hive with its two combs, which had been taken from the stand. These two combs, when the queen was put up, probably had a good quantity of eggs, and brood in all stages. They now contain none but sealed brood, some queen-cells and a pretty heavy supply of pollen. Or, it may be that eggs from an imported queen were given, and the queen-cells are to be saved. A goodly number of bees adhere to the two combs and I know of no nicer way to start a new colony, than simply to place the hive in a new location. Or, the bees may be shaken off at the old stand and the combs used again to do duty as they have done during the last 10 days, or given to a nucleus which needs them.

"It may be objected that this keeping bees queenless for 10 days makes them work with less vigor. I am not sure but it ought, but I must confess I have had no strong proof of it come directly under my own observation. So far as I could tell, these bees seemed to work just as hard when their queen was taken away as before. In the spring of 1885 one colony was, by some means, left entirely away from the proper rows—some 3 rods from any other colony. I took it away, put it in proper line, and left to catch the returning stragglers a hive containing one comb, this comb having no brood and very little if any honey. This colony having been a very weak one, very few bees returned to the old spot, but these few surprised me by filling a good stock of honey in empty comb, before they were put with the rest of the colony.

"Swarms treated on this 'putting up' plan often swarmed again, but if they did they were put up again. An objection to the plan was that these 'put-ups' were in the way and had to be lifted down when anything was done with supers. Still, for any one who allows the bees to swarm, and who does not object to the lifting, the plan is a good one."

Bee-Paralysis.

Can a colony of bees contract the disease known as paralysis from a comb taken from a diseased colony and given to a healthy colony? WISCONSIN.

ANSWER.—I don't know. We seem to know very little about bee-paralysis. But it's a good plan to be on the safe side.

Alfalfa and Cottonwood.

1. Does alfalfa fail to yield nectar where it is irrigated?
2. What would be a fair average when three crops per year are cut?
3. Is cottonwood a good honey-producing tree?

NEW YORK.

ANSWER.—1. I think no one has reported a failure wherever irrigation has been practiced, as is the case in the West. The reports of failure seem to come from places farther east, but whether irrigation or the lack of irrigation has anything to do with failure is a question.

2. I don't know how much honey can be obtained from a given area of alfalfa. That's a hard thing to tell about any honey-plant. Alfalfa is counted a great yielder, but there is no close agreement as to the amount yielded. It has even been estimated that two or three acres are needed for each colony. With three crops of hay taken in a season, much would depend upon the time of the cutting. If cut

each time just before the bloom was far enough advanced for the bees to work on it, not much nectar could be expected.

3. I don't know. The fact that little or nothing has been said about it as a honey-tree makes it doubtful whether it has much value. Who can tell us?

"A Good Feeder.—An ordinary frame partly enclosed with a board on each side, so as to hold the syrup used in feeding, with a slip of wood floating on the syrup so bees need not drown."—Australian Bee Bulletin.—That's the Doolittle frame-feeder, with a float added, the float not being needed in the least, and sometimes a damage.

Clipping Queens had some discussion in the Ontario convention, as reported in the Canadian Bee Journal. Mr. McKnight said the only advantage of clipping that he could see was to prevent the queen flying away; it did not prevent her being lost. Mr. Hall thought he would have his work greatly increased with unclipped queens. Clipping helps to tell the age of a queen. While working in his shop he may see a swarm out, and he is in no haste to drop his tools and run. He knows the queen is clipped, and sometimes several swarms are out at a time.

Reformed Spelling is a tabooed subject in Gleanings in Bee-Culture, but Dr. Miller gives this parting shot in a stray straw:

"It cost me several years of close application to spell the old way," says Rambler. That's about as strong an argument as I ever saw against the old way. A man with Rambler's heart ought to be willing to suffer a little inconvenience rather than have all future generations work as he and I did to learn to spell. We may just as well own up that the objection to Bro. York's spelling is prejudice pure and simple. His way of spelling 'through' sends a chill thru me. But an Englishman has the same chill when he meets 'honor' without a 'u' in it, and will not read a book, much less buy it, if that 'u' is omitted, according to a writer in the Sunday School Times."

Gladiolus and Dahlia are highly recommended in one of the foreign journals as honey-plants. It is somewhat noticeable that these and many other flowering plants are prominently mentioned in bee-journals in other languages, but not mentioned in American bee-papers. Some of these plants are so rich in nectar that it may be seen falling in drops. But there is a good reason for silence regarding them. Take the abutilon, highly valued as a house-plant. Drops of nectar may be seen falling from it so rich that it might be called honey rather than nectar. If one could have an acre of such plants it would mean quite a crop of honey. But the honey obtained would probably not go very far toward purchasing plants for an acre, to say nothing about planting and cultivating. The only wonder is that foreign journals give so much space to such plants.

Starved Brood.—A Canadian bee-keeper had trouble with some kind of dead brood in his colonies. He tried the starvation plan, as for foul brood, and melted up scores of combs, but the trouble still continued. Wm. McEvoy replies to him in the Canadian Bee Journal, urging that it is not always enough to have plenty of honey in the hive, there must be unsealed honey. He says:

"Your colonies ran out of unsealed honey when they had a large quantity of brood on hand to feed, and then your bees did not uncap the sealed stores fast enough to keep pace with the amount of brood that required feeding, the result being that considerable brood had to die thru not being fed. And for some time after that the brood would suffer in proportion to the length of time that the brood-nest was out of unsealed stores, and end in an increase of starved brood, which the bees would allow to remain in the combs for some time after the honey-flow commenced. You never would have found one cell of dead brood in any of your colonies if you had kept them well supplied with unsealed stores."

VOL. 40. APRIL 26, 1900. NO. 17.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

The Brosius Pure-Food Bill.—Rev. Emerson T. Abbott, we learn from the St. Joseph (Mo.) Daily Gazette, has been appointed a member of the legislative committee of the National Pure Food and Drug Congress. Mr. Abbott's duties will consist in creating sentiment and bringing influence to bear on the members of the United States congress from Missouri in favor of the Brosius pure-food bill. He was appointed by J. E. Blackburn, president of the Pure Food and Drug Congress, upon the recommendation of Dr. H. W. Wiley, and after consultation with the secretary and assistant secretary of agriculture. Mr. Abbott has been signally honored, and will undoubtedly give a good account of himself, as he is an earnest advocate of pure-food legislation. It is also a splendid thing for honey-producers to have such an able representative, and one of their own number, besides. We trust that Mr. Abbott will have the hearty co-operation of all in his work.

LATER.—Since the foregoing was written we have received a copy of a letter which Mr. Abbott has address to the two Missouri members of the Inter-State Commerce Committee, in whose hands the "Brosius Bill" is at the present time:

ST. JOSEPH, Mo., April 16, 1900.

MY DEAR SIR:—I have been appointed by the National Pure Food and Drug Congress a member of the Leg-

islative Committee, whose duty it is to look after the interests and urge the passage of the measure which is endorsed by the Food Congress, and known as the "Brosius Bill." This bill is now before the committee of which I believe you have the honor to be a member, and I desire to urge upon you the importance of giving it your hearty support, and also the importance of doing what you can to secure an early and favorable report on the same by your committee. It seems to me that the "Brosius Bill" should have the unqualified support of every man who believes in common honesty and the right of a purchaser to get the thing for which he pays his money when he makes a purchase. I do not believe that any one who manufactures or deals in adulterated goods will have the temerity to deny the proposition that when a man pays his money for an article he is entitled to know fully what he is getting in return for his money. This being true, every article of commerce should be plainly and clearly labeled in a manner that will fully explain what it is, and the manufacturer should be held responsible to society and the purchaser if any article does not prove to be in every respect what it claims to be. This is all that the "Brosius Bill" asks, and without any disposition to reflect on other bills now asking for recognition at the hands of the national law-makers, I desire to say that, in my opinion, this is one of its strong points. We are not asking in the "Brosius Bill" that any legitimate industry be destroyed, or even hampered, but only what common honesty between man and man demands.

You will find it necessary to contend with two adverse influences in your attempt to aid this measure in becoming a law, viz.: the opposition of a class of people who think the "Brosius Bill" is not drastic enough, and does not protect "our industry" enough—a selfish motive; and another class of people who want to secure the money of their fellow men by dishonest methods, and therefore are opposed to any kind of pure-food legislation.

As to the first influence, I call your attention to the fact that the "Brosius Bill" has the unqualified endorsement of the National Pure Food and Drug Congress, which, as you are probably aware, is composed of representative men of nearly all of the productive industries of the United States—men who are not influenced by any selfish motives, and who only ask that the present generation, and the generations who are yet to come after them, be protected from fraud and deceit. The bill also has the endorsement of the present Secretary of Agriculture, whose good judgment and disinterested enthusiasm for the peoples' interests along these lines is not questioned by even his political opponents. As to the other opposition, I feel quite sure it will have no influence with you, as I am convinced that you recognize the fact that evil-doers should have nothing to do with shaping the laws of our great nation.

I am sanguine that this bill will have the endorsement of most, if not all, of the congressmen from our State, and that it will have the hearty support of the majority of the members of the House when it comes before them. Therefore, I again urge upon you, in conclusion, the importance of giving your influence to a favorable report by your committee at an early date. Trusting you will give this matter the attention its importance demands, I am, sir,

Very truly yours,

EMERSON TAYLOR ABBOTT,

Member Legislative Committee, National Pure Food and Drug Congress.

It is Mr. Abbott's intention to get a copy of the foregoing letter into the hands of each congressman from Missouri. He feels very certain that if all bee-keepers in the country would take the matter up at once and write a letter something like the one above, to each of their congressmen, the "Brosius Bill" would soon be a law.

If there is any one thing above another that we as bee-keepers should be deeply interested in, it is that of securing and enforcing anti-adulteration laws. Let us all bring every honorable effort and influence possible to bear in this matter, in order that honesty and the right may prevail.

"Bees and Horticulture: Their Relations Mutual" is the title of a 12-page pamphlet just issued by the National Bee-Keepers' Association, and edited by General Manager Eugene Secor, of Forest City, Iowa, from whom a copy may be had free on application.

As stated, "the purpose of the pamphlet is to put into

condens form, for the use of bee-keepers and fruit-growers, such information as is at hand, derived from experience and recent investigations, relating to the economy of nature in plant and insect life, and to show their mutual interdependence."

Extracts are taken from various reliable sources and put into handy form on the value of bees in the pollination of fruit-blossoms, for distribution among those who need to be informed along the lines indicated by the "purpose" of the pamphlet.

The subject of "Spraying Fruit-Trees" is also treated, followed by "Recent Laws on the Subject of Spraying."

It is just such a publication as has long been needed, and we trust every one interested will write Mr. Secor for one or more copies. If not already a member of the National Bee-Keepers' Association, we would advise every one to enclose \$1.00 for a year's dues when asking for a copy of the pamphlet referred to.

The Illinois Food Commission.—We called at the offices of the State Food Commission recently, and had an interview with Mr. E. N. Eaton, the State analyst. While they have begun their work to a certain extent, we presume the real test will come after July 1, when the new law takes effect.

In a measure, our Food Commission is exploring new ground, and it is their desire to go carefully but certainly and thoroly. They desire to establish principles that shall govern instead of enumerating specifically. For instance, the following are their

PRINCIPLES GOVERNING COLORING.

Harmless artificial coloring may be used for the sake of variety or uniformity, or in deference to demand of consumers in goods when such coloring is not used to conceal inferiority, to indicate strength, or to imitate a higher priced article.

The fact of artificial coloring need not be markt on the label—

- 1st. In pure goods of fixt composition. (Example—Mustard, spices.)
- 2nd. In goods sold under distinguishing names. (Example—Butter.)
- 3rd. In mixtures of indefinite composition sold and known under their own names. (Example—Catsup.)
- 4th. In goods with establishd standard of strength or quality. (Example—Lemon extract.)

COLORING FORBIDDEN.

MARKT.

- | | |
|-------------------------|---------------------------------------|
| Low wine vinegar. | Artificial extracts. |
| Grain and beer vinegar. | Cider vinegar, if mixt with low wine. |
| Vanilla extract. | Cherry phosphate. |
| Extract of vanalliu. | Fruit syrup. |
| Extract of cumarin. | Artificial jellies and jams. |
| Milk. | Prepared mustard. |
| Cream. | Canned goods. |
| Skim cheese. | |

COLOR ALLOWED WHEN UNMARKT.

- | | |
|------------------------|------------|
| Malt vinegar. | Mustard. |
| Cider vinegar. | Spices. |
| Lemon extract. | Butter. |
| Full-cream cheese. | Catsup. |
| Maple sugar. | Chow-chow. |
| Pure jellies and jams. | Chocolate. |
| Celery salt. | Candy. |

Mixtures and compounds are permissible when the cheaper ingredient serves some useful purpose, and is not added simply as a dilutent or cheapener. Examples:

ALLOWED.

FORBIDDEN.

- | | |
|-----------------------------|---------------------------|
| Coffee and chicory. | Mixt maple syrup. |
| Mixture molasses and syrup. | Mixt maple sugar. |
| Mixt wheat flour. | Compound cream-of-tartar. |
| Compound mustard. | "Compound" mixt spices. |
| Prepared cocoa. | Mixt vinegar. |
| Compound vanillas. | Diluted milk. |
| Mixt buckwheat flour. | Diluted lemon extract. |

Prepared by E. N. EATON, State Analyst.

Approved by A. H. JONES, Illinois Food Commissioner.

The foregoing principles, etc., were originated and approved this month, and so do not appear in the pamphlet

issued by the Commission some time ago. They will likely be incorporated in the next edition.

The rule governing honey at present is the following:

"Honey adulterated with glucose or any other substance not deleterious to health may be sold when labeled 'Adulterated Honey.'"

While this rule may practically prohibit the sale of adulterated honey, we believe that if honey were included in the last list markt "Forbidden," it would be more satisfactory to the general consuming public. There is really no valid reason for adulterating honey, and there is every good reason that its adulteration should be strictly forbidden. Surely, when any one desires to buy honey he wants *honey*—not the adulterated article. If the Food Commission wishes to allow the sale of the mixt article, we would suggest that it be markt or known by some other name—a name that does not contain the word "honey" at all. Then, if a consumer wishes to purchase the cheap mixture he will not ask for "honey," and he will then know he is not getting honey.

We trust the Illinois Food Commission will realize to the fullest extent the great responsibility of their position, and work in the interest of the consumers. Already there are insinuations that political jobbery and influence of various kinds may be brought to bear on them, but we want to assure Commissioner A. H. Jones and his assistants that the honey-producers are with them in every honest effort to enforce the anti-adulteration laws of this State, and fully expect to support them until there is some good reason to do otherwise.

THE WORCESTER COUNTY BEE-KEEPERS' ASSOCIATION was organized at Berlin, Mass., April 14, with about 20 members. We wish it success. It should join the National Bee-Keepers' Association in a body at once.

HON. EUGENE SECOR has been appointed judge of the apianian exhibit at the Iowa State Fair to be held next fall. We believe this is the second notice of this kind we have given about Mr. Secor lately. He seems to be very popular as a judge of bee and honey exhibits. But so long as that popularity is so well deserved, we see no need of objecting.

DR. C. C. MILLER, writing us April 17, closed with this encouraging paragraph, which, tho not about bees, ought to be read with interest by bee-keepers everywhere:

"Yesterday was election day in Marengo, and there were many hearts anxious as to the result, saloon-keepers not excepted. It was a question which, or whether any, of the three wards would go no license. When the count was made last night it was found all three wards went dry, giving a total majority of 57 against the saloon. So saloons will close business in Marengo after two years rule. Hallelujah!"

Hurrah for Marengo! But what a pity it is that all the temperance men all over this broad land don't get together and wipe out forever the awful curse of the saloon. When they do so unite, the American saloon—canteen and all—will go down everlastingly, and there will then go up from the millions of the rum-curst such a "Glory hallelujah" shout as will set all Heaven ringing. In fact, it will be Heaven to those who have had to endure the terrible misery, and sorrow, and woe, that the demon drink causes. Oh, that the end might come this very year, ere the new century dawns! It might easily be done, if every Christian man would only do his duty.

The New RUMELY Thresher

will save enough extra grain in threshing to pay the taxes of the ordinary farm. It combines the open and vibrator principles and is as far ahead of other threshers as they are in advance of the man with a flail. They thresh fast enough and have capacity enough to suit the thresherman, and it

Threshes Clean enough to suit the most exacting farmer. Last indefinitely. Send for free catalogue of Threshers, Tractors, Portable and Semi-Portable Engines, Horse Powers, Saw Mills, etc.

M. RUMELY CO., LA PORTE, IND.

Please mention Bee Journal when writing.

Comb Foundation

Is one of our Specialties—no one undersells us. Our price is very low. Catalog of everything a bee-keeper needs, including Bees and Queens, free. Untested Italian Queens, 75 cents each.

Apiaries—Glen Cove, L. I. I. J. STRINGHAM, 105 Park Place, New York, N. Y.

Please mention Bee Journal when writing.

WALKER CARRIAGES AND HARNESS are sold direct from factory at WHOLESALE PRICES

Highest quality, finest workmanship and perfect finish, yet at lowest cost. We ship any style vehicle anywhere for examination and subject to approval. No matter how far away you are you can do business with us and save money. We make all the vehicles we advertise, also fine harness. Send for our FREE illustrated book. It tells our plan in full.

EDWARD W. WALKER CARRIAGE CO., 50 Eighth St., Goshen, Ind.

Please mention Bee Journal when writing.

HONEY MONEY results from the best care of the bees. That results from the use of the best Apiary appliances.

THE DOVE-TAILED HIVE shown here is one of special merit. Equipped with Super Brood chamber, section holder, scalloped wood separator and flat cover. We make and carry in stock a full line of bee supplies. Can supply every want. Illustrated catalogue FREE.

INTERSTATE MANFG. CO., Box 10, HUDSON, WIS.

Please mention Bee Journal when writing.

ALBINO QUEENS If you want the most prolific Queens—If you want the gentlest Bees—If you want the best honey-gatherers you ever saw—try my Albinos. Untested Queens in April, \$1.00; Tested, \$1.50.

12A26t J. D. GIVENS, LISBON, TEX.

Queens, Bees, Nuclei, Etc.

Having been 27 years rearing Queens for the trade on the best plans, will continue during 1900 to rear the BEST we can.

- PRICES:
- One Untested Queen \$1.00
 - One Tested Queen 1.25
 - One Select Tested Queen 1.50
 - One Breeder 3.00
 - One Comb Nucleus 1.80

Untested Queens ready in May. Tested are from last season's rearing, ready now.

COMB FOUNDATION FROM PURE YELLOW WAX.

Send for price-list of Queens by the dozen; also sample of Foundation. J. L. STRONG, 14A1f CLARINDA, Page Co., IOWA.

Please mention Bee Journal when writing.

Marshfield Manufacturing Company.

Our specialty is making SECTIONS and they are the best in the market. Wisconsin BASSWOOD is the right kind for them. We have a full line of BEE-SUPPLIES. Write for free illustrated catalog and price-list.

MARSHFIELD MANUFACTURING CO., Marshfield, Wis.

GENERAL ITEMS

Good Results in Wintering.

We have taken out a part of our bees, and found good results in wintering. Out of 229 colonies that we have removed from winter quarters we found only 10 dead ones. We had to quit taking the bees out on account of a snow-storm, so we have not taken them all out yet.

ADA L. PICKARD.
Richland Co., Wis., April 13.

A Beginner's Report.

I started last spring with 3 colonies and increased to 11. Not having a hive prepared for the last swarm I had to put it into a hive without foundation starters, and it made the comb cross-wise of the brood-frames, so I had to kill it. I got 340 pounds of comb honey. As I did not know anything about bees before, I think I did well. The last of November I put 10 colonies into the cellar. I looked them over in February and found one dead. I don't know what the trouble was, but most of them had left the hive, and there was about 30 pounds of honey in it. I put the 9 colonies out of the cellar April 14, and they seem to be all right.

OSCAR NORDIN.
Barron Co., Wis., April 18.

Many Weak Colonies.

I took the bees out of the cellar the forepart of April—13 colonies dead out of 75 put in, and a good many very weak. But they wintered better than I expected, as they were in very bad condition last fall, owing to being short of honey, and not breeding. I fed rather late and consequently had but few bees in a hive, and they were mostly old ones. I fed 1,000 pounds of granulated sugar last fall for winter stores.

I think I have one of the best beecellars in the State, and will describe its construction later on.

Sweet clover is coming up nicely, and we are having a big rain. The temperature is 55° above zero.

FRED C. LEFEVRE.
Adams Co., Nebr., April 16.

Wintered Well—Bees and Fruit.

Bees have wintered very well in this locality. Some of my neighbors have not lost any, and others have lost only a small percent. My loss was 4 colonies out of 84, and those that died were small swarms that issued late last fall. I finish taking them out of the cellar April 2. I never took them out so late before, but they seemed to be quiet and satisfied in the cellar, which was the best place for them during the cold weather that we had in March. I generally take my bees out about the first of March, and they get pollen from the soft-maple and the white elm about March 15, but this spring everything is late. I noticed the bees bringing in some pollen to-day.

As I wrote some time ago about clover bearing all right in this vicinity, I am pleased to say that it is all right

Sharples Cream Separators: Profitable Dairying

The Mississippi Valley Democrat —AND— Journal of Agriculture, ST. LOUIS MO.

A wide-awake, practical Western paper for wide-awake, practical Western farmers, stock-raisers, poultry people and fruit-growers, to learn the science of breeding, feeding and management. Special departments for horses, cattle, hogs, sheep, poultry and dairy. No farmer can afford to do without it.

It stands for American farmers and producers. It is the leading exponent of agriculture as a business, and at the same time the champion of the Agricultural States and the producer in politics. Subscription, One Dollar a Year.

Labor Saving Conveniences.

Success on the farm today is largely proportioned to the saving of time and labor—which means economy of production—and not higher prices for farm products. Probably no single machine or appliance saves in the aggregate so much time and hard labor as the modern low-down handy wagon. Take for instance the

ELECTRIC

loading and hauling of manure, ensilage corn, grain in the straw, corn-fodder, hay, etc., all hard to load, the use and advantages of a low-down wagon are almost inestimable. The Electric Low-Down Handy Wagon excels for these purposes. Has the famous Electric steel wheels, is light, strong and durable. Write Electric Wheel Co., box 16, Quincy, Ill., for catalogue. Please mention the Bee Journal.

SPRAYING

still. The pastures are lined with white clover, and the meadows around here are thick with alsike—that good old standby. It is the clover for wet land, and I think will grow on high land just as well as red clover, and will stand more cold weather and just as much drouth. We have grown both, side by side, on high clay loam, and find that the alsike holds its own with the red varieties.

I have a neighbor who came to me a few days ago, wanting me to take care of his bees. He bought 5 colonies at a sale, but has never seen the inside of a hive, tho he seemed to know that bees would be a benefit to his orchard. He thought that by having a few colonies he would not only have more fruit but better fruit. I then explained to him what honey was for, and that it was the best thing for his children, his wife and himself.

I think that many more farmers could keep a few bees and have their own honey, and the bees would not hurt their crops but would be an advantage to them. I do not know of anything that is healthier than honey and fruit, and why not have some of both, if we can? JACOB WIRTH.
Henry Co., Ill., April 14.

Colonies Strong in Bees.

My bees are flying nicely to-day. They are carrying in pollen. I feed artificial pollen to build them up for the honey-flow. They seem to be strong in bees this spring.

THEADORE SIMPSON.

Greene Co., Pa., April 16.

Dividing Colonies—Decoy Hives.

I commenced keeping bees last year. There were 20 colonies left in my father's apiary when the yard was cleared up, and I had three of my own at home. I increast his to 46 colonies and mine to 6, making 52 in all. My work was done mostly by dividing, and I think it the best way to handle bees. The honey-flow was light owing to the season.

I find that it is a good thing to have hives put up in trees close by the apiary, as in this way I catch swarms that come off when I am away. I had one colony at home from which I extracted 72 pounds of honey, which I consider pretty good for a dry year. I hope 1900 will be a better honey-year.

I have read the American Bee Journal for some time and like it very much. JOHN C. SILVER.
Seward Co., Nebr., April 13.

Bees Wintered Well.

I put 90 colonies in a shed Dec. 5, 1899, and on April 4 I took 86 out, all in good condition. I also put 90 colonies into the cellar in the fall, and on April 7 I took out 89, all strong and full of bees. All that I did with the bees when putting them into winter quarters was to take the tops off the hives and leave the honey-boards sealed on just as the bees had them, and pile the hives one on top of the other three high. I did not look at them once during the winter. My hives are 14x12 inches, and 14 inches deep. The entrance is 6 inches by 1/2 inch, with a one-inch hole in the middle of the front that gives them two entrances. The

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.10, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO., 118 Mich. St., Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

back of the hive is movable, so that I can take all the frames from the back of the hive and not lift them out. I can also take out the back and clean the whole hive without interfering much with the bees.

I hope we will have a good season this year.
WM. J. HEALY.
Iowa, Co., Wis., April 16.

Bees in Fine Condition.

My bees are in fine condition except that they are not breeding very strong on account of the cool, late spring. It is about two weeks late and we had no growing weather until yesterday. We have about 25 or 30 acres of alsike clover for the bees this summer, and we sowed about that much this spring. The last week in January I purchase a few of the Danzenbaker hives in the flat, and had them nailed and painted and bees put into them. I went to a public sale and purchase some bees in large box-hives. The colonies were very strong and had lots of honey. I paid only 90 cents apiece for them. After I got them home I took them into the shop and transferred them into the Danzenbaker hives.

L. A. HAMMOND.
Washington Co., Md., April 16.

Good Honey-Year Expected.

Our bees came thru the past winter in exceptionally good condition. Of 210 colonies only one became queenless, and the rest are strong in numbers. We look for a good honey-flow the coming season.

In our native country they have a saying:

"Candlemas Day bright and clear,
Is a sign of a good honey-year."

It was a good, clear day in this section of the country, and we will see how near the saying will hit the mark.

B. W. HAYCK.
Adams Co., Ill., April 16.

Queens the Whole Secret.

I have been amused at times for more than 25 years in reading different views on the production of the best queens; and all this time I have been experimenting how to produce queens that would produce long-lived workers. About 10 years ago I found just how to succeed, and since then I have kept my colonies supplied with queens that produce large, hardy, and long-lived workers. I have tested the longevity of many colonies, by taking from them their queens in September, and find the next June, by giving them queens again, they will become very strong, and after July will do as much honey-gathering as any colonies I have. The whole secret is in the manner queens are reared.

When one has colonies of long-lived workers, the risk of wintering and spring dwindling is almost overcome. By supplying each colony with 40 or more Langstroth combs, they will store large quantities of honey when there comes a flow. Let any person examine, and where he finds strong colonies he will find long-lived workers, and just the reverse in weak colonies.

Large, rugged, and prolific queens will also produce the best drones, which I prize very highly. Always in September I remove a few of the

Please mention the Bee Journal when writing Advertisers.

queens from colonies that produce the largest and best drones, so as to preserve their drones for fall and spring service when there are no other drones.

I work wholly for extracted honey, and with my bees I want a hive with not less than 40 Langstroth combs, and, when all is right, a good queen will maintain 20 pounds of workers during the honey season, and will not attempt to swarm if upper stories are kept supplied with empty combs. Such colonies will safely pass the winter when chaff cushions are used, even without queens, on the summer stands. Lucas Co., Iowa. GEO. W. RIKER.

All Wintered in Good Condition.

The weather is fine here this morning. Our bees are in splendid condition this spring. We put 25 colonies into the cellar, and took the same number out. They are all in 10-frame hives. We used plain sections with fences, and like them all right.

We secured 1,530 pounds of comb honey last season from 17 colonies, and had only 3 swarms, but we had the pleasure of capturing 5 "strays." I carried a swarm tied up in a gunny sack eight miles one day in a buggy. It was Aug. 12, and they filled their hive with honey.

CHAS. A. FAIRBANKS.
Jones Co., Iowa, April 14.

Bees in Good Condition.

I put 20 colonies into the cellar under the dwelling-house Nov. 28, and carried out 20 on April 6—all alive and in good condition. The next day was warm and calm, so they went to work carrying in pollen in good earnest.

JOHN CLINE.
Lafayette Co., Wis., April 10.

Backward Season.

The season is very backward this year. Maple trees have not begun to bloom yet. New Jersey seems to be as cold as a bee-convention would be without Dr. Miller.

F. G. HERMAN.
Bergen Co., N. J., April 11.

Carrying a Swarm in a Hat.

In the Bee Journal for Sept. 7 I read an article about carrying bees on a bicycle. This reminded me of a little experience I had a few years ago. Soon after I came here to work running a pump, some one told me that there was a runaway swarm on a little tree about a quarter of a mile from the house. So a little later, having time, I concluded to investigate, and found a bunch of about a quart or two on the bush. I lookt towards the house, thinking that it was a long way to make a trip for a box, and wondering what I should do. I then thought of my hat, a small brown felt. I took it off, shook the bees into it, and turned it over and hung it on a sliver of the tree, waiting for the bees to collect that had started up from the shaking. Then I took it by the crown and started home in triumph, with a few bees following on the wing. I hived them, and they made a good colony, and not one offered to sting me while moving them.

Another time I got one about a mile from home. This time I took a box

Yellow Sweet Clover Seed

WE HAVE IT AT LAST!

We have finally succeeded in getting a SMALL quantity of the seed of the YELLOW variety of sweet clover. This kind blooms from two to four weeks earlier than the common or white variety of sweet clover. It also grows much shorter, only about two feet in height. It is as much visited by the bees as the white, and usually comes into bloom ahead of white clover and basswood. We offer the seed as a premium

A QUARTER POUND FOR SENDING ONE NEW SUBSCRIPTION.

So long as it lasts, we will mail a quarter pound of the seed to a regular paid-up subscriber who sends us ONE NEW subscriber for the American Bee Journal one year, with \$1.00; or ¼ pound by mail for 30 cents.

We have been trying for years to secure this seed, and finally succeeded in getting it. It is new seed, gathered last season by an old personal friend of ours, so we know it is all right. But we have only a small supply. When nearly out we will mention it.

GEORGE W. YORK & CO., 118 Michigan St., - CHICAGO, ILL.

and a man along to help me. It took us a couple of hours, as I had to shake them into the grass to get them off the limb, and we got them all over our legs and arms, but did not get stung. We carried the box between us without taking any pains to make it air-tight, and not a half-dozen bees left while on the road. This last swarm served me for a second start here, as I had been away for 18 months, and the first swarms that issued had disappeared when I came back.

I have three colonies now from last year. I had one swarm this summer, but as the season was bad I lost it.

C. L. GORE,
Tacaticas, Mexico, Sept. 11, 1899.

Wintering Bees.

Last fall I built my second bee-cellar, which I made much larger and handier than the first one. This new cellar is 12x10x6 feet, and I can place nearly 100 colonies in it, tho I have but 40 in it now. I think it is one of the finest in this country.

A few days ago I went down to see how the bees were getting along, and found them wintering nicely, and very quiet. I have swept up about ½ peck of dead bees from the cellar-bottom, which I think is not bad from 40 colonies.

I have 20 colonies in my old cellar, but I can't tell how they are getting along as I have not opened the door since I put them in, tho I hope they are all right. I always try my best to keep colonies strong, and try to have them go into winter quarters with as many young bees as possible and plenty of good honey.

About the middle of September I go over all the hives and take off the fall crop. I weigh every hive and if some don't weigh from 70 to 75 pounds each, without supers, I feed them until they do. I have fixt the bees for winter in this way for about 6 years, keeping the temperature of the cellars as near 42° as possible, and I always have good luck in wintering. I have lost only 3 or 4 colonies in the 6 years. I use the 10-frame dovetailed hive as I like it the best. I generally put the bees out between the first and the middle of April.

Every Saturday when I go to town the first paper I look for is the American Bee Journal. It is a great help to any one who keeps bees, and I would not like to do without it, as I have sometimes found things in it that are worth to me many times its cost for one year.

TOFIELD LEHMAN.
Fayette Co., Iowa, March 12.

Inky Drops from Smokers.

I have seen several articles in the American Bee Journal about inky drops from smokers, and as I have had no trouble in that way perhaps my method will be of some value to those who have. I use only saltpeter rags and rotten wood. I had some pine trees cut down several years ago, and the stumps have rotted. I take the rotten wood and put it in a cake-pan, breaking it up into small pieces, and put the pan into the oven, leaving it there until the wood is thoroly dried thru, so there can not possibly be any dampness. Then I keep the holes cleaned out on the under side of the smoker fire-box, and in that way I have

not had any inky drops since using that kind of fuel.

I have two text-books, but could not think of getting along without the American Bee Journal. There is something fascinating about it. If one of the neighbors brings it to me at bedtime I must see all of the headings and read some of the articles. I don't think Mr. Doolittle is named right, for he *does so much*. I enjoy reading his articles. Then the patience that Dr. Miller has, to answer so many questions, makes me feel that if I can do anything that will benefit any one else I ought to do so.

As the past three years have been poor here, I thought I would try keeping pigeons with the bee-business, so I have commenced with 13. I have had a hard time this winter getting their places ready, and the nests made. I have made 18 nests, and paid only 5 cents in money for one box. I have made it all myself, and have had hard work to get it done. I am not ashamed of it, considering the materials I had, but I think I did pretty well for a woman in her 71st year.

MRS. SARAH J. GRIFFITH.
Cumberland Co., N. J.

Little Loss in Wintering.

Bees are doing nicely so far. As a rule not over 3 percent are lost. Prospects are good. G. W. VANGUNDY.
Uintah Co., Utah, April 8.

Prospects Good.

Bees are wintering pretty well. We lost 4 colonies out of 15. The prospects are pretty good. Pussy-willows are beginning to bloom.

HENRY ROORDA.
Cook Co., Ill., April 13.

Wintering and Springing Bees—Laying Workers.

Altho some claim to have reached the highest attainments in winter management, the reports of the winter of 1898-99 did not bear out the statement. I do not claim to have reached perfection by any means, but I think I have a good method of winter management, as I did not lose any colonies in the winter referred to.

The situation of the apiary and the position of the hives are of vital importance to successful wintering. Our apiary is south of the main building, and west of the poultry house. These, of course, shield it from the cold wind.

The hives are facing south now, and alternately east and west in summer.

The two main points to consider are, plenty of stores and a tight hive. There need not be so much attention paid to the quality of the stores, and their position in the hive, as we seldom have more than a week or ten days here without a day or two fit for the bees to cleanse themselves. I use a modification of the Hill's device, or a chaff tray over the frames, and a board that will just fill up the space. A hive so packed is equal to a box-hive for wintering.

The colonies in this country, worthy of the name, commence breeding about New Year's in small dimensions at first, but increasing until in March, the best hives are pretty well filled up with bees. In the latter part of March, or first of April, brood-rearing commences in earnest. At the same time the work for the season commences in earnest.

The first thing to attend to is to see that all colonies have good queens. The next in order is queen-clipping and general hive-cleaning, and putting in foundation. Then comes the big job—putting on the sections. I would not unpack the ends of the frames until settled warm weather.

As I have said above, the best colonies were the ones that breed all the latter part of the winter unhindered. And these *best* colonies are the ones that store the surplus honey; quite different from Mr. Doolittle's bees that store no surplus if they commence breeding before spring. But that is very easily accounted for; Mr. D.'s honey-flow comes in July from basswood, while ours comes from clover in May, and from basswood in July.

We had plenty of laying-worker experience in the apiary last summer. Of course that does not show up very well for the apiarist, but I suppose I may be excused if I have established a cure. The case cited came about in this way:

A certain colony became queenless, and we at once ordered a queen. In the meantime I gave the colony a frame of brood to keep, on which they at once started queen-cells that became so nearly ripe that I had to remove them. I failed to give brood of the right stage for queen-rearing. When the queen arrived, and I started to introduce her, I found that laying workers had made their appearance. I was afraid to risk the fine queen in such an abnormal colony, so I got a queen from a very cross colony, and caged her upon the

DITTMER'S FOUNDATION

Wholesale and Retail

This foundation is made by an absolutely non-dipping process, thereby producing a perfectly clear and pliable foundation that retains the odor and color of beeswax, and is free from dirt.

Working wax into foundation for cash, a specialty. Write for samples and prices. A full line of Supplies at the very lowest prices, and in any quantity. Best quality and prompt shipment. Send for large, illustrated catalog.

The Emerson Binder.

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

GEORGE W YORK & CO.
118 Michigan Street, CHICAGO, ILL.

California! If you care to know of its Fruits, Flowers, Climate or Resources, send for a sample copy of California's Favorite Paper—

The Pacific Rural Press,

The leading Horticultural and Agricultural paper of the Pacific Coast. Publish weekly, handsomely illustrated, \$2.00 per annum. Sample copy free.

PACIFIC RURAL PRESS,
330 Market Street, SAN FRANCISCO, CAL.

Messrs. B. F. McBurney, Theo. Rockenfeller and B. B. Boyer, formerly connected with the Farmers' Colonization Company, have entered into a limited co-partnership under the firm name of MCBURNEY-ROCKENFELLER COMPANY, for the control, purchase, and sale of farm lands in the West, Northwest and Southwest. They want good, live, active agents for the sale of their lands in Wisconsin, Minnesota Iowa, North and South Dakota, Arkansas and Southeast Louisiana, and will pay liberal commissions to the right persons. Correspondence should be addressed to the McBurney-Rockenfeller Company, 708 Fisher Building, Chicago, Ill., mentioning the American Bee Journal.

Rocky Mountain Bee-Plant Seed!

(*Cleome integrifolia*.)

...FREE AS A PREMIUM...

The ABC of Bee-Culture says of it: "This is a beautiful plant for the flower-garden, to say nothing of the honey it produces. It grows from two to three feet in height, and bears large clusters of bright pink flowers. It grows naturally on the Rocky Mountains, and in Colorado, where it is said to furnish large quantities of honey."

We have a few pounds of this Cleome seed, and offer to mail a 1/2-pound package as a premium for sending us ONE NEW subscriber to the American Bee Journal, with \$1.00; or 1/2 pound by mail for 40 cents.

GEORGE W. YORK & CO.

FREE OX-BLOOD TABLETS for thin blood people. — Nervousness, Indigestion — Rheumatism—Female Disease—Brain Food. A SURE CURE.....

This preparation contains in a concentrated form the active principles of healthy bullock's blood combined with the most valuable nerve, brain, blood and flesh producing drugs known to the practicing fraternity.

Greatest discovery of the age for suffering people. Less than a year since first put in use, and thousands are being cured every day. To convince you we give a 3 weeks' treatment free—all we ask is for you to send 10 cents to pay postage on sending it. This is safer than paying a doctor \$25 to experiment on you. 3 weeks' treatment sent free on receipt of 10 cts in stamps. Testimonial:

"I wish to say to you that after many long months of suffering and a broken-down system from the effects of child-bed fever, and at a very large expense with different physicians, and after using 26 bottles of patent medicines and no relief, my husband was compelled to give a mortgage on our home to send me to a hospital, where I still suffered and no relief. I was induced to try your three weeks' treatment of Ox-Blood Tablets and gained so much in the three weeks that I consented to continue the treatment with a 50c box. They have taken all the pain away. I have gained wonderfully in flesh and feel as if I had never been sick a day in my life. I advise all weak women to try Ox-Blood Tablets and get the same results I have." MRS. F. G. EDWARDS, Clarinda, Iowa.

50 cts. a box or 6 for \$2.50.

Address, W. A. HENDERSON, Clarinda, Iowa.

comb with a Hutchinson cage. I left her there five days, and in the meantime the laying workers were making good use of their laying authority by filling every cell at their command with from one to six eggs. Some were even daring enough to lay on the comb the queen was on. I had no hope of her ever being received, but I determined to release her, so armed with this determination I went to the hive, lifted the comb the queen was on, and released her among her rival layers, when lo and behold! she was received loyally, and that was the last of the laying workers.

I notice that Dr. Miller advises uniting a colony so infected with some other one. Now I wish the Doctor, or any other bee-keeper, would try the above plan and report, if they think it worthy of trial. But probably no one else would be so careless as to let laying workers get a hold.

WILLIAM T. STEPHENSON.
Massac Co., Ill.

Honey that Causes Throat-Burning.

In the American Bee Journal Dr. Miller asks what the honey is gathered from that causes a burning sensation in the throat. We call it "hot honey." We have had only one season that the bees gathered it; it was a dry season, and they could not find anything else. It was gathered from milkweed, or snow-on-the-mountain, as some call it. I took a sample of it to the national convention held in St. Joseph, Mo., in October, 1894, and I think most of the members tasted it just before going to dinner. I have some of it on hand now; it has improved a little with age, but is not good yet.

The Bee-Keeper's Guide

Or, Manual of the Apiary,

—BY—
PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipt, or his library complete, without THE BEE-KEEPERS' GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. WILL YOU have one?

BEE-BOOKS

SENT POSTPAID BY

George W. York & Co. 118 Mich. St. Chicago.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopaedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers, \$1.00.

Biennen-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Bienezucht und Honigerwerbning, nach der neuesten methode (German) by J. F. Eggers.—This book gives the latest and most approved methods of bee-keeping in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condense treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cts.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cts.

Foul Brood Treatment, by Prof. F. R. Chesshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohoke.—Origin, Development and Cure. Price, 10 cents.

Capons and Caponizing, by Dr. Sawyer, Fauny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 20 cents.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about Poultry Business. 64 pages. Price, 20 cents.

Italian Queens One Dollar Each.

Queens from our select stock during May and June, \$1.00 each. Orders will be booked and filled in rotation.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, April 19.—Market is well cleared of white comb honey; a little choice has sold recently at 16c, but dark and mixt goods are slow of sale. Extracted, white, 8@9c; amber, 7@8c; dark, 6@7c, according to quality and package. Beeswax in good demand at 28c.

R. A. BURNETT & Co.

CINCINNATI, March 3.—There is some demand for extracted honey from manufacturers at 7@7½c for amber and Southern; clover, 8@8½c. Comb honey is selling firm at 14@16½c in a small way. Beeswax, 25@27c.

C. H. W. WEBER,
Successor to Chas. F. Muth & Son and A. Muth.

BOSTON, March 9.—Our honey market is showing some signs of lower prices, altho the stock on hand is not large. At the same time prices are so much higher than previous years that the trade have taken it very slowly and the results are that the holders are willing to range prices quite a little in order to move stock on hand. Prices range: Fancy white, 17@18c; No. 1, 15@16c; amber, 10@12c; buckwheat almost unsalable. Extracted, best white California, 8½c.

BLAKE, SCOTT & LEE.

KANSAS CITY, Mar. 19.—We quote fancy white comb, 15c; No. 1, 14c; No. 1 amber, 13c; No. 2 amber, 13½c. Extracted, white, 8c; amber, 7c; dark, 6c. Beeswax, 22@25c.

C. C. CLEMONS & Co.

DETROIT, Feb. 10.—Fancy white comb, 15@16c; No. 1, white, 13@14c; fancy amber, 11@12c; dark and undesirable lots, 8@10c. Extracted, white, 7@7½c; amber and dark, 5@6c. Beeswax, 25@26c. Supply of honey fair with light demand.

M. H. HUNT & SON.

BUFFALO, April 20.—For strictly fancy white one-pound comb honey we are getting 16@17c. Any grade sells high—10@15c, as to grade.

BATTERSON & Co.

NEW YORK, April 9.—Market is practically bare of comb honey of all description. Little lots arrive here and there and sell readily at from 10@11c for buckwheat and 12@15c for white, according to quality and style of package. The market is well supplied with extracted, which we think, however, will be moved before the new crop arrives. Beeswax is in good demand at from 27c to 29c per pound.

HILDRETH & SEGELKEN.

SAN FRANCISCO, Apr. 11.—White comb, 11½@12½c; amber, 8@10c. Extracted, white, 7½@8c. light amber, 7@7½c; amber, 5@5½c; Beeswax, 26@27c.

Stocks of last crop are nearly exhausted, with present business in the same mainly of a light jobbing character at practically same rates as lately current. New crop is expected to put in an appearance in quotable quantity inside of 30 days. The yield north of Tehechapi will be a fair average, but very light south of the point named.

OMAHA, Mar. 13.—Demand shows some improvement in January, having been much more active, but as anticipated there is no advance in prices. Market remains steady at 14@14½c for fancy white comb and 8½c for white extracted. The latter is pretty well cleaned up along the Missouri River, and it looks as if there would be some shortage before another crop comes in. From present appearances there is about enough comb honey to go around at the present prices, hence we look for no particular change in values.

PEYCKE BROS.

Convention Notices.

Connecticut.—The annual meeting of the Connecticut Bee-Keepers' Association will be held at the Capitol, in Hartford, Wednesday, May 2, 1900. The meeting will be called to order at 10:30 a.m. MRS. W. E. RILEY, Sec. Waterbury, Conn.

Illinois.—The spring meeting of the eastern part of the Northern Illinois Bee-Keepers' Association will be held at the residence of William Farnham, 4 miles southwest of Rockford, Ill., on Tuesday, May 15, 1900. All are cordially invited.

DR. MILLER'S Honey Queens

One Untested Queen Free as a Premium for sending ONE New Subscriber to the American Bee Journal for one year.

We have been fortunate in making an arrangement with DR. C. C. MILLER—the well-known honey-specialist—to rear queens EXCLUSIVELY FOR US DURING THE

SEASON OF 1900. These Queens will be mailed in rotation, beginning about June 1, so "first come first served." We are ready to book orders now.

The Queens Dr. Miller will send out on our orders will be precisely the same as those he rears for his own use, so of course they will be from his best stock. His best colony in 1899 had a queen reared in 1898; May 5, 1899, it had brood in 4 frames, and he gave it at that time a frame of brood without bees. It had no other help, but May 25 a frame of brood with adhering bees was taken from it, and the same thing was repeated June 3, leaving it at that time 5 frames of brood. It stored 178 sections of honey, weighing 159 pounds (and that after July 20, in a poor season), being 2¾ times the average yield of all his colonies. A point of importance is the fact this colony did not swarm, and an inspection every week or 10 days showed that at no time during the entire season was there even so much as an egg in a queen-cell. Dr. Miller expects to rear queens from this one during the coming summer.

The demand nowadays is for BEES THAT GET THE HONEY when there is any to get, and Dr. Miller has such bees. You will want to have a queen from his best, we are sure, even if she is not pure Italian.

Do not send any orders to Dr. Miller, as all orders MUST come thru us, according to our agreement.

Remember, send us \$1.00 for ONE NEW SUBSCRIBER to the American Bee Journal for one year, and YOU will get ONE OF DR. MILLER'S UNTESTED HONEY-QUEENS FREE AS A PREMIUM. This offer is made only to our present regular subscribers. Orders for queens to be filled in rotation, beginning about June 1st.

Address all orders to GEORGE W. YORK & CO., 118 Michigan Street, CHICAGO, ILL.

CONTRIBUTED ARTICLES

House-Apiaries—Their Successful Management.

BY B. J. CHRYSOSTOM.

WHEN the reasonable objections have been obviated, and have been substituted by beneficial and substantial improvements, then is the house-apiary destined to come rapidly into favor—not only because of the great convenience it affords, but chiefly on account of the beneficial results obtained by the saving of money, time and labor, the last mentioned being often attended with considerable disagreeable inconvenience.

I am personally acquainted with only two bee-keepers who wintered their bees in cellars. One of them lost every colony one winter, and the other was so severely stung while removing them to the yard that his life was endangered. He is now engaged in other pursuits. These two cases, and the reports appearing from time to time relative to this subject, in periodicals devoted to apiculture and the production of honey, have led me to regard cellar-wintering of bees as a necessary evil consequent on the introduction of the loose-frame hive, which has proven a most destructive invention for bees, especially when it was first introduced. Hence, the object of this article is to give some facts and figures that perhaps may be of benefit to those who may wish to have a better and cheaper method than they at present possess.

Sometimes a small improvement effects a complete change in a whole system. As far as my experimental work has gone in house-apiaries, it has been most satisfactory, and has given good results with comparatively little labor and expense. With a suitable house and a perfect hive, the business is simplified and becomes more agreeable and pleasant.

There is at the University of Notre Dame a bee-house having eight sides—a frame with single walls one inch thick—built without any regard to warmth. It serves its purpose perfectly. It is just large enough to admit three hives to each side, with plenty of room for a low operating or work table in the center, and space on one or two sides for storing away boxes and supplies. It has during six years given entire satisfaction, excepting in one thing, which is that the windows are too small, and are in two sashes. The windows in bee-houses should be large enough to afford plenty of light, and so elevated as to let the light into the hive while operating. It is a great convenience to have the sash all in one piece and hung on four rods, one in each corner, so that it could be easily pushed out enough to let the bees out at the four sides. Bees that leave the hive or the combs while being handled, will settle on the glass and give no further trouble. When the work is finished in one hive the window may be opened and the bees all disap-

pear instantly. So far as is known not one queen has been lost by entering other than her own hive. As the bees of every three hives fly in from different points of the compass, they are not liable to mistake their respective hives.

The cost of such houses is so small, and their construction so simple, that it requires but little skill to build them. Any one that can build or put up a board fence might succeed in a building of this kind. Hives kept all the time in the dry will last more than a lifetime. There is no warping of hives and covers; in fact, the covers can be dispensed with and substituted with a strip of burlap and a mat of some kind to retain the heat of the bees. This in the hot season may also be laid aside. I simply mention these small matters, not altogether for their recommendation, but chiefly as hints, which, after mature deliberation, the reader may or may not think fit to adopt—for what may succeed well with one may not do so well with another. After all, technicalities are not so important. Principles are more to be taken account of in questions of house-apiaries and hives. Is it not better for hives and bees to be kept at all

A View of a Portion of the House-Apiary.

times in the dry and shade than to have them exposed part of the year to extreme changes of weather? Much of the work can be done in the house when it would be difficult to do it outside.

If, as good results are obtained in the production of honey in the house, then the balance is in favor of the house. In a house of eight sides, 18 or 21 hives may be so convenient that supers may be put on or taken off without moving more than two steps, which may be done during a shower, or in the morning or evening. It would be disagreeable to do the same work at the same time if the hives were here and there in the grass.

Another principal advantage is that the hives do not get out of repair, and are always convenient. The principle involved in wintering is also important. In a house of the above description, when it is a question of packing the hive for winter, all that is required is a board fence or partition made in sections and set in the rear of the hives to keep the packing about them. In the spring this may be set aside and the packing stored away for the next fall. All this can be done while the bees are busy storing honey. Then the care of the bees is over till next spring.

It might be more convenient to have a covering for each hive made like a bed comforter padded with cotton or wool. The principal thing in packing is to retain the heat of the bees in the walls of the hive, always bearing in mind that it must not be so dense as to prevent evaporation. The covering that would keep the bee-master comfortable in bed during the winter season might be about the right thing for his little servants. When hives are packed in the dry, the covers should be left off.

In connection with the house-apiary, the most important principle or factor for good results is the hive. Loose-frame hives are out of the question in house-apiaries, for many reasons. The chief reason is that they are too cold in winter, spring and fall. The hive requisite to give satisfaction in a house-apiary is either a box, straw skep, or a tight-frame hive, on the same principle as the Notre Dame hive.

The life and health of the bee require a dry and high temperature. These two essentials can not be effectually maintained unless the bees are protected from drafts of cold air, and the hives protected from severe cold. When bees are thus protected they require very little ventilation, their nature not needing much air. On hot summer days they will remain for hours in great clusters. Excessive heat, either produced by too much packing or the rays of the sun, will drive them out of the hive. Bees require a very high temperature for comb-building, and the air-spaces around the frames militate against this work. But when they are in close, tight hives, kept warm by packing, they can control the temperature of the hive with less labor. I wonder how many bee-keepers realize what a great and continued exertion the bees in a loose-frame hive have, to keep the cold from penetrating the clusters when the air is rushing into the hive at a temperature of 25 degrees below zero.

A few years ago all our bees were on loose frames and protected in the best possible manner. We had a severe snow-storm lasting about (as near as I can remember) 48 hours, and the mercury indicated 25 degrees below zero. I visited the hives several times during the storm, and the bees kept up a noise night and day, the same as they do in the evening of a warm day after storing a liberal amount of nectar. Colonies that had not enough bees to keep up the hum were husht forever. I closed the entrance of some hives with snow, when in a very short time the noise ceased—because there was no need of a counter current.

The suffering endured by these little creatures from cold in the loose-frame hive is difficult of estimation. It is certainly cruelty to animals to keep bees in winter quarters where they die by pints, quarts, and bushels, from the effects of cold or damp. If farmers kept their horses, cows and sheep, or even hogs, in quarters in which they would die from the effects of cold or damp in the same ratio as do bees, they would be prosecuted for cruelty, and it would not serve them either to say that they died of old age.

From the best authorities we have on apiculture queen-bees live three and four years. If I mistake not I have read of a bee in Kentucky that ruled her hive eleven years. But these were queens and mothers. Yet a queen is a bee, and a queen will live three years and show no sign of superannuation. Therefore, a bee may live three or more years. The workers or field-bees do not live so long. Their days are shortened by violent deaths caused thru enemies feeding on them, inclement weather, and a variety of other causes, not to speak of the sickness and epidemics common to all animals.

In some localities, from July 1 to the middle of September, the average age of the workers may not be more than 20 days, while in other places, where their enemies are not so numerous, it may average 30 or 40 days, more or less. Perhaps of the millions of bees that perish every day in the working season not 100 of them can be truly said to have died of superannuation, or of old age, no more than it can be said of the English soldiers who went on the hills of South Africa to look for Boers.

If I make a strong plea for the betterment and comfort of the honey-bee I am not condemning the loose-frame hive, which is certainly a beneficial improvement on the old plan in favor of the honey-producer; I am only contending for an improvement on the same hive for the benefit of the bee. Since this improvement has been effected, and has given complete satisfaction for two years, and as it costs so little per hive, it must strongly recommend itself as one of the essential principles in the care of bees.

Some may prefer an open shed to a house. For the benefit of those I have done some experimental work, and beg to give the results.

Last October I packed three hives in chaff on the summer stands. They were in an open shed, and stood about four inches apart. I made a box of rough boards long and wide enough to set over them, allowing about a two or three inch space between this box and the hives for packing. Full depth supers were then put on the brood-chambers and filled with chaff, which was also packed about the hives till the box was full to the brim. Some boards were then put on to keep out the drifting snow. A thermometer was put in the packing between the hives and one outside. Here are the registrations:

January 27	thermometer	outside	indicated	zero.
" 27	"	inside	"	49	degrees above zero.
" 29	"	outside	"	5	" below zero.
" 29	"	inside	"	50	" above zero.
February 1	"	outside	"	10	" below zero.
" 1	"	inside	"	50	" above zero.
" 5	"	outside	"	28	" " zero.
" 5	"	inside	"	52	" " zero.
" 16	"	outside	"	2	" below zero.
" 16	"	inside	"	50	" above zero.
" 17	"	outside	"	21	" below zero.
" 17	"	inside	"	49	" above zero.

These registrations I think show conclusively that bees wintered in the Notre Dame hive are not affected by sudden changes, nor do they suffer from severe cold, since the temperature on the outside walls of their hives never fell below 49 degrees above zero. The temperature inside the hive is certainly much higher, and it can be controlled by the bees to their own liking. The queens in two of these hives are young, the one in the other about 18 months old. All three are wintering perfectly. As these hives have wire-cloth doors on the porticoes it is not difficult to ascertain the number of bees that have died since last fall. The temperature in the hive being very comfortable, a sick bee can generally get into the portico to die even in the very cold weather. The old queen, in all probability, has not lost 150 of her bees by sickness since last fall. This kind of hive being the essential element towards making the house-apiary popular it may not be out of place here to devote a small space to it.

Since the ordinary loose-frame hive can be so easily changed by means of the Notre Dame Device into one that possesses all the requisites necessary to insure safe, dry and comfortable wintering to the bees, and at the same time lose none of the advantages afforded by the loose frames, but in many ways be a notable and useful improvement, there can be no objection in the mind of one who thinks for himself why it should not have a fair trial. After two years' use of this device in the hives and supers I can say in its favor that the danger of exciting or killing the bees is much less in handling hives, supers and frames. I have less propolis than before, and the bees have become so gentle that the smoker is very seldom required.

As the pressure of the screws may be several hundreds of pounds, hives and supers should be well nailed, otherwise their ends will expand. The bottom strip of frame should be made stronger, and nailed inside instead of on the end of the pieces. This insures better joints and prevents the bottom strip from bulging. In nailing the frame I have a little device for holding it, so exact in form that the frame can not be put into it if any one of the pieces be the slightest shade too large—and if too short a shaving or piece of paper may be inserted. These precautions are not necessities, but are certainly advantages that year after year continue to give satisfaction.

When the bee gets a new house she walks around, noting all cracks and crannies in which the wax-moth might

ledge. If the surface is rough it must be planed and made smooth. For this propolis is necessary. Anticipating her wants in this respect I made it a point to have tight joints and a smooth surface. For this purpose I use tallow for filling up all inequalities of surface. It also makes the joints tighter when the device is screwed up against the frame, thus preventing the wax-moth from getting between the frame and board. I have never known the wax-moth to burrow in tallow. It does not seem to be agreeable to its taste. When the bee finds that her wants in these respects have been attended to, and having no use for propolis, she is well content to leave it outside. I do not recommend tallow as necessary any more than I would axle-grease for wheels. The purpose is almost similar in both cases.

Some time ago I read a rhyme criticising the inventors of fads and follies in the apicultural world. I believe the reading of this rhyme run all the smoother for having in its composition "lightning and tallow."

As I have no further interest in the Notre Dame hive than to place its good qualities before the public, I shall leave its adoption and manufacture to whom it may concern.

After all, it is only the application of the vise to a new purpose. Since the screw of the steamer has wrought such wonderful and beneficial results in navigation, shall it be a greater surprise if the vise placed in a bee-hive should also effect a like revolution in its manufacture—especially when the principal requisites of a perfect hive are involved?

St. Joseph Co., Ind.

No. 9.—The Queen-Excluding Honey-Board— How to Get the Most Out of It.

BY "OLD GRIMES."

THIS very convenient implement for the bee-keeper has received its due share of praise and blame, and of course with those who praise it the excluder has come to stay.

Perforated metal, when first introduced, was chiefly recommended for entrance-guards, and the Alley drone-trap was constructed chiefly of this metal. When first introduced a large number of the latter were sold, from the fact that they were a new thing, and something of a novelty, but we guarantee that not one in ten of those purchased is in use, and the most of them will be found in the pile of "has beens," and it is so to a considerable extent with the entrance-guards.

In the Grimes apiaries we use queen-excluding honey-boards, but use a small amount of perforated metal; it is economy to use less metal, and not obstructive to the bees. As ordinarily used the perforated metal is placed upon the hive in sheets, or it is made into a wood-slatted honey-board, and there is no way for the bees to pass except thru the perforation.

As previously stated, we use a 10-frame hive, and we make a frame for our honey-board just as tho we were going to use the slats and strip of zinc, but instead we insert a thin board the whole size of the top of the hive excepting a three-eighth inch space on each side. This space allows the bees free communication from brood-chamber to super, but it is along the outside of the outside combs. The queen scarcely ever visits the outside of the last comb in a 10-frame hive, or even an 8-frame hive, and the chances for her to get above thru the openings are small—in fact, we have had small queens get above even when perforated metal was used.

In the box-hive days the bees would work quite as well in the supers, and have access thru only two or three auger-holes, and in recent days some have recommended honey-boards with only one row of perforated metal. Now, why have any perforations if the bees work as well, or even better, and the queen stays where we want her?

There are times, tho, when we desire the metal, and a good share of our boards are provided with a simple device whereby a strip of perforated metal can be attached over the spaces. This is used when we desire to rear a queen in the upper portion of the hive, and is not intended to prevent the old queen from coming up, but to prevent the young queen from getting down. We also use the metal upon our excluder when we first hive a new swarm and wish to keep the queen from getting into the sections, but in this case the use is only temporary, or until the brood-nest is established in the proper place, and then it is removed.

When working for extracted honey the excluder is used for a considerable period, for it enables the bee-keeper to secure combs solidly filled with honey, instead of half honey and half brood. In an ordinary season all of this

brood in the super would hatch, or the young bees would become mature too late to gather honey, and they become consumers, as they have already been in the larval state. With a close watch of the honey-resources of a given locality, much money can be saved that would otherwise be uselessly consumed.

There are other times when the queen-excluder can be used to advantage. During a short honey season it is well to restrict the number of bees, and to keep the colonies weak instead of strong—it means less feeding.

In the Grimes apiaries we use the Porter bee-escape, and a few of our honey-boards are fitted with them. Strips of tin are placed over the two open spaces, cutting off all communication except thru the escape. We use this device for the removal of the most of our comb honey.

We use the bee-escape only to a limited extent upon our extracting supers—it is hardly quick enough in operation for our work. Our honey extracts better when taken directly from the bees. When the escape is used several hours must elapse before the supers can be removed, and if the escapes are put upon the hives in the evening, the honey is quite cool by the time we extract, and does not flow so freely from the combs; and, on the whole, the boys prefer the brushing and shaking process. With our shallow supers the bees are soon removed, and sometimes the brushing is not resorted to.

We expect that further developments will enlarge the usefulness of both the queen-excluder and the bee-escape.

Increase—Its Control and Management.

BY JOHN R. SCHMIDT.

ALl bee-keepers, practically speaking, are troubled with their bees increasing more or less beyond only a certain number of colonies which they desire to care for. This additional increase, especially in the production of comb honey, is hard to control. Numerous plans have been given in the bee-papers explaining how this evil may be overcome, but most of these plans either cause much extra labor or are altogether unprofitable. It is not a question of what *can* be done to prevent this increase, but a question of what can be done *profitably*.

The plan I propose, I think, will meet all requirements, and also saves one-half the work when preparing for winter, such as packing, feeding, etc.; in short, only half the number of colonies are to go into winter quarters that have produced honey during the season. I say produced honey, because if there was any nectar to be gathered all colonies would have been in a condition to store a surplus. Now, you undoubtedly know from what I have already said, such a state of affairs can only be brought about by uniting. I know many are opposed to uniting, but do not condemn it just yet—it is so easy when done right, and this is what saves lots of labor, and allows the bees to work according to nature the following spring. This is how it is done:

For example, the bee-keeper desires to keep only 50 colonies, and 25 hives contain bees at present. These colonies are built up in the spring by the various methods until all the hives are overflowing with bees, and all are ready to swarm. Now instead of removing queens and the like to prevent swarming, give room in the supers, and all that are ready to do so will begin to store their honey in the supers; some will give up the swarming inclination and continue to store in the supers thruout the whole season. So far so good; but there are others that are not so willing, and persist in swarming, and if prevented will waste much time in loafing. Now all colonies which act thus are actually encouraged to cast a swarm, for the sooner we relieve this pressing desire the sooner they will be willing to work, for it was long ago proven that it is wrong and almost useless to attempt to force a colony in such a condition to store honey in sections.

As soon as the swarm issues it is hived and placed next to the parent colony; thus the hives are always arranged in pairs, which prevents the loss of queens to a great extent as when the hives are in long rows, and also gives lots of room to work between each pair.

From now on the swarming can be controlled quite easily, and is under perfect control, as far as these two colonies are concerned. They are now given plenty of room in the supers, *but not too much*, just enough for them to occupy comfortably and *keep warm*. The old colony may be either supplied with a young laying queen, or allowed to rear one. In a few days if it shows any signs of swarming again, it is taken bodily and set on the opposite side of the

new colony, thus throwing nearly all the force into the swarm, which will be in excellent condition for working in the supers, no signs of swarming, and working vigorously. The old colony, by being changed from one side to the other whenever it shows signs of swarming, has the swarming element removed, and supplanted by bees which have no inclination to swarm; thus both colonies will become extra strong, and will work with a vim and vigor, and victory is sure to be ours. By this method we have doubled our number of colonies, and all are working just where we want them.

"But now we have as many colonies as we desire to keep, and we can not follow this plan the next spring," some will say. This is only half the plan, and now we are at the close of the honey season with just twice the number of colonies that we intend to winter. Each pair of hives is now examined, and one queen is destroyed, which should always be the inferior one, if there is any choice between the two. Here we can always find a loop-hole to get rid of any inferior stock, or if all are choice many can be sold by advertising in the fall at a low price.

The queenless colony could be left in this condition for at least two days, and then set on top of the other hive with a bee-escape board (with escape removed) between the two stories; in a few days the colonies will be safely united. The bees will remove the honey thru the hole in the board to the combs below, where they can get at it more readily during the winter.

After the 21st day after the queen was removed, all bees will be hatched, and the extra set of combs may be lifted from the hive and stored away, ready to receive a swarm again the coming spring, and the colony given the final preparation for winter.

In this way 50 colonies, which might need feeding to carry them safely thru the winter, can be safely united and wintered when reduced to 25, and all the expense of feeding, and half the work of winter preparation be saved.

This plan of controlling increase may be modified by dividing instead of allowing the bees to swarm, which would make it more convenient for those who can not be present when swarms issue; and also the method of uniting may be changed somewhat to suit those who may have a favorite way of their own; but this would not alter the plan any, which will practically remain one and the same thing.

It really looks to be very troublesome, and involving much labor when explained in print, but there are some things in this world the actual doing of which is much easier than the explanation of how to do them, and this is one of those things. Try it and be convinced.

Hamilton Co., Ohio.

A California Method of Managing Swarms.

BY MRS. F. S. A. SNYDER.

NATURE provides that bees should swarm, so I allow each colony to throw off one good swarm in a season. Have all ready made up and fully equipt one new brood-chamber and as many supers as you have colonies that you think will swarm, and 8 or 10 new frames (whichever number you use) for each super, with one-half sheets of comb foundation in each frame, tho the frames are wanted for the brood-chambers and swarms, as I will show. I use seven for each brood-chamber of foundation, and then place a frame with a little honey and brood out of a full hive in the center for the eighth, to encourage the swarm, and to keep them from absconding.

Now cut as many pieces of wire-netting just the size of the brood-chamber as you have supers, and two strips of wood one inch in width for the sides, and two strips of wood the same width for the ends, and about the thickness of a shake, or, if you have them, the strips of wood used to raise the brood-chamber from the bottom-board are just what you want, but you will want two instead of one; for the ends I use a shake cut in strips just the length and width of the ends and sides of the hive.

My method requires that you should be on the spot and know to a certainty which colony has swarmed. Directly the swarm has issued, and you are sure the queen is with them, remove the old hive from its stand and place the one brood-chamber with 7 frames of foundation, and one with a little honey and brood on the old stand, then place the wire-net separator over it, and then the sticks with one nail in each to keep them in place. Now cut a piece the size of an inch out of the middle of the end stick at the back end of

the brood-chamber, so the young bees can have an entrance distinct from the swarm to fly from. Now place one empty super on top of the shakes, and above the swarm already hived in the new brood-chamber. Cut all queen-cells out of the old hive, and place the frames, young bees and brood, over the swarm in the empty super. If it is a two-story hive use two supers, and the bees will be that much stronger, and you can use the old brood-chamber with 7 new frames of foundation, and one from a strong hive with a little honey and brood in it for the next swarm, and proceed as before.

The first hive I fixt this way I did not think the wire-net separator or separate entrance for the young bees necessary, consequently the young bees hatcht out and fell among the empty frames or on the bottom-board and perisht from hunger, and were hustled and jostled out half-dead by the hurrying bees of the swarm.

In from seven to ten days, according to the honey-yield, the queen of the swarm will have laid the frames in the brood-chamber full of brood, and the young bees will all have hatcht out of the frames in the super. They seem to know intuitively that there is a queen in the hive under the wire separator, and make no attempt to build queen-cells; however, the frames should be lookt carefully over, and if any cut them out.

Now remove the wire-net and place the empty combs out of the super in the brood-chamber, and the combs full of brood from the brood-chamber in the super, replace the super on the brood-chamber without the net separator, and if there is a good honey-yield 9 or 10 days after, you will find all the bees hatcht out of the frames in the super, and instead of brood each comb will be full of capt honey.

By this method you will have 40,000 worker-bees in the field, and 60 pounds of honey ready to extract in just 30 days after the bees have swarmed; and you need have no more colonies than you care to increase to; and with diligent extracting you need fear no more swarms.

Sonoma Co., Calif.

Feeding Whiskey in Honey to Bees.

BY C. P. DADANT.

MR. DADANT:—Did you ever hear of any one feeding whiskey to bees in honey, and is it true that it renders them bolder and causes them to try to rob other hives? About a week ago, a man who has three colonies of bees, told me that some strange bees were completely robbing one of his colonies. To-day very probably the same bees were robbing one of mine, and I only have three. I stopt up the entrances, and that help some, for my bees are quite strong.

I was told that when bees were fed whiskey in honey it makes them bold to rob other people's bees. What is your opinion? ILLINOIS.

In the first place, one thing which we must establish before all others, is that the bees do not discriminate between the colonies which belong to their owner and other people's bees. It looks as if it might be superfluous to mention this, but I have often heard the remark that Mr. So-and-So's bees were robbing Mr. Somebody's hives, just as if a man could "set" his bees onto another man's apiary as bad boys "set" one dog onto another, or as some of our so-called civilized Christians organize a prize-fight.

Bees have no sense of morality outside of their home interests. They love their home, they love their own sisters, and they love their mother with a reverence which resembles veneration; and all their actions, whether they be beneficial or injurious to the apiarist, are the result of these feelings, if we may so call their instinct. As a matter of course they love honey, but if they gorge themselves with it, honestly or dishonestly *in our eyes*, whenever occasion offers, it is only with the intention of taking it home and placing it in the cells for the common good of the colony. They do not know of any friends outside of their home, and all other hives are considered either as enemies or as possible plunder. So they will rob your own bees as well as those of your neighbor, and if whiskey has any influence over them, and makes them more vicious (and it is quite possible that such be the case, since it is the case with human beings), it would only add to the possible trouble in your apiary as well as in your neighbor's.

I have never heard of strong drink being used in feeding bees, except in one instance. I remember reading in L'Apiculteur years ago, of an old-time bee-keeper having fed his bees with bread dipt in honey which had been mixt with a proportion of wine, to cure them of diarrhea early in the spring. Having never tried it I can not say whether this recipe was of any value as a tonic for diseased bees.

The bee-keeper whose colonies are robbed by other bees, whiskey or no whiskey, can lay the blame on himself,

and himself alone. A colony of bees in healthy condition and properly managed should fear nothing from robber-bees, except by some accident beyond the control of the apiarist, such as the breaking down of combs by heat, or the upturning of the hive by wind or mischievous animals or human beings.

When there is no honey in the field (and this is the only time when robbing is to be feared), if the weather is hot, the bees usually cluster at the entrance in sufficient numbers to repel all invaders, from an elephant to a mosquito. If the weather is cool, or the colony weak, it is the duty of the bee-keeper to see that the entrance be reduced in proportion to the strength of the colony. Then the only time when there will be any danger at all for a weak colony will be in cool mornings when the bees are clustered away from the entrance, and then only if the robbing colonies are early in the field, and excited to action. In such cases, if the apiarist foresees any trouble he can readily avoid it by closing up the hive-entrances of his weak colonies till the weather is warm enough to enable them to make a good stand at the door.

But why should any one keep weak colonies in this condition? At any time during the season, except in the winter, it is easy enough to strengthen a weak colony by helping it with brood or hatching bees from stronger colonies, tho this must be done with discernment, care being taken not to give them more than they can readily keep warm.

In the case mentioned in the above enquiry, it is evident that some colony of bees in the town found honey in some uncovered situation, either in a hive of which the bees had died, or in a queenless hive (which amounts to exactly the same thing), or in some open shed, etc. The finding of honey in times of scarcity has an effect on the bees well known to the practical bee-keeper, and the colony that has made the "find" is easily recognized, for its bees get into a condition of intense excitement. Those who have discovered the spoils evidently have a way of informing the others, but they have no means to tell them the spot, and since it is only by following them, or by hunting on their own account, that their sisters can be informed, the result is that the whole neighborhood is scoured by eager scouts. Every hive is examined, every crack in the bee-house, every shingle in its roof is scrutinized, and nothing escapes their vigilant search. Then let the exposed weak colonies beware—the robbers flock to them by hundreds, and will force an entrance unless a good defense is at hand.

There is no need of whiskey to cause this. A few neglected combs, a few drops of liquid honey, even a few spoonfuls of sweet juice of fruits, or of syrup, will do the mischief, and the bee-keeper who cares for his own bees, will carefully avoid any such excitement. The man who would cause this robbing with dishonest intent towards his neighbors' bees, would run the risk of being the first victim.

"WEEDS IN CITIES AND TOWNS"—SWEET CLOVER.

Mr. Lyster H. Dewey, assistant botanist of the Department of Agriculture, in the last Year Book issued, had something to say on the subject of "Weeds in Cities and Towns."

Weeds in vacant lots and waste-places may be of some use, or may be very noxious according to their kind. Mr. Dewey mentions a number of weeds as dangerous, owing to their poisonous qualities; others as disagreeable, owing to their bad odor. He overlooks the bad effect of the ragweed, in its deleterious influence on the lungs of persons subject to what is known as hay-fever, which has often been ascribed to the action of the pollen of this plant. But among the pleasanter weeds he classes clovers, asters, and the much-abused sweet clover. Altho the essay does not consider weeds in their capacity as honey-producing plants, yet in its conclusions it rather favors the very plants that are most useful to the bee-keeper.

If an outyard or a waste corner is to be left growing in weeds, it is much better for it to produce such a plant as sweet clover, which spreads a pleasant smell in the air, injures no one, and enriches the soil, while, on the other hand, it may be very readily destroyed if need be, than to have it overgrown with the stinking ragweed, the poisonous jimson weed, or datura stramonium, or thistles. The opposition to sweet clover as a weed where weeds must grow, is beyond my understanding, for I have never known this "weed" to do any harm to any one, as it is most readily exterminated when the soil it occupies is put under cultivation. Hancock Co., Ill.

Spraying Fruit-Trees—The Ontario Law.

BY R. F. HOLTERRMANN,
Ex-Editor of the Canadian Bee Journal.

THERE is no doubt that the Canadian readers, and probably others, of the American Bee Journal, would be interested at this season in having a word upon the subject of spraying fruit-trees. Having been interested in bees and fruit, and having come in contact with many of our best authorities in both of these branches of agriculture, it may be of advantage to both classes to set forth their views. Ontario bee-keepers also welcome any copy they can secure of the "Act for the Protection of Bees." More than that, I have every confidence that were some one to print private postal cards or circulars, and supply them at a reasonable rate, many would order them by post, and send them to those likely to spray in their vicinity; or at a certain rate they could be mailed and address at the office where printed. Such a direct and unexpected notice would no doubt have a very wholesome effect as an educator. The card might be headed, "PLEASE TAKE NOTICE."

The best-informed fruit-men are fully aware that bees are of very great value to them in assisting in the fertilization of blossoms. True, their value varies, but the more uncertain the weather, the fewer the bright and sunny days in which the pollen is dry enough to be distributed by currents of air, the greater the value of the bees; they can do much valuable service in a very short time.

That it is becoming more and more necessary to spray to secure perfect fruit, there is no doubt. Insect pests are on the increase; and while rapid transit and the interchange of products between different countries has its advantage, there is no doubt that insect pests, disease, etc., have also thru it been spread.

No one in Ontario can get profitable returns from orchards without care and attention. "In the sweat of thy face shalt thou eat bread till thou return unto the ground," is true of every one that depends upon the soil for a living. These pests can only be kept down with toil. So that we might as well make up our minds that spraying will continue until the curse is removed.

But do bee-keeping and fruit-growing interests clash upon this important question? Not at all. The best horticulturists tell me that the mixture used for spraying is strong; that it must be used with care and caution, and by deviations in the quantity used in the compound, even the foliage of trees has been injured. They also say that if this mixture comes in contact with the delicate part of the flowers when in blossom, it is likely to injure them to such an extent that they will not set fruit at all. I know of an instance where such a result was clearly indicated. More than that, to spray during that time is a waste of time and material. Spraying should be done *after* the fruit has set and *before* the fruit set turns down; there is no necessity for spraying so close together. If these rules are observed the fruit-grower will profit, and the bee-keeper will not have bees destroyed.

Now some bee-keepers feel that they should make an example of some one in each neighborhood—not with the object of punishing the offender, but to draw attention to the law—to educate. It would be well if such could be avoided; law does not promote harmony among neighbors, and certainly does not advance the cause of Christ.

Many have a book professing to give information upon many subjects, and the directions in this book are to spray when the trees are in blossom. I found several spraying in my vicinity upon the strength of this authority. I do not think any one should be prosecuted until they have had the law shown to them, and it is as follows:

1. No person in spraying or sprinkling fruit-trees during the period within which such trees are in full bloom shall use, or cause to be used, any mixture containing Paris green or any other poisonous substance injurious to bees.

2. Any person contravening the provisions of this Act, shall on summary conviction thereof before a Justice of the Peace, be subject to a penalty of not less than \$1.00, and not more than \$5.00, with or without cost of prosecution; and in case of a fine, or a fine and cost being awarded, and of the same not being upon conviction forthwith paid, the Justice may commit the offender to a common goal, there to be imprisoned for any term not exceeding 30 days, unless the fine and costs are sooner paid.

Where bees were supplied with sufficient stores last fall they have wintered well. Clover is also in good shape. Spring has opened up late, and it appears to be making up for lost time now. Ontario, Canada, April 24.

The Premiums offered on page 288 are well worth working for. Look at them.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Methods of Making Nuclei.

Will this plan do for making nuclei? I have a colony on 8-frames; would it do to take 2 frames of bees and brood (one having the queen on it) and place in new hive, and then let the 6 remaining frames rear a queen? PHILA.

ANSWER.—The plan will be all right providing you put the queen with two frames on a new stand and leave the remainder on the old stand. But it will be rather expensive to do all that for one queen. Cheaper to buy a queen, if your colony would do any good at storing honey. You might vary the plan in this way: Nine days after taking the queen away, put her back again with her hive on the old stand. Make 3 nuclei of the 6 frames, taking with the combs the adhering bees, and put the weakest of these nuclei, if there's any difference in strength, on the stand the old queen was just taken from, and put the other two in new locations. Divide the queen-cells among the three nuclei as nearly equal as possible.

Queen-Excluders—Granulated Honey.

1. My bees wintered well. I have 15 colonies in movable-frame hives of my own construction. I want to run 8 colonies for extracted honey. Would you advise me to put on queen-excluders with an entrance to each story?

2. I sold a 60-pound can of extracted honey to my local druggist; it was fall honey, and now it has granulated so that he cannot let it out to put it into his medicines. He thinks I adulterated it. How can I convince him that it is pure? I would like to supply him further on.

3. Would you advise queen-excluders for comb-honey production? INDIANA.

ANSWERS.—1. Yes, use excluders and have full entrance to the upper story. While this upper entrance might not do for comb honey, it is well to have a big entrance for extracted honey, as it helps no little to keep down swarming.

2. Tell him to get some honey that he *knows* is pure, let it run out of the comb and keep it over a year. If the honey was produced in Indiana, it will be sure to granulate, altho some honey in the South may not granulate. Those who are informed will tell you that honey that stands over the winter without granulating is pretty surely adulterated, for glucose is the principal adulterant, and will not granulate.

3. In most cases they are not needed.

Keeping Down Increase, Etc.

1. I do not wish any increase in the number of the colonies of my bees. What and how must I do with the swarms?

2. I notice granulated honey in the brood-chamber of some of my colonies. What causes it?

3. Can the bees use it?

4. What time should I put on the supers? Will it do to put them on any time in the spring so they will be certain to be there when the bees need them? TENN.

ANSWERS.—1. A very, very hard question to answer, if you are working for comb honey. You might give the swarm *all* the bees from the old colony when they swarm, or in other words take away all the frames of brood and honey, leaving all the bees on the old stand with the queen. The brood can be distributed among other colonies so long as there are those which need it, and afterward it can be piled up two or three stories high on the weaker colonies, and later some uniting may be necessary.

Perhaps this way may suit you better: When a colony

swarms, kill or remove the old queen (the bees will do it for you if the queen is clipped, altho she may be left a number of days.) When the first young queen emerges, which will be 8 days or so after the prime swarm, cut out all queen-cells, and there should be no more swarming. If you are working for extracted honey the problem is easier. Just before time to swarm, put all the brood in a second story, leaving the queen in the lower story with frames of foundation or empty comb, an excluder between the two stories, and there will be little or no trouble with swarms.

2. I don't know just why honey seems anxious to granulate as soon as it can, but it is a very common thing to find some honey granulated in brood-combs. The colder it is, the worse the granulating.

3. Yes, but sometimes they throw out the granules. It has been recommended to take out such combs, spray or wet thoroly with water, and when returned the bees will work up the granules.

4. It is unwise to put supers on early in the spring. It cools off the hive, and if sections are put on they will not be kept so clean. It is better to put them on a *little* too soon than to put them on too late. Try to get them on about a week before you think the bees will need them. If white clover is your first harvest, put on supers about the time you see the very first clover in bloom, for the bees will not be fairly at work on it till a week or ten days later.

Separating United Swarms.

How can I separate two or more swarms of bees that unite in swarming? IOWA.

ANSWER.—First hunt out the queens. You will often find each queen surrounded by a ball of bees. Put each queen into the hive prepared for it, a few bees with each queen, then distribute the bees equally.

Queenless Colony.

I have a strong colony that has been queenless for 12 or 15 days; they have 5 queen-cells, some nearly ready to hatch. Do you think the colony will be all right, or should I get a queen? PENNSYLVANIA.

ANSWER.—The probability is that the colony will come out all right. If the queen begins to lay within two weeks after issuing from the cell, there is little danger of anything being wrong, altho there is a bare possibility that she might be a drone-layer, which can be decided as soon as brood is sealed. If the brood in worker-cells, instead of being sealed over so as to have the usual flat appearance, looks rounding like a lot of little marbles, the queen is a drone-layer and worthless.

Stimulating Brood-Rearing—Getting Increase.

1. When using an extra hive-body underneath in the spring, do you feed or otherwise stimulate brood-rearing?

2. What plan would you adopt to build up colonies in the spring where the honey-flow commences about June 1, and there is apt to be considerable cold, windy weather during April and the forepart of May, the bees being wintered outdoors?

3. Suppose you wanted to double your number of colonies and have the new queens in the new hives with the new combs, leaving the old queens with the old hives and combs, the young queens to be reared from brood of one or two selected queens, how would you manage it? COLO.

ANSWERS.—1. Generally not.

2. See that they have abundance of honey and are as snug and warm as possible, then let them severely alone.

3. The case is hardly a supposable one. One way would be to build up on the nucleus plan, then take all old combs out of your new hives and exchange for new combs found in other hives.

May be Paralysis—Working for Extracted Honey.

1. One of my colonies with a select tested queen which I got last summer seems to be losing a larger number of bees than the others; every day I see from 10 to 20 dying bees outside the hive, some very dark and shiny, and some have the abdomen swelled. There are no half-dead bees in front of any other hive. Would it be owing to some weak-

ness in the queen? I was intending to rear queens from that colony. Would you advise doing so? I have another untested one, gotten at the same time, which, as far as I can see, was purely mated. Would it be better to breed from her?

In working for extracted honey, would it be a good plan when the hive (I use the 8-frame Langstroth) is getting nearly full of brood, which will be about the beginning of May, to put on a second story, full-size frames, and when the flow is coming on, about 5 weeks later, put a queen-excluder between the two stories? or would it be better to put on a third story with an excluder under it?

The bees are doing well so far, some colonies having now (April 15) five frames nearly full of brood and eggs.
BRITISH COLUMBIA.

ANSWERS.—I. From the description it seems to be a case of bee-paralysis, and as far north as you are the probabilities are that it will soon disappear. You hardly need be afraid to breed from the queen.

2. Either plan is good, the last being perhaps best. If you prefer to have no swarming, you may like better, at the beginning of the flow, to give an empty story below, putting the queen in it and an excluder over it, and putting the two stories with brood over the excluder.

Fastening Wood-Splints in Comb Foundation.

How do you put whole sheets of foundation in the brood-frames with splints? Do you put them opposite each other, one on each side of the foundation? Will they interfere with brood-rearing? Where could I get some of the splints?
SUBSCRIBER.

ANSWER.—The splints are put only on one side. I don't believe there would be any advantage in having them on both sides, and it would be more trouble. I never could see that the splints interfered in the least with brood-rearing. I could show you frame after frame filled solid with brood, and you would find no signs of any splints present, only in some cases you would find a row of cells right over one of the splints projecting slightly above the sealing about them. But you would have to look pretty close to see it. Any establishment that has a machine for slicing wood separators can easily slice the sticks. Ask for sticks 1-16 inch square and $\frac{1}{8}$ inch shorter than the inside depth of your frame.

Sowing for Honey—Best Extracting Frame—Clipping and Swarming—Cyprian Bees.

1. What is the best plant to sow, that will bloom the same summer, for honey alone, besides white clover?

2. Which is the better frame to use above the brood for extracted honey, the ordinary brood-frame or the shallow extracting-frame?

3. If a bee-keeper should clip the queen's wings, and go thru the hives and take out every queen-cell, would not swarming be reduced to a distant possibility?

4. Can you tell me who keeps Cyprian bees for sale, or queens?
MINNESOTA.

ANSWERS.—1. Perhaps buckwheat. You'll get all you can ever get from that the first year, and white clover will hardly do a good job the first year.

2. The shallow frame. Bees occupy it more promptly, fill it more promptly and more uniformly, the queen is not so likely to lay in it if no excluder is present, and the uncapping is easier.

3. Looks very nice on paper, but when you try it in practice it doesn't fully meet expectations. Clipping a queen's wings doesn't make a particle of difference about swarming. The swarm will issue just the same as if the queen had not been clipped. But it does make a difference about the swarm going off. Cutting queen-cells answers sometimes to prevent swarming, and sometimes you may miss a cell, and it sometimes happens that a colony may swarm the next day after you cut the cells, just to spite you. It is true, however, that if you cut out all queen-cells faithfully you will have less swarming than if you let them alone.

4. I only know them as they are advertised, and about this time of year you will find advertisements in the newspapers of about everything to be had in the bee line.

Getting a Start in Bees.

How and where could I get a little start in bees, say about 2, 3 or 6 colonies with queens? Can you forward them? What would they cost?

I got a good, nice colony last summer from a friend, and they did well right along, and over the winter till now. About the middle of March a mouse made its nest in the hive, and all the bees died, leaving the hive full of combs and a few pounds of honey. I suppose that the old combs would be all right to start a new colony. Would one pound or $\frac{1}{2}$ pound of bees for each colony be enough to make a start with?
NEBRASKA.

ANSWER.—You will find among advertisements in this journal those from whom you can obtain bees and queens. I do not deal in bees or queens, except to furnish the queens ordered thru George W. York & Co. It is not too far to get bees from Illinois or farther; only the farther they are the heavier the express charges are. Perhaps you may do as well to find some one near by from whom you can get a full colony to start with. A pound of bees with a queen put on your old combs can be built up into a good colony. Much depends on the season. In a very poor season they might hardly be got ready for winter without feeding, while in an extra season they might gather more than enough for winter.

A Beginner's Questions.

Last fall when my son George went away he and his brother-in-law gave me a colony of bees, but when we went to get the honey out, about the last of October, the queen, or a queen, was in the super, and she died. The bees did not swarm last summer, and stored nearly 100 pounds of comb honey, and seem to be very strong. We thought perhaps it was a new queen or she would not have gone into the super. The bees are in a fine modern hive. How can I tell if they have a queen? What would I better do? What would a queen cost if I need one? And where could I get it?
ILLINOIS.

ANSWER.—Whether the queen was a new or an old one, there is good reason to fear it was the only one in the hive, and perhaps too late for a chance to have another one reared. You can decide the matter by seeing whether any worker-brood is present in the hive, that is, brood in worker-cells, the smaller cells that measure five to the inch. There is, however, a chance that there may be a drone-laying queen or laying workers present, in which case the sealed brood, instead of being flat, will be rounding like a lot of little marbles. You can get an untested queen for a dollar, generally, and any of the advertisements in this paper will tell you where to order from.

A Drone-Laying Queen.

I have a case of a queen laying all drone-eggs this spring, that I can't account for. I reared the queen in June, 1898, from an imported mother. She built up the colony nicely that season, and last spring my son and I clipped the right wing, so that in case of swarming we would not lose her, as she is a fine one. This morning (April 17) seeing some young drones at the entrance of the hive, I opened it, thinking my fine queen was gone, and a young one had been hatched too late to be mated; but to my astonishment I found the fine clipped queen on the comb busy laying, and nothing but sealed drones in worker-comb, and brood in all stages from the eggs to drones, hatching out.

1. Is there any likelihood of the queen changing and laying worker-eggs again?

2. Will her drones be good to breed from with young queens before the usual hatch of mixt drones comes on?

3. I took the queen out with one frame of bees and brood and put them in an observatory box to see what the result will be. I gave the colony a frame of eggs and brood from one of my imported queens. Did I do what is for the best?
ILLINOIS.

ANSWERS.—1. It is not uncommon for a queen when she becomes old to lay part or all drone-eggs in worker-cells, but not often so young as your queen. It is not at all likely she will ever be any better.

2. Her drones are all right for breeding, except that the size of those reared in worker-cells is objectionable.

3. Quite right.

NO. 18

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

The Brosius Pure Food Bill, we learn, will likely be reported very soon in the House. It is hoped that Congress will approve it promptly, so that its wise provisions may be applied at once.

Which is the Most Hopeful Field for improvement in bee-keeping? is the question to which Editor Hutchinson is anxious to learn the right answer. He asks for light, throwing out the hint that it may be in the line of wintering bees, planting for honey, improvement of stock, or marketing honey.

California Bee-Keepers' Exchange.—C. H. Clayton gives in Gleanings in Bee-Culture seven reasons why it has not been a greater success, viz.: Selfishness; trying to get more separately than thru the organization; mortgaged crops; rebates on commissions; intimidation from buyers; apathy; jealousy; dissensions. Too bad that bee-keepers don't "get together" better than they do.

The National Bee-Keepers' Association.—Editor Root is quite enthusiastic over the results of the effort to down adulteration in Chicago, and thinks the efforts of the Association, together with the new Illinois law to go into effect in July, "are going a long way to wipe out adulteration in

one of the worst centers of adulteration in the United States." He continues:

"Indeed, I should not be surprised if it would stamp it out entirely. In either event, no one will know just how much the Association has contributed to bring about this very desirable result. But that it has certainly done *something* can not be denied. I tell you, brethren, we ought to stand by the Association. Give it your dollars, because it is fighting *your* battles in a way that you can not do single-handed and alone, and I promise you there will be some later developments that will be an eye-opener if nothing else.

"By the time the National meets in Chicago, in August, I hope there will not be a pound of adulterated goods to be had in the city."

In-Breeding.—A. Alfonsus, a prominent German writer, scouts the idea of deterioration on account of in-breeding, in consideration of the fact that the queen may meet drones from a long distance.

The Inventor of Perforated Zinc.—Hanneman was lately visited in South America by Editor Schenk, of the Brasilianischen Bienenpflege. He is more than 80 years old, and has now 335 colonies of bees, besides being engaged in grape-culture. He is called the inventor of giant colonies, uniting a number of swarms in one after sifting out the extra queens. In one case he had 123 pounds of bees in one hive, taking from them 880 pounds of honey. For hives he uses kerosene-cases, from each of which he cuts one-third for a super. Altho he has an extractor, he takes out the honey by steam by a specially constructed arrangement.

Shall Granulated Honey Be Put on the Market?—Chalon Fowls rather pokes fun at the men who favor it. He says in Gleanings in Bee-Culture that it may be the best that Mr. Aikin and others can do in Colorado, where alfalfa honey candies so quickly, but it doesn't follow that it is best in the East, with different honey. If the work is properly done the first time, there need be very little gathering up and melting of clover and basswood. He thinks good prices can be obtained only by keeping the honey liquid. Editor Root thinks Mr. Fowls might change his mind if he would study the Colorado markets, and says there are many who eat candied honey as so much confectionery, and prefer it.

Improvement in Bee-Stock.—In the last number of Gleanings in Bee-Culture, Uncle Lisha goes sidewise at the question of improvement in bees, reporting conversations with several of his neighbors somewhat prominent in different lines of stock-breeding. As an outcome some very telling facts are brought out. The popular Concord grape was obtained by successive improvements made on the wild fox-grape only fit for partridges and wild Indians to eat. From the wild hog has come the plump porker of to-day. A man who averaged 5 pounds of wool from each sheep in 1865, now averages 10 pounds. A man who 30 years ago got 200 pounds of butter to the cow now gets 300. After this is all brought out in an interesting manner thru conversations with the different men, Uncle Lisha has a closing conversation with his neighbor Simpson, who has been listening in mute astonishment, Uncle Lisha saying:

"You see," said I, "improvement is the watchword with every profession nowadays; and if the bee-keepers don't improve their stock they will get left."

"Geewhittaker! I should say!" exclaimed Simpson. "But what is the use of wasting your time in trying to improve your bees when you can just as well keep bees enough to get all the honey there is, and they will board themselves and work for nothing, as I have heard folks say?"

"Just this," said I. "The flowers within range of my home yard give on an average yearly, say 10,000 pounds of honey. Now, if I keep the average run of bees it will take

about 100 colonies to gather it, or 100 pounds of honey for each colony. Of this it will take about 70 pounds to keep each colony a year, leaving me only 30 pounds of surplus to the colony, or 3,000 pounds from the whole yard. But if I keep stronger and more industrious bees, so that each colony would gather 140 pounds while the other was gathering 100 pounds, it would require but 71 colonies to gather the whole 10,000 pounds; and as it would not require any more to keep each colony than it does the poorer stock, I should get 5,000 pounds of surplus instead of 3,000 pounds, when I had to keep 100 colonies, to say nothing of the smaller number of colonies to care for, or hives to keep in repair. And what is true of my home yard is true to a greater or less extent of any other yards. See?"

The Weekly Budget

DR. C. C. MILLER AND FAMILY (Mrs. Miller and her sister, Miss Emma Wilson) gave us a short office call last week when in Chicago on a shopping expedition. They may well be called "The Happy Three."

SWEET LABOR.—"How is it you're such a great worker?" askt the grasshopper.

"Because I love to work," said the busy bee. "I couldn't be happy without it. In fact, you have noticed when my busiest season is on I'm in clover."—Philadelphia Press.

MR. W. J. PICKARD, of Richland Co., Wis., dropt in to see us on Thursday of last week. He reported their nearly 400 colonies of bees as having wintered with a loss of only about 10. His daughter, Miss Ada, will run her large apiary again this season, as usual. Mr. Pickard has been investing in a few young samples of Polled Angus cattle. With the good women of the family to look after the bees, and Mr. P. to take care of the blooded farm stock, they have a pretty strong combination.

EDITOR ERNEST R. ROOT had this to say in the last number of his paper, dated April 15:

"I have just returned from attending a convention of the Chicago Bee-Keepers' Association—an organization that takes in bee-keepers of the city and immediate vicinity. The convention, while not large in attendance, was an excellent one, and the discussions were of the very best. After the convention I had a delightful visit with Dr. Miller and his family."

EDITOR LEAHY'S GOOD-BY.—An editorial in the Progressive Bee-Keeper begins by saying that in these days of telephones the word "good-by" has not connected with it the pathos of the olden time, but the good-by that he is now to speak is sad as that of yore. After thus stirring one up to wonder whether his editorial pencil or typewriter is to be forever stilled, or what other thing is to happen, he relieves the strain by saying that about 300 delinquent subscribers are to be "good-byed" if they don't at once walk up to the captain's office and settle. Business, that.

THE DEPARTMENT OF CRITICISM, in the Bee-Keepers' Review, which for some time has been in charge of Hon. R. L. Taylor, appears for the last time in the April number. Editor Hutchinson gives as the reason for its discontinuance: "I think the space can be better used in a *different way*." No doubt about that. Mr. Taylor is a clear and forceful writer, and undoubtedly a good bee-keeper, but how he could consent to put in his time and space, as he sometimes did, in petty pickings and hypercriticisms, is beyond our comprehension. But, then, we are just a little city editor of a bee-paper that only aspires to give its readers the genuine gospel of practical bee-keeping, and likely will be excused if we fail to appreciate some of the fine attempts to show the wonderful difference existing between the tweedle-dee and the tweedle-dum in things apicultural.

Bees and Fruit.—Every fruit, flower and vegetable grower should keep bees to aid in disseminating pollen on those blossoms that do not thoroly fertilize themselves. Good trees, buds and blossoms do not insure a fruit crop, but the pistil must be fertilized, cultivation continued, and the tree sprayed to check the ravages of destructive pests. —American Fruit and Vegetable Journal.

Ants in the Honey-Room.—H. D. Burrell says in the Bee-Keepers' Review:

"If you are troubled by ants, make a bench to keep honey on by laying 2x6 inch pieces of lumber edgewise on the floor and covering them with boards. Make a chalk-mark one inch wide entirely around the middle, lengthwise, of the 2x6 pieces, and not an ant can crawl up over it. They can't get a foot-hold."

Tall Sections.—C. A. Hatch argues in the Bee-Keepers' Review for 4x5 sections. For some reason they are better finishd, and the yield is larger. He says:

"In answering the most common argument against tall sections, viz., cost of extra supers, we will ignore the first point in their favor, *i. e.*, better appearance, and take only the last two—finish and quantity. I think, from extended observation at the apiary of Mr. Mendelson, who had 4x5 sections by the ton, that the grade was raised on at least 10 per cent. But, to be moderate, we will cut that in two, and call it 5 percent; and the 10 percent of increase of yield we will also halve, so, on a 50-pound yield, we would have 2½ cents gain for grade, and 25 cents for yield; which would give us a gain of 27½ cents. Can a man afford to lose 27½ cents to save the cost of a 15-cent super?"

Production of Extracted Honey with 8-Frame Hives is the topic of Harry Lathrop in the Bee-Keepers' Review. He thinks it better to be prepared to work for both comb and extracted, as conditions may be more favorable for one or the other; prefers a 2-frame Cowan to any 4-frame extractor. Whenever a colony becomes strong enough, he would give a second story of brood-frames, if necessary changing combs from one story to the other, so as to get brood in as many as possible. At the beginning of the honey-flow, an excluder is put over and a third story given for surplus. When this is pretty well filled, it is raised and another put under it. If necessary, a fifth story is added, always keeping the ripest honey at the top, and extracting as soon as fit. If the honey in any comb is the least bit watery, it is returned to the hive for ripening.

Management of Swarms for Comb Honey is given by J. F. Otto in the Bee-Keepers' Review. A swarm is put into a hive consisting of two Heddon brood-cases, the upper one only being provided with narrow strips of foundation. Mr. Otto continues:

"The next swarm that issues is handled in the same way; and then carried and set by the side of the other swarm that issued first. The two swarms are left that way until each swarm has built its upper case full of combs. As soon as that is done, I remove the lower empty brood-case of each swarm, and unite the two swarms by putting the two brood-cases, with queens and bees, one upon the other, on one bottom-board, thereby making one colony of the two. I put on the cover and leave them that way until the next day, when I lift off the upper brood-case, put a queen-excluding honey-board on the lower case, shake all the bees from the upper case down in front of the hive, and put the upper case back on the hive, leaving the queen-excluder between the two cases. Then I go to the old colonies from which the swarms issued, take off the supers and put them on this young newly united colony."

"The old colonies are supplied with Heddon brood-cases filled with empty combs, and are kept busy filling old combs with honey which is to be extracted, or to be used in the fall for supplying such colonies as are in need of honey."

THE AFTERTHOUGHT

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Richards, Ohio.

THE UNCAPPING-KNIFE AND ITS USE.

Did I hear you say, Mr. Grimes, that knife-makers should make the knife hold fast in the handle? I'm afraid that's a little like saying that commission men should be honest. Speak to us again when you have devised some way to make 'em do so. No one should be asked to pay a dollar and over for a knife unless it is put together, and put together for keeps. You see (despite the excellent Grimes advice to use the honey-knife only for uncapping) I use mine to clip my asparagus-green shades; and I have to curl my trigger-finger around it, like I was about to shoot a Boer, or Britisher. Not quite sure we should *always* cut the comb down to level relentlessly. And he didn't tell about late uncapping, when the combs have been on the hives all summer. Who'll get up a tournament, with a prize for the best and most rapid uncapping, and a reporter capable of describing the different ways of manipulation in which the champions proceeded? Page 178.

A COMPARISON THAT DIDN'T COMPARE.

In the last Aftersight, page 246, there is a bad "out," in which figures for comparison are given, and nothing to compare them with. The idea was that one colony has 20,000 field-bees out of a total of 30,000, while another has only 2,000 out of a total of 20,000. The home bees not counting, it is plain that a field which would supply nectar for 50 colonies of the former would supply 500 of the latter. And this element is one usually overlooked in such calculations.

MR. VAN BLARICUM AND HIS APIARY.

Mr. Van Blaricum, you look business in your long, single-line, flight-o'-ducks apiary. But what was the special need of warming your thumb? Did a bee make too free with it? And is that your remedy for stings? Your extempore shades of sunflower are good—makes them last all the fall, to keep the blossoms cut off. Page 177.

APIARIAN STATISTICS OF THE COLORADOS.

From 65 tons of honey in 1889 to 600 tons in 1899 is rapid growth for Colorado. They are happy in having things in shape out there to know a little more about bee-population and crops than some of the other States can at present. Page 181.

RELATIVE LONGEVITY OF STRAINS OF BEES.

H. Rauchfuss, of the Colorados, once more turns our minds to that important (important if true to report) consideration, the relative longevity of different strains of bees. Is it not strange that we should be so sadly lacking in definite evidence on such an important point? A comrade will tell us that his favorite bee is longer lived than other bees; but whether they live 15 days longer or 15 minutes longer—he hasn't got so far as that yet. Definite proof of how long worker-bees live is not very hard to get. Who will keep some long-lived bees and some short-lived bees side by side under identical conditions, and show us just how many days of difference there is during the honey-flow in June? Ere we spend very much time and cash, let us first be sure we are not pursuing a will-o'-the-wisp. You see it *might be* that the supposed short-lived ones are really just as long-lived as the others—the real trouble being an unusually large percentage of defective and worthless individuals among the brood. Page 182.

WAX-SECRETION AND HONEY-GATHERING.

Mr. Rauchfuss also says he has several colonies in his apiary market approvingly because they use wax to build the burrs on top, where other colonies use propolis largely. Shouldn't wonder if he were on track of something valuable. I suppose the idea is that such bees do not use propolis because wax is *plenty* with them—and that plentiful wax-secretion goes with plentiful honey-gathering. Does it always? Page 182.

BETTER "SEASON" NON-SWARMING THINGS.

President Aikin is a wise man. He always partakes of a grain of salt when he hears of non-swarming bees. Better include non-swarming hives and non-swarming methods—and double the dose of salt, and take it every half hour. Page 182.

THE BLACK BROOD SCOURGE.

What shall we say about P. W. Stahlmann's report of black brood on page 204? To lose 200 colonies out of 450 in one season is rather a shocking record for a person to make who seems to be reasonably diligent and expert in his craft. Perhaps it's mainly because no one knows yet how to proceed against a new disease; but again, perhaps—perhaps we have a plague on our shores that's going to sweep the country despite all that can be done.

"WATER ON THE HEAD" FOR BEE-STINGS.

Henry White, page 203, is certainly a veteran; but to souse one's head in a tub of water when an army of infuriated bees are grubbing it over—that's what some of the veterans would call one of the greenest of greenhorn tricks. You see, wetting does not improve their temper much; and you fix 'em so they can not leave you when they get ready.

PURE-FOOD LAWS AND THEIR ENFORCEMENT.

Mr. Abbott may be right that the matter of pure food and honey should be left in the hands of the Commissioner of Agriculture; but somehow it seems a little to me as if an officer with no other duty to perform would be less likely to neglect duty. A thoroughly competent and good man would get to work in either case; but even a rather poor stick (such as the political machine is apt to give us) would do *something* if wicked obstruction or utter idleness were the only alternatives. Page 199.

FULL FOUNDATION SHEETS IN SECTIONS.

The appearance of the thing on page 196 is that five of the Colorados believe in full sheets of foundation in sections, and act accordingly, while 13 more believe the same thing but don't live up to their faith. Still, those who believe in total depravity are all the better for not living up to it.

FASTENING FOUNDATION IN SECTIONS.

Keep your cut foundation as cold as ever you can, by some extemporized refrigerating arrangement, if you are going to set it by the hot-plate process. New idea to me, but looks very sensible. They didn't agree as to whether the hot plate should be allowed to warm the wood of the section a little.

WINTERING BEES IN A "CEMENT CISTERN."

Bingham's bee-cave looks dreadfully sinister somehow. One would think that, if not actually a den for the commission of crime, at least the slaughter of innocent little lambs must be carried on inside that dark, wigwam-like structure. Am not quite sure I like the idea of wintering bees in a cement cistern—but that feature of the thing could be modified—and "pretty is that pretty does." If this new departure in wintering-repositories does all that is expected of it, it will be as pretty as Annie Laurie herself. Excellent plan to weigh the dead every exact month, so the bee-keeper knows just "where he is at." So far the record is lovely at a loss of about a third of an ounce a month per colony. This would be about 93 bees out of say 14,000—but wait till you hear from the *last* month. Page 193.

INTRODUCING QUEENS.

Mr. Bonney might have carried his safe-introduction plan a little further yet. Of a colony having lots of brood one can not impound all the bees *a la* Doolittle; but just previous to running in the queen and the first half of the bees, those left in charge of the brood can also be shaken out and put in "durance vile" for a season. In returning these last, just set them near the door and let them go home individually, instead of all in a rush. Page 196.

BLOCKING THE BROOD-CHAMBER WITH HONEY.

So according to Mr. Aikin, page 195, a weak colony will always crowd the brood-chamber with honey, if they have the honey to do it with, and the strongest will do the same thing in just the requisite kind of a slow flow. Sensible—but! Are there not some bees with which you'll never have a blocked brood-chamber if the colony is fairly populous?

California Queens.

OF PURE ITALIAN STOCK.

(THREE-BANDED.)

No other bees within a radius of TEN MILES. Eight years' experience in practical bee-keeping. Untested Queens, 90 cts. each; \$9 per doz. Discounts after July 1. Write for price-list.

18A13t H. L. WEEMS, Hanford, Calif. Please mention Bee Journal when writing.

SURE HATCH INCUBATOR.

True to its name. It is made to hatch and doeshatch. No excess heating in center of egg chamber. Entirely automatic. Hundreds in use. Common Sense Brooders are perfect. GENERAL ITEMS

Bees Doing Well.

My bees are doing fine, all having come thru the winter all right except one colony, which died from exposure. I winter my bees on the summer stands in dovetailed hives, with no protection but the chaff cushions on top. They are now bringing in plenty of pollen, and the hives are full of brood and young bees. I practice spreading the brood-nest, and find it a great advantage. I expect to double the number of colonies I now have by increasing. I have some blacks, but will substitute them with Italians, by Doolittle's plan.

My bees did not do so well last season, as the season was too dry still I can not complain, as I got from 30 to 40 pounds per colony, but did not increase any. I sold all my money in neighboring towns, and could have sold more if I had had it. I sold it for 11 to 12 1/2 cents, and had no trouble. I put my honey up nicely, and in both small and large packages, so as to please all.

P. I. HUFFMAN. Rockbridge Co., Va., April 18.

Have Filled Two Supers Each.

I have 40 colonies of black bees which are doing well at the present time; some have already filled two supers, each containing 18 one-pound sections. By the first of June everything dries up here, so there is nothing but grapes and fruit for the bees to work on.

JAS. PETERSON. Tehama Co., Calif., April 17.

Wintered Nicely in the Cellar.

I put 60 colonies of bees into the cellar Nov. 15, and lost 4 by starvation, being rather light when put in. I took them out April 3, and they carried in the first pollen April 7, from soft maple and poplar. My bees wintered nicely, and are strong. The temperature in the cellar was mostly 38 degrees above zero, and at no time 45 degrees. Bees seemed most quiet at 38 degrees. My thermometer hangs about the center of the cellar. G. P. TENDORFER. Sibley Co., Minn., April 19.

Laying Workers and Their Progeny

I notice on page 39, some one asks what makes a laying-worker. I don't propose to answer this question for Dr. Miller, but confess "I don't know." But there is one thing I do know, and that is that when I am so careless as to let a colony of bees get into a condition to expect laying workers, I must hop and skip until all of their brood is destroyed; and if any have emerged from the cells, some of the good plans given in our text-books must be speedily applied to destroy these worthless inmates of the hive. They are nothing more than "faulty drones," and have given much trouble in my bee-yard.

I rear queens for my own use, and after 15 years of experience I boast that I know pretty well how it is done. When I rear fine, large, prolific queens and they mate with these "faulty drones," I have a queen whose daughters produce bees that are weak, and in most cases have bee-paralysis.

Early in the spring of 1887 I bought a tested Italian queen, and reared queens, divided, and sub-divided, until I had a considerable number of colonies, and they went into winter quarters swarming in a sea of glory. But long before the calendar changed to 1888, quite a number of the bees had deserted their hives, and the following spring found me with but few colonies and a small number of bees in each. From the hive in which I wintered the tested queen I noticed drones flying freely. Upon examination

18E2t

W. A. HENDERSON, Clarinda, Iowa.

I found the tested queen gone, and the bees rearing drones in worker-comb. From the amount of brood, and the drones already hatched, I judged that they were at work in good earnest. These faulty drones were beautiful in color—the yellowest I ever saw. A new idea struck me, and I concluded I would rear some queens and have them fertilized by these yellow drones before there were any drones from the other colonies. I reared 3 queens, and they were laying by April 15, before there were any drones from the other colonies. As soon as these bees began to emerge from the cells, I selected the queen that produced the best market bees to rear queens from.

After rearing several queens from her, and introducing them into my best colonies, I began to congratulate myself upon what a wonderful piece of machinery man was that he could dive so deep into Nature and bring out the hidden mysteries, when, to my surprise and sorrow, these last-reared queens produced bees that had bee-paralysis. This may be a matter of locality, but I find that queens produce bees that are much better honey-gatherers when they mate with drones from the best honey-gathering colonies.
H. B. LAMBERT,
Simpson Co., Ky.

No Loss in Wintering.

This is a nice, warm week, the peach-trees are blooming, and the bees are making use of the bloom. I wintered my bees on the summer stands with the loss of none out of 68 colonies.
L. A. HAMMOND,
Washington Co., Md., April 21.

Wintered Especially Well.

Bees have wintered especially well in this locality (eastern Ontario) and prospects are good for the season. **G. G. SHIRREFF,**
Ontario, Canada, April 18.

Combining Bees with Other Things.

I have 30 colonies of bees in good shape, with plenty of sweets and lots of brood. I have had a severe case of bee-fever for about 3 years, and I can't see that it is abating any; rather I am sure I've had a relapse, and at this writing the fever is very high, and I rather think it will terminate in the higher stage of the fever—that of general bee-keeping. Of course, I don't mean by this that I will make the one pursuit of bee-keeping my only and entire business, for I mean to keep several good milk cows and patronize the creamery, and will rear thorobred O. I. C. hogs and barred Plymouth chickens. But with all this I am to keep at least 25 or 30 colonies of bees.

I propose to plant such forage as will produce both nectar for bees and feed for cattle and horses, thereby getting the extra crop of honey which I would lose if I had no bees. In these days people ought to plan to make all they can, and save all they make. See?
WM. HITCHCOCK,
Lonoke Co., Ark., April 21.

Robber Bees and Their Treatment.

Some of the incidents of my experience with a certain case of robbers may be suggestive as a help to other amateur bee-keepers.

Soon after placing my bees (20 colonies) out of the cellar, the unwelcome sound of prowling robbers was heard. Fighting was noticed at the entrances of 6 or 8 colonies, but finally nearly the whole force concentrated at one place. I tried to help the colony by contracting the entrance so that only about a space of one inch remained open. In front of this a little block was placed, which is a great help as a protection for the defense. In ordinary cases this arrangement is effective. This time the siege was continued and in a few days the robbers overpowered.

They now began to go in and out the small entrance quite freely.

Two of the colonies were noticed to be flying stronger and with more intent than

Yellow Sweet Clover Seed

WE HAVE IT AT LAST!

We have finally succeeded in getting a SMALL quantity of the seed of the YELLOW variety of sweet clover. This kind blooms from two to four weeks earlier than the common or white variety of sweet clover. It also grows much shorter, only about two feet in height. It is as much visited by the bees as the white, and usually comes into bloom ahead of white clover and basswood. We offer the seed as a premium

A QUARTER POUND FOR SENDING ONE NEW SUBSCRIPTION.

So long as it lasts, we will mail a quarter pound of the seed to a regular paid-up subscriber who sends us ONE NEW subscriber for the American Bee Journal one year, with \$1.00; or 1/4 pound by mail for 30 cents.

We have been trying for years to secure this seed, and finally succeeded in getting it. It is new seed, gathered last season by an old personal friend of ours, so we know it is all right. But we have only a small supply. When nearly out we will mention it.

GEORGE W. YORK & CO.,
118 Michigan St., - CHICAGO, ILL.

the others, so they were suspicioned as the ones making the trouble. As a test, the entrance of the colony being robbed was screened with wire-cloth, and in 15 or 20 minutes it was removed again. The robbers in the hive having filled themselves, and anxious to leave, came out like the beginning of a swarm. It was easy to note that they went to those two colonies in question.

I now tried the sawdust project, even to extreme measures, closing the entrance of the robbers' hives almost entirely. But in less than 5 minutes they would be at their more important business again.

In the evening the colony was moved to another place. The next morning the robbers were out again. Then came their downfall. Their hives were turned half way round, which completely confused them nearly all day. The next morning they were turned back, and slightly confused again. If necessary I meant to repeat the turning but have not been bothered since.

Conclusion: Try to locate the robbers. If found, don't fail to completely disturb them in some way. E. S. ROE.

Photography and Bees.

There is a man in Rogers Park who is an enthusiast in bee-culture. He has achieved a measure of success, and supplies his im-

"Rear Elevation—Cross Section."

mediate neighbors with a superior quality of honey at a normal price. So he is naturally proud of his hives.

One of his neighbors is equally enthusiastic over photography, and so it came about that the bee-man invited the camera-man to take a picture of the hives. So the photographer came and planted his tripod, while the honey-man posed beside the hives.

While adjusting his camera, with the cloth over his head, the picture-maker became aware of a loud buzzing inside the cloth. Supposing it came from an ordinary fly, he shook the cloth impatiently. The buzzing became more angry, and he began to move his arms and flop the cloth. That spoiled the picture, for two or three bees jabbed their stingers into him simultaneously, and he jumped into the air, upsetting the camera and uttering loud cries.

"What do you do that for?" said the bee-man; "just keep quiet and they won't hurt you."

"Won't hurt me, you lunatic," responded the camera-man, gathering up the wreck

and climbing over the fence rapidly. "Won't hurt me! I tell you they have hurt me, and I believe you told them to do it. You and your bees be hanged!"—Chicago Daily News.

Is Onion Honey Injurious to Bees?

The winter of 1898-99 I lost 20 colonies that I built up on the nucleus plan. June 30, 1899, we had a hard freeze which killed all the bloom, and in August I fed the 20 colonies, expecting a flow in the fall, which we did not get. The season being extremely dry, all colonies filled the hives with honey gathered from onion bloom, of which there was a nice crop planted for seed.

In February, 1900, I noticed that my bees were dying at a rapid rate. I examined the hives, and found the combs black, and the honey strong. There was no other bloom last fall to speak of. My bees did not have to go over 10 or 20 rods to gather the honey. All the old colonies came thru in good shape, but it almost cleans me out of the business.

I wish to keep bees, but if my neighbors persist in raising onion seeds, I would rather go out of the bee-business, in case of a poor season; in a good season it would be different.

F. McBRIDE.

Hardin Co., Ohio, April 21.

"Long Ideal Hive" Satisfactory.

Mr. Poppleton's explanation (page 212) of the term "Long Ideal Hive" is perfectly satisfactory to me. I agree with him about the offensiveness of the term "Long Idea." As I do not remember seeing any previous explanation, I suppose I may be excused for thinking that the new term was a mistake. Mr. Poppleton has my thanks for the correction, and I apologize to the Boiler.

WM. MUTH-RASMUSSEN.

Inyo Co., Calif.

[The apology is accepted.—BOILER.]

Wintered Well Outdoors.

My bees wintered well on the summer stands and all are in good shape except one colony, and that was in a common box. I had to feed them. On the 7th of this month another colony came over and went in with them, so I just transferred them into a frame hive, and they are working nicely, carrying in pollen. It made a strong colony.

I get lots of information out of the Bee Journal.

S. S. SIMPSON.

Marion Co., Ohio, April 21.

The Old City of St. Joseph, Florida.

April 9 to 14 I was cruising around in the Gulf of Mexico and St. Joseph's Bay, in search of health, recreation, and gathering of shells.

We spent one day at St. Joseph's Point; the waters were very warm, the air genial, and drest in bathing suits, we waded in the briny, clear water in search of shells. Many conchs were found, and building a fire on the beach, these were boiled in a tin can, until their occupants could be removed; then washt, dried, and packt away in the boat, to be taken home, as trophies of our trip.

We sailed from here to Eagle Harbor, and spent a day; when inclination prompted we crosst the narrow peninsula to the Gulf side, and reclining upon the white sand dunes, or sitting upon drift-wood, watcht the great white billows rolling in like leaping, prancing, white horses, and spreading out upon the shore.

Letters had been sent by us to fishermen camp at Ship Yard, and we sailed thither. Here were 4 crews with their paraphernalia for fishing—seines, reels, boats, etc. They had comfortable sleeping apartments in their tents, tables and benches for eating, cooking stoves protected by boards from winds, and their coffee-mill screwed to a pine tree.

One crew caught 8 barrels of Spanish mackerel one night while we were there, and numerous small shark were thrown

A HANDY TOOL-HOLDER!

Sent by Express, for \$1.50; or with the Bee Journal one year—both for \$2.00.

Every Manufacturer, Miller, Carpenter, Cabinet Maker, Machinist, Wheelwright and Quarryman, Farmer, or any one using a grindstone, should have one of these Tool-Holders. One boy can do the work of two persons, and grind much faster, easier and with perfect accuracy. Will hold any kind of tool, from the smallest chisel to a draw shave or ax. Extra attachment for sharpening scythe blades included in the above price. The work is done without wetting the hands or soiling the clothes, as the water flows from the operator. It can be attached to any size stone for hand or steam power, is always ready for use, nothing to get out of order, and is absolutely worth 100 times its cost.

No farm is well-equipped unless it has a Tool-Holder. Pays for itself in a short time.

How to Use the Holder.

DIRECTIONS.—The Tool is fastened securely in the Holder by a set-screw and can be ground to any desired bevel by inserting the arm of the Holder into a higher or lower notch of the standard. While turning the crank with the right hand, the left rests on an steady the Holder; the Tool is moved to the right or left across the stone, or examined while grinding, as readily and in the same way as if held in the hands.

For grinding Round-Edge Tools, the holes in the standard are used instead of the notches.

Journal of Agriculture,
ST. LOUIS MO.

A wide-awake, practical Western paper for wide-awake, practical Western farmers, stock-raisers, poultry people and fruit-growers, to learn the science of breeding, feeding and management. Special departments for horses, cattle, hogs, sheep, poultry and dairy. No farmer can afford to do without it.

It stands for American farmers and producers. It is the leading exponent of agriculture as a business, and at the same time the champion of the Agricultural States and the producer in politics. Subscription, One Dollar a Year.

upon the shore. What silvery beauties these fish are, with 3 rows of polk-a-dots on their sides; how delicious they were when cooked upon a charcoal fire in our boat.

A short distance away was the site of the historic city of St. Joseph, once having 5,000 inhabitants, but now not one or a single residence. Its desolation reminded me of the prophecies of Jeremiah; her wharfs are gone, nothing of the railroad remains except the ties, which are of pitch pine, and as sound as when laid, nearly a century ago, the third railroad in the United States. Yellow fever, tidal waves, hurricanes and forest fires wiped her out of existence. The rattle-snake has his hole, wild turkeys rear their broods, the doe and her fawn skip over her brick pavements, and an occasional bear growls and panther shrieks.

The captain had told me that there were many bee-trees in the swamp back of the town site, and I had brought along a globe bee-veil expecting a heap of fun getting wild honey. But I had forgotten to bring any bait; the ax was not along and the captain said he could not go into the swamp on account of snakes, so the project had to be reluctantly abandoned.

Mrs. L. HARRISON.

Washington Co., Fla., April 17.

Colonies Wintered Strong.

I wintered 7 colonies in the cellar; they came out strong and are building up very fast. Young bees are hatching out every day. They have more than two combs of brood now. The prospects for a big crop of honey are good, and I think the bees will hustle me around pretty lively, as I lack a great many things necessary to properly take care of a large crop from 18 colonies, being only a beginner. (I have just bought 11 colonies more.)

If this weather continues a few days fruit-bloom will be out. Bees are very busy today carrying pollen, and are getting some honey.

Geo. A. OHMERT.

Dubuque Co., Iowa, April 22.

Apiaries in Fine Condition.

Reports from all of my Wisconsin apiaries are that the bees have wintered almost without loss, and are in fine condition.

FRANK McNAY.

Columbia Co., Wis., April 19.

Prospects Favorable.

My loss in bees the past winter was one colony out of 84. Those alive are in good condition at present, and the prospects are favorable for a good honey harvest.

F. C. SNYDER.

Jones Co., Iowa, April 21.

Bees Troubled with Moths.

On page 630 (1899) Illinois asks, "What is the matter with my bees?" and says that "for a long time they have been bringing out dead brood from the hives in the nymph stage, and also full-grown bees." Also on page 667 (1899) the man who boils beedom down mentions a smaller wax-worm reported by Dr. Miller in Gleanings in Bee-Culture, and winds up by asking if the Doctor has made a new acquaintance, or whether it is only our old friend *galleria cereana* in a different role.

It is well known that the common wax-moth, or at least the one that some beekeepers dread so much, completely destroys the combs and leaves them a mass of filthy webs. There is a smaller kind called the "center-moth." The name is appropriate, for it works in the brood-nest (which is the center of the colony) and in the center of the combs. It is the terror of nuclei and weak colonies, and sometimes injures strong ones. Its presence in the brood-nest is indicated by one or more mature young bees with their heads bare (they being unable to leave the cell), and also by bare-headed brood, tho I am not sure that it causes the bare-headed brood in every in-

stance. When the bees start in after these moths they go clear thru the combs. When you see combs that have been used in brood-rearing full of holes, as if made for passageways, the center-moth has been there.

I do not know why it should be called center-moth, for I am sure it does not eat wax. True, it makes passageways from one cell to another, and thru the dividing-wall between the cells, but I have seen them come out of the bodies of dead bees which they had fastened in the cell with their webs. When you pull out one of those bees you will have to look into the cell quickly before it wriggles out of sight into some other cell. They sometimes pull out with the bee, but not every time.

Being desirous of increase the past season (1899) I used the nucleus plan, but by the help of a bad season and the center-moth I made a failure of it. One nucleus which became infested in May was left to itself to see what would become of it. By the middle of September it was weak in numbers, had no honey for winter, the combs full of holes, and most of the mature brood fastened in the combs with webs.

My bees are blacks, Italian-hybrids, Carniolans and Adels. Only the two latter ones were free from the pest the entire season. Strong colonies seem to be better able to withstand them than the weaker ones. But who is it that rears queens and has them all fertilized in strong colonies? I would be glad to find some means whereby I can be master of the center-moth. Who can do anything for me?

CHESSLEY PRESSWOOD.

Bradley Co., Tenn.

Carriage and Harness Business.

—It is not so very long ago that any stock article, however much of worth or durability it had, lacked, as a rule, all elegance of design. In other words, it had no style. Fortunately, all this is now past. The article of moderate cost has a character and finish that could not be had a few years ago except in high-priced made-to-order goods. It is nowhere more noticeable than in some of the modern lines of vehicles and buggies now being offered direct to the consumer by means of advertising. Take the catalog we have just received from the Kalamazoo (Mich.) Carriage & Harness Company, since it illustrates the principle referred to. Their goods equal in every way, so far as we can see, the product of certain factories which cater exclusively to the wealthy, and sell their vehicles by old methods of high-priced salesmen and expensive repositories in many leading cities. By such concerns, vehicles apparently no better than these are sold at from three to four times the price. In dealing direct with the Kalamazoo Carriage & Harness Company all expenses, such as city stores, salesmen, margins for bad accounts, etc., are saved. You pay only one profit, and that a very modest one. It is impossible for us, within the limitations of this paragraph, to give more than a hint of the complete line of the Kalamazoo Company. The catalog in itself is a very handsome one, and is an earnest of the good things inside. There are vehicles of every conceivable style, and all at very low prices. Every condition of taste, need and purse are met. The farmer who looks first for service, then for economy and cost, finds these qualities combined with a certain exclusiveness of design which will make his rig a noticeable one when he drives out; while the town and city man who wants more of lightness and elegance will not turn elsewhere unsatisfied. The Kalamazoo Carriage & Harness Company are strictly manufacturers, and not jobbers. Every vehicle they sell is produced in their own works, and is guaranteed. The foregoing holds good, too, regarding their harness lines, which the catalog covers fully. Send for a copy and verify for yourselves that nothing but personal inspection will do the book and its contents justice. Address, Kalamazoo Carriage & Harness Co., Kalamazoo, Mich., and mention the American Bee Journal when writing.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, April 19.—Market is well cleared of white comb honey; a little choice has sold recently at 10c, but dark and mixt goods are slow of sale. Extracted, white, 8@9c; amber, 7@8c; dark, 6@7c, according to quality and package. Beeswax in good demand at 28c.

R. A. BURNETT & Co.

CINCINNATI, March 3.—There is some demand for extracted honey from manufacturers at 7@7½c for amber and Southern; clover, 8@8½c. Comb honey is selling firm at 14@16½c in a small way. Beeswax, 25@27c.

C. H. W. WEBER.

Successor to Chas. F. Muth & Son and A. Muth.

BOSTON, March 9.—Our honey market is showing some signs of lower prices, altho the stock on hand is not large. At the same time prices are so much higher than previous years that the trade have taken it very slowly and the results are that the holders are willing to range prices quite a little in order to move stock on hand. Prices range: Fancy white, 17@18c; No. 1, 15@16c; amber, 10@12c; buckwheat almost unsalable. Extracted, best white California, 8½c.

BLAKE, SCOTT & LEE.

KANSAS CITY, Mar. 19.—We quote fancy white comb, 15c; No. 1, 14c; No. 1 amber, 13c; No. 2 amber, 13½c. Extracted, white, 8c; amber, 7c; dark, 6c. Beeswax, 22@25c.

C. C. CLEMONS & Co.

DETROIT, Apr. 23.—Fancy white comb, 15@16c; No. 1, white, 14@15c; amber and dark, 10@12c. Demand and supply both limited. Extracted, white, 7@7½c; amber and dark, 5@6c. Beeswax, 2@27c.

M. H. HUNT & SON.

BUFFALO, April 20.—For strictly fancy white one-pound comb honey we are getting 16@17c. Any grade sells high—10@15c, as to grade.

BATTERSON & Co.

NEW YORK, April 9.—Market is practically bare of comb honey of all description. Little lots arrive here and there and sell readily at from 10@11c for buckwheat and 12@15c for white, according to quality and style of package. The market is well supplied with extracted, which we think, however, will be moved before the new crop arrives. Beeswax is in good demand at from 27c to 29c per pound.

HILDRETH & SEGELKEN.

SAN FRANCISCO, Apr. 11.—White comb, 11½@12½c; amber, 8@10c. Extracted, white, 7½@8c. Light amber, 7@7½c; amber, 5@5½c. Beeswax, 26@27c.

Stocks of last crop are nearly exhausted, with present business in the same mainly of a light jobbing character at practically same rates as lately current. New crop is expected to put in an appearance in quotable quantity inside of 30 days. The yield north of Tebechapi will be a fair average, but very light south of the point named.

OMAHA, Mar. 13.—Demand shows some improvement in January, having been much more active, but as anticipated there is no advance in prices. Market remains steady at 14@14½c for fancy white comb and 8½c for white extracted. The latter is pretty well cleaned up along the Missouri River, and it looks as if there would be some shortage before another crop comes in. From present appearances there is about enough comb honey to go around at the present prices, hence we look for no particular change in values.

PEYCKE BROS.

Illinois.—The spring meeting of the eastern part of the Northern Illinois Bee-Keepers' Association will be held at the residence of William Farham, 4 miles southwest of Rockford, Ill., on Tuesday, May 15, 1900. All are cordially invited.

DR. MILLER'S Honey Queens

One Untested Queen Free as a Premium for sending ONE New Subscriber to the American Bee Journal for one year.

We have been fortunate in making an arrangement with DR. C. C. MILLER—the well-known honey-specialist—to rear queens EXCLUSIVELY FOR US DURING THE

SEASON OF 1900. These Queens will be mailed in rotation, beginning about June 1, so "first come first served." We are ready to book orders now.

The Queens Dr. Miller will send out on our orders will be precisely the same as those he rears for his own use, so of course they will be from his best stock. His best colony in 1899 had a queen reared in 1898; May 5, 1899, it had brood in 4 frames, and he gave it at that time a frame of brood without bees. It had no other help, but May 25 a frame of brood with adhering bees was taken from it, and the same thing was repeated June 3, leaving it at that time 5 frames of brood. It stored 178 sections of honey, weighing 159 pounds (and that after July 20, in a poor season), being 2½ times the average yield of all his colonies. A point of importance is the fact this colony did not swarm, and an inspection every week or 10 days showed that at no time during the entire season was there even so much as an egg in a queen-cell. Dr. Miller expects to rear queens from this one during the coming summer.

The demand nowadays is for BEES THAT GET THE HONEY when there is any to get, and Dr. Miller has such bees. You will want to have a queen from his best, we are sure, even if she is not pure Italian.

Do not send any orders to Dr. Miller, as all orders MUST come thru us, according to our agreement.

Remember, send us \$1.00 for ONE NEW SUBSCRIBER to the American Bee Journal for one year, and YOU will get ONE OF DR. MILLER'S UNTESTED HONEY-QUEENS FREE AS A PREMIUM. This offer is made only to our present regular subscribers. Orders for queens to be filled in rotation, beginning about June 1st.

Address all orders to GEORGE W. YORK & CO., 118 Michigan Street, CHICAGO, ILL.

CONTRIBUTED ARTICLES

Cement Foundation Mold or Press.

BY ADRIAN GETAZ.

REFERRING to my description of a cement foundation press, on page 402 (1899), a correspondent asks the following questions:

1. How strong should the frame be for the mold? Is one inch by one inch square all right?
2. What kind of wood should it be?
3. How is the cement paste made, with or without sand?
4. Will not the wood swell by keeping the mold wet awhile, and then shrink away from the cement when drying?
5. How would you combine the mold and press so as to be a perfect success?

I will answer the above questions in the same order as they are asked.

1. I don't think it is material, only the frame should be made of such a size as to give the mold a sufficient thickness. There is no strain at all on the frame, and all that is needed is to confine the cement while hardening, and fasten the hinges. As to the thickness of the cement plates, mine are $1\frac{3}{4}$ inches thick, and backt with a strong piece of plank of about the same thickness. It depends what kind of press is used. If the press has large platens, the mold would not need to be more than one inch thick, and well leveled so as to fit between the platens when prest. If the pressure is applied between two cross-bars like mine, then the molds should be either of sufficient thickness to prevent its breaking, or backt by a piece of plank. Mine was made to use plaster-of-Paris, and is thicker than would be necessary for cement. The press was already made, and is used mostly for a different purpose.

2. The kind of wood is immaterial. I used pine $1\frac{3}{4}$ x 2 inches.

3. The paste was made without sand. The sand might make the surface coarser.

4. No, not in my case. It was, however, Southern pine, very resinous. You must recollect that wood swells and shrinks only across the grain, and not in length; and the swelling and shrinking of a piece only one or two inches thick does not amount to much.

5. I don't know. The combination that I would try first would be to fasten the "book" on a strong frame, and have the frame holding the screw hinged to it, as shown in the illustration herewith.

Knox Co., Tenn.

The Premiums offered this week are well worth working for. Look at them.

NO. 7.—COMB HONEY PRODUCTION.

Bait-Combs—Adjustment of Supers—Value of Daily Weighing.

BY R. C. AIKIN.

THE management of supers during the honey-flow is a matter requiring good judgment and skill. It will not do to put on a lot of sections and then let the colony do the rest—that is, if you will get best results. It requires a close watch and a pretty nice estimate of what a colony will do, to know when and how to adjust supers.

I try to have bait-combs in the first super put on, and if there is a little honey in those baits all the better. The position of the baits in the super I vary according to supply and demand. If I have plenty to supply each first super, I usually put two in each corner, or a row thru on each side, or a row in the center, or possibly one in each corner, and two or more near the center. When in the corners or outer rows, it tends to start and keep the outsides going so as to be complete as soon as the center. A center row will not finish the super nearly so even. Having but few baits so that I have to economize to make them go around, I put in one to four usually near the center. The center position, or

Open. Mr. Getaz's Comb-Foundation Molds. Closed.

at the front end, will draw out and start weak colonies quicker than the other positions.

If you can have any unfinished sections, be sure to use them for baits. Even if some of them are half or two-thirds full of honey use them; the ones with honey are as good as

any. Those with old honey, especially if dark or candied, just mark by an "X" or some simple pencil-mark on the top, then when cleaning and casing put them into culls or No. 2 grades. The baits often make two or three days to a week of difference in the time that the colony will take to the super, and that may make all the difference between swarming and not. Baits are of such importance in a weak flow, and with the weaker colonies, that I would use them even if the honey had to be extracted, the combs being dark or otherwise off-grade.

Once the super-work is begun, as soon as the first one is one-fourth to three-fourths full, lift it and put a fresh one under. Notice whether the flow is free or slow, and judge about how soon the first super will be filled. I say *filled*, not *finisht*. A super may be full, but not sealed, and when full should be lifted and a new one put under. A colony may, when strong and the flow free, fill two, or even three, supers before the first is ready to come off.

So I say, watch the rapidity of the flow, and how fast the supers are being filled. If the gain is at the rate of five or six pounds a day, a six-pound gain means about three to four of honey; six days would just about fill a super. If the work is so rapid, do not wait until the first super is more than one-fourth to one-half full before putting on the second. With a much slower flow wait until the first is two-thirds to three-fourths full.

Sometimes it is best to put the fresh one on top of the other. The flow may be slow and the weather very hot. If the filling is going on tediouslike, and at the same time the heat drives the bees out, put the fresh super on top, if there seems to be probable need of another on at all. A colony will pass thru the full one to the top to work if there is need, yet the full super being below and nearest the brood-chamber, they will complete it even if an empty is above. Just how freely a colony will pass thru a full or nearly full super to an empty above, depends on the strength of the colony, the freeness of the flow, and the temperature.

At the first end of the flow I take more risk of getting too much room, particularly putting *empty* supers under ones partly workt, because the tendency to the swarming-fever is *very much* greater at that time, and I give the room and put the partly workt super *on top* to stretch the colony and relieve the brood-nest. After the flow has been on *two* weeks or more, the bees seem to forget about swarming and push the honey-business, and then they will stand more crowding than before.

Another object in placing the empty super on top, is that the other will be filled more compact and even. Should we stretch the colony too much by putting empties under partly filled, we are liable to get a lot of light-weight sections, and also poorly attached to the wood. A colony working *up thru* the nearly full one to an empty, will almost invariably finish that full one well, that is, fill the sections *plump*, if there is a flow sufficient to induce them to work that upper one at all. They should be watcht, and as soon as the lower super is filled ready to seal, raise it to the top so they will not travel over it so much while sealing. Then, too, the closer the sections are to the brood while being sealed, the more likely to mix old, dark wax in the capings. Also, right at the top I suspect is the better place to ripen the honey, because of the heat.

When the flow is coming to a close, is the time to use the greatest care about stretching too much, and having a lot of unfinisht sections. The best we can do will usually leave us quite a lot of unfinisht—such I use for baits the next year. If by close watching I can judge of the flow, I time the super arrangement so that the last super is workt up thru the next to the last one put on, until the latter is ready to seal, when it should be raised. If there is a time that the colony will stand crowding, it is at the close of the flow. Then is the time to disregard the lying out of the bees, and crowd them so they will finish the last plump.

Just at this stage is another place that a strong colony shows its superiority. Having kept them pretty well crowded the latter part of the flow, they naturally have the brood-combs pretty well packt with honey, and the last few days, when the flow is "tapering off," they will move up some of the honey to make room for breeding, and so help finish the sections.

But how may we tell of the rapidity of the flow? The best way to do this is to keep a colony or two on scales, and weigh daily. By so doing you come very near knowing just to the day when the flow starts and stops, and its variations. The ups and downs of the super-work will not tally exactly with the scale tally. The scales will show two, even three or more, days of nice gain before the supers

do, and likewise the super work will continue proportionately beyond the gain shown by the scale record.

The nectar, when first brought in, is mostly retained in the honey-sacs for ripening, being unloaded very unripe only when the supply is so great they can not hold it all. From the time in the morning that enough nectar is brought in to load the sacs of the inside workers, all the rest of the day the bees are carrying around their loads of nectar. If it comes in too fast for them, they stick it in wherever there is an empty cell, often putting small drops here and there (everywhere) about the combs where there is a little cup or cavity that will hold a drop, later gathering it up and storing it regularly where wanted. Thus it happens that for one or two days, and to some extent for three or four days, after the flow has practically ceased, the work goes on in the sections. Honey in full cells down close to the entrance, and in parts of the hive where it is in the way of breeding and pollen storage, is removed to the sections. Don't you see how you can soon make a cheap scale pay for itself—one of the \$2.50 to \$3.50 kind sold by supply dealers?

Larimer Co., Colo.

What Should Hives Be Placed On ?

BY J. L. STRONG.

WHEN I first began bee-keeping, more than 30 years ago, I thought two bricks good enough to set a hive on—one under the front end of the old-style Langstroth hive, and the other under the rear. The first was laid flat on the ground, and the other on edge, to give the required slant to keep the entrance dry. This did very well for a few hives, but when I had 50 or more I wanted something better, so I tried stakes driven in the ground. To do this quickly, and have the stakes just where you want them, make a frame large enough to go over the hive without touching. Drive a stake in each corner of the frame, and you have a stand that is easily leveled, and will be good until the stakes rot. The rotting of the stakes is the only trouble with the plan.

I next procured 100 tiles. Those with a piece broken out of one end are just as good as any, and cost little or nothing at the factory. I soon had 25 hives sitting on them, with no great amount of work—much less than would be required to replace the stakes when rotten for ten years, unless more lasting wood was used than I have usually had.

In the spring of 1899 I found some stakes broken off, and having nothing suitable for stakes, I was looking for something when I came across some long-neck bottles that had been in the way for some time. The thought came to me that they would be just what I was looking for. So I put the long neck of the bottle in place of the rotten stake, thus accomplishing a double purpose—getting rid of the bottles and making a permanent stand for my hives.

This pleased me so well that I began to wonder how I could get as many as I would want. I accordingly offered a boy five cents per dozen for long bottles. They began to come in by the dozen in baskets, in little wagons and other ways until I will have all I want, notwithstanding the fact that I will put out 150 additional nuclei, and set them all on bottles, as I think them the cheapest and best of anything that I can get.

In the spring of 1899 I found my bees in fair condition, having wintered them in cellars. The season, tho late, was quite favorable after April 10. They increast in bees and brood, and gathered honey nicely until the latter part of June, when the dry weather checkt the bloom, and honey came in very slowly for the balance of the season; altho there was enough gathered to keep robber-bees from being troublesome.

My 100 colonies are now in fine condition, as nice and clean as when they were put in Nov. 11, 1899, about two weeks earlier than they are usually put in the cellar.

QUEEN REARING AND FERTILIZATION.

Can queens be fertilized above a queen-excluding honey-board while a queen is laying below ?

In 1893 I procured Doolittle's "Scientific Queen-Rearing," having been much interested in what had been previously publisht in the papers on that subject; and especially on the advantage of superseding a queen at pleasure, without the trouble of hunting and destroying the old queen below. But after repeated trials I have nothing but failure to report. The bees would accept and build out the cells in an upper story, and the queens hatch as I expected

them to do, but invariably would get lost before commencing to lay.

Being quite anxious to succeed if possible, I determined to try again the past summer on a little different plan. Having a number of cells in an upper story with an excluder between, I placed an oilcloth on the excluder on one side of the hive. After cutting off all cells but one, I brought the frame with this one on it, then put an excluding division-board between these three combs and the balance of the hive.

I now awaited results with great hope of success, and when I lookt the next day and found the queen crawling over the combs as if she were at home, I thought that I was on the right track, and closed the hive to await results.

About three or four hours later I again opened the hive, and found her on the division-board, the workers following her as tho they would kill her. I took the three frames and queen and placed them in a band-box, and set it beside the hive. I thought they would realize their condition and take care of the queen; but when I lookt again she was dead. This makes about 50 queens that I have lost in this way. I may try again this season a three-story hive.

Page Co., Iowa.

Moving Bees Short Distances—Spring Dwindling

BY G. M. DOOLITTLE.

QUESTIONS keep pouring in, with the request that I answer in the American Bee Journal, and as long as they do so it will be mostly answers to such questions that I shall give in these columns; but in answering I shall try to go somewhat into the minutia of the thing, explaining as fully as possible, so that perhaps the matter may be as interesting to the general reader as articles from my own selection would be. The first question lying before me is regarding moving bees short distances, and reads as follows:

"I wish to move my apiary of 40 colonies about one-fourth of a mile to a new place which I have bought, having rented thus far. How can I do this and not have the bees go back to their old location on their first flight? Also, tell me how I best can move them."

ANSWER.—The best way to move bees in early spring is on a sled, if there is snow, and I should use a sled with broad or wide runners, or a stone-boat, even if there was no snow, providing that the roads were soft, or very rough, as they almost always are in early spring. If the roads are smooth and hard, then a wagon is a good thing for moving bees, especially where one with springs can be used. No matter what vehicle is used to do the moving with, all but the spring-wagon should have plenty of straw on the bottom to take off or help neutralize any sudden movement or jar which may come from the moving vehicle.

Where bees are to be moved from a few rods to not more than 20 or 30, a stretcher, made by using two poles with canvas or some kind of stout cloth attach to each, the same being used by two men to carry two hives, is better than anything else. Bees can be moved in this way where care is used, and they not know they have been disturbed at all.

Having decided on the kind of vehicle to be used when doing the moving, the next thing is to know *when* the bees should be moved. Whenever bees are confined to their hives in the spring from a week to ten days by rainy, cold, snowy, or stormy weather, they will mark their location anew on their first flight afterward, the same as a new swarm marks its location upon its first flight after being hived; so, should there come a few days of stormy weather, so as to keep the bees in their hive, then is your time to move them; and it is well not to delay more than six days from the time they flew last, or warm weather may suddenly come upon you, when you will not be able to move them till after another stormy spell, without its costing you more work than is required at such a time.

After they are moved, if warm weather is delayed, you are safe in any event. Should no such cold or stormy time come, then I would move the strongest of the colonies, and let the weaker ones be strengthened by the returning bees from those thus moved. If this is done, it is well to move the weaker ones partially toward the stand of those moved, so the returning bees may not fail to find this weaker colony, from the greatness of the intervening distance between it and the old stand of the colony moved. But if the stronger and weaker colonies stood farther than 10 feet apart, this plan can not be adopted, for a success can not be attained in drawing bees much farther than five feet from their old location, even tho their own hive stands that

near to where it formerly did. If you move the weaker colony more than the five feet you lose whatever bees may fly from that, and it is well not to lose a *single* bee in the spring of the year, where the life of that bee can possibly be saved, for one bee at this time of the year is of more value than 50 in August.

Should no stormy time come, as spoken of above, and the bees must be moved, and should it not be advisable to adopt the strengthening plan, then move them in the evening, or on some rainy day when all are in their hives.

After they are on the stands in the new location, go to the first hive and blow in smoke at the entrance. After the first two or three puffs, commence to pound with the fist on top of the hive, pounding as you smoke, striking say five or six blows, when you will pass to the next, treating it the same way; and so on till 10 to 15 have been thus treated. When you have done this, go back to the first one and treat it the same way again, and so on till you have past over the whole number (10 to 15) again. Such treatment will cause them to mark their location over again, but not as fully as will the stormy weather; and by way of an additional help, along the marking line, it is well to stand a wide board up in front of the entrance to each hive when you are thru smoking and jarring them. This board should be wide enough so as to darken the entrance to a considerable extent, and so as to turn the bees to one side when they fly the next time. In this way bees notice at once that something is wrong, which causes them to mark their location anew; otherwise some would start off in a straight line as usual, and come back to the old location and be lost.

The old place should be cleared of everything which would look homelike to the bees, where stormy weather has not prevailed before they were moved, which helps much in the matter. Then, after all, if we go to the old place when the bees first fly, we will find many bees hovering about in spite of all we have done; but after careful watchings for many years, I am satisfied that all such bees finally go back to the new location, if they have been treated as here given.

PREVENTING SPRING DWINDLING.

"As I understand it, spring dwindling comes about by a bee or two at a time leaving the hive in unpropitious weather until all are lost. If this is right, why can not it be prevented by placing wire-cloth before the entrance to keep the bees from flying when the weather is not fit?"

ANSWER.—So far as my experience goes, it is *never* best to confine the bees to the hive by placing wire-cloth over the entrance, except when they are to be moved some distance, or shipt when a sale is made, and in these cases wire-cloth placed *only* at the entrance often ruins the colony if it be a strong one, where there is necessity for keeping it there more than half an hour or so. The matter seems to be like this:

When the few bees which act as sentinels go to the entrance from any cause, and find their exit is cut off, they at once communicate this fact to the rest of the colony, when more bees come to go out, and finding they are not able to do so they begin to bite the wire-cloth, and make a fuss generally, till the whole colony is aroused, and a commotion caused to such an extent that the meshes of the wire-cloth are clogged with bees so that no air can get thru. When this happens, the bees become very hot, or heated like fermenting vegetation, the honey in their honey-sacs is disgorged till the bees become all wet and daubed, when they perish with a sufficient heat often to melt combs.

There can be no assurance that this may not happen at any time, unless the weather is so cold that it causes the bees to cluster compactly, and were bees to be shut in hives when so clustered, the apiarist would need to be on hand, when the weather moderated, to take off the wire-cloth, or a loss would occur. I doubt whether there can be any means used in unpropitious weather in the spring by which bees can be kept from flying out of the hive, that will not cost more than the benefit derived will amount to.

Where bees are in chaff hives they are not so easily enticed out every sunny day, when the air is too cool for them to fly safely. If a wide board is placed sloping in front of the entrance, so as to exclude the rays of the sun from the entrance and lower part of the hive, bees will not venture out unless the air is warm enough for them to fly safely; but as these boards have to be removed every time the weather is suitable for the bees to go out, I doubt about enough bees being saved to pay for the trouble. I have practiced this to quite an extent in former years, but of late I do not, because I do not think it pays where a person has much else to do.

Then, spring dwindling is not the result of a loss of the

few bees that chance to go out for forage when the weather is unpropitious, but from the result of poor wintering, where the vitality of the old bees is worn out, so that they go out of the hive to die, and not for forage. A real case of spring dwindling can not be remedied by keeping the bees in the hive, for they would die in the hive just the same as tho they were allowed their liberty. At least this is the conclusion I have arrived at after a careful watch along these lines for more than a score of years.

The remedy for spring dwindling is successful wintering. Onondaga Co., N. Y.

Belgian Hares and Bees—A New Combination.

BY PROF. A. J. COOK.

THE Belgian hare industry has attained marvelous proportions in an exceedingly short time in Southern California. Our own county of Los Angeles is the center, the city of Los Angeles being the focus. For a new business to gain standing so quickly argues that it is more than a fad. This fact becomes emphasized when we learn that some of our most clear-headed business men are engaged in this Belgian hare propagation. One of the best business men I know in Southern California belongs to a firm that is said to have invested \$25,000 in this new industry.

The Belgian hare, like the shorthorn cow, has been so carefully bred that its habits are very much modified. Its growth and vigor is something remarkable, its prolificness is exceedingly great, and it is so neat that it can be bred and cared for in the small compass of a dry-goods box and yet retain its vigor, health, and fecundity.

It has often been asked if there is not danger in introducing this new comer into our State and country. May we not repeat the experience of Australia in importing the European hare into that country? The law first suggested by Darwin—that introduced species are always likely to manifest greater vigor and prolificness than is shown by the native, closely allied species—should always make us wary to contemplate any such enterprise. As I have stated in our public meetings, where this matter has been under discussion, I do not think the danger need be feared in the case of the Belgian hare. Like the shorthorn, the Belgian hare is bulky, fat and logy. This rabbit, therefore, while admirable for feeding and breeding, would be illy adapted to succeed in the struggle of life out on the plain or in the bush. I think in such a case the excellence of his flesh would soon be tested by dog or hound rather than by human epicure. I have never seen the Belgian hare on the race-track, but from viewing him from the show-box or rabbitries so common in this region, it has never seemed to me that he could be any match at all to the cotton-tail or jack-rabbit. This latter has a hard enough time in its struggle against dog, coyote, and the hunter. I greatly doubt if the Belgian hare could exist at all.

We know that the care and domestication of the silk-moth by man has made it so dependent upon him for its food and protection that were we to cease rearing silk-moths for one year, it would cease to exist. In developing the splendid insect with an eye single to silk-production, we have utterly destroyed its ability to care for itself. I think the Belgian hare is, like the silk-moth, only to a less degree, less qualified to fight its own battles. I believe running wild and extermination would go together. Another reason why this danger would be minimized comes in the very value of these animals. Like the lost coin, the whole country would be swept and garnished to find a single missing rabbit. Therefore, I do not believe we need to fear the introduction of this valuable animal into our State and country.

I have alluded to the great value of these animals. I have heard of cases where \$250 or \$300 have been paid for a single male. Of course, this shows that great pains has been taken to develop these animals in the way of prolificness and meat-production.

WHY IS THE BELGIAN HARE SO VALUABLE?

There are several points in this business which will aid to foster its rapid development. The Belgian hare puts its entire energy into growth and reproduction. Thus it exercises very little, and a large number of rabbits can be kept in a small space. I know of a rabbitry of over 100 individuals kept wholly in dry-goods boxes. These rest on a platform about three feet from the ground. The whole space occupied by the rabbits is less than three rods square. Thus the man in the city is not precluded from engaging in this business.

Again, the animals are so neat that ill-health is hardly likely to interfere with success. I have heard of only one case where any one has had any loss from disease. In this case there was a sore lack of knowledge of the business. I think it is as safe as anything in which one can engage.

Again, the cost of keeping rabbits is very light indeed. A friend of mine, who is a very careful man, estimates that when hay is \$9.00 a ton, two cents per month will keep a full-grown rabbit. It is said that alfalfa hay alone, dry and green, will do for food. It is probable, however, that they might do better with a greater variety.

It follows from the above that it will cost very little to produce meat. Another friend said to me a few days since, "I can produce the meat at a good profit if I can get nine cents a pound." When we remember that it sells readily now for 20 cents a pound, we understand why the business is so profitable. The excellence of the meat is also a substantial argument in favor of the industry. Even epicures smack their lips in rehearsing the excellencies of the rabbit for table use. We had these on our table more or less for a week with very little intermission, and we all pronounced the meat first-class in quality, even to the last meal.

THE FUTURE OF THE BELGIAN HARE INDUSTRY.

It is often asked, "Will not the excitement soon pass by, and the rabbits fail to pay expenses?" When we remember the millions of mouths to be fed, the appetizing character of the meat, and the cheapness at which it can be produced, I doubt if we need fear that it will be soon overdone. Many prefer the rabbit to chicken, and 12 to 15 cents a pound is paid for chicken pretty generally thruout the country.

BEEES AND RABBITS.

One disadvantage that the bee-keeper labors under comes from the fact of off years. One off year is frequent, two off years in succession not uncommon, and he is a lucky apiarist who has not had more than once three successive off years.

Again, the bee-industry does not claim the whole time of the bee-keeper all the year, and he may well add another string to his industrial bow. Poultry-keeping has often served admirably for this extra string. I believe the Belgian hare will even eclipse the hen in this desired comradeship. I have a neighbor who lives between here and the foothills. He has a large apiary which has only been an expense now for over two years. I frequently pass by his place on my way to the canyons. As I have seen his brood of children—a very large one, by the way—I have felt pity for the household, despite the fine flock of chickens which adorn the home yard. I feel less pity now, as the gentleman told me the other day that he had made over \$600 clear in Belgian hares during the last year. I am thus led to say: "All success to a co-partnership between bees and the Belgian hare." Los Angeles Co., Calif.

Dots by the Apicultural Wayside.

Read at the Wisconsin Convention, held at Madison, Feb. 7 and 8, 1900.

BY JACOB HUFFMAN.

THIS subject embraces so much, and presents so many topics, that I am at a loss to know what points to select that would prove the most beneficial. The magnitude of scientific apiculture would occupy a natural lifetime. Were we to go back no further than the last century, and show the wonderful developments made in this one branch, its profits, incomes, and the immense increase of colonies, the revenue that it brings to this country, it would by far excel any other rural branch in point of profit from the capital invested.

The history and working of the honey-bee are wonderful indeed, affording man a great and beautiful study, as well as a good income for the time and labor given. From historical facts we are led to believe that the honey-bee has been a companion of man from the earliest civilization. Scientists have given this one subject deep thought; they have been able to trace the little busy bee far back in the dim dawnings of history, and unlike many other things no change has been made in the bee itself—it works without rules, plumbs or guides, but the habits, dispositions and instinct of the bee have been studied by man. The great researches must be attributed to man. The bee, ever unchangeable only by constant handling, becomes more submissive.

Science has also demonstrated some of the wonderful

results that have occurred by application of certain principles, and new light has dawned upon the bee-keeper's pathway.

It might be well for me to give a short history of my own experience, and a few practical thoughts on my own observation.

About 23 years ago I started with four colonies in box-hives. By the help of a friend who had some knowledge of the bee, we succeeded in getting them transferred into movable-frame hives.

Pardon me if I add here a meed of praise to Mr. Langstroth for the invention of the movable-frame hive, introduced about 1850, which opened up a wide field of study—in fact, it was the invention of the age, regarded so by intelligent bee-keepers, and upon it has hinged most of the progress that has been made since.

I transferred quite early, and by dividing I increased my apiary from 4 to 12 colonies, ready for winter quarters.

All came out of the cellar the following spring in good shape, and with the help of the gentleman before mentioned, we made our own hives, and, by dividing, by fall we reached 50 colonies, with a surplus of about 300 pounds of extracted honey.

Well, you may imagine my feelings—I considered myself a full-fledged bee-man—yes, may I say, an expert in bee-culture!

I put the bees into a bee-house for winter quarters, and awaited results.

Spring came, and to my chagrin I had 8 colonies instead of 50! Shall I say it was the best lesson I ever had in apiculture? Yes, for it was. Then I commenced aright, cautiously and carefully. I secured a few Italian colonies, my first ones having been black bees, and Italianized the whole apiary. I then commenced as an amateur apiculturist. I found that what I did not know would fill a volume of 600 or 800 pages, largely illustrated. I state this for the encouragement of beginners. No matter what your failures may be, or have been, if you have studied your locality, studied the experience of older and wiser heads, and do not come too hastily to conclusions, you will be sure to succeed.

Since 1882, with the exception of dry seasons, or those too wet, I have realized more clear profit from my bees than from the farm.

There is comfort in the knowledge so often expressed—experience is the best of teachers. I believe a man will best succeed who loves bee-keeping. Other industries can be successfully carried on when followed only for the profit, but I think it necessary to love bee-culture in order to succeed.

I have at two different times started, or carried on, apiaries at a distance of $2\frac{1}{2}$ to 6 miles from the home-apiary, but I found they added greatly to the work already on hand, so I sold them. I do not condemn the handling of several apiaries if a man has plenty of help that understands the business, or is willing to put forth a persistent effort to bring about the best results.

Bear in mind that it is a very easy thing to overstock your fields. In such cases I would advise the scattering out of the colonies. In my locality I can easily keep from 100 to 150 colonies if the season be favorable.

I believe the great problem in successful wintering of bees is plenty of young bees in the fall, and plenty of good honey in store. See that all are in good shape for winter late in the season. A good cellar for wintering is where the temperature is easily kept above 40 degrees, and well supplied with pure air. I have tried a few colonies out-of-doors several winters. I like the idea of packing, but I think it is not enough better than cellar-wintering to pay for the extra labor.

Misfortunes or accidents often develop important truths. By observation I have found that cold and frost are deadly enemies. Cellar-wintering requires the least consumption of food, and the least amount of respiration and exertion. I believe it to be the most perfect system—I mean one that will invariably produce the same results.

A system of wintering bees, in which the conditions are likely to be different each year, can never be a perfect one. We can, of course, have uniformity of stores when wintering in the open air, but the severity and irregularity of the weather are beyond our control.

Speaking of last year, one would naturally conclude that bee-culture was becoming less profitable. By investigation we learn the profit in bee-culture is just being reached, while basswood in some sections is being thinned out, and by heavy drouth and severe winters the white clover may be killed out for a season, or even more. Plants

with their honey-producing qualities have been studied, so that it is possible for bee-keepers to produce their own pasturage to a certain extent. Good locations are more carefully selected, and to have necessary articles for convenience at hand, add to the scientific handling and the remunerative proceeds.

Time and space forbid speaking of many things I would like to mention. I would like to touch the subject of queen-rearing—I like home-bred queens better than imported ones. Mr. Doolittle informs us that American breeders take more pains than they do over the water. He thinks many are taken from a promiscuous selection, taken from second and third swarms, therefore are not likely to build up and make good honey-gathering colonies.

I would also like to mention the subject of bee-pasturage, and the profit in running for extracted honey over that of comb honey when the season is short. I would like to say something in regard to our foul-brood law; I would advise that subject to be agitated throughout America. Brother bee-keepers, we must fight our greatest enemy if we succeed.

It is not true that all can keep bees successfully—only such should undertake it as are by nature adapted to it, and will give it the same thoro, continued application as is required to make any branch of business profitable. Bee-culture demands more study, more skill, than any other rural employment, hence our ranks are not likely to swell to great dimensions. No honest employment can be little in any sense. What we need is more little successes and less big failures. Green Co., Wis.

A Short Sermon on Progress and Reforms.

BY L. L. SKAGGS.

LET'S come down to facts and not fancies, and see which is best. What do we want with silent letters? Would you keep three horses when two will do your work? The extra one is in the way, costs something to feed it, and care for it in general. And so it is the same with silent letters. I have asked professors all my life what good they did, and so far I have failed to find one that could tell. Their answer is, "Oh, it is customary." So we keep on in the same old rut, and will not try to get out; and if any one tries to help us out, we make a terrible noise, and sit back. "If we like old ways, let's go to China—we can get them there. Oh, my, what a fuss people do make at any improvement!"

In 1874 and 1875 I lived in Southern Texas, where the people were nearly all Mexicans. For illustration, I will try to tell how they made their plows. They cut a tree that had two limbs that set contrary to each other on opposite sides; one they used for a handle, and on the other they fastened a sharp, pointed piece of iron, to tear up the ground; and the main body was for a beam. Well, you would split your sides with laughter if you could see one, and see the work it does. You can't tell which way their rows run. The corn looks as if it had been scattered broadcast. And what a crop of weeds they would raise, and get about 8 or 10 bushels of corn per acre. Now they tell me they raise from 40 to 50 bushels. While I was there the owner of the ranch sent a lot of improved plows to the ranch, for his hands to work with. The owner was a white man. Well, if you could have heard what a fuss they made about those plows, you would not wonder at people kicking at reform spelling. They said the owner of the ranch was the biggest fool they ever knew. No, sir, they would not try to use those plows at all.

I have never known any improvement offered to the public but what there was a great kick; and if the improvement is not backed with money it is put aside.

To be sure, there is no one to put up money on simpler spelling, because it is the children that need it. The old folks have gotten into the habit of plowing with forked sticks, and carrying rocks in their sacks to balance with their corn, so they think it is death to quit. Now, let's have some reason. We know that everything we do is good or bad, one or the other, so if silent letters are of no use, drop them. It is the readers who have to suffer, not the editors. The more type the more paper and ink they use, and then the more our reading will cost. It is not for the good of the editor at all. He charges according to the work and outlay. If it was for the good of the editors, reform spelling would be adopted in less than six months, and the readers would never get a vote at it. No, sir, we would never get a chance to kick at all. Did the A. I. Root Com-

pany let us vote on the changes in their catalog? If they did, I never knew of it.

Less than a week ago an old man, who has a better education than I have, drove 10 miles over as rough road as I ever saw, in the rain, to get me to order some bee-hives for him. He could not understand Root's catalog. Don't think he is behind on bees, for he has the prettiest lot of hives I know of, and his bees are well bred up. I showed him a copy of the American Bee Journal, and he was delighted with the improvement in spelling. I haven't found any one yet but what says it is a good thing for the future. I can't see anything but selfishness that would cause anybody to kick against the spelling reform. Any one can tell who is selfish by the way some threaten to stop taking the Bee Journal. I have always heard just such threats at anti-whiskey elections. Take heed from that. I have known men that were very prominent to get frightened and vote with the whiskey crowd so as to be on the popular side, and thus ruin themselves. The whiskey men won't support them in an election; they have no confidence in a man that they can turn. Everybody admires a man that will do his duty, and let the world say what it may.

Look at Lincoln. Suppose he had been turned and easily frightened—we would be buying and selling God's people to-day as if they were corn or wheat. Be sure you are right, and then go ahead. Take Christ for your leader; he is safe and sure. Men are like the wind—you never know when to depend upon them.

Suppose Gleanings in Bee-Culture would listen to some people, and stop its home talks; where do you think it would go? That would give it a set-back in the Christian homes, and they are the ones that have spread it over the land. I hope I may see the day that Jesus can get room in every book and paper in the land; then we will not be afraid to send money to an advertiser, and the get-rich-quick fellows will have to go to work like all honest people. Wheadon, the crooked commission man in Chicago, a few years ago, tried very hard to get my honey, but I simply refused to have anything to do with him, because his quotations never appeared in the American Bee Journal. Oh, what a kick he did make at Editor York; but kicks against an honest man do him more good than harm.

Look at the newspapers—what attention do we pay to their advertisements? I have never taken a newspaper but what would advertise anything for money. How much respect have we for the editors of such papers. The more people kick at a good thing the more good people will like it; and that is one sign it is gaining ground; for that is what causes the worst kick. We find the same thing in regard to temperance. Llano Co., Tex.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Italianizing Colonies of Blacks.

I would like to ask about Italianizing black colonies of bees, referred to on page 38. I see that your Italian colony, which we will call No. 1, gets to breeding up and swarming first. When it swarms, put the swarm on the stand of No. 1, and set No. 1 in place of another strong colony, say No. 2, setting No. 2 in a new place, and so on. I would like to know if the flying bees from No. 2 going into No. 1 won't be stung to death? That is what I understand by reading and talking with bee-keepers. MAINE.

ANSWER.—No, no danger. At a time when bees are swarming, the returning bees always come in from the field laden, and will be kindly received. At a time when no honey is coming in there might be some danger, in some cases great danger that bees would be killed, but when honey is yielding, bees are very good-natured about being mixt up.

Dividing for Increase.

1. How shall I divide a double 8-frame Langstroth hive to produce comb honey in order to get surplus from both colonies, the original hive having brood in both stories?

2. If this cannot be done successfully, what is my best method of dividing them? IOWA.

ANSWERS.—1. It is somewhat doubtful whether you can manage any way that will give as much honey from the two as by keeping the force united. You might do it in some places where there is a heavy flow late in the season, but hardly in Iowa.

2. This way might answer: Pick out the frames with least brood and put in one of the stories with the queen, setting this story close beside the old stand, leaving on the old stand the other story containing the eight frames that have the most brood, doing this just before swarming-time. If no queen-cells were present when this was done, there will be some ready to hatch in 10 days or more. So 9 days after making the division, move to a new stand the queenless hive, and the depletion will discourage the bees so that only one queen will survive.

Using Combs Again in a Case of Supposed Bee-Paralysis.

I had a colony die last fall from a disease that I believe was paralysis. The hive is full of good combs. Would you advise me to put another swarm into that hive, and leave the old combs, or should I melt them up? PENN.

ANSWER.—I hardly know, but there might be no great risk in using the combs again, if you are sure it was nothing worse than paralysis, which is not generally a very bad thing as far north as Pennsylvania.

Caged Queen and Swarming.

Will placing a caged queen in the hive produce swarming? If so, about how soon after putting in the queen will it result? MINNESOTA.

ANSWER.—I don't know, but I should have little faith in it. A sealed queen-cell would be more likely to produce swarming. If conditions for swarming were unfavorable, the cell would be unceremoniously torn down. If conditions were favorable, a sealed cell might (this is only a guess) produce swarming in 3 or 4 days.

Spacer-Nails—Wide Bottom-Bars.

1. Can you sell me some of those spacer-nails, or where can I get them?

2. Why do you want so wide a bottom-bar when a comb is only $\frac{7}{8}$ inch? MISSOURI.

ANSWERS.—1. You can get them in any hardware store. Just common $1\frac{1}{4}$ inch wire nails. If your hardware merchant keeps more than one weight, get the heavier ones, with heads 3-16 across. That's the kind he is most likely to have if he has only one kind. To drive them in the right depth, use a block $\frac{1}{4}$ inch thick with a slit sawed in half an inch. Or you can make a very good work by having a stick $\frac{1}{4}$ inch thick and holding it beside the nail. A nail made with a special head to drive just deep enough would be just the thing, but you can't get them.

2. I've hardly used them years enough to be entirely certain it is best to have such wide bottom-bars. The chief object in having them so wide is to prevent building comb between them.

When to Put on Sections.

1. When is the proper time to put on sections?
2. I use Hoffman frames and put in foundation starters 2 inches wide. Is it necessary to use separators?
3. Is it advisable to put supers on swarms that come off in June and July? NEW HAMPSHIRE.

ANSWERS.—1. The old rule is to put on supers when you see bits of white wax along the top-bar and upper part of the comb. The rule is a very good one if you have no objection to swarming, but if you desire to avoid swarming in every possible way, it is better to have supers on a little sooner. In New Hampshire your first storing in supers is

probably from white clover. If you watch *very closely*, you will see a scattering blossom of white clover some 10 days before the general bloom, and you will do well to put on supers within 3 or 4 days of seeing this very first clover bloom.

2. I'm not sure whether I understand you. Hoffman frames are used only for brood-frames, and it certainly is not necessary to have separators between brood-frames. It is generally best to have separators between sections, if the sections are to be packed for shipping, but for home use separators can be dispensed with.

3. With right management, yes. Put your prime swarm on the old stand, with the mother colony close beside it, and a week later set the old colony in a new place. Twenty-four hours after hiving the swarm, take the supers from the mother colony and give to the swarm.

Divisible Brood-Chamber Hives and Fixtures.

1. As I am thinking of adopting the Heddon hive I would like to know why you do not use it, as it seems to me to possess great advantages.

2. Mr. Heddon's patent is supposed to cover horizontally-divisible brood-chambers; if I use the Danzenbaker or dovetailed hives—two bodies to the brood-chamber—do I infringe on Mr. Heddon's patent? If not, why not?

3. If I use close-fitting closed-end standing frames, like those used by the Rauchfuss brothers, of Colorado, in ordinary dovetail bodies; do I infringe on the Heddon patent, which is supposed to cover these constructions?

4. What was the thickness of the combs in those 4¼ x 5-x1¼ sections?

5. Will you feel like using more of them this year?
YANKTON.

ANSWER.—1. I do not see enough advantages in them to make it worth while to try them. If you do, you certainly ought to try them.

2. Others claim that such things were in use before the issuance of Mr. Heddon's patent. The fact that they are in common use with no prosecution for infringement makes it probable that you would be running no risk by using two bodies to the brood-chamber.

3. I think the Rauchfuss brothers are not supposed to infringe on any patent.

4. About 1¼.

5. Being well stocked with fixtures for the old kind, I shall not go heavily into the new. In such things each one must carefully study his own market.

The Rapidity of Bees' Wings is something marvelous. A. Gustin says in *Le Rucher Belge* that when bees are ventilating, the wing-beats are more than 400 in a second. Pretty fast work.

For Stimulative Feeding the following is said by Bulletin de la Somme to increase brood-rearing: Boil 4 pounds of wheat-bran ½ hour in 7 pints of water. Strain, add 2 pounds of sugar, 4 or 5 pinches of salicylic acid, mix thoroughly, and give to each colony 2 or 3 pounds of this preparation at a single feeding.

One or Many Foul-Brood Inspectors for a Province or State is a question somewhat discussed. At the Ontario convention there were reasons given on both sides. It takes lively travel, and much of it, for a single inspector to get around, but he has more power than local inspectors, and more experience.—*Canadian Bee Journal*.

Early Bee-Pasturage is discussed by G. M. Doolittle in *Gleanings in Bee-Culture*. Skunk-cabbage comes first in his locality (Onondaga Co., N. Y.) blooming somewhere from March 25 to April 20, yielding pollen but no honey. A week or ten days after skunk-cabbage come the pussy willows, of which there are several kinds, some being a month later than others, yielding pollen but no honey. The first honey comes from golden and white willow, plants of great

importance, from which, when the weather is right, a colony may store 10 to 15 pounds of honey. They yield no pollen. Their greatest value comes from their yielding at a time when they so largely affect the building up of a colony. With favorable weather during the blooming of these plants and during fruit-bloom, colonies are in best shape for the clover and linden harvest.

Queen-Excluders Make the Difference of opinion between large and small hive men, says H. H. Hyde in the *Progressive Bee-Keeper*. With excluders in use, the queen never has a chance properly to spread herself, so the excluder man thinks a small hive is large enough. Mr. Hyde wants no queen that is not able to have 12 frames filled with brood by the commencement of the honey-flow, and he has had queens at that time with 18 frames of brood.

"A Trust, or Co-operation, needed in bee-keeping," is the heading of an editorial in the *Bee-Keepers' Review*, which ends by saying:

"I believe that this question is one that might be profitably discuss. If there were some way by which we bee-keepers could know what the crop is as soon as it is off, and could then decide what prices ought to be, and would all stand by those prices, it would be accomplished. Sounds simple enough, but how can it be done?"

To Avoid Bubbles in Bottling, here is something that seems important from H. Rauchfuss, in the *Progressive Bee-Keeper*:

"In bottling honey, it should be of a certain temperature, no more and no less, to avoid incorporating bubbles of air. If too thick, the down-flowing stream of honey will waver from one side to the other, lapping over itself when it reaches the honey in the vessel, thus enclosing streaks of air. If too thin, it will pierce right into the honey below, dragging down the air with it in the form of small bubbles. It should be of just the right thickness to spread out in the form of a cone when it strikes the honey below, neither depressing its surface nor piling upon it, but uniting with it at once whenever it touches."

Black Brood.—Dr. Howard's words with regard to the New York bee-disease are not very reassuring. He says in *Gleanings in Bee-Culture*:

"Here is a disease in which it is strongly suspected that flying bees are affected; and of these, thousands daily leave their hives never to return, scattering the germs far and wide, to be borne by the strong winds, or wafted by the gentle zephyrs to new fields of infection.

"In conclusion let me say that sufficient evidence has been presented to show that we have something new, and at present, apparently, more malignant and more destructive than the worst enemy hitherto known; but careful, practical, and experimental work in the presence of this disease when at its worst will, I feel confident, discover some practical plan for its successful eradication."

Closing Hive-Entrances.—In reply to an inquiry, Dr. Miller tells in *Gleanings in Bee-Culture* how he closes the entrances of hives for hauling, and also for carrying in the cellar if they must be carried in at a time when closing is necessary. He says:

"A proper entrance-guard that will quickly close and unclose a hive is a very desirable thing. The ones I now use are entirely of wire cloth, with a single stick to fasten them on the hive. They are made especially to suit the entrance when the bottom-board has the deep side up, making an entrance 12½ x 2, but might be varied for any entrance. A piece of wire-cloth 13½ x 4 inches is doubled over at the bottom, and at each end ¾ inch or less (bending it over a saw-blade), so that it will be just long enough to fit inside the 12½ entrance. Then a piece of lath holds it with one or more nails. This gives all the ventilation needed for spring and fall hauling.

"But the wet cloth is far and away ahead of a wire entrance-guard when it comes to shutting bees in the hive when carrying in the cellar. Shut bees in with wire, and they are more anxious than ever to get out, the excitement being mischievous. They shriek from the wet cloth, and conclude they *don't want* to get out; so the cloth can be taken away as soon as they are placed in the cellar, leaving them quiet. Ordinarily, however, there ought to be no necessity for fastening the bees in when carrying them in cellar."

VOL. 40. MAY 10, 1900. NO. 19.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

The Brosius Pure-Food Bill.—We received the following from Mr. Abbott, May 4:

EDITOR YORK:—I have just received word that the Inter-State Commerce Committee has reported favorably on the "Brosius Bill." Very truly yours,

EMERSON T. ABBOTT.

Every honest producer of honey will be glad to hear the above. Now, we trust the House will approve the report of the committee, and that the Senate will concur, and thus the long-hoped-for National anti-adulteration legislation be completed.

The Question of Separators or No Separators is one upon which there always has been a difference of opinion, and it is not likely there will ever be entire agreement. One man says he has straight enough work without separators, another says he has not. As a matter of fact, the work may be alike in both cases; but one man is more exacting in his requirements than the other. A man who ships honey to a distance, whose honey will be handled by careless and inexperienced hands, needs sections built more true than one who produces honey merely for his own use, or who furnishes sections to a grocer near by, with whom he keeps in close touch.

Under favorable conditions good work may be done without separators. Those conditions, however, are not

always—perhaps not often—under the control of the bee-keeper. Under any and all conditions one is sure of straight work with separators; so it is probable that the general trend will be toward the general use of separators; and, indeed, that seems to have been the general trend for some time.

Bees for House-Apiaries Should Be Gentle.—So says, in his circular, Mr. Jewell Taylor, son of the lamented B. Taylor, who has had experience with house-apiaries, and favors their use. Mr. Taylor says:

"If you contemplate building a house-apiary do not stock it with anything but gentle bees. Handling bees that stampede over the outside of their hives is a disagreeable task under any circumstances, and is especially so in the house-apiary."

Barrels for Honey do not suit C. Davenport. He says in the Bee-Keepers' Review that he has never been able to get any that would not leak honey after a time, no matter how well made, seasoned, tightened, and waxed. He had a large alcohol barrel full of white honey, and before he knew it the barrel was empty from leaking. He thinks of having several cans of galvanized iron large enough to hold 1,000 pounds of honey each, these cans or tanks standing high enough so the honey can be drawn from them into shipping-cans. After the honey has stood in these cans 24 hours all impurities will rise to the top to be skimmed off, so it will need no straining.

Organized Marketing has an earnest plea made for it by R. C. Aikin, in Gleanings in Bee-Culture. He cites the case of a local organization of fruit-growers of which he is a member. He picks his fruit and delivers it at the depot, and there his care of it ends. The manager ships it to so much better advantage than he could, that Mr. Aikin gets more net money than if he shipped himself, and has none of the trouble. He says:

"The manager or shipping agent puts himself in communication with all possible customers or outlets for fruit, selects his customers before the fruit is ready, has access to commercial reports, etc., and, when the shipping season is on, he gets daily quotations showing supply, demand, and prices in the various localities. The growers deliver the fruit some time before trains are due out, and the agent ships according to supply and demand. If the supply here exceeds orders, he divides the surplus, shipping it to the market that is most likely to be able to use it, favoring the most reliable customers. This avoids a glut in one place and a scarcity in another, and results in far less numbers of losses, both of overripe or soft fruit because of delay, and in defaults of payment by irresponsible firms. Besides the saving to shippers in this way, any unavoidable losses are prorated among the members, and the association bears this loss, and not individuals."

Light-Weight vs. Full-Weight Sections.—The problem of the section is a many-sided and a perplexing one. Not the least troublesome phase is that of weight. There is no question that in many, if not most markets, light-weight sections are most called for by grocers. Vigorously do many bee-keepers object to light-weight sections, and in some cases, at least, there is good ground for the objection. The grocer wants to buy by weight and sell by the piece, or, to put it very bluntly, he wants to buy at the actual weight and then sell for a pound a section that weighs less than a pound. There is nothing immoral in producing or selling sections that weigh 13, 14, or 15 ounces each, *providing* they are sold for what they are, with no deception. If each section is weighed and sold at so much per pound, it matters little whether the weight be 13 or 18 ounces.

But some insist—and they give good reasons for insisting—that every section should be sold by the piece. It is also insisted that every section should be full weight. No man

living can produce a crop of section honey without considerable variation in weight, and if it is insisted that no section shall fall below 16 ounces, then there must be many which shall exceed that weight.

This one thing, however, ought to stand out clear: If the grocer sells sections by the piece, he ought to be willing to buy them the same way.

Wild Bees and Honey in Connecticut.—The Country Gentleman of recent date contained the following paragraph concerning the wild-bee-and-honey "industry" in Connecticut:

"A despatch from Winsted, Conn., to the Hartford Courant says that the extent to which hunting for wild honey is carried on in that section is not generally known. One of the Winsted hunters says that there are probably 15 to 20 men there who engage in the business, more or less, and take up altogether nearly a ton of honey in the season. He estimated that in Litchfield County there were nearly 100 bee-hunters, and that their gatherings amounted annually to 8 or 10 tons. As the honey is worth about 20 cents a pound, these figures make the value of honey gathered in the woods in Litchfield County nearly \$4,000. Canaan Mountain is said to be one of the best localities. Over 20 trees were found there last fall, yielding from 50 to 100 pounds each. The flavor of the wild honey of this region is said to be much more delicate than that of the domestic product."

"We were not aware before that Connecticut "bee-keepers" had so many apiaries that were not only out-apiaries, but also up-apiaries as well. Perhaps our giving the above notice a wider reading will cause an overstocking of bee-keepers in that locality. That would be a variation on the occasional complaint of an overstocking of bees. What a fine field for the old-time as well as the new-time bee-hunter that must be. And it seems their efforts are not unrewarded. However, *in this locality*, we prefer to continue to keep bees on the earth, instead of in trees. Of course, localities often differ!

A New Comb Foundation.—Henry Vogeler, of California, has patented an improvement in comb foundation that seems to have possibilities in it, altho only actual experiment in the hive can decide its real value. The improvement consists in a subsequent operation, after the foundation has left the mill. Mr. Vogeler says:

"I form the comb foundation or series of cells with very thin walls—that is to say, with walls which are as thin as experience has shown to be practicable—and I provide the same with thickened rims or outer edges. The said rims may be produced by laying on melted wax with a brush. This construction secures two important advantages—namely, it greatly strengthens the foundation, and renders it more rigid, so as to better resist injury in shipment and attachment to comb frames, and it provides surplus wax for use of the bees in lengthening the cells to approximate or equal natural cells in depth. Such lengthening is effected by the bees drawing out and thinning the beadlike rims until they are reduced to the same thickness as the adjacent interior portions of the cell-walls.

"I prefer that the thickness of the beads or rims shall be gradually reduced from the top of the foundation, where the greatest strength is required, downward to the bottom or lower end, where the cells are constructed in the usual way, or without thickened rims."

Formation of Spores.—Dr. Wm. R. Howard gives in *Gleanings in Bee-Culture* the following interesting information:

"*Bacillus milii* belongs to a form known as *endosporeus*—spores formed within the bacillus or germ. *Bacillus thoracis* belongs to the so-called *arthrosporeus* form, in which the spore separates itself from the rod or germ by fission or transverse section, and does not form within as in *Bacillus milii*. In some species spore-formation takes place only when the pabulum is about to be exhausted, and remains at rest until a new nutritive medium is furnished, when they vegetate and again become *bacilli* or germs.

There are other species which form spores when the conditions are most favorable for a continued development. The spore-formation of the germs under consideration belongs to this latter class.

"The relation of spores to germs is quite similar to that of seeds to plants. Spores possess a greater resisting power to drying, heat, chemicals, atmospheric changes, etc., than do the germs themselves. Spores of *endosporeus* bacteria are more resistant than those of the so-called *arthrosporeus*; accordingly, spores of *Bacillus milii* would have greater resisting power than those of *Bacillus thoracis*, all other things being equal; but *Bacillus milii*, being *aerobic*, growing better without oxygen or atmospheric air, the exposure of these germs or their spores to the atmosphere would possibly prove detrimental to their vitality. While *Bacillus thoracis* is *aerobic*—thrives better in the atmosphere, it would possibly resist atmospheric influences for a longer period. The spore formation of *Bacillus alvei*, the germ of foul brood, has been carefully studied, and, altho *endosporeus*, and retires to the spore or resting stage only when the food medium has lost its nutritive qualities, the spores lose their vitality in 24 to 36 hours when exposed to the atmosphere. [Author's *Foul Brood*, p. 21.]"

A Lively Picture of Swarming is thus given in the Australian Bee-Bulletin:

"A swarm! A swarm! Where from? They are flying all about the place. Quietly wait. Look at the entrance of each hive, and around same. Now where are they issuing from? We are too late to see. Perhaps it might be here. See those newly-born bees outside. They are too young to follow the rest of the swarm, and are about the front of the hive. But look, what is that cluster on the ground about two feet away? Yes, sure enough it is the queen, she was clipped and couldn't fly, and a few faithful attendants are sticking to her. We pick her up carefully, put her in a cage, then open the hive. Yes, only a few bees are left. What is the matter? See, here are queen-cells. Cut them out, then liberate the queen on the combs. See, the swarm is coming back. Just watch them running in. What a hurry they are in."

But some of the particulars are at variance with the usual course on this side of the globe. It is unusual to find a cluster of bees with the queen before the return of the swarm. She generally scrambles for herself till after the return of the swarm, and she is likely to be among the first to get back home. It is by no means the rule that the queen will be found on the ground with a cluster of bees, in this country. Neither is it often the case that the bees are so slow about returning that there will be time to cut out queen-cells before their return.

Queens Not Balled Thru Robbers.—H. Mulor says it is incomprehensible to him how bee-keepers of experience can think that queens are balled or lost because robbers have entered and attacked them. The robbers are intent upon just the one thing of getting booty, and don't trouble their heads about the queen. Much more reasonable to say that robbing occurs because the queen has been balled. In nine cases out of ten the balling occurs, not thru field-bees or robber-bees, but thru young bees between 5 and 14 days old that have strayed into the wrong hives. When hives stand near together and young bees are out for play, the wind often blows them to the wrong entrance.—*Machrische Biene*.

York's Honey Calendar for 1900 is a 16-page pamphlet especially gotten up to create a demand for honey among should-be consumers. The forepart was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample free; 25 copies for 30 cents; 50 for 50 cents; 100 for 90 cents; 250 for \$2.00; 500 for \$3.50. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices. □

The Weekly Budget

HON. EUGENE SECOR, General Manager of the National Bee-Keepers' Association, has been appointed a member of the legislative committee of the National Pure Food and Drug Congress, representing the State of Iowa. No better selection could have been made.

"THEY DEST MAKE HONEY."—Mr. E. S. Roe, of Todd Co., Minn., sends us the following:

"I am very fond of children, and last evening I was delighted to make the acquaintance of a bright little girl only three years old. Her manner of talk was very bright and attractive. We finally talkt about the bees, and when she was askt what her papa's bees made, she said: 'Oh, they don't make anything. They dest make honey—that's all!'"

COMMISSION SWINDLERS GROWING LESS.—The National Produce Review, of April 21, referring to South Water Street, Chicago, gives this encouraging paragraph:

"In speaking of the condition of the Chicago commission street, the manager of R. G. Dun Co. stated the other day, that in all his 20 years' experience, he had never known the street to be so free from swindlers as it is at present. This paper believes it is entitled to some credit for this condition of affairs."

True, and the American Bee Journal had at least a little to do with helping to clean out some of those who were swinding the honey-producers.

STENOC, in his department "Pickings from Our Neighbors' Fields," in Gleanings in Bee-Culture, usually begins with an original stanza. The one appearing April 15 is this:

The drizzling rain, the swelling buds,
The song of birds in trees,
All speak of spring's return at last,
And end of winter's freeze.

Speaking of poetry, reminds us of a little experience we had a few years ago. Some chap who evidently was trying to earn a living by writing alleged poetry, sent us a sample, with the suggestion, "Pay expected." The particular sample referred to imagined a young lady smelling of a fragrant rose in which a bee had grown. We responded with the return of the poem, saying that we did not use much poetry in the American Bee Journal, and added, using about the same meter and accent as he had written—

But when we do,
It must be true.
A bee never grows
Inside a rose.

MR. J. W. WINDER, of Louisiana, was reported in Gleanings in Bee-Culture for April 15, as having died April 8. Here is what Editor A. I. Root says of him:

"The veteran readers will remember, without doubt, Mr. Winder. About the time Father Langstroth got out his first honey-extractor, Gray & Winder made a revolving-frame extractor. Mr. Winder was originally a photographer. He soon became an enthusiastic bee-keeper, attended all the conventions for years, was one of the first to rear queens and advertise them; and to the day of his death he made bees and honey his principal occupation. He died April 8, aged 71 years. I have mentioned Mr. Winder in my visits to New Orleans, and the courteous way in which he gave his entire time to piloting me around thru the different portions of the city. He held his health remarkably. Even when nearly 70 years old he would walk a dozen miles a day, and almost without fatigue. We are informed by his son, A. T. Winder, that bronchitis was the cause of his death. One more of the old veterans has past away."

We remember Mr. Winder as the Louisiana bee-keeper who used to send our worthy predecessor, Thomas G. Newman, a box of beautiful sweet-scented flowers early each spring, long before outdoor flowers were growing naturally

here in Chicago. Yes, the old leaders are being removed from us. One by one they drop out, and the younger hands and hearts are left to carry on the work. How wise a provision it is, that while the workers fall the work itself goes on.

MR. W. A. HENDERSON, of Clarinda, Iowa, who has had an advertisement in this journal the past few weeks, offering "ox-blood tablets," has removed to the Masonic Building, Des Moines, Iowa, owing to the increase in his business, and for better facilities for reaching the trade. His advertisement this week shows the change of address as well as the new firm name. Both Mr. Henderson and his remedy come to us very highly recommended, else we would not think of allowing the advertisement to appear in these columns. We are exceedingly careful as to the character of our advertisers and the goods they offer. We will not knowingly permit anything or anybody at all questionable to appear. We want to protect our subscribers in every way possible, and trust that they will report to us any who fail to live up to the agreements they make in our advertising columns.

We have said the latter portion of the above paragraph because there are some people who don't believe in advertised remedies, or, for that matter, in medicines of any kind. That class of course are not supposed to buy them. We have no objection to offering or taking medicines that are all right and that do good if taken.

JOINING THE NATIONAL IN A BODY.—In the last issue of Gleanings in Bee-Culture, Editor Root says this on local bee-keepers' associations joining the National Bee-Keepers' Association in a body, at the half-rate, or 50 cents each:

"At the last meeting of the Philadelphia convention a clause was inserted in the proposed constitution by which any local society, State or county, might join the National Bee-Keepers' Association, on payment into the National treasury of 50 cents per member, *providing* that such members *went in a body*. It was urged by Mr. York, who proposed the insertion of this clause, that we could thereby secure more funds and more members—members who would not otherwise come into the Association; and so far the results in practice are as good as they were in theory. Quite a number of associations have already joined the National. At a meeting of the Chicago convention this matter was discust quite thoroly. Finally it was voted to join the National Association in a body.

"This action on the part of the Chicago Association entitles all the members of that organization to all the privileges and benefits of the National, and at the same time they do not lose any of the benefits accruing from membership in the local organization. In the case of the Chicago Association the membership fee is \$1.00, and it would cost \$1.00 to join the National as an individual member; but by voting to join the National in a body, that same dollar extends their privileges to those of the National."

We should think that every local bee-keepers' society in the United States would jump at this chance to get into the National. It will not only help in members, but in dollars (or half dollars) as well. We can assure all who join the National that every dollar put into its treasury will be well spent in the interest of the pursuit of bee-keeping. Already much good work has been done, and with the able men now at the head, the National will undoubtedly acquit itself nobly in the months and years to come.

The American Fruit and Vegetable Journal is just what its name indicates. Tells all about growing fruits and vegetables. It is a fine monthly, at 50 cents a year. We can mail you a free sample copy of it, if you ask for it. We club it with the American Bee Journal—both papers one year for \$1.10.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the new bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us *one new* yearly subscription to the American Bee Journal at \$1.00.

Root's Column

SHALL WE ADOPT

PLAIN SECTIONS AND FENCES?

Perhaps you are debating this question now. It is not too late yet to make a trial of these goods this season, and no doubt you would like to know what has been the experience of other bee-keepers who have tried them. We have on hand some

EVIDENCE.

If you wish we will gladly send you a copy. You will find much interesting reading, and it may be worth many dollars to you. See what bee-keepers all over the United States and Canada have to say. Ask for Bulletin A. Do not delay, but send your request at once.

Do you want an EXTRACTOR this season? Investigate our

Cowan Reversible Ball-Bearing Extractors

We have a little pamphlet giving some information about these. Send for it if interested.

We are pioneers in the manufacture of modern fixtures for Plain Sections and Fences (as well as all other Supplies.) If you want them right, send to us or our Branch Offices and Agencies.

The A. I. Root Co., MEDINA, OHIO.

Please mention this paper when you write. Watch for our ad. next issue.

GENERAL ITEMS

A Beginner's Experience.

I started last spring, purchasing two colonies and capturing one strong swarm. I now have 9 colonies in fair shape. White clover is in bloom, and I will unite and equalize for the flow at once. My bees wintered well, with stores to spare. We have an early spring and lots of fruit-bloom, which started the bees early. I had a swarm issue April 8, and the rest swarmed within 5 days. The last was a poor honey-year in this section. I got all experience, so I am now able to manage the bees this season with success.

B. T. TILLER.

Maury Co., Tenn., April 30.

Loss and No Loss in Wintering.

The reports from 15 bee-keepers in the Bee Journal for April 26, show that their total winter loss is 30 colonies, and they all report that bees "wintered well." I presume that those whose bees did not "winter well" will not report. I visited several apiaries yesterday, and all have met with some loss—one lost one-half—one other I visited a week ago lost 50 percent, and it will take until July to make full colonies of what remain.

In Gratiot and Isabella Counties the loss is 60 percent. I read in a St. Louis paper the other day that the loss in wintering bees was greater than all other losses combined. Bees are at rest during the winter months, and if properly cared for there certainly should be no loss of colonies. A few bees in each hive will die of old age, yet the loss will not be great.

Once every week the past winter, commencing Nov. 23, I have opened the storm-entrance to my hives and counted the dead bees brought out, and for the 4 months confined (I took off the storm-doors March 23) the average of dead bees was 7 per week, calling it 17 weeks. The entire loss is only 119 bees per hive. From two late swarms there was only 1 to 2 per week. Every week, at any temperature, the dead bees will be brought into the storm-sheds.

D. H. METCALF.

Calhoun Co., Mich., April 28.

Suggestions on Paint for Hives.

I have read with much satisfaction the contribution by "Old Grimes," on how to get the most out of the hive, and for me it is not a question whether to paint or not, but *how* to paint, and I believe I have the problem solved about as perfectly as the science will permit at present. I do not claim the honor of the discovery—it is due to an honest painter.

If you should ask a professional painter to give you a formula for making the very best white paint you would receive almost invariably the following answer: "Pure white lead in boiled linseed oil with a little turpentine for drier." This would be his standard of the very best white paint. But the professional needs to be edu-

Four Celluloid Queen=Buttons Free AS A PREMIUM.

For sending us ONE NEW SUBSCRIBER to the Bee Journal for the balance of this year, with 50 cents, we will mail you FOUR of these pretty buttons for wearing on the coat-lapel. (You can wear one and give the others to the children.) The queen has a golden tinge. This offer is made only to our present regular subscribers.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate, it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

Prices of Buttons alone, postpaid: One button, 8 cts.; 2 buttons, 6 cts. each; 5 or more, 5 cts. each. (Stamps taken.) Address,

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO.

cated, as such a statement is at variance with the facts. While it will look nice and slick when first put on, it will commence to "chalk off," and is so porous as to be little better than no paint at all, in many instances.

If you want a white paint that will stand the weather there is nothing better than white oxide of zinc. Use strictly pure raw linseed oil to mix with it, without a particle of drier of any kind; if you can get oil that is from 8 to 10 years old it will have more body, will dry quicker, and will be a little nicer to handle in painting. White zinc will not chalk, and will stay on until it wears off if put on properly. Turpentine or japan injure the oil, but they are used by painters as it makes the paint work better. White zinc makes a very white paint, but when first put on with raw oil it has a creamy look, and it is almost impossible to do what painters would call a good job, as it will be streaked almost in spite of you. But its looks improve with age, so by the end of a year it looks all right. After the hives are painted set them in the sun, and they will dry in a short time; raw oil dries very slowly in the shade, and the sun-shine does not injure it in drying.

W. S. DONER.

Pottawattamie Co., Iowa.

Wintered Well—A Warning.

Thruout the country generally I think bees have wintered well, but in certain small localities where perhaps little attention was given in the fall, the mortality was quite large. My own colonies have come thru on the summer stands thus far, but there are yet 2 or 3 weeks of critical times to tide over.

The clovers which appeared nearly all dead last fall, have come out under the heavy mantel of snow in full vigor of spring; and if we should be favored with good weather we will certainly expect a better harvest than we had a year ago.

If a kind providence spares me until the last week in August, I hope to have the pleasure of meeting with the bee-keepers in Chicago. That is, if I may expect to be better treated (not at the bar) than happened to be my lot at Buffalo 2 years ago. I refer only to the congested state of the city, and the difficulty of finding a comfortable place to rest one's weary head. If it should so happen that I am permitted to meet with Uncle Sam's "boys" in convention in Chicago, and the editor has any old scores to settle with me, he would better commence early practice at the "punching-bag" with "bare knuckles," because I would not stoop to an encounter with gloves.

I might just add, that I am in fine condition, so look out for a pleasant time. The only one of the "boys" that I feel some fear for is Dr. Mason, and the big G. M. D. Who will protect me? Perhaps Uncle Sam himself.

D. W. HEISE.

Ontario, Canada, April 23.

[Now, look here, Mr. Heise, if all you think of is punching somebody, we'll try to accommodate you should you risk coming to Chicago next August. The idea of a short and fat little Canuck sending a warning in ad-

Apiarian Conditions in Utah.

Some time ago I made a tour of Salt Lake, Davis, Weber, Morgan and Summit Counties, and send a few notes gathered by the wayside. I found as a rule that all bees that went into winter quarters moderately strong appeared to be in pretty good condition, altho some of the bees were dead, and a few were still weak from the effects of smelter-smoke, or other causes.

The weather in the month of May is considered the key to the situation here as far as the bee-industry is concerned, for when the weather is fine in May the bees build up fast, and a prosperous, successful season is the result. Last year the weather thru that month was more like March, the bees died off instead of building up, and the result was a failure for some of our bee-keepers.

While we are aware that Salt Lake County has a great number of careless, uninterested bee-keepers, we find that there are also a great many in the surrounding counties. Progressive, fairly up-to-date bee-keepers can be counted by the hundred in this county, Utah, Davis, Weber and other counties, who take sufficient interest in their bees so that as a rule the results are a success; but in some localities, I think if a test were made, we would find that the careless, indifferent bee-keepers would probably be in the majority, as many of them leave everything to chance. Often they do not give the bees room in any form, and they seldom, if ever, supply them with combs, foundation, etc. Their universal excuse is that they haven't the time to attend to them, and yet if we investigate we find that three out of four of them spend their time on something that does not net them over 50 percent, and sometimes not even 25 percent, of what they would realize from their bees if they were properly cared for. One thing that imprest me forcibly in traveling around among the bee-keepers, was that every subscriber to the American Bee Journal was a first-class bee-keeper, and such, as a rule, make a success with their bees.

While I found several bee-keepers at nearly every place whose bees did fairly well last season, only a very few reported that their bees did first-rate, the greater portion reporting from 1/2 to 2/3 of a crop, while some who gave little attention to their bees reported a partial or total failure.

A few of our prominent bee-keepers purchase a quantity of bees in box-hives, and some of them died, while others lingered along and did little or nothing all summer. But those who had their bees on straight frames, with a supply of extra combs and foundation, when the season did become favorable, had the satisfaction of seeing their bees build up strong, and the results were gratifying. The lack of

\$5.00 per month will pay for medical treatment for any reader of the American Bee Journal. This offer is good for 3 months ONLY— from May 1 to Aug. 1. Dr. Peiro makes this special offer to test the virtue of small price for best medical services. Reply AT ONCE.

these requisites in a season like the last is the main reason why bee-keepers who content themselves with sticking an empty box on their hives get little or no honey. E. S. LOVESY. Salt Lake Co., Utah.

Vicious Advice on Spraying Fruit.

A few weeks ago I received a circular from a prominent manufacturer of spraying pumps, offering to sell at reduced prices if ordered within 30 days, and also stating on an extra slip that he had a secret on spraying which had produced wonderful results where used last season; and if the extra slip were returned with the order for a sprayer, the secret would be sent with it.

Being in need of a sprayer, and having used one of his manufacture, which I borrowed from a neighbor, and knowing it to be good, I took advantage of his offer and ordered one forthwith. The machine was promptly sent, as per his offer, and is all right; but the wonderful secret is simply vicious and detestable, especially from a bee-keeper's standpoint; it is simply to give one spraying *when the trees are in full bloom*. How does that strike you? Here is what he says:

"The second spraying, and which I consider the most necessary, is to spray the trees when they are in full bloom, using for this application the Bordeaux mixture, and adding thereto Paris-green in the proportion of one pound to 100 gallons of Bordeaux mixture. I strongly urge this point of spraying in full bloom, notwithstanding the objections which have been raised to it. Orchards which have been sprayed, which have been given this spraying in full bloom this past year, the results have been simply wonderful, in most cases the trees being overloaded, with scarcely a wormy or scabby apple, pear or plum to be found."

This is simply an overdrawn picture of the results of such spraying, and the man giving such advice is an enemy to both the bee-keeper and the fruit-grower. Even granting there might be a slight benefit in such spraying, which is very doubtful, to say the

Please mention Bee Journal when writing.

least, it would be only a matter of a short time until every bee in the country would be killed, and the fruit-grower would lose the most important factor in the pollenization of his fruit, to say nothing of the loss to the bee-keeper. A. H. SNOWBERGER. Huntington Co., Ind., April 30.

[We trust our readers will heed the above; and we would suggest that any manufacturer of spraying outfits who gives such abominable advice as did the one referred to, deserves not to be patronized at all. If the one in question were an advertiser in the American Bee Journal, we would refuse to continue to run his advertisement, and give him a free notice besides, that would likely not help his business very much.—EDITOR.]

The Prospects—Good Advice.

The past winter was not very severe, and bees have wintered first-rate in this vicinity.

I started into winter with 69 colonies and have 65 now. I had two queenless, one whose queen turned drone-layer in the cellar, died, and left the hive, scarcely a bee alive or dead remaining in the hive. I also lost one weak colony in trying to unite it with a queenless one that was very strong and had quite a little brood.

White clover, which was eaten down pretty close last summer, owing to dry weather, revived considerable from the effects of rains and warm weather late in the fall; but the winter was snowless, and a cold spell of weather in February almost "fixt" the clover as the memorable cold spell of February, 1899 did. As it is, the indications point to a fair stand of clover except such pastures as were fed down close. The alsike has come thru all right.

ARE YOU FULL OF GINGER?

The Modern Remedy Co., Kewanee, Ill.

I am quite sure, from several years' observation, that alsike is hardier than common red clover. I don't think it is any hardier, tho, than white clover.

The forepart of April the weather was quite unfavorable for bees here, as there was an unusual lot of cold, cloudy and windy weather. Lots of bees were lost in attempting to get water, so that it is doubtful if there are as many bees now in the hives as there were when put out of the cellar. They have all the brood they can cover, so that unless the weather continues cold and cloudy we shall soon see an increase in the numbers.

It is noticeable almost all over the country this spring that the bees have wintered well, and the prospects for a honey crop are fair. There is one thought in connection therewith that bee-keepers ought to keep in mind. If the season continues favorable up to, or into, the flow from clover, don't get over-confident and tell every one that

asks you that there'll be the biggest honey crop for years, or since such and such a year when honey was perhaps a drug on the market in some places. Remember, "there's many a slip 'twixt the cup and the lip," and even if we should get a big crop there is no necessity of advertising that much. Times are good, and most people are willing to pay a fair price for anything they want. If the new crop starts at a fair price it will not be so hard to hold to it; but almost impossible to advance it after once starting at a certain figure.

I would not want any one, after reading the above, to think that I would approve of lying, or trying to deceive any one in regard to the size of the honey crop, but I know we are apt to get enthusiastic or excited, or something, and tell more than we are apt to.

Crawford Co., Iowa, April 24.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, April 19.—Market is well cleared of white comb honey; a little choice has sold recently at 16c, but dark and mixed goods are slow of sale. Extracted, white, 80@90c; amber, 70@80c; dark, 60@70c, according to quality and package. Beeswax in good demand at 28c.

R. A. BURNETT & Co.

CINCINNATI, March 3.—There is some demand for extracted honey from manufacturers at 7@7½c for amber and Southern; clover, 80@8½c. Comb honey is selling firm at 14@16½c in a small way. Beeswax, 25@27c.

C. H. W. WEBER,
Successor to Chas. F. Muth & Soa and A. Muth.

BOSTON, March 9.—Our honey market is showing some signs of lower prices, altho the stock on hand is not large. At the same time prices are so much higher than previous years that the trade have taken it very slowly and the results are that the holders are willing to range prices quite a little in order to move stock on hand. Prices range: Fancy white, 17@18c; No. 1, 15@16c; amber, 10@12c; buckwheat almost unsalable. Extracted, best white California, 8½c.

BLAKE, SCOTT & LEE.

KANSAS CITY, Mar. 19.—We quote fancy white comb, 15c; No. 1, 14c; No. 1 amber, 13c; No. 2 amber, 13½c. Extracted, white, 8c; amber, 7c; dark, 6c. Beeswax, 22@25c.

C. C. CLEMONS & Co.

DETROIT, Apr. 23.—Fancy white comb, 15@16c; No. 1, white, 14@15c; amber and dark, 10@12c. Demand and supply both limited. Extracted, white, 7@7½c; amber and dark, 5@6c. Beeswax, 20@27c.

M. H. HUNT & SON.

BUFFALO, April 20.—For strictly fancy white one-pound comb honey we are getting 16@17c. Any grade sells high—10@15c, as to grade.

BATTERSON & Co.

NEW YORK, April 9.—Market is practically bare of comb honey of all description. Little lots arrive here and there and sell readily at from 10@11c for buckwheat and 12@15c for white, according to quality and style of package. The market is well supplied with extracted, which we think, however, will be moved before the new crop arrives. Beeswax is in good demand at from 27c to 29c per pound.

HILDRETH & SEGELEN.

SAN FRANCISCO, Apr. 25.—White comb, 11½@12½c; amber, 8@10c. Extracted, white, 7½@8c; light amber, 7@7½c; amber, 5@5½c; Beeswax, 26@27c.

Small quantities of new crop have been received, but not enough has been yet done in the same to clearly define values. Current quotations would not likely be sustained under anything like free offerings. The yield will undoubtedly prove light, and the market shows a generally firm tone.

OMAHA, Mar. 13.—Demand shows some improvement in January, having been much more active, but as anticipated there is no advance in prices. Market remains steady at 14@14½c for fancy white comb and 8½c for white extracted. The latter is pretty well cleaned up along the Missouri River, and it looks as if there would be some shortage before another crop comes in. From present appearances there is about enough comb honey to go around at the present prices, hence we look for no particular change in values.

PEYCKE BROS.

Convention Notice.

Yellow Sweet Clover Seed

WE HAVE IT AT LAST!

We have finally succeeded in getting a SMALL quantity of the seed of the YELLOW variety of sweet clover. This kind blooms from two to four weeks earlier than the common or white variety of sweet clover. It also grows much shorter, only about two feet in height. It is as much visited by the bees as the white, and usually comes into bloom ahead of white clover and basswood. We offer the seed as a premium

A QUARTER POUND FOR SENDING ONE NEW SUBSCRIPTION.

So long as it lasts, we will mail a quarter pound of the seed to a regular paid-up subscriber who sends us ONE NEW subscriber for the American Bee Journal one year, with \$1.00; or ¼ pound by mail for 30 cents.

We have been trying for years to secure this seed, and finally succeeded in getting it. It is new seed, gathered last season by an old personal friend of ours, so we know it is all right. But we have only a small supply. When nearly out we will mention it.

DR. MILLER'S

Honey Queens

One Untested Queen Free as a Premium for sending ONE New Subscriber to the American Bee Journal for one year.

We have been fortunate in making an arrangement with DR. C. C. MILLER—the well-known honey-specialist—to rear queens EXCLUSIVELY FOR US DURING THE

SEASON OF 1900. These Queens will be mailed in rotation, beginning about June 1, so "first come first served." We are ready to book orders now.

The Queens Dr. Miller will send out on our orders will be precisely the same as those he rears for his own use, so of course they will be from his best stock. His best colony in 1899 had a queen reared in 1898; May 5, 1899, it had brood in 4 frames, and he gave it at that time a frame of brood without bees. It had no other help, but May 25 a frame of brood with adhering bees was taken from it, and the same thing was repeated June 3, leaving it at that time 5 frames of brood. It stored 178 sections of honey, weighing 159 pounds (and that after July 20, in a poor season), being 2½ times the average yield of all his colonies. A point of importance is the fact this colony did not swarm, and an inspection every week or 10 days showed that at no time during the entire season was there even so much as an egg in a queen-cell. Dr. Miller expects to rear queens from this one during the coming summer.

The demand nowadays is for BEES THAT GET THE HONEY when there is any to get, and Dr. Miller has such bees. You will want to have a queen from his best, we are sure, even if she is not pure Italian.

Do not send any orders to Dr. Miller, as all orders MUST come thru us, according to our agreement.

Remember, send us \$1.00 for ONE NEW SUBSCRIBER to the American Bee Journal for one year, and YOU will get ONE OF DR. MILLER'S UNTESTED HONEY-QUEENS FREE AS A PREMIUM. This offer is made only to our present regular subscribers. Orders for queens to be filled in rotation, beginning about June 1st.

Address all orders to GEORGE W. YORK & CO., 118 Michigan Street, CHICAGO, ILL.

CONTRIBUTED ARTICLES

"The Best Hive for Northern Illinois," and Its Successful Management.

BY W. C. LYMAN.

ON page 146, Mr. Edwin Bevins refers to an article which I wrote for the Chicago Bee-Keepers' Convention last fall on the above subject. I made the article as short as I well could, simply as a "starter" for the discussion of the subject, not expecting to see it in print.

From my point of view the subject should not be the best hive, but the best management for Northern Illinois, where the surplus crop is white honey, and the season is short and comes in midsummer. Because I did not state clearly the ideas I wish to convey, it seems Mr. Bevins has been led into a mistake in supposing that I use brood-frames deeper than the Langstroth, and eight to the hive. I have never tried such frames, but have used the Heddon hive, which, as I use it in winter, is a deep *brood-chamber*, and amounts to about the same thing. I have had the Heddon hive in use for 14 years, and the dovetail 8-frame hive since it was introduced by the A. I. Root Co. Previously I had used several styles of hives taking the Langstroth frame, and it was while using the 10-frame Langstroth hive that I came to the conclusion that the supers of that size were too large to tier up to the best advantage *in this location*.

I therefore had queen-excluding honey-boards made (which would fit a 10-frame brood-chamber) and an 8-frame super. When so used the ventilation was very poor, for the hives had bottom-boards nailed on, and not a large entrance; so I gave them up.

Perhaps 8-frame supers on shallow 10-frame brood-chambers, with loose bottom-boards, might be all right, but I have not tried them.

Referring to Mr. Bevins' article, he says in regard to using deep brood-chambers until swarming-time, and then shallow ones until the end of the white honey harvest, "This practice, it seems to me, would be attended with a good many difficulties and no adequate compensating advantages." I certainly do not find it so.

In Gleanings in Bee-Culture, Mr. L. Stachelhausen says under the head of "The Hive Question:" "By the present management we can not use the advantages of large hives in producing comb honey, so we can form only one conclusion, and that is, *the present management is incorrect*"....."The problem is to find out a management by which all advantages of large hives can be

utilized, and at the beginning of the honey-flow to get the colony in such a condition that the work in the supers is started at once, and all the honey stored there."

Now having the bees in the fall in hives of sufficient brood-chamber capacity to contain honey enough to carry them thru to another season's work, it seems to me is the cheapest and least troublesome plan of getting them in good condition for the harvest.

Having brought the bees up to such a condition that they are ready to cast strong swarms, I would like to have them swarm as soon after the opening of the harvest as possible; and these swarms I would hive in shallow brood-chambers on full drawn combs with queen-excluders, and the supers with full sheets of comb foundation in the sections, also the supers from the hive from which the swarm issued put immediately on the new hive before the swarm is run in. The old brood-chamber I would remove and run for extracted honey.

In regard to these small brood-chambers Mr. Bevins says: "There may be seasons in which there may not be much honey gathered after the white honey harvest, and then one might wish that some, or all, of the white honey surplus was in the brood-chamber, and the brood-chamber was a little large." Just so. But in a season when I should want the white honey surplus in the brood-chamber, I should not expect many swarms, and the honey would go into the large brood-chambers which the bees would have previous to swarming.

He also says: "To be sure, one could resort to feeding, but feeding is something Mr. Lyman would avoid." I think he will find, if he looks again, that I said feeding "*in the spring*."

My motto in regard to feeding is: "Give her of the fruit of her hands, and let her own works praise her in the gates;" and a little farther along I will tell how.

On page 211 of the American Bee Journal for 1894, is

Lyman's Bee-Escape Honey-Board.

described the bee-escape honey-board (shown here) which is useless for the purpose there recommended, but which is of so much use in transferring or changing bees from one hive to another, that I am using it entirely for that purpose. In fact, I believe its use is the easiest plan of transferring of which I know.

"Now, as the harvest draws to a close, I would prepare some of the brood-chambers such as I winter the bees in, with full combs of honey or empty ones, as seems best according to the season, and have them ready to place on the stands which are occupied by swarms in shallow brood-chambers. When the time comes to take off the last of the comb honey, take one of these prepared brood-chambers and put it on the stand of one of the small brood-chamber colonies; on it (the prepared brood-chamber) put one of the bee-escape honey-boards; first having taken the queen from the small brood-chamber and put her in the large one; and above the bee-escape honey-board put the brood-chamber from which the queen was taken, then carry the comb-honey supers removed from the small hive to the honey-house.

As the bees hatch out from the small brood-chamber the drones and young queens, if any are reared above the excluder, as is sometimes the case, will pass out thru the bee-escape in the front end of the honey-board to the outside of the hive, which ends all bother with them, and the brood-chamber becomes a super for extracting the fall honey.

Mr. Bevins further says: "Of one thing I am tolerably well convinced, and that is, that the wintering of bees without the necessity of feeding, and the securing of a large amount of surplus, are things which can not be with any certainty combined."

By the above method the labor and expense of feeding is reduced, and the amount of surplus obtained from the colonies which swarm has often been one-third more than from the best of those which did not swarm. The hives from which the swarms issued, and those which are not strong enough to work well in the boxes, are used to fill extracting-combs, and of these enough are used for feeding purposes.

As I am living in Northern Illinois, and not in a very good location for honey, I will say that I am very well content with the amount of surplus which "Providence and the bees permitted me to have" during the last season, which was a little over 50 pounds per colony, spring count; tho it was not obtained as Mr. Bevins says, in his last paragraph, he would get it.

I have read his articles as coming from a practical bee-keeper of experience, and I think we would not differ much on general principles.

To sum up, my plan is simply this: Use any kind or size of hive you like, according to your location, so as to have the bees send out strong swarms as near the opening of the honey harvest as possible. Have these swarms in shallow brood-chambers, on *full drawn combs*, to make them more contented to catch all the pollen, and to save buying foundation from year to year for use in hiving swarms. Use only the swarms, and the strong colonies which do not swarm, for comb honey, and use all others for extracting, or for honey to feed as needed. When the comb honey is removed, transfer the bees in small brood-chambers back to large ones by the use of bee-escape honey-boards. The use of sectional brood-chamber hives would make it unnecessary to transfer the bees, but it is so easy to transfer that any one who prefers larger frames can have them in use for the greater part of the year. Dupage Co., Ill.

Shipping Queens with Old Bees—Backward Spring.

BY G. M. DOOLITTLE.

MY experience has again told me this spring that old bees, or such bees as have been wintered over, those which emerged from their cells last September or October, are practically worthless for shipping queens in early spring. I began to suspect this some years ago, since when I have been keeping a sharp lookout in the matter.

Some years ago the call for early queens was great, as it always is, and thinking to please my customers, I shipped very many within a week after the bees were out from the cellar. The result was that more than half so shipped were reported as arriving dead. This I could not understand, for I had used the same cages, food and ventilation as were used the fall before without a single loss. Later on, after

there was plenty of suitable-aged bees to send with queens, I met with the same general success which had been attained before. This set me to studying, and I soon arrived at the conclusion that the trouble lay in having to use old or nearly worn-out bees, where queens were sent prior to a month from the time of setting from the cellar.

The next year I tried again, and found that my loss in queens sent out from one to three weeks after setting from the cellar was fully as great as it was the year before. I then refused to send queens before the bees had been from the cellar 30 days unless the purchaser would take the risk on them; so I sent very few, as the purchaser always wishes the seller to guarantee safe arrival.

This year, at the urgent request of a few parties, I have sent out a few queens, only to experience the same loss as before, and so I write this, advising all of our northern queen-breeders to guard against such loss, by not sending queens till they can find bees of suitable age to send with them, for a queen will not live long in early spring after her accompanying attendants are all dead. The trouble seems to lie in the fact that the vitality of a bee which has lived from September to May is nearly gone, and when they come to stand the strain of confinement they are soon exhausted, and die in a very short time.

This loss of early queens in the mails is something very undesirable, not only to the seller, but to the purchaser as well, even where the seller guarantees safe arrival; for where a loss is reported the seller has at once to make another of his full colonies queenless in addition to the first, for this loss comes at a time of year when it is too early to rear queens advantageously. Then the buyer, expecting his queen, has usually made a colony queenless to fit it to take the expected queen with the least danger from losing her by introduction, and where she reaches him dead he has a queenless colony on hand to wait till he can get a letter to the breeder, and the breeder send another queen back if he can do so. If he can not send another queen right away, then the purchaser must allow his colony to rear a queen from the brood in the hive, or send to some one else for a queen, which, in either case, generally results in a colony whose usefulness is destroyed for that season as far as surplus honey is concerned.

But how old should bees be to be of suitable age for sending with a queen? My experience proves that the younger the bee, providing said bee has had a chance to fly out from the hive and empty its intestines, the better for successful results. As bees, when in a colony is in a normal condition, do not fly out of the hive till they are six days old, those suitable for shipping with a queen should be from 6 to 12 days old.

And how do I tell bees of this age from those both older or younger? In this way: From experience I have found that where combs of brood are taken from the bees and kept at a temperature which will perfect the brood by keeping this brood in a warm room over a strong colony with wire-cloth between, or in a lamp-nursery, till enough bees have emerged to protect this brood, the young bees will fly out to empty themselves on the first pleasant day after they are five or six days old, so that in from two to six days more the older bees will be of suitable age for shipping with the queen. Now, if we open the hive containing these bees of right age we will find that a certain part of the bees will almost immediately thrust their heads into the cells and begin to fill with honey. By examining closely we will note that such as are filling themselves are not the young fuzzy ones, nor those which show by their light, downy appearance that they are next older than the fuzzy ones; nor are they those whose abdomens are distended with excrement from the food consumed in the larval state. Consequently they must be the bees which have flown, and those are just the ones we want.

Then, again, open a hive which you know is composed of bees over 20 days old, and unless you pour in too much smoke, or jar the hive, or handle the combs roughly, scarcely a bee will put its head into the cells to take honey; neither will the old bees from hives recently brought from the cellar be seen with their heads in the cells on opening the hive, if it is opened as it should be. Therefore, in putting up queens I catch the bees which are to accompany her from those which have their heads in the cells loading up with honey as soon as the hive is opened, this loading up telling me that they are the bees most suitable for the purpose of keeping a queen safe and sound to her journey's end. And I now do not feel like guaranteeing the safe arrival of queens until I can find such suitable bees to put up with them for shipment.

BACKWARD SPRING IN NEW YORK.

Our spring here is very backward. The snowbanks and ice in the lakes held on very late, and it did not warm up sufficiently so I could set the bees from the cellar till the 18th and 20th of April, those at home being set out on the first date, and the out-apiary on the latter. A few days of comfortable weather brought out the elm and soft maple bloom, but with it came cold high winds from the north-west, with floating clouds. The bees seemed determined to secure some of the pollen, so they would go to the trees when the sun would come out only to be blown down by the wind, and chilled when clouds went over the sun. In this way things went on for a week when it came on freezing nights, and on the mornings of May 4th and 5th the ground was covered with snow, it snowing more or less all day the 5th. There seems to be no warm-up to it, and the bees are getting in hard shape. But I look for better days, and expect when it does warm up it will be hot enough to make up for lost time. And the bees need the hot weather *now*.
 Onondaga Co., N. Y., May 7.

Some Improvements in Beeswax Extractors.

BY C. G. FERRIS.

WHILE it is practical to render a very small quantity of wax by the various ways discust and presented by many of our bee-keepers, I would say to the apiarist having any amount of combs to render, than he can not depend upon some of the wax-extractors now offered. The

The Extractor Basket.

larger the extractor the better the demand, and this to-day contains nearly 4,000 cubic inches to work with in the baskets. This, assisted by having extra baskets in reserve, makes the working-space always to its fullest capacity. By using the press and follower (see illustration) we can in a few moments have the basket and refuse ready to be aken from the extractor, and while the basket removed is being cleaned an extra one takes its place, giving the operator clean ones to continue the operation indefinitely.

The baskets are interchangeable, as much so as the frames in our hives; they are made of extra-heavy galvanized wirecloth in a most substantial manner, all in one piece, united and soldered to galvanized hoop-iron at the

Longitudinal View of the Extractor.

ends of the baskets. All rims and parts in their construction are made upon the self-spacing principle.

To both Mr. Hetherington and Mr. Boomhower I am indebted for ideas and suggestions that have enabled me to

place this wax-extractor in the position it occupies to-day. Improvements will be made in the future as fast as pointed out by my friends, and any that are found valuable in practical use will be paid for.

The second cut is a longitudinal section showing the basket and extractor cut thru the center. No. 14 is the follower, to be placed on top of refuse when ready to use the

A Three-Basket Wax-Extractor.

press. No. 11 is an iron bar holding the screw. No. 12 the basket. To remove the bar and screw we give it a few turns when the screw leaves the hole in the follower, when a movement either way towards either end of the basket (No. 15) releases one end, then the bar and screw can be lifted from the basket. One motion puts it in place, and the instant pressure is applied fastens it.

Nos. 2, 6 and 7 are for the escape of steam and foul odors to the stove. The surplus steam enters at No. 2 down to No. 6, and in the stove at No 7, where an open lid or ringed griddle should be used for the small extractors. No. 9 is where water is supplied to the tank, and also shows when more water is needed, as when the water gets below the top of the hole the steam escapes in volumes; also, at a glance, in attending to the extractor, we can see how much water there is, as it shows from the outside.

The above cut shows one of the most rapid machines—a three-basket, using five to great advantage. The first basket in this cut has half of it taken away to show the follower and press in actual position. After using the machine until the refuse becomes objectionable, put on the follower, No. 14, adjust the screw and bar in the basket as shown in the cut, and run the screw down as far as desired, with this pressure under live steam there is no danger of wax granulating by coming in contact with cold air as with other devices that make it necessary to remove the refuse from the baskets. The result can not be but highly gratifying to practical bee-keepers.

After draining under steam and pressure for a few moments, one or more of the baskets should be removed, and while the cleaning them out of refuse is going on, extra ones take there place, whereby no delay is caused in the rendering, enabling us to get better results with the smaller machines also; for with a single-basket extractor, by using two baskets, the rendering is not interfered with by the refuse. With a two-basket machine of course we do double the business done with a single. We get the greatest results ever attained in a steam wax-extractor by using five baskets, as stated above.

Spreading Brood—Its Dangers and Advantages.

BY C. DAVENPORT.

THERE has in the past been some discussion in regard to spreading brood in the spring in order to increase brood-rearing, and thus have a larger force of bees for the early white honey-flow. Like many other things discust in relation to our pursuit, there are some who are strong advocates of the practice, and others who oppose or condemn it. Mr. Doolittle, who it is needless for me to say is one of the most experienced and practical men in our ranks, advocates and practices this spreading of brood in the spring, and it is a success in his hands; but many of us lack the skill and judgment he possesses, and then I think, too, locality has a great deal to do with

our success or failure in the matter. I have largely practiced it in the past, but of late I have discontinued it almost altogether, for here with what skill, or perhaps I should say what judgment, I possess, taking one year with another, nothing is to be gained by the practice.

It is true, some years a considerable increase in bees can be secured by spreading, but it is equally true that some years nothing is gained; while, again, some years I have had the practice result in a serious loss of brood, which was more valuable at the time it was lost than twice or even three times the same amount would be later in the season. The trouble is, that here in the spring, during the time brood must be spread in order to secure much advantage from the practice, the weather is too uncertain. A warm, mild spell may be succeeded for a considerable time with so low a temperature that colonies of ordinary strength will hardly be able to protect what brood they would naturally have, so if the brood has been spread during or just previous to the warm spell, some of it must perish, and in some cases many adult bees will also be lost, for they may stay spread out trying to protect the spread brood until they succumb to the cold; but it is only in very exceptional cases that many bees themselves are lost, and this occurs when the weather turns cold very suddenly. When the change comes on gradually the bees keep contracting the space occupied until, if necessary, they are as compactly clustered as they are during cold weather late in the fall.

But I think there is no question but what a large increase in brood-rearing can be secured, or at least started, by spreading the brood. But it should be done with great caution in localities that are like mine—subject to sudden changes during the forepart of the season.

To show the danger there is in the practice here, I will briefly cite an instance in this respect that occurred with me a number of years ago. That spring the weather until the middle of April was cold and unfavorable, then it suddenly turned warm, and I expected the cold weather for that season was over, and as there was but little brood in the hives I commenced spreading it, and brood-rearing increased very rapidly, but the last of April it suddenly turned cold again, and we had quite a snow-storm, and it continued cold until about the middle of May. That spring I noticed a number of farmers planting corn with overcoats and mittens on. When warm weather came again I found, upon examination, that a large part of the colonies were in a deplorable condition; they were very weak in bees, and a large part of the brood had perished. Besides this, spreading of brood had caused them to use much more of their stores than they would otherwise have done, so I had to do a good deal of feeding that would not have been necessary if the brood had not been spread. Besides the work it involved, I lost by it that year, at a low estimate, \$200.

Perhaps most of those who read this will say, Well, you spread too much and too soon. If they think so, my object is gained, for I have merely described my loss as a caution to others. But it should be understood that all I have said in regard to this matter refers to single-walled hives, for I use no other. In the long ago, I made a number of double-walled chaff hives, but a large percent of the colonies in them, if the hives were left outdoors, perished during the winter or following spring, and if colonies in them were wintered in the cellar I could not see that they did any better in the spring, or gathered any more honey during the season, on an average, than colonies in single-walled hives, so I discontinued their use, for they were much more unwieldy to carry into and out of the cellar, and more unhandy to manipulate in the summer.

Mr. Doolittle claims, I believe, that bees winter enough better in chaff hives in the cellar to pay for the extra trouble and expense of using them, but how or why they can, in a cellar, be kept at the proper temperature is something I can not understand, except if the packing overhead is arranged so as to absorb dampness that may arise from the cluster, this might in a damp cellar be a benefit; but the same benefit could be more cheaply secured by putting a packt super over a single-walled hive. Be this as it may, at the time I had a few double-walled hives in use I knew nothing about spreading brood in the spring, so I can not say from experience whether as much caution would be necessary when using them. It looks very reasonable to suppose that a colony in a packt double-walled hive could protect more brood during a cold spell than the same colony could in a single-walled hive. However it would be in the case of spread brood, probably all know that there is a considerable difference of opinion between men of experience in the matter as to whether a chaff hive is an advantage or

not during the changeable weather of spring to a colony of average strength left in normal condition.

Of course, there are times late enough in the season when there is no danger of brood being chilled, when the brood in a certain colony can be spread to great advantage; in other cases it will result in great advantage to a colony to have their combs rearranged early in the spring, for in some cases there is so much honey in the combs next to the cluster that brood-rearing will not increase as fast as it naturally should, for the bees can remove and change honey from one comb to another, sometimes they do this work too slow in the early spring; besides, there may not be anywhere to put it.

When using a small hive like the 8-frame Langstroth, one of the things that has to be watched and guarded against is not to allow too much honey in the brood-nest during the time brood-rearing is desired, for brood-rearing can not, of course, be carried on unless there are empty combs in which the queen can deposit eggs.

Dr. Miller would probably say, Give them another story of empty combs, then at the beginning of the white flow, if thought best, they can be reduced down to one story again. This is a good plan to practice if one has the empty hives and drawn comb, but there are probably many who run for comb honey who do not have many of these extra hives unless a severe winter loss has occurred. This is the case with me, and with frame hives I find this matter can be as profitably arranged here without going to the expense and work of keeping a large number of extra hives and combs, for there are usually enough colonies short, or that can at least take more stores without curtailing their brood-rearing, so that by exchanging combs enough brood-room can be secured for all.

There are exceptional cases, as when, for instance, the brood-nests are on an average unusually well filled in the fall; and again, when more than the usual amount is secured from the early spring flowers. Under these conditions the extractor is brought into play, which soon remedies the matter; but in other localities, like I imagine Dr. Miller's to be, where there is a longer time from the beginning of settled warm weather until the main flow, it might be money well invested to have an extra story with drawn combs for all strong colonies. Southern Minnesota.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Transferring—Bee-Keepers Mostly Non-Tobacco Users.

1. My 15 colonies came thru the winter strong. One colony, tho, had no queen lately; and I feared they had foul brood, but there was no smell. Some brood was brown, and on one side of the cell, and would stretch out about $\frac{1}{2}$ inch; some was dried up. I tried to transfer them, but they would not be transferred. They were an immense colony. I tore their box up and let them scatter to the four winds, as I had no queen and could not find theirs. I transferred 4 other colonies the same day (April 15) quite successfully. I believe. This is the way I did it:

I put a super where the old box stood; turning the old box upside down about 5 feet back, and setting the new body on top. I drummed and smokt from the old box nearly all the bees with the queen, I suppose, into the new body. Then taking the body, I placed it on the old stand under the super. I used about 3-inch starters. Did those homeless bees go to other hives, do you suppose?

The colony I could not transfer had lots of moths on the bottom, inside of the hive. I am worrying some for fear they might have had foul brood.

2 I am having some extracting-hives made with closed-end frames $1\frac{3}{8}$ inches wide. The bodies and supers are the same size— $5\frac{7}{8} \times 14\frac{1}{4} \times 17$, inside measure. I can put two to-

gether for a hive-body, and can alternate or change frames easily. What do you think of it?

3. LATER.—Those colonies I transferred were robbed out, except one. Well, I'll live and learn. There being a dearth of honey, somewhat, I had to do something with those new hives, so finding another queenless colony with some straight comb and frames nearly the same size of the Langstroth frames, full of honey, I divided them around with the adhering bees. The balance I left in the hive and set them on top of another colony, bees and all, smoking them well. How will they do? Will they fight or live peaceably?

4. I have met quite a number of bee-keepers, and loan them my journal, as I am anxious to have them subscribe. There seems to be a fraternalism among bee-keepers. So far I have not found a tobacco-user among them. Is that generally the case?
WASHINGTON.

ANSWERS.—1. If those bees that you let "scatter to the four winds" had nothing left on their own stand in which to enter, they no doubt entered other hives near by. It will be well for you to keep a sharp lookout for foul brood. The moths cut no figure in the case.

2. For extracting-supers you will like these shallow bodies. Some also like them for brood-chambers, but the majority seem to prefer something deeper.

3. It's a toss-up whether it's peace or war. You ought to be able to tell very shortly after putting the queenless bees on top. If they did not unite peaceably you would find dead bees thrown out at the entrance. It's rather risky to unite bees in that way when no honey is coming in.

Look here, won't you please quit trying to transfer or doing anything else with bees that will tend in the least to start robbing, unless at a time when they are gathering? Transferring is usually done when fruit is in bloom, with no tendency to robbing.

4. There are tobacco-users among bee-keepers, especially in other countries, and in the German bee-journals it is a common thing to find tobacco and bee-keepers' pipes advertised. But for some reason the number of bee-keepers that use tobacco in this country is small. At bee-conventions, or any place where a crowd of bee-keepers is found, the absence of tobacco-smoke is very noticeable. Perhaps bee-keepers get all the smoke they want when smoking bees.

Amount of Brood in a Hive by April 20—Foundation in Brood-Frames.

1. I have 15 colonies of bees in chaff hives, 14 of them having Italian queens, but only 4 mated with pure drones. I got a tested queen a year ago last fall, and have reared my queens from her. April 18 there was brood and eggs in 8 frames in the hive that queen is in.

1. Do bees usually have that amount of brood by April 20?

I found in another hive 6 frames of brood and eggs. But most of them had only 3 or 4 frames.

2. Does it pay to put full sheets of foundation in brood-frames?

My hives are all 10-frame except two; they are eight.
IOWA.

ANSWERS.—1. The amount of brood in a hive April 20 depends not only upon the colony, but also the place and the season. Two apiaries 3 miles apart may show a decided difference. In the present case the colony seems to have been unusually good.

2. Yes, if for no other reason than to get all worker-comb.

Some May-Day Apiarian Questions.

1. In looking thru a colony about the first of May, how is a beginner to judge whether there is enough stores to last the bees "at least two weeks"?

2. Is it likely, or possible, that one will find enough honey left over in an 8-frame Langstroth hive, wintered on the summer stand, to make the use of an extractor advisable in May?

3. If so, on what basis should one determine to use the extractor?

4. Why do you not, in your department, insist that the editor shall print the questions and their answers alternately instead of seriatim?
NEBRASKA.

ANSWERS.—1. That's a very sensible question, but the answer is not so easy. One with experience in judging the matter will find it easier to decide than to tell another how

to decide. Generally, however, if you see a single spot of sealed honey along the upper part of any comb without lifting out any of the frames, you may judge there is no immediate danger of starvation, for the bees will have at least a small store of unsealed honey in or near the cluster. If sealed honey is to be seen along a number of the combs, you may feel easy for the next two weeks. Lifting out the frames, you can estimate pretty well by inspection how many pound sections of honey would equal the honey in the hive, and if two pounds are there they may be left for two weeks with no anxiety.

2. To say the least, it is a very remote contingency.

3. If you find less than three combs in which the queen can lay, it may be worth while to consider the question of giving more room. This answer at a guess, for I think I never felt called upon to extract in spring to make needed room.

4. I have all I can do to scrape up answers to fit all the questions that come, without getting into a row with the printer, his devil, and other angels, about the order in which the questions are printed. That's his part of the business, and if I should go to interfering I'm afraid the reputation of the "Old Reliable" would suffer.

Transferring After Swarming.

If I have bees in box-hives, and combs in poor shape to transfer, can I let them send out a prime swarm, then catch the virgin queen in a trap as she comes out for her wedding flight, put her in a new hive with full foundation, and place the box-hive above with queen-excluder, and in 21 days have the box-hive empty of bees and brood? If not, what is my best way to get them into new hives, with good, straight combs, with the least loss of time and bees?
IOWA.

ANSWERS.—It is somewhat doubtful whether your plan would work to your satisfaction. It may work better to leave the young queen undisturbed till 21 days after the prime swarm, and then drum out the bees and queen. If you put the prime swarm on the old stand, setting the old hive close beside it, a week later putting the old hive on a new stand, you will have a strong force for surplus in the prime swarm, and no second swarm will be sent out. By waiting 21 days before making the drive, you will lose a little in the way of eggs and brood from the young queen, but not much.

Cottonwood and a Wax-Plant.

Cottonwood yields plenty of pollen, but is no good for honey. Better plant "measly box-elders," as Mr. Secor calls them—he might get a little honey from them.

I have a vine in the house that beats all the honey-plants I ever saw to yield honey. When it blooms, the flowers look like wax, and the nectar stands in drops that a bee could fill up on in short order. We call it a wax-plant, and the book calls it Hoya.
KANSAS.

ANSWER.—The wax-plant, or Hoya, is a great yielder of nectar, and several other greenhouse plants are so rich in nectar that a field of them would make bees disgusted with such slow-yielding things as clover and linden; but the trouble is that they are so expensive that the honey from them would cost a dollar a pound or more.

Thanks for information about cottonwood.

Queen-Excluders That Were Used Over Foul-Broody Colonies.

Late last season I purchast a quantity of queen-excluders which had been used (unknown to me) over bees having foul brood. Could they be used again, and with what precaution, or would it be safer to discard them altogether?
ONTARIO.

ANSWER.—It will be all right to use them if they are first thoroly boiled.

The American Fruit and Vegetable Journal is just what its name indicates. Tells all about growing fruits and vegetables. It is a fine monthly, at 50 cents a year. We can mail you a free sample copy of it, if you ask for it. We club it with the American Bee Journal—both papers one year for \$1.10.

CONVENTION PROCEEDINGS

Report of the Northeastern Ohio and Western Pennsylvania Bee-Keepers' Convention.

The Northeastern Ohio and Western Pennsylvania Bee-Keepers' Association held their 19th annual convention at Andover, Ohio, Jan. 12 and 13, 1900. Owing to the fact that a farmers' institute was being held in the neighborhood, and, as nearly all the bee-keepers were farmers, they were really more interested in the farmers' meeting. The attendance at the bee-keepers' convention was rather slim. In fact, the convention was more informal than regular. Nevertheless, the enthusiasm displayed would have done credit to a much larger assemblage. All those in attendance felt that their time had been well and profitably spent, and all departed for their homes avowing renewed allegiance to the association, and promising their best efforts for the success of future meetings.

It was at Andover that the association had been organized 20 years before. In fact it was, I believe, one of the pioneer bee-keepers' associations of this country. It was here that some of their most enthusiastic and largely attended conventions had been held. These earlier meetings were attended by some of the best bee-keepers in the country. The early records of the association show that Thomas G. Newman, then editor of the American Bee Journal, was one of those who attended and took an active part in the affairs of the association. Among those in attendance at the last session was a number of those who had signed the roll at the initiatory meeting 20 years before.

The first day's session was given over to a kind of an historical reminiscence of the association and its early members. One of the most pathetic incidents of the convention was when Mr. M. E. Mason, one of the founders of the association, took the old record-book and called the roll that had been signed at the first meeting in 1880. As the names were called those present told what had become of the former members, how this one had moved here, and that one there, how this one had been dead for nearly 20 years, and how that one had gone into other business, and so on until nearly all of the early members had been accounted for. The home-coming to Andover was within itself a pathetic incident. It had started out from there 18 years before in the full vigor of youth, strong in members, and rich in enthusiasm; and now, after flitting hither and thither, it returned like the prodigal of old, weak and worn, and in a not overly prosperous condition.

The convention was called to order by Pres. Spitler. After the usual preliminary business was disposed of, the first thing on the regular program was an essay on "Spring and Early Summer Management of Bees," by Mrs. C. J. Cornwell. [This and other essays will appear later.—Ed.]

Mr. O. O. Belden followed with an interesting talk on the "Desirability of Preventing Swarms." He argued that while it was not desirable at all times to prevent swarming, it was a very desirable thing to know how to do it; that increase was easy at all times, but the curtailing of swarms was one of the most difficult problems that the bee-keeper with a large number of colonies had to contend with; and very often the success or failure of the season depended upon curtailing, or at least controlling, the swarms. He would manage by putting on sections just when the bees were ready for them. He thought that putting on sections too early would not discourage swarming, but, if anything, rather encouraged it.

Full sheets or starters was the next discuss. All present favored full sheets in the brood-chamber, and the majority would use full sheets in the sections.

The advantages of producing extracted honey were set forth in an article by Mr. B. W. Peck.

Mr. M. E. Mason gave a very interesting talk on the "Best and Cheapest Method of Producing Comb Honey." The success or failure of the season, as to comb honey, he considered, depended largely upon the spring and early summer management of the bees. In general, he endorsed the management of Mrs. Cornwell for this time of year. He thought that too rapid breeding early in the spring was not desirable, and that when the hives became overcrowded

before the honey-flow, it superinduced the swarming inclination. He favored drawing brood from the strong colonies and building up the weak, and he said the successful comb-honey producer must know his flora, and when to expect the honey-flow, and then try to time his bees so that they will reach their maximum strength at the right time to take care of it. His method and system of management was practically the same as the Danzenbaker system.

The next thing on the program was an essay on "Bees as Pollenizers of the Blossoms," by Ed Jolley.

Jefferson, Ohio, was chosen as the next meeting place, and the following officers were elected for one year:

President, B. W. Peck; Vice-President, M. E. Mason; Secretary and Treasurer, Ed Jolley, of Franklin, Pa.

The convention then adjourned to meet Jan. 9 and 10, 1901.

ED JOLLEY, Sec.

The "Old Reliable" seen thru New and Unreliable Glasses.

By E. E. HASTY, Richards, Ohio.

RED-RIBBON YOUR APIARIAN TOOLS.

If you want to be "in town" paint your little tools red (but not the town); then you can find 'em when they get lost in the grass. Some folks, however, dread to meddle with paint. These can tie strips of red cloth to the tools and find it answers the same purpose pretty well. My way (my ideal, at least) is to keep the ground so cleanly hoed that things can not hide very easily. Page 211, Geo. G. Scott.

WAX FROM CAPPING AND VIRGIN COMB.

In Dadant's excellent marketing article, page 211, we read, "Wax from cappings is the very best that can be had." Presumably he means the best which is on the market in large quantities. Wax from select bits of virgin comb would naturally be expected to be much better. But when you come to melt it up it won't look white like the comb does—one wonders why—and your scheme of getting rich by selling half-ounce cakes for ladies' work-baskets is likely to come to grief, just because the "monopolist's" bleached wax will look so much better than yours. Five cents a cake is \$1.60 per pound for your wax—in the money is "sour" like the grapes.

BIG BOTTOM-BOARDS—CHEAP CRUDE OIL.

Bottom-boards 25 feet square, all in one piece—why, they won't do at all, Mr. Jameson. Too big for the bee we now have, and too small for the one we read of a few weeks ago. But California crude oil at \$1.50 per barrel ought to be cheap enough paint, if it can be made to dry. Page 212.

SMITH'S SECOND SWARMS.

Those second swarms of S. B. Smith, 21 days after the primes, were mathematically but not bee-ologically "seconds." They were prime swarms of a new series, and somewhat interesting on account of the very brief time they got around in. Presumably the first prime came out with a virgin queen, another queen emerging and taking possession of the old hive the same day. If she got to laying in six days that would leave her 15 days in which to fill the brood-combs with brood, and swarm. Page 213.

AUTOMOBILES AND CANYON ROADS.

The California folks have discovered that the automobile is an "animile" that will not snort, kick, nor run away, not even from an idle California apiary in which the bees have a good dash of Cyprian blood. But I sadly fear the automobile trust will see to it that we don't get that \$300 vehicle right away. And, let me see, are the boulders of the canyon roads just the things to run automobiles over? Page 214.

NATURAL SWARMING, AND NON-SWARMING.

On the natural-swarming matter I can both yelp with the hound and hop with the rabbit—I can be fascinated with Mr. Doolittle, and be disgusted with Dr. Miller to the cows—

broken-into-the-garden point. All a matter of "locality" in the almanac. But as years wear on I find the Dr. Millerish aspect of the case arrives earlier in the swarming season than it used to do. Don't anybody who finds a *satifactory* non-swarming system hide it in the earth to save interrupting my fascinations. I'll intermit often enough to get all the fascination I really need, if somebody'll only give me such a system. Page 217.

PLAN OF FEEDING A POLLEN SUBSTITUTE.

Dr. Miller's style of making his bees dig corn-oats pollen from a reversible side-hill is commendable. A similar reversible side-hill can be operated on a big tray of cappings. Page 214.

WATER-CURE REMEDY FOR STINGS.

The success of the wet-sheet pack narrated on page 218, adds one more reason for thinking that the water-cure remedy for stings may ultimately come to be regarded as the standard remedy both for man and beast.

LONG-RANGE SMELTER SMOKE AND BEES.

What E. S. Lovesy says on page 223 about the disastrous effects of smelter smoke seems almost too much for belief; and yet the writer is too reliable a person for us to get away readily thru the gap of incredulity. To kill bees ten miles off is better execution than modern artillery can be depended on for.

MR. HARTER, HIS APIARY AND EXPERIENCES.

Mr. Harter, your apiary, page 225, looks like many other apiaries; but its position with nothing visible between it and boundless infinity, as we look to the horizon, appeals to the imagination somewhat. You didn't say you *always* walk around in shirt sleeves Jan. 19th out there. That nice Italian queen roasted in the sun was rather a sad payment of experience tuition. Sometimes the sunshine is such that it would have been delightful to the chilly queen and her subjects; but sometimes, as you found, it is deadly. This difference seems to be caused by the difference of transparency and amount of vapor in the air. Doubtful if any of us could live an hour tied to a smooth wall in direct sunshine, if the air was *entirely* transparent and free from vapor. It is one of the niceties of manipulation in the apiary to know just when it won't do to leave a queen-cell or a frame of brood where a murderous sun can hit it, even for a little while—and likewise when it would be foolishness to make any particular fuss about the sunshine. If you have a solar wax-extractor which you are trying to run, that will tell you.

MR. AIKIN'S POINTS POINTED OUT.

R. C. Aikin touches a good point (page 226) where he says that 50 pounds of sections stored by one colony will be a better lot, and nicer in finish, than 50 pounds stored by two colonies. But, Mr. A., you're still a little "off" on the swarming question if you think dividing colonies will always prevent swarming. Sometimes increases the total number of swarms.

THAT QUEEN-REARING FIGHT.

In the queen-rearing fight (page 226) I don't assuredly know how matters are, but I guess that *sometimes* Mr. Doolittle's queen, reared by a quart of well impounded bees, would be a tolerably fair one. I somewhat more than guess that the queenless half of a divided colony rears a fairly good queen sometimes. They say "blood will tell;" and even in case a very short-lived queen is reared, if superseding is then allowed to take place naturally (and soon, as it naturally would), is not the ultimate result a queen nearly or quite as good as any? But of course what the queen-breeders should go for is a method, not too bothersome, that will bring a good queen every time as nearly as may be.

WHAT SHALL BE DONE WITH QUEEN-BREEDERS?

Those are strong words of Frank Coverdale, on page 228, that nearly every one of 50 purchast queens fell short of common stock on the honey-gathering point—said queens not being all from one breeder, but from several. Shall we "edicate" our breeders, or stop buying queens, or what?

RENDERING OLD COMB INTO WAX.

Sad to hear that none of the high and mighty methods of rendering old comb into beeswax satisfy Mr. Doolittle. He just puts the old comb into the solar, rubs it up with a trowel once when nice and hot, and takes the consequences. Probably right for small quantities. If the quantity is large, I'm suspicious. If vinegar will do even almost as

well as sulphuric acid in cleansing processes, that is quite important. My idea is that bees hate sulphuric acid, and rather like vinegar. Page 228.

DR. MILLER'S "LITTLE HATCHET"—BASSWOOD GROWING.

And it's a hatchet instead of a knife that the good Doctor scrapes a hive with when he wants to get the propolis out of it! Never should have thought of it.

My idea of basswood is that it grows better self shaded, or even shaded by other trees, than it does in the open. So I think Dr. Miller's answer (page 231), to thin the young basswoods to 30 feet apart, rather rank. The clumps of five I mostly wouldn't thin at all at present, and the clumps of 15 only to 10 feet or less.

BEES WORRYING IN SHIPMENT.

That bees will worry themselves to death on a long journey unless they have either a queen or some unsealed brood to maintain the home feeling, is a point of bee-nature and practical apiculture that some of us might forget if not reminded of it. Presumably, Editor Pender is right about it. Page 234.

Ripe or Unripe Honey for Extracting.—R. C. Aikin takes the ground in the Progressive Bee-Keeper that it is cheaper to extract honey after it is ripened and sealed. G. M. Doolittle combats this, but finally joins hands with Mr. Aikin that honey should never be extracted till well ripened in the hive, because of the all-important matter of flavor, no honey ripened out of the hive being equal in flavor to that ripened by the bees.

To Bleach Pollen-Stained Sections.—Some time ago it was said Byron Walker had a scheme to accomplish this, but he never seemed to have time to tell how it was done. Editor Root has finally learned that the plan is to put the sections in the sun in a window for 2 or 3 days. Sunlight has no effect on travel-stained and greasy sections, the only ones affected being those that appear pollen-stained or have a yellowish coating over the cappings.

Difference in Candying of Honey from Same Lot.—The question has been asked, "Why is it that two jars of honey may be drawn from the same tank of honey, one of them remaining liquid a long time and the other candying almost immediately?" S. T. Pettit says in Gleanings in Bee-Culture it is because in the tank the watery part of the honey rises to the top, the most dense being in the bottom. That drawn first from the tank will differ in density from that drawn last, hence the difference in granulation.

Early Swarms Not Desirable.—A. E. Hoshal says in the Canadian Bee Journal:

"No doubt some will be bragging next month in our bee-journals about their early swarms in May; we read such accounts almost every year. This does not necessarily mean that their colonies are any stronger than those of many other bee-keepers, who understand their business better, and whose bees consequently have not swarmed; they are simply advertising their failure to prevent them swarming, and proclaiming their ignorance."

The Grape-Vine Apiary was formerly recommended in A. I. Root's A B C of Bee-Culture, and Mr. Root practiced what he preached by planting a grape-vine for each hive. But it does not seem to be a thing that bears acquaintance, for Editor E. R. Root now says:

"The grape-vines, our people all voted as a nuisance. The young shoots with their tendrils will sprawl all over, catching in clothing and veils while one is working the hives. While vines afford fairly good shade they need a great deal of care, and then it is practically impossible to work with bee-tents, which we consider so necessary in queen-rearing, during the robbing season."

VOL. 40. MAY 17, 1900. NO. 20.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

The Michigan Adulterated-Honey Case.—Accompanying the report of Secretary Mason, on this page, sent to us for publication by General Manager Secor, was the following letter:

FOREST CITY, IOWA, May 3, 1900.

EDITOR AMERICAN BEE JOURNAL.—

Dear Sir:—I enclose copy of report of Dr. A. B. Mason, Secretary of the National Bee-Keepers' Association, who went to Jackson, Mich., at my request, to attend the trial of M. G. Hakes, a groceryman, who was arrested for selling adulterated honey. The report will explain itself, and you are at liberty to use it in the columns of your journal if you so desire.

As the National Bee-Keepers' Association has undertaken the work of aiding prosecutions against the sale of adulterated honey, it becomes my duty to lay before our members, many of whom are readers of your journal, the facts gleaned in the performance of that duty, no matter how unpleasant the facts are to me personally.

Yours truly, EUGENE SECOR,
General Manager.

As Secretary Mason's report speaks so well for itself, it is hardly necessary for us to add any comment on the particular case in question. All of our readers know how bitterly we are against every adulterator of honey, no matter whether he be the humblest member in our ranks, or the highest official. We say, the higher the standing and intelligence of the adulterator, the greater the offense.

We are glad that the National Bee-Keepers' Association

presents such a solid and united front against the arch enemy of the producer of honest honey—adulteration.

Dr. Mason's report reads as follows:

Report of the Jackson, Mich., Adulterated-Honey Case and Conviction.

STATION B., TOLEDO, OHIO, April 5, 1900.

EUGENE SECOR, *General Manager of the National Bee-Keepers' Association*—

DEAR SIR:—In complying with your request for a report of the proceedings in the case of M. G. Hakes, of Jackson, Mich., who was arrested and tried in the Circuit Court of Jackson County for the sale of adulterated honey, I have this to report:

On the 20th of January last I received a request from you to attend the trial of Mr. Hakes, as the representative of our Association, and do what I could to help in the prosecution of the case that was to be tried on the 22d. In compliance with your request I attended the trial.

I learned that, last fall, Mr. W. D. Soper, a bee-keeper living near Jackson, Mich., and who also deals in honey, discovered that what he thought was adulterated extracted honey was being placed upon the market at Jackson. He bought a sample of the honey, and sent it to the Michigan State Dairy and Food Commissioner. On Sept. 29, 1899, Mr. Carl Franke, a State Food Inspector, of Monroe, on his regular inspection tour at Jackson, called at Mr. Hakes' place of business and purchase of him two one-pint cans of what he was selling for honey, one of them being labeled and ready for the market, and the other was taken from the original package, a five-gallon can. Mr. Franke had explained to Mr. Hakes that it was his duty "to keep tab on all the foods that were exposed for sale, and also on honeys," and asked him to sell him a package of honey, which he did willingly. The cans were labeled, "M. G. Hakes, Pure Honey, Jackson, Mich."

At the trial of Mr. Hakes in the Circuit Court for the county, in Jackson, Mr. Franke stated, in substance, while on the witness stand, that when food samples were procured for inspection, certain records were made, and in this case the record of the inspector showed that in the sale of this adulterated honey, Martin G. Hakes acted as agent, and that the manufacturer was James Heddon, of Dowagiac, and the package was marked, "Pure Extracted Honey," and was purchase of Mr. Heddon about Aug. 21, 1899.

Another witness, the Food and Sanitary Inspector of Jackson, testified that the original package from which the sample of honey in question was taken had not been opened till Mr. Franke opened it, and that Mr. Hakes acted as agent "for Mr. Heddon, of Dowagiac."

Mr. Franke, on cross-examination, testified that other samples from Mr. Heddon's "place" than the one under consideration had been sent to the State Analyst, and all were adulterated to about the same extent as this, except one of comb honey.

Mr. R. E. Doolittle, State Chemist, of Lansing, Mich., testified to having examined the sample under consideration, and found it to be adulterated honey. The percent of adulteration I do not now remember, but it was large—I believe about 57 percent of glucose.

Mr. Doolittle, in reply to a question by the attorney for Mr. Hakes, said that he had always had the impression that Mr. Hakes was only the agent for Mr. Heddon, and that Mr. Heddon had done the mixing.

In reply to the question, "Was this honey represented to you as pure by Mr. Heddon?" Mr. Hakes testified that a few days before he was arrested (he was arrested Oct. 11, 1899), he was told that he was selling adulterated honey, and he said that he wrote Mr. Heddon a letter, telling him that one man (a stranger) had offered to bet him \$25 that the honey was not pure, and Mr. Hakes told him that he "would put up the money any minute; but before I would do it I sat down and wrote a letter to Mr. Heddon, and said to Mr. Heddon: 'I want to know now, Mr. Heddon, if I am selling pure honey, or if I am not.' He wrote me back, stating that 'if my honey goes from me to you, and from you directly to your customers, just as you get it from me, rely upon it, it is strictly pure; but,' said he, 'I would not bet.' That is the first thing that opened my eyes."

At the close of Mr. Hakes' testimony the court instructed the jury, and they returned a verdict of guilty, without leaving their seats.

I felt pretty well satisfied that Mr. Hakes supposed he was selling pure honey, and I believed that the members of our Association cared more for the conviction of those

guilty of selling adulterated honey, and stopping the practice, then to punish a party who seemed so innocent of fraud as Mr. Hakes seemed to be; and, being under that impression, I askt the court to impose the lightest penalty the law would allow, which the court did, fining him \$25, which I believe was paid by some of Mr. Hakes' friends.

As an officer of an organization that has for one of its objects the prevention of the adulteration of honey, I was very much interested in this case; and as the evidence seemed to indicate that Mr. Heddon was guilty of selling adulterated honey, and that he did the adulterating himself, I have taken some pains to learn if he really was engaged in such business; and the first thing to hand is Bulletin No. 50, of the Michigan Dairy and Food Department, and under the head "Honey," I find this:

"No A 298. Sample of honey (brand 'Pure Extracted Honey') taken from original package at Jackson. Sold (1899) by M. G. Hakes, Agent, Jackson. Producer, James Heddon, Dowagiac." Then follows a statement of the analysis of the sample, and following this are the words, "Glucose flavored with honey."

On the same page of the Bulletin on which the above appears are three other similar reports in which each sample examined was markt "Pure Extracted Honey. Producer, James Heddon, Dowagiac." and on each exhibit is markt, "Glucose flavored with honey."

On the next page of the Bulletin are two more reports, similar to the above, in which James Heddon appears as the "producer," and Mr. Hakes as "agent," and I believe it is claimed there was about the same amount of adulteration in each sample as in the one for the sale of which Mr. Hakes was convicted—about 57 percent.

In an article which appeared in the Farm Journal, of Philadelphia, for January, 1900, in an editorial under the heading, "Food Adulterations," the editor says: "Some important facts on this subject are found in the recently issued Bulletin No. 50 of the Dairy and Food Department of the State of Michigan. . . . Eight samples of honey variously markt as 'Pure Extracted,' 'York State,' etc., were found to be only glucose flavored with honey. Six of these samples claimed to be produced by a person having a name well known and honored among bee-keepers." The other two samples are markt, "Producer, Steele-Wedeles Co., Chicago, Ill."

On Feb. 8, 1900, Mr. Wm. A. Selser, chemist, of Philadelphia, makes this report: "This is to certify that I have analyzed the sample of honey sent, markt No. 1, bought of James Heddon by L. H. Warren, Jennings, Mo., and found the same to be 52 percent to 54 percent adulterations of glucose;" and on the same date Mr. Selser certifies that another sample sent him, "bought of James Heddon by L. H. Warren, Jennings, Mo.," was found to contain "58 percent to 60 percent of glucose."

Wishing to know what Mr. Warren had to say, I wrote him March 12, and in his reply dated March 17, 1900, he says: "I bought 70 60-pound cans of extracted honey from James Heddon, which I received as follows," and then gives the number of cans received at different times, 5 cans in September, 1899; 15 cans at each of two shipments in November, and 35 cans by two shipments in December.

Mr. Warren says: "It may seem strange to you that I bought so much, and will explain. The first lot of five cans which I got as a sort of sample was adulterated very little; but every lot got worse; a small sample of this lot which I have on hand now has granulated solid, but streak; another lot only looks cloudy. . . . The last lot does not granulate any more than any other glucose. . . . Analysis of this shows 58 percent to 60 percent glucose. . . . Only about 200 pounds of the last lot was turned back on me. . . . I had no suspicion of this honey being adulterated until I had disposed of nearly all of it. . . . After I found out that the honey was not pure I wrote to Heddon, asking for a written guarantee of its purity. . . . He wrote back, "I take pleasure in certifying that I shipt you pure extracted honey."

Mr. Warren is a member of the firm of Warren & Mange, dealers in staple and fancy groceries, flour, feed, and general merchandise.

In a letter written by Mr. Heddon on Feb. 15, 1900, he says that Hakes "never sold honey for me. He bought of me, paying cash in advance. . . . I shipt him pure honey, and I rather think that he sold it as I shipt it to him. Of course, I do not know; and, so far as my personal interest is concerned, I do not care. . . . I think I have had ample evidence that chemists can not tell adulterated from pure honey. . . . It appears they guess at it. . . . In view of Mr. Hakes' testimony, as reported from his customers, if the

honey I sent him was adulterated, it would probably be beneficial to both producers and consumers if all honey was adulterated in the same way."

Several years ago, perhaps 12 or 13, some well known bee-keepers felt satisfied that Mr. Heddon was engaged in adulterating honey and selling it to his customers, and since that time several have complained that the honey purchased of him as pure was adulterated before it reacht them, and have stated that the packages they received showed no signs of having been changed or tampered with in any way from the time they were shipt till received by them.

A little over six years ago there was an impression that Mr. Heddon was engaged in adulterating honey; and a chemical analysis of some honey, claimed to have been bought of him, showed that it was adulterated with at least 50 percent of glucose, as was shown in Gleanings in Bee-Culture at that time.

It is possible that this report is too long, and may contain matter that may not have any bearing on or connection with it; but I thought it might be well, in every possible way, to expose the adulterators, whoever they may be, and so put producers, dealers in, and consumers of, honey on their guard against adulterators; and if but a small portion of the statements and affidavits before me are true, one of our own number has gone astray, and, if so, should be exposed.

Very truly yours,

A. B. MASON,

Secretary of the National Bee-Keepers' Association.

The Weekly Budget

THE "FAKE WRITE-UP" CROWD.—At a meeting of the Chicago Trade Press Association, held April 26, 1900, the following report was presented, and the members of the Association, and all other class and trade papers (and other publications that can do so) were requested to publish it for the protection of their readers:

"At a recent meeting of the Chicago Trade Press Association, an organization whose membership comprises the most influential trade journals in the West, it was determined to take some action to protect manufacturing and mercantile firms from the depredation of the 'fake write-up men.'

"A number of alleged trade journals (several of them being printed in the Southern States) send out thousands of circular letters to merchants and manufacturers, enclosing proofs of ingeniously prepared write-ups. Each person to whom a letter is directed is led to believe that he has been selected because of the prominence of his firm. The men whom it is sought to victimize are informed that no charge will be made for the printing of this complimentary notice, but that sample copies will be sold at 15 cents per copy, or at 8 cents per copy in thousand lots. These journals have no legitimate standing in the community, and represent nothing except the desire of their managers to extort money from business men. The circular letters are so shrewdly worded, and the office of publication is usually so far removed from the persons to whom the letters are sent, that many firms have been victimized. Almost every department of industry is represented by one or more reputable journals, and manufacturers and business men generally are advised to communicate with publishers of whom they have some knowledge before being led into fake schemes.

"The several papers comprising the membership of the Chicago Trade Press Association have agreed to print this statement with a view of protecting their patrons and business men generally, from loss thru such deception."

Belgian Hare Breeding is the title of a pamphlet just publisht, containing 10 chapters on "Breeding the Belgian Hare." Price, 25 cents, postpaid. It covers the subjects of Breeding, Feeding, Houses and Hutches, Diseases, Methods of Serving for the Table, etc. It is a practical and helpful treatise for the amateur breeder. (See Prof. Cook's article on page 292.) For sale at the office of the American Bee Journal. For \$1.10 we will send the Bee Journal for a year and the 32-page pamphlet on "Belgian Hare Breeding."

BEE-BOOKS

SENT POSTPAID BY

George W. York & Co. 118 Mich. St. Chicago.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apizry, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopaedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book: 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers, \$1.00.

Bienen-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Bienenzucht und Honiggewinnung, nach der neuesten methode (German) by J. F. Eggers.—This book gives the latest and most approved methods of bee-keeping in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cts.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cts.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 20 cents.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about Poultry Business. 64 pages. Price, 20 cents.

BY RETURN MAIL.

GENERAL ITEMS

Bees Wintered Well.

The bees have wintered well, so far as I have been able to learn, in this section of the country. I lost but one colony out of 42. The heaviest loss that I have heard of near here was 5 percent. The colonies are very strong for this time of year, and will certainly be in great shape for the honey-flow when it comes. ED. HOLLEY.

Venango Co., Pa., April 28.

Perhaps the Queen's Mating.

I wish to tell of something I witness among my bees yesterday that I have never seen described, altho I have read a great deal of bee-literature. About 2 p.m. I was plowing near the apiary, and coming to the end next to the bees I noticed that they were making considerable noise, so I lookt that way to see if there was not a swarm in the air. There were some low bushes between me and the hive, but I saw rising above them a small cluster of bees about as large around as my hat. Every little while a point would shoot out and the mass would assume the shape of a half open fan, about 2 feet long and 10 or 12 inches wide at the widest part. It wavered about somewhat but the movement was generally upward, not by a regular ascent but with loops and bends; sometimes almost still, when it would assume the circular form, then the point or apex would dart upward again until it reached about 50 feet in length, when it suddenly vanished. The distance was too great for me to distinguish single bees in flight, but the cluster was so intense that its outlines were plainly visible. I immediately conjectured that it was a virgin queen taking her wedding-flight followed by a retinue of rival drones, and as soon as the nuptials were accomplished they disbanded, and were no longer visible to me. I immediately went to the hives known to contain virgin queens, hoping to see her return, but I was disappointed. J. S. SARGENT.

Lee Co., Fla., April 23.

Rendering Wax—Honey-Dew—Toads.

In regard to the article on rendering wax (page 251); I should say, in trying anything that does not have reason in sight, one should expect a failure. If those who have a little wax or bits of comb to save will nail together four boards 12 inches wide, making the ends and sides to suit the glass, tack strips on either side from one end to a little past the middle, the strip being 3 inches from the top at the end, and 9 inches to the top at the other end, put in a V-shape center, tack on a sheet of tin, nail on a bottom, and frame a glass for the top, they will have a solar wax-extractor costing not over 38 cents—the price of the tin and the glass. Block up one end, and be sure to have the V-center at least one or two inches from the end of the tin, lest the wax runs down the strip.

I note what A. J. McBride says about honey-dew (see page 253). Let me say

DITTMER'S FOUNDATION

Wholesale and Retail

This foundation is made by an absolutely non-dipping process, thereby producing a perfectly clear and pliable foundation that retains the odor and color of beeswax, and is free from dirt.

SHALL WE ADOPT

PLAIN SECTIONS AND FENCES?

Perhaps you are debating this question now. It is not too late yet to make a trial of these goods this season, and no doubt you would like to know what has been the experience of other bee-keepers who have tried them. We have on hand some

EVIDENCE.

If you wish we will gladly send you a copy. You will find much interesting reading, and it may be worth many dollars to you. See what bee-keepers all over the United States and Canada have to say. Ask for Bulletin A. Do not delay, but send your request at once.

Do you want an EXTRACTOR this season? Investigate our

Cowan Reversible Ball-Bearing Extractors

We have a little pamphlet giving some information about these. Send for it if interested.

We are pioneers in the manufacture of modern fixtures for Plain Sections and Fences (as well as all other Supplies.) If you want them right, send to us or our Branch Offices and Agencies.

The A. I. Root Co., MEDINA, OHIO.

Please mention this paper when you write. Watch for our ad. next issue.

that honey-dew can cover trees without any insects, altho they perhaps do at least 90 percent of the work. A hot day with a dry spell will, under certain circumstances, crack the leaves, when the juice will issue and the hot sun will boil it down to a sweet taste. I have seen oak-trees drip from this cause, when later in the day it is boiled thick by the sun. Honey-dew is better than saw-palmetto honey.

I believe toads are worse enemies than moths, birds, or roaches. The toads here, if left so that they can get to the entrance, will "pop" more bees than would die in the same length of time. The pop noise they make draws the bees out, and Mr. Toad takes them one after the other. Where a hive is not over 4 inches from the ground, if a 1/4-inch-mesh wire 4 inches high, with ends bent so they clamp on the sides of the hive is used, he can see but can not get the bees, as this wire is from 2 to 2 1/2 inches out. If the alighting-board is 4 inches, place the protector half way and they can be left on all of the time. If the board is only 2 inches it is better to remove the wire during the day. JAY S. BROWN.

Bradford Co., Fla.

Fine Spring for Bees.

We have had a fine spring for bees. Some of my colonies increase in weight over 15 pounds in 3 days, from white willow—April 29, 30 and May 1—but a frost on the night of May 1 stopt it.

Filmore Co., Minn., May 3.

Bees Wintered Better Than White Clover.

I find the bees all over Wisconsin have wintered well—better than the white clover in the lower tier of counties.

N. E. FRANCE.

Grant Co., Wis., May 4.

Experience with Bees in California.

My first experience as a bee-keeper dates back to the fall of 1895 when I began by taking bees out of trees and rocks. In the spring of 1896 I bought 16 colonies for \$40 on 60 days' time, at one percent per month. They were in old hives of the J. S. Harbison pattern, and badly split at that. I lost 2 colonies in moving them, and did not get a single pound of honey or a swarm that season.

The spring of 1897 was more favorable, and I left my bees for my father and brother to take care of while I went to work for a neighbor who had 3 apiaries. I worked for \$20 per month and board, lodging, and experience, the latter being of more value than all the rest. Any man who has not had experience with bees will do well to work with an experienced bee-keeper one season before going into the business.

The season of 1897 we secured 11,040 pounds of extracted honey from 86 colonies, spring count; 1898 was a dry season and we had to move the bees to save them. I moved about 300 colonies nearly 75 miles on a wagon and lost only 3 colonies in so doing. We secured about 1,000 pounds of honey that season from 115 colonies. 1899 was also a dry season. From 116 colonies

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.10, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.00.

GEORGE W. YORK & CO., 118 Mich. St., Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

we secured about 1,560 pounds of extracted honey, and moved our bees about 60 miles on a wagon without losing any. This year promises to be a poorer year than any since I have been in the bee-business.

In 1898 I bought 7 colonies of bees, and when looking them over in June I found that one had lots of dead brood which was brown and ropy and smelled bad. I burned it, fearing it might be foul brood. At that time I did not read a bee-paper and did not know anything about foul brood. This season I have found one case of the same disease and have given it the same treatment. In both cases the extracting-super was full of capt honey, but as my motto is "Practice what you preach," that was burned also. Was this foul brood or black brood? I think my treatment a sure cure in either case.

In regard to painting apiarian tools (see page 211)—no insinuation meant—it looks to me as tho the man who has not time enough to keep the grass cut out of his bee-yard has not time enough to attend to bees at all, especially when the season is as dry as ours.

SUBSCRIBER.
San Diego Co., Calif., April 14.

Bees Strong and Will Soon Swarm.

Our rose-bushes are full of buds, and will soon be in bloom. Our fruit-bloom is about over, and the bees will have to take to the willows and wild flowers. Bees are very strong, and will be swarming soon. I wish I could keep them from swarming, but these "dagoes" that I have will swarm, and I guess I will have to let them.

SAMPSON STOUT.
Cowley Co., Kans., April 30.

No Spring Dwindling.

Bees in this country wintered generally very well, and are in a great deal better shape than last year. There has been no spring dwindling.

GUSTAVE GROSS.
Vernon Co., Wis., May 3.

Easy Method of Transferring.

We have had a very mild winter in this part of our State and the bees seem to be all right. We have had but few losses, most colonies are strong, and bee-keepers are looking for a good year.

As I have noticed nothing in the Bee Journal that approacht my method of transferring I will give it, altho it may be an old one. I have always disliked the work, but when I had an opportunity to buy bees at \$1 or \$2 per colony I would buy them and transfer.

Three years ago I purchast quite a number of colonies, and when the time came I began the work of putting them into new hives, but after working about one day I became tired of the job and tried to devise some way of doing the work easier. After thinking the matter over I came to the conclusion that it was natural for bees to store honey above the brood-nest, and I would try an experiment. I therefore took a hive with frames and starters and put it under the one I wisht to transfer; in short, I tiered up, and left the bees to their own sweet will, and as a result at the end of the honey-flow I found my bees transferred and

the upper story or old hive with the crooked combs filled with honey. I then put on a Porter bee-escape and in about two days had the bees all out and the crooked combs in the solar extractor. Since then I have followed this plan, but I would recommend using full sheets of foundation instead of starters as the bees will make better—and all-worker—comb.

Now transferring has no terrors for me. Last season I tiered up some with supers and sections, finding that they were being crowded for room, and they filled them also.

I had several hives last season with the bottoms nailed on. These I simply turned bottom up, closing up the entrance and putting bee-space sticks crosswise on the top of the frames in the bottom hive, to keep the frames from being fastened together.

I have tried this plan of transferring for 3 years or more, and it works all right.

W. W. WHIPPLE.
Arapahoe Co., Colo.

Cool and Dry Weather.

We are having cool, dry weather, but brood seems to be going ahead as usual at this season. I put my bees out of the cellar April 8. They were in winter quarters 4 days less than 5 months. Brood is now hatching.

Clare Co., Mich., May 7.

Bees in a Telephone-Box.

Several months ago a swarm of bees settled in a telephone switch-box on Vanderbilt Avenue, just below Park Place, Brooklyn. About 8 o'clock one morning in December, a couple of linemen came along and looked up the post on which the "bee-hive" was perched. The neighbors immediately suspected what was the matter, for all took an interest in the "hive," and had pointed it out to their friends as one of the things that help to make Brooklyn unique. Many rushed out to watch the proceedings and offer advice.

"You go up and open the switch-box," said one of the linemen.

"Not on your spurs," said the other.

"Why, it is rank folly to talk of going up and opening that box when it is full of bees," said a man in a smoking-jacket. "The way to do is to take the box down very gently at night and then place it over a hole in the ground that has a sulphur candle in it and cover the whole thing with a horse-blanket. The sulphur smoke will kill all the bees and you can then take out the honey without any trouble."

"Great head," said one of the linemen. "Now if you tell me how to take down a switch-box full of live wires and bees in the dark of the moon, I'll go snacks with you on the honey."

"Aw, stop guessing," said the other lineman, who had something of an air of authority. "Put on your rubber gloves and go up and hoist them bees down."

The man did as he was ordered and the crowd scattered back. He shinned up the post and opened the switchbox. There was no excitement.

"Say, the bees are all stupid with the cold," said he. "Um-m-m, but there is a lot of honey in here."

"Pick it out carefully," called out a man, "and I'll buy it from you. I have

The Bee-Keeper's Guide

Or, Manual of the Apiary,

—BY—
PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPERS' GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal with \$2.00, and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,
118 Michigan Street, CHICAGO, ILL.

HONEY MONEY

results from the best care of the bees. That results from the use of the best Apiary appliances.

THE DOVE-TAILED HIVE shown here is one of special merit. Equipped with Super Brood chamber, section holder, scalloped wood separator and flat cover. We make and carry in stock a full line of bee supplies. Can supply every want. Illustrated catalogue FREE.

INTERSTATE MANFG. CO., Box 10, HUDSON, WIS.
Please mention Bee Journal when writing.

Four Celluloid Queen=Buttons Free AS A PREMIUM.

For sending us ONE NEW SUBSCRIBER to the Bee Journal for the balance of this year, with 50 cents, we will mail you FOUR of these pretty buttons for wearing on the coat-lapel. (You can wear one and give the others to the children.) The queen has a golden tinge. This offer is made only to our present regular subscribers.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate, it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

Prices of Buttons alone, postpaid: One button, 8 cts.; 2 buttons, 6 cts. each; 5 or more, 5 cts. each. (Stamps taken.) Address,

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO.

\$5.00 per month will pay for medical treatment for any reader of the American Bee Journal. This offer is good for 3 months ONLY— from May 1 to Aug. 1. Dr. Peiro makes this special offer to test the virtue of small price for best medical services. Reply AT ONCE.

DR. PEIRO,
34 Central Music Hall, CHICAGO.

Yellow Sweet Clover Seed

WE HAVE IT AT LAST!

We have finally succeeded in getting a SMALL quantity of the seed of the YELLOW variety of sweet clover. This kind blooms from two to four weeks earlier than the common or white variety of sweet clover. It also grows much shorter, only about two feet in height. It is as much visited by the bees as the white, and usually comes into bloom ahead of white clover and basswood. We offer the seed as a premium

A QUARTER POUND FOR SENDING ONE NEW SUBSCRIPTION.

So long as it lasts, we will mail a quarter pound of the seed to a regular paid-up subscriber who sends us ONE NEW subscriber for the American Bee Journal one year, with \$1.00; or 1/4 pound by mail for 30 cents.

We have been trying for years to secure this seed, and finally succeeded in getting it. It is new seed, gathered last season by an old personal friend of ours, so we know it is all right. But we have only a small supply. When nearly out we will mention it.

an idea that electric honey would be a new thing on the market, and would make a hit."

Just then something happened. The lineman had wrenched loose the honey, and the bees, which had simply retired to the warmest corner of the box behind the comb, buzzed out into the face of the marauder. For the next few seconds no one within ear-shot would have recognized the fact that Brooklyn is the City of Churches. A bee with a tail like a live wire and the activity of a Tesla oscillator, located itself behind the enemy's ear and sent about 2,000 volts thru his bump of combativeness. With a yell he started on a disorderly retreat and reached the ground in two slips and a jump. But the cold air soon stupefied the bees and in a few minutes they were all lying on the ground as if dead. In an almost equally short time the face of the lineman looked like a South African landscape. There was a kopje on his right cheek, another on his left eye, and others scattered around his face in wild disorder.

"You should have your face insulated before trying to deal with electric bees," said a professional joke-writer in the crowd, and then he stooped to make a note on his cuff.

Policeman No. 2805 appeared on the scene.

"What's the matter here?" he inquired in his professional tone.

"Just a little eviction," said the joker.

"What's this? Bees? Who's been havin' bees inside the city limits? There is an ordinance against it, I think," observed the cop.

The case was explained to him and

A HANDY TOOL-HOLDER!

Sent by Express, for \$1.50; or with the Bee Journal one year—both for \$2.00.

Every Manufacturer, Miller, Carpenter, Cabinet Maker, Machinist, Wheelwright and Quarryman, Farmer, or any one using a grindstone, should have one of these Tool-Holders. One boy can do the work of two persons, and grind much faster, easier and with perfect accuracy. Will hold any kind of tool, from the smallest chisel to a draw shave or ax. Extra attachment for sharpening scythe blades included in the above price. The work is done without wetting the hands or soiling the clothes, as the water flows from the operator. It can be attached to any size stone for hand or steam power, is always ready for use, nothing to get out of order, and is absolutely worth 100 times its cost.

No farm is well-equipped unless it has a Tool-Holder. Pays for itself in a short time.

How to Use the Holder.

DIRECTIONS.—The Tool is fastened securely in the Holder by a set-screw and can be ground to any desired level by inserting the arm of the Holder into a higher or lower notch of the standard. While turning the crank with the right hand, the left rests on an steady the Holder; the Tool is moved to the right or left across the stone, or examined while grinding, as readily and in the same way as if held in the hands.

For grinding Round-Edge Tools, the holes in the standard are used instead of the notches.

Address, **GEORGE W. YORK & CO.**

CHICAGO, ILL.

he became good-natured at once. In the meantime different persons pickt up pieces of the honey and after brushing off the dust began to eat it. Those who tried it assert that it was fine.

[The above account was taken from the Brooklyn Sun, and sent to us by Mr. Geo. P. Prankard, of Bergen Co., N. J.—EDITOR.]

Wintered Better Than Ever.

My 98 colonies came out of winter quarters in better condition than ever before—very strong and with a good many young bees. I put them out April 6, and on April 7 they were carrying in pollen. One colony was queenless and one rather weak so I united them. This leaves me 97. I was 79 years old on April 7. Don't you think it is about time for me to quit the bee-business? **JOHN TURNBULL.**

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, April 19.—Market is well cleared of white comb honey; a little choice has sold recently at 16c, but dark and mixt goods are slow of sale. Extracted, white, 8 1/2@9c; amber, 7@8c; dark, 6@7c, according to quality and package. Beeswax in good demand at 28c.

R. A. BURNETT & CO.

CINCINNATI, March 3.—There is some demand for extracted honey from manufacturers at 7@7 1/2c for amber and Southern; clover, 8@8 1/2c. Comb honey is selling firm at 14@16 1/2c in a small way. Beeswax, 25@27c.

C. H. W. WEBER,

Successor to Chas. F. Muth & Son and A. Muth.

BOSTON, March 9.—Our honey market is showing some signs of lower prices, altho the stock on hand is not large. At the same time prices are so much higher than previous years that the trade have taken it very slowly and the results are that the holders are willing to range prices quite a little in order to move stock on hand. Prices range: Fancy white, 17@18c; No. 1, 15@16c; amber, 10@12c; buckwheat almost unsalable. Extracted, best white California, 8 1/2c.

BLAKE, SCOTT & LEE.

KANSAS CITY, May 9.—We quote: No. 1 white comb, 14@15c; No. 1 amber, 13@14c; No. 2 white and amber, 13@13 1/2c. Extracted, white, 7 1/2@8c; amber, 7c. Beeswax, 22@25c.

The receipts and stock of honey on hand are light; demand fair.

C. C. CLEMONS & CO.

DETROIT, Apr. 23.—Fancy white comb, 15@16c; No. 1, white, 14@15c; amber and dark, 10@12c. Demand and supply both limited. Extracted, white, 7@7 1/2c; amber and dark, 5@6c. Beeswax, 26@27c.

M. H. HUNT & SON.

BUFFALO, April 20.—For strictly fancy white one-pound comb honey we are getting 16@17c. Any grade sells high—10@15c, as to grade.

BATTERSON & CO.

NEW YORK, April 9.—Market is practically bare of comb honey of all description. Little lots arrive here and there and sell readily at from 10@11c for buckwheat and 12@15c for white, according to quality and style of package. The market is well supplied with extracted, which we think, however, will be moved before the new crop arrives. Beeswax is in good demand at from 27c to 29c per pound.

HILDRETH & SEGELKEN.

SAN FRANCISCO, Apr. 25.—White comb, 11 1/2@12 1/2c; amber, 8@10c. Extracted, white, 7 1/2@8c. Light amber, 7@7 1/2c; amber, 5@5 1/2c; Beeswax, 26@27c.

Small quantities of new crop have been received, but not enough has been yet done in the same to clearly define values. Current quotations would not likely be sustained under anything like free offerings. The yield will undoubtedly prove light, and the market shows a generally firm tone.

OMAHA, Mar. 13.—Demand shows some improvement in January, having been much more active, but as anticipated there is no advance in prices. Market remains steady at 14@14 1/2c for fancy white comb and 8 1/2c for white extracted. The latter is pretty well cleaned up along the Missouri River, and it looks as if there would be some shortage before another crop comes in. From present appearances there is about enough comb honey to go around at the present prices, hence we look for no particular change in values.

DR. MILLER'S Honey Queens

One Untested Queen Free as a Premium for sending ONE New Subscriber to the American Bee Journal for one year.

We have been fortunate in making an arrangement with DR. C. C. MILLER—the well-known honey-specialist—to rear queens **EXCLUSIVELY FOR US DURING THE**

SEASON OF 1900. These Queens will be mailed in rotation, beginning about June 1, so "first come first served." We are ready to book orders now.

The Queens Dr. Miller will send out on our orders will be precisely the same as those he rears for his own use, so of course they will be from his best stock. His best colony in 1899 had a queen reared in 1898; May 5, 1899, it had brood in 4 frames, and he gave it at that time a frame of brood without bees. It had no other help, but May 25 a frame of brood with adhering bees was taken from it, and the same thing was repeated June 3, leaving it at that time 5 frames of brood. It stored 178 sections of honey, weighing 159 pounds (and that after July 20, in a poor season), being 2½ times the average yield of all his colonies. A point of importance is the fact this colony did not swarm, and an inspection every week or 10 days showed that at no time during the entire season was there even so much as an egg in a queen-cell. Dr. Miller expects to rear queens from this one during the coming summer.

The demand nowadays is for **BEEES THAT GET THE HONEY** when there is any to get, and Dr. Miller has such bees. You will want to have a queen from his best, we are sure, even if she is not pure Italian.

Do not send any orders to Dr. Miller, as all orders **MUST** come thru us, according to our agreement.

Remember, send us \$1.00 for **ONE NEW SUBSCRIBER** to the American Bee Journal for one year, and **YOU** will get **ONE OF DR. MILLER'S UNTESTED HONEY-QUEENS FREE AS A PREMIUM.** This offer is made *only* to our present regular subscribers. Orders for queens to be filled in rotation, beginning about June 1st.

Address all orders to **GEORGE W. YORK & CO.,** 118 Michigan Street, CHICAGO, ILL.

CONTRIBUTED ARTICLES

Something About the Bellows Bee-Smoker.

BY T. F. BINGHAM.

IN his article on page 50, "Old Grimes" claims for M. Quinby what I think there is a lack of evidence that M. Quinby ever claimed himself, viz.: that he was the inventor of the bellows bee-smoker. In the position he occupied it would have been impossible to have been ignorant of the position and details of the old German bellows bee-smoker in common use in the old country, and brought to this land by bee-keepers who came here bringing their knowledge and implements.

After bee-keepers learned that an improvement in bee-smokers had been made, they would come to me in their enthusiasm to tell me of their old bellows bee-smoker, and compare it with the new wonder that would burn anything and not go out. Of course, I express a wish to see the smokers, as I was very much interested in them. I learned of several, and one bee-keeper offered to give me his old one as a curiosity, and I gladly accepted it. I kept it, with one of M. Quinby's earliest makes, as curios till my smoker factory was destroyed by fire, and with it my precious old smokers. It was a finely made affair, with a nicely fitted hinged door, and a slide vent to be used when the smoker was laid down, showing plainly that it was made in large

numbers for sale, and not as a single experiment. I enclose a rough sketch of it. It will be observed that all the change necessary to make it a first Quinby would be to bend the exhaust in such a manner that the fire-box would stand upright, and the bellows stand on end instead of lying down. Of course, it had the same tendency to go out as the Quinby invention Mr. Grimes refers to—neither of them would keep sound wood burning—unless the bellows was worked.

I think M. Quinby never claimed that he invented the bellows bee-smoker, but that he did invent the Quinby bee-smoker. And I have never been accused of claiming the invention of the bellows bee-smoker, that I know of. But I do claim to have invented the first bellows bee-smoker that would burn anything combustible without working the bellows, and not go out.

Clare Co., Mich.

Pollination the Best Work of the Honey-Bees.

BY PROF. A. J. COOK.

THE castor-oil plant is a very beautiful and a most interesting plant. The rich color, the vigorous habit, the finely cut leaves, and, perhaps most of all, the curious bloom can but attract and greatly interest any who give it careful attention. It is one of those plants that cry out in its very structure in loudest praise of the mission and work of the honey-bee. I now have very interesting classes of 38 who are studying these things, and all have studied this plant with enthusiastic interest. Bee-keepers may well feel very kindly towards this plant, for it is always praising the bees. The flowers are in a crowded raceme, almost a spike, and with the similarly colored leaves of rich, brownish red are most pleasing to look upon.

The most interesting thing of these flowers is the fact that they are monœcious. By this we mean that the pistillate flowers—those that have only pistils and bear the seeds—are separate from the staminate ones, or those that bear only stamens, and of course can never bear seeds. These flowers are not only on the same plant, as is the case with all monœcious plants, but in this case they are in the same flower cluster. In many plants like the willow the staminate and pistillate flowers are on different plants. These are called diœcious.

In the plant in question, the pistillate flowers are at the tip of the flower cluster, and open before the other flowers do. Thus these flowers are pollinated before the basal or staminate flowers open. Thus the pollen for which they hunger must come from other flowers. Before the closely neighboring and as closely related staminate flowers are open at all, they are well along in the race of development. The staminate flowers do, however, aid the others indirectly, as they are rich in color, and are a signal to the bees that here is rich nectar for them, and that they can not afford to pass it by. Later, after the seeds have developed quite considerably the staminate flowers open, and offer to the bees their rich stores of pollen, which is thus borne off to other pistillate flowers to fructify other ovules, or embryo seeds, that they may push on towards fully developed seeds.

Two important truths are gathered from this interesting plan of the castor-oil plant. First, the waiting pistillate flowers would starve for the needed pollen and come to naught, were it not for the kindly ministries of nectar and pollen loving insects, chief and by far the most important of which are the honey-bees. The ovules, to develop, must have pollen, and that must come from other flowers, perhaps from a long distance away. The other point is equally patent: "Nature abhors close fertilization." She enforces cross-pollination in case of the castor-oil plant. She does the same in more emphatic words in case of all diœcious plants, like the willow, oak, and walnut. Here the pollen must come from other, very likely far distant, plants, and the aid of bees is still more imperative.

In many hermaphrodite plants, where the stamens and the pistils are side by side in very close proximity in the same flower, as in case of many pears, apples, and other fruit, the same law is announced in the fact that these fruits are sterile to their own pollen. We find the same

truth proclaimed in the higher, animal realm. Closely inbred cattle are more ready to contract disease, like consumption, than those not consanguineous. The laws in some States against intermarriage of near relatives is not the creature of a nervous imagination. Ask Nature, and she will say, "Don't."

Close investigation, carried on by myself and many others, has shown that this necessity of cross-pollination is very general. With most of our valuable plants we can not hope for full fruitage unless there is opportunity for this cross-pollination. In many cases the cross-pollination must be provided for or there will be no crop at all. I have a case in point: A sister living on the Sacramento River has a large and very productive orchard of pears, apricots, cherries and prunes. I visited her in 1891, and she asked me regarding the reason that her orchard was producing less than formerly. The trees *bloomed heavily*, but the fruit *did not set*. I asked if there were not more bees formerly than at that time. She bethought herself and answered yes. I said when good, vigorous trees blossom heavily and do not fruit well, always suspect lack of pollination. She at once engaged an apiarist to move his bees to the place, and at once received market benefits. She has kept the apiary there ever since. She feels that she can afford to pay for the presence of the bees, and she is right.

I visited her the other day, and upon examination it was found that trees in near proximity to trees of other varieties were setting far more freely than those farther off, and the decrease was very marked. This was a very graphic object lesson. I have no doubt but the annual loss from the absence of bees and the planting of varieties in solid blocks, is tremendous. We have our orchards in great proportion, often hundreds of acres in one place. Indigenous or native insects can not do the large work of pollination, and we must bring the bees to the rescue. No doubt "Good cultivation" may well be the motto of the orchardist, but close along side should be the second one, "Mixt varieties and the honey-bee."

We have had two fine rains within a week, the best of the season. They are late for the honey product, but will do immense good, and may help the bee-keeper. The alfalfa fields are increasing very rapidly, and will in the future become more important even than in the past, as a source of excellent honey. Los Angeles Co., Calif., May 11.

NO. 8.—COMB HONEY PRODUCTION.

Method of Taking off Supers—When and How.

BY R. C. AIKIN.

THERE seems to be much difference of opinion as to how to get supers off and free of bees. This is like many other things in the business, just what and how to do depends upon circumstances.

In the midst of the flow, when bees are busy in the fields, they will often allow honey to stand exposed all day and not rob. At such time the removal of supers of sections is a very easy matter, about as easy as anything we find to do in the apiary. I begin at one end or corner of the apiary and work regularly over it, lifting the cover and looking at each to see if anything needs to be done to supers. I have a pile of empty supers ready carried into the apiary, and wherever one is needed I give it as directed in the preceding article, and where I find a super ready to take off I remove it in this way:

If I know before opening the super that it is ready to take off, if it be on top I begin to pry up the cover and shoot smoke under it as quickly as there is a crack big enough. I start the cover gently, not necessarily slowly, but so the bees are not angered, pumping the smoke hard enough to spread it all over the section tops (I use a board cover), frightening the bees, but not making them angry. I do not smoke in the entrance at all, not using smoke about the entrance except when they are touchy, when I give enough over the alighting-board to frighten back the guards.

Having started the smoke over the sections in this way, the bees start running down, and without delay I keep the smoke right up after them, and do not let them have time to stop running. Do not smoke clear down thru the super at once, but keep the smoke right *after* them so they will *keep on the run*. It is hard to describe so you can do it the first time, but after reading this description you can very soon get the knack if you try carefully. As soon as the *bulk* of the bees have past below, very quickly remove the

super, and turn it up endwise on the left arm till it is perpendicular, or a little more, so it will rest back against the arm, and, with a proper sweeping-instrument, *at once* sweep the bees off the bottom, and then stand the super on *end* on a hive or the ground.

The best broom I have ever found is a wisp of grass about as long and big as my arm, and wrapt with stout cord in two or five places. Make it out of slough-grass, or some long-bladed kind, and not too stemmy or stiff. Keep the brush in the yard, tighten the cords occasionally, and when it gets dry and brash dip it in water. Such will sweep almost the entire bottom of a super at one lick.

Notice that these operations must be done promptly. From the time you start the cover till the super is off and the bees brushed from the bottom, and the super is standing on end out of your hands, is much quicker than you can read this description, the only stop necessary is just a few seconds, or a minute to allow the bees time to run down. If you get to dallying, and let the bees turn back to recover the combs, you will find it harder to drive them down the second time. For this reason it is important to determine quickly whether the super is ready to come off, and proceed at once to get it off.

If it is necessary for me to look to see if it is ready, I very frequently look at the bottom of it *first*, by prying it up at one end, the other still resting on the hive, and as the bees retreat upward I see very quickly if the sections are finished at the bottoms, particularly the outer corners, and, if ready, at once let it down in place again, and send the bees down from the top before they have recovered from their first fright.

In this way I go thru the yard taking off supers and standing them on end, usually on top of the hive from which taken; putting on empties where needed; shifting a bottom super to the top, or *vice versa*; and, whatever is needed in the arrangement of supers, doing the whole job regularly. Thus the yard is put in shape to wait several days or a week for another similar overhauling.

After I get thru with the removing, putting on and arranging supers, I carry in those scattered about the yard. If the honey-house is right by I do not take much pains to get any bees out that still remain, but take the supers to the honey-room and stand them on end again before a window screened, but with an escape of some kind. The remaining bees will very soon pass out at the window, and the supers can be piled regularly later.

If many bees are yet in the supers when I get ready to carry them in, and I want them all out, I smoke thru the super, holding the smoker in the left hand usually, the brush in my right, and as fast as they come out I sweep them off. If this process be gone thru with when there is honey being gathered, it is a very quick and successful method. It will not do to leave supers about the yard when bees would rob. Neither should the work be done in the early morning unless there be unsealed honey in plenty for the bees to load their sacs, better wait a little till enough bees come from the field so they are already loaded.

But the time when the great danger comes is when no nectar is being gathered, and more so if the honey is nearly all sealed, for then the bees will bite open the cappings to get their sacs full, and so mar the sections. At such times it is possible to send the bees down *on the run* before they can think of cutting open sealed cells, and care must be exercised to drive them nearly all out before stopping. Also, when a super is off the hive go at once with it to the honey-room to keep it from robbers. A careful taking off of honey in this way will prove most expeditious, and will get it off in good shape and free from any serious puncturing of cappings by the bees.

If the honey-house is distant, a small room or tent by the apiary will be very convenient to keep supers in over night. Take off in the middle of the day, and very few bees will be left in over night; if any should remain they hunt home early in the morning. I practice this almost exclusively, and can take off a ton of honey in a very few hours at most, when not doing other work with this. My escapes are on the windows. I have some in the shop, but never use them. This plan leaves the escape out of sight when used in a board to place under the super.

It may look to many as if it was a lot of work to do so much watching and manipulating of supers—it does take some time, but it is time *well spent*. Have every hive equipt with a honey-board above the brood-combs, so there are no burr-combs built to the section-bottoms; a bee-space and board-cover over the sections, then it is a very simple matter to handle supers. They should come off clean, and *no*

drip whatever from burr-combs or attachments between supers, or super and brood-combs.

This does not close all I have to say about comb honey, but as I want all to be reasonable, I will in the next article take up the question of the *production of extracted honey*. After the production has been discussed, we will consider grading, packing, and marketing. I ask for these articles a careful reading, and if there is anything amiss anywhere I would be pleased to have any one point it out.

Larimer Co., Colo.

Causes of Large Losses of Bees in the Winter and Spring of 1899, in Clark Co., Wis.

Written for the Wisconsin Convention, held at Madison, Feb. 7 and 8, 1900,

BY HERBERT CLUTE.

IT is hard to say what was the real cause of the loss of bees, as there are so many bee-keepers that differ; but I wish to give the causes as I see them, and as I have persuaded others to see them, altho they would have it that it was bad honey, until they had examined the hives.

To begin with, on July 25 and 26, 1898, we had rain with some hail. This shut the bees off the latter part of the bass-wood bloom, and ruined the nectar-bearing plants. From that date until the bees went into winter quarters, they never gained a pound, according to the scales under the hives. They even lost three to four pounds per day for some days, regardless of the great amount of brood in the hives that consumed much feed. There was lots of pollen coming in that deceived a portion of the real loss, so that I say our great loss was by starvation, and nothing else.

In my Greenwood apiary the bees were placed in the root-house, as I knew that they were light, and it takes little honey there to last until spring, and the chances were that I would have to feed them. When spring came all were placed on the summer stands, very strong in bees, but light in honey. I noticed a large number had not over a pound of honey, while 20 colonies perished before being put out without any honey. The covers on some of those put out did not fit tight. At this time I received a telegram notifying me of my father's sickness, and I had only an hour and a half to catch the train. I saw a young man that promised to fix the covers and feed the bees the one-half barrel of extracted honey, and also a large amount of honey in extra combs, which I had saved for that purpose. In a couple of days he wrote stating that he had fed the bees, and I did not worry so much about them after that.

It was 12 days before I could return, and, when I did, I found that over 180 colonies had perished, and the rest were lighter than the day they were put out. In looking at the feed in stock I found that not over 15 pounds had been used for the whole apiary. Of course, the young man did the best he knew how, altho it was very different from what I had told him. I fed at once so as not to lose any more, and they were very weak.

Hearing of other heavy losses I visited George Drinkwine, who had the same number of colonies as I had and had lost as many. He claimed that the cause of the loss was bad honey, and would have it so, until we examined the hives where bees had died, and found that there was honey excepting in a few of the outside combs.

I then called on Walter Miller, who lost all but two out of 70 colonies. His bees had been in a very cold place, so they had consumed lots of honey, and were starved long before spring.

One lady had 12 colonies in a garret that was quite warm, and the bees being disturbed, consumed lots of honey, and the hives were empty of feed long before spring. Another lady lost 70 colonies in a bee-cellar that was heated by pipes; she had wintered them before in this cellar and had never lost any.

Of the 30 different apiaries in this county the loss was from 50 percent to an entire loss, except two apiaries that were fed plenty of honey—more than their year's gathering. These apiaries did not lose a colony, but were very strong. One of these yards containing 25 colonies was increased to 35, and produced an average per colony of 160 pounds of extracted honey. If it was bad honey that caused the loss, why did not these bees perish, as they were fed the same kind of honey as we fed ours?

I also noticed an apiary of 50 light colonies at the time I began feeding after returning home. I found on opening the hives that some of them contained one or two pounds of honey, and a few contained from six to eight pounds. Not having the feed or the capital to buy sugar for feed, the

bees took their course, to live or die. They dwindled up to the time new honey came in, and half of them were starved. They began to make a gain in breeding, while those with the most honey in the hives picked up the poorest. If this lot of bees dwindled from any other cause than starvation from the time I began to feed at Greenwood, why did not my bees then dwindle from the time of feeding, etc.? If the great loss was caused by the severe winter, how was it that many a colony wintered all right on the summer stands all un-packed for winter, that had never a top box on so as to store honey that had to crowd out the brood and then store honey in the commencement of the honey harvest? They had no protection in the least, but were on a bench 2½ feet from the ground to give the wind and the cold full play. Each year before last there have been colonies wintered safely in the same way.

Clark Co., Wis.

How Far Will Bees Go for Food, or Gather Profitably?

BY C. P. DADANT.

THERE has been considerable comment in the bee-papers on the question of how far bees will go in search of honey. I take it that the only thing of importance to the bee-keeper at large on this subject is, "How far will bees go and harvest honey to make a crop pay?" I have written on this subject a number of times, but have perhaps never given a summing up of our experience, which I propose to do now, leaving the reader to draw his own conclusions. And here, let me say that I do not seek to make a great display. I do not claim the best results, or to have done more than others; in a word, I am not trying to "astonish the natives." The results we have obtained are very ordinary, and I feel sure that no one after reading this will feel unable to follow in the same path, for it is a very prosaic one, and not a difficult one. The crops were not astonishing, but they were fair and steady, and in the end have paid for the labor with a good profit.

The first out-apiary that we ever put out was placed in 1872, five miles north of our home-apiary. This apiary, two miles from the Mississippi River, was removed after three years to a location on the edge of the river, and about the same distance from our home-yard, as mentioned above. Then another apiary was established in 1876, three miles northeast from the latter, and about two miles from the river. Another one was placed shortly after five miles southwest from our location, also on the river shores, but in a spot where a number of islands and lowlands furnish some fall pasturage. Later apiaries were successively placed, one at Keokuk, back of the city half a mile, one on the lowlands of the Mississippi River, south of Warsaw, 12 miles from home, another later on the edge of the bluffs in the same vicinity, and still two more such apiaries about three miles apart along those bluffs. Another was also placed two miles south, about four miles from where we live, in a good clover neighborhood. From time to time an apiary was discontinued and another established, but we have at no time had less than two apiaries since 1872, a period of 28 years, and for 20 of those 28 years we have had six apiaries at one time in different locations.

As to the number of colonies, we have never permitted it to exceed 120 in any place. The average number was from 80 to 90 in each apiary, and the aim was not to allow any more increase than would make up for winter losses. This has been generally observed, as our methods do not give much incitation to the swarming-impulse.

Our experience has been, all along, that with the same care, the same management, and hives of similar shape and size, the results in one apiary invariably differed from those of another, and nearly always in the same proportion, evidently according to the location, even tho this location was only a short distance—never less than three miles from any other apiary—in all cases but one.

In the locations near the Mississippi, we found invariably a smaller crop than anywhere else. We must remark that the Mississippi at this point is about a mile wide, and in our estimation it acted almost as a barrier to the work of the bees on that side, altho we have evidences that they, in many cases, crossed the river for honey. Yet none were found very far on the other side, and the flight of the bees as they emerged from the hives evidenced the fact that they were not prone to go in that direction. Approaching the apiary from the east the roar of the bees could be plainly heard at a quarter of a mile, caused by the foragers passing

over our heads, while, if we approacht the apiary from the river shore, no noise was heard till we were at the side of the hives.

The three apiaries that we had along the bluffs south of Warsaw, about three miles apart, were from two to four miles from the river, and separated from it by the richest land in the State except the upper apiary, which was separated from the river by a number of sandy ridges that grew little more than cockleburrs and willows, but the rich lowlands were even there only a mile and a half away. The best yielding portion of these bottom-lands is that which is least adapted to cultivation, being too low to drain well, and producing only knot-weeds and Spanish-needles in profusion during the months of July, August and September, when the waters recede and the moisture evaporates sufficiently to enable them to grow and thrive. We have every season invariably harvested larger crops from the apiary which was the nearest to these lowlands—only a quarter of a mile—than from either of the others.

The difference in the quality of the honey, from one apiary to another, has also shown itself plainly, even when they were but three miles apart. Here we must say that the soil being very varied the crops are dissimilar, but during a clover crop, when clover was to be seen everywhere, one might have expected the honey to be similar, yet we have always been unable to sell clover honey from one apiary upon a sample taken from another, and the same may be said of the fall crop.

Not only have the above-mentioned remarks shown that the bees harvested only the local crop of their immediate neighborhood, but we have noticed, in two or three seasons of scarcity, that they were unable to find blossoms located five miles away, and even less. The bees of our home-apiary generally take their bee-line in a northeast direction up the valley on which we live, probably because there are no impediments in their course in that direction. Very few go west in the direction of the river.

In 1880, the worst year of honey famine we have known, a neighbor's bees, located close to the river west of us, were storing honey and whitening their combs on the honey harvested from a couple hundred acres of lowland, while ours, less than two miles off, had not found it. In that same year we removed one entire apiary, as mentioned above, to the heart of the lowlands, below Warsaw, to the overflowed lands which were covered with a luxuriant growth that had sprung up as fast as the high waters of the river receded, while our hills were parcht by drouth. This apiary produced an abundant crop, while apiaries five miles off in a bee-line in the hills had to be fed for winter.

From all this it appears to me that if we want success we must place our bees within a short distance of the crop, and that distance, in my own case, I place at a mile and a half at the outside.

Do not understand me as taking exception to the statements made by some apiarists that bees do go six, eight, and even 10 miles in search of honey, but you can readily see from this experience of 28 consecutive years that one can not consider such distances as safe to be relied upon for a good honey crop. If bees make a practice of flying after food so far would there be any chance of overstocking any location, even if one kept a thousand colonies in one place? An area of say eight miles in every direction makes a pasture of the extent of some 250 square miles, or 160,000 acres, allowing the fractions for the rounding off of the outline. Just think of it! You would have a practically unlimited field, and the kind of crop that might be produced in your vicinity would cut very little figure in your crop since bees fly fast enough to make the time occupied in the trip of little importance.

But that which evidenced to us most emphatically the importance of location close to the pasture was the amount of honey harvested. If I remember rightly, the highest average per colony in one apiary during our very best season, amounted to some 140 pounds per colony, but during that same season an apiary in a poorer location yielded only an average of 50 pounds, and the result was the same every year; the latter location making a less amount of harvest proportionally. The apiaries located at the edge of the bluffs always gave a big crop of fall honey, while those entirely on the bluff, and away from the lowlands, gave the bigger yield of clover crop.

Hancock Co., Ill.

The Premiums offered this week are well worth working for. Look at them.

The Early Bee—What "He" Is, and How to Get "Him."

Written for the last Convention of the California Bee-Keepers' Association,
BY W. A. PRVAL.

YOUR secretary askt me to contribute a paper on some bee-topic for your edification. In an evil hour my egotism prompted me to give him an affirmative answer. Then for days I rackt my brain in an endeavor to hit upon an original subject. This effort on my part came near being my undoing; it addled my brain, and started several screws, all of which will account for the oddity of the remarks which follow. My choice of a subject, I think, is a good one, and I have chosen to lay it before you in the shape of an epistle, rather than in the hackneyed form of an essay, learned and dry.

There is an old saying that "the early bird catches the worm," which I am going to paraphrase by saying, "that the early bee catches the honey." Of course this is not exactly true, as we know that the bee does not catch anything, as he is neither a baseball player, a policeman, nor a terrier, tho he is something of a bird of rare plumage, especially when he is of the five-banded golden kind we read about in the advertisements of queen-breeders who vie with one another in their endeavor to disseminate *Apis Americana*.

But I must be more serious, for I recognize the fact that I have the honor of having these crude, and, I am afraid, uninteresting statements read to a body of gentlemen who are wont to be of a contemplative disposition, for Nature has, particularly here in the Golden State, destined most bee-men to pursue the even tenor of their way in some quiet ravine, or, may be, on the slope of some towering sentry of a mountain-range, where the white hives add a gravelike stillness to the scene by their tombstone appearance. It is a life among the bees amid such surroundings that makes our bee-men to a great extent hermits and lovers of the serious side of life.

Then, I must say that joking is not in my line; and, besides, I should not attempt it. I have heard of a couple of bad instances where the malady has strangely afflicted persons connected with apiarian pursuits, and, if I am not mistaken, the affliction has been a source of annoyance to some of their friends. I believe, gentlemen, that you are aware of how this trouble has taken a deadly hold of some of the brightest minds that adorn the pages of our modern bee-literature. Just look at the havoc it has made with Editor York, of the American Bee Journal. Behold his well-turned puns, and see how they run rampant thru the pages of the "Old Reliable" weekly. Then, Ernest Root's foot-notes in Gleanings in Bee-Culture are editorials indeed, but in them lurk the root of many a cunning joke. In "Stray Straws" a Miller (C. C.) sees a means of grinding out a crop of chaff and substantial food at the same time; and, perhaps, just beside him may be that prince of apicultural humorists, the never-to-be-suppress Rambler, whose fun and frolic is known to you all. I trust for your sake that he is far away from you during this meeting, as otherwise his pen and crayon and tell-tale camera may be getting in their deadly work on some unsuspecting attending honey-producer!

But what has all this to do with the early bee, you may ask? Surely nothing.

Gentlemen, I shall not joke. I will be serious, and proceed to find the early honey that catches the bee—no, I mean the early bee that gathers the honey, and like a good dog that has retrieved your game, lay it before you.

To begin, I will state there are several kinds of early bees. The one I dread the most is the too previous bee. I dare say you have run against this amusing little creature on more than one occasion. He usually makes your acquaintance when you least suspect his presence. He darts from his hive at all seasons, early and late, tho seldom behind time, as he tries to be never late in getting in his work upon you, which is too often done in a decorative sort of way about your optics.

Perhaps you have heard of the spelling-bee. Of course you have, and I shall not waste time in referring to the thing. It cometh in the night, and is too late for notice by me any way. Ditto husking-bee.

My bee is not any of these; neither is he *Apis dorsata*, *Apis Filipino*, or even *Apis Aurora borealis*, whatever the latter may be in the bee-line.

Another early bee, and the one I believe you think I have in mind, is the one that riseth from his soft and downy couch in the wee sma' hours of morning, throws off his

nightcap, rubs the cobwebs from his eyes, eats his breakfast of flapjacks and honey, and sallies forth to meet the rising sun and the expanding nectar-laden flowers down by the riverside. This is the industrious little bee that we heard so much of during our childhood years—our parents told us of this little morsel of the insect world when they wish to impress upon us ways of usefulness and neatness, and teachers sermonized to us about him and the ant—how industrious they were, and what lessons we should learn from them. For the present I shall pass this bee by as not being the one I am after. Your old bee is behind the times for me; mine is trained to a different manner of life. I will state that he is no spring chicken, which may seem strange, since I have held out to you that he is an early bee.

This bee of mine has become hardened by the frosts of winter; he has learned to wear an overcoat, and at the first approach of spring he discards the garment and lies himself to the flower-fields, there to gather in the nectar in a way that makes the bee-man's heart rejoice. No wonder you are already proclaiming him a most wonderful honey-producer. I feel that there is not a bee-keeper in this glorious country of ours but wants this remarkable little worker. My friends, he shall be yours, if you only do as I have done to get him. In finding him I was necessarily under much expense and trouble, but never mind, I have found him, and will charge you nothing for my labor. I shall feel well repaid if you have the same success with him as I have had.

As you must be impatient by this time to know all about this early bee, I shall hurry to tell you all about him.

My bee is one that does not require a warehouse full of provisions to supply his kitchen during the days that are dark, and cold, and dreary—those days when good nitrogenous food is required by man and beast to put an extra coat of fat where it will do the most good to ward off cold. We know that an old animal is more susceptible to cold than a young animal; that the latter does not require so much fat-producing food as the other; neither is he so likely to hug the fire of a cold day, tho he may have to put on a warm overcoat to keep the cold out. Now, the bee I have for wintering is the very youngest bee I can get. He is padded with fat, and walketh like an alderman.

We know that no matter how well filled a hive of bees may be in the fall, it won't have near so many occupants at the approach of winter. To some extent this is a wise provision of Nature, as there are less bees to feed.

Where I have managed bees for so many years I find that it is wise to leave the colonies to their own sweet will after the first week in July. It is after this time that the queen ceases to lay as many eggs as she did during the forepart of the year. The population of the hives is daily diminishing, so that by the beginning of winter, as I have intimated, the colony will be much reduced in number. Now, I do not want my colonies to dwindle down to a hatful of bees. I want good, strong colonies to take thru the winter, even if they will consume a goodly supply of honey. And I do not want a lot of old bees for this purpose, either. The latter are not likely to hold out thru the winter, many of them will die during those balmy winter days we are wont to have in this climate, for bees will venture out every time the sun casts his beaming countenance on a gladsome earth. Too oft are such days but traps to catch the unwary bee; with merry hum he flies forth, but ere he has time to return a fatal change may take place and dash the busy worker to an untimely grave. A young bee is more apt to withstand such hardship, but not so the bee of last year.

To get this early and young bee I proceed in late October, after the colony and the queen have had sufficient rest, to arrange the supers with feeders so as to coax the queen to renewed egg-laying by stimulative feeding. The feeders allow but a limited quantity of liquid to flow, as it is only desirable to build up gently. By this plan I have had a queen fill the brood-chamber with bees by Christmas, after which time I ceased to provide further feed. And by this time, too, the hive was well provisioned with stores, so that in some instances it was necessary to remove a few combs of honey, which, at this period of the year, are serviceable in assisting destitute colonies to "keep the wolf from the door," if I may be allowed to use the expression.

After the queen has been the means of producing such a large stock of young bees at a season when nature intended that she should take a rest from her maternal duties, it is well to remove her to a hive where she will not be called upon to do much egg-laying until spring is well under way. In her place introduce a young queen of known prolificness that has not yet been called upon to propagate her species

out of season. Your hive is now ready to begin its spring campaign in a most wonderful way, as you will find out if you give this method a trial. The colony will be strong and vigorous, and by the middle of February, if not before, it will be in a condition to swarm, but this is not yet desired. If it is too strong, and there is evidences of its swarming, you might take some of the combs with adhering bees and give them to a weak colony, say the one you placed the mother of your "early bees" with.

I do not know of a better way of having populous colonies at the earliest date possible than by the plan just outlined. It gives you strong colonies for winter, and as the inmates, with few exceptions, are young bees, they live well into spring. For the apiarist who desires to build up by division this is a capital plan, at least I have found it so. He is given the material at the very opening of spring, and by judicious manipulation he may increase two-fold and have a good working-force when the main honey crop arrives.

Now, my friends, I have told you what I know about the early bee, tho it took me some time to do so—perhaps I should have taken a bee-line and have gotten at my object sooner. I hope my subject and its treatment has not disappointed you. You may have expected something better. I feel confident that after you have given the method a thoro trial you will exclaim, as I did after discovering it, "Eureka!" Pray do not let me hear that any of you were "onto" this trick long ago, as that would be a sad disappointment to me, and blast my hopes of being considered one of the great lights in the galaxy of apicultural giants. My place along with Langstroth, Huber, Dzierzon and other big guns would be "knockt into a cockt hat."

Thanking you, my friends, for allowing me to tire you with the foregoing remarks, wise and otherwise, and asking your pardon for having repeatedly referred to your little pets as belonging to the masculine gender, when, I believe, most of you hold that I should have called the worker-bee an "it" or a "she;" and promising not to disturb your equanimity further during this meeting, I beg to subscribe myself—

YOURS FOR THE EARLY BEE.
Alameda Co., Calif.

Essential Points in Rearing Good Queens.

BY J. P. MOORE.

TO rear good queens, equal to those reared under the swarming-impulse, three essential points must be observed, viz.:

1st. They must be reared from small larvæ. Those 12 to 24 hours old are just right for the purpose. If bees are given larvæ of all ages from which to rear queens, some of the queens will be almost worthless. Doolittle puts the limit at 36 hours, but, to be on the safe side, I would advise the use of larvæ not more than 24 hours old; for no queen-breeder will say that the former are better than the latter.

2d. The queen-cells must be built in full colonies well supplied with young bees. The young bees do the nursing; therefore, it is necessary to have plenty of young bees to feed the embryo queens a large quantity of the royal food, that strong, well-developed queens may be produced.

3d. They must be either reared during a good honey-flow, or in the absence of this, liberal feeding must be practiced.

This is highly important, and is the only way in which we can rear good queens after the honey season is over.

During my 20 years' experience in queen-rearing I have tried every method which has been brought to public notice, and I consider Doolittle's method far superior to all others. This method combines the essential points mentioned above in the highest degree. By it we are enabled to have queen-cells built in the upper story of any colony devoted to the production of extracted honey, having a queen-excluding honey-board between the upper story and brood-chamber. Remove two frames from the upper story of such a colony, and in their place put two frames of unsealed brood. The object in doing this is to draw a large force of nurse-bees above to attend to the queen-cells. Two days later remove another frame from the upper story, spread the two frames of brood apart, and place a prepared frame between them. By "prepared frame" is meant a frame containing a number of queen-cell cups, each supplied with a little royal jelly and a larva about one day old. About 15 cells are as many as a colony should be allowed to build at one time.

To describe the manner of making the cell-cups and grafting them would make this essay too long for this oc-

casian; therefore, I must refer you to Doolittle's "Scientific Queen-Rearing" for this information.

In order to improve our stock for honey-gathering we must keep a record each season of our best colonies, and rear queens from the stock giving the best results. Have them cross as far as possible with drones not akin, of other good stock. This is accomplished by stocking our apiary with drones not related to our breeding-queens. This is very important, and must not be overlooked if we desire to improve our stock.—Pendletonian (Ky.).

[Doolittle's "Scientific Queen-Rearing," referred to by Mr. Moore, is a cloth-bound book which we send postpaid for \$1.00; or will club it with the American Bee Journal for one year—both for \$1.60, provided all arrearages on subscriptions are paid.—EDITOR.]

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Management with Little Attention.

We are going to move some of our bees about 25 miles from here, and can not visit them oftener than once every week or 10 days. We thought of putting on an extracting-super, and a comb-honey super on that. Then cage the queen and put on entrance-guards. Is this as good a plan as we can adopt?

MISSOURI.

ANSWER.—Try some of them this way: Give abundant room for the queen to lay, abundance of surplus room, and abundant ventilation by having full entrance to each story, and omit caging and entrance-guard.

Feeder Flows Too Fast.

I have two Boardman feeders. I use three parts water and four parts sugar (best granulated) by measure. The syrup flows out too fast even for a strong colony of bees to take it. What is the cause and how is it managed?

IOWA.

ANSWER.—Without seeing your feeders in place it is hard to say just what is the trouble. With a Boardman feeder there ought to be no trouble about the syrup flowing out too fast, even if it stood a year without any bees to take it. It is just possible that the glass jar is not down in its proper place in its receptacle. It may be that the hive is not level, for if too much out of level the syrup would flow till the can is emptied, even with no bees to take it.

Bees Under a Bathroom Floor.

I was taken with the bee-fever several months ago, and being ignorant on the subject of bees, I purchased "Langstroth on the Honey-Bee," which I read with much delight. What I want to know is, Why do the bees continue using a home under a floor, as shown in the enclosed clipping, when there is very much noise created above them? The books and bee-papers tell me that to make the bees go down from the supers when they are storing, beat a stick on top of the hive. Which is it that drives them down, the noise or the smoke? If it is the noise, then why is not this colony always disturbed?

MARYLAND.

ANSWER.—The clipping tells about a colony of bees that were lodged under the floor of Mr. Godman's bathroom, entering thru a hole in the wall, the bees furnishing a large amount of honey. The clipping continues

"The 'robbing' took place in the fall. A small amount was left for the bees to subsist upon. Mr. Godman thought

that it would be better to transfer the bees to a hive and take them out of the house. There were some disadvantages connected with their presence in the bathroom now, especially since the hole had been bored in the floor to get at them. The children could enter the room and take the bees up from their place by the double handful, and smooth them along their laps with their hands, but the workers of the colony were opposed to certain members of the family, and stung them whenever they got a chance. That was why Mr. Godman desired to put them in a hive in the yard.

"The hive was prepared, and an effort was made to induce the bees to enter it, but the effort was not a success. It brought about a schism in the colony, however, and nearly all the bees went away. During the blizzard last February the colony that remained beneath the bathroom perished."

Bee-keepers will be somewhat skeptical as to accepting all this as entirely reliable. Replying to your question, the smoke alone, or the noise and jarring alone, is enough to drive bees out of a hive. The jarring probably has more to do with it than the noise. But a little bit of smoke, or a little bit of jarring, would not dislodge them. The jarring must be heavy and continuous. You might walk all day over the top of a hive, and it would irritate the bees, but would not drive them out of the hive.

Old Queen with the First Swarm.

When a colony of bees casts the first swarm, is it the old queen or the young one that goes out? Some tell me it is the old one, some say the new.

CALIFORNIA.

ANSWER.—The old queen goes with the prime swarm, and young queens with after-swarms.

Queen-Excluders from Foul-Broody Colonies.

In reply to an inquirer I said such excluders should be boiled before being used on healthy colonies. Wm. McEvoy is much better authority upon foul brood than I, and he says in the Canadian Bee Journal:

"Queen-excluders that have been used on foul-broody colonies are perfectly safe to use on any hive of bees without any disinfecting. The larvæ to become diseased must be fed in a corrupt cell or with diseased honey, and as queen-excluders have nothing on them for the bees to feed to the brood they can not disease any colony of bees."

Perhaps a Peculiarity of the Queen.

1. On April 24 I changed an outside empty frame to the center of the brood-nest of a colony, placing it between two frames of brood. May 1, I found upon examination that many of the cells contained two eggs, laid sometimes on one side and sometimes on the bottom of the cell; the colony was of fair strength and the brood apparently in good shape. The queen was two years old, and possibly three. I also found some cells uncapped containing larvæ in the pupa state. These conditions were peculiar to this one comb only. I saw no others in a similar condition in the hive, and none in the apiary. Can you tell me the cause?

MICHIGAN.

ANSWER.—No, I don't know enough to give the cause. I have had two cases a little on the same line. An imported queen laid eggs on one side of the cell for a few days, and afterward laid normally. It is not impossible that a queen may have some temporary derangement that makes her do irregular work.

Transferring—Bees in a Brick House.

1. I have one colony in a box-hive from which I wish as much increase as possible. I also wish to transfer into a movable-frame hive. When should I transfer them?

2. I have a colony of bees in a brick house. Their entrance is under the window-sill on the second floor between the two walls. Would it pay to try to get them into a hive? If so, how could I get them, and when would be the best time? Would they swarm if left alone?

SUBSCRIBER.

ANSWERS.—Wait till they swarm, and hive the swarm in a new place, leaving the old hive on the old stand. After they swarm the second time (if they do swarm again), set the second swarm in a new place, and then transfer what is

left in the old hive. If they do not swarm again, transfer about two weeks after the prime swarm issues. But it may be better for you to be satisfied with only one swarm, setting the swarm on the old stand, the old colony beside it. A week later move the old hive to a new place, and 21 days after swarming transfer.

2. It depends on the value of the wall as compared with the value of the bees. The chances are in favor of their swarming, especially if strong and the season good. If you decide to get them out, you will have to take down enough of the wall to expose the combs, then cut them out, and take bees and all.

Did the Onion Honey Kill Them?

1. Is onion honey injurious to bees?
2. Does onion honey become strong as it becomes old?
3. Is there any opium in onion honey?
4. If not, what killed the bees that had onion honey, as there was no disease that I could find?

The point I wish to know is, did the honey kill them, or did some man kill them? They were threatened by a very bad man. My bees never did any harm to any one. They were a very gentle strain of Italians, 150 feet from the street, in good hives with movable-frames. OHIO.

ANSWERS.—1. I did not suppose it was, from the fact that I have read of its being gathered, but never heard of any harm from it.

2. Instead of the honey becoming stronger, I have read that it loses some of its rank onion taste with age, becoming milder.

3. I think not.

4. I am at a loss to say. Possibly some honey-dew was present. Possibly the bees may have had access to something poisonous.

Questions on Various "Styles" of Bees.

As I have what is called the golden Italian bees, I was thinking of introducing new blood, so I ask these questions:

1. Are the golden and the 5-banded the same?
2. Are the leather-colored and the 3-banded the same?
3. Are the Cyprians in any way superior to the Italians?
4. Are the Cyprians in any way related to the golden Italians?
5. Would you advise introducing a Cyprian queen in a yard of Italian bees?
6. Would the cross be any better than new blood of the Italian? WISCONSIN.

ANSWER.—1. I believe they are the same.

2. Not necessarily so. What are considered as pure Italians coming from Italy have 3 bands, but all are not leather-colored; some are lighter.

3. They have the reputation of excelling the Italians as stingers. Whether they have any extra vigor in working to correspond, I do not know.

4. No, no more than they are to all Italians, which they so much resemble in appearance.

5. I think I should prefer Italian, but others might think differently.

6. That question can hardly be answered by a straight yes or no. You might strike a combination that would give better results than some Italians, and you might strike something worse. Taken in general, you may get better results from the Italian.

Wants No "Shortening" in Pie.

When Editor York began to spell it *thru* instead of *through*, several cold chills ran up and down my spinal column. Since then I have gotten reconciled to the change, and am inclined to the belief that I am beginning to like it.

But I notice with alarm that he quotes (I thought) approvingly what somebody says about dropping *all* of the silent letters in the English language. I want you to join me in protesting against the dropping out of the *e* in *pie*. How is any one to know whether printer's pi or apple-pie is under consideration? The change is too suggestive of vanishing visions of those peach and pumpkin and mince and custard things which tickled the palates and destroyed the digestion of so many in Yankeeland and elsewhere. I do not eat pie any more, but in behalf of a great number of prospective dyspeptics who persist in the use of these pleas-

ing abominations, I hope you will join me in the attempt to persuade Mr. York not to eliminate the *e* from *pie*.

EDWIN BEVINS.

ANSWER.—Decidedly yes, Mr. Bevins, we must stand up for our rights, and draw the line at pi. I'd stand a good deal from Editor York, but I'm not ready to submit to have cold lead crammed down my throat in place of that toothsome combination between crusts ending with an *e*.

Eggs of a Virgin Queen.

Are the eggs from a virgin queen fertile, and will they hatch? NEW YORK.

ANSWER.—The eggs of a virgin queen are not fertilized, but they will hatch, producing only drones. They are exactly the same as the eggs that a good laying queen lays in drone-cells.

York's Honey Calendar for 1900 is a 16-page pamphlet especially gotten up to create a demand for honey among should-be consumers. The forepart was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample free; 25 copies for 30 cents; 50 for 50 cents; 100 for 90 cents; 250 for \$2.00; 500 for \$3.50. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

Belgian Hare Breeding is the title of a pamphlet just published, containing 10 chapters on "Breeding the Belgian Hare." Price, 25 cents, postpaid. It covers the subjects of Breeding, Feeding, Houses and Hutches, Diseases, Methods of Serving for the Table, etc. It is a practical and helpful treatise for the amateur breeder. (See Prof. Cook's article on page 292.) For sale at the office of the American Bee Journal. For \$1.10 we will send the Bee Journal for a year and the 32-page pamphlet on "Belgian Hare Breeding."

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the new bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us *one new* yearly subscription to the American Bee Journal at \$1.00.

Dr. Miller's Honey-Queens are offered as premiums, on another page, for sending us new subscribers to the American Bee Journal. The offer is limited to our present regular subscribers, and the queens are to be mailed in rotation, beginning about June 1st, so first come first served. Look up a new subscriber, send in his name with \$1.00, and we will enter your order for a Dr. Miller Honey-Queen.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it.

The American Fruit and Vegetable Journal is just what its name indicates. Tells all about growing fruits and vegetables. It is a fine monthly, at 50 cents a year. We can mail you a free sample copy of it, if you ask for it. We club it with the American Bee Journal—both papers one year for \$1.10.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY,
118 Michigan Street, Chicago, Ill.

(Entered at the Post-Office at Chicago as Second-Class Mail-Matter.)

EDITOR:

GEORGE W. YORK.

DEPARTMENT EDITORS:

C. C. MILLER, "Questions and Answers." ** E. E. HASTY, "The Afterthought."

LEADING CONTRIBUTORS:

G. M. DOOLITTLE, F. A. SNELL, C. P. DADANT, R. C. AIKIN, PROF. A. J. COOK, "OLD GRIMES."

IMPORTANT NOTICES:

The Subscription Price of this journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec00" on your label shows that it is paid to the end of December, 1900.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

VOL. 40.

MAY 24, 1900.

NO. 21.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

Shipping Bee-Supplies Promptly.—It seems from statements made by several of the larger bee-supply manufacturers, that they are not having much trouble so far this year about filling orders promptly. Doubtless there is scarcely a dealer who would from choice delay filling orders. We believe that almost invariably the present-day bee-supply dealers are prompt and reliable.

It doesn't take long to find out that delays and anything but up-to-date methods must inevitably bring on failures in these days. Buyers are fast learning whom they can trust, and who will serve them best. It is well that it is so. Honorable and conscientious dealing will always prove to be the best in the long run. Careless and dishonest methods will soon bring on heart-failure and quick dissolution to any business, as properly should be the case.

Bran for Bees.—Mr. A. I. Root, in Gleanings in Bee-Culture, tells in the following how the bees "go for" bran as a substitute for pollen:

"Our neighbor across the way, a grain-dealer, got in a carload of bran in bulk; and on this beautiful 16th day of April they began shoveling it up to store it in their warehouse. But the bees from our apiary just across the way, in consequence of the cold March and April so far, were lacking in pollen, and they pitch into the bran with such vim that the men who were shoveling beat a retreat. Why,

it made one think of a leaky carload of honey, only the bees seemed to be very happy and civil in their rejoicing over their big find of pollen. I got one of our biggest wheelbarrows, loaded it up with bran, and wheeled it out into the apiary as a 'counter-irritant;' I think that is what the doctors call it, don't they? Well, just now (about three in the afternoon) it makes me feel like old times to hear the bees humming and rejoicing over that big wheelbarrow full of bran. I tipped it up edgewise so the coarser particles would run down over the side, and that seems to be just the thing to suit them."

Comparative Weight of Sections.—Altho the editor of Gleanings in Bee-Culture is by no means a figure-head, he seems to have quite a head for figures, and gives a bewildering array of figures with regard to the weight of sections of different sizes. In one lot of honey the average weight of $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{8}$ bee-way sections was 14.94 ounces; of $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{2}$ plain, 13.83 ounces. A $4\frac{1}{4}$ plain by $1\frac{1}{2}$ holds a plump pound. The 4×5 is supposed to run more nearly a pound than any section on the market. A whole lot of figures is given, showing the cubical contents of the sections of different sizes, but the actual amount of honey is by no means always in the same proportion.

Granulated Honey is having much said in its favor nowadays. G. M. Doolittle says in the American Bee-Keeper:

"If the bee-keepers of the land had tried as hard to educate consumers regarding the merits of granulated honey as they did to put only liquid honey before the public, the call for liquid honey would have been changed to that of granulated honey long ago. My customers, for the past five years, have all called for the granulated article, nearly all of them preferring to use it that way, while the convenience of carrying it home in a paper sack, or a box lined with paper, with no leaking or daubing of things with liquid honey, adds to the popularity of honey in its granulated form."

Management in the Extracting-Season.—In the discussion of this topic at the Toronto convention (reported in the Canadian Bee Journal), the point was made that in locations where the weather turned cool at the close of the honey season it was better to extract before the bees began to shrink away from the upper combs, for this would allow the honey to become thin. Care should be taken to keep white clover and linden honey separate, especially if the honey is to be shipped to England. Bees will go to work more promptly upon combs that have just been extracted than they will on dry combs. Where there is danger of foul brood in some colonies, it is safer to give back to each colony its own combs after they are extracted, but it takes more time. Some did not find it necessary to have excluders under extracting-supers on established colonies.

Young Queens to Prevent Swarming.—It is a common belief that a colony with a queen of the current year's rearing will not swarm. The belief has been held for many years, and for a long time was left undisputed. Then when Italians came upon the field, it was said that the rule did not always hold true with them, but was still valid with blacks. Possibly there is not so much difference as supposed between the two kinds of bees, the difference in results being rather owing to treatment than to difference in bees. As a matter of fact, when other conditions are all favorable for swarming, the introduction of a young queen will not prevent swarming, even if she has been laying only a day or two. But when a young queen is not introduced, but reared in the hive, then it may be expected to prevent swarming. Gravenhorst gave this as reliable, and said he could not explain why there should be the difference between a queen introduced and one reared in the hive. In the American Bee-Keeper G. M. Doolittle gives what is

probably the true reason. When a queen is reared in the hive there is a break in the laying that throws the colony out of its normal condition as to eggs and brood, resulting in no swarming. But he says this break, to be effective, must come not earlier than 10 to 15 days before the main honey harvest begins. And with this break of 10 to 20 days duration, even an old queen will not swarm.

Do Not Keep Virgin Queens Away from the Bees.—G. M. Doolittle thinks that where the right temperature is maintained it may do to keep queen-cells away from bees, but he is quite sure it is bad to keep virgin queens at any time without the immediate touch of worker-bees. He says in *Gleanings in Bee-Culture* :

"About 15 years ago I had a mania for introducing old virgin queens to nuclei, so that I might be able to send off queens to the trade much faster than by the cell plan, giving one of these old virgins to a nucleus at the same time that I took a laying queen away. Then I also sent virgin queens to other parties to have them mated and returned to me, and out of scores tried for the different purposes I never had one *single* queen thus treated live two years, while very many of my other queens, which were in immediate touch with the bees at all times, live to be four and five years old. At that time I had 'growls' from my customers regarding the short lives of some of the queens purchast of me; but since I adopted the motto of 'No queens but what the bees cared for *all* the time,' I have had no complaints of inferior queens in any respect."

Improving the Stock of Bees is a matter that seems to have more attention given to it lately than ever before. J. B. Hall thinks it worth while to take such pains in selecting and breeding as to make his queens cost a good deal. His plan is given in the *Canadian Bee Journal* as follows :

"I have a record slate on every hive; I have the age of the queen, when she was clipped, and when I saw her last. I use the letters A, B, C—C is killed at once; B is killed when I can do so profitably; A we don't breed from; A 1, we do sometimes; A I X we breed from; A I X X we mark to rear queens from the next year. I could not rear them to sell that way unless I got 2 or 3 dollars each for them."

Do Bee-Keepers Want Adulteration to Stop?—Commenting upon the 12 carloads of adulterated honey turned out in 60 days, that was reported in *Gleanings in Bee-Culture*, the American Bee-Keeper says :

"The injustice to honest producers resulting from such wholesale adulteration must be apparent to all, as it must also be that our plain duty is to *stop it*. It is not as if we had no representative organization to deal with such problems; in that case the matter would indeed be serious. We may congratulate ourselves on having an efficient association at this time; and its board and executive staff being composed of men eminently qualified to guard our interests with vigilance and tact, should be a source of satisfaction and confidence. The case rests with the producers themselves. Shall we exterminate the offenders and reap the full rewards of our labor, or shall we indifferently permit the very foundation of our industry to be stealthily withdrawn by those engaged in the illegitimate practice of adulteration?"

Bingham's Expansive Hive.—T. F. Bingham, of smoker fame, describes in *Gleanings in Bee-Culture* the hive he has been using for many years, as follows :

"This is composed of 7 tight-end frames clamped together with a wire link or loop which is tightened by a stick which spreads the link, thereby shortening it so as to hold firmly the movable sides against the frames, rendering the whole practically a box which rests on a loose bottom-board having on either of its two edges a square strip $\frac{3}{8}$ inch by 24. These strips leave an entrance the length of the sides of the hive. Above this hive is a clamp (or super) holding 18 one-pound sections.

"That is all there is of the hive. If not large enough, any number of just such hives and clamps of sections may be set under or over it to suit conditions."

The Weekly Budget

C. B. BANKSTON, of Rockdale, Tex., judging from several reports we have received, is accepting money for queens which he does not send. When written to afterwards it seems he makes no reply. So far as we have noticed he is not advertising in any of the bee-papers this year, but has advertised in other years. We give this word of caution so that our readers may be careful not to send him any orders unless they know that he is in business and doing all right.

THE BOY WITH THE SPADE.

No weight of ages bows him down,
That barefoot boy with fingers brown.
There's nothing empty in his face,
No burdens of the human race
Are on his back, nor is he dead
To joy or sorrow, hope or dread,
For he can grieve, and he can hope,
Can shrink with all his soul from soap.

No brother to the ox is he,
He's second cousin to the bee,
He loosens and lets down his jaw—
And brings it up—his gum to "chaw."
There's naught but sweat upon his brow,
'Tis slanted somewhat forward now.
His eyes are bright with eager light,
He's working with an appetite.

Ah, no! That boy is not afraid
To wield with all his strength his spade!
Nor has he any spite at fate—
He's digging angleworms for bait!

—Chicago Tribune.

DON'T CROWD YOUR ADVERTISING SPACE.—There should be plenty of white space in an advertisement, and that white space should be well distributed and clean looking. Don't let your advertisement look choked for breathing-room. Ventilation in an advertisement suggests healthfulness and prosperity, a liberal-mindedness that it will be a pleasure to meet in a business way. An advertisement which looks as tho its owner was afraid some little quarter of an inch of space would be paid for without being utilized puts the prospective customer in an unconscious attitude of dealing with a close-fisted merchant.—*Profitable Advertising*.

A Furnace in a Bee-Cellar is all right, according to J. B. Hall in the *Canadian Bee Journal*, if there is a brick wall between the furnace and the room containing the bees.

"A Solar Wax-Extractor With Bottom Heat is no new thing in California. E. H. Schaeffle has devised and uses an extractor that uses solar heat on the bottom thru reflection."—J. H. Martin, in *Gleanings in Bee-Culture*.

To Introduce a Valuable Queen, W. B. Ranson gives the following in *Gleanings in Bee-Culture* :

"Take a large Benton cage and provision it, and put the queen in it all alone. Take out the queen from the colony to be requeened, and at the same time pick off from the combs 12 or 15 young bees just hatched; put them in a cage; wait a moment for these babies to crawl over the queen and scent her with their damp feet and wings. Now pick off another lot, a little older, and put them in, and in another minute pick off a dozen still older, say those old enough to

shed their veils. Now close up the hive for an hour. Take the cage with the queen and 40 or 50 bees, and notice them carefully; and if the older bees should attack her, smoke them; but they would hardly do that. In a few minutes you will find the oldest bees caressing the queen, having accepted her in the cage. Now give them to the colony to eat out the candy and liberate the queen; and if the work was properly done, the queen is perfectly safe. It seems that the damp feet and wings of the very young bees in crawling over the queen cause the older bees to accept her in the cage; and once they commence to caress her in the cage she is safe. I introduce virgin queens in this way without difficulty."

Bees on Shares in California.—J. H. Martin says in *Gleanings in Bee-Culture*:

"So far as my observation and experience go in this State, the owner of bees does not allow the party of the second part to have any of the increase. The plan usually followed, and one that seems to be the most satisfactory to all concerned, is for the owner to furnish the bees, hives for increase, and receptacles for his share of the honey. The party of the second part has half of the honey and wax; provides receptacles for his portion of the honey, and leaves enough honey in the hives at the close of the season for the sustenance of the bees. As both parties are after the most profit possible in the amount of honey, it is for the interest of both to prevent swarming as far as possible; and where the extractor is used the swarms are few. The equal division of the products is easily accomplished, and there is seldom disagreement."

The Four Classes of Soiled Sections.—Dr. Miller has already spoken of the confusion that seems to exist over the question of travel-stained, soiled, yellow, greasy or water-soakt sections. All of these terms have often been confounded for one and the same thing. There are really 4 classes of discolored sections, each due to a distinct and separate cause. First, there is what is called the real travel-stained section. As its name indicates, the cappings are soiled because the bees have gone over the surfaces of the cappings with their dirty feet.

Then there is another lot that are stained because the boxes are capt over in the vicinity of old comb, dirt or propolis. If the faces of such sections are examined carefully it will be found that the stain or discoloration goes *clear thru*. These discolorations are due to the fact that the bees take up pieces of old black wax, propolis, or anything that will answer as a substitute or filler for pure wax. I have seen the cappings of some sections of this sort filled with bits of old rope, lint from newspapers, small hard chunks of propolis, fine slivers of wood—anything and everything

that is right handy. Sections of this class often look like those of the first class, hence the frequent confusion.

In the third class are those with soiled cappings, due to pollen dust or possibly a thin layer of propolis stain. All such may be bleached white, but the other two are hopelessly beyond remedy. All white honey with yellow cappings is apt to be in the third class.

The fourth and last class takes in all those that are called "greasy" or "water-soakt," having cappings that lie on the honey. The covering to each cell is more or less transparent, or water-soakt—the transparent part being half-moon shaped, or in the form of a ring encircling a white nucleus center that is not greasy or transparent. The general surface of such sections is mottled with little transparent half-moons or circles over many of the cells.

If the reader will look over the unsold odds and ends of the grocer's he will be able to find samples of all these classes, and it is a good time of the year to find them, as they are the last to sell.—Editorial in *Gleanings in Bee-Culture*.

To Get Candied Honey Out of Combs, Mrs. J. M. McLean gives the following in *Gleanings in Bee-Culture*:

"I uncapt some, and then filling a large tub with cold water, in which I put about a quart of vinegar, I filled it with combs, put a weight on to hold them down, and left them 24 hours, when they came out as clean as ever—no honey, no pollen. They were a little *sticky*, but I hung them in some empty hives, and the bees soon cleaned them up. I used the one tub of water for all the combs. I cleaned about 150, and then put the honey and water into the vinegar-barrel."

Management of Swarms to Prevent Increase.—QUESTION: What is the best method of handling swarms so as not to increase the number of colonies?

Mr. Hall—In 1883 we took 25,000 pounds of comb honey on that principle. We had more swarms that year than ever we had. In one apiary we had 80 colonies, and we increased to 84; in another, 120 colonies and increased to 128. We had an abundance of swarms; we hived every swarm on half combs and half foundation, full sheets of foundation, (4 sheets to the pound,) placing the old colonies alongside the new swarms; 6 or 7 days after we shook all the young bees that had hatch in that time into or in front of the swarm, making it very strong, and took the brood away and hived a swarm on it. There were no eggs and little or no uncapt larvæ. Every swarm of bees we put upon those combs staid and went right to work, we carried that out thruout the season. We started with 200 colonies of bees and we finish with 212, and we took 25,000 pounds of honey.—Canadian Bee Journal.

ARE YOU FULL OF GINGER? If you want health and vigor, good appetite and sound sleep, take **LAXATIVE NERVO-**

VITAL TABLETS, the quick and safe cure for Constipation, Nervous Dyspepsia, Insomnia, Nervous Affections, the "Blues" and all attendant evils. It aids digestion, purifies the blood, strengthens the nerves, improves the appetite, induces sweet sleep, tones up the whole system and makes you a new creature. It not only makes you feel well, it makes you really well. It gives you that vim and

LAXATIVE

vigor which makes life worth living.

NERVO-VITAL

TABLETS

It contains no narcotics nor bromides nor other injurious drugs. We give the formula with every box. You know exactly what you are taking. Originally put up for physicians' use. Ask your druggist for a **FREE SAMPLE.** If he hasn't it, don't take a substitute, but send us a stamp for our

book on "Health" and we will send you a free sample, sufficient for you to try it and test its merits to your own satisfaction. *Isn't it worth trying free?* It positively cures. Price 10c and 25c per box. Don't delay sending.

The Modern Remedy Co., Kewanee, Ill.

Langstroth on... The Honey-Bee

Revised by Dadant—1899 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the Ameri-

can Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helpt on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

Rocky Mountain Bee-Plant Seed!

(*Cleome integrifolia*.)

...FREE AS A PREMIUM...

The ABC of Bee-Culture says of it: "This is a beautiful plant for the flower-garden, to say nothing of the honey it produces. It grows from two to three feet in height, and bears large clusters of bright pink flowers. It grows naturally on the Rocky Mountains, and in Colorado, where it is said to furnish large quantities of honey."

We have a few pounds of this *Cleome* seed, and offer to mail a ¼-pound package as a premium for sending us **ONE NEW** subscriber to the American Bee Journal, with \$1.00; or ½ pound by mail for 40 cents.

GEORGE W. YORK & CO.

118 Michigan St., CHICAGO, ILL.

Bees Doing Splendidly.

The bees came thru in fine shape last winter, and as we are now in the midst of fruit-bloom they are doing splendidly. After selling some I still have 35 colonies—about as many as a man past 80 years of age can take care of.

J. KENOYER.

Whitman Co., Wash., May 7.

Blocking the Brood-Chamber with Honey.

I was compelled to transfer a colony in an old 12-frame no-spacing hive this spring to an up-to-date hive, and this was done five weeks after they swarmed (on account of rainy weather I could do it no sooner), and to my surprise every cell was jam full of honey and sealed, and the bees were constructing one-sided combs on each side of the hive, which were partly filled with honey. There were a great many bees in this hive.

JAY S. BROWN.

Bradford Co., Fla., May 5.

Bees in Fine Condition.

My few colonies are in fine condition, the only one I lost being queenless. I found it was queenless when I returned from St. Louis last fall, but it was too late to help it then. I had introduced a queen from an Eastern breeder when I went away in July, and it seems she didn't suit them.

MRS. N. L. STOW.

Cook Co., Ill., May 11.

Bees Doing Well.

My bees are all doing well. One colony is at work in the second story. I lost one colony this spring, but all the rest wintered well, and are in fine condition.

I have very many visitors to my yard from the city and county, and have been working them to form a local bee-keepers' association. The bees are my best friends, and all my spare time is spent among them.

DANA H. GRAHAM.

Lancaster Co., Pa.

Early Honey-Storing, Etc.

Bees are just booming in this locality. I have several colonies that have stored from 20 to 30 pounds each of willow honey in supers. At one of my out-apiaries a week ago to-day I noticed two colonies from which there seemed to be scarcely any bees flying, and I thought they must be weak, but on examination I found that their combs were all full of bees and honey, and they were loafing and building queen-cells. I gave one of them another story of empty combs, and the other a shallow extracting-super with foundation. When I went back to-day I found that the one with the shallow extracting-super had the foundation all drawn out, and that both of them were full of eggs and honey. I never before had bees store any honey in the supers in

Sharples Cream Separators: Profitable Dairying

DITTMER'S FOUNDATION

Wholesale and Retail

This foundation is made by an absolutely non-dipping process, thereby producing a perfectly clear and pliable foundation that retains the odor and color of beeswax, and is free from dirt.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.10, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO., 118 Mich. St., Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

April. I also found something else that I never saw before, and would like to know if any one can tell the cause of it:

On opening one hive I saw hundreds of slick, shiny, young bees that could not fly, on top of the frames, as I have seen them dragging out of the hive in the spring when taken out of the cellar. On examination I found that they were queenless, with nothing but a little drone-brood in the hive. Oh, yes, I know Mr. Doolittle says it does not pay to re-queen, as nine times out of ten the queen will be superseded before she becomes unprofitable. That must be another case of location, as in this part of the country nine times out of ten she will *not*. H. J. CHAPMAN.
Dallas Co., Iowa, May 2.

Bad Weather for Bees.

The weather is bad. The temperature was at 74 degrees for a few hours on May 9; inside of an hour it fell 23 degrees, and the next morning the ground froze hard. This was the first warm spell in May. This weather has kept colonies reduced, as the bees would go out for pollen and never return.
HENRY ALLEY.
Essex Co., Mass., May 11.

Common Parsnip.

I send a plant which, in some years, furnishes quite a little honey. Some of my neighbors claim the plant is poisonous. What is its name? Is it poisonous to animal life?

Prof. C. L. Walton, of the Lake View High School, Chicago, reports as follows on the above:

The plant in question is the common parsnip, *Pastinaca sativa*, and belongs to the poisonous parsley family. To this family belong the very poisonous cowbane, fool's parsley, poison hemlock, etc. The beautiful harbinger-of-spring and the aromatic rooted sweet

Fire boxes surrounded with water. Make also Threshers, Horse Powers and Saw Mills. All fully described in our illustrated catalogue. Ask for it. Mailed free.

M. RUMELY CO., LA PORTE, IND.

Please mention Bee Journal when writing.

cies are also members of this same family.

I believe the common parsnip is not considered poisonous to any considerable extent, but rather quite harmless. The natural instinct of animals is usually sufficient to prevent disastrous results from eating poisonous weeds too freely.

Bees may visit a very poisonous plant with impunity, and bear away the precious nectar, while the same quantity of the sap of the plant would prove highly injurious.

Western Honey Crop for 1900.

The honey crop of Utah will not be up to the average. There will not be more than five counties that will ship out honey this year. About two-thirds of an average crop will be the limit. Many bees died last year, and the re-

A HANDY TOOL-HOLDER!

Sent by Express, for \$1.50; or with the Bee Journal one year—both for \$2.00.

Every Manufacturer, Miller, Carpenter, Cabinet Maker, Machinist, Wheelwright and Quarryman, Farmer, or any one using a grindstone, should have one of these Tool-Holders. One boy can do the work of two persons, and grind much faster, easier and with perfect accuracy. Will hold any kind of tool, from the smallest chisel to a draw shave or ax. Extra attachment for sharpening scythe blades included in the above price. The work is done without wetting the hands or soiling the clothes, as the water flows from the operator. It can be attached to any size stone for hand or steam power, is always ready for use, nothing to get out of order, and is absolutely worth 100 times its cost.

No farm is well-equipped unless it has a Tool-Holder. Pays for itself in a short time.

How to Use the Holder.

DIRECTIONS.—The Tool is fastened securely in the Holder by a set-screw and can be ground to any desired bevel by inserting the arm of the Holder into a higher or lower notch of the standard. While turning the crank with the right hand, the left rests on an steady the Holder; the Tool is moved to the right or left across the stone, or examined while grinding, as readily and in the same way as if held in the hands.

For grinding Round-Edge Tools, the holes in the standard are used instead of the notches.

The Bee-Keeper's Guide
Or, Manual of the Apiary,
—BY—
PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipt, or his library complete, without THE BEE-KEEPERS' GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,
118 Michigan Street, CHICAGO, ILL.

\$5.00 per month will pay for medical treatment for any reader of the American Bee Journal. This offer is good for 3 months ONLY—from May 1 to Aug. 1. Dr. Peiro makes this special offer to test the virtue of small price for best medical services. Reply AT ONCE.

FREE OX-BLOOD TABLETS for thin blood people. — Nervousness, Indigestion — Rheumatism—Female Disease—Brain Food. A SURE CURE.....

This preparation contains in a concentrated form the active principles of healthy bullock's blood combined with the most valuable nerve, brain, blood and flesh producing drugs known to the practicing fraternity.

Greatest discovery of the age for suffering people. Less than a year since first put in use, and thousands are being cured every day. To convince you we give a 3 weeks' treatment free—all we ask is for you to send 10 cents to pay postage on sending it. This is safer than paying a doctor \$25 to experiment on you. **3 weeks' treatment sent free on receipt of 10 cts. in stamps.**

"I wish to say to you that after many long months of suffering and a broken-down system from the effects of child-bed fever, and at a very large expense with different physicians, and after using 26 bottles of patent medicines and no relief, my husband was compelled to give a mortgage on our home to send me to a hospital, where I still suffered and no relief. I was induced to try your three weeks' treatment of Ox-Blood Tablets, and gained so much in the three weeks that I consented to continue the treatment with a 50c box. They have taken all the pain away. I have gained wonderfully in flesh, and feel as if I had never been sick a day in my life. I advise all weak women to try Ox-Blood Tablets and get the same results I have." **MRS. F. G. EDWARDS,** Clarinda, Iowa.
50 cts. a box or 6 for \$2.50. Address, **W. A. HENDERSON CO.**

The **BEST FAMILY TRADE** in Honey and Maple Syrup in U. S. A. Best Clover and Basswood Honey was sold for 25 cents a pound past winter. Residence telephone connecting with 5,000 other residence 'phones. Personal introduction given to about 2,000 patrons. Refer to Editor of American Bee Journal. Address, X Y Z, care American Bee Journal.

sult will tell on this year's product. Bees have generally wintered well, and a superior grade of honey may be looked for. Idaho, Nevada, and Southern California will not have enough honey to supply their local markets; while Colorado will produce about the same amount as last year. April was severe on Colorado bee-keepers, and Utah had but little pleasant weather during that month. Tho stormy and windy, the weather was not as cold as is usual here.

The general outlook for the West is certainly not any more favorable than last year, for a fair honey crop.

GEO. E. DUDLEY,
Utah County, Utah, May 14.

Honey-Flow Commenced.

Our honey-flow commenced about two weeks ago, and we have taken some honey. I am experimenting this season with the plain sections and fence separators. The honey in them is fancy and white.

The American Bee Journal's weekly visits are always welcome. The latest issue for May 10 is especially full of "good things."

W. T. STEPHENSON,
Massac Co., Ill., May 10.

More About Belgian Hares.

I perused with great interest the article on Belgian hares by Prof. Cook, on page 292, and as a breeder of two years' experience, I agree in the main with the remarks therein made, with one exception, viz.: He says the Belgian hare is "bulky, fat, and logy." Now, I would like to know where Prof. Cook saw hares answering to that description. And is it a fact, as often hinted, that California is in the lead as far as numbers go? She is not in quality, for I have not seen any true Belgian

Yellow Sweet Clover Seed

WE HAVE IT AT LAST!

We have finally succeeded in getting a SMALL quantity of the seed of the **YELLOW** variety of sweet clover. This kind blooms from two to four weeks earlier than the common or white variety of sweet clover. It also grows much shorter, only about two feet in height. It is as much visited by the bees as the white, and usually comes into bloom ahead of white clover and basswood. We offer the seed as a premium

A QUARTER POUND FOR SENDING ONE NEW SUBSCRIPTION.

So long as it lasts, we will mail a quarter pound of the seed to a regular paid-up subscriber who sends us ONE NEW subscriber for the American Bee Journal one year, with \$1.00; or ¼ pound by mail for 30 cents.

We have been trying for years to secure this seed, and finally succeeded in getting it. It is new seed, gathered last season by an old personal friend of ours, so we know it is all right. But we have only a small supply. When nearly out we will mention it.

hares that those terms, even in the broadest sense, could be applied to; in fact, quite to the contrary, they are slim, slick, and racy. Why, 20 points out of a possible 100 in the standard are applied to shape, the sections of which read as follows:

"SHAPE—Body long, thin, well tucked up flank, and well ribbed up; back slightly arched; loins well rounded, not choppy; head rather lengthy; muscular chest; tail straight, and all together possessing a racy appearance.

"SIZE (5 points)—About 8 pounds.

"CONDITION (5 points)—Not fat, but firm like a race-horse."

As regards logy, I would like to see a kinoscope reproduction of Prof. Cook catching one in a building 12 feet square; it makes me smile to think of it; I've been there.

Some of the readers may think the high prices stated are far-fetched. I know of three hares in Prof. Cook's vicinity that could not be bought for \$500, and the owner of "Fashoda" refused an offer of \$1,000 for him.

I hope nothing of the above will give Prof. Cook offense, as I do not so intend it.

BEE-BOOKS

SENT POSTPAID BY

George W. York & Co. 118 Mich. St. Chicago.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—This nicely illustrated, contains 160 pages, beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers, \$1.00.

Bienen-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Bienenzucht und Honiggewinnung, nach der neuesten methode (German) by J. F. Eggers.—This book gives the latest and most approved methods of bee-keeping in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cts.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cts.

Foul Brood Treatment, by Prof. F. R. Chesshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 20 cents.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about Poultry Business. 64 pages. Price, 20 cents.

BY RETURN MAIL.

Golden Beauty Italian Queens, Reared from imported mothers.

Untested, 50 cts.; 12 Untested, \$5.50; Tested, \$1.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, April 19.—Market is well cleared of white comb honey; a little choice has sold recently at 16c, but dark and mixt goods are slow of sale. Extracted, white, 8@9c; amber, 7@8c; dark, 6@7c, according to quality and package. Beeswax in good demand at 28c.

R. A. BURNETT & Co.

CINCINNATI, March 3.—There is some demand for extracted honey from manufacturers at 7@7 1/2c for amber and Southern; clover, 8@8 1/2c. Comb honey is selling firm at 14@16c in a small way. Beeswax, 25@27c.

C. H. W. WEBER,

Successor to Chas. F. Muth & Son and A. Muth.

BOSTON, March 9.—Our honey market is showing some signs of lower prices, altho the stock on hand is not large. At the same time prices are so much higher than previous years that the trade have taken it very slowly and the results are that the holders are willing to range prices quite a little in order to move stock on hand. Prices range: Fancy white, 17@18c; No. 1, 15@16c; amber, 10@12c; buckwheat almost unsalable. Extracted, best white California, 8 1/2c.

BLAKE, SCOTT & LEE.

KANSAS CITY, May 9.—We quote: No. 1 white comb, 14@15c; No. 1 amber, 13@14c; No. 2 white and amber, 13@13 1/2c. Extracted, white, 7 1/2@8c; amber, 7c. Beeswax, 22@25c.

The receipts and stock of honey on hand are light; demand fair. C. C. CLEMONS & Co.

DETROIT, Apr. 23.—Fancy white comb, 15@16c; No. 1, white, 14@15c; amber and dark, 10@12c. Demand and supply both limited. Extracted, white, 7@7 1/2c; amber and dark, 5@6c. Beeswax, 26@27c.

M. H. HUNT & SON.

BUFFALO, April 20.—For strictly fancy white one-pound comb honey we are getting 16@17c. Any grade sells high—10@15c, as to grade.

BATTERSON & Co.

NEW YORK, April 9.—Market is practically bare of comb honey of all description. Little lots arrive here and there and sell readily at from 10@11c for buckwheat and 12@15c for white, according to quality and style of package. The market is well supplied with extracted, which we think, however, will be moved before the new crop arrives. Beeswax is in good demand at from 27c to 29c per pound.

HILDRETH & SEGELKEN.

SAN FRANCISCO, Apr. 25.—White comb, 11 1/2@12 1/2c; amber, 8@10c. Extracted, white, 7 1/2@8c; light amber, 7@7 1/2c; amber, 5@5 1/2c; Beeswax, 26@27c.

Small quantities of new crop have been received, but not enough has been yet done in the same to clearly define values. Current quotations would not likely be sustained under anything like free offerings. The yield will undoubtedly prove light, and the market shows a generally firm tone.

OMAHA, Mar. 13.—Demand shows some improvement in January, having been much more active, but as anticipated there is no advance in prices. Market remains steady at 14@14 1/2c for fancy white comb and 8 1/2c for white extracted. The latter is pretty well cleaned up along the Missouri River, and it looks as if there would be some shortage before another crop comes in. From present appearances there is about enough comb honey to go around at the present prices, hence we look for no particular change in values.

DR. MILLER'S

Honey Queens

One Untested Queen Free as a Premium for sending ONE New Subscriber to the American Bee Journal for one year.

We have been fortunate in making an arrangement with DR. C. C. MILLER—the well-known honey-specialist—to rear queens EXCLUSIVELY FOR US DURING THE

SEASON OF 1900. These Queens will be mailed in rotation, beginning about June 1, so "first come first served." We are ready to book orders now.

The Queens Dr. Miller will send out on our orders will be precisely the same as those he rears for his own use, so of course they will be from his best stock. His best colony in 1899 had a queen reared in 1898; May 5, 1899, it had brood in 4 frames, and he gave it at that time a frame of brood without bees. It had no other help, but May 25 a frame of brood with adhering bees was taken from it, and the same thing was repeated June 3, leaving it at that time 5 frames of brood. It stored 178 sections of honey, weighing 159 pounds (and that after July 20, in a poor season), being 2½ times the average yield of all his colonies. A point of importance is the fact this colony did not swarm, and an inspection every week or 10 days showed that at no time during the entire season was there even so much as an egg in a queen-cell. Dr. Miller expects to rear queens from this one during the coming summer.

The demand nowadays is for BEES THAT GET THE HONEY when there is any to get, and Dr. Miller has such bees. You will want to have a queen from his best, we are sure, even if she is not pure Italian.

Do not send any orders to Dr. Miller, as all orders MUST come thru us, according to our agreement.

Remember, send us \$1.00 for ONE NEW SUBSCRIBER to the American Bee Journal for one year, and YOU will get ONE OF DR. MILLER'S UNTESTED HONEY-QUEENS FREE AS A PREMIUM. This offer is made only to our present regular subscribers. Orders for queens to be filled in rotation, beginning about June 1st.

Address all orders to GEORGE W. YORK & CO., 118 Michigan Street, CHICAGO, ILL.

CONTRIBUTED ARTICLES

Natural or Artificial Swarms—Which ?

BY C. P. DADANT.

THIS question, asked by a correspondent—"Which are the better, natural or artificial swarms?"—is a rather complex one, and the answer depends upon conditions to be decided by the questioner. If you desire to buy swarms of bees, I will say by all means buy natural swarms, and the earlier the better. The very best swarms are those that are hived early, mainly because they are the offspring of the very best colonies, or of good colonies that have found themselves in exceptional conditions favoring the production of brood. An early swarm of good strength means a good breeding-queen, and, as she goes with the swarm, she is secured by the purchaser of the swarm.

When I speak of an early swarm, I mean of course a natural swarm, caused by the overcrowding of the hive, and not a deserting swarm, which may be leaving the hive for want of food, or owing to distressing conditions. Practical bee-keepers discriminate at a glance between the two, but many beginners are deceived. A natural swarm issues only in a good honey-producing time, while a deserting colony absconds usually during a shortage of food. The one is always large, the other nearly always small. The one goes with a good supply of food, the other is on the verge of starvation, and I have seen the bees of a deserting colony in summer drop from the cluster from mere exhaustion.

A good early natural swarm hived on full sheets of foundation, or, still better, on full combs from deceased colonies, may, in a good year, prove as profitable as a producer of honey as the colony from which it issued. Instances are plentiful of swarms filling their hive and swarming again, especially in small hives.

But natural swarms are not always best. It very often happens that their queen is old, that she has very nearly attained the age of barrenness, and, within a very few months her colony may decrease and perhaps dwindle to nothing owing to her old age. The bees usually attend to the replacing of the queen by rearing a younger one, when they notice that their mother is lessening her breeding. But sometimes also this is deferred until it is too late, and the end of the season finds them in an abnormal condition with a worthless queen and no brood from which to rear another. Most of the winter losses of queens in otherwise healthy-appearing colonies are due to this.

Personally I prefer artificial swarming (or dividing) to natural swarming for the increase of colonies in an

apiary, for a number of reasons. I hold that the best colonies for honey-production are the very ones that would swarm most, if circumstances are such as to induce natural swarming. Therefore, by allowing your bees to swarm, or by causing them to swarm, you lose the best of your chances for a honey harvest. It is true that very often, especially with small hives, it is impossible to prevent bees from swarming during a good honey-flow. For such a condition there is no remedy unless you want the swarms, and begin by dividing the colonies early enough to avoid the swarming-fever. In this case you sacrifice the crop for an increase. But if only a moderate increase is wanted, and honey is expected, the swarming may be limited to a certain extent even with small hives, by making all the circumstances as favorable as possible to the comfort of the bees. Plenty of space in the hive, a good, free ventilation

Bitter Sweet.—(See page 345.)

(From the painting by V. Tojetti.)

thru a wide and deep entrance; a good shade during the hot hours of the day, and little or no drone-brood allowed in the hive—these arrangements will go a long way towards preventing natural swarming, even from the very strongest colonies, and a fair crop of honey will be the result. If there are swarms they will be good ones.

But some apiarists I have seen, who, in order to procure an increase, purposely leave off the supers, confine the bees to the brood apartment, and try by all means to induce the casting of swarms, thinking this the best way of securing a profitable addition to their apiary. It would be much better if they avoided the annoyance of having to watch their colonies, and to hive the swarms by making artificial swarms.

Divisions may be made in many different ways, and each apiarist with a little experience has his own method. But the *sine qua non* of successful dividing is in the supply of good, healthy queens from the very best stock. It is in this item that there is a most decided advantage in artificial swarming over natural swarming, for, with a little care, you can rear your queens from the very best mothers of the very best variety, and secure uniformity, prolificness and purity, and, altho perfection is never to be attained, and inferior stock will ever be found, yet the careful selection of breeders is the surest way for advancement in the breeding of bees, as well as in raising chickens or any of our domestic animals.

It is always best, if you wish a careful selection, to rear your own queens, and to rear them as much as possible in full colonies; but I cannot agree with those who hold that queens reared in nuclei are worthless. If the apiarist is careful to start his queen-cells in a good colony they may be hatch in nuclei without danger, provided these nuclei are supplied with bees enough to keep warm all the space they are given. We used to rear queens by the hundreds every year, and all our apiaries have been stocked at different times with such queens, and our experience in honey-production warrants us in saying good queens may be reared, and just as good ones are reared, by artificial methods as by natural swarming. And why should they not? Is the son of the laboring-man born in a hut, or in the fifth story of a tenement house, less sturdy, less able to work and produce, or less able to reproduce his race than the pampered and overfed son of wealth? Descent has the greatest influence on generations, but the children usually inherit their ancestors' ability for work, strength and vigor, even when reared under the most unfavorable circumstances.

Hancock Co., Ill.

The Relation of Honey-Bees to Practical Horticulture.

(From Proceedings of the Columbus (Ohio) Horticultural Society for 1899.)

BY PROF. WILLIAM R. LAZENBY.

TO what extent the pollination of the blossoms of our more common cultivated fruits is dependent upon the honey-bee is a question of practical interest to every horticulturist.

During each spring for several years past a series of observations bearing on this question have been made by the Horticultural Department of the Ohio State University, and the results of these observations may be briefly summarized as follows:

The apricot, which is frequently planted in sheltered positions having a warm exposure, is usually the first fruit-tree to blossom in Central Ohio, and honey-bees have occasionally been seen working quite freely upon these trees as early as April 1st. Some years, however, it is as late as April 20th before the blossoms appear. Closely following the apricot are some of our early-blooming plums, and where different varieties of this fruit are grown, the period of blossoming is quite extended. For example, during the past season in our University garden, plum trees were visited by honey-bees from April 16th until May 10th, inclusive, a period of 25 days; the Japanese plums being the first, and some of the European varieties the latest in blooming. This length of period is only possible where several distinct varieties or groups of plums are grown. For any one variety or group the season is much shorter. The pollen-collecting and honey-gathering period is rarely more than five or six days for an individual tree. If two or three days of this time are cloudy, rainy or windy, the chances of pollination are lessened.

Pears and peaches soon follow the apricots and the earliest plums, and these in turn are closely followed by the

cherries, the early sweet being first, and the early sour a little later. Apples come into bloom last among our common tree fruits, but their period of blooming, as a class, is somewhat longer than that of the peach, plum or cherry.

Arranging the fruits grown in this latitude according to the date of blossoming, beginning with the earliest, the sequence would be apricots, plums, sweet cherries, sour cherries, pears, peaches and apples.

Arranging them according to the frequency of the visitation of the honey-bees, the sequence would be plums, cherries, apples, peaches and pears, and this is based upon the collection of pollen rather than honey. In the way of honey-production I would place apples first, then cherries, plums, peaches and pears.

The following tabulations show the activity of bees at certain periods, the comparative number collecting pollen and honey, the approximate number of flowers visited, the weights of bees, and the weights of the loads of honey and pollen that were carried at certain dates:

TABLE I.—Number of bees leaving and returning to hive at different intervals, and number collecting pollen and honey, May 3, 1899—plum and cherry trees in height of bloom.

TIME.	Number of Hive.	Outgoing Workers.		Returning Workers.			
		Number leaving in 30 minutes.	Number per minute.	Number returned in 30 minutes.	Number per minute.	Loaded with Pollen.	Loaded with Honey.
8:30 to 9:00 A.M.	1	1050	35.0	900	30.0	640	260
	2	1206	40.2	930	31.0	626	304
11:30 to 12:00 M.	1	1200	40.0	1248	41.6	240	1008
	2	1452	48.4	1542	51.4	178	1354
2:30 to 3:00 P.M.	1	2340	78.0	2424	80.8	75	2349
	2	2530	84.3	2862	95.4	57	2805
<i>May 7, Apple-Trees in Full Bloom.</i>							
8:30 to 9:00 A.M.	1	696	23.2	702	23.4	164	538
	2	1140	38.0	825	27.5	606	219

It should be noted that in no instance were the bees counted as pollen-laden unless an appreciable amount of pollen could be seen in the pollen-baskets.

Careful and repeated observations made on different days and different hours of the day have clearly shown that when the weather is pleasant, and bees numerous, a very large percent of the blossoms of some of our fruit-plants are visited by one or more bees. In every case coming under my own observation, I found plums and cherries visited the most frequently of the tree fruits. Altho peaches have a very showy and apparently attractive flower, and the pear-blossom a marked odor, bees do not visit them in anything like the number that they do the plum and cherry. Apples are visited more freely than pears and peaches, but not so freely as plums or cherries.

Bees do not appear to be attracted by the flowers of the common garden currant, but with the gooseberry they seem a little more familiar. Raspberries and blackberries are visited freely, especially the red raspberry. During a single favorable hour I have seen nearly every blossom on an average-sized stool of a Turner raspberry visited or touched by bees.

Strawberries are infrequently visited by bees. Upon several occasions I have carefully observed good-sized strawberry plantations when in bloom, and can count upon my fingers the bees I have actually seen in contact with the flowers. They are often seen flying over the strawberry-plants, appearing to have been attracted by the early and rather showy flowers, but they rarely alight upon them, at least on our own grounds.

During the height of the strawberry-bloom I have seen dozens of bees upon the flowers of the weeds that were among the strawberry-plants, but seldom one on the flowers of the strawberry.

If I were to mark the different common fruit-plants on a scale of 10, showing the comparative number of flowers of each visited by honey-bees, as observed on our own

grounds, and under essentially the same conditions, the grading would be as follows:

Red raspberry, 9.5.	Gooseberry, 4.5.
Blackberry, 9.	Peach, 3.5.
Plum, 9.	Pear, 3.
Cherry, 8.5.	Currant, 2.
Blackcap raspberry, 8.	Strawberry, 1.
Apple, 6.	

On the morning of May 17th, between the hours of 8:30 and 9:30, 16 bees were caught singly as they came from the hive and were immediately killed by means of a cyanide bottle. Each bee was weighed separately, and the results are given in the following table:

TABLE II.—Giving weights of outgoing bees.

No.	Grams.	No.	Grams.
1.....	.092	9.....	.083
2.....	.071	10.....	.071
3.....	.075	11.....	.075
4.....	.075	12.....	.075
5.....	.078	13.....	.073
6.....	.083	14.....	.081
7.....	.078	15.....	.087
8.....	.091	16.....	.081
Total weight.....	1.267 grams.	Average weight.....	.079 grams.

It will be seen that the lightest bee weighed .071 of a gram, and the heaviest .092 of a gram, the difference between the extremes being .021 of a gram. The average of the 16 weighed is .079 of a gram, or 1.219 grains. According to this average it would require in round numbers 5,750 bees to weigh a pound. A prosperous colony of 30,000 workers would weigh at this rate about 5 1/5 pounds.

On the morning of May 19th, between the hours of 8:30 and 9:00, 16 bees were caught singly as they entered the hive. None were taken except those that bore every evidence of being honey-collectors. These bees were immediately killed and weighed separately as before. The results are shown in the following table:

TABLE III.—Giving weights of honey-collecting bees.

No.	Grams.	No.	Grams.
1.....	.122	9.....	.073
2.....	.083	10.....	.086
3.....	.116	11.....	.081
4.....	.085	12.....	.122
5.....	.105	13.....	.086
6.....	.100	14.....	.096
7.....	.082	15.....	.082
8.....	.114	16.....	.078
Total weight.....	1.511 grams.	Average weight.....	.094 grams.

It is shown by the table that the honey-loads of bees are quite variable, and it is probable that their efficiency as honey-collectors is like the efficiency of men as money-makers—some accumulating great stores, while others, apparently as industrious, have little or nothing to show for their labor.

If we take the average weight of the out-going bee (.079 of a gram), and deduct this from the heaviest honey-laden bee, the weight of which is .122 of a gram, we have a difference of .043 of a gram. This means that a bee that is an energetic and capable honey-collector returns to the hive considerably more than one-half heavier than when it begins its collecting trip.

Deducting the average weight of the out-going bee (.079 of a gram) from the average weight of the in-coming honey-laden bee, .094 of a gram, leaves .022 of a gram as the normal or average weight of the honey-load. This is 27 percent of the average weight of a bee, or a little more than one-fourth of its own weight.

On May 26th, between the hours of 8:30 and 9:00 a.m., 12 pollen-laden bees were taken just as they were entering the hive. Their individual weights were as follows:

TABLE IV.—Giving weights of pollen-laden bees.

No.	Grams.	No.	Grams.
1.....	.091	7.....	.080
2.....	.091	8.....	.092
3.....	.077	9.....	.091
4.....	.081	10.....	.080
5.....	.098	11.....	.081
6.....	.075	12.....	.079
Total weight.....	1.019 grams.	Average weight.....	.085 grams.

Taking the average weight of the out-going bee, which we found to be .079 of a gram, and deducting this from the pollen-laden bee, we have .006 of a gram as the average weight of a load of pollen. This is about 7.5 percent of the average weight of the bee.

Taking the average weight from the weight of the heaviest laden bee, we find that the pollen weighs something over 16 percent of the weight of the normal bee. In other words, a bee may carry about one-sixth of its weight of pollen, altho the average load is certainly much less.

The statement is frequently made that bees collect honey and pollen at the same time. My observations lead me to believe that this is not the case. I have killed scores of pollen-bearing bees just as they were entering the hive, and have never found one loaded with more honey than one is likely to find in any worker-bee when it leaves the hive. The bee acts upon the maxim that "a little provender hinders no man," and almost invariably takes a lunch, or carries a small supply of food when starting out on a collecting-trip. Altho the pollen-gatherers, as we have seen, do the light carrying work of the hive, I am firmly convinced that they are of equal if not of greater service in the work of pollination than the honey-gatherers.

Painstaking counting under many different circumstances shows that for the same time, and speaking with reference to our common fruit-plants, the pollen-gatherer visits from three to five times as many flowers in a given time as the honey-collector.

The observations I have briefly recorded, while not important in themselves, may stimulate others to investigations of equal interests and profit to apiarists and horticulturists.

No. 10.—Our Helpers—How to Get the Most Out of Them.

BY "OLD GRIMES."

AS to human beings, the most of us are like the magnet, either positive or negative, and in varying degrees—some attract and some repel. In every-day life Old Grimes meets people he attracts and others that he repels, and sometimes he thinks that those he repels are in the majority, and this subtle force is felt not only between us and the stranger, but with our own blood in our own family. To get the most out of the growing helpers in our own family there should be the utmost confidence between parents and children, there should be no stage secrets, and no skeletons in the closet. The word fitly spoken, with the heart and not the lips, in the way of advice, commendation, sympathy, or as an incentive to better things, has saved many a young person, while the need of it has sent many to the pit.

Old Grimes gets along fairly well with his helpers, and especially with our boys there has always been harmony. It is well to give the boys and the girls a share in the proceeds of the apiary, and a liberal share at that. If the boy confides in you, and makes a good use of his share, it can be profitably increased the next year, for your boy's welfare is yours. If he does not make good use of it don't discourage him and harden his heart by cutting off his share, but do not increase it until he does make a good use of it, then there will always be an incentive to better deeds.

The Grimes family have generally been able to do their own work, but sometimes when the older boys were called away to an early term in the academy, an outsider was called to fill their places for a few weeks. We always take a new man upon probation, for the bee-business calls for certain traits possess by but few, but in the first place we have no use for a drunkard or for a person who uses profane or filthy language; this settled, the next consideration is our status toward each other. If we are both of the kind that repel, the helper will not stay long, and he will probably go away with not a very good opinion of us. If, on the contrary, we attract each other, we get along finely for awhile, and if he readily takes to the management of bees we may get along one season together, but we are so chummy that it is not long before the helper has an idea that he owns the apiary and takes a fatherly interest in the owner; when that trait develops, the helper would better go.

If the conditions are just right between us, there are many features that arise during the probationary period that try the patience. Perhaps he is careless and always breaking things, or leaving things where it requires half an hour to search for them, leaving the doors open, putting supers or covers on askew, or the honey runs slow from the tank, and he slips away to do something else and forgets the tank, but by and by suddenly thinks of it, and comes around with a rush and finds the receptacle full and 30 or 40 pounds upon the floor. And right here Old Grimes wishes to say

that he has some sympathy for the helper, for he has done the same trick himself—and pray what bee-keeper has not?

By the exercise of charity and patience, which virtues every bee-keeper should have a good amount of, we can get along with the erring one, and finally make a very good bee-keeper of him. Next to the sin of drunkenness in a helper is the one who gives us eye service only—we do not need that kind. We are not so particular as to expect a man to take the interest that he would in his own property, but there is an interest just as valuable to us, and that is when the helper desires to get as much out of the apiary as any one else ever did, and leave it in good condition. When such a man is found—and we are happy to say there are many of them—stick to him, hire him every year if you can, pay him well, take an interest in his welfare, and when he sets up in business for himself don't forget him.

The ever-faithful horse is a helper not to be overlooked, and for the movement of bees and honey the characteristics must be docility and patience. A horse that shies is always a source of anxiety, and is liable to run the wagon into the ditch, and a consequent tip-over, and a balky horse is an abomination not to be endured. Two horses are better than one, and the business should be large enough to enable us to employ them. We like to be upon good terms with our horses as well as with our other helpers; we like to feed them well, and groom them, and when upon the road use judgment in loading and driving them. Some drivers can get a great deal more out of a team and not injure them than others can who abuse their horses.

A horse will seldom learn to take bee-stings with equanimity—the dear animals are used to being bitten with flies all day and mosquitoes all night, but when a bee punctures them with its business-end a deadly, vindictive enemy is recognized, and the horse becomes frenzied with fright. Our first care is to have gentle bees, and to manipulate them so as to let this trait develop to the utmost. In the early spring or autumn we can drive the team near the apiary with safety, but in the height of the honey season it is well to keep proper distance, or to come near only in the night. Where much hauling is done large blankets should be provided, and when upon the road it is handy to have the whiffletrees so constructed that they can be detach at a moment's notice; these precautions, if heeded, will in many instances save our four-footed helpers.

Recently there has entered into the life of our home circle a very quiet helper. When "Kate" is harnest and Joe is invited to get into the wagon to go to an out-apiary, he says, "No, pa, with my helper I will get there and have half of the work done before you get there;" and he generally does. What wonderful applications of mechanical principles we witness in these latter days—not only can the young man fly, as it were over the roads, but the old man can renew his age and race over the earth faster than he ever could in his youthful days. We can sit down to machines, and on machines do a great amount of work, and now we can sit down to walk and to run. Thanks to the bicycle, it is a pronounced helper in the apiary.

Hiving and Managing Swarms Advantageously.

BY C. DAVENPORT.

I HAVE before in these columns mentioned the fact that I largely practice hiving two swarms in one hive. These swarms may be either natural or artificial, or one may be a natural issue and the other artificial—it depends upon circumstances, but it is all practically the same thing, and the thought may have occurred to some who have not been engaged in our pursuit long, whether it pays to have two swarms together, and if more surplus can be secured in this way than if each swarm is allowed a separate hive. It undoubtedly pays with me, and I will endeavor to explain why. This will necessitate briefly describing my locality in respect to the time, character and duration of its honey-flows or yields, for upon these things or conditions—or, in other words, the locality largely determines the question of whether it pays to have two swarms in one hive, but in this case the word "locality" must be considered in a broad sense or view, for the conditions in some of the middle or even southern States might be similar enough in some respects to what we have here, to make the practice pay, while in other latitudes, even as far north as this, they might not.

As a usual thing the early spring flows here are sufficient to support brood-rearing, but after fruit-bloom, until white clover commenced to blossom, there used to be a short

spell during which it might be necessary to feed in order to have brood-rearing kept up as rapidly as it should at this time, but of late dandelion bloom has bridged the gap between fruit and clover bloom. This has nothing to do with the matter being discusst, but I mention it because it is, to me at least, very curious how rapidly this dandelion bloom has increased. There has always been some here, but nothing compared to what there is at present, and formerly it was about gone soon after fruit-bloom. Of late it has kept in blossom more or less all the fore part of the season, in fact it is becoming too much of a good thing, for I have had bees working on it at the same time white clover was yielding, and when it is mixt with clover honey it nearly ruins the latter, for it is dark, rank-tasting honey, fit only for brood-rearing, or to sell for manufacturing purposes.

The properties of the two plants are such as greatly to favor both being workt when they are in bloom at the same time, for white clover, as a rule, does not yield as well during the fore part of the day as it does the latter, and dandelion bloom yields and is at its best in the morning. Later the blossoms completely close up so that on low pasture lands here that may be literally yellow with its bloom in the forenoon, there may not be a single blossom to be seen in the afternoon.

Three years ago I extracted about 2,000 pounds of nearly pure dandelion honey before white clover commenced to yield. White clover usually commences to yield slowly about the first of June, basswood the first of July, and lasts about 10 days. This gives us a white honey-flow of about 40 days duration, tho the time this flow commences, as well as its length, may vary considerable, owing to the season or the failure of one or the other of its sources; but I can say in favor of my locality that in my time clover and basswood have never both failed the same season. At least 80 percent of what swarms I have are made or issue during the first three weeks of June.

I can imagine some are now saying, "You are away off, old man; you should have your swarming all done and out of the way before your main flow commences." This can not profitably be done here. The time previous to this, that is, the length of time between settled warm weather and the fore part of June, has not been sufficient so the colonies on an average will become populous enough to swarm sooner naturally, and so far as I understand it at present artificial swarming should not be performed until it is a necessity, in order to prevent natural swarming. Many of the strongest colonies might naturally swarm about the first of June, but my practice along towards the last of May is to take the combs of brood and young bees from the strongest colonies and exchange them with weaker colonies for empty combs, or those which contain no brood, and I consider that this pays, for it prevents a large percent of the swarming that would otherwise take place, or have to be done.

Now it will be noted that what swarms I have, taking an average, will have about 30 days or less in which to gather white honey. As it takes the eggs about 35 days to develop into field-bees, it will be seen that these swarms have not time to develop brood into field-bees to work on this white honey-flow, so the less brood they rear the more surplus white honey, for what brood they do rear is reared on this white honey; and another thing is, that with less brood to tend there is a larger force free for field-work.

Now, if two swarms are hived together in a hive the brood-nest of which is only as large as would be allowed if they were hived separately, only half the amount of brood can be reared that could be if they were each given a hive; and from long practical experience in the matter I know that taking one year with another I can here with swarms secure nearly, if not quite, as much again white honey by hiving two together; and I work for white honey regardless of increase; and also of amber and dark honey. Whether the practice would pay if one desired these things to be considered is another question.

When hiving two swarms in one hive, if small hives are used, two stories should be allowed for a brood-nest until they get well started to work; then the lower one can be removed and more surplus given in its place; for often two large swarms will not stay and commence work willingly in one small hive, no matter how many supers filled with sections are placed on top. They can be forced to stay, of course, but this forcing is often a difficult matter, and they may sulk away much valuable time before commencing work.

Another important thing which will apply to swarms hived either singly or together, is to keep the empty hives in a cool, airy place until needed. A swarm hived in a hive

that has been out in the hot sun is much more apt to desert, and after the swarms are hived their hives should be kept well shaded for a few days. The most satisfactory shade is obtained by the use of a shade-board, which is large enough to project over the hive six inches or more all around. But this board should not rest down flat on the hive-cover; if it does, and is dark colored, as they soon get to be when made from unpainted lumber, it may do more harm than good. Provided the cover is painted white, there should be an air-space of at least a half inch between the two.

With cool, well-shaded hives, and at first a brood-nest in proportion to the size of the swarms, I do not consider it necessary to raise the hive up from the bottom-board all around. I allow only the usual entrance in front, and place a queen-trap or entrance-guard on until they get well settled down to work. Of late it is very seldom that I have swarms attempt to desert, but I do not wish to run any risk with these big, double swarms, and when swarms desert they often leave without clustering.

With clipt queens zinc is not so necessary, but it might prevent a clipt queen being lost or destroyed by crawling into another hive, but when it is used, and there are a great number of drones with the swarm, it should be removed when they are anxious to get out. Then if it is replaced while they are having their flight, most of them will be shut out, and soon join the bees of other hives.

Southern Minnesota.

Devices for Use at Swarming-Time.

BY F. A. SNELL.

IN years past numerous contrivances have been gotten up by bee-keepers for catching swarms when they issued during swarming-time. These were much lauded by their inventors, who seemed, at the time, to think they had invented something that would be all that could be desired for the purpose intended. The various devices were tried for a few years, and all but two were dropt. These are Manum's swarm-catcher and Alley's drone and queen trap, which are now in use, and have proved of much practical value, and, it would seem, have come to stay.

Manum's swarm-catcher is used after the bees have clustered. The bees are allowed their own sweet will in coming forth from the parent hive, circle about and cluster where they please. The swarm-basket can be used on a rod, or rods, at the option of the apiarist. In our apiary we have rods of different length. The basket with its bail is in a moment detach from one rod and slip into the upper end of another. The length of rod should be such that the bee-keeper can reach the swarm when standing on the ground.

When the swarm is clustered the attendant takes the catcher, and throwing the basket-cover back, places it under the cluster, and by a slight upward movement dislodges the larger part of the swarm, which drops into the basket. The basket is given a little turn, so as to close the cover. The lower end of the rod is pushed into the ground, and two iron rods used as braces are also made firm at their lower ends in the ground, forming a tripod. The limb may be shaken by a rod or pole with a hook on it to slip over the limb, if at much height from the ground. The bees shaken off will soon all cluster on the outside of the basket. This swarm may be carried and shaken down at the entrance of any previously arranged hive, or, if other swarms are out, the first swarm may be left until the second one is caged in the swarm-basket. I find it advisable to have two or more swarm-catchers in readiness.

By using this device very much handling of ladders, and hard climbing, are saved, which saves the danger from the ladder slipping off a weak limb and giving one a fall.

We have one pole without the braces, and shorter, with which we take down swarms when only above one's head, as he stands upon the ground.

The catcher, as soon as the swarm is in the basket, or the larger portion of it, should be placed at once so the basket will be near where the swarm was clustered. This is important, as the bees when on the wing quickly cluster at this place, and would not join the caged bees when only a few feet away very readily; they cling to this clustering place with tenacity. When the catchers are used there need be no carrying of hives to where the swarms are clustered.

The above described device is worthy of a place in every apiary where the queen's wings are unclipt, and will pay its cost many times each season when much swarming occurs.

The Alley trap is used at the hive-entrance, and when a

swarm issues the queen in her attempt to leave with the swarm is trapt, and the swarm missing her will return to their old location. If the apiarist wishes increase he can, while the swarm is in the air, remove their hive and put an empty one in its place supplied with starters or full sheets of foundation in the brood-frames. The swarm on its return will enter the new hive, to which the trap should have been transferred; and, when nearly all are in, the queen is allowed to enter the hive, and the work of hiving the swarm is done.

For out-apiaries this trap will prevent effectually the loss of swarms, accompanied at least by old queens, during the owner's absence. On visiting the apiary the queen will be found in the trap, so arranged that she can not enter the hive if desired. The division of the colony can then be made if the apiarist so chooses, or the queen may be returned to the old hive after removing the queen-cells, which, if near the close of a good honey-flow, may end the desire to swarm for the season.

At the swarming-time these traps where used should be placed at the entrance of all hives having strong colonies that are likely to cast early swarms.

The two devices above-described have been well tested, and have been of value to many, and should be tried by all who do not clip their queen's wings. In our apiary we have tried other devices for catching swarms, only to throw them aside, but the above we have found valuable.

At the close of the swarming season the catchers should be housed, and, when thus cared for, will last many years. Carroll Co., Ill.

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Richards, Ohio.

INITIAL STAGES OF FOUL BROOD, ETC.

Our British friend, F. Gordon, on page 242, we thank for his suggestions that larvæ restless and turned wrong in the cells marks a mild initial stage of foul brood. Seems reasonable. But he must remember that we are getting a large assortment of diseases over here. He can hardly know but some of our new-fangled diseases also make larvæ restless in the cells sometimes. We will receive his saying that it takes three weeks or more for incipient foul brood to develop into malignant foul brood as a lively contribution to our stock of good guesses. And his experience that izar is not enough of a cure to cure a lot of colonies in a diseased apiary is in line with what our best authorities have been finding out about other cures.

ABOUT THAT CITY BEE-KEEPER.

"Urbanite" did well in his Chicago bee-keeping on the roof. Instructive to see that the non-swarming arrangements resulted in a swarm, and that the swarm was so kind as to come back in the course of an hour. And his vote that sweet clover honey is superb is a timely vote, even if not a conclusive one. Page 244.

HONEY-EXTRACTOR HISTORY AND HONORS.

That was rather a strange mistake of Gleanings in Bee-Culture—and we'uns—that Peabody was first to put an extractor on the American market (patent 1869) when Langstroth advertised one February, 1868. Probably it came about by Peabody advertising and selling freely, and Langstroth advertising and selling but little. M. M. Baldrige, by making and selling a geared extractor the year before the Peabody ungeared came out, seems to deserve an honorable mention. Page 245.

WONDERS OF PLANT ECONOMY AND GROWTH.

Yes, Prof. Cook, we have lots of ignorance to dissipate, and lots of wrong ideas to be disabused of, in the matter of plant growth. When I began the reading of your article, page 243, I had no distinct idea that the chlorophyll of leaves was ever, in the plant economy, used for anything. Thought it was like the paint on a house—put there for keeps. That an unhealthy plant looks yellow because it

gets its green used up, and is too feeble to make more, is a novel way of putting it. And how handy it is that starch and sugar and woody fiber are chemically similar and transmutable! But I believe the scientists do not tell us of a plant ever transmuting woody fiber *backward* into either of the others. The glucose-maker can do it—we'll play that the plant is too honest. How convenient the non-solubility of starch in cold water makes it for keeping supplies on hand for time of need! The solubility of sugar makes it difficult to keep—or perhaps the difficulty is rather in keeping it restrained to one locality. The sugar-cane keeps its reserves as sugar by filling all the cells of the stalk with it

VARIOUS METHODS OF LEARNING APICULTURE.

Mr. Whitney reminds me of that learn-to-swim individual who lay down on a big table and went thru the frog motions of arms and legs before going into the water. 'Spects swimming can be learned that way quite as well as apiculture. Page 245.

APIARY FENCED IN WITH EVERGREENS.

We sometimes forget a lesser advantage in contemplating a greater one. Most of us have in mind the great advantage of having an apiary fenced in by big evergreens during a windy winter—but those windy spring days when we want to open hives, and prudence bids us abstain, or imprudence makes us go ahead and realize more harm than the operations do of good—evergreens would be very desirable then also. Moreover, we often experience discomfort and bother from wind when no serious damage to brood or bees follows, yet it would be nice to be relieved of the bother. Page 250.

TOO MUCH SOAP IN RENDERING BEESWAX.

It seems strange that Mrs. Woodmansee, page 251, should with worthy intent to have things as nice as possible, get so much soap in her beeswax as to spoil it. Am tempted to wonder if there was not an unnoticed something else that did most of the mischief. Mush instead of a cake of wax sometimes results when there is too much honey in the refuse; but in that case the wax is not really damaged at all, only put into a state from which it is some bother to recover it.

MR. STOLLEY'S SHED-APIARY.

Mr. Stolley, your apiary, page 257, seems to be the best looking one of its kind that has been presented to us lately. Not a very common kind is the bee-house with one side of the house left off. You omitted to state how you get at the hives to manipulate them—whether by removing some of the nuclei, or by slipping a hive to the rear, or by thrusting forward from the rear one's nose and paws. Storms can drive under your structure somewhat worse than with the lower and less "scrumptious" little sheds we have contemplated heretofore. Brilliant idea to utilize good-looking and ill-behaving hives as roof ornaments—only perhaps some brethern, of a particular turn of mind, would not enjoy looking upon their own costly foolishness so constantly.

NON-SEPARATED HONEY.

"Control all the necessary elements, and you can have fair sections of honey without separators, but you *can not* control all"—that is a lucid way of putting it, Comrade Aikin. And the man who ships cases of sections which can not be rearranged hit or miss without bumping is second cousin to the man who ships unripe extracted honey—destroys other people's market, as well as his own, rather than fulfill the conditions of furnishing a really first-class article—too lazy—and greedy. Thunder and lightning in store for you, Mr. A., as a reward for your article on page 259; but you are right, let 'er thunder!

A "QUEENLY" COMMENT.

Your best girl, if rescued from the ruins of a house wreckt by a tornado, might not look her best just then—and you would not think of demanding it—but when a queen goes thru the round of Uncle Sam's mail-bag cyclone, straightway you remark that she looks small, unshapely, dark and unpromising generally. 'Spects Henry Alley is right, on page 261, that we should hold our maledictory "hosses" until the poor queen has had time to brush up and look in the glass.

PUTTING ON SUPERS—SWARMING.

"Put on supers ten days after you see the first clover blossom." Strikes me, Dr. Miller, that is a helpful general maxim for clover territory, if not ridden too hard. Not quite sure I like those big hatcheries five stories high. As

in other baby-farms, I fear there is much infantile death that comes nigh unto murder. But I *am* quite sure I don't like swarm-controlling beatitudes when they begin with the words, "When a swarm issues and returns." Page 262.

REMOVING QUEENS IN SEPTEMBER.

George W. Riker takes away the queens of strong colonies in September to keep drones for the early spring. I think that careful observation and report as to what proportion of the drones survive the winter, and when the last finally die, would be acceptable information to some of us. Page 268.

BEES AND STRAWBERRY-BLOSSOMS.

In these papers heretofore I have spoken quite decidedly about the rarity of bees visiting strawberry-bloom. Perhaps I would better begin eating my words before somebody heaves bricks. This year during cold weather in fruit-bloom bees visited strawberries quite persistently. Perhaps if I had lookt as carefully as I have this year I would have seen it before. Also, I have seen several species of little insects that work at the same business. Some of these are sized about right to crawl under the stamens and get pollen on their backs. Somewhat to my surprise most of these little chaps are also bees, or insects closely related to the bees. One species seems to be the familiar sweat-bee that visits our sweaty arms and necks, and gives us a tiny sting when we crowd him. The plentiest one is black and very spry, and the "cut of his jib" almost tempts one to call him a winged ant.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Increase by Dividing.

I have one colony and would like to make two out of it. My idea is to take a few of the frames with brood and fill with frames with foundation the remainder of the hive, and put in a new queen. Is my idea right? NEW YORK.

ANSWER.—Your plan will work. Keep in mind that the part put on the new stand will lose all its field-bees, as they will return to the old stand. So you must put most of the bees on the new stand, if you want anything like equal strength in the two parts.

Wood Splints Instead of Wires in Frames.

A couple of months ago splints were recommended instead of wires, and again recently appeared an answer to a subscriber giving some further directions, but I am still at sea as to how to use them. I judged first that they were to be the length of the frame, so as to fit in between the end-pieces; that is, they were to lie horizontally; but later the directions were that they are to be cut an eighth of an inch shorter, and, I would judge, to stand perpendicularly, but it didn't say so; nor was it told how they are to be fastened in, whether by imbedding slightly into the comb foundation, or by sticking with a little wax.

Again, I am puzzled to know why they should be cut $\frac{1}{8}$ inch shorter if they are to be set in perpendicularly; in fact, the instructions are entirely too meagre, or else my brain is too dull. A great deal of the value of many good things is lost because of the way in which they are written.

ONTARIO.

ANSWER.—It is an unfortunate thing that room is limited in these columns; for in spite of trying to condense, it sometimes happens that the printer has hardly room enough for all the answers in this department. Again it happens that when a thing is once given in full it will hardly do to repeat it in full within a short time. Still again, when a

question is asked, if that question is fully answered, you ought not to be too hard on the one who gives the answer because he fails to tell some things you want to know about but have not taken the trouble to ask. On page 70 of this journal for Feb. 2, 1899, you will find full instructions in the matter of foundation-splints, the instructions being as follows:

"The splints or little sticks are 1-16 square, and $\frac{1}{8}$ -inch shorter than the depth of the frame, inside measure. The paraphernalia needed to do the work are: A pair of pliers to lift the sticks out of the melted wax, a board to use as a presser, $\frac{1}{4}$ -inch shorter than the inside depth of the frame, 3 or 4 inches wide and $\frac{1}{4}$ or $\frac{3}{8}$ inch thick, with one edge kept well soaked in water so the wax will not stick to it, and a board $\frac{3}{8}$ -inch thick just large enough to slip loosely inside the frame, having strips nailed on the sides as stops so that the foundation will rest on the board while the frame rests on the stops. Put a bunch of the sticks in the heated wax. They will froth up at first because of the air and moisture in the wood. In a little while that will be cooked out and the wax will settle down clear. Then with the pliers lift a stick out of the wax and lay it on the foundation, and with the wet edge of the presser press it into the foundation. Being hot it will melt its way into the foundation, and if pressed too hard or too long may cut the foundation in two. A little experience will enable you to do it right. It is perhaps well to heat the wax little more than enough to keep it melted, for if too hot there will not be so good a coating of wax on it, and if you use a stick not coated with wax at all the bees will dig out the stick. The sticks are put perpendicularly, one about an inch from each end, one in the middle and one on each side of the middle one-half way between it and the end one."

The only thing not answered therein that you ask is the reason for having the splints $\frac{1}{8}$ -inch shorter than the depth of the frame inside measure. The splints are made of basswood, and basswood is said to swell and shrink endwise. A stronger reason, however, is that if you have the splints full length it will be very troublesome to get them into place. It doesn't matter whether they are close to the top-bar or bottom-bar. If other points are desired, ask, and your questions will be cheerfully answered.

Copper Wire for Wiring Frames.

Will copper wire affect comb or honey? I should like to use it for wiring frames. IOWA.

ANSWER.—I don't know, but I should be afraid of it. The ordinary galvanized iron or steel wire is all right.

Putting Nuclei on Moldy Comb.

I have kept a few bees for 12 or 15 years, but for the last 8 years for bees and not for honey. I sell colonies to the greenhouses that raise cucumbers (there are about 40 houses here.) I put 20 colonies in the cellar last November, that I thought had honey enough; but 8 starved, and 2 died, and left honey, after March 1; the other 10 I sold. I think the cellar was too damp, as the comb left by those that died is very moldy. Is it safe to put 2-frame nuclei on that moldy comb? MASSACHUSETTS.

ANSWER.—There is no objection to giving moldy combs to nuclei except that they may be too slow in cleaning them up. A good way is to put them at once under strong colonies, then they will be in nice condition when needed for the nuclei.

Swarming and Nuclei Management.

1. In a strong colony of bees with 7 frames of brood, if you take a frame of brood from them will it help them, or will it make less average in the surplus honey from them?
 2. To start nuclei, is it better to take six frames of brood, or two frames of brood with bees and use a division-board? ARIZONA.

ANSWERS.—1. If a colony will hold all its force without swarming, that's the thing to give results in the surplus apartment, and every frame of brood taken away would be taking something from the surplus. If a colony swarms, of course that reduces its surplus, and there might be such a thing as taking away brood to prevent swarming, but a single frame of brood taken away would have but little effect in that direction. Put it down as a basic principle that

keeping the whole force of a colony together is the way to get a good yield of honey.

2. To use six frames of brood for a nucleus would be rather expensive, and is not necessary. Two frames of brood with adhering bees make a good nucleus, providing none of the adhering bees return to their old home. Take bees that have been queenless two or three days, and they will stay much better where put. Two nuclei can be put in the same hive, with entrances at opposite sides, a bee-tight division-board between.

Mating of a Clipt Queen.

If the queen mates with the drone while on the wing, would not a clipt queen have to be replaced this spring?
 SUBSCRIBER.

ANSWER.—No, a clipt queen doesn't need replacing any more than she would with whole wings; a queen mates once for life.

Queen-Excluders from Foul-Broody Hives.

In reply to a question not long ago, I advised boiling such excluders before using again. In a subsequent number I gave the opinion of the expert, Wm. McEvoy, to the effect that no boiling was necessary. Now we have a varying opinion from Editor Root, also high authority in foul brood. In any case it can do no great harm to boil. Mr. Root says, in *Gleanings in Bee-Culture*:

"While there is a possibility that queen-excluders in foul-broody hives might not carry infection to colonies in hives on which they were placed, yet I would never take any chances. I would put the whole bundle in a kettle of water and boil not less than two hours, this extent of time being necessary to kill the spores; for, as Mr. Cowan points out, spores are very different from microbes."

Swarming Management—Belgian Hares.

1. After a swarm issues, will shifting the old hive from one side to the other of the swarm prevent an after-swarm, or must the queen-cells be cut out?
 2. When is the proper time to cut them out?
 3. Where can I get the Belgian hares, and what are they worth per pair? MINNESOTA.

ANSWERS.—1. The right kind of shifting ought to prevent swarming without cutting out queen-cells. The favorite way is as follows: Hive the swarm on the old stand, setting the old hive close beside it. A week later, move the old hive to a new place. The bees will do the rest.

2. If you want to prevent swarming by cutting out cells, listen at night to hear the young queen piping. This may be as early as 6 days after swarming, but most likely later. Next morning after hearing the piping, cut out all queen-cells.

3. I don't know. If Belgian hares get to be popular with bee-keepers, no doubt they will be advertised in these columns.

Arranging Hives—Changing Sections—Shorter Spelling.

1. On account of space, I have my apiary arranged in rows, 14 hives in a row, 2 feet apart in the row, and the rows 18 feet apart. Would it be better to pair them so as to have each two hives 6 inches apart, and the 3 feet or so between the pairs?

2. I am using $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{3}{8}$ sections. Would you change to the Ideal, $3\frac{3}{8} \times 5 \times 1\frac{1}{2}$?

3. I like the *Bee Journal* best of all the bee-papers, tho I don't like the short way of spelling. I saw where a fellow had "least" (smallest) a piece of ground to run an apiary on. ALABAMA.

ANSWERS.—1. Yes, better have them in pairs with 2 or 3 inches between the two hives of each pair. Then there will be only half the chance for a queen or a worker to enter the wrong hive.

2. That cannot be answered till you find out whether the tall sections will sell better in your market.

3. Yes, one of the unfortunate things about our language is that the same word has often more than one meaning, as when it is said that a corn-stalk has on it two ears (organs of hearing); or poetry has so many "feet" to the line, and yet can't walk.

VOL. 40.

MAY 31, 1900.

NO. 22.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

The Weather has been as fickle and changeable as—the weather. During the first half of May the temperature was abnormally high some days, and after the middle of the month came March weather. Those who, trusting to a continuance of warm weather, had ventured to do a good deal in the way of spreading brood, found instead of an increase a shrinkage in the amount of brood in the hive. It is these unwelcome spells of cool weather that make the spreading of brood such a doubtful procedure. The building up of colonies has been much interfered with, but better weather will surely come. In the meantime, look out sharp for starving.

Clipping Queens' Wings seems to be gaining in popularity. The objection that a clipt queen may be lost, or get in the wrong hive, is not denied, but the clippers reply that it is better to lose the queen alone than to lose both queen and bees. And it is probably true that when the queen is lost because no one is present to watch the swarm, there would be an almost certain loss of both queen and bees with a flying queen.

Another argument in favor of clipping is that it is much easier to manage swarms with clipt queens. Mr. Doolittle declares in Gleanings in Bee-Culture, "I would rather care for three swarms whose queens have their wings clipt than for one where the queen is not clipt." He uses a Manum swarm-catcher, puts the queen in a round wire-cloth cage an inch in diameter, and four or five inches

long, and while the queen is farthest away from the open end of this cage he holds the cage with the open end where 12 or 15 of the bees of the swarm will enter it as they rush from the hive; then puts the cage in the swarm-catcher, and the buzzing bees in the cage will make it easier to get all the bees into the catcher.

Some prefer to remove the old hive from its stand and put the new hive in its place for the swarm to enter, when it returns on missing its queen, allowing the queen to run in with the returning swarm. In this case the queen is caged and released at the entrance when the bees begin to enter.

The best thing about clipt queens, according to Mr. Doolittle, comes into play when swarms unite. He says:

"In all apiaries having more than four or five colonies, there is always sure to come a time when two or more swarms will issue together. If two or more swarms come out at once, I always use the catcher as first given, using one of the queens to secure the swarms. The other queens are caged with a few of their bees, and left in a shady place till I get all in readiness, when I place one at the entrance of each hive prepared to receive a swarm, except the hive that is to have the queen now in the catcher. I now carry the combined swarm around to the hives, placing one-half, one-third, one-fourth, etc., of the bees in front of each, according to the number in the combined swarm, letting a queen go in with each part, when the work is done. In this way it is no more trouble to manage several swarms where they come out together than it is to hive them if they were to come out singly. Thus much of the dread which used to be experienced when two or more swarms come out together is done away with."

Bee-Keeping as a Sole Business can not be recommended. When a novice with three or four colonies has a net return of \$10 or \$15 to the colony, the most natural thing in the world is for him to go figuring on the profit from a larger number. If \$10 are to be had from one colony, of course 100 colonies will bring \$1,000. That's easy. The only thing is to get the 100 colonies. But that isn't a very hard matter either. Are there not accounts of 6, 8, and 10 colonies from one in a single season? As he has done so well in surplus, surely he can do as well in increase. His 4 colonies can expand into 32, or at least 24, and at the end of two years there will be no question about the 100 colonies. But two years is too long a time to wait, and the purchase of a few colonies now will make sure of the 100 colonies at the end of the year. So he lays his plans to get out of all other business, devote himself entirely to bee-keeping, and later increase to such an extent as to have an income of several thousand dollars from the bees.

But when it comes to actual practice, things don't pan out as he had figured. The next season may be a poor one, giving neither surplus nor increase, or if the matter of increase is forced, the colonies will be so poorly developed and supplied with stores that they never see the anniversary of their birth. If he is so successful as to reach his 100, he finds that with that number he by no means secures the same average as with the original four.

The moral of which is that no one is wise to give up other business for bee-keeping until he has first made sure by actual trial for a series of years that he can at least make a living out of his bees alone.

Honey for Poverty of Blood.—Gleanings in Bee-Culture says: "An Italian bee-journal reports the case of a girl in Switzerland suffering severely from poverty of blood, and who could get no relief thru medicine. At last she tried a honey cure, which restored her to permanent health in something over a month. The treatment was as follows: Morning and evening, honey dissolved in hot milk; honey-water at will. Honey taken during the day, in all about two pounds each week."

"Doolittle Queen-Cell Cups by the Peck" is the somewhat sensational heading of an editorial in the last number of *Gleanings in Bee-Culture*. But there seems to be good ground for the sensation when we are told that such progress has been made that the Doolittle cell-cups can now be turned out at the rate of 2,000 in an hour. The man who has achieved this is W. H. Pridgen, who has clearly put a lot of brains into the thing. Instead of making the cups one by one, a number of pegs are fastened to a stick, and at one dip each peg gets its portion of wax. Instead of the whirling that each cell had to have to make the wax uniform on all sides—which whirling could hardly be done with more than one cell at a time—Mr. Pridgen finds that a little jerk to throw off the superfluous wax is all that is necessary.

The outcome of this wholesale sort of production will probably be that Doolittle cell-cups will be listed among regular bee-supplies at such price that no bee-keeper can afford to make them for himself. In view of such 16 to 1 steps in advance, who is ready to say that no further advance in bee-keeping need be expected?

The Weekly Budget

BITTER SWEET—the engraving on the first page—is kindly loaned us by Mr. James G. Moulton, whose fine art galleries are found at 45 East Jackson Boulevard, Chicago. Visitors in the city are always cordially invited to inspect his large stock of art productions; and then, of course, he will not object should the visitors select one or more paintings to take with them for the adornment of the walls of their homes.

MR. HARRY S. HOWE, of Cuba, wrote us May 15 as follows:

"The rainy season is on here, but we still get some swarms between showers. Yesterday one came out in a heavy rain. There are four of us American bee-keepers near here, and all are just going to do it next season!"

Mr. Howe says that he is just out of the hospital, and intimates that too much bicycle, etc., in a climate like Cuba is bad for weak hearts. We trust that he may soon recover and be able to make a success of bee-keeping in his new location.

POST-CHECK MONEY.—*Gleanings in Bee-Culture* has described this new form of "money" so well, and also pointed out the great advantages to be derived therefrom, that we may as well quote what its publishers have said, as we concur most heartily in all they say in regard to it:

Our attention has been called to a system of currency called "post-check money," which consists of fractional bills of denominations of 5, 10, 15, 25 and 50 cents of small size, and 1, 2 and 5 dollars the size of ordinary bills. These are to be used for ordinary currency in passing from hand to hand, but on one side are arranged blanks for affixing a postage stamp, and writing in the name and address of the party to whom you wish to make a remittance. Sign your own name and address. The bill then becomes a check for safe transmission thru the mails. When the party to whom it is sent receives it he acknowledges the receipt of payment in a blank provided, presents it at the post-office, and receives a fresh one in its place, which may be past as money. The advantages of this system will be very apparent to one who examines it. It makes it very convenient to send a remittance of a small amount in a way that is safe. To inclose an ordinary bill in a letter is considered rather risky. If the latter is stolen, the money contained may be used by

the one who gets it, and can not be identified; whereas, with post-check money, one of these bills filled in as provided becomes as safe as an ordinary bank check or draft, and is not subject to the usual charge for collection that banks make on checks, nor to the inconvenience of going to the post-office to obtain a postal money order. The government still retains the revenue feature by stamps affixed when these bills are written upon and remitted thru the mails.

The foregoing paragraph appeared Jan. 15, and then May 15 this:

In the Jan. 15th issue of *Gleanings in Bee-Culture* I called attention in this department to a proposed form of currency called "post-check" money, briefly describing it and calling attention to a few of the advantages that would be derived from its use. A bill was introduced March 16, 1900, in both houses of Congress, under the title, "A bill to prevent robbing the mail, to provide a safer and easier method of sending money by mail, and to increase the postal revenues."

We are constantly annoyed by losses of small amounts remitted to us in the mail by present methods. Very often during the warm summer weather we receive postage-stamps all stuck fast to the letter accompanying, or to each other, and it is about all they are worth to soak them off, regum, and use them. If you could appreciate one-tenth as much as we do the great convenience and saving this post-check money would secure to the great mass of the people who have to transact some of their business by mail, you would sit down at once and write a letter to your United States Senators, urging the importance of passing at an early date Senate bill No. 3643. And you will write another letter to the Representative from your district in Congress, urging his support of House bill No. 9632, the "Post-check" bill. In order that you may become more familiar with the bill and the post-check money it proposes to provide, the great convenience it will furnish the mass of the people, send a stamp to C. W. Post, Battle Creek, Mich., with request for pamphlet on post-check money; ask for several if you can place them in the hands of those who will be interested, and would be likely to urge the passage of the bill by a personal letter to your Representatives in Congress. Do not put this off, but write at once. Remember that the interests of the express companies in the fees from their money-order business may induce them to work in opposition to the bill, and the active support of the people is required, not only to offset this opposition, but to bring such pressure upon your Representatives as will make them feel that the people are back of this measure, and desire its enactment into law. It may also assist the cause to write to Postmaster-General Smith, and to the Secretary of the Treasury, Lyman J. Gage, requesting them to use their influence in support of the post-check bill now before Congress.

R. HORNIE, a merchant of Beuthen, Upper Silesia, had in stock 1,300 kilograms of honeyed syrup, which he sold for pure. Taken before a tribunal he was fined \$75 for violating the law concerning adulteration of food. In Schleswig-Holstein the inspectors have taken not less than eight samples of honey adulterated with sugar syrup. The editor says, speaking for his own country, Belgium:

"We have also a law designed to repress the adulteration of honey; but the eye of the inspectors seems to be obstinately closed in regard to the introduction into the country of a lot of mixtures that have no honey about them but the name."—*Gleanings in Bee-Culture*.

THE TRANSVAAL AND ORANGE FREE STATE Governments have prohibited, under severe penalties, the sale of anything, not the natural product of the bee, under the name of honey. Syrups may be sold as such as long as they are not called honey.—*Gleanings in Bee-Culture*.

Belgian Hare Breeding is the title of a pamphlet just published, containing 10 chapters on "Breeding the Belgian Hare." Price, 25 cents, postpaid. It covers the subjects of Breeding, Feeding, Houses and Hutches, Diseases, Methods of Serving for the Table, etc. It is a practical and helpful treatise for the amateur breeder. (See Prof. Cook's article on page 292.) For sale at the office of the *American Bee Journal*. For \$1.10 we will send the *Bee Journal* for a year and the 32-page pamphlet on "Belgian Hare Breeding."

GENERAL ITEMS

A Happy Philosopher.

BY R. F. GREENE.

I like the weather rainy, an' I like the weather dry,
 I like the world an' like the plan the Ruler runs it by!
 Ther's mebbe droughty seasons in some fair and farmin' spot,
 While a streak of too wet weather blights another, like as not;
 But I so love earth's roses that the little thorns don't hurt,
 An' life to me is somethin' more than drudgery and dirt;
 God turned my taste to sweetness, so I shun the bitter lees,
 An' find so much of honey I'm a-robbin' of the bees.

A happy life's dependent not on gumption or on grit,
 But jes' the plain philosophy of make-the-best-of-it!
 Of course, I ain't denyin' Sorrow's stalkin' thru the land,
 But her sister, Joy, is with her, an' a-holdin' of her hand.
 So write me down as happy, in the summer, spring, or fall,
 An' even storms o'winter doesn't ice the blossoms all.
 So I jes' keep on a-huntin' in the fragrance of the freeze,
 An' I find so much of honey I'm a-robbin' of the bees.

— Youth's Companion.

Spraying Fruit - Trees While in Bloom.—The following letter, just received from Prof. W. J. Green, of the Ohio Experiment Station, will explain itself:

MR. A. I. ROOT:—I enclose a letter from the Farmer's Guide; also a clipping from that paper, which was sent me by the editor. I knew some time ago that there were people who believe that spraying trees when in bloom is more beneficial than just before or just after, but I was not aware that any one would give such advice as Mr. Stahl does. Mr. Stahl's position is such that he can do great harm in this way, because he has numerous correspondents, and it is quite likely that he will induce a great many to spray trees when in bloom.

I was present at the New York State Horticultural Society meeting last winter, and heard the statement made that there were fruit-growers in the State who intended to spray their trees when in bloom, and pay the penalty if fined, as there is a law in that State against spraying trees when in bloom. If this sentiment becomes at all universal among fruit-growers it will work great injury, not only to bee-keepers, but to fruit-growers as well.

May 9. W. J. GREEN.

The letter referred to from the Guide Publishing Company, of May 7, is as follows:

Horticulturist, Experiment Station, Wooster, Ohio.

DEAR SIR:—Herewith find page of last week's issue of The Farmer's Guide, in which we criticise the advice given by William Stahl, of Quincy,

California Queens.

OF PURE ITALIAN STOCK.

(THREE-BANDED)
 No other bees within a radius of TEN MILES. Eight years' experience in practical bee-keeping. Untested Queens, 90 cts. each; \$9 per doz. Discounts after July 1. Write for price-list. 18A13t H. L. WEEMS, Hanford, Calif.
 Please mention Bee Journal when writing.

POULTRY PAPER Twenty or more pages each month, neatly illustrated and UP TO DATE. Four months trial subscription 10 cents. One year 25 cents. Sample copy free. Mention this paper. Inland Poultry Journal, Indianapolis, Ind.

EGGS From Barred PLYMOUTH ROCKS Thorobred, Fine Plumaged Fowls. Farm Raised—75c per dozen.

Italian Queens \$1.00 during May and June. Nothing sent out but beautiful Queens, from our best workers. Safe arrival guaranteed. D. J. BLOCHER, 22A4t Pearl City, Ill.

GINSENG We are Headquarters for Seed & Plants.
 Valuable book about it, telling how to grow thousands of dollars worth, what used for and who is growing it. Sent for 10c.
 AMERICAN GINSENG GARDENS, ROSE HILL, New York.
 20E8t Mention the American Bee Journal.

Rocky Mountain Bee-Plant Seed!

(*Cleome integrifolia*)

...FREE AS A PREMIUM...

The ABC of Bee-Culture says of it: "This is a beautiful plant for the flower-garden, to say nothing of the honey it produces. It grows from two to three feet in height, and bears large clusters of bright pink flowers. It grows naturally on the Rocky Mountains, and in Colorado, where it is said to furnish large quantities of honey."

We have a few pounds of this Cleome seed, and offer to mail a 1/4-pound package as a premium for sending us ONE NEW subscriber to the American Bee Journal, with \$1.00; or 1/4 pound by mail for 40 cents.

GEORGE W. YORK & CO.
 118 Michigan St., CHICAGO, ILL.

Ill., on spraying fruit-trees in full bloom. We are in receipt of a letter from Mr. Stahl in response to our criticism in which he says:

"I regret that you are just a little behind the times in giving your advice. Spraying in full bloom is nothing new to me, as I have been experimenting in this direction for several years. My own trees have not only been sprayed once, but have been sprayed twice, and I have most excellent prospects. It may be well to state, in connection herewith, that, in the grape-growing section of Nauvoo, which is only 50 miles north of here, and consists of 500 acres, almost every acre will be sprayed this year in full bloom."

Mr. Stahl enclosed a copy of a letter from Mr. J. H. Fishel, a fruit-grower of Grant Co., Ind., in which he says that he has been spraying in full bloom for 3 years, and that his fruit is 90 percent perfect, and that he has plenty. He intimates that he has kept his plan a secret, and adds:

"I am aware that the idea prevails that it kills honey-bees, and I have found, also, that it is not necessary to have bees to fertilize the bloom of fruit. I have been frequently asked why I have such perfect fruit and so much of it when others have scarcely any, and what they have is not worth anything. I do not tell my secret, for fear of being blamed of killing bees."

Now, if we are behind the times we want to know it and to know the safe, sure, and good way to catch up. If spraying in full bloom is better than otherwise, if bees are not needed in fertilizing and pollenizing, and that it is right to kill them in secret, or otherwise, we should like to know it.

We are addressing this letter to 7 experiment stations besides yours, and await the replies with considerable interest. THE GUIDE PUBLISHING CO. May, 1900.

The clipping from the Guide, which we believe to be absolutely correct, is as follows:

A farmer came into The Guide sanctum Saturday, bearing a look of unusual disgust. He had recently ordered one of Stahl's spray-pumps, and with it had received a letter from the manufacturer vouchsafing to him a great secret, which is furnished with every spray-pump upon request, which secret is as follows:

"Give your vines and trees one additional spraying this year when in full bloom, using for this spraying Bordeaux mixture, and adding thereto Paris green in the proportion of one pound to 160 gallons of Bordeaux mixture."

The manufacturer states that, where the spraying was done where the trees were in full bloom, the results were simply wonderful. If the sprayer manufactured and sold is of as much doubtful utility as the above advice is unsound, then would we hesitate to buy it or advise its purchase. Any benefits that spraying might have on the fruit while the trees are in full bloom, over omitting the spraying at this time, is surely overcome by the destruction of the fruit-growers' best friends, the bees. Spraying with Paris green at the rate of one pound to 200 gallons of water is sufficient to destroy injurious insects; but when the amount of Paris green is increased, the destruction of the honey-bees and other pollenizing insects is enhanced. This is so plainly recognized in Michigan, New York, and other States, that laws have been passed forbidding the use of poison-

Root's Column

GLEANINGS IN BEE-CULTURE.

THERE are some things every bee-keeper must have, and we believe no one can expect to succeed as a bee-keeper without reading one or more good papers devoted to this industry. Gleanings in Bee-Culture will not only keep you posted on all important topics but is always on the alert to bring to its readers' notice new methods proposed by able writers, new implements for labor saving, and everything by which a larger and better crop of honey can be secured. We believe it pays to use a superior quality of goods, and there is no doubt but what improvement can be made in the appearance of honey by use of the BEST methods. Gleanings tells you all these and tells you where to market your honey after you get it, by our HONEY COLUMN. Our market reports are ALWAYS UP-to-date, and can be DEPENDED upon. We know of many bee-keepers losing a good crop of honey by sending it to some irresponsible party. Avoid this by subscribing to Gleanings and getting the best MARKET REPORTS.

Some bee-keepers like to take a bee-journal during the honey season only; some want to try it a few months before subscribing for a longer time. To accommodate such we offer Gleanings in Bee-Culture SIX months for ONLY 25 CENTS. There will be many important things brought out in its columns during the coming six months. Do not fail to send an order at once for this time.

If you wish to subscribe for a whole year, we shall be glad to have you avail yourselves of any of the following:

Special Offers for New Subscribers.

Offer No. 11.

Gleanings in Bee-Culture, 1 yr. \$1.00
 The Prairie Farmer, 1 yr. 1.00 All
 The Poultry-Keeper, 1 yr.50 for

ons spraying mixtures while fruit-trees are in bloom.

We have gone thru the bulletins of the experiment stations on file in this office, and do not find in any of them a recommendation to spray while the trees are in full bloom. On the contrary, we find advice to *never spray a fruit when it is in blossom*. This we find italicized in Bulletin 142, Cornell University Experiment Station, Ithaca, N. Y. Following the above words are: "You can reach the insect and fungus enemies just as effectively, and in some cases more so, either just before or just after the trees bloom."

The foregoing bulletin is by Prof. M. V. Slingerland, one of the best entomologists in this country, and what he says upon the subject is reliable, and is at variance with the advice given by the manufacturer of the Stahl sprayer.

This man Wm. Stahl, while prominent as an advertiser, may not know very much about the subject of spraying. To tell the editor of The Farmers' Guide, and practically say to all experiment stations that they are "just a little behind the times," is as egotistical as it is impertinent. It is to be regretted that the State of Illinois does not have a law against the spraying of fruit. Such laws are already in force in Michigan, New York, Colorado, and bills have been or are being introduced before many of the State legislatures. When I was in New York recently I learned that the most progressive fruit-growers are not in favor of spraying during fruit-bloom. They state that it is not only unnecessary, but that it actually kills their very best friends, the bees. Of course, there are a few who are of the contrary way of thinking, but they do not represent the up-to-date growers.—Gleanings in Bee-Culture.

Bees Building Up Well.

My bees wintered well, are building up well, and there is clover enough to make at least a good prospect.

HARRY LATHROP.

Green Co., Wis., May 19.

Heavy Loss in Wintering.

There was great loss in bees in this section last winter. I have only 6 colonies left out of over 50. There is more than 7/8 of the bees dead in this locality. There is a bee-keeper near me who has only one colony left out of 48.

I have been working for a day or two cleaning out the hives and frames, and there is no dead brood in the frames but quite a lot of honey. Some hives have from 25 to 30 pounds in them. The top-bars and the sides are all daubed up as if some one had turned black molasses on them, and some of them do not smell the best. My beeyard makes me think of the cemetery just across the road from me—lots of monuments but no life. The empty hives are there to mark the place of a once active city of bees. It would be enough to discourage a novice, but I have had the experience once before,

DITTMER'S FOUNDATION

Wholesale and Retail

This foundation is made by an absolutely non-dipping process, thereby producing a perfectly clear and pliable foundation that retains the odor and color of beeswax, and is free from dirt.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1 10, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO., 118 Mich. St., Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

ALBINO QUEENS If you want the most prolific Queens—If you want the gentlest Bees—If you want the best honey-gatherers you ever saw—try my Albinos. Untested Queens in April, \$1.00; Tested, \$1.50. 12A26t **J. D. GIVENS, LISBON, TEX.**

but this winter has been the worst for bees ever known here.

The bees did not have a flight all winter. Two or three bee-keepers here lost every colony they had.

I hardly know what to do with my frames of comb and honey to keep them from the moths. I could probably take 200 or 300 pounds of honey from the frames and melt-up the rest into wax. I would like to ask what would be the best to do with them? Perhaps some one will give good advice thru the American Bee Journal, and if any one can do so I would like to have him say why there should be such a loss, with so much stores of honey left in the hives. Some or most of the hives had a large amount of bees in them, but no brood in the combs.

The spring has been very backward and cold, but for the last two days it has been up into the 90's. Apple-trees are just beginning to bloom. I have a few frames with honey outside for the few bees that I have left, to work on, but they don't seem to care much for them. I have been examining them and they have a nice lot of brood, and seem to be building up quite fast.

I see good reports from some localities as to bees wintering well. I am glad, for I love the honey-bee. I like to see them work.

The American Bee Journal meets me at the post-office every Friday night, and it is received with much pleasure; and I hope by its help to get started in the bee-business again.

GEO. H. ADKINS.
Essex Co., N. Y., May 17.

Wintering Reduced to a Science.

Never since I have been a bee-keeper have my bees wintered so well as the past winter. They came thru without the loss of a single colony. Every colony is boiling over with bees. I surely have reduced the wintering of bees to a science. I have not lost 5 colonies during the winter since I have been a bee-keeper.

B. T. STONE.
Preston Co., W. Va.

A Notable Early Report.

Bees came thru the winter in excellent condition. On the third of March one-half depth supers containing some drone-brood were put on the colonies having the best queens; and then the winter packing was replaced. The object of putting them on at this date was to get drones early in the season. By the first of May these colonies were well stocked with drones.

On May 5th the winter packing was removed, and on examination the supers put on in March were well filled with honey collected from the maple, and especially the poplar, which bloomed about April 25th. Four colonies were so crowded with bees that it was thought best to take their brood from them. The brood-nests containing 16 full-depth frames were removed and others of the same dimensions were given them, with the filled super and a second one for the fruit-bloom. So the artificial swarms had 16 full-depth-frames and 16 half-depth.

On May 16th we commenced to extract the spring harvest. The supers on the four above-mentioned hives weighed respectively 52, 46, 48 and 47

The Bee-Keeper's Guide

Or, Manual of the Apiary,
—BY—
PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPERS' GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,
118 Michigan Street, - CHICAGO, ILL.

HONEY MONEY
results from the best care of the bees. That results from the use of the best Apiary appliances.
THE DOVE-TAILED HIVE shown here is one of special merit. Equipped with Super Brood chamber, section holder, scalloped wood separator and flat cover. We make and carry in stock a full line of bee supplies. Can supply every want. Illustrated catalogue FREE INTERSTATE MANFG. CO., Box 10, HUDSON, WIS.

pounds, and the supers of the second-class colonies varied from about 26 to 31 pounds.

On account of the cold northeast winds in the latter part of April and the first part of May, this season was not so favorable for storing honey as the preceding one had been.

In making the artificial, or divided swarms, it was necessary to lift out all the frames of one hive to find the queen, when it was observed that she had 14 frames of brood and eggs, which was thought something unusual before fruit-bloom; but the queen that had the strongest field-force and stored the most honey is one that I bought in the southern part of Indiana, in August, 1896. The one from whom I bought her remarkt in his letter that she was a "fine specimen, worth 5 times 50 cents. She is one year old." She ruled her colony prosperously till last fall, when I took her out and gave her to an after-swarm that had lost their queen. She is clipt, and is also a notable queen, so I cannot be mistaken either in her age or identity. Such excellent returns from a 5-year-old queen is thought to be notable.

To-day bees are working on raspberry and sundry other blooms.

Man may labor, but God gives the increase.
B. J. CHRYSOSTOM.
St. Joseph Co., Ind., May 20.

Good Report for Last Season.

My report for 1899 is as follows: I started in the spring with about 200 colonies in fair condition. There was no honey-flow till the latter part of July, when heartsease commenced to yield nectar. August and part of September were fine. My honey crop was about 6,000 pounds of comb honey and 3,500 of extracted. All was sold long ago, and I got about \$11.00 for it.

Nov. 22, 1899. I put in 225 colonies, and took out 225 all alive, April 15 to

\$5.00 per month will pay for medical treatment for any reader of the American Bee Journal. This offer is good for 3 months ONLY—from May 1 to Aug. 1. Dr. Peiro makes this special offer to test the virtue of small price for best medical services. Reply AT ONCE.

DR. PEIRO,

Yellow Sweet Clover Seed

WE HAVE IT AT LAST!

We have finally succeeded in getting a SMALL quantity of the seed of the YELLOW variety of sweet clover. This kind blooms from two to four weeks earlier than the common or white variety of sweet clover. It also grows much shorter, only about two feet in height. It is as much visited by the bees as the white, and usually comes into bloom ahead of white clover and basswood. We offer the seed as a premium

A QUARTER POUND FOR SENDING ONE NEW SUBSCRIPTION.

So long as it lasts, we will mail a quarter pound of the seed to a regular paid-up subscriber who sends us ONE NEW subscriber for the American Bee Journal one year, with \$1.00; or 1/4 pound by mail for 30 cents.

We have been trying for years to secure this seed, and finally succeeded in getting it. It is new seed, gathered last season by an old personal friend of ours, so we know it is all right. But we have only a small supply. When nearly out we will mention it.

GEORGE W. YORK & CO.,
118 Michigan St., - CHICAGO, ILL.

Isn't it worth trying free? It positively cures. Price 10c and 25c per box. Don't delay sending.

The Modern Remedy Co., Kewanee, Ill.

A HANDY TOOL-HOLDER!

Sent by Express, for \$1.50; or with the Bee Journal one year—both for \$2.00.

Every Manufacturer, Miller, Carpenter, Cabinet Maker, Machinist, Wheelwright and Quarryman, Farmer, or any one using a grindstone, should have one of these Tool-Holders. One boy can do the work of two persons, and grind much faster, easier and with perfect accuracy. Will hold any kind of tool, from the smallest chisel to a draw shave or ax. Extra attachment for sharpening scythe blades included in the above price. The work is done without wetting the hands or soiling the clothes, as the water flows from the operator. It can be attached to any size stone for hand or steam power, is always ready for use, nothing to get out of order, and is absolutely worth 100 times its cost.

No farm is well-equipped unless it has a Tool-Holder. Pays for itself in a short time.

How to Use the Holder.

DIRECTIONS.—The Tool is fastened securely in the Holder by a set-screw and can be ground to any desired level by inserting the arm of the Holder into a higher or lower notch of the standard. While turning the crank with the right hand, the left rests on a steady the Holder; the Tool is moved to the right or left across the stone, or examined while grinding, as readily and in the same way as if held in the hands.

For grinding **Round-Edge Tools**, the holes in the standard are used instead of the notches.

Address, **GEORGE W. YORK & CO.**

CHICAGO, ILL.

18, only 3 or 4 being queenless. All came out very strong, and gathered more honey in April than I ever knew them to do before in all my bee-keeping experience. Willow and box-elder yielded more honey than I ever saw. Bees gained as high as 4 pounds a day on willow in April. They are in very fine shape now, ready to swarm. The first swarm I heard of in May was on May 12. The prospects are fine now for a crop this year. We had a fine rain last night. **N. STAININGER.**
Cedar Co., Iowa, May 19.

Good Prospects.

My bees wintered well and are doing nicely in building up. The prospect for honey in this locality is very good, and I hope we will not be disappointed. **HERMAN L. GLOEGE.**
Greene Co., Wis., May 20.

Good Honey Prospects—Honey-Dew.

The prospects for a good honey crop are very fine here in North Alabama. For the past 20 days there has been one continuous flow from poplar. This poplar honey is well tasted, but rather dark. June brings us the nice honey—basswood, sumac, etc.—almost white, and very mild.

I had 43 colonies, spring count, and have increased by natural swarming to 66. I will get a ton of comb honey. That amount always satisfies me, as it brings \$250 at the apiary, and I hardly miss the time from the store attending to them.

We are not as adverse to honey-dew as some of our friends in the North. We are always glad when it comes. There is a good deal more "rabbit" about it all being "bug-juice" than you heard there was. Most of those insects seen on the leaves are there on the same mission the bees are.

R. V. GOSS.
Walker Co., Ala., May 12.

Bees Quite Strong—Swarming.

I wintered 147 colonies of bees in the cellar, and lost only two; but after I took them out of the cellar I doubled them down to 115. They are in better shape than I ever had them before.

Here is something that I wish some of the bee-keepers would try:

When a colony swarms hive them on the old stand, according to the Heddon method; leave the supers on the old hive, and after the young queen hatches out and kills all her sisters, change hives again. That is, move

The Mississippi Valley Democrat —AND— Journal of Agriculture, ST. LOUIS MO.

A wide-awake, practical Western paper for wide-awake, practical Western farmers, stock-raisers, poultry people and fruit-growers, to learn the science of breeding, feeding and management. Special departments for horses, cattle, hogs, sheep, poultry and dairy. No farmer can afford to do without it.

It stands for American farmers and producers. It is the leading exponent of agriculture as a business, and at the same time the champion of the Agricultural States and the producer in politics. **Subscription, One Dollar a Year.**

the old hive back to where it was first, and the new hive where the old one was. Probably Mr. Heddon will try it and report results. WM. KERNAN, Sullivan Co., Pa., May 19.

Wintered Well—Early Swarming.

Bees have increased wonderfully fast during fruit-bloom, and nearly all colonies are on the verge of swarming. I had two large swarms May 13. The prospect is not very bright for a good honey-year, as the white clover froze out a good deal. Well, we have the bees now, if it does come.

CHAUNCEY REYNOLDS,
Sandusky Co., Ohio, May 17.

Texas.—The Central Texas Bee-Keepers' Association convenes in seventh annual convention, at Hutto, Tex., July 12 and 13, 1900. All are cordially invited to attend. Excursion rates, and no hotel bills to pay.

BEE=BOOKS

SENT POSTPAID BY

George W. York & Co. 118 Mich. St. Chicago.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apizry, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopaedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers, \$1.00.

Bienen-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Bienenzucht und Honiggewinnung, nach der neuesten methode (German) by J. F. Eggers.—This book gives the latest and most approved methods of bee-keeping in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cts.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cts.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohke.—Origin, Development and Cure. Price, 10 cents.

Capons and Caponizing, by Dr. Sawyer, Fauny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 20 cents.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about Poultry Business. 64 pages. Price, 20 cents.

BY RETURN MAIL.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, April 19.—Market is well cleared of white comb honey; a little choice has sold recently at 16c, but dark and mixt goods are slow of sale. Extracted, white, 8¹/₂@9c; amber, 7¹/₂@8c; dark, 6¹/₂@7c, according to quality and package. Beeswax in good demand at 28c.

R. A. BURNETT & Co.

CINCINNATI, March 3.—There is some demand for extracted honey from manufacturers at 7¹/₂@7³/₄c for amber and Southern; clover, 8¹/₂@8³/₄c. Comb honey is selling firm at 14¹/₂@16¹/₂c in a small way. Beeswax, 25@27c.

C. H. W. WEBER,
Successor to Chas. F. Muth & Son and A. Muth.

BOSTON, March 9.—Our honey market is showing some signs of lower prices, altho the stock on hand is not large. At the same time prices are so much higher than previous years that the trade have taken it very slowly and the results are that the holders are willing to range prices quite a little in order to move stock on hand. Prices range: Fancy white, 17¹/₂@18c; No. 1, 15¹/₂@16c; amber, 10¹/₂@12c; buckwheat almost unsalable. Extracted, best white California, 8¹/₂@9c.

BLAKE, SCOTT & LEE.

KANSAS CITY, May 9.—We quote: No. 1 white comb, 14¹/₂@15c; No. 1 amber, 13¹/₂@14c; No. 2 white and amber, 13¹/₂@13³/₄c. Extracted, white, 7¹/₂@8c; amber, 7c. Beeswax, 22@25c.

The receipts and stock of honey on hand are light; demand fair. C. C. CLEMONS & Co.

DETROIT, May 24.—Fancy white comb, 15¹/₂@16c; No. 1, white, 14¹/₂@15c; amber and dark, 10@12c. Extracted, white, 7c; amber and dark, 5@6c. Beeswax, 25@26c.

Supply and demand for honey both limited. M. H. HUNT & SON.

BUFFALO, April 20.—For strictly fancy white one-pound comb honey we are getting 16@17c. Any grade sells high—10@15c, as to grade.

BATTERSON & Co.

NEW YORK, May 21.—Our market is practically bare of comb honey, and there is a good demand for white at from 13@15c per pound, according to quality and style of package. The market on extracted is rather quiet, and inactive. New crop is slow in coming in, and prices have not yet been established. Beeswax holds firm at 27@28c. HILDRETH & SEGELKEN.

SAN FRANCISCO, Apr. 25.—White comb, 11¹/₂@12¹/₂c; amber, 8@10c. Extracted, white, 7¹/₂@8c. Light amber, 7@7¹/₂c; amber, 5@5¹/₂c; Beeswax, 26@27c.

Small quantities of new crop have been received, but not enough has been yet done in the same to clearly define values. Current quotations would not likely be sustained under anything like free offerings. The yield will undoubtedly prove light, and the market shows a generally firm tone.

OMAHA, Mar. 13.—Demand shows some improvement in January, having been much more active, but as anticipated there is no advance in prices. Market remains steady at 14@14¹/₂c for fancy white comb and 8¹/₂c for white extracted. The latter is pretty well cleaned up along the Missouri River, and it looks as if there would be some shortage before another crop comes in. From present appearances there is about enough comb honey to go around at the present prices, hence we look for no particular change in values. PEYCKE BROS.

DR. MILLER'S

Honey Queens

One Untested Queen Free as a Premium for sending ONE New Subscriber to the American Bee Journal for one year.

We have been fortunate in making an arrangement with DR. C. C. MILLER—the well-known honey-specialist—to rear queens EXCLUSIVELY FOR US DURING THE

SEASON OF 1900. These Queens will be mailed in rotation, beginning about June 1, so "first come first served." We are ready to book orders now.

The Queens Dr. Miller will send out on our orders will be precisely the same as those he rears for his own use, so of course they will be from his best stock. His best colony in 1899 had a queen reared in 1898; May 5, 1899, it had brood in 4 frames, and he gave it at that time a frame of brood without bees. It had no other help, but May 25 a frame of brood with adhering bees was taken from it, and the same thing was repeated June 3, leaving it at that time 5 frames of brood. It stored 178 sections of honey, weighing 159 pounds (and that after July 20, in a poor season), being 2½ times the average yield of all his colonies. A point of importance is the fact this colony did not swarm, and an inspection every week or 10 days showed that at no time during the entire season was there even so much as an egg in a queen-cell. Dr. Miller expects to rear queens from this one during the coming summer.

The demand nowadays is for BEES THAT GET THE HONEY when there is any to get, and Dr. Miller has such bees. You will want to have a queen from his best, we are sure, even if she is not pure Italian.

Do not send any orders to Dr. Miller, as all orders MUST come thru us, according to our agreement.

Remember, send us \$1.00 for ONE NEW SUBSCRIBER to the American Bee Journal for one year, and YOU will get ONE OF DR. MILLER'S UNTESTED HONEY-QUEENS FREE AS A PREMIUM. This offer is made only to our present regular subscribers. Orders for queens to be filled in rotation, beginning about June 1st.

Address all orders to **GEORGE W. YORK & CO.,** 118 Michigan Street, CHICAGO, ILL.

CONTRIBUTED ARTICLES

Marketing Honey—Carton Suggestions.

BY F. GREINER.

A GREAT deal has been written from time to time on marketing honey, and, as time goes on, more will be written, providing we are progressive.

Dear reader, you may think the above subject is entirely out of season at this time, a time when there is no honey to market. Mr. Editor, you may be edging toward your capacious waste-basket—that dreaded monster of the “Would-be-Writer.” But when we take into consideration that the first step in marketing is “producing”—producing that which is wanted—and that in this article I wish to speak of the package best adapted for the retail trade, which we will have to adopt now or wait till another season comes around, then, Mr. Editor, my article may *not* be considered out of season.

I believe most honey-producers will agree with me that but a very few grocerymen and clerks may be found who understand how to handle comb honey properly. I myself have witnessed a groceryman taking the honey out of a non-drip shipping-case and pile it section upon section pell-mell on his scales in order to ascertain the correct weight of the contents of a case of honey, apparently not having faith in the honesty of the producer, who had marked each case with

ington to cheat him, when it was himself, and he only, who caused the mischief. But it is just such men who are expected to handle our product, and it would be an advantage if we could so put up our honey that even such awkward men as the above-mentioned could handle it without damaging it.

It may be true that few consumers are willing to pay for glass and pasteboard; but just as long as inexperienced men handle the honey crop “*glassing the sections*” seems to be the only way out; and a properly-gotten-up carton solves the question to perfection. The carton offered for sale now does not fill the bill; it does not show the honey. The carton of the future must be partly of glass, and right here is where Mr. Betsinger’s carton is superior to any other. Herewith is an illustration of the same in its different parts.

The carton is composed of three pieces. Two of them are like Fig. 1; when folded ready for use they appear like Fig. 2. They are made according to size of sections, of square or oblong pieces of pasteboard as shown in the illustration. A large opening “G” is made, over which is pasted a piece of glass of suitable size. The section of honey is encased in these two pieces, and then the third piece, the rim (Fig. 3), is slipped over the whole. This rim or frame is a narrow, long piece of pasteboard of the width of the section, folded properly and glued together.

These cartons may be shipped in the flat like the old style. They weigh, glass and all, just one-fourth pound, and cost by the thousand about \$20. In selling them with the honey by weight they fully pay for themselves.

A slight difficulty comes in here: The trade calls for a section of *one pound*, not over that. It is evident that we must adopt a smaller section than the one-pound section, or one that when well filled weighs not over three-fourths

Fig. 1

Fig. 2

Fig. 3

the net weight. It seems that groceryman must have paid dearly for his mistrust, for scarcely a single section came out of that “screep” wholly intact. That man understood nothing about the nature of honey, and he probably laid all the blame of that honey leaking afterward upon that dishonest bee-man who traveled 200 miles to the city of Wash-

ington. A narrower section is just the thing, and those bee-keepers who use T supers can very easily make the change necessary, but we who use wide frames and section-holders, especially when fitted up with fences or cleated separators, are in a sad predicament.

While the carton directly increases the cost of market-

ing, there indirectly occurs a saving. The cases need not be glass, and the paper trays and the little strips now used in the non-drip cases may be omitted. When we further take into consideration that the new carton, as stated above, when sold by weight, sells for more than cost of the carton, and that the honey, when put up in these, sells quicker, and probably brings more than honey without the cartons, it will be seen that it is a good business to invest in "glass cartons." We shall use some, if—we have any honey to sell! The patent is held by N. N. Betsinger, who exhibited the carton at the last New York State bee-keepers' convention at Geneva.

For the purpose of supplying the trade with fancy extracted honey, glass packages, such as we already have, are probably best; at least I know of nothing better. Many years ago I put up my best extracted honey in the square one-pound Muth honey-jar. The cases I made cheap and strong, holding 24 jars with pasteboard partitions between the jars—egg-crate-filler fashion. Thus they carried nicely, and the prices obtained then were entirely satisfactory, being 35 cents per jar; but the time of high prices is past and gone, and we will be satisfied with half of that price; we are therefore looking constantly for cheaper packages.

Where extracted honey can be sold to consumers in 60-pound lots not at fancy prices, a wooden pail answers our purpose quite well. Enough of second-hand candy-pails may be picked up during the summer at our different grocery-stores to store several tons of honey. Their cost is only 10 cents, and they need but little cleaning. Mr. Chas. F. Dodd, a New York bee-keeper, sold all of his extracted honey, put up in such candy-pails, to a Pennsylvania firm for their trade in a mining town.

I have used regular butter-tubs for the same purpose. The wooden pail I would not fill until the honey is about ready to granulate. As soon as it is solid the covers may be nailed on, and the net weight marked on each package, when they will be ready to ship. Ontario Co., N. Y.

General Directions for Finding the Queen.

BY ERNEST R. ROOT.

IF the bees are Italians, queens can usually be found at least on the third or fourth frame taken out of the hive. A practical bee-keeper will first pull out the center frame, and look for freshly laid eggs. Failing to find these he will take out another frame from another portion of the brood-nest. If he finds the eggs, then he has reasonable assurance that the queen is *somewhere* in this part of the hive. He looks the frame over carefully, and, failing to find her, he takes out the next one, each time following in the wake of the eggs. While it is no sure rule that the presence of freshly laid eggs in any portion of the brood-nest is evidence that the queen is in that part of the hive, yet, generally speaking, she will be found near them. If, for instance, I have found no fresh eggs in the center frame, and none in the next frame that I may have out on one side of the brood-nest, then I take the opposite side till I find the eggs. But suppose I have found them, and I do not find the queen. Well, it sometimes happens that a queen will suddenly leave a large fresh patch of eggs in one portion of the brood-nest, and then go clear across the whole hive to the other side, and begin operations there.

It not infrequently happens that one has to look over every frame, not once, but twice. If she is not found on the frames, then she may be on the bottom-board or inside of the hive. If the bees are black, and the queen of the same race, she will be more than likely to be in a bunch of scrambling bees in one corner of the hive.

If the queen is not found at the first or second going-over of the frame, I shut such hive up and go back in the course of an hour. This time I use very little smoke, and proceed as quietly as possible so as not to disturb the bees. If the queen once gets frightened she will run and hide. If the bees start to running and buzzing again, better shut the hive again, to be visited later, for there is no use in wasting time.

I remember I had once been hunting for a black queen for perhaps 15 or 20 minutes. I finally called to one of the boys in the apiary, and we together scanned both sides of the frames at once—he on one side of the frame and I on the other, for I thought I had caught a glimpse of her going on the other side of one comb just the moment the frame was turned toward me. Having caught sight of her, we watch her for the fun of it. My friend got back of a clump of bushes where he could not be seen. Curiously

enough, this queen would hover around in a little space between the bottom of the comb and the bottom-bar. Whenever I turned one side of the comb toward me, she would quickly go on the other side. Upon my word, if she did not dodge back and forth as I turned the comb! No wonder I could not find her, for she had learned her trick of dodging, and kept it up. I have seen this with other black queens, and perhaps with hybrid queens, but I do not know that an Italian queen among Italian bees would ever do this. One very valuable quality of the Italians is their perfect at-homeness on the combs, whether the hive is open or closed; and one very mean trait of black hybrids and blacks is their fashion of running and scrambling over the combs, scaring the queen in their general rough-and-tumble confusion, one bee over the other. Whenever I have occasion to find black queens in populous black colonies, I always feel that I have a "job" on my hands. About the first thing I do is to tuck my pants down my stockings; and then if I can have an assistant, he is asked to use his eyes.

Some bee-keepers, when they desire to find black queens, take all the combs out, take the hive and dump it in front of the entrance, set it back, and clap an entrance-guard over the now empty hive. The bees are all shaken off the combs, and the entrance-guard is eagerly scrutinized to see when her majesty strikes the obstruction. I do not know but, all things considered, this is about as quick a way to find black queens among black bees as to undertake the very uncertain and laborious method I have already described.

Some of those who use shallow brood-chambers advise shaking the black bees out of the combs by shaking the whole chamber, and then watching the bees as they crawl toward the entrance. It is said that the queen can be easily seen among the bees, and picked out. I have tried this a number of times, but have never been successful. In the first place, it took more strength than I had, to do a thoro job of shaking; and in the second place it takes a pretty sharp pair of eyes to see the queen among a lot of bees an inch or so deep, all of them working toward the hive.

Unless one wishes to clip a queen's wings, to replace or sell her, it is a waste of time to try to find the queen. If one sees eggs regularly laid, and brood in all stages, sufficient stores, there is no need whatever of hunting a queen. Beginners often spend a lot of useless time in this way, sometimes leaving the combs exposed to the sun. Robbers start in the meantime, and there is a "general row."—Gleanings in Bee-Culture.

Giving a Queen to an Old Colony Immediately After It Has Swarmed.

BY G. M. DOOLITTLE.

QUESTION.—"A friend tells me if I wish to be successful as a honey-producer I should give the old colony a queen immediately after it has cast a swarm. Is this right? I wish to know so I may prepare hives for nuclei for the rearing of such queens this winter if this is the best way. Please tell us about it in the American Bee Journal."

ANSWER.—This is a theme much harped upon some years ago, but of late not so much has been said about it. At that time we were told that the bee-keeper who wisht to secure the best results from his bees should have a laying queen ready to give to each colony as soon as it casts its first or prime swarm, as the time lost to the old colony in rearing a queen was equivalent to a swarm of bees. I went to experimenting, and the truth of the statement that the time lost by the bees in rearing a queen was equivalent to a swarm of bees was just the thing which made the plan unsuccessful with me. If it were *bees* that I had wisht, it would have been a success.

In this locality white clover yields only enough honey, as a rule, to keep the bees breeding nicely, and thus swarming is brought about from June 20th to July 1st. Our main honey harvest is from basswood, which blooms from July 4th to the 16th. All who are familiar with natural swarming know that bees are comparatively few in the spring, and increase by the rapidly increasing brood produced by the queen until a swarm is the result. By giving a laying queen to a colony immediately after it has cast a swarm, the same conditions are brought about as before—natural swarming. The only difference is, that having plenty of brood at the time the queen is given they build up faster, so are prepared to swarm in a shorter time. Now this last swarming, brought about by the giving of the queen, will

come right in our basswood honey harvest, so it cuts off what we are seeking after, namely, surplus comb honey; for it is well known that bees having the swarming-fever do little or no work in the sections; and if allowed to swarm again the section honey we were seeking for has past away with this second swarming.

Now let us look and see how the matter would have stood had we allowed the colony to rear its queen, instead of giving one:

Eight days after the swarm issued the young queen would have naturally emerged from her cell, and if at that time we remove all other queen-cells from the hive all second swarming is entirely prevented. In ten days more, this young queen is ready to lay, which is about the time basswood begins to yield honey freely. During the period between the time the prime swarm issued and when the young queen commences to lay, the bees not having any brood to nurse for the last half of the time, consume but little honey, hence, as fast as the young bees emerge from the cells they are filled with honey, for bees not having a laying queen, nor any unsealed brood, seldom work to any amount in sections. So when the young queen is ready to lay she finds every available cell stored with honey. At about this time, or perhaps a day or two before, the instinct of the bees teaches them that they must have brood or they will soon cease to exist as a colony, and a general rush is made for the sections. The honey from below is carried above, and this, together with the large amount coming in from the field at this time, results in nearly completed sections in a week's time, so that by the time the basswood flow is over we have well filled sections of the very finest quality, such as always bring the very top price in market. Many and many a time have I had such colonies fill and complete section honey to the amount of 60 pounds in from 10 to 12 days, while, when I was experimenting with the plan recommended to the questioner, those upon which it was tried, did little else than swarm during the same time.

Different localities give different results, and where a locality gives one continuous yield of honey for months at a time, then the giving of a laying queen to the old colony immediately after swarming would work better, especially where working for extracted honey. But according to the various localities reported to me during the past 30 years, it is evident that by far the larger number of localities give a large flow of honey at a certain period rather than a continuous yield during the whole summer.

Then I have another reason for not liking the plan in a locality which does not give a steady yield, which is this: After basswood we have a honey-dearth, hence the bees from the introduced queen are of no special value, but, on the contrary, are brought on the stage of action only to become consumers. On an average it takes 37 days from the time the eggs are laid till the bees from such eggs go to the fields as laborers; hence the eggs for the honey-producing bees must be deposited in the cells that length of time before the honey harvest ends, or else they are of no value as honey-gatherers. As the basswood is all gone before the eggs of the introduced queen become honey-producing bees, and as the larger part of them die of old age before buckwheat or fall flowers yield honey, it will be seen that we are only working to a loss by giving such queen, and that a great gain is made by letting each old colony, having cast a swarm, rear its own queen: for thereby we save the expensive feeding of the larvæ, which are only to become expensive consumers of the honey brought in during the harvest.

Again the chances are that the colony rearing its own queen will be better stocked with bees of the right age for wintering at the close of the season than will the one having the introduced queen.

All of these things need to be considered before we enter any matter which has not been fully tried with us. It is always well to go slow in any new thing till we have proven it a success, then we can enter it largely, with assurance, if successful. Onondaga Co., N. Y.

Report of the Wisconsin Inspector of Apiaries for 1899.

BY N. E. FRANCE.

THE severe cold weather last February was as hard on Wisconsin bee-culture as ever recorded. Out of several hundred reports I received from various parts of the State, I judged about 70 percent of the colonies of bees, fall count, in 1898, died before warm weather of 1899. A large

portion of the bees were wintered in cellars, either built for the purpose or under residences. A lack of proper heat and ventilation caused a great loss. There being no snow on the soil in the southern and eastern parts of the State at the time, this cold wave killed the white and alsike clover and many other valuable honey-plants. The result was a light crop of Wisconsin's noted white honey. The river bottoms and marshes in western and central parts of the State produced a good yield of fall honey.

Many Wisconsin bee-keepers keep only a few colonies of bees, and seldom read a bee-journal or book on modern methods of bee-culture. Such persons know nothing about diseases of bees. There is a great need of education in this branch of agriculture.

The university short course in agriculture and farmers' institutes held thruout the State have greatly improved the agricultural resources of Wisconsin. I am pleased to state bee-culture is of late being called for at the farmers' institutes. Several of the institutes I have attended showed as much interest in bee-culture as any topic on the program. I also found the two days I spent at our State Fair, showing diseased combs and answering the many questions to bee-keepers in attendance, was valuable to many.

I hope soon to see this valuable branch of Wisconsin agriculture encouraged more at our State and county fairs.

The white grades of Wisconsin honey are noted as being in quality equal to that of any other part of the earth, and by a little encouragement and better methods the product could be doubled.

Some years ago an eastern United States bee-keeper located in San Diego County, Calif. His success became noted, other parties engaged in the enterprise, and by the encouragement of the county, and later the State, said county became noted, as shown by the report: Said first bee-keeper in 1870 harvested 3,750 pounds of honey, 17,000 pounds next year, 30,000 pounds next season, and in 1873, 61,000 pounds. Said county shipped 75 carloads of honey in 1895; 15 carloads in 1896, and 85 carloads in 1897.

Wisconsin has averaged more honey per colony for a term of years than California. There are Wisconsin bee-keepers whose honey crop is from 25,000 to 52,000 pounds per year.

As there are many bee-keepers in Wisconsin that could not understand my circular on diseases of bees, I had 1,000 copies translated into German.

Chapter 150, Laws of 1897, have been revised, and so materially varied that I am compelled to work to a disadvantage. This year I had to leave some diseased counties not cared for, as a result. To show the need of Sec. 4 Chap. 150, Laws of 1897, I call attention to an example:

I found foul brood quite bad in an apiary with several other apiaries near. I quarantined the diseased apiary and gave the owner full instructions for treatment and cure of the disease; said owner to follow printed directions and report to me later. In a few days I received a letter from one of the neighboring apiaries, stating those diseased combs had not been burned as directed, but had been put in exposed places where bees from other apiaries were working freely on them, taking to their hives the diseased honey. The next day I found the complaint was correct. I at once saw all diseased material properly cared for; but our present revised statutes provide no penalty for such crimes, or compulsion to make said owner do as instructed. The Wisconsin State Bee-Keepers' Association carefully drafted the law of 1897, and I hope the next Legislature will place the same back on the statutes.

Out of 4,454 diseased colonies I have inspected, I am pleased to state that with a few exceptions like the above, the owners have been anxious to know what was the trouble with their bees, and almost every one who followed my instructions now has a healthy apiary. If it were not for the few exceptions and a little importing of the disease into our State from adjoining States and Cuba, I fully believe by this time I could have eradicated the disease in Wisconsin. Most of the honey-producing counties are now free from foul brood, and bid fair again to export their carloads of honey.

I wish before closing to quote from one of our former bee-keepers in his report at the 30th annual convention of the United States Bee-Keepers' Association, Sept. 5, 6 and 7, in Philadelphia:

"So plentiful is foul brood in Cuba we have nearly all had a sight of it. I know of over \$100 worth of bees to dwindle out of existence from its ravages in Havana Province alone, and I still know of hundreds of colonies on the same road to sure and certain death. Many of the affected

ones have been sold, and hauled hither and thither, until the question is, Where can I locate and be safe and secure? I myself took in 90 days from 100 colonies 2,400 pounds of fine honey—but where is that 100 colonies now, and still another 150 that I had in Cuba? All dead from foul brood. I shall try it once more, as the leading bee-keepers of the island now have a move on foot to establish a foul-brood law with an inspector to inspect and condemn all infected colonies”—as they do in Wisconsin, Colorado, California, New York, and other States.

Grant Co., Wis., Nov., 1899.

Honey-Production in Old Palestine.

BY SELAH MERRILL (CONSUL).

IN ancient times, Palestine was famous for its honey, and it has always been produced here, but until recently the methods employed have been crude. The credit for developing this industry by the introduction of improved modern appliances is due to a family named Baldensperger, which came from Switzerland in 1849, and settled at Artas, a small village about seven miles south of Jerusalem, and near the famous pools of Solomon. The father had always been interested in bee-keeping, and began to keep some bees in native hives—that is, long terra-cotta jars. What he actually accomplished in this line was of little account, except to awaken in his five sons an interest in this business, which, thanks to their enthusiasm and perseverance, has become a success.

The Baldensperger boys needed instruction, but books were dear, and communication with Europe infrequent, and it was not till the year 1880 that a real start was effected. In 1883 they adopted the plan of transporting their bees from one locality to another. From the region of Ramleh they carried them to Yafa, a distance of 12 miles, to give them the benefit of the orange-blossoms there. Women carried the hives on their heads all the way, each woman carrying one hive. They had a rich harvest of orange-blossom honey during the month of April, and in other places two crops from cactus and acacia blossoms, respectively. They also started another apiary, and secured from other localities crops of honey from lemon blossoms and from wild thyme. The next year, also, they had good crops of honey, the 50 hives at Yafa alone yielding 6,000 pounds in less than one month.

It was not long before this industry began to attract the attention of the government, and at first a tax of a little less than 10 cents a hive was imposed, but this was very soon increased by an ingenious device whereby the officials not only counted the actual hives, but every door, window and hole in which they could see any bees moving was reckoned as a "hive," with the result that 150 hives were counted as 2,000. The matter had to be carried to court, and was not settled till after two years of litigation, when the Baldenspergers were found in debt to the government to the amount of about \$500. This decision affected one large apiary only.

It was in 1889 that this judgment was rendered, and, as the Baldenspergers refused to pay, this apiary was sold at auction in Jerusalem for about \$1.25 per hive. The difficult part of the work was to deliver the goods to the purchaser, which the officials were bound to do. The purchaser, the officials, and a large number of camels and camel drivers went to the place where the apiary stood, expecting to take it away, but as the bottom-boards of the hives happened to be unhooked, the bees, when the hives were touched, swarmed out, and everybody had to retreat.

A compromise was effected, one-half the amount demanded being paid, and the bees remained in the hands of their original owners.

The bee-keepers had to contend with enemies, which at times nearly ruined their industry. Large yellow hornets came in such numbers that they prevented the bees from working, and destroyed multitudes of them. Sparrows, swallows, and bee-eaters (*Merops apiaster*) also did a great deal of mischief. Badgers, during one winter, destroyed 15 colonies. Rats are very troublesome; they do not eat the honey, but destroy the bees. Two kinds of lizards do much harm. There is also a destructive moth, called "death-head moth," which appears in autumn and enters the hives to eat honey, but does not harm the bees. One of these moths will take a teaspoonful of honey at a time. A strong colony of bees will sting the intruders to death. The greatest enemy is man. Wherever an apiary is set down, the sheiks of the nearest villages have to receive a certain amount of

honey, otherwise the bees will be stolen. When a hive is stolen, fire, and sometimes water, is used to destroy the bees. About one-tenth of all the honey produced must be given away to prevent people from taking the hives.

Furthermore, when the bees are being carried from one place to another on camels, the Bedouins, or wild Arabs, occasionally steal the camels. If to this list is added the taxation, it will be seen that the industry of keeping bees in Palestine is beset with many and serious obstacles, and requires patience, tact and perseverance.

When it seemed probable that this industry, so far as the Baldenspergers were concerned, would be ruined by excessive taxation, they sold a large number of colonies, some to natives who had been their servants, and had learned the business from them, and some to a small colony of Jews in Wady Hanein (on the plain of Sharon, south of Ramleh), so that there are now about 700 colonies of bees at work besides those belonging to the Baldenspergers.

A good market is found for all the honey produced. It is sent to Germany, Switzerland, England, and a very little to France. Last year (1899) the market was unusually good, because the yellow hornet had been so destructive to the native bees.

The export duty is one percent.

The average yield per colony is about 100 pounds of honey. The working months are April, May, June and July. After October nothing is taken from the bees. They are then allowed all the honey they have—25 to 30 pounds per colony—to live upon. In January the keepers begin to feed them some stimulating food.

Natives all over the country produce honey after their crude methods, as they always have done; but they neither produce nor sell much, and since they can not remove the honey without destroying the bees, their business is not profitable. The "extractors" which the Baldenspergers use contribute largely to their success.—*The National Rural*.

Jerusalem, Jan. 25, 1900.

Bee-Keeping in Clark County, Wis.

Written for the Wisconsin Convention, held at Madison, Feb. 7 and 8, 1900.

BY HERBERT CLUTE.

FOR the benefit of bee-keepers in Clark County I will try to give all and each a little insight into bee-keeping here.

First, we have the pasture so that our bees as well as the apiarists have great advantages over those of the localities in other parts of Wisconsin, as well as in most of the other States.

Our bee-pasture is located on a very fertile belt of land that is very heavily timbered with basswood, two kinds of maple, also any amount of thorn-apple trees, wild plums, cherry, etc., and gooseberries and raspberries in large quantities. Besides this we have the wild myrtle, which I have never seen growing elsewhere. It grows in every foothold that it can find, and the bees store considerable honey from it if they are strong in time to catch it. It grows some like the blueberry-bush, only it is more like a vine, and has a long, yellowish blossom. We also have the willow-herb and two kinds of asters.

John R. Schmidt says on page 785 of the *American Bee Journal* for 1899, that there is only one kind of aster, and that he thinks the color leads to the false idea that there are two kinds, but if he will come here and examine the aster he will find two, if not three, different kinds. They are different in size of stalks; one kind branches out very wide and low, with a very small blossom, and the other kind grows tall, with a very large blossom. We also have more white clover and dandelions in Clark County than almost any other part of the State.

For drawbacks in Clark County I will say that there is just one, and that is that we have so much rain in the spring at breeding-time. Still, the rainy spell varies so that we sometimes get our bees bred up quite strong before it sets in; but should it begin at the time the bees are put out on the stands, and last any length of time, then generally the case would show an unfavorable result. Still, I think and know that the rainy spell in the spring would not be so bad if it were not for there being so much sap in the maple-trees to encourage the bees to come out. Without the rainy spell, and if perchance a week or so of fine weather, even if the snow is not all off, the bees will fetch in from one-half to 10 pounds of the thin, watery sap of maple-trees. But if the rainy spell sets in the bees get excited over it, and will go out just the same if it is rainy or

Comb Foundation Factory, Apiary, and Home of Gus Dittmer, of Augusta, Wis.

drizzly, and they become chilled and do not return; but the worst part of it is, if the drizzling rain is warm, and then between 2 and 4 p.m. the wind turns to the north or west. At such times I have seen logs, trees, fences, etc., all covered with chilled bees so that the colonies that have but little brood are "gone up" for the season, while those with lots of hatching brood make prosperous colonies, so we need lots of brood at this time of the year, and must feed early. If the rainy spell doesn't come until late, we are prepared for it, as the bees will be very strong, even to swarming, the last of April and along to May 9.

When I sold bee-supplies, different ones would come for hives the last week in April, saying that their bees had swarmed. Instead of deserting, as some may say, they were not deserters, but good, big, natural swarms, and would build or draw out worker-comb, sometimes getting 8 frames nearly full of comb and brood in a week's time. I have noticed that the comb drawn out at this time of the season seems to be of different color, and of coarser work than that done later in the season, as tho they had worked rotten wood of pine logs in.

We have read the discussions over pollen-feeding, some using flour, and others something else, while here there are very large logs of pine everywhere lying on the ground, and in spots they are very rotten. The bees go to them sometimes by the hundreds, and kind of dig away until they get quite a load of the fine, rotten pine wood on their feet, and then away they go. Another man and I watched one place on a log where there were from 400 to 500 bees at work carrying the rotten pollen of the pine log for a week, even after the alder and willows, acres of each of which are quite near, had begun to furnish pollen plentifully. From this it would seem that it would pay all bee-keepers to feed pollen where the bees did not have it natural as here.

It is almost disgusting to look below where the country is old, tho probably once when it was new large yields of honey were secured from it, while to-day the bee-pasturage has mostly "played out." But no matter how poor it seems, there are a great many that seem to think it good, and crowd in a lot more bees by the side of other apiaries located there long before. If such wish to keep bees they can do it successfully in just one way, which I will name here. While on some one else's overstocked field, neither of them will make a profit out of bees, but if they will move north with the bees there are miles of good bee-pasture that is not occupied. Clark County is not the only county in which bees will do well.

It is true that our willow-herb belt is not very wide; some places it is 18 to 20 miles wide, while in other places it is up to 150 miles in width. But I think the length of it extends from below Split Rock in this State thru to Minnesota, while the aster belt reaches thru to the Lakes. I believe that 200 miles north of here is the most northern apiary in the State, consisting of 60 colonies; one might as well say two apiaries of 30 colonies each, as the man and his wife could not agree, and so divided the colonies—one lives on each side of the road, and each year they both get a large crop of very white honey. I visited their apiaries in 1897, and saw some of their honey, and it looks like the

very whitest lard when candied, and when in the liquid state it looks clearer than water.

Now for bee-pasture: All of the 200 miles between here and the northern part of this State is unoccupied by bees, with the exception of a yard scattered here and there every 75 or 100 miles. Better honey, better yields, etc., are secured than in almost any other places in the lower States. Asters grow on every hillside, also thousands of other flowers.

Of course Clark County varies to a certain extent in bee-pasture. About 18 to 20 miles south of Greenwood the pasture gets very poor, on account of the large belt of almost worthless sandy land, where willow-herb or the basswood will not thrive. Nothing but blueberries, jackpine, cranberries, etc., thrive on it for miles.

As to being cold in Clark County, it is not as bad in the winter or in the summer as in lower Wisconsin, Northern Illinois, and in that vicinity. Here in the summer the air is still, while there on the prairie there are steady cool breezes. In the winter here there is not much wind, and the air is drier, while there the snow drifts high, and there is a steady, sharp breeze.

Our bee-pasture will be getting better as the land is cleared up, as we now have more basswood than the bees can handle while in bloom. Also, as the land is cleared up clovers are sown. In the meadows five years ago there was not the first acre of alsike clover grown. To-day there are acres of alsike sown, and the farmers are encouraging it to be grown for seed, as it fills well here, and they are now talking of getting in a huller and raising the alsike for its seed.

Another advantage in Clark County is being in direct line to the large markets for shipping honey. We have the west very handy, also all the north, besides any amount of large consuming towns thru the county. Bee-supply factories are near at hand, lumber is cheap, clover and hay grow two or three tons to the acre, oats and peas 65 to 75 bushels to the acre, and oats have in exceptional years grown 100 bushels to the acre. This shows the condition of the soil.

We put the bees out on the summer stands in this climate about the last of March or the first of April, and put them into winter quarters from the first of November up to the middle of December.

We can not have failures here if bees are strong, still we can, and have lost lots of nectar by having the bees begin breeding as the new nectar came in, and as the honey harvest was past and the bees put in shape by the majority of bee-keepers.

It is estimated by Rufus Barman that there are from 300,000 to 400,000 feet of basswood (three trees to the thousand) within two miles of me. J. C. Miller, a big logger, estimates that there are 4,000 trees that are fit for lumber, besides the crooked and small ones. After the bees quit work on the maple sap they go to work on the willow and the two kinds of alder, then come the pin-cherry, choke-cherry, etc., besides gooseberries. After these are the wild plum, maple, box-elder, elm, etc.; then the thorn-apple, wild pea, and the dandelion; then come wild myrtle (which lasts three weeks), white clover, raspberry, willow-herb and basswood; next, thorumwort, motherwort, wild catnip, wild anise, spike sumac, buckwheat, mints, heartsease, goldenrod, and lastly the asters.

Clark Co., Wis.

Belgian Hare Breeding is the title of a pamphlet just published, containing 10 chapters on "Breeding the Belgian Hare." Price, 25 cents, postpaid. It covers the subjects of Breeding, Feeding, Houses and Hutches, Diseases, Methods of Serving for the Table, etc. It is a practical and helpful treatise for the amateur breeder. (See Prof. Cook's article on page 292.) For sale at the office of the American Bee Journal. For \$1.10 we will send the Bee Journal for a year and the 32-page pamphlet on "Belgian Hare Breeding."

The Premiums offered this week are well worth working for. Look at them.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Extracting Unsealed Honey.

Can I extract honey that has not been sealed? I have reference to uncap honey. Will it be just as good? OHIO.

ANSWER.—You can extract it with less trouble than to wait for it to be sealed, but it is not so good. One of the things that has badly damaged the reputation of extracted honey is putting such unripe honey on the market. Some say that with the proper appliances they can ripen such honey artificially, but nothing can be better than honey ripened perfectly on the hives.

Probably Short of Stores.

My bees have wintered well. Altho I have but 3 colonies I cannot get along without the American Bee Journal. Two of my colonies did not have a pound of honey left, and I have to feed them as the weather is bad, and there are no flowers for honey yet. Last year was not a very good one here for honey.

I noticed this morning that one colony had carried out some dead bees which were young and not yet colored, but had wings and legs formed. Do you think this anything serious? J. F. B.

Buena Vista, Co., Iowa, April 17.

ANSWER.—If only a small number of such immature bees are carried out, it means nothing serious, and may result from the work of the wax-worm. If the number is large, it is likely the bees are short of provisions, and the first sign of starvation is their sucking out the juices of the brood. Sometimes bees thus starve even after clover is in bloom, and when remains of young bees are thus found in front of a hive, it is well to look after the stores.

Swarming Indications—Fears In-Breeding.

1. I procured two colonies of bees and think I have fully my money's worth. After feeding them a little daily for 9 days, I opened the hives to see what I had. I found some sealed brood, some sealed honey, some unsealed honey, and a good many empty cells. The hives are so filled with young and old bees that I was glad to get the combs back without crushing a lot of bees. I transferred them to larger chaff hives and put a new frame with full foundation between the middle combs. The bees commenced working with vigor on this new comb. To-day some bees carried pollen while hundreds of them kept flying in front of the entrance. Also, some drones past in and out. Does this indicate that they are about to swarm? or, is this excitement caused by the transferring to new hives and moving a little from the old place?

2. Where a person has but two colonies, and when there are no other bees around, would you deem it advisable to buy and introduce a tested queen for the mother colony? Or wouldn't it be better not to let them swarm, and increase by dividing, and give a tested queen to such newly-made colony?

My idea is to prevent in-breeding, for where there are but two colonies, the chances are one out of the two that the young queen in the mother hive (after the old one leaves with the swarm) will be mated with her brother. Am I right, or am I wrong? SOUTH DAKOTA.

ANSWER.—1. Any change in the appearance of the front of the hive would make bees hesitate about promptly entering, and a change in position would have the same ef-

fect, the bees hovering on the wing some time before entering. This flying at the entrance would in no case be an indication of approaching swarming, for there are times when every colony will have its play-spell, the young bees having a jolly time sailing about with their heads toward the hive. Neither is the presence of drones to be understood as indicating swarming.

2. Other things being equal, you will have more of the new stock if you get the new queen before dividing or letting the bees swarm. There probably is no great danger of in-breeding, for in all probability other bees are within two miles of you.

Doolittle Cell-Cups in Queen-Rearing.

How do you manage to have the Doolittle cell-cups accepted by the bees when transferring larvæ into the cups? Do you give them to queenless bees, or are they given to bees in an upper story as given in Doolittle's "Scientific Queen-Rearing?"

I have tried both of the above-mentioned plans, and failed with both. If you will kindly give me your plan perhaps I can succeed easier than by trying to follow that cracker-jack, of New York. ILLINOIS.

ANSWER.—That "cracker-jack" is all right. I half suspect that you didn't notice carefully what he says on page 99 of his book on queen-rearing. "It is essential, if we would produce good queens, to feed the queen-rearing colonies when honey is not coming in from the fields." Even with all the feeding you can do, if the weather is too cold you cannot get cells accepted and completed. With reasonable weather and feeding, I have no trouble in following Doolittle's plans, but it's a good deal better to have a good flow coming from the fields. Stick to it, and you'll come out all right.

Killing Bumble-Bees—Gill as a Honey-Plant.

My bees are in fine shape—no winter loss. I can today take nicely finished sections from my 6-frame hives, but none from my 10-frame.

We have the greatest amount of bumble-bees this year than we ever had; they are so thick that they drive the honey-bees off of the best honey-producing plants or flowers. So my wife, myself and children made war on them. We each took a small paddle and killed 614 in two days. They are all queens, or last year's bees, so each one this season would have been a colony or nest.

I enclose you a few branches of probably one of the finest honey-producing flowers in the world. Can you tell me what it is? It grows some like a vine, but not long. It blooms as soon as the snow is off, and continues until mid-summer. Bumble-bees, and honey-bees, too, will fill themselves so full of nectar from this plant that they cannot fly. It grows best in moist places, but not in wet ones. OHIO.

ANSWER.—The plant sent is gill, or gill-over-the-ground, or ground ivy (Nepeta Glechoma), a near relative of catnip. It is of great value as coming at a time when it keeps up brood-rearing. "A B C of Bee-Culture," which gives a picture of it, says the honey from it is a little dark and strong, but passes very well when perfectly ripened.

Irregular Laying—Cross Bees—Sawdust Packing.

1. What is wrong when from two to six eggs are found in one cell?

2. What causes an occasional egg left on the side of the cells about half way down?

3. Is dry cottonwood good fuel for the smoker? It holds fire the best of anything I can get.

4. What will prevent bees from being cross? I have 50 colonies of my own, and they are kind and gentle; but one of my neighbors hired me to take care of his, and they are as cross as can be.

5. Bees wintered well last winter. The way I prepared mine for winter is this: I built a box about six inches wider than the hives, and 18 feet long; placed the hives about 6 inches apart, put a board in front of the hives, placed blocks between the hives to hold the front board about one inch above the alighting-board of the hive; pulled the hives close to the front board, and filled in between the hives and at their back with sawdust. Thus the hives are protected on three sides with about 6 inches of

sawdust; the front facing the South is left open. The house is built high enough to let supers stand under them. I will leave the hives in the house or shed all summer to protect them from the sun. Will it do to leave the sawdust in during the summer? UTAH.

ANSWER.—1. When a very prolific queen has not a very strong force of bees, so that her field of operation is limited, she may lay two or three eggs in a cell, hardly more, and not often more than two. When laying workers are present, you will generally find from two to a dozen eggs in a queen-cell or in drone-cells. In worker-cells laying workers may do their work as regularly as a queen.

2. Sometimes there seems to be some imperfection that makes an otherwise good queen do so, perhaps only for a time. Generally, however, it is the work of laying workers which seem to have difficulty in reaching to the bottom of the cell.

3. Anything in the line of wood that holds fire well and makes a good smoke is all right.

4. Almost any bees will be cross if handled at inopportune times, as at times when the weather will not allow them to fly, too early in the morning, or too late in the evening. Sometimes a colony will be very cross, and the next time you handle them they will be very gentle, because the last time was in the middle of the day and they were busy gathering. Of course, the manner in which they are treated has something to do with it; go at them gently, using smoke in advance only as needed. There are bees, however, that are so vicious in disposition that they are cross at all times, and the only cure is to pinch the queen's head. Remember, however, that sometimes a whole apiary seems cross, when in reality, if you observe very carefully, you will find all the cross bees belong to a single colony.

5. I think it is generally believed they are rather better without the sawdust in summer.

Plan for Italianizing Black Bees.

1. I have two colonies of bees, one Italian and the other black, and I want to keep only Italians. Will it be all right to let the Italians swarm, and then divide the black colony, and give a frame with queen-cells from the Italians to each of the colonies that I have divided, and kill the old black queen? NEW YORK.

ANSWER.—That may work all right, but you may like this way better: When the Italian colony swarms, set the swarm where the Italian colony stood, put the Italian colony in the place of the strongest colony of the blacks, setting the latter in a new place. In a week or 10 days the Italian colony will swarm again, when the swarm will be put in the place of the strongest remaining black colony, and the latter will be put in a new place. A day or so later another swarm will issue from the Italians, and the process will be repeated as long as the swarming continues, each time putting the Italian swarm in place of the strongest of the blacks.

Belgian Hares.

On page 292 there is an interesting article on "Belgian Hares and Bees." I believe the combination one well adapted to this island. Where can a pair of breeders be obtained, and at what cost? Has this industry been introduced into the Southern States? CUBA.

ANSWER.—I cannot answer the first part of your question, but you will probably find Belgian hares advertised in these columns shortly. The industry is having a big boom in California, and possibly in other places south.

Hakes-Heddon Adulteration Case.—On page 312 we publish a report of the Hakes-Heddon adulteration case, as reported by Dr. Mason. The following further statement in regard to the matter appears in Gleanings in Bee-Culture, written by Editor E. R. Root:

In the Bee-Keepers' Review for May, Mr. Hutchinson gives a summary of the Hakes-Heddon adulteration case. In this connection Mr. Hutchinson says a sample of a lot of honey which he sold to Hakes, and which he (Mr. Hutchinson) says he bought of us, was also pronounced by the chemist to be adulterated. This matter was brought to our

attention; but from the best information we could then get hold of the matter seemed to be very much mixed. Further investigation shows that the sample came from a shelf on which there were also bottles of Hakes-Heddon honey—all of the packages "having the same labels," and right here would be a big chance for a mistake as to the source. In any case the sample is reported to have been "adulterated the same as the Hakes-Heddon honey."

We want the truth, no matter where it hits. If the honey came originally from us, it is some we sold to Mr. Hutchinson some three years ago. This he used for exhibition purposes, and afterward, as he says, sold it to Mr. Hakes. Mr. Hutchinson believed it to be pure, and so did we, and we think so yet. Even if the honey came from Mr. Hutchinson, it is not altogether clear that it came from us. Referring to the lot of honey that Hutchinson sent him, Hakes writes that Hutchinson wrote him that *some of it* might have come from the A. I. Root Co. This would indicate that Hakes had some honey from Hutchinson that did not come from us. In my talk with Dr. Mason I took it that he (Mason) gathered the same impression from correspondence he had had with Hutchinson. Here again there may be a mistake. I don't know. But however this may be, it is of small consequence, as Mr. Hutchinson would no more adulterate, or knowingly sell adulterated goods, than we. We understand also that the food commissioner visited Hutchinson, inspected his honey, and pronounced it all right.

The sample of the so-called Hutchinson-Hakes honey was not purchased by the food inspector as were the other samples referred to in Secretary Mason's report, and as a consequence no regular records were made as would be required from the inspectors. The sample was simply bought by Mr. Soper, and sent to the chemist after the food commissioners had bought the Hakes-Heddon honey. This is the reason why the matter did not appear in the Michigan Dairy and Food Bulletin No. 50.

It is our rule to buy of reputable producers; and, so far as we know, we have never sold an ounce of adulterated honey.

DR. MILLER HONEY-QUEENS.—Dr. Miller writes us that he now expects to begin very slowly sending out queens on our orders by or before June 10, accelerating as time passes. He will mail to each queen-customer a postal-card a day or two before sending the queen, so that it may be known just when to look for the queens.

MR. O. O. POPPLETON, of Florida, writes that he expects to attend the Chicago meeting of the National Bee-Keepers' Association next August. It will likely be a big gathering. Every bee-keeper who can possibly do so should be present. The date is August 23, 29 and 30.

C. B. BANKSTON, formerly a queen-breeder at Rockdale, Tex., was referred to in this column about two weeks ago. Mr. C. H. Lothrop, of Massachusetts, wrote to us as follows May 20, concerning his experience with Bankston:

EDITOR AMERICAN BEE JOURNAL—

Dear Sir:—I write you in regard to C. B. Bankston. I find out by writing the post-master at Rockdale, that he has left for parts unknown. Therefore, he does not receive the money-orders, etc. He also tells me that his brother, J. M. Bankston (I think those are the right initials) takes his (C. B.'s) mail-matter. I got my order back from the brother. If any of your subscribers wish to get their money back, write to the brother.

The American Fruit and Vegetable Journal is just what its name indicates. Tells all about growing fruits and vegetables. It is a fine monthly, at 50 cents a year. We can mail you a free sample copy of it, if you ask for it. We club it with the American Bee Journal—both papers one year for \$1.10.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY,
118 Michigan Street, Chicago, Ill.

[Entered at the Post-Office at Chicago as Second-Class Mail-Matter.]

DEPARTMENT EDITORS:

C. C. MILLER, "Questions and Answers." * * E. E. HASTY, "The Afterthought."

LEADING CONTRIBUTORS:

G. M. DOOLITTLE, C. P. DADANT, PROF. A. J. COOK,
F. A. SNELL, R. C. AIKIN, "OLD GRIMES."

IMPORTANT NOTICES:

The Subscription Price of this journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec 00" on your label shows that it is paid to the end of December, 1900.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

VOL. 40.

JUNE 7, 1900.

NO. 23.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

Honey Quotations.—After writing to honey-dealers to inform himself in the matter, Editor Hutchinson now keeps standing at the head of his honey-quotations the following:

"The prices given in the following quotations are those at which the dealers sell to the grocers. From these prices must be deducted freight, cartage and commission—the balance being sent to the shipper. Commission is 10 percent; except that a few dealers charge only 5 percent, when a shipment sells for as much as \$100."

We were quite a little surprised, at the Philadelphia convention last September, to learn that there was a misunderstanding existing in reference to the market quotations on honey. We presumed that everybody understood that commission men always quoted the price that they sold honey for to the local dealers, from which of course would have to be deducted freight, cartage and commission, the balance being what the shipper or producer would receive for his honey.

The Use of Bait-Combs to get bees to work in supers sooner than would be the case without such bait, is favored by a large number of bee-keepers. Others say there is no need of them; bees commence soon enough without any bait. Possibly both are right. They are looking from different standpoints. The one uses a management that includes a prime swarm from each colony, the earlier the better. So there is no objection to having the bees crowded to the point of preparing to swarm before entering the supers.

But the number of those who would like to dispense with swarming is large, and apparently on the increase. There are not wanting those who formerly maintained that best results could be obtained by having one swarm from each colony, who are now among the most eager seekers for the solution of the non-swarming problem. It is generally admitted that at least one of the factors in the problem is abundance of room, and the early occupation of the surplus chamber consequently is an aid to prevention of swarming. That bait-sections hasten the ascent of the bees is pretty clear from the testimony of many who say the bait-sections are the first occupied, and of some who testify that in a poor season they have had a single bait-section in a super filled and sealed, with not another section in the super drawn out.

As to the best method of using baits, there is not entire agreement. There is general agreement that it is best to have a full super of nice white bait-sections for each colony, but not often are such sections in sufficient numbers for this. If only a single bait can be had for each colony, the place for it is in the center of the super. If as many as four baits can be had for a super, the choice lies between putting the four in or near the center and putting one in each corner. If one is put in each corner, the whole super will be more evenly finished up, for the corner sections under ordinary circumstances are the last to be filled. But the bees are likely to commence work in the super at least a little earlier with bait in the center, and some are not anxious to have the corner sections keep pace with the others, considering it better to take off the super while the center sections are white, uniting in a single super the unfinished corner sections for several supers, and returning them to be sealed. This still leaves the question open, whether with four baits to a super it is better to have the four compactly placed in the center, or to have one diagonally adjoining each corner section.

National Queen-Breeders' Union.—Mr. J. O. Grimsley, in *The Ruralist*, complains very bitterly that the organization of which he is secretary has not been given a lot of free advertising by the bee-papers. Here is a portion of his wail:

"There are a few of our leading apiculturists who are antagonistic to the National Queen-Breeders' Union, claiming that with the National Bee-Keepers' Association so ably doing its work, there is no need for a queen-breeders' organization. Who ever heard of a dairy association kicking because there was an organization of Jersey breeders? Who ever heard of the wool-growers kicking because there was a sheep-breeders' association?"

"Queen-breeders are as distinct from honey-producers—bee-keepers—as swine-breeders are from pork-packers; in fact, the same relations exist, yet some of our leading bee-journals have been as silent about the National Queen-Breeders' Union as if it was a disgrace to the bee-keeping world. Pick up any kind of a 'specialty' journal—poultry, pigeons, swine, or, in fact, any except bee-journals—and any movement for improvement is heralded with joy. Not so with the Union. Now the question is, Why this antagonism?"

We believe the American Bee Journal has noticed the organization in question, giving its officers, and naming its objects. As it is limited to only a few persons interested in bee-keeping (or, more properly, bee-selling), we have not felt it necessary to use much space in calling further attention to it.

The National Bee-Keepers' Association is an organization of which every one at all interested in bees should be a member. It is not restricted to a half-dozen or so people who have something to sell to bee-keepers, but it is in the interest of all who keep bees.

Suppose the supply-dealers should form a union, telling how honest they are, and how excellent are their goods—

does any one think we would use these columns to boom such organization? Hardly; unless the space were paid for like any other legitimate business or enterprise that wishes to do business with our subscribers for profit would be required to do.

We bear not the slightest ill-will toward the National Queen-Breeders' Union, or its members; and would say that so far as we know they have a perfect right to organize for their mutual advantage; but when they charge that because the bee-papers do not turn in and help along their pet scheme such papers are "antagonistic;" and that some bee-keepers are giving "kicks" when they ought to give encouragement—well, we don't know anything about the latter, but, speaking for one paper, we can say that we have never antagonized the Queen-Breeders' Union—have never closed our advertising columns to any of its officers or members, provided they were willing and able to pay the price we charge for advertising space; and, further, we are ready at all times to help on any good cause that has for its object the general advancement of the welfare of bee-keepers.

We must, however, be allowed to decide as to what shall, and what shall not, go into these columns. We are not running the American Bee Journal for the good of a few, but for the benefit of *all* who pay for it, and read it from week to week.

An Improvement in the Ferris Wax-Extractor is noted in the Bee-Keepers' Review. A screw and follower has been added, which can be applied while the slungum is still under steam heat. "It would seem," says Editor Hutchinson, "as tho this left nothing further to be desired in the line of wax-extractors." The only wonder is that an improvement in use so long a time in Europe should not sooner have been introduced into this country.

Trials of a Bee-Supply Dealer.—We have no doubt that a very interesting as well as a large and amusing volume might be written on this subject, could only one-half of the experiences of bee-supply dealers be gotten together. It was our good fortune, or misfortune, to have been initiated into the variegated bee-supply-dealing field when in the employ of the former owners of the American Bee Journal. We then became familiar with a few of the unreasonable people who somehow have drifted into bee-keeping, and we still frequently hear of some of the trials that they cause the overworked supply-dealer to whom they send their little orders.

And isn't it strange that usually the chap who wants only a total of 75 cents worth of sections, foundation, shipping-cases, etc., is almost sure to have more "kicks" to offer than the man that orders \$75 worth at a time?

A supply-dealer once received an order for a few pounds of brood foundation which was to be of sheets 16 and *seven-eighths* inches long. It so happened that foundation 16 and *six-eighths* inches long was unintentionally sent, and perhaps it was just the slightest shade darker in color than the former order received by the customer.

Well (would you believe it?), that bee-keeper actually complained, saying he could not use the foundation that was just *one-eighth* inch shorter than he ordered, without cutting strips to fill up that one-eighth space in the frames! He also found fault with the color of the foundation, claiming that it was of second quality, etc., when it was of the very best manufacture in this country, of pure beeswax, and of excellent color for brood foundation. Suppose it wasn't as clear as some other—it would answer every purpose for brood foundation, for in a year or two it would be no darker than would be any kind of foundation used in the brood-chamber.

When the customer was written to, and kindly informed

that there was not sufficient difference to make any real difference, either in the length of the sheets or the color of the foundation, he replied that he wisht it understood that he proposed to run his own business, and intimated that no bee-supply dealer need attempt to interfere, either. He really expected the dealer to go to the expense of at least a dollar to exchange the few pounds of foundation, so that the sheets might be one-eighth inch longer, and the color—perhaps no lighter. The dealer offered to bear half of the expense, but that didn't suit Mr. Bee-Keeper.

There should be reason exercised in all things, and we believe that nearly all bee-supply dealers are glad to meet a customer half way, or do what is right in all cases. But some people seem determined to be dissatisfied, no matter how great an effort is put forth to please them. And, ten chances to one, in two or three years such will be entirely out of the bee-business, where they should have remained in the first place.

Another experience: A dealer recieved an order amounting to less than \$1.50—the whole thing making just a small package—one that would probably be lost or smasht if sent by freight, so it was sent by express. It called for less than 20 brood-frames, besides some other goods. When received the customer opened the parcel, and immediately wrote that it was short perhaps a half dozen frames, and intimated that they were purposely omitted; that if the error was not immediately corrected, he would warn others to extend their patronage elsewhere, etc. He also complained because the order was sent by express instead of freight.

Other illustrations might be given, but we will not take up space to tell of them. Let the ones mentioned suffice to teach this lesson: If you must enter a complaint, do it in a courteous way, and give the dealer a chance to correct any errors, before denouncing and threatening him. If you don't, he will likely put you down as a confirmed crank, and prefer to spend his time, and efforts to please, upon some more worthy specimen of humanity.

Again, don't "go for" the dealer unless there is something really worth mentioning. If you havn't confidence in a dealer's honesty, his goods, and his desire to give satisfaction, don't patronize him. He will be more than pleased to have you send elsewhere, especially if you are anything like the two cases we have mentioned. Life is too short, and the busy season with the bee-supply dealer is too trying any way, to spend much time with unnecessary complaints.

Of course, we believe in fair play, and full justice to all, but we also believe that all concerned would be happier, live longer, and succeed better, if a little reason and consideration were exercised by those would get the best service from their bee-supply dealer.

York's Honey Calendar for 1900 is a 16-page pamphlet especially gotten up to create a demand for honey among should-be consumers. The forepart was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample free; 25 copies for 30 cents; 50 for 50 cents; 100 for 90 cents; 250 for \$2.00; 500 for \$3.50. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

Dr. Miller's Honey-Queens are offered as premiums, on another page, for sending us new subscribers to the American Bee Journal. The offer is limited to our present regular subscribers, and the queens are to be mailed in rotation, beginning about June 1st, so first come first served. Look up a new subscriber, send in his name with \$1.00, and we will enter your order for a Dr. Miller Honey-Queen.

Northern Italian Queens!

Rared by the best methods from my GREAT HONEY-GATHERERS. Price, \$1 each. Orders for queens to be filled in rotation beginning June 1st. Ready to book orders NOW.

GENERAL ITEMS

Wintered Nicely—Early Swarming.

Bees wintered nicely and are in good condition, but clover is not. Swarming commenced May 11—the earliest in my experience of 25 years.

FRANK McNAY.

Columbia Co., Wis., May 28.

A Woman's Excellent Report.

I have 22 colonies, and last year I got over 1,000 pounds of honey from them. From 3 colonies I secured 144 pounds each. I had 6 supers on each one of them, and my friends here say that if they hadn't seen it with their own eyes they never would have believed it. I sold it at 15 cents per pound, and it was nearly all white honey, mostly from sweet clover. All of my last year's crop is sold except a few boxes of amber—perhaps 10 or 12 pounds.

I run exclusively for comb honey, and I have never shipt one pound. I have customers who take 300 or 400 pounds in a season, to retail.

MRS. COLIN BAIRD.

McHenry Co., Ill., May 20.

Wintered in Good Condition.

Our bees came thru the winter in very good condition, altho I had taken almost too much honey from them last fall. I will try not to do that again, for it made me feel badly and seemed like something was saying to me, "I have been hungry and you have not fed me." I have not lost a single colony out of 19. They commenced swarming about a week ago, and had a good time on fruit-bloom. So far we have had one of the finest springtimes in 25 years. Wheat looks very fine.

F. B. WEDEL.

McPherson Co., Kan., May 17.

Colonies Building Up Finely.

Bees are building up finely this spring, some swarming as early as April 10. My winter loss was about 2 percent, while it was 60 percent hereabouts. White clover is beginning to bloom in extra-sheltered localities.

The Bee Journal is all right. How a bee-keeper can carry a dollar and do without it, passes my dull comprehension.

C. E. MORRIS.

Carroll Co., Iowa, May 26.

Willow-Herb Honey—Foul Brood.

As a result of so many fires in this State I expect a good yield of willow-herb honey. There has been a variation as to the wintering of bees here. Some bee-keepers have lost all of their bees, while others only a part.

My brother started a year ago this spring with 15 colonies, two being queenless. He increased them to 36 and took 1,490 pounds of honey during the season. All came thru the past winter, but he detects that dread scourge of foul brood, and is taking extreme

Root's Column

If you would secure a good crop of honey, you should aid the bees by providing them with

The A. I. Root Company's
Weed New-Process

Foundation,

which is known by these trade marks:

The Weed New-Process Foundation has been indorsed by experiment stations and agricultural colleges as well as by private individuals. Wherever it has been placed in competition with ordinary Foundation it has been found that the bees will not only take to it more quickly, but will draw it out more fully. The result is that sections containing the Weed New-Process Foundation will be filled and capt over sooner than those containing the old process.

Our Foundation is put up in pasteboard boxes holding 1, 2, 3, and 5 pounds, respectively, also in neat wooden boxes of 5, 10, 15 and 25 pound sizes. Bee-keepers will find it a great convenience to get their Foundation in these regular packages, as it is sure to reach them in first-class order. Parties who buy in considerable quantities to supply their neighboring bee-keepers will find these small pasteboard boxes a great convenience, and to such we make a special rate which we will quote on application. Our prices are as follows:

Table of Prices of Root's Weed New Process Comb Foundation.

When you order, be sure to tell which grade you want, and give price.

NAME OF GRADE.	Size and sheets per pound.	In lots of				
		1 lb	5	10	25	
Medium brood	7 3/4 x 16 7/8	7 to 8	48	46	44	43
Light brood	7 3/4 x 16 7/8	9 to 10	50	48	46	45
Thin super	3 3/8 x 15 1/2	28	55	53	51	50
Extra thin	3 3/8 x 15 1/2	32	58	56	54	53

You are likely to find right in the midst of the honey harvest that you are short of Foundation. Do not lose dollars by neglect, but order a box of Root's Weed New-Process Comb Foundation at once.

You can get this Foundation promptly of any of the following dealers. Send to dealer nearest you and save heavy transportation charges.

measures to stop it. He is using carbolic acid with apparently good results. The recent extreme drouth (just broken last night), with the cold, has been against the bees, and caused much chilled brood over the country.

D. REID KIRKPATRICK.
Kalkaska Co., Mich., May 28.

Expects an All-Right Year.

My bees are doing fine this year. I never have seen them in better condition this time in the season than they are now. If the weather continues the same this will certainly be an all-right year.

R. D. MINEHART.
Linn Co., Iowa, May 30.

Not a Good Bee-Land.

Bees are not working much at present—kind of "on the loaf." Pasture is scarce, and we have to depend upon a fall flow. There is very little white honey for we have had too much rain and too many cool days. It is warm enough now, and the dagos swarm some, but not like they do on a good flow of honey. This will never be a good bee-land, for the clovers do not take well with us, and we have no hills to grow buckwheat on. But I intend to keep a few bees for the fun there is in it. I have 48 colonies.

SAMPSON STOUT.
Cowley Co., Kans., May 30.

Italians on Red Clover.

I have learned something new today about bees, and that is, my Italians are working strong on red clover. My father is 60 years old, and never saw bees work on red clover before this, to speak of. I certainly am well pleased with the queens I have received from some breeders whose advertisements are in the American Bee Journal, and I have it demonstrated to a certainty that tongues of Italians are longer than those of blacks, from a practical standpoint. I counted something like 4 Italians to 10 feet square of red clover, and no blacks; while in an adjoining field of white clover I saw many blacks and few Italians.

Ray Co., Mo. DAVID M. KITE.

Winter Losses a Fifth to a Half.

In this section of Ontario bees have not wintered as well as they did a year ago. The losses run from one-fifth to one-half. We had a short crop of honey last season, and I attribute the losses to lack of vitality, as bees did not breed up much last season after the short honey-flow was over, consequently they went into winter quarters short of young blood and vitality.

Honey has been sold very clean in this Dominion, so if we get a crop there will be no old honey to stand as a barrier to a fair price.

WM. FILMAR.
Ontario, Canada, May 29.

Late After-Swarms.

On page 213, S. B. Smith tells of after-swarms issuing 21 days after the prime swarms. Mr. Hasty, on page 310, says that they were "seconds" mathematically but not bee-ologically. "Localities" differ. I had an experience once that proves to me that it is

Or, Manual of the Apiary,
—BY—
PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPERS' GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00, and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

possible that Mr. Smith's swarms were second swarms, both mathematically and bee-ologically.

I had a powerful colony of Italians, from which a nice prime swarm issued with a laying queen. I listened for piping on the 7th, 8th and 9th days, but heard none. On the 16th I heard piping, and on the 21st an after-swarm issued. On the 22nd a third swarm issued.

This goes to show that when the prime swarm issued no preparations had been made for swarming. Will some one explain why the young queen waited five days after she came from the cell before she issued with the swarm?

W. T. STEPHENSON.

Massac Co., Ill.

Bee-Keeping in Snowland.

I may say I have just started on a small scale in bee-culture. I succeeded in securing two colonies of bees last season, and three others this season, and the increase of last season, in all 8 colonies. Last season was unusually wet, but this year so far is fine, and the bees are doing well.

I am living in a very extreme northern latitude, and have been repeatedly told by the best bee-authorities in Ontario, Canada, that bees will not live thru the severe winters. On one occasion I sent \$15 to a bee-keeper in Ontario, and requested him to forward me two colonies; he immediately returned the money, and told me he had 200 colonies for sale, but thought it unfair to ship bees to a country which he knew they could not reach alive, and, if they did they could never come thru the long and severe winters we have in northwest Canada.

A friend of mine came here to look up the country two years ago this month, desiring to move here. He bought a farm, and went back that fall for his

\$5.00 per month will pay for medical treatment for any reader of the American Bee Journal. This offer is good for 3 months ONLY—from May 1 to Aug. 1. Dr. Peiro makes this special offer to test the virtue of small price for best medical services. Reply AT ONCE.

Price 10c and 25c per box. Don't delay sending.

The Modern Remedy Co., Kewanee, Ill.

family and effects, to come here. Last spring, before leaving, I talkt the beequestion to him, and told him to bring me two colonies, and not to heed what people might say.

About two weeks before he left for here he sent me a card saying that the people all told him that it was no use to bring the bees. On receipt of his card I wired him, "It is not the business of your people, but my own. Bring the bees without fail." He did, and in addition to mine he brought one colony for himself, and to the astonishment of many, and myself, he wintered his bees out-of-doors on the summer stands, and they came thru all right. I wintered mine in the cellar. I put them in Nov. 7, and took them out on Good Friday, this spring, all right.

I am more than delighted with my enterprise. The bees I got this spring cost me \$16 per colony, on arrival here—\$6.85 express charges, and \$7.00 per colony for the bees first cost, \$1.50 for a new hive, and 75 cents for cartage from here to Edmonton, our nearest station. They are pure Italians—beautiful bees.

I am not dissatisfied, altho the outlay is much more than it would be in the East; still, I am more than pleased with my bees. I am only beginning to understand them. I have been reading up this winter all the bee-books I could find, and the American Bee Journal is the third I am subscribing for.

G. T. MONTGOMERY.

Alberta, Canada, May 21.

The Value of Comb Foundation.

If you use only a starter, you will save about five cents on each frame. Is that a real saving in the long run? Let us see. With only starters you may count on the bees building drone-comb in the different frames, in some more, in some less, in all enough to make a full frame of drone-comb. You have saved 40 or 50 cents on foundation by using starters, but you have this drone-comb. Instead of having reared in that drone-comb bees that will add to the wealth of the colony, you will have those that will be only a bill of expense. It will cost as much to rear them as to rear workers, and they will have to be fed as long as they live. Suppose you are unusually fortunate, and have only half a frame of drone-comb in all in the hive. It will take as much to rear the drones as to fill the same comb with honey, and after the two or more broods of drones are reared they will eat a lot of honey, so it will easily make you a frame of honey less than you would have if you had all worker-comb. That honey will be easily worth 50 cents each year. The comb will last 30 years, but if it should only last 10, that will make a loss of \$5 to offset your saving of 50 cents. Where are you now?—National Stockman.

Bleaching Travel-Stained Comb-Honey.—I will try to tell how we bleach travel-stained honey. We first fumigate with sulphur, then place the

FREE OX-BLOOD TABLETS for thin blood people. — Nervousness, Indigestion — Rheumatism—Female Disease—Brain Food. A SURE CURE.....

This preparation contains in a concentrated form the active principles of healthy bullock's blood combined with the most valuable nerve, brain, blood and flesh producing drugs known to the practicing fraternity.

Greatest discovery of the age for suffering people. Less than a year since first put in use, and thousands are being cured every day. To convince you we give a 3 weeks' treatment free—all we ask is for you to send 10 cents to pay postage on sending it. This is safer than paying a doctor \$25 to experiment on you. **3 weeks' treatment sent free on receipt of 10 cts. in stamps.**

TESTIMONIALS:

W. A. HENDERSON,
Dear Sir:—Enclosed find 50 cents for which please send me a 50-cent box of your Ox-Blood Tablets. The 3 weeks' treatment that you sent me free did all you claim for it. GEO. FILLMAN.

From MRS. CARRIE OWENS, Clarinda, Iowa.
I cannot say enough in praise of Ox-Blood Tablets. I have suffered everything for months with a hurting in my head and a stomach trouble. After persistent efforts to get relief from other remedies and failed, I was cured with one box of Ox-Blood Tablets.

50 cts. a box or 6 for \$2.50. Address, **W. A. HENDERSON CO.** Masonic Building, Des Moines, Iowa.

Please mention Bee Journal when writing.

Four Celluloid Queen=Buttons Free AS A PREMIUM.

For sending us **ONE NEW SUBSCRIBER** to the Bee Journal for the balance of this year, with **50 cents**, we will mail you **FOUR** of these pretty buttons for wearing on the coat-lapel. (You can wear one and give the others to the children.) The queen has a golden tinge. This offer is made only to our present regular subscribers.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate, it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

Prices of Buttons alone, postpaid: One button, 8 cts.; 2 buttons, 6 cts. each; 5 or more, 5 cts. each. (Stamps taken.) Address,

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO.

Please mention the Bee Journal when writing Advertisers.

combs where the sun will shine on them, and that is the whole process.

I build a frame on the south side of my honey-house, and cover the same with cotton-cloth. A door opens from the honey-house into this room. I place shelves on the side and ends of this room, the bottom shelf being a wide board to be used as a table. I place the combs on these shelves so that the sunlight will strike them. Dark combs will require several hours. This plan will whiten dark combs here in California. If you fumigate a few combs, then place them on a window-sill where the sun will shine on them, you will be convinced.

In placing the sections on shelves in the morning, I find the following plan good: On the shelves at the east and west end of the room I place sections end to end lengthwise of the shelves, two rows on each shelf, one row on the outer, and the other on the inner edge. The morning sun strikes one side, and the afternoon sun the other side. On the front shelves I set them crosswise of the shelf, far enough apart so as not to shade each other.

I pack them away every evening; all not white I put out again next morning. Some of them will bleach quite slowly, but I have been able to whiten the worst ones by perseverance.—A. E. WHITE, in Gleanings in Bee-Culture.

Fruitful Fields of Waste=Places.

The great West contains vast stretches of the richest land, which needs only water to transform into fruitful fields. In many places also the water is available, but running to waste, and all that is needed is the expense of labor to create farming lands of the most profitable character, and at nominal prices.

The possessor of an irrigated farm is in a measure independent of the weather. The drouth at the seeding or in the growing time or rain at the time of harvest have no terrors for him, but he can apply water when and in quantities as needed to produce the largest yield, and pursue his harvest at his leisure, sure of a full yield and a perfect product.

There are many thousands of irrigated systems in successful operation; in fact, this is perhaps the oldest and most scientific system of farming. Many systems have also failed because the promoters have over-reach themselves in trying to acquire riches by bonding and stocking such systems too heavily, and expecting the settler to step under and shoulder the load, which he is wisely wary of doing.

Some prominent members of the rural press have undertaken to make a large body of about 100,000 acres of very valuable land near Denver, Colo., available by the application of water, utilizing for the purpose the joint funds of those who want to occupy or invest in the land. In this way the lion's share of the profits, which usually goes to enrich the capitalist who supplies the funds, is saved to the purchaser of the land. As a consequence, the settler or investor is supplied with land and water at a mere nominal price without subsequent charges for water rental. In addition also under the plan the pioneers—those who subscribe for portions of the first 10,000 acres of the tract, and thus supply the initial capital—are given a share in the profits which will result

from the sale of the water-rights to the balance of the tract, town lots, etc. There is reason to believe sufficient profit will be made, even while selling the land and water-rights to the balance of the tract at a nominal price to eventually pay each back the amount of his original investment, giving these pioneer purchasers their land and water free. The first subscribers are also given a concession of over one-third in the purchase price.

Another commendable feature of the plan is that each of these pioneer purchasers, being interested, becomes an active agent in assisting in selling the balance of the trust. Also this very liberal policy insures rapid settlement and a rapid sale of the balance of the tract.

The plan is proving a great success. From the announcements in one farm paper alone over 8,000 acres of the first division of 10,000 acres have been subscribed for in about 4 weeks' time. Twelve other influential farm papers have now been enlisted in the work, so that it will be widely and influentially advertised.

There are about 2,000 acres of the first 10,000 left. If any of the readers of this paper want an irrigated farm, or to invest money in a substantial way to great advantage, they will do well to investigate at once, while the opportunity remains to get in on the ground floor.

The land is adjacent to two trunk lines of railway, only 36 miles from Denver. That city and the mines afford a home market at good prices for all products. Five tons per acre of alfalfa per year can be produced upon this land. There is also an unlimited stock range adjacent. The opportunities for stock, dairying or poultry-raising are above the ordinary. Also grains, vegetables and fruits may be produced in more than ordinary abundance.

The climate of Colorado is proverbial

Texas.—The Central Texas Bee-Keepers' Association convenes in seventh annual convention, at Hutto, Tex., July 12 and 13, 1900. All are cordially invited to attend. Excursion rates, and no hotel bills to pay.

for its excellence. Those seeking a better climate or to better their material condition, especially renters who want to become farm owners, or young men with some means seeking farms, will find this the opportunity of their lives.

As soon as the first 10,000 acres are taken the remaining lands and water rights will be sold at advanced rates, but on payments running 10 years, to give all a chance.

A party of 16 farmers from different States went out on an excursion May 1 to investigate, all of whom approved of the project and subscribed for land and water-rights. Another large excursion will go out June 5. The date of the next will be June 19. The rate, one fare plus \$2.00 for the round trip. Tickets can be obtained at your home office. Take any route going to Denver and meet at the office of the Company, 1025 17th St., Denver, Colo.

James W. Wilson, editor of the National Rural, Chicago, Ill., who has established several settlements upon a like liberal plan, is the father of the plan. Those who want to investigate further should send at once for maps and literature, which can be had by addressing, THE RURAL PRESS CO., 79 Dearborn St., Chicago, Ill.

The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, April 19.—Market is well cleared of white comb honey; a little choice has sold recently at 16c, but dark and mixt goods are slow of sale. Extracted, white, 8@9c; amber, 7@8c; dark, 6@7c, according to quality and package. Beeswax in good demand at 28c.

R. A. BURNETT & Co.

CINCINNATI, March 3.—There is some demand for extracted honey from manufacturers at 7@7½c for amber and Southern; clover, 8@8½c. Comb honey is selling firm at 14@16½c in a small way. Beeswax, 25@27c.

C. H. W. WEBER,
Successor to Chas. F. Muth & Son and A. Muth.

BOSTON, March 9.—Our honey market is showing some signs of lower prices, altho the stock on hand is not large. At the same time prices are so much higher than previous years that the trade have taken it very slowly and the results are that the holders are willing to range prices quite a little in order to move stock on hand. Prices range: Fancy white, 17@18c; No. 1, 15@16c; amber, 10@12c; buckwheat almost unsalable. Extracted, best white California, 8½c.

BLAKE, SCOTT & LEE.

KANSAS CITY, May 9.—We quote: No. 1 white comb, 14@15c; No. 1 amber, 13@14c; No. 2 white and amber, 13@13½c. Extracted, white, 7½@8c; amber, 7c. Beeswax, 22@25c.

The receipts and stock of honey on hand are light; demand fair. C. C. CLEMONS & Co.

DETROIT, May 24.—Fancy white comb, 15@16c; No. 1, white, 14@15c; amber and dark, 10@12c. Extracted, white, 7c; amber and dark, 5@6c. Beeswax, 25@26c.

Supply and demand for honey both limited. M. H. HUNT & SON.

BUFFALO, April 20.—For strictly fancy white one-pound comb honey we are getting 16@17c. Any grade sells high—10@15c, as to grade.

BATTERSON & Co.

NEW YORK, May 21.—Our market is practically bare of comb honey, and there is a good demand for white at from 13@15c per pound, according to quality and style of package. The market on extracted is rather quiet, and inactive. New crop is slow in coming in, and prices have not yet been established. Beeswax holds firm at 27@28c.

HILDRETH & SEGELKEN.

SAN FRANCISCO, Apr. 25.—White comb, 11½@12½c; amber, 8@10c. Extracted, white, 7½@8c. light amber, 7@7½c; amber, 5@5½c; Beeswax, 26@27c.

Small quantities of new crop have been received, but not enough has been yet done in the same to clearly define values. Current quotations would not likely be sustained under anything like free offerings. The yield will undoubtedly prove light, and the market shows a generally firm tone.

OMAHA, Mar. 13.—Demand shows some improvement in January, having been much more active, but as anticipated there is no advance in prices. Market remains steady at 14@14½c for fancy white comb and 8½c for white extracted. The latter is pretty well cleaned up along the Missouri River, and it looks as if there would be some shortage before another crop comes in. From present appearances there is about enough comb honey to go around at the present prices, hence we look for no particular change in values.

PEYCKE BROS.

DR. MILLER'S Honey Queens

One Untested Queen Free as a Premium for sending ONE New Subscriber to the American Bee Journal for one year.

We have been fortunate in making an arrangement with DR. C. C. MILLER—the best specialist—to rear queens EXCLUSIVELY FOR US DURING THE

SEASON OF 1900. These queens will be mailed in rotation, beginning about June 1, so "first come first served." We are ready to book orders now.

The Queens Dr. Miller will send out on our orders will be precisely the same as those he rears for his own use, so of course they will be from his best stock. His best colony in 1899 had a queen reared in 1898; May 5, 1899, it had brood in 4 frames, and he gave it at that time a frame of brood without bees. It had no other help, but May 25 a frame of brood with adhering bees was taken from it, and the same thing was repeated June 3, leaving it at that time 5 frames of brood. It stored 178 sections of honey, weighing 159 pounds (and that after July 20, in a poor season), being 2½ times the average yield of all his colonies. A point of importance is the fact this colony did not swarm, and an inspection every week or 10 days showed that at no time during the entire season was there even so much as an egg in a queen-cell. Dr. Miller expects to rear queens from this one during the coming summer.

The demand nowadays is for BEES THAT GET THE HONEY when there is any to get, and Dr. Miller has such bees. You will want to have a queen from his best, we are sure, even if she is not pure Italian.

Do not send any orders to Dr. Miller, as all orders MUST come thru us, according to our agreement.

Remember, send us \$1.00 for ONE NEW SUBSCRIBER to the American Bee Journal for one year, and YOU will get ONE OF DR. MILLER'S UNTESTED HONEY-QUEENS FREE AS A PREMIUM. This offer is made only to our present regular subscribers. Orders for queens to be filled in rotation, beginning about June 1st.

Address all orders to **GEORGE W. YORK & CO.,**

CONTRIBUTED ARTICLES

The Common Black, or Yellow, Locust.

BY JOHN R. SCHMIDT.

BETTER known by some as "honey"-locust is one of our most fragrant and beautiful honey-plants. Unfortunately it is seldom found in large numbers in any one place, and the nectar, which is borne more abundantly than in some other honey-plants which receive more attention but possessing less desirable qualities, seldom reaches the supers, and therefore this desirable honey-yielder is little known to the bee-keeping fraternity.

The tree is of very rapid growth, and blooms profusely when only a few years old. The specimen from which the sprig was taken to be photograph was planted seven years ago, then only a small sapling less than four feet high, and about three-fourths of an inch in diameter. Now, the thickest part of the trunk is five inches thru, and it was necessary to use a 12-foot ladder to reach some of the lowest branches. This will give some idea as to its rapid growth.

The blossoms make their appearance about the second week in May, and are of a creamy-white color, hang in clusters like so many bunches of grapes, and are intensely fragrant. The odor is so very pronounced that it often causes one to have a headache when the blossoms are smelled for any length of time, or when they are present in large quantities in a closed room.

Bees work upon these blossoms from morning until night, and the hum, when one is under a tree in full bloom, almost resembles that of a swarm clustering among the branches. Several times I have stopt and examined the tree to see if such were not the case.

The time of bloom which I have already mentioned make it a most desirable tree for the bee-keeper in this section, as it comes when there is nothing for the bees to work upon, and continues to bloom until the last of May, when white and sweet clover open our main honey-flow.

This tree, if planted in groves like linden or basswood, would rapidly mature and yield a good crop of honey each year. I do not remember ever seeing the bees fail to work upon it. These are its good points. Now I will mention some of its faults, as much as I know :

1st. The trees are always worm-eaten ; that is, worms are always present in the wood, and they eat the very life out of the trees. This causes many dead branches and much dead wood among the trees when they become old.

2d. It is said they are very susceptible to lightning, and many people refuse to have them on their premises for this reason. Personally, I do not think them more so than the oak, but I have seen many large trees which were struck.

3d. Owing to the above faults, many trees soon lose

their symmetrical appearance and beauty, and therefore are not so attractive in appearance as the linden and some others.
 Hamilton Co., Ohio, May 19.

The Food of the Larval Bees.

BY PROF. A. J. COOK.

THE great difference between animals and plants consists in the fact that animals must digest their food, while the plant takes a food that needs no digestion. By digestion we mean the changing of food so it can be

Locust Blossoms.

absorbed or taken thru an organic membrane. We call this osmosis. A good definition, then, of digestion, is that it renders the food osmotic. It is often defined as the process of solution, or dissolving the food. This is not correct. Some substances are not osmotic, like the albumen of an egg or blood, altho these are liquids. These substances, then, must be digested or they can not be absorbed. There are other liquids of like nature. Some liquids, like cane-sugar, while readily soluble need digestion. Thus without doubt cane-sugar must be digested before it is absorbed into the blood. The bee does this with the cane-sugar of nectar, and thus changes it into the reducing-sugar of honey. When we eat honey the bee has done our digestion for us, but when we eat cane-sugar we must do it for ourselves.

The lowest branch of animals, the protozoa, have but a single cell, and are thus in structure like the yolk of an egg. These, of course, have no digestive canal, but they have a wonderful power of taking their food into themselves and digesting it, and thus are as truly animals as are we ourselves. The little microscopic *amœba* is one of these protozoas. Nearly all other animals possess an alimentary or digestive tube. I say nearly all, for some animals, like the tape-worm, have, in the economy of their lives, found places where their food is already digested, and thus need no digestive canal, so they have none. Doubtless they once had one, but thru disuse it was snatcht away. If we wish to keep our organs vigorous and intact we must use them.

The coral animals have a digestive canal, but only have a mouth-opening. The animals above the coral branch, if they have an alimentary canal at all, have a complete one; that is, a tube with an opening at each end. Most animals with a complete alimentary canal have the tube differentiated into mouth, œsophagus, stomach, small and large intestines. The bee is no exception to this statement. Thus in the bee we have a mouth, œsophagus, two stomachs, small and large intestines. The mouth of the bee, like our own, receives the salivary liquids, which, in their case, unlike ours, are the main digestive liquids. The œsophagus of the bee is small, and conducts from mouth to stomach. The honey-stomach is just above the true-stomach, and this is doubtless the seat of all honey-digestion. That is, the cane-sugar of nectar is changed to the reducing-sugar of honey, which is a mixture of dextrose and lavalose in this honey-stomach. This honey-stomach, then, is not comparable to the crops in chickens. The crop is simply a store-house for food, while this honey-stomach is really a true-stomach, in that digestion is done in it.

Succeeding the honey-stomach is the long, bent, true-stomach of the bee. This is considerably larger than the honey-stomach, and in this the digestion of the albuminoids or of the bee-bread or pollen takes place. There are many short tubes attacht at both ends to the true-stomach. These were once thought to act as does the liver of higher animals. But they are now known to be organs of excretion, and so answer to our kidneys. Indeed, the structural difference is not great, for our kidneys consist of a great number of small tubules. In the bee these tubules, instead of being mast together, as in the kidneys, are separate. We know that these are kidneys in function, as urea has been found in them. These are often called malpighian tubules, which word is strangely misspelt in the last edition of the "A B C of Bee-Culture." The small and large intestines are probably little more than conduits for the waste of fecal matter. Doubtless digested material not absorbed in the stomach may be taken into the blood from the intestines.

There are very large glands in the head and thorax of all worker-bees. The upper head-glands of the thorax empty in the common tube just at the base of the ligula or tongue of the bee. There is little doubt that this secretion furnishes ferment which digests the cane-sugar of nectar. Its position and the large extent of the glands make this almost certain. The further fact that we know of no other source for this digestive liquid adds to the argument. It is marvellous how much the bee does at one time. It gathers honey, gathers pollen, and is at the same time hard at work digesting the honey in the honey-stomach. And added to this is its hard labor in flying from flower to flower, and in carrying its load of pollen to the hive. Bees have been found to make a mile in five minutes, altho loaded with nectar.

The lower head-glands empty on the side of the mouth. They look like a string of onions, and are very ample. Cheshire is assuredly mistaken in stating that these glands furnish the food for the larva. I have tried experiments which I shall speak of later, which entirely disprove this

statement. Their real function is, without doubt, to digest the pollen or bee-bread, changing this into chyle, which process takes place in the true-stomach.

As we have said, the honey-stomach is the reservoir in which the honey is conveyed to the hive, and also the digestive cavity where the cane-sugar of nectar is changed to the reducing-sugar of honey. At the lower end of the honey-stomach is the little globular stomach-mouth, a curious little organ, which undoubtedly serves to obstruct the pollen-grains which are taken in with the nectar from this liquid as the bee is gathering or flying to the hive. If we quarter an apple and imagine the quarters slightly separated yet united at the peel by elastic rubber strips, we will have a close copy of this stomach-mouth. The inside of the quarters should be covered with long hairs which point downward. These quarters, as the bee is flying, are constantly opening and shutting. The nectar passes in between them, carrying the pollen-grains. As they close they pass the honey back into the honey-stomach, but the hairs hold on to the pollen-grains, and so they are constantly past thru the true-stomach where, as we have already seen, they are digested. The bee also takes the bee-bread from the cell into its mouth, mixes this with the secretion from the lower head-glands, already described, and then passes this into the true-stomach. Only the nurse-bees, or younger workers, possess these lower head-glands in full development. Thus the nurse-bees for the most part digest the proteid food.

A loose tube extending from the lower part of the stomach-mouth reaches down into the true-stomach. Thus unless the honey-stomach is drawn up this serves as a valve, preventing any regurgitation of the food from the true-stomach. But in case the bee wishes to regurgitate this chyle, as the digested pollen is called, it simply raises the honey-stomach, drawing this valve-like tube up. Thus it may or may not act as a valve at the pleasure of the bee.

The drones and queen have not the lower head-glands, and thus can not digest pollen. Thus the nurse-bees have to feed not only the larvæ, but also the drones and queen. The drones and queen are posses of the other glands. Indeed, they need them as the honey is not fully digested or changed into reducing-sugar, and the drones and queen take honey for food, and so need to digest it in part. Even a part of this digestion, as we have already seen, is performed by the worker-bees, as they digest the nectar *en route* to the hive.

As before stated, Cheshire argues that the secretion from the lower head-glands forms the food of the larval bees. As stated above, I have proved as have others, that this is an error. The nurse-bees digest the pollen, and probably add more or less honey, and jelly or chyle is the food of the larval drones and queen. We know that charcoal is entirely non-osmotic, that is, it can not be absorbed. Therefore if we feed charcoal to an animal it would never pass into the blood. I fed honey with finely pulverized charcoal mixt with it, to a colony of bees in confinement. The bees were not only feeding common brood, but also adding the royal jelly to queen-cells. I found the charcoal in the royal jelly, as also in the cells with the ordinary brood. This proves that this food is chyle, and so regurgitated from the true-stomach. If Cheshire were correct, this charcoal must have past thru the walls of the stomach and intestines into the blood, and again thru the walls of the lower head-glands to be mixt with the secretion of these glands. We know that this could never take place. As the larva food is chyle, this charcoal must of course pass with the chyle as it is regurgitated from the true-stomach.

Dr. de Planta has shown that the chyle fed to the queen-larva is quite different from that fed to drones and worker-larva. If this were as Cheshire holds, a secretion, we could not explain this difference. If, on the other hand, it is chyle, we can certainly see this, by adding more or less honey, its nature can be readily changed, as it must be by the nurse-bees.

A few years ago I announced the fact in the bee-journals, that honey is digested nectar. There was a great cry from the bee-men, fearing that their product might be injured by such statement. They had no need to be thus frightened, for the truth never hurts any one. Indeed, the bee-men should be glad to know and herald forth this fact. I feel sure that honey is a safer and better food than cane-sugar, and just for this reason, that the digestion is partly performed by the bees. There are few acts in all the culinary processes that are so neat and unobjectionable as is this wonderful transformation in the honey-stomachs of the "pets of the hive." If, as sometimes stated, cane-sugar is

not so safe a food as honey—and I think there is much reason for this opinion—then it is because of this previous digestion of the honey by our little industrious friends.

Spring and Early Summer Bee-Management.

Written for the Northeastern Ohio and Western Pennsylvania Convention,

BY MRS. E. J. CORNWELL.

WHILE thinking of the subject assigned me, it seemed that I must know how the bees had been prepared for winter the previous fall. I will consider that they have been wintered on the summer stands, in chaff hives, with plenty of stores of their own gathering in old combs, each hive weighing not less than 35 pounds. If we did our duty last fall and saw that they went into winter quarters with abundance, there is no need to trouble them in the spring, aside from cleaning the dead bees away from the entrance, and off the bottom-board, which may be done without disturbing the live bees.

Don't fool too much with your bees in the spring, especially if the weather is cold. Better not touch them at all, except when it is pleasant and warm enough for bees to be flying. If you lift out the combs you can easily chill the brood. Don't be in too great a hurry to take away the winter packing—better to leave it till settled warm weather. It is just as important to have them warm early in the spring as in winter, for they have commenced brood-rearing, and that requires warmth.

If you are not certain that your bees have plenty of stores to last them thru, go to the hive the first warm day that the bees are flying, and look for sealed honey along the top of the combs. If you find it there, you need not look further; but if no sealed honey is in sight, you would better lift out a comb, and if they have not plenty give them a comb taken from a stronger colony last fall, or some of those partly filled sections that were not good enough for market. If you can't give them honey, feed a syrup made from granulated sugar. Bees can not thrive upon scant supplies. Be sure that they never lack stores, for when stores run low the queen will stop laying, giving you a weak colony later on when it should be strong.

In spring, when but little honey is coming in, is the time to build up the colonies and have them strong for the honey-flow by and by. In the production of honey, either comb or extracted, the most essential thing is to have good, strong colonies at the right time. In this section the first honey and pollen is from the soft maples and willows; then along thru the blooming of the different fruits; and we often have swarms issue the last of May, owing to the large flow of honey during the blooming of the apple orchards. White clover is our main dependence for surplus honey.

The boxes for surplus honey should be put on at the first appearance of white clover blossoms, which may be seen about the middle of June, and we may look for sealed honey about the last of the month. Remove it as fast as finished, and give new boxes to be filled; and from then on watch closely, both the boxes and the combs to be extracted, and remove them as fast as capt, and return new boxes and empty combs.

Do not be content to fill an upper story once, to be extracted in the fall, but remove the honey from the combs as fast as capt. It is important to attend to this at the proper time, for the honey-flow will not wait for other work to be done first. To make the apiary a success, it is important that the work should be done on time.

There are only three things necessary to successful bee-culture, viz.: "One should know what to do, how to do it, and then do it on time."

It is a matter of wonderment that so few farmers keep bees. Every farmer ought to keep bees on his farm for the proper fertilization of his crops; but aside from this he should keep bees for the honey they gather. Honey is the purest and most healthful sweet known; while it is considered something of a luxury it should be on every table, and certainly the farmer can gather it much cheaper than he can buy it. Thousand of pounds of this delicious sweet go to waste annually because there are not bees enough to gather it. Any farm, no matter how small, has room for a few colonies of bees.

Bees are great public benefactors in the fertilization of flowers, and day by day investigation reveals the importance of the honey-bee to plant life. In Germany it is estimated that the value of each colony of bees in the matter of fertilization alone is equal to ten dollars.

Ohio alone has 50,000 colonies, which produce annually 1,300,000 pounds of honey. You can readily see that the honey-bees contribute not a little to the value of the agricultural products of the State.

There is no doubt but that love for any pursuit is desirable if the best results are to be obtained, yet success is possible if the work be well done, even if doing it be not so agreeable to one's taste. But of all occupations bee-keeping leads to enthusiasm, even if not so pleasing at the start, and the more the little details are attended to the more is the interest aroused in the mystery within the hives; and if the little details are well attended to, and on time, there is no branch of farming that will pay better for the labor and money expended. Ashtabula Co., Ohio.

Bees on the Farm—Their Advantages.

Written for the Stark Co., Ill., Farmers' Institute,

BY DR. C. C. MILLER.

YEARS ago it was a common thing to see a group of bee-hives standing near the farm-house, and the annual "taking up" of the heaviest and lightest was an event of interest, not only to the immediate family, but to the friends and neighbors less fortunate in the possession of the frugal honey-gatherers. At the present day one may travel many miles without even the sight of a hive. Keeping bees has become to a greater or less extent a business by itself, there being a comparatively small number of bee-keepers, each of them, however, keeping a considerable number of colonies of bees, ranging from 50 up into the hundreds, and in a few cases into the thousands.

This falling into the hands of specialists might be a good thing if they were evenly distributed over the country, but it results in a double loss when the apiaries are so distributed that any considerable portion of the country is out of the reach of the bees. The double loss comes from the double duty the bees perform. Very likely, if the average farmer were asked what double performance is expected of the bee, he would reply, "Making honey and stinging."

A magnified conception of the amount of stinging done is generally entertained. I get my full share of stings when working with the bees, perhaps an average of five a day thruout the season. A million bees may be flying in the course of the day, and I would rather that the five that sting me would turn their attention in some other direction; but think of the nine hundred and ninety-nine thousand, nine hundred and ninety-five that *don't* sting me!

No, stinging is not an important occupation of the honey-bee, not one bee in five thousand ever stinging a human being. A much more important occupation than stinging—aye, more important even than honey-gathering—is the fertilization of the flowers. If no apiary is kept within two or three miles of your farm, you will be wise to have at least one colony of bees, even if you are so afraid of them that you must enclose them with an eight-foot fence. If an important apiary is located near you, then it is unwise to attempt keeping bees. The ground is already occupied, and the ground may be overstocked with bees as well as with cattle.

Time does not allow to go fully into a statement of the work performed by bees in the way of fertilization, but mention may be made of one of the commonest fruits—the apple. The stamens are on the same apple-blossom with the pistil, and at first thought one would conclude that there would be no trouble about fertilization, for the pollen could hardly help falling from the stamens upon the pistil. But Nature seems to guard carefully against in-breeding, and in this case the pistil is no longer in a receptive condition when the pollen is ripe. In other words, the stamens and pistil of a blossom are not ripe at the same time, so no blossom is ever fertilized by its own pollen, but the pollen must be carried in some way from some other blossom, and the honey-bee is the chief performer in this service.

You are familiar with the two kinds of blossoms on cucumbers, squashes, and other vines; false and true blossoms they are called. Before it is in full bloom, enclose one of the true blossoms in netting close enough to prevent a bee getting thru. It may be so coarse that the wind might easily blow into it pollen from one of the staminate or false blossoms, but if no bee can enter it will blast.

If then, no bees are within two miles of you, it will pay you well to keep bees, even if you never get an ounce of honey from them.

A few words about honey: Physicians say that much of the trouble in kidney diseases, and diseases of the stom-

ach and intestines, comes from the sugar that is eaten, the difficulty being that the cane-sugar must be changed after it is eaten, but honey does not need the same change, hence is a more wholesome article. Children have an intense love for honey, and it is for their health that such craving be satisfied. Give them bread and honey: unless wrongly trained, they do not care for butter with it. Honey is much cheaper than butter, better for them.

Some say, "Honey never agrees with me." Neither would many another article agree with you if you should make a pig of yourself and eat a lot of it after taking a full meal. Let honey be eaten in moderation as part of the regular meal, and you will easily become accustomed to it. In Germany it is not an infrequent thing to hear of people of great age attributing their long life to the use of honey.

McHenry Co., Ill.

Some Difficulties in Connection with Foul Brood

Written for the California State Bee-Keepers' Convention,

BY THOS. WM. COWAN.

THOSE who have had very much to do with foul brood will readily admit that, for the average bee-keeper, there are many and serious difficulties in connection with this disease which baffle him, and can be overcome only by an intelligent mastery of the subject. The disease is allowed in many cases to break out and spread, without the slightest precaution being taken, sometimes thru ignorance, carelessness, or indifference on the part of the bee-keeper, to the detriment of others keeping bees in the vicinity. In consequence of this it is no wonder that foul brood is spreading, and that there is a demand among intelligent bee-keepers in all countries for legislation to prevent the industry from being destroyed. To be brief and concise, I will mention only some of the difficulties we have to encounter to make people understand the conditions under which the disease exists, or to study its etiology.

1. That foul brood is terribly contagious, and that as great care should be exercised in dealing with it as with smallpox or cholera. What these diseases are to man, foul brood is to bees.

2. That foul brood is a germ disease, and is produced by the presence of a minute organism called *Bacillus alvei*, which exists in two different forms. In the earliest stages of its existence it is in the form of a rod, and is usually then termed *bacillus*, to distinguish it from the latter stage, or *spore*, as it is then commonly called.

3. That there is a great difference between these two stages, and as both may exist in the hive at the same time, the treatment that would destroy the one would have no effect upon the other.

4. That *Bacillus alvei* is in form rod-shaped; and each rod, as it attains full growth, splits in two, each of these taking up an independent existence, and going thru the same process; and as two generations can be reared within one hour, the same rate of progression being kept up by each individual, it is not astonishing that foul brood spreads so rapidly.

5. That under certain conditions bacilli have the power of forming spores which are analogous to seeds or plants, and are endowed with wonderful vitality, being able to endure adverse influences of various kinds, without injury so far as their germinating powers are concerned. Boiling water and freezing will kill bacilli, but not their spores. In the same way chemical reagents which readily destroy bacilli have no effect upon the spores, unless given in such strong doses as would kill the bees. (It is extremely difficult to make people understand this great difference in the vitality of bacilli and their spores, and it is here that the great danger arises.)

6. That spores coming in contact with suitable nutrient material have the power to germinate into bacilli, after the lapse of long periods; and according to Dr. Klein, one of our best authorities, there is no reason to assume that these periods have any limit. That is why the disease sometimes breaks out in districts where bees have not been kept for years.

7. That experience has shown with foul brood, as in all epidemic diseases, the weak, sickly, and badly nourished are attacked and become centers of infection to others; and so rapidly does the disease spread by contagion that, unless precautions are taken, a whole neighborhood may become affected in a short time.

8. That colonies suffering from foul brood are usually weak, and this induces bees from other hives to rob them of

their honey, and thus carry off the germs of the disease along with their ill-gotten gains.

9. That combs which have contained foul brood retain the spores. The queen lays eggs in the cells, and the workers deposit their honey and pollen in them. Both honey and pollen in this way become vehicles for the transport of the disease to the larvæ in the process of feeding by the nurse-bees. The workers, in endeavoring to clean the combs, scatter the spores, which may also be driven out of the hive by the current of air produced by the fanners at the entrance in their endeavor to rid the hive of foul odors.

10. That, if on examining the combs, to all appearance healthy, with brood compact and larvæ bright and plump, we find here and there a cell with young larvæ moving un- casily, or extended horizontally instead of being curled up, and changing to a pale yellow color, we at once detect the first symptoms of foul brood. The germ at this stage being only in the rod form, the further progress of the disease can be arrested by feeding the bees with syrup, to which a suitable antiseptic drug is added. The bees then generally remove the dead larvæ.

11. That apart, however, from experienced bee-keepers or trained experts, very few are fortunate enough to detect the disease at such an early stage, or effect a cure so easily.

12. That when the combs have irregular patches of brood, with sunken and perforated cappings to the cells containing the putrid, coffee-colored, ropy mass inside, the treatment should be:

a. If the colony be weak, destruction of bees, combs, frames, and quilts, together with thoro disinfection of hives, is by far the best course to pursue. We thus destroy the spores, and so remove the source of infection.

b. If, on the contrary, the colony be still strong, the bees may be preserved by making an artificial swarm of them, and feeding them on medicated syrup for 48 hours, after which time they can be placed in a clean hive furnished with sheets of foundation, and fed with medicated syrup for a few days longer. The combs, frames, and quilts are burned, and the hive disinfected by being either steamed or scrubbed with boiling water and soap, and then painted over with a solution of carbolic acid; and when the smell has disappeared, the hive is ready for use. (The bees are allowed to remain 48 hours in the empty hive, for by that time the honey that they may have taken with them, and which might contain spores, will have been consumed, and the diseased bees will have died off.)

13. That in his endeavors to rid his apiary of foul brood, the bee-keeper must also raise to its proper standard the lowered vitality of the bees which enabled the disease to get a footing. This he must do by keeping his bees strong with young and prolific queens, good wholesome food, cleanliness, and proper ventilation.

14. That the bee-keeper may himself be a cause of spreading foul brood by indiscriminately manipulating, first diseased and then healthy hives, without taking the precaution to disinfect himself or his appliances. Clothes, appliances, and hands should be washed with carbolic soap, and other articles disinfected by spraying with some suitable disinfectant.

These are only a few of the many difficulties, and only the fringe of the subject has been touched upon; but sufficient has been said to show that, unless great precautions are taken, it is very difficult to get rid of the disease. It thus becomes obvious that those who fail to realize the danger of infection, and who will not take proper means of ridding their apiaries of foul brood, or of preventing its introduction, are a real danger to the industry.

Relieving the Pressure on the Queens.

BY HARRY LATHROP.

I PRESUME a good many bee-keepers are engaged these days in doing the same work that I am, that is, relieving the pressure on the queens, by giving them more room. A year ago at this time bees were destitute of stores in this locality, and the combs became dry and devoid of honey or brood. Now the problem is, How to prevent restricting of the queens by reason of there being so much honey and pollen in the combs.

To-day I have been going over one of my yards, adding extra stores in all cases where it seems necessary, adhering to my rule not to take from strong colonies in order to build up the weaker, but giving them plenty of room and allowing them to become as strong as they may.

I do not always pursue the same course in giving extra

room. In some cases I give the queen access to the added set of combs; in others I remove one or two combs containing the most honey from the brood-chamber, place them in the super that is to be added, replace by the same number of empty combs in the brood-chamber, and keep the queen below with an excluder. This will give more room, retard, if not prevent, swarming, and insure a strong colony, as all the combs in the brood-chamber will be full, or nearly full, of brood as soon as the queen lays in the two empty combs given. And the two removed and placed in the upper story will contain more or less brood that will hatch and augment the already strong colony.

A little later, when the white honey season has well begun, I will reduce many of these two-story colonies (I use 8-frame hives), and give them one or two supers of sections in place of the upper stories. Swarming may, or may not, result. If swarming does result, I will manage to keep the working force together. The upper stories removed will be placed on weaker colonies (or on any colony that I think will not do good comb-honey work) for the production of extracted honey.

FULL SHEETS OR STARTERS IN SECTIONS—SEPARATORS.

I am using full starters of extra-thin foundation, but have not as yet tried bottom starters. It seems to me that putting foundation in sections is the most tedious work a bee-keeper has to do; and, as far as my experience goes, it can not be delegated to cheap help. One of the largest producers of fancy comb honey in this State will not trust this work to any one but himself. He produces straight combs in 7-to-the-foot sections without separators. I get part of my crop without separators, and for part I use the regular 1 $\frac{1}{8}$ -inch section with separators, and don't know which is the better.

Well, bee-keepers, I hope to see you all as members of the National Bee-Keepers' Association, at Chicago, next August. Green Co., Wis., May 29.

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Richards, Ohio.

HOUSE-APIARY AND WINTERING.

The house-apiary of Notre Dame, as we see it on page 273, looks substantial, and made to endure. You see an institution is not expected to terminate with one man's life. And how happy is the honey market of a college! The youths who are so sincerely interested in the Commons Hall three times per diem will not haggle over the question whether the product of the apiary is estimated at 5 cents a pound or at 50 cents a pound. Down she goes all the same. Instructive circumstance that the house has wintered its bees well for six years, the hives, but not the house, being packed. I'll venture to guess that that Kentucky 11-year-old queen was in three successive volumes unbeknownst to the keeper. And so Mr. Chrysostom would like to go on a crusade against cellar-wintering and the loose-hanging frame! Well, as the bumpkin said of Niagara, "What's to hinder?" He'll find the Saladins on the other side a smiling, and not very belligerent, lot.

GETTING THE MOST INTO AN EXCLUDER.

Say, Grimes, it's not to get the most out of it, but to get the most *into* it, that's the main thing anent the excluder. Most of us can get out somehow or other whatever gets in. Interesting to see that so able an operator as Grimes succeeds with communication to the super only around the outside, all the middle being thin board. This critic conjectures that some strains of bees will stand that all right, and that some will not stand it at all. Page 275.

METHODS OF CONTROLLING INCREASE.

The method of controlling increase given by John R. Schmidt, page 275 (double every spring and nrite down one-half every fall), I think to be well up to the high water mark of our present knowledge. Still, we shall not be entirely satisfied with our "hoss" and his training until we can

make him whoa. Moreover, once in awhile there will come a destroying winter that will sweep away two-thirds of the consolidated one-half; and *then* we will regret that every good colony was not allowed to try its luck. Mr. Schmidt's method of *repeatedly* moving the parent colony from one side to the other of the new one seems to be good—or would be if it did not require such close attention.

And Mrs. Snyder, she is one of a small army at work on another controlling scheme let the colony become two, and then wheedle both into one again without waiting for winter. This scheme subdivides naturally into two schemes, the perambulate-'em-round method, often called the Heddon method, and the put-'em-up-stairs method, which we have immediately under consideration. Interesting to see that Mrs. S. finds newly hatched bees, emerging under unnatural conditions, to perish in large numbers from hunger, and from being hustled by their elders. Page 276.

BEEES ROBBING—FEEDING-WHISKEY NONSENSE.

Mr. Dadant doeth well to remind the greenhorns (whose legs and arms are sticking out of the world's windows all around) that a man cannot take a colony of bees and "sic 'em on" to his neighbor's bees, as if they were dogs. They would go for a colony in his own yard first. Sorry he didn't say right out that the idea of feeding bees whiskey to make them rob must be considered rank nonsense until some proof of its success is shown. May succeed to the extent of getting the inebriated colony robbed by a sober one adjacent. And robbing once begun may run a long course. Page 276.

POINTS ON SPRAYING FRUIT-TREES.

Mr. Holtermann makes two excellent points about the spraying question. If a spray kills leaves (and it sometimes does), the essential parts of a flower are more tender than leaves, and therefore more liable to destruction—the horticulturist biting his own nose off, as it were. And the man who would fain spray in full bloom might profitably receive by mail a card with the spraying law printed on it. Page 277.

ONION HONEY FOR WINTER STORES.

I hope Mr. McBride has it a little too rank. I still want to think that a big field of onion bloom might not *always* prove a curse in a barren season. Doubtless the hives smelt bad; but perhaps the practical result *might* have been the same had the bees stocked up for winter on some other second-rate bloom. Page 286.

THE BELGIAN HARE AUXILIARY.

Happy the bee-man be's of late,
He's found a boom for his ebbing fate;
Yea, found for his biz a running-mate;
It's the Belgian hare, which the world shall ate,
All born and bred in an onion-crate.—Page 292.

Still something within me cries out that that starting an auxiliary business is the first step towards abandoning the bee-business altogether.

WHERE TO PLACE BAIT-SECTIONS.

Place bait-sections in the center to get reluctant or weak colonies started quickly, but around the corners if to encourage even work thruout the case. Guess that is about correct, Mr. Aikin. But I thought I was almost the only one contrary enough to put in baits with old honey in them—and lo, he steals my dirty trick! Shake, brother! The ups and downs of super work do not exactly correspond with the gatus and halts of the honey-flow, as shown by the scale colony. Yes, that's so, too. Page 289.

PUSSY-WILLOW AS A NECTAR-YIELDER.

I think that the statement made on page 295, that the pussy-willows yield no honey, should be taken with considerable allowance and margin for different localities and weather. Very likely it is not common for it to yield enough honey to increase visibly the amount on hand in the hives.

EMPTY BOTTLES FOR HIVE-STANDS.

Set the hive on empty brandy bottles, eh? Four, with the necks driven into the ground. Some of the brethren will think the suggestiveness of that a little too strong. Dr. Miller, if you don't drink brandy you can use beer-bottles. Also, those who have got onto the trick of using oil instead of butter can use oil-bottles—a relief to find some use for them for which they do not have to be cleaned. But still, my preference is strong in favor of having things fixt so bees cannot cluster underneath a hive. If you do use bot-

ties, crowd the vacant space full of sawdust or cinders just the same.

Our comrade was also going it strong when he stuck to his efforts to have queens get to laying up-stairs until he had lost an even 50 queens—with no success to balance. Page 290.

TWO KINDS OF PRICES.

"Decide what prices ought to be, and then stand by those prices." Page 295. That sounds like the millennium—but that isn't here yet. Alas, in the noddles of bee-folks, all the same as other folks, the "price that ought to be," and the highest price that can be extorted from the buyer, get swapt in the cradle, somehow.

ROBBER-BEES AND BALLED QUEENS.

On page 297, that quotation from a foreign bee-paper, about the foolishness of thinking that robber-bees ball a queen, is probably all right in the main. Robbers are indeed there for honey—not for reginacide—but perchance no one interferes, and after awhile the honey is gone, and the hive is filled with a miscellaneous crowd largely new comers, who are like a city mob, "the more part know not wherefore they are come together." Who wants to guarantee the queen's life, then? Not I. And I doubt whether mysterious balling comes as often from young alien bees, as Mr. Mulor thinks. More than half the time her own children do it, I suspect. They think wrongly that she needs superseding. More strictly speaking, they don't think at all; but it is part of their duties to supersede when there is little young brood and little scent of fertility in the hive. Unfortunately, these same lacks come about in famine times without the queen's being to blame, and they are unable to discriminate.

THAT CALIFORNIA COMB FOUNDATION IMPROVEMENT.

If Mr. Vogeler's patent wrinkle concerning foundation proves to be of decided value he'll have a lovely time keeping possession of it—it is so easily done—just a brush and some melted wax. Easy to see that natural comb in process of construction always has a rim at the mouth of each cell. This rim is steadily moved upward by pinching. But I opine that side-walls will have to be higher than we usually see in foundation before rims can be brushed on. Page 297.

VALUABLE "SMASH" HONEY IN CANAAN.

Another peculiarity of that Canaan honey of Connecticut, which you overlookt, Editor York, is that producing it in brood-comb and recovering it from the smash of a tree makes it worth 20 cents a pound. Page 297.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

What to do with Frames of Comb and Honey.

Geo. H. Adkins, (on page 348) should not think of melting up the combs left by those 44 colonies that died, but should bend himself to the task of having them all occupied by bees before the summer is over. If they are kept in a cool, dry cellar, worms will make progress in them very slowly. A damp cellar will do if a dry one is not to be had, and will prevent progress of the worms just as well, but the combs are more likely to be moldy. Occasionally the combs may be lookt over, and wherever the web of a worm is seen the worm can be dug out with a wire-nail. Under each of the six colonies a hive full of combs can be put, and it will be all the better if the bees are obliged to pass down thru the lower hive to find an exit. After the bees have had this hive-full of combs for a few days, perhaps for a week, another hive-full can be put between the lower story and the one containing the colony.

When the first swarm issues, or is made artificially, use for it a hive full of combs that have been cleaned up by the bees (a swarm is likely to object to being put on unclean combs), and a few days later this swarm can have a hive full of combs put under to be taken care of, and later another. In this way, as increase goes on, you can have an additional number of combs cleaned up and kept clean, and if the original 6 be increast to 17, all your combs can be in the care of the bees. Even supposing the original 6 becomes only 13, in which case all would be likely to be quite strong—you can put not only two stories of combs under the colony, but you can put a story over the colony.

I have had 3 hive fulls of combs taken care of in this way: The 3 stories were piled over the colony, and from the colony was taken a frame of brood with adhering bees to put in the upper story. This had the effect to oblige the bees to traverse all the stories in going from the lower story to the brood in the upper. A hive full of combs could also be put under the colony, thus making the pile 5 stories high.

That keen-eyed observer, E. E. Hasty, albeit he claims not to see as well as he would like, hints on page 342 a fear of infantile death in the 5-story arrangements. Mr. Hasty, no doubt the matter could be arranged to that effect, but as a matter of fact my bees have taken good care of the brood in these upper stories. C. C. MILLER.

Young Bees Flying—Width of 10-frame Hive—Langstroth's Book.

1. When young bees take their first flight, do they not run up the side of the hive before flying, just like robbers do?
2. What is the width of a 10-frame dovetailed hive?
3. Is there much difference between the editions of "Langstroth on the Honey-Bee" of 1862 and the present one revised by the Dadants? OHIO.

ANSWERS.—1. Not generally so much "up the side of the hive" as on the alighting-board. Then they fly circling with their heads toward the hive, and a novice sometimes thinks they are robbers.

2. 14 and $\frac{7}{8}$ inches, inside.
3. A great difference.

Bees Killing Each Other—Brood Died—Italianizing—Sowing for Honey.

I have one colony of Italians that kill each other. They seem to be diseased in some way. Some of them vary in size and color, some being as black as coal. They just fight and kill each other at the entrance of the hive. They were all right early in the spring, and were the prettiest Italian bees I ever saw. Is it bee-paralysis? What ought I to do with them? I had a colony affected in that way in 1898, but they are all right now.

2. I have a young swarm that (most of) the brood died about the time it was two-thirds grown, and the bees would carry it out. It looks very much as if it had starved. It is not ropy, and looks very white except on its abdomen, which looks dark. I took it away from the bees and gave them some more combs. What is the matter? What is the remedy?

3. I have 22 colonies of bees, the most of them blacks, and I want to Italianize them. Can I divide the Italians into 2-frame nuclei and rear queens that will be all right? If so, when will be the best time? Any information about queen-rearing will be appreciated. I have tried dequeening a colony and supplanting them with eggs to rear a queen, but it takes some time and does not give a well-mated queen every time; besides, the whole colony loses too much time. I think that by rearing several queens in small hives I can test them before I introduce them.

4. Will buckwheat do well to sow after wheat? We harvest about June 1st.

5. Will sweet clover do well this far South? GA.

ANSWERS.—1. Very likely it is bee-paralysis, and you can only hope it will disappear as it did before. Many remedies have been given, but so far nothing that seems reliable.

2. It looks like starving, and, if so, all is no doubt well by this time. Still, so much trouble is coming lately from new diseases that one cannot but feel uneasy, and if the trouble continues it might be well to consult Dr. Howard or Mr. McEvoy, who are experts in such matters.

You cannot rear good queens without their costing something. You can divide a colony into a number of small

nuclei and let each start its own cell and rear its own queen, but I wouldn't take such a queen as a gift. Don't think of having cells started in anything but a strong colony and leave them there at least until they are sealed. Better not give a cell to a nucleus until within a day or two of the time for the queen to emerge. If you want to rear several queens, it will pay you well to have Doolittle's book on queen-rearing. In the meantime here is a plan you may take to start a few: Build up your best colony strong by giving frames of hatching brood from other colonies, unless it is already very strong. Not sooner than a week after giving the last frame of brood, take away the queen with one or two frames of brood with adhering bees, and put in a hive on a new stand. Ten days later put this hive with the queen back on the old stand and take away the hive of queenless bees. Make nuclei from the contents of this hive, putting one of the nuclei (the weakest) on the stand from which the queen has just been taken. Put two frames of brood in each nucleus, and let each nucleus have at least two good-looking cells. If the cells are bunched on one or two combs, you must cut them off and fasten on the combs that need them, using a common wire-nail to fasten them on. Do not leave a cell on the bottom of a frame, but cut it off and fasten where it will be sure to be kept warm by the bees. If you gave sufficient brood from other colonies to bring your best colony up to 20 frames of brood or more, you will have no trouble in starting 10 or more nuclei.

4. It may do well unless too late, and some farmer in your locality who has tried it could tell better about it.

5. Sweet clover will probably do well with you, and is perhaps the best thing to sow specially for bees.

A Queenless Colony.

As I was going past my neighbor's place he called me in to see a colony of bees. They were good and strong, but they were rearing all drones, not a worker among them. They had a queen nearly hatched. Will the queen be any good? They have no queen alive with them.

COLORADO.

ANSWER.—It is possible that a played-out queen had been laying drone-eggs almost entirely, but among the few worker-eggs one had been used in a queen-cell, in which case the young queen will be all right. More likely the queen-cell "nearly ready to hatch" contains only a drone, and will never hatch. The chances are many to one that the best thing you can do is to break up the colony.

Bees Affected With Foul Brood.

I have a colony of bees in which there is a number of combs half full of dead brood. The caps are sunken, and the brood is coffee-colored. When I stick the point of my pocket-knife into a dead larva, it draws out in one thread about an inch. Some time ago the bees began to cluster out, and I raised the front of the hive about one-third inch. Shortly after came on a cold spell, and as the dead brood is mostly in the front of the hive, I thought they might be chilled.

1. Does the "back presentation" always accompany foul brood?

2. If more brood keeps on dying, so that I am sure it is foul brood, what course would you advise me to pursue?

MICHIGAN.

ANSWER.—1. If by "back presentation" you mean the young bees are in their cells wrong end foremost, it may be said that it does not always accompany foul brood.

2. I don't believe I should want to be any more sure about it, but would at once burn up the whole business, or bury it beyond the hope of resurrection. Better get Dr. Howard's book on foul brood, from the American Bee Journal office, by sending 25 cents.

Young Brood Hatching and Dying.

I am in trouble with my bees, and would like to know what is wrong with them. As fast as the young brood hatches they go out and die. I have 60 colonies, and two weeks ago they were nearly ready to swarm; to-day they are no better than when I put them out. I have been 5 years in the business, and never saw the like before. They are not starving, as they have honey. All drone-brood cappings I

shaved off, and let the bees carry out the larva. I did that this year for the first time. I would like to know if that would cause the trouble. What would be good for it?

CANADA.

ANSWER.—From the description given it is impossible to tell what is the trouble. It is not likely that shaving the drone-brood has anything to do with it. You do not say whether it is confined to one colony, or how many. Possibly it is spring dwindling, altho rather late for that. Possibly poison may have something to do in the case. It is to be hoped that by this time they have recovered without further loss.

Affected With Bee-Paralysis.

I have a colony of bees that have something ailing them. They crawl out of the hive, and are dragged out by the other bees, and they look as if they had been varnished, and somewhat swollen. They crawl over the ground, and have a tremulous motion of the wings; they seem to be unable to fly. What is it? Is the disease contagious? What will cure them? The colony has swarmed, and both old and new are affected alike.

INDIANA.

ANSWER.—Bee-paralysis. No reliable cure seems to have been found, but as far north as Indiana the disease generally disappears without doing much damage, and does not appear to be contagious.

Buying Pure Extracted Honey.

How can I be sure, in buying extracted honey, that it is not adulterated? Where could I learn how to analyze it? I produce comb honey, but I buy quite a good deal of extracted for some of my neighbors who prefer it.

N. J.

ANSWER.—One of the best ways to be sure of buying pure extracted honey is to buy of an honest producer, or an honest dealer who says he knows the honey is pure. Unless you expect to handle large quantities of honey it is doubtful whether it would be worth while to be your own analyst. You can get honey analyzed by the chemist connected with your State University, and perhaps learn the process from him.

Perhaps Bee-Paralysis.

I have 3 colonies that act as if there was some disease working on them. The bees crawl out of the hive and are not able to fly, and the abdomen is black. They crawl off in the grass and die. What is the matter, and how can I get rid of it? All the rest of the apiary seem to be healthy and all right.

WASHINGTON.

ANSWER.—From your description it is probably bee-paralysis, and unfortunately no sure remedy is known. In the North it generally disappears of itself, but in the South it is a bad scourge. Very likely yours will not do any great damage.

Using Drawn Combs for Swarms.

As I am considerably short of surplus combs, and have a large amount of foundation to draw out, and can give only about two combs to each swarm in the brood-chamber (when hiving bees), would you put the two drawn combs in the center, filling up with foundation? or would you put one comb in each, outside?

ONTARIO.

ANSWER.—I believe I should do neither, but put the two combs together at one side of the hive. If the combs are in the middle, or one at each side, there is more chance for the bees to bulge the old combs into the foundation. With the two combs together at one side, they could do no more than to bulge into one side of one frame of foundation, and might not do that.

Dr. Miller's Honey-Queens are offered as premiums, on another page, for sending us new subscribers to the American Bee Journal. The offer is limited to our present regular subscribers, and the queens are to be mailed in rotation, beginning about June 10th, so first come first served. Look up a new subscriber, send in his name with \$1.00, and we will enter your order for a Dr. Miller Honey-Queen.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY,
118 Michigan Street, Chicago, Ill.

[Entered at the Post-Office at Chicago as Second-Class Mail-Matter.]

DEPARTMENT EDITORS:

C. C. MILLER, "Questions and Answers." ** E. E. HASTY, "The Afterthought."

LEADING CONTRIBUTORS:

G. M. DOOLITTLE, F. A. SNELL, C. P. DADANT, R. C. AIKIN, PROF. A. J. COOK, "OLD GRIMES."

IMPORTANT NOTICES:

The Subscription Price of this journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec00" on your label shows that it is paid to the end of December, 1900.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

VOL. 40.

JUNE 14, 1900.

NO. 24.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

To Kill Grass and Weeds About Hives, salt is quite commonly used. F. Greiner says in *Gleanings in Bee-Culture* that he has had some unpleasant experience with it, that if stock finds it there there will be no end of trouble, and much mischief may be done in a little time. Instead of salt he has used a solution of carbolic acid, but seems to prefer a solution of sulphate of copper, a pound to one or two gallons of water. Editor Root replies:

"The sulphate-of-copper solution, I have no doubt, will do the work very thoroly; but will it do it as cheaply as an application of salt? It is our practice to buy a barrel of common rock salt, which is sufficient to take care of an apiary of 300 or 400 colonies for two or three years. Once or twice a year we sprinkle a very little salt around each entrance. Very often one application each year will answer, provided there are not too many rains, so as to start up the grass again."

The Variation in Honey-Yield seems to be considerable in more than one direction. There is alfalfa—one of the finest honey-plants in the world, according to a multitude of witnesses in several of the States of the West. But it is of no value whatever, according to the testimony of the few who have observed it in places east of the Mississippi. A difference in place or conditions makes all the difference between a valuable and a worthless plant for nectar. So it is with many other plants. Some, however, seem to do well everywhere. Sweet clover is a fair example.

The value of a plant also varies with the season. Some

seasons white clover is an utter failure, altho blooming bountifully. Some plants vary greatly with the season in one locality, and almost not at all in another locality. In some locations buckwheat may be counted a success nine times out of ten, but in others a failure nine times out of ten.

With all this in view, it is not strange that there is conflicting testimony as to honey-plants. Lately one of the bee-editors express doubt whether bees got anything but pollen from dandelion. Mr. Davenport's report of 2,000 pounds of dandelion honey in one season settles the matter for at least one locality. A difference of testimony may come from the fact that in one locality a plant may be abundant, and scarce in another locality. If a man had a single plant of white clover, he might find it little visited by the bees, but would appreciate its value in the same place when acres were in bloom.

Another reason for variation lies in the fact that in one locality a certain plant may be the only kind in bloom, while in another locality it is entirely overshadowed by another and a better honey-yielder. Prof. Lazenby rates gooseberry rather low, but in another place it is highly prized, perhaps because no other plants are yielding at the same time.

The study of this subject is an interesting one, the limits of which are not easily reacht.

Drone-Cells vs. Dipt Cups.—H. L. Jones says in *Gleanings in Bee-Culture*: "I have repeatedly tried dipt cells and drone-comb cells in equal numbers on the same stick, and almost invariably got better results from the drone-comb." Editor Root stands up for the Doolittle cups, saying that their queen-breeder, Mr. Wardell, objects to new-fangled plans so long as he gets good results with plans that he knows *just how to work*. In a postscript, however, he says he is surprised to find that Mr. Wardell has been trying the drone-cells, and speaks favorably of them. But Mr. Root insists that the Doolittle cups are larger, stronger, and look more like peanuts.

Queen-Rearing is the special topic of the May *Bee-Keepers' Review*. Mr. H. E. Hill tells how he has cells built so as to be easily separable. Eighteen little square blocks are cut from a piece of section-box, and on each of these a queen-cell cup is fastened, each block being slid in a groove in a supporting slat, so the whole 18 are supported on the one slat somewhat after the manner of movable-block letters sometimes used in signs.

Mr. H. D. Burrell emphasizes the importance of rearing queens from a good mother, considering the working qualities of her progeny the first requisite, and beauty the last. All the workers should show three yellow bands, and hardness in wintering, gentleness, comb-building, and large, uniform size of workers, should be considered in the order named. Drone-rearing should be encouraged in a few choice colonies, and suppress in others. He believes in strong colonies for queen-rearing, and the Doolittle plans. Not every one, however, would approve making cell-cups of a mixture of beeswax and rosin.

Mr. W. H. Laws, from a professional queen-breeder's stand-point, prefers for queen-rearing a frame half the size of the Langstroth frame, or about $9\frac{1}{8}$ inches square. He makes these from Langstroth frames already occupied, by sawing off the projecting ends of the top-bar, then sawing thru the middle of the frame, comb, brood, and all, and nailing a top-bar on the raw edge. Thirteen of these small frames occupy one story of a hive, and two such stories make a full colony. Five of them are used for a nucleus. Whatever be the size of frame used, if queens are to be

reared thruout the season, he thinks success can not be attained without having full colonies on the same kind of frames used in the nuclei.

Mr. W. H. Pridgen furnishes the prize article, which occupies (including illustrations) nearly nine pages. Mr. Pridgen is a genius. He has carried to great perfection the producing of Doolittle cell-cups, making them by wholesale so rapidly that some one with the proper apparatus should furnish them ready-made at a comparatively low price. Probably Mr. Pridgen is the man for this. One way of making them grinds them out with a crank! The forming-sticks project from the circumference of a wheel, and revolving the wheel allows each stick to dip in order in the melted wax. He goes into full details of the queen-rearing business, and any one intending to rear queens for the market will find this one article worth much more than a year's subscription to the Bee-Keepers' Review.

The Dr. Miller Honey-Queens.—Owing to the fact that Dr. Miller is receiving orders for queens which he can not fill, and also to avoid possible disappointment, he sends the following for publication:

MR. EDITOR:—To save disappointment on the part of some who have written me ordering queens, I desire to say that I have no queens at disposal, having engaged them all to the publishers of the American Bee Journal. I hope no more will send orders or money to me, as I can only fill orders that come thru the American Bee Journal.

In reply to some who have asked that advance notice be given when a queen is to be sent, I may say that in all cases notice will be sent a day in advance of mailing the queen.

I am a little afraid that some will be disappointed in getting queens that are not handsome, nor the mothers of yellow bees. They are bred for work, and not for color. Some will be as good as the stock from which they are bred, and no doubt some will fall much below. Those who get untested queens must take the chances. The only thing I can be entirely sure about is that the mother of the queen sent out has proved to be the mother of workers that have given unusually good results in their performance.

C. C. MILLER.

When it is remembered that the main requirement of bees to-day is that they shall gather much honey, rather than be noted principally for their beauty of color or purity of blood, we have no doubt those who get a Dr. Miller queen will be well satisfied. The only fear we have is that he may not be able to rear them fast enough to meet the demand.

The Doctor expected to have begun to mail the queens on advance orders before this number of the Bee Journal is sent out.

A Honey-Bee's Load.—A member of the American Bee Journal's family writes us as follows on this subject:

"That report of Prof. Lazenby, on page 336, is a valuable contribution to our bee-literature, and he is not justified in saying his observations are not important in themselves. He is perhaps the first who has said that bees do not collect both honey and pollen on the same trip, and it is to be hoped that others will confirm or refute his conclusions. Some of his conclusions confirm the saying: 'Bees never do anything invariably.' He says, 'Strawberries are infrequently visited by bees.' If he had been in this region at the time of strawberry-bloom he might have said: 'Bees work busily upon strawberries.' They were at work on strawberries and raspberries at the same time, altho they were more plentiful on the raspberries. There were perhaps twice as many bees on the raspberries as on the strawberries; certainly not eight times as many, as the Professor's table shows.

"In view of the fact that an item is at present going the rounds of the papers (not the bee-papers) to the effect that a bee carries a load three times as heavy as the weight of its own body, it is interesting to note that Prof. Lazenby makes it only one-twelfth as much, or one-fourth as much as its own weight. But I can not figure it out so large as that. Taking the Professor's figures, the average weight

of an outgoing bee is .079 of a gram, and its weight is .094 as it returns with a load of honey. This, he says, leaves .022 as the average honey-load, or 27 percent of the average weight of the bee. I figure the difference to be .015 gram, or 19 percent of the weight of the bee, or less than one-fifth its own weight. Is there something wrong in my figuring, or is there something askew in the figures of our good friend in Ohio?"

There certainly seems to be discrepancy somewhere, and probably the best thing will be to ask Prof. Lazenby to kindly help us out of the tangle.

Hauling Extracting-Combs Home Instead of Honey.

—R. C. Aikin is a revolutionist. No one has before hinted that he had any right to haul home combs full of honey from an out-apiary, said combs to be extracted and then returned. But that is exactly what he has been doing, as related in the Progressive Bee-Keeper. He objects to extracting at the out-apiary, because the extractor, etc., must be hauled out, the "etc." including all the vessels to hold the honey. It is troublesome to have a place to extract the honey without the chance of being greatly troubled by robber-bees some of the time. If unripe honey is thrown out, as will almost surely be the case, it is immediately canned or barreled to the detriment of the good name of the producer. So he does all his extracting at home, having arrangements looking toward securing the honey in the best and ripest form. His extracting-chambers hold 40 to 45 pounds when full. Of these he has 25 to 50 extra, with which he starts with one horse to the out-apiary, and he gives the particulars as follows:

"In the morning I drive to the apiary with 25 extras, take off an equal number of full ones, and put the empties in their place. If it is a time when robbing will not trouble, the full ones are just set about the yard wherever taken off, sometimes set singly and sometimes in piles of from two to four, but always as open and airy as possible. The combs are not shaken singly, but the bees are mostly smoked down and the chamber taken off without removing a comb from it. The first thing is to get these chambers all off so the bees will be leaving them for home, and while this is going on do such other work as I have to do in the yard.

"When about ready to start home I load the chambers, and if there are still bees in them the disturbance of loading, and when in the wagon the excitement and hum of the many disturbed and lost bees realizing they are away from home and queen, causes them rapidly to leave the combs.

"When all is loaded, I put a canvas over the horse, covering head, ears and all complete, hitch to the wagon and start off. As soon as out of the yard, if no fighting bees are about, the canvas is pulled off the horse and we move leisurely toward home, and as we go the remaining bees continue to leave the honey, and before out of range of the yard, very few bees are left in it. In this way I go out three miles, take off a load of honey and drive home and into the honey-house before dinner. My house is constructed with a driveway right into the building alongside of the honey-rooms, and the wagon can be driven in head first or back in. The wagon stands in this driveway when not out on trips, and the honey can stay in the wagon as long as I please till I get ready to unload, and is free from robbers. Also I can load the chambers that have been extracted and are to go out again at any time, and the wagon is ready to hitch to when I am ready.

"I anticipate that many will say, 'Why do you haul those combs back and forth? Why not extract at the yard and save so much hauling?' I have been asked that many times. With just as much propriety might I ask, Where is your thinker and reasoner? If I do not haul out a set of combs empty and back a set full, I should have to haul out and back barrels, kegs or cans to put the honey into, and all the extracting machinery besides. Which will make the most hauling, the machinery and cans or the super and combs? The honey must be hauled whether in barrels or combs. At home the extractor is all ready set, the uncapping-box is there, the strainer, too—in fact, everything is in place and ready for business, and not a robber-bee nor flies."

The Premiums offered this week are well worth working for. Look at them.

FOR SALE!

50 Dovetailed bee-hives, 8-frame, 1½-story, of the G. B. Lewis make; 10 in flat, 5 in woven boxes that were never opened—just as they came from the factory; 10 set up and painted two coats of white, but not used; 30 set up and painted white and used one year only, and partly filled with comb; supers filled with sections and foundation starters. I will sell as much as any one wants, for 80 cents each, f.o.b. at Roseland, Nebr. For particulars write to

GENERAL ITEMS

Bee-Industry Extensive There.

Bees in this vicinity wintered with but little loss, but are in light condition as to stores, and have been slow in breeding up. Those who have not fed enough to stimulate breeding still have light colonies, but they will build up very rapidly as alfalfa is now blossoming, and promises a good flow of honey. The bee-industry is quite extensive in this valley, and, as a rule, very profitable. **F. E. BENEDICT,** Otero Co., Colo., June 4.

Honey Crop Almost a Failure.

I am in a mountainous section of country—one of the best locations in this part of the State.

We had a fine, open winter, and the hills were green all thru it. The early rains began in October, 1899, and lasted until May, 1900. As much as 22 inches of rain must have fallen, but the honey-crop will be almost a failure, as we have had very little honey so far, and there was a frost on May 25th. All of the flowers (principally sage) bloomed during the fine weather early in the season. We have ball sage and blue sage, but no white. There is some black sage about 8 or 9 miles from my apiary.

There is very little fruit around here—possibly about five acres—but my bees got honey from blossoms somewhere. They would have to go five or six miles to get it, proving that bees will go that far for honey. The honey is of a fine flavor, but is not clear.

We expected a good season, but it is a failure so far. We may get some honey later on, as bees work here off and on until October. I have been in the bee-business for 20 years, and never yet failed to get some honey.

T. KEATING.

Santa Clara Co., Calif., May 28.

A Happy Bee-Fever Patient.

If Blunk ever catches Dr. Miller and George York—well, they would better try to get that gun from Doolittle. Why? Well, it was those chaps who inoculated me with a terrible dose of bee-fever over two years ago, and when they had the patient where he could not rest easy for a moment, then along came Gleanings in Bee-Culture and also began to prescribe. Will the patient ever be cured? I think not, but he must take their remedies the rest of his days. One good thing for the patient is that he appears to relish their medicines.

The good book says, "Charity covereth a multitude of sins." It is my opinion that charity can be applied in various ways. Now, I won't say that those men are sinners, but if they are, I think their act in inoculating me with the fever has created a happiness within which I enjoy (a mild way of putting it), and their act was a charitable one, as I look at it.

In 1899 I increased from 5 colonies to 12, and got 500 pounds of comb honey. We had eaten it all by the holidays.

The Queen Crank

Is before the readers of this Journal with a petition for orders for as fine Queens as he has ever been able to rear. They are being, and have been for some weeks, reared in triple-decker 10-frame hives, from choice Golden and Three-Band Mothers, in a Golden yard. The Bee-Keepers' Review, of Flint, Mich., for May (which is a special queen-rearing number) tells how it is done. Ask for a copy. Tested, \$1.00; untested, 75 cents. Money order office, Warren, N. C. **W. H. PRIDGEN,** 24Att Creek, Warren Co., N. C. Please mention Bee Journal when writing.

Yellow Sweet Clover Seed

WE HAVE IT AT LAST!

We have finally succeeded in getting a SMALL quantity of the seed of the YELLOW variety of sweet clover. This kind blooms from two to four weeks earlier than the common or white variety of sweet clover. It also grows much shorter, only about two feet in height. It is as much visited by the bees as the white, and usually comes into bloom ahead of white clover and basswood. We offer the seed as a premium

A QUARTER POUND FOR SENDING ONE NEW SUBSCRIPTION.

So long as it lasts, we will mail a quarter pound of the seed to a regular paid-up subscriber who sends us ONE NEW subscriber for the American Bee Journal one year, with \$1.00; or ¼ pound by mail for 30 cents.

We have been trying for years to secure this seed, and finally succeeded in getting it. It is new seed, gathered last season by an old personal friend of ours, so we know it is all right. But we have only a small supply. When nearly out we will mention it.

Root's Column

If you would secure a good crop of honey, you should aid the bees by providing them with

The A. I. Root Company's
Weed New-Process

Foundation,

which is known by these trade marks:

The Weed New-Process Foundation has been indorsed by experiment stations and agricultural colleges as well as by private individuals. Wherever it has been placed in competition with ordinary Foundation it has been found that the bees will not only take to it more quickly, but will draw it out more fully. The result is that sections containing the Weed New-Process Foundation will be filled and cap't over sooner than those containing the old process.

Our Foundation is put up in pasteboard boxes holding 1, 2, 3, and 5 pounds, respectively, also in neat wooden boxes of 5, 10, 15 and 25 pound sizes. Bee-keepers will find it a great convenience to get their Foundation in these regular packages, as it is sure to reach them in first-class order. Parties who buy in considerable quantities to supply their neighboring bee-keepers will find these small pasteboard boxes a great convenience, and to such we make a special rate which we will quote on application. Our prices are as follows:

Table of Prices of Root's Weed New Process Comb Foundation.

When you order, be sure to tell which grade you want, and give price.

NAME OF GRADE.	Size and sheets per pound.	In lots of			
		1 lb	5	10	25
Medium brood	7 1/4 x 16 7 to 8	48	46	44	43
Light brood	7 1/4 x 16 9 to 10	50	48	46	45
Thin super	3 3/4 x 15 1/2 28	55	53	51	50
Extra thin	3 3/4 x 15 1/2 32	58	56	54	53

You are likely to find right in the midst of the honey harvest that you are short of Foundation. Do not lose dollars by neglect, but order a box of Root's Weed New-Process Comb Foundation at once.

You can get this Foundation promptly of any of the following dealers. Send to dealer nearest you and save heavy transportation charges.

THE A. I. ROOT CO.,
MEDINA, OHIO.

Before we sell any we must have more than we can consume on the farm, as I tell the good woman we are entitled to it as pay for all of those stings.

This spring we took from the cellar all the colonies that we put there in December. Our queens are all clipt and we expect no trouble in finding them during swarming-time. One could see a pin on the ground about the hives as there are no weeds or grass. Yellow willow afforded early feed. Swarming now begins, and of course the patient is happy.

If the Doctor and "George" would do penance just once, and go a-fishing with the patient, he would forgive them for what they did, and furthermore would furnish the bait.

"George," you go to your mailing-list, hunt up Blunk's name, and you will find a c just before the k. Knock it out, for it is silent, and no good. The old man Blunk brought that "c" over from Germany with him a long time ago, and he is a believer in short spelling, since "George" prescribes it.

I would say to "Afterthought," that my bees and strawberry bloom don't mix. I saw only one bee on the strawberry bloom, and I have kept close tab on both bees and berries.

J. P. BLUNK.

Webster Co., Iowa, May 31.

[All right, Mr. B., we have knocked that "c" out of your name on our list, and now it looks ever so much better.

Dr. Miller and "ye Editor" never have time to go fishing, sorry to say. Many thanks for your kind invitation. —EDITOR.]

Much Rain—White Clover Scaree.

We are having a great deal of rain, and bees seem to be doing well. My bees never have built up so fast as they have this spring. The hives are "boiling over" with bees and they are bringing in the honey, but I don't know where they get it, for white clover is a very scarce article in this locality.

GEORGE SAGE.

Greene Co., Ind., June 3.

Poor Prospect for White Clover.

This has been the driest spring I can remember. There are as yet no white clover heads to be seen. I called on Mr. Boardman, of Huron Co., Ohio, and he predicts no white clover this spring. Five days ago we had our first rain for this spring. I have just been out examining the roadsides and other places, and find clover coming up, but no signs of any heads as yet, however there may be some. Our bees are now working on mustard. H. G. QUIRIN.

Erie Co., Ohio, June 1.

Cause of Loss in Wintering.

Mr. Geo. H. Adkins' loss in wintering (see page 347) is undoubtedly caused by the *Bacillus mitii* in a mild form. This will cause general uneasiness, and, assisted by a poor quality of honey, the result is general disaster.

In regard to handling the surplus combs, sort out all the objectionable ones part drone, and particularly those that are foul and contain the most pollen, and render into wax. There is no

The Bee-Keeper's Guide

Or, Manual of the Apiary,
—BY—
PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipt, or his library complete, without THE BEE-KEEPERS' GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,

use in trying to save more than the bees you have can use this season, as there is and will be danger in using them.

Should you not be able to extract the honey, owing to its granulating, cut it out by itself, and when rendering your wax run it by itself, running it into a tall receptable like our sap buckets, when, if you are careful about not running the water from the spout into the receptable, the wax and honey will be separated when cool. The honey can be used to stimulate brood-rearing, and is a clear gain.

Reduce all combs now in hives, that is, do not ask the bees to clean up badly smeared combs for brood-rearing, but select all those that are free from old pollen and desirable; procure a sprinkler, and purchase either gasoline or naphtha, and sprinkle thoroly. One gallon will do for 100 combs, and this instantly destroys all traces of mold, making the combs fresher, and owing to its rapid evaporation leaving no trace of the objectionable odor of petroleum products.

My fear was that the bees would object to the combs so treated. Late experiments prove quite the reverse; the queen lays freely, and as I have now the eggs hatch into the larval stage, I hope for good, even combs of brood, which I have failed to see for some time.

While perhaps I will not be able to cure a diseased apiary by this method, surely by giving them good, clean combs that will produce a good, full frame of brood each, will go a long way towards the desired end.

A few of my neighbors have lost heavily. One box-hive bee-keeper put in 250 colonies, and now has 30 hives with bees in. Another modern apiarist put in 175, and now has 25 left. His showed the same trouble as they all do. The vegetable germ in the

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The holsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your **POCKET-KNIFE** will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.10, or give it as a Premium to the one sending us **THREE NEW SUBSCRIBERS** to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO., 118 Mich. St., Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

Please Mention the Bee Journal when writing Advertisers.

pollen entering the very structure of the bee, as well as sapping the vitality of the larva, is giving us a bee that can not stand protracted cold weather. I put in 120 colonies, and have lost and doubled up until now I have 70 left. These will be built up by giving cleansed combs as fast as needed.

C. G. FERRIS.

Herkimer Co., N. Y., June 1.

Producing Honey Without Any Swarming.—Mr. B. F. Blakely, Jr., of Kansas, writes how he manages in producing both comb and extracted honey, and at the same time avoids swarming. When the hive is full of bees, honey and brood, and the honey-flow begins, he removes all of the brood-combs except about four that contain the greatest amount of brood. These are alternated with frames containing strips of foundation for starters, and the super put on the hive. No bees are taken from the hive, they being shaken off the combs that are removed. A colony treated in this way works and acts very much like a swarm. The removed combs are given to the colonies that are worked for extracted honey, these colonies sometimes being piled up four stories high. In short, this is a peculiar system of division, if such it may be called, in which the comb-honey colonies are robbed of so much of their brood, at exactly the right time, that swarming is prevented; while the brood is placed in colonies so worked for extracted honey that they do not swarm. It is a peculiar system, and one that requires the production of both comb and extracted honey.—Bee-Keepers' Review.

Rendering Beeswax by Steam.

The process is thus given in detail by the editor of Gleanings in Bee-Culture:

About rendering by steam, we find no trouble along that line. We run a jet down into our tank, and let it snap for half an hour. But there is perhaps one thing that we do that Mr. H. does not, and therein lies the trouble. I would advise him to place about two pailfuls of water into a barrel holding about 31 gallons. If it is of the 50-gallon size, then use three pailfuls. Into the water pour from one-half to one pound of commercial sulphuric acid, such as can be bought at any drug-store—that is, providing the wax is very dark. If the wax is of a leather color, and it is desired to bring it to a lemon color, put in only about 4 ounces of the acid. Turn a jet of steam down into the water, using a common half-inch steam-pipe. Let it snap until the water is hot, and then add the chunks of wax gradually until the barrel is nearly full of melted wax and water. Allow it to snap for a few minutes, seeing that the water, acid and wax are thoroughly mixed. Remove the steam-pipe, put the lid on the barrel, and cover the whole with old blankets, old carpets, or any old thing that will help to confine the heat in the barrel, keeping the wax in a liquid condition as long as possible. At the end of three

PROFIT FOR MAKER ONLY

We manufacture 178 styles of vehicles and 65 styles of harness and sell them to you direct from our factory at wholesale prices. In fact, we are the largest manufacturers of vehicles and harness in the world selling to the consumer exclusively. When you buy on this plan you pay only the profit of the manufacturer. No traveling expenses, no losses, no agent's commission and no dealer's profits.

No. 130—Double Buggy harness, with nickel trimmings. Complete with collars and hitch straps, \$32. Good assels for \$30. and steel, good paint and varnish. Illustrated catalogue FREE.

No. 717—Canopy-Top Surrey, with double fenders. Price, complete, with curtains all around, storm apron, sunshade, lamps and pole or shafts, \$75; just as good as sells for \$40 more.

WE HAVE NO AGENTS preferring to deal with you direct. We have followed this plan for 27 years. No matter where you live, we can reach you and save you money. We ship our vehicles and harness anywhere for examination and guarantee safe arrival. We manufacture everything we sell, and we can assure you of good quality from beginning to end; good wood work, good iron, good finish, good trimmings, fine style and the largest selection in the land. Large illustrated catalogue FREE.

Labor Saving Conveniences.

Success on the farm today is largely proportioned to the saving of time and labor—which means economy of production—and not higher prices for farm products. Probably no single machine or appliance saves in the aggregate so much time and hard labor as the modern low down handy wagon. Take for

ELECTRIC

instance the loading and hauling of manure, ensilage corn, grain in the straw, corn fodder, hay, &c., all hard to load, the use and advantages of a low down wagon are almost inestimable. The Electric Low Down Handy Wagon excels for these purposes. Has the famous Electric steel wheels, light, strong and durable. Write Electric Wheel Co., Box 16 Quincy, Ill., for catalogue.

or four hours, or longer if possible, dip off the wax from the top, a dipperful at a time.

Omitted to state that the wax, as fast as dipt off, should be placed in tin pans or pails that have been greast. After the wax cools, turn the pails bottom up, and, presto! you will find nice yellow cakes of wax. If, perchance, they are too leather-colored yet, next time use a little more acid; but do not use more than is necessary.

In cleaning tin utensils, never scrape, for that will remove the tin, and the iron, or steel, rather, will rust. To get the wax off, turn a jet of hot steam right against the inside of the pails or pans used. This will disengage every particle of wax used.

If one does not have steam he can use an ordinary iron kettle, being careful to observe about the quantity of acid and water. The vinegar, for such it really is, will be so weak that it will not attack the iron enough to cause any serious trouble.

Discoloring of Comb-Cappings.—I

have always understood the appearance of comb honey is the production of certain strains of bees—the Asiatic varieties tending very much that way. In the same apiaries some colonies produce more or less greasy-looking capping to their comb. The dark races of bees cap their honey with white caps. The goldens do not produce so white a capping as the black bee. The Ligurian produces honey more greasy in appearance, and the Holy Land bees very greasy. Such has been my experience, but in all apiaries of colored bees the capping varies. Is that caused by weather or the strain of bees? Have you ever noticed that sections over the center of the brood have a more greasy appearance than those to one side? What is the cause?—Australasian Bee-Keeper.

A Bunch of Stray Straws, by Dr. Miller, in Gleanings in Bee-Culture:

George G. Scott takes up half a column of the American Bee Journal in saying that hive-tools and other things likely to be lost should be painted a brilliant red. The advice is worth all the room he has taken.

The membership of the National Bee-Keepers' Association is a little more than 500. It's sad that it's so small; but there's encouragement in the thought that never before were so many bee-keepers banded together in one body in this country. And the number is all the time growing.

Two mysteries in connection with finding queens. You look very, very carefully all over a comb, and the queen is not to be seen; but suddenly she appears, calmly walking right before your eyes. Where or how she was hidden is the mystery. Another mystery is that often a queen is harder to find in a mere handful of bees than in a strong colony.

The age at mating of 30 queens is given in Bienen-Vater. It varied from 4 to 9 days, the largest number being at 6 days, and the average of all being 6 1/3 days. [I once conducted a series of experiments, and, if I remember correctly, the average date seemed to be 7 days, and the earliest 3 days; but in this case I had reason to suspect the queen had been confined in the cell by

Four Celluloid Queen=Buttons Free AS A PREMIUM.

For sending us **ONE NEW SUBSCRIBER** to the Bee Journal for the balance of this year, with **50 cents**, we will mail you **FOUR** of these pretty buttons for wearing on the coat-lapel. (You can wear one and give the others to the children.) The queen

has a golden tinge. This offer is made only to our present regular subscribers.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate, it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

Prices of Buttons alone, postpaid: One button, 8 cts.; 2 buttons, 6 cts. each; 5 or more, 5 cts. each. (Stamps taken.) Address,

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO.

the bees after the regular day for hatching.—ED.]

John R. Millard gets some sound instruction on page 352. The problem being to get a stock of drones from a choice young queen, this might be worth trying: Add brood from other colonies so as to get the young queen's colony very strong. Then have plenty of drone-comb in one or two of the central combs. As soon as the queen fills these drone-cells, take the comb and give to another colony, and replace with fresh drone-comb as fast as taken away.

In working bees from other frames to dovetail frames, one way is to put the hive with brood over the dovetail hive, an excluder between, the queen below. But the queen is very slow about laying, apparently thinking she ought to get above to lay. A better way is to brush all bees from the old comb into the new hive, and put the beeless brood over another strong colony with excluder. If desired, this brood may be put back over its original queen 10 days later.

Equalizing colonies is all wrong. And it's all right. Depends. In the spring, take two colonies, one with three frames filled with brood, the other with enough brood in three frames to make one full frame. Take a frame full of brood from the strong and give to the weak, and you have equalized the brood. Three weeks later there will not be as much brood in the two hives as if you had let them alone. But let them alone till the stronger has 6 or 8 frames of brood, and then you will gain by equalizing. The secret of it is that a colony with brood enough to fill only one frame full stands nearly still, while one with 3 or 4 frames booms right along.

Doolittle talks sense when he favors leaving queen-cells and young queens with the bees from start to finish. And he will probably agree that for the best results it is desirable that the cells be in a strong colony at least till they are sealed, and that it is at least a little better that the young queen be in a strong nucleus till she lays. We are not likely to reach the time when good queens can be reared for nothing.—[I have said a good deal in favor of bees for business, and have rather decried the evident rage for color, which rage now seems to have all but died out. Would it not be well to talk about high-priced queens? One reared by the most approved plans in a strong colony, under the swarming-impulse, or same impulse brought on artificially by feeding, ought to be worth twice as much as one reared in the old-fashioned method in a queenless colony without feeding—a method that is apt to result in small, inferior queens.—ED.]

Have you tried the French way of using the Porter escape? Instead of having the escape open into the hive below, have it open *outside*, in front, above the hive. One advantage claimed is that you can see if the springs of the escape do not work exactly right. [This method is all right under some conditions. H. R. Boardman has practiced it for years, and I do not know but he is using it now. It has the advantage, according to Mr. Boardman, of getting the bees out of the supers a little quicker, because the bees work

toward bright daylight. The young bees that happen to be in the supers come out in front of the hive, and naturally find the entrance, so none are lost; but as a general rule Porter escapes are put on at night between brood-nest and sections, and the next morning the supers are *supposed* to be free of bees; but according to my experience they are not *always* thus freed, for I have found anywhere from 30 to 40 bees in the super next morning. I suppose H. R. Boardman, by his plan, induces the bees to leave earlier, with the result that the work is accomplished in less time, and more thoroly. It might be well to try this matter this coming season.—ED.]

Langstroth on... The Honey-Bee

Revised by Dadant—1899 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the Ameri-

can Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.
118 Michigan Street, CHICAGO, ILL.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, June 8.—Not any new comb honey has appeared on the market, but it would sell at 15 cents, as there is a demand for it that can't be supplied for some time hence.

Extracted from the Southern States is coming forward quite freely, but is not active and prices are lower. White sells at 6½@7c; amber, 6@6½; dark grades, 5@5½. Beeswax, 27c for prime.

R. A. BURNETT & Co.

KANSAS CITY, May 9.—We quote: No. 1 white comb, 14@15c; No. 1 amber, 13@14c; No. 2 white and amber, 13@13½c. Extracted, white, 7½@8c; amber, 7c. Beeswax, 22@25c

The receipts and stock of honey on hand are light; demand fair. C. C. CLEMONS & Co.

DETROIT, May 24.—Fancy white comb, 15@16c; No. 1, white, 14@15c; amber and dark, 10@12c. Extracted, white, 7c; amber and dark, 5@6c. Beeswax, 25@26c.

Supply and demand for honey both limited. M. H. HUNT & SON.

NEW YORK, May 21.—Our market is practically bare of comb honey, and there is a good demand for white at from 13@15c per pound, according to quality and style of package. The market on extracted is rather quiet, and inactive. New crop is slow in coming in, and prices have not yet been established. Beeswax holds firm at 27@28c. HILDRETH & SEGELKEN.

SAN FRANCISCO, May 29.—White comb, 11½@12½c; amber, 8@10c. Extracted, white, 7@7½c. light amber, 6½@7c; amber, 5@5½c; Beeswax, 26@27c.

Moderate quantities of new crop are coming forward, mostly amber extracted from the San Joaquin. Altho supplies of old honey are about exhausted, demand for new does not appear to be very active or urgent. Sales of new amber extracted have been mainly within range of 6½@7c., little commanding over 6½c in anything like a wholesale way.

Texas.—The Central Texas Bee-Keepers' Association convenes in seventh annual convention, at Hutto, Tex., July 12 and 13, 1900. All are cordially invited to attend. Excursion rates, and no hotel bills to pay. Hunter, Tex. LOUIS SCHOLL, Sec.

The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

DR. MILLER'S Honey Queens

One Untested Queen Free as a Premium for sending ONE New Subscriber to the American Bee Journal for one year.

We have been fortunate in making an arrangement with DR. C. C. MILLER—the well-known honey-specialist—to rear queens EXCLUSIVELY FOR US DURING THE

SEASON OF 1900. These Queens will be mailed in rotation, beginning about June 10, so "first come first served." We are ready to book orders now.

The Queens Dr. Miller will send out on our orders will be precisely the same as those he rears for his own use, so of course they will be from his best stock. His best colony in 1899 had a queen reared in 1898; May 5, 1899, it had brood in 4 frames, and he gave it at that time a frame of brood without bees. It had no other help, but May 25 a frame of brood with adhering bees was taken from it, and the same thing was repeated June 3, leaving it at that time 5 frames of brood. It stored 178 sections of honey, weighing 159 pounds (and that after July 20, in a poor season), being 2½ times the average yield of all his colonies. A point of importance is the fact this colony did not swarm, and an inspection every week or 10 days showed that at no time during the entire season was there even so much as an egg in a queen-cell. Dr. Miller expects to rear queens from this one during the coming summer.

The demand nowadays is for BEES THAT GET THE HONEY when there is any to get, and Dr. Miller has such bees. You will want to have a queen from his best, we are sure, even if she is not pure Italian.

Do not send any orders to Dr. Miller, as all orders MUST come thru us, according to our agreement.

Remember, send us \$1.00 for ONE NEW SUBSCRIBER to the American Bee Journal for one year, and YOU will get ONE OF DR. MILLER'S UNTESTED HONEY-QUEENS FREE AS A PREMIUM. This offer is made only to our present regular subscribers. Orders for queens to be filled in rotation, beginning about June 10.

Address all orders to **GEORGE W. YORK & CO.,** 118 Michigan Street, CHICAGO, ILL.

CONTRIBUTED ARTICLES

Bee-Keeping for Women.

Written for the Wisconsin Convention, held at Madison, Feb. 7 and 8, 1900.

BY MRS. JENNIE TOWLE.

TO make a successful bee-keeper, in my opinion, requires several traits of character which are indispensable. One must be patient, persevering, ingenious, industrious, and, last but not least, *thoro*. That last word *thoro* needs to be emphasized. Bee-keeping is a work that cannot be slighted, nor neglected and allowed to run itself.

If a lady wishes to engage in bee-keeping, either as a pastime or to earn a living, she ought not to attempt too much at the beginning, as it requires labor and lots of nerve to endure the stings and hardships belonging to the work. She should commence on a small scale, and increase her colonies only with her increase of practical knowledge of bee-keeping, and means and facilities for caring for them. She can obtain a practical knowledge of the art of handling bees by studying standard books on bee-culture, taking and reading bee-papers; but, best of all, by actually acquainting herself with her own work, and fearlessly doing whatever she finds necessary to do, and, at the right time, observing well the old maxim, "Never put off till tomorrow what should be done today." ☐

Bees increase very rapidly, and each new colony means an additional expense as well as work, so unless one has an abundance of means and plenty of help, it is better to use a

little caution at first, or soon she will find an "elephant on her hands," which she will be at a loss to know how to dispose of. Besides, experience teaches us that a small farm well cultivated is much less expense and work than a large farm slighted, which also holds good in bee-keeping.

Bee-keeping is a pleasant and fascinating work, when it can be done without overwork and worry. But it is impossible to make a success of bee-keeping and attend to all the requirements of society and fashion. One cannot attend all the picnics, celebrations, circuses, tea-parties and sociables going on in the neighborhood, for bees require care, and, if not cared for at the right time, will take care of themselves in their own time and way, without regard to the pecuniary interests of their owner.

But circumstances alter cases, and a little practical experience combined with a little native "gumption" will do more for a novice than pages of other people's opinions.

Many a lone woman who is toiling over her needle or washboard to earn a scanty living for herself and children, could find in bee-keeping a far more congenial and lucrative occupation if her location were only suitable. Still, there are some risks to run, and it requires a little means to start, and live until some returns are received. Yet it requires but little more capital, and not one-half the vexation and annoyance, to successfully keep bees, than it does to raise poultry, and the receipts are far more satisfactory. Clark Co., Wis.

Mrs. West and Daughter, of Rock Co., Wis., in the Apiary.

(Mrs. W. does all the work with her bees.)

Enameled Cloth for Covering Bees, Etc.

BY G. M. DOOLITTLE.

FOUR questions come from one person to be answered thru the American Bee Journal, and I think they will not make too long an article if I answer them all in one number.

QUESTION.—If bees need water in summer why do they not need it in winter also? If so, why would it not be a good plan to use an-enameled cloth covering over the brood-frames in the winter? With such a covering over the

frames, the condensation of moisture on it would give them water in winter as well as in summer.

ANSWER.—The above is quite ingenious, to say the least; and if I really believed that bees needed water while in winter quarters, I might be persuaded to try enameled cloth for that purpose, as it would be much easier supplying water in that way, than by giving it to them in a sponge at the entrance, as has been recommended many times during the past, where bees were being wintered in the cellar. But bees use water of any account only when breeding rapidly, and as winter breeding is poor economy in this latitude, and something I do not wish to encourage, I do not care to supply that which brings on what is a damage to me; for I believe winter breeding to be only a damage to any beekeeper residing at the North.

I have tried enameled cloth several times over the cluster of bees during winter, and, in every case where tried, those colonies did not come out nearly as strong as did those with absorbents over them, while many colonies, in proportion to those so tried, died, or were so weak as to be nearly worthless. A few have recommended enameled cloth over the bees during winter, but with me the moisture arising from the bees condenses in drops on the cloth, until they become so large that they fail to hold to the cloth, when they drop down on the bees, thus keeping the bees from damp to wet, and in a condition not suitable to their wintering in the most perfect order.

I doubt whether enameled cloth for bee-quilts would ever have been thought of had it not been for its non-sticking character. What I mean by this is, a sheet of enameled cloth will not be glued down by the bees so but what it will readily cleave from the top of the frames and hive with a little lifting by one corner. This makes it desirable during summer where a hive is to be opened often, as in the case of queen-rearing, or an experimental hive. Aside from this I think enameled cloth of no advantage, but rather a detriment.

REARING QUEENS BEFORE SWARMING.

QUESTION.—I wish to rear some queens before the swarming season of bees arrives. How can I secure royal jelly for the purpose of putting in the cell-cups, aside from queen-cells built in natural swarming?

ANSWER.—I have never found any trouble in securing royal jelly at any time when there is young brood or bees in the larval form in the combs in any hive. All there is to be done is to make a colony queenless which has such larval bees, and in from three to five days, after taking away the queen, you will find cells enlarged and the occupants swimming in royal jelly; or at least to a sufficient extent so that enough can be obtained to start from 15 to 30 cups, for rearing that many queens. Take the larva out, then with a little stick stir and mix the jelly all up, being careful not to break thru the sides of the cell, when you will have the whole of an even consistency, as that next to the larva is quite thin, while that next to the bottom of the cell is quite thick.

Now put a quantity in each cell-cup of the amount of a single "B" shot, or about what would amount to three or four turnip or cabbage seeds as to quantity. After once getting started, you will remember to take off one or two of the cell-cups a half day before the bees would seal up the larvæ in them, and if you should not wish to use the royal jelly they contain within a few days to two weeks, take out the larva, stir the jelly up as you did the first, when you will hold the mouth of the cell near a stove or lamp till the wax at the end becomes soft, when you will wet the thumb and forefinger and press the end down tight, thus sealing it up as tight as if in a glass can. In this way the jelly can be preserved for some little time, but after two or three weeks it will begin to dry down and change so that it is not acceptable to the bees.

IS AN EARLY POLLEN SUBSTITUTE NECESSARY?

QUESTION.—Is it necessary for bees to have pollen in the hive in early spring, before they can secure it from the fields, for them to rear brood?

ANSWER.—It is my opinion that if such a condition were possible as not to have a single particle of pollen in any of the combs in the hive, and where nothing of the kind could be obtained by the bees from any source, no brood could be reared and brought to perfection, but I doubt the possibility of there being such a condition as absolutely no pollen in any hive having honey enough in it in the fall to carry it over till the pollen-producing flowers open in early spring. All honey contains more or less floating pollen; combs in which pollen has been stored previously

contain many particles of the same, according to some of our most scientific bee-keepers; and where nothing else is available, bees will collect fine particles of wood and use in place of farina from flowers, as I have frequently seen them doing from a pile of fine sawdust which is taken from the shop and thrown out nearly every spring.

Elisha Gallup told us in the columns of the American Bee Journal, years ago, how he hived a swarm of bees so late one year that they built only three pieces of comb a little larger than the hand, and, as an experiment, he fed them honey all winter, and in early spring they commenced brood-rearing before being taken from the cellar, finally building up to a fine colony and storing considerable surplus honey that season. I have had similar experiences, but find that the less pollen there is in the hive the less brood there will be reared, and where there is scarcely any pollen, or what most folks would call none at all, there would be but few cells of brood reared, and this brood be scanty in food, and appear weak and sickly.

Nothing incites brood-rearing like plenty of pollen in the hive, with the necessary honey; and with the advent of new pollen, brood-rearing commences in earnest. I have fed the bees meal and flour many times, thinking that it would take the place of pollen from the flowers, but after a careful watching I am satisfied that such is not the case, with me.

AMOUNT OF SMOKE TO USE IN HANDLING BEES.

QUESTION.—How much smoke should be used in opening hives?

ANSWER.—Well, for a brief answer I would say, the less the better. But that would not fully answer, so I will say, from none up to enough to thoroughly subdue the bees, just in accord with the amount necessary for ordinary handling, which means careful handling of the combs and hives—not rushing at and thru them, as a baggage-smasher handles trunks; the latter being the way some people manipulate bees.

With the ordinary Italians most colonies can be opened during the spring months without any smoke, but it is always best to have smoke on hand so it can be used in case of an accident with the most peaceable bees. Later on in the season, except with the vicious colonies, two or three puffs of smoke are sufficient to blow over the frames when the hive is first opened. With very vicious colonies, blow 8 or 10 puffs in at the entrance, jarring the hive at the same time by pounding on it with the fist, then wait three or four minutes, and on opening it blow four or five puffs over the frames, and you are master of the situation.

The Bee as a Pollenizer of the Blossoms.

Read at the Northeastern Ohio and Western Pennsylvania Convention,

BY ED JOLLEY.

THE bee as a pollenizer of the blossoms is one of the greatest of our natural benefactors. The nectar hidden in the well of the flower is but the bait that lures the bee unwittingly to perform a vastly more important function than gathering and storing honey for either itself or man.

As we look at the high state of perfection of our apple, peach and pear, our berries and small fruits, our melons and squashes, we are apt to regard them as fixtures, as having always existed as they now exist, while, in fact, nothing could be further from the truth. The present high standard of our fruits represents the labor of the bee for ages.

No where is the natural law of evolving from a lower to a higher degree of perfection more clearly demonstrated than in the vegetable kingdom. Nearly all of our fruit-bearing trees are double-sex (hermaphrodite), and are capable of being fertilized from their own bloom. But the effect of close in-and-in breeding is just as markt, and just as detrimental in the vegetable kingdom as in the animal; and to guard against this nature has placed a tiny drop of nectar in each blossom to entice the bee to the blossom. The amount of nectar in each blossom is so small that the bee is obliged to visit blossom after blossom in order to secure its load. In this way the pollen is carried from blossom to blossom, from tree to tree, and from one variety to another.

By way of illustration, if you have an orchard of a single variety—Baldwin apples for instance—and the orchard is so far from any other variety that the bees can not carry

pollen to the orchard from any variety, the seed from the fruit of this orchard will bring forth nothing but Baldwins. If your orchard contains a number of different kinds of apples, the seed bring a blending of the different fruits, or a seedling different from any in the orchard, and in all probability superior to any of them.

If you were to plant a single Baldwin tree on an island, so far isolated that the bees could not reach it, it might still bring forth fruit, but the seed from this fruit would be sterile and utterly incapable of reproduction. So you see that without the aid of bees, the tree on the island was incapable of reproducing itself, and when the tree had aged and died, the island was without fruit. So it would be with the world—remove the pollenizers of the blossoms, and when the present standing of fruits had past away there would be none to replace them.

You may isolate a single Baldwin tree so far from any other tree that the bees can not carry pollen from one to the other; so that it will be fertilized by its own bloom, and the seed from this tree will bring forth a Baldwin—one that is slightly inferior to the parent tree. If this in turn is allowed to be fertilized from its own pollen there will be a still lower order of the Baldwins. This work of retrogression might be carried on until the once fine apple had degenerated back step by step to the origin of the apple, which, by our best authorities, is said to be the common wild rose. All our fruits have had their origin equally low, so that the bee, in bringing them up to the present high standard, has doubly earned its title, "busy bee." And as the natural inclination of the bee is to zeal and untiring industry in its work, we may expect that thru its efforts the progress of our fruits will be ever onward and upward to a still higher perfection.

No. 1.—EXTRACTED HONEY PRODUCTION.

A Near Approach to Control of Swarming—A Cause of Poor Wintering Discusst—Shallow-Hive Uses.

BY R. C. AIKIN.

IN the preceding articles on comb-honey production, the matter of building up the colonies before the honey-flow was fully discusst. As the management is the same for either comb or extracted, so far as the general spring work is concerned, up to about the opening of the flow, we need not repeat that here.

As in comb-honey production strong colonies are a necessity to best results, so in extracted, tho not so imperative. Almost invariably when extracted honey is produced there is much ready comb in the extracting-super, and where bait-combs are a great help in comb-honey supers, the greater quantity used in extracting-supers is proportionately beneficial. Where a comb-honey colony will scarcely take hold in a super at all, the colony with combs for extracting will go at once into the extra. The surplus strength of the colony being drawn to the super-combs, and finding storage-room, the brood-chamber is left largely to the queen, and the congested condition so favorable to swarming is materially decreased, and with it swarming decreases. So very much more easy is it to control the swarming thus, that we may make it *almost* a qualified success.

There is one thing to keep in mind, and that is, that when extracted honey is produced the very thing that so largely stops swarming—*i. e.*, plenty of brood-room below and storage-room above—leaves the colony with a host of bees in the fall and a limited amount of stores. I have produced both comb and extracted honey for many years, using like hives many times for both, and in the same apiary, and after starving hundreds of colonies of bees because of the shortage of stores in the extracted stock, I now unhesitatingly declare in favor of larger hives being used when extracting than for comb.

I say I have starved hundreds of colonies of bees. Some of them were simply and purely starved outright because there was no honey left for food. Many, however, were, more properly, stinted to their death, and to my financial loss. I will tell you how it comes about:

A comb-honey colony building comb in sections will fill the brood-combs very full of honey, and in so doing crowd brooding to the minimum. Not every comb-honey colony will do this, but the greater part do, so much so that it becomes a settled rule. Much honey—minimum amount

of brood and normal colony to consume the stores—leaves the bees in shape for fair wintering. A feature of the heavy, close-packed stores is that the cluster can not get far from the honey, so feed and winter better.

With those for extracted honey the conditions are almost the reverse. Much store-comb, and often extracted, stores *very largely* going to the super, a brood-chamber well filled with brood, pollen abundant, and little honey. The hive is "hefted" for stores, or guest at, the greater weight of bees, brood and pollen making the owner think them sufficient to winter all right. In reality the stores are scanty; instead of thick, well-stocked combs they are thin and lank, are scattered in outside combs or distant parts of the hive, and out of reach except in mild weather, and the colony starves. We find *some* honey in the hive, and say they could not have starved, yet that is *often* just what happened.

Suppose the colony survives the winter and gets to the spring with scanty stores, the limited supply in sight causes them to curtail breeding, and they fail to grow in strength and prosperity as they should, are weak all spring, and never get to be a prosperous and profitable colony, and simply for lack of a few pounds of honey. It is ever so much better that the colony must move honey to have breeding-room, than to have to be hunting every corner of the hive to get what little there is scattered about. I tell you the truth in these comparisons, truth that has been burned into my memory by a very large experience and at much cost of wealth. When my extracted-honey colonies would not winter equally with comb-honey stock, and that in the same yard, same hives, same stock, everything the same save the difference herein described, I was forced to find the cause, and I found it.

Now I give my extracted-honey stock from 1/5 to 1/3 more brood-chamber room, and, many times, more than this, and the wintering is equal, or perhaps a little in favor of the extracted stock, because they go into winter with a great abundance of bees, and the wintering is especially noticeable in colonies having unusually large hives. I have just been examining about 100 colonies run for comb honey, and about 150 run for extracted. Some of the latter were wintered on 12 to 18 Langstroth frame capacity combs, having just about twice the stores the smaller hives had. They had all the breeding-room wanted in the fall; the hives were two-story, and the bees worked *upward* in winter, and always had stores above them. I must tell you that some of those 2-story colonies are not equaled in the amount of bees, brood and stores by a single one of the smaller hives, and I have been borrowing stores from the big ones to help weaker ones.

Brethren, these ideas are worth looking after. Early and later yielding of nectar help to overcome some of the evil effects of this short-stores-and-small-hive matter, but if you are not blest with the early and late flow, better look into this question.

Now, since it is so important to have the larger hive for the extracted stock, there comes in a very nice arrangement by which we may go far toward the full control of swarming. The presence of great abundance of store-comb in the super drawing the storage work there and easing the brood-nest pressure, does do away with much swarming, *because* the queen has *much laying-room*. If there can be plenty of *empty* comb between the brood and the *entrance*, it decreases the swarming about as much as the store-comb does in the super, hence the two together reach well nigh the goal—non-swarming—if the two can be brought to bear in the proper season. To make very clear just how it works when applied to the best advantage, I will tell just how I have made the application in many cases:

I am running two out-apiaries that are in American hives. Some of these hives have been modified or changed from the deep suspended frame to a shallow standing frame. (The matter of hanging or standing, self-spacing or to be spaced, shallow or deep frames, has nothing to do with the principle, tho some of these features have to do with a successful, easy and expedient application.) Two of the shallow chambers equal one of the full depth, being the same except in depth. One of the full depth, or two of the half-depth, equal about the same as a 10 Langstroth frame hive capacity.

Suppose I winter and spring a colony in two sections of shallow frame hives. There is no trouble until about the June flow, then they want to swarm. Just before they get the swarming-fever, I take away both the sections containing the colony, place on the stand (bottom-board) a single section or set of frames containing *dry brood-combs*; place on this the section of the original hive containing the least

amount of brood, put over this an excluder, next an extracting-chamber, and above all the section of the hive having the *most brood*. This would then be recorded as "dry-brd-extra-brd," entering also the date of record. This means that, counting from the ground up, they have a set of dry combs, a set of combs of brood, an extracting-super, and on top a set of combs of brood—three shallow sets and the super.

I have used full-depth hives in this manner except that it would be a set of dry combs on the bottom, brood-nest next, and extracting-super on top over an excluder. This being done before the colony gets ready to swarm, has a *very* decided tendency toward no swarming by colonies so treated. For tremendous colonies the two regular brood-chambers are all right, but in this case there can not be a hive of brood on top. Brood above the extracting-combs draws the bees well up, and the honey is stored in the super and that top brood-chamber. Such arrangement without the dry combs beneath will go far toward keeping them from swarming, but not in so satisfactory a degree. That brood on top I leave until I have occasion to look into the hive again, or for a week or two, when it can be used in making increase or adding to nucleus colonies. If the brood is in shallow frames, two sets put together in a new colony and supplied with a queen make a very nice colony; the hatching bees promptly populate it, and the honey stored as brood, hatch while yet on the parent hive, makes them at once almost ready for winter.

My field supplies little nectar outside of June, July and August—from about June 15th to Aug. 15th—and I find that these big hives, composed sometimes of three or four shallow sections, or two deep chambers, or one deep and one shallow, give me the best colonies. Colonies in single-story hives I have to feed in May or early June, but the big ones not.

I do not want this article to be read as a boom for shallow chamber hives, but one fact stands prominent—the shallow frame enables us to contract or expand the brood-nest without adding too much, and gives us a chance to place brood quickly above the super to stretch the colony, yet that brood on top having served its purpose can be quickly placed back in the brood-nest. The shallow hive makes easy the application of other principles where the deep one would be too bulky or expensive. This system is not suitable for comb-honey work, but is a success in the production of extracted honey. Larimer Co., Colo.

A Plague of Bees in Africa.

BY C. V. A. PEEL.

I HAD been enticed into the Haweea country, N. E. Africa, by reports of elephants. From the time I set foot in that miserable country to the day I shook off the dust on leaving it I was pestered by a perfect plague of bees. The country was nothing but a wilderness—stony ground covered with thin thorn-bushes. The afternoon of my arrival, after a terribly tiring march over stone and rock, I pitched camp by the side of a deep well in the solid rock. When my tent was up I threw myself on my bed—for I was dead beat—hoping to find rest. Not a bit of it. I jumped up quicker than I lay down, stung in the back by a bee. "No peace for the wicked," I said to myself as I took up my sponge, intending to have a bath, only to be stung in the hand by a swarm of bees which had settled upon the damp thing, and were eagerly sucking up the moisture. It was becoming more than a joke. I poured out the water into my India-rubber bath amidst a buzz of approval from my thirsty companions. I took off my clothes, being stung in the attempt by a bee which had crawled thru my stocking, and got into my bath. This, apparently, was the signal for a combined attack upon me. After the first spongy of water had gone over me, a perfect swarm of the pests attacked my head, whilst dozens crawled all over my naked body. Twice was I stung in the head, and three times I picked out the stings from my body.

At length I could stand it no longer. I ran amuck, threw bath, pail, water, sponge, towels, and bad language in every direction, dashed out of my tent and fled naked out of my zereba, followed by a grinning crowd of natives inquiring if I had taken leave of my senses. I sat for the rest of the afternoon in the shade, and as far from any water as possible, until the sun set, not venturing back to my tent. When the golden orb at length disappeared, I returned to camp in my birthday garments, feeling rather

chilly, and anointed my numerous stings with ammonia. Upon my tent floor I discovered with my bare feet there still crawled the little demons, but they had mercifully ceased to fly for the night.

The next day was destined to be the most miserable I spent in this detestable country. From the very moment the sun peeped up over the horizon until it set like a great ball of fire in the west, an enormous army of bees pestered and annoyed me. I could not eat, drink, sit, sleep, stand nor walk, but they would crawl all over me and sting me. It was all very fine to say, "Do not touch them, and they will not sting you," but the plagues tickled me so dreadfully as they crawled up my breeches, down my socks into my shoes, round my head, and over my whole body, that it was impossible not to keep brushing them away. I was stung almost everywhere.

I was driven from my tent into a native tent, from there to the shade of a tree, from the tree to my tent again, but all to no purpose—the villains still pursued me. At length, in despair, I sat in the heat of a roaring fire. The scorching rays of the sun, the blinding heat of the fire, and the poisoning heat developed by my numerous bee-stings nearly drove me into a frenzy. All day long I waited on the chance of the men I had sent out in every direction coming back to camp with news of elephants, but they came not.

The bees appeared to attack me and my "boy," and nobody else. Poor Deria stamp and jumped, and cursed and swore from morning till night. But then Deria was always in hot water. If a man threw a stone, it was always Deria's head which would intercept it. Whilst on the march before daylight, if the branch of a tree protruded beyond the rest, Deria's face would feel its thorns. If a camel fell, and store-boxes flew in all directions, who was always found to be underneath but Deria? No wonder he wore such a disagreeable expression. The only thing against the willing boy were his looks.

At night all my men returned reporting only old elephant spoor.

Next morning I sent them all out again in different directions, while I determined to wage war upon my enemies, the bees. Accordingly I started off, accompanied by some half a dozen of my men, in search of their dwellings. We had not proceeded more than a few hundred yards when we came upon a huge ant-hill about 12 feet in height. In and out of a hole, high up on the ant-hill, came bees by the thousand. We held a council of war. I suggested we should make a large fire close to the ant-hill before commencing the attack. My men, who were very anxious to get at the honey without the slightest delay, pooh-pooed the idea. No, they would throw stones at the huge pillar, make a breach of it, and abstract the honey.

No sooner suggested than attempted. We attacked the stronghold with stones until a gaping hole was made in the fortress, when out issued thousands upon thousands of the enemy. The attacking force fell backwards into the bushes, and were literally covered with the enemy's poisoned arrows. Those who had not fallen rushed madly thru the bushes, swinging their arms about and tearing their sides with the thorns as they dashed panic-stricken thru the bushes. For a moment I stood still and fairly shrieked with laughter, but the instant I took to my heels I was followed by the enemy, who wounded me in the head in several places. With the utmost difficulty I gathered together my scattered forces, some of the men having run a distance of a quarter of a mile away. Oh! how I laughed when I saw the swollen faces of my men. One of them had both his eyes bunged up, and his under-lip was swollen and pouted out to such an extent as to make him barely recognizable. The groans and "Allahs" emitted on every side betokened our utter defeat.

We now set to work to collect wood, which we piled at the base of the ant-hill, and set fire to it. Sending back a man for a piece of rope and a couple of axes, we attached the former around the center of the pillar, and with one united pull the wall of the stronghold fell with a crash. An enormous swarm of bees shot up into the air, but the heat from the fire was too great for them. The citadel was taken. Attacking the earth with an axe, we at length got at the hard-earned spoil. Every now and then a shriek would go up as one of us got stung! but when the great heat from the roaring furnace at last drove us back, we had filled two large bucketfuls of most excellent honey.

As no fresh elephant spoor could be found, I packed up next morning and marched, heartily glad to get out of the country, and its plague of bees. I laughed afresh at the sights of my men as I applied ammonia to their poisoned wounds.—The Field.

A New Winter-Case Arrangement.

BY F. B. THOMPSON.

SOME time ago I wrote that I used a hive, or rather a winter-case, that I had not seen on the market, and think it a complete success. For those wishing to winter bees on the summer stands, which is my only successful way on account of dysentery, I have seen nothing so easily manipulated, simple in construction, and cheap.

The bottom-board, which I use for both summer and winter, is cut 3 or 4 inches wider and longer than the inside hive-bodies, according to the width of chaff space desired. The edges may be rabbeted or not, as the winter-case which is made of 9-inch shiplap siding, can rest on the edge of the bottom-board, but is safer in a rabbet. Then nail a frame on the bottom-board for the inside hive to rest on, the thickness of which will regulate the depth of the entrance, and

1—Summer Entrance.

2—Winter Entrance.

let the front ends extend out to the outside case. This frame should be nailed so that there will be equal chaff space all around, and be beveled off at the sides and back to run the rain off in summer, as indicated in the outline drawing.

To prepare for winter, set the outside cases over the hive and down in its place on the bottom-board, and then lay a thin strip, as wide as the chaff space, across the entrance-frame to keep the chaff out of the entrance; then pour in the chaff, and pack tight with a stick, and put on the chaff cushion and cover.

I have said nothing about the inside hive arrangement, as this case will not interfere with whatever may be desired. I use a $\frac{1}{4}$ -inch honey-board in winter, with two holes to feed thru in the spring, and a 3-inch entrance, altho the entrance may be cut as large as in summer if desired.

The cover I made of tin, for the chaff must be kept dry. I use the same cover in summer, but it is a little warm and unhandy.

My bees in winter were quiet and dry, and came out in the spring strong and healthy, without loss.

Wayne Co., Ind.

My Experience as a Bee-Keeper in Tennessee.

BY ADRIAN GETAZ.

I BEGAN bee-keeping in 1886 or 1887. I first bought four bee-gums, paying \$5.00 apiece, taking the pick of the apiary. I made my hives according to the instructions of some European books advocating the Dadant plan; only I made them smaller, as I thought such would be better for this country. The only American book I had was Quinby. I soon after bought the "A B C of Bee-Culture" and subscribed for Gleanings in Bee-Culture. It was a revelation to me. I concluded that I would begin by following the "authorities," with the exception of experimenting on a small scale. Well, I did not do any good. I blamed the bad seasons, the greenness of the apiarist, accidental circumstances, etc. Gradually I realized that I was confronted by not only one but five conditions, viz.:

1st. Considerable loss of bees in winter by coming out during warm spells, and loss of brood reared during these spells and chilled afterward.

2d. Excessive swarming at the expense of surplus.

3d. Bee-paralysis.

4th. Long but very irregular flow, never strong.

5th. Poor locality, decidedly.

There I was. However, all this did not come all at once, but gradually.

WINTERING BEES.

I use chaff hives, or rather, some equivalent, only one and a half or two inches of any kind of packing that happens to be handy. Not only the brood-nest but the supers and covers are double-walled and packed. Only $\frac{1}{2}$ -inch lumber is used, and the weight is not increased. The advantages are, protection against cold, or rather, variations of temperature during the winter, and against excessive heat in summer. And in the spring of the year that protection keeps the supers warm, and induces work therein much sooner, which, in this locality, is a very important item.

The Dadants say they would rather have their bees flying occasionally. That's all right, if occasionally means three or four times during the winter, but when it is an almost weekly "condition" the loss in bees and brood is fearful.

EXCESSIVE SWARMING.

This is chiefly what decided me to adopt large hives and correspondingly large colonies. I had some correspondence with the Dadants, and stated that there was no demand here for extracted honey. They replied that a market could be created, that they had done so. Unfortunately our honey is rather dark and of very variable quality, and to create a special market it is necessary to have honey of good and uniform quality.

As I expected, large hives prevented swarming only to a certain extent. I then experimented with non-swarmers, and with fair success. But while experimenting two of my colonies became queenless somehow or other, and while queenless filled two supers each in a short time.

Needless to say that "removing queens" became my hobby. However, in this locality removing queens has a serious disadvantage. The swarming occurs in May; our last honey-flow is in July. Removing queens in May means the loss of the very bees which would be field-workers in July. It is necessary to requeen, otherwise, if the queen is not vigorous, swarming may occur again later.

Later on I discovered that by using the kind of hives described above, giving all the bait-sections possible, putting on the supers early and protecting them against the cold nights, having queens not too old, etc., I could reduce the swarming to from 5 to 15 percent of the number of colonies. So now I only treat the colonies that actually swarm, or that I discover to prepare for swarming. This I do by removing the queen and letting the young queens fight it out (a queen-trap is necessary), or remove the queen and queen-cells, and give a young queen, but not until they have been at least four days without unsealed brood. This point is the key to success. Giving a young laying queen before would not help very often. The queen-cell building would go on all the same, but will not be resumed after a few days without unsealed brood; unless later on the queen fails or is lost, or the hive becomes too hot or too crowded. But such things can be avoided.

BEE-PARALYSIS.

For quite a number of years I did not know that there was bee-paralysis in my apiaries, and in fact in all apiaries of this section of the country. I had seen, every spring, black, shiny bees in countless numbers, but I thought they were robbers. I had seen bees die rapidly and thought they had been poisoned, and noticed other irregularities, but never suspected what was the matter for several years. This condition is not entirely solved.

I keep camphor in my hives from early in the fall until as late in the spring as possible. That is so as not to injure the surplus as the honey takes the odor and also the taste of the camphor. As long as the camphor is there the malady will not develop itself, but will reappear invariably, more or less, about six or eight weeks after, showing that the presence of the camphor has only prevented its development. It is necessary also to renew the queens every two years at least, as they eventually contract the disease, and, if not superseded before, eventually lay infected eggs. Needless to say that the loss of the colony follows almost invariably. This is what some writers have called the second stage of the disease.

HONEY-FLOW AND ITS MANAGEMENT.

This and generally all the Southern States have a difficult honey-flow to manage. It lasts several months, or rather there is a succession of flows during that time. But some of these flows fail, some are very abundant for only a few days, some last longer, but are only light. And the worst of it is, you don't know which flows will give, and

which will fail, or how many will give, and how much. This necessitates the keeping of strong colonies throught the whole season, and every season, so as to be ready for any flow, big or small, that might happen.

Building up a colony strong, *a la* Doolittle, just for a two or three weeks' flow, and letting it go down afterward is easy enough, but keeping it strong during four months is quite another thing, and Doolittle's methods are then a stupendous failure.

POOR LOCALITY.

This condition is as far from a solution as ever. I will have to move. I could go to the mountains and get tons of honey, but I would not like to live there. Then, the honey is like down here—of inferior quality. Another scheme would be to buy poor, worn-out land, stock it with sweet clover, and enrich it, and eventually sell it for three times the buying price, besides having the honey for the trouble. "I don't know" what would be the best.

Knox Co., Tenn.

Production, Care, and Sale of Extracted Honey.

BY H. D. BURRELL.

WHILE extracted honey may be produced in any movable-frame hive, it is best to use a hive adapted to the work. In this hustling age, one who would not "get left" in the race, even in honey-producing, must cut all the corners he can. In long practice, I have found a "divisible-brood-chamber" hive best for extracting. With such a hive, rousing colonies may be had by easily increasing the size of the brood-chamber, and simply manipulating its parts. I have united many colonies at about all seasons when bees can be handled, by merely smoking them a little and placing one hive upon another, with nothing between, and have yet to have harm done by quarreling. If one queen is superior, kill the other; if not, let the bees manage that matter. If we want increase, it is readily had by division; and I have easily worked thru whole swarming seasons without a swarm, by a plan by which it is not necessary to go to the apiary oftener than once a week. Such hives are also good for wintering bees, indoors or out. Honey in them can be handled easily by the case, which saves time, trouble, and bee-stings, and there is no danger of the frames sliding together, and causing leakage.

It is best to have plenty of extracting-combs, and not let the bees run short of room. Queen-excluding honey-boards simplify the necessary work. When honey is about three-fourths capt over, it is usually ripe enough to extract; but it is better to tier up and leave it on the hives until the end of the season. In localities where there are two crops in a year, a light-colored one and a dark, with a dearth between, it is better to keep the two crops separate, by removing the light honey just as the dark flow is commencing. In the hot weather usually prevailing at this season, honey will soon ripen in the hive, and may be extracted if not capt at all. At the end of the dark honey-flow it is usually cold or cool weather, and unfinished honey will not ripen nor be capt over. This unripe honey should be kept separate, and sold for manufacturing purposes, or to some other cheap trade. Sell none but well-ripened honey for table use, if you would build up and hold a profitable retail trade. That is a trade that pays. It is not necessary for honey to be mild and white to be good. I have many customers who prefer good buckwheat or goldenrod honey to white clover.

In taking honey from the hives it pays well to have some bee-escape boards. They save smoking, shaking and brushing bees. The Porter is the best of the many escapes I have tried. Insert them at any time when convenient, and if there is no brood or queen above them, the upper stories will usually be practically free of bees in 24 hours or less. Extracting from the brood-chamber is seldom necessary or advisable, with good management.

It is essential to have a bee-tight extracting-room; and a stove in it greatly simplifies the work. Almost any small room may be cheaply made air-tight, and easily warmed, by lining it with heavy building-paper, lapping the paper well, and tacking lath over the joints. In such a room honey can be easily extracted at any convenient time, summer or winter. If the weather is cool or cold, pile the honey on empty caps or temporary benches, above head-height if possible, heat the room to a temperature of 90 degrees, or higher, and keep it so for 24 to 48 hours, according to the length of time the honey has been exposed to a low temperature. It will then extract easily. Some

kinds of honey will soon candy in the comb, and must be extracted soon after being stored; but most honey keeps best in the combs, and it is better to leave it there until wanted for sale or use.

An active 12-year-old boy, with any 2-frame extractor, will throw out honey as fast as almost any man can uncapp it. Expensive, reversible extractors are nice to have, but seldom necessary. It is best to have two uncapping-knives, and keep one all the time in hot water, changing often. A small oil-stove is handy for this.

For storing extracted honey, or shipping it in a candied state, or for holding cappings and draining them, I know of nothing handier or much cheaper than lard-cans. They hold about seven gallons; and I get them of my grocery-man at 10 cents each after the lard is sold; and can get them new of the butcher or hardware man at 25 to 30 cents. For uncapping, arrange a can in a convenient place, put a wooden frame on top to rest the honey and clean the knife on, and let the cappings drop inside. Have a strainer made of tinned wire-cloth, 12 meshes to the inch, soldered to a circular tin rim with sloping sides, and a little larger than the top of a can. Place this, convex side up, on a can of cappings, and invert all on another can. After the cappings are well drained, put them thru a solar wax-extractor, even if it is necessary to wait for warm weather in the spring.

In warm weather the bits of comb and other foreign matter that will always get into honey while extracting, will soon rise to the top, and may be skimmed off. In cool weather, however, they must be strained out, and the honey must be heated in order to do it quickly. A good and simple plan is to put it in 5-gallon screw-cap tin cans and heat it slowly to a temperature of 120 to 115 degrees. A piece of iron or stone one inch thick placed under one side of the can will prevent danger of burning the honey. Attach a cheese-cloth sack, about 5x12 inches in size, to a sliding honey-gate, screw the gate on the can, tip it on one side, and draw the honey thru the sack into any convenient receptacle. A hole made in the top of the can with an awl, or some other sharp-pointed tool, will give vent, and the honey will run more freely. The hole can be stopt when necessary with solder or wax.

It saves watching, and some danger of having a muss to clean up, by having the extractor on a bench high enough so a can on a platform scales can be set under the honey-gate. A tin funnel, unusually large at both ends, is often a very handy implement. Get a Daisy thermometer for 25 cents, to test temperature with, and be very careful not to let the honey get too hot. That will injure the color and flavor, and melt the wax in it, which will adhere to the inside of the can, or spoil the strainer.

Don't use galvanized iron for any purpose where honey will come in contact with it. The acid in honey affects the plating. I once had an extractor-can made of it, and if a small quantity of honey was left in the can a short time it acquired a peculiar, offensive taste and smell.

From the finer flavored honeys it is better to exclude the air, but the stronger flavored kinds are improved by exposure to the air in a well-ventilated room, care being taken of course, to exclude dust and insects. If you are troubled by ants, make a bench to keep honey on by laying 2x6 inch pieces of lumber edgewise on the floor, and covering them with boards. Make a chalk-mark one inch wide entirely around the middle, lengthwise, of the 2x6 pieces, and not an ant can crawl up over it. They can't get a foothold.

For shipping liquid honey, perhaps the square tin cans are best, but for cheap honeys, barrels or half-barrels are cheaper.

Produce a good, well-ripened article of extracted honey, "get a hustle on," and sell it directly to customers yourself for a fair price. Do this and observe the Golden Rule, and you will find pleasure and profit in the business.—Bee-Keepers' Review.

Van Buren Co., Mich.

York's Honey Calendar for 1900 is a 16-page pamphlet especially gotten up to create a demand for honey among should-be consumers. The forepart was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample free; 25 copies for 30 cents; 50 for 50 cents; 100 for 90 cents; 250 for \$2.00; 500 for \$3.50. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Perhaps Pickled Brood.

Enclosed find sample of brood taken from the bees this morning, only one colony is affected.

1. What is the trouble with the brood?
2. What is the cause and cure?
3. If no cure, what shall I do with the combs and hive?

IOWA.

ANSWERS.—1. I suspect it is a case of pickled brood.

2 and 3. Old and bad pollen is supposed to be the chief factor in producing the disease, and as your bees by this time have plenty of fresh pollen, the disease may disappear. The leaflet on pickled brood will tell you about all that is known about the disease, but these bee-diseases are sometimes very serious matters, and I am not an expert in them, so it would be well for you to send a sample to Dr. Howard.

Moving and Italianizing Bees.

I have five old-style box-hives of black bees, and want to move them 20 miles, change them to Langstroth hives, and Italianize them. How must I do all this work, and when must I go about it?

MISSISSIPPI.

ANSWER.—It would take more space than the printers would allow me here to answer fully your questions, which you will find mostly answered in your text-book on bee-keeping. Other things being equal, the sooner all is done the better, altho you may do better to let the bees swarm before transferring, putting the swarms in new hives, and transferring 21 days after swarming. The chief thing in moving is to see that the bees have abundant ventilation, by means of wire-cloth at the entrance and on top, having the frames run across the wagon. If you don't mind night work, the bees will suffer less to be moved at night.

Queen-Cell Questions.

1. On page 103 (1899), F. L. Thompson says when you are cutting all the queen-cells you can shake the bees off the combs. What I want to know is, in what way does it injure the young queen in the cell to shake the bees off the combs? Would shaking the combs do in place of cutting cells?

2. Under what conditions is a queen-cell protector necessary?

WISCONSIN.

ANSWERS.—1. The young queens in the cells are very tender at certain ages, and a rough shake might produce death, or, what in some cases might be worse, such an injury that defective wings or legs might result. If this latter should happen, you can see that shaking would not do instead of cutting out cells.

2. It is necessary when you want to give a cell to bees that are not queenless, or that are not yet conscious of their queenlessness. Also, when more than one cell are in a hive, and you do not want the first queen that emerges to destroy the others.

Transferring Bees and Rearing Queens.

Ten miles from here I have now four colonies in Langstroth frames, two in one place and two more a mile away. May 27 I went to see them with extra hives, etc. At J. W. Foster's my colony swarmed May 11. They put it in a box. About May 24 they came out again, but went back. How many other times they swarmed nobody knows. There were about a dozen empty queen-cells in the hive. I could not

find a queen or an egg, only brood ready to hatch, and about a tablespoonful of honey. Now this is what I did:

I transferred all the bees out of the box by driving, and shaking the balance on the open top of a new hive. I then placed a super on both hives and divided the comb, putting it in the supers of the two hives. I expect the bees to take an egg from that comb and put it in a queen-cell and thus supply themselves with a queen. At W. Ferguson's I divided my colony May 17; both colonies were storing honey. They had only brood-chambers. One had no queen or eggs, or sign, as I could see, so I exchanged a couple of frames so they could be sure to have eggs with which to rear a queen.

This is the way I save my swarms from absconding: When I imagine they are about ready to swarm, I transfer them by placing a new hive on top of an old box with the queen with half or more of the bees. I don't see any use in using an extra box and handling them twice.

WASHINGTON.

ANSWER.—I'm not sure I fully understand your performance, except that the bees had empty queen-cells and also had eggs, and you expect the bees to take an egg from a worker-cell and put it in a queen-cell. They'll fool you—sure. I never knew a case where queenless bees did such a thing, and never heard of one. But they will proceed to rear a queen from a larva in a worker-cell by feeding it properly and enlarging the outer part of the cell. The brood being in the super, the young queen will be reared in the super.

You are entirely right to drum bees directly into the new hive without first driving them into an extra box. The latter plan is only necessary where the new hive has a fast bottom, or where the hives are so much unlike in size that one can not be made to fit on the other.

What to Do to Stop Robbing Bees.

What are some of the methods employed by experienced bee-keepers to stop robbing? The "ABC of Bee-Culture" says, "Contract the entrances," but that does not seem to stop it.

Will Mr. McIntyre's trap (described on page 254 of the "ABC of Bee-Culture,") work where several colonies are being robbed, and a person has no honey-house, or any such place, to which to take the robbed colonies? What is the slow process of robbing which he refers to but does not explain?

CALIFORNIA.

ANSWER.—In probably the majority of cases robbing starts with a colony that is queenless and of little value. Robbing such a colony may be hindered for a time, only to be commenced again as soon as your back is turned, and in the end you will not save the weakling. You may as well break it up. If there are enough bees and brood to be worth saving, give to some other colony, and take away most of the honey, but do not take away all, and do not take away the hive. Leave the hive for the bees to work away at, and when they have finished the last drop of honey in it they will keep on for a little time, and then quietly leave. If you take away the hive, they will pitch into another hive near by, and perhaps master that.

If the colony has a queen and is worth saving, you may beat the robbers in this way: Pile straw or hay at the entrance and continue it up to the top of the hive and around the sides; in fact, bury the hive in straw, and keep the straw sprinkled with water until the robbers give up.

Mr. McIntyre's trap is not generally used in connection with a honey-house, but if anything of that kind is needed an ordinary cellar will do.

I do not recall what he means by slow robbing.

Yield of Buckwheat Honey.

How many acres of buckwheat will it take to pasture 100 colonies of bees?

WISCONSIN.

ANSWER.—Any guess upon the matter will probably be very "rough" indeed, and I will leave it for some one else to make. M. Quinby estimated that an acre of buckwheat would yield 25 pounds of honey a day. If we estimate that it would take from 5 to 10 colonies to gather this, it would take from 10 to 20 acres to pasture 100 colonies. But there's a great difference in the yield of buckwheat. In some places it is quite reliable; in others it fails oftener than it yields nectar.

VOL. 40.

JUNE 21, 1900.

NO. 25

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

"That Poor Joke" is what the Farm, Field and Fireside calls the newspaper yarn printed on page 249 of this journal, and credited to the New York Mail and Express. The story was copied from the New York Mail into the Farm, Field and Fireside, with no hint that it was anything but news, whereupon we sent a letter of protest to the publishers of the Farm, Field and Fireside. This latter paper seems deeply impressed with the fact that those who have to do with bees are a very serious people, and is evidently very much surprised that the American Bee Journal could not see at a glance that the whole thing was "intended as a pleasantry," and closes by saying:

"All this is sad if it is not funny. If there is a child six years old who reads the Farm, Field and Fireside, and who does not know that the bee makes over what it gets from the flower, or from the feeding-tray, and produces real honey; and if there is any one of our readers that did not see the 'pleasantry' in the glucose story, we certainly recommend to them a vacation, and a little free air and sunshine. They are working too hard. And our good friends of the Journal need to cheer up and expend a little of the proceeds of their industry in making a good newspaper, in a playtime in the country. We would be pleased to join them in a good, old-fashioned bee-hunt, such as we used to have with our father, either in apple-blossom time or later, when the goldenrod is out, and the bees are happiest."

The need of "a playtime in the country" is felt to the full; and there is no doubt the Farm, Field and Fireside people would be pleasant companions, but a bee-hunt in

apple-blossom time would be somewhat ill-timed, seeing that is the time in the year when the bees' stores get to their lowest. However, it is not easy to see how a playtime in the country would help toward nullifying the ill effects of "that poor joke." Even admitting that the readers of the Farm, Field and Fireside are so intelligent that they need no vacation, it does not follow that some of the borrowers of the paper might not be misled.

It is a matter of history that not many years ago the statement was made as a "pleasantry" that glucose was put into artificial comb, sealed up without the aid of bees, and put upon the market in large quantities. Of course, it was much easier to see the pleasantry in that than in the "poor joke" in question, but for all that it was taken seriously by the great public as it made the rounds of the papers, giving a severe blow to the sale of comb honey from which it took years to recover. That this "poor joke" will do harm in the same way is hardly doubtful, and those who have helped to speed it on its way ought to be glad to undo so far as possible the harm they have done to an industrious, if also a very serious, class of people.

It is to the credit of the Farm, Field and Fireside that it has done its part toward discrediting the "poor joke," and it would be still more to its credit if it could have made a manly retraction without the attempt to bring ridicule upon those who made a proper protest against its unintended injustice.

It is to be hoped that good, and good only, will come to the six-year-old readers of our esteemed contemporary from its wholesale recommendation of a vacation, for it is certain that not one of them knows "that the bee makes over what it gets from the flower or from the feeding-tray and produces real honey," seeing that even a brilliant six-year-old can hardly *know* what is *not true*.

Keeping Up Honey-Prices.—Mr. E. B. Foster, in Gleanings in Bee-Culture, gives his method of trying to maintain the present prices of honey in his home market. Here is a copy of the letter he has sent to the bee-keepers in his immediate locality:

MR. BEE-KEEPER:—I take this means of laying before you a matter of much importance and interest to you, which I trust you will carefully consider. The present indications are such that we can look for some surplus honey this season. Now, the vital question that confronts us will be the converting of that honey into the largest possible amount of cash. You no doubt have observed the steady advance in price of nearly all articles we consumers have to buy; you are also aware that the honey quotations rule about 20 percent higher than last year. Why not maintain the present price of honey by combining our interests and holding out for the advanced price, thereby causing that which we have to sell to compare favorably in price with what we have to buy? The only way we can accomplish the desired result is not to sell our honey for less than the present price, and prevail upon our neighboring bee-keepers to do likewise. As an illustration:

A farmer bee-keeper, a year ago, had some dark and travel-stained comb honey which he disposed of at a price that enabled the grocer to whom he sold it to put a glaring advertisement in the local paper, "New comb honey, 8 cents per pound." That "8 cents per pound" was a criterion the rest of the season. Every customer whom you told that you were asking 15 cents per one-pound section would say, "Why, I can buy honey at the grocery store for 8 cents." You know the result. While you were not asking more for your fancy white article in nice clean sections than it was worth, you were compelled, nevertheless, to lower your price to meet the values created by that one inferior batch of honey that some thoughtless or ignorant keeper of bees had placed on the market. Our customers do not realize the difference in honey as they do the difference in price.

E. B. FOSTER.

We commend Mr. Foster's sensible plan to bee-keepers everywhere who have a home market for their honey crop. There is no doubt much money lost to bee-keepers every

year by reason of some ignorant or careless bee-keepers who do not find out the crop and market conditions, but rush their honey to the grocery store for any amount they can get. Some small bee-keepers seem to think that what they can realize out of their honey is just like *finding* so much money; so stopping to think that they are thus injuring their neighbors who must depend upon the income from their bees for a good share of their living, and who must take an unreasonably low price for their honey because some one has foolishly set the price too low in advance.

We do not think that bee-keepers should ever combine to get more for their honey than it is really worth, but we do say that they ought always to do their best to get a good price for it, for there is little danger of being able to get too much for the best grades of honey. But by using a little co-operation, better financial results should be secured.

LATER.—Right in line with the foregoing is this by Editor W. J. Craig, taken from the Canadian Bee Journal for June:

"The question presenting itself to many just now is whether the better prices for honey can be maintained when the new crop comes in. Certainly there is an excellent opportunity for making an effort in this direction if bee-keepers will only be unanimous and talk the matter up and work it thru their local associations. The poor-price difficulty originated not with the bee-keepers who depend upon bee-keeping for a living, but with those who make it a side line, and who retail their little in their local market at whatever price they can get for it.

"When talking up price it would be well to keep up quality—this after all has much to do with the free sale of the commodity. Unfortunately, many of our bee-keeping friends are not aware how very sensitive honey is, and how easily it is affected by its surroundings. Keep cans covered and as air-tight as possible, not only for the sake of cleanliness, but to retain the fine aroma of the honey. Much of the distinct flavor of the basswood is lost by the heating and exposure in liquifying."

Bees and Spraying—A Warning.—In the Country Gentleman (a most excellent New York farm paper), for June 7, we find the following by the State Entomologist, which will be of interest to bee-keepers everywhere:

The Albany Argus of May 22 contained a brief account to the effect that many honey-bees had been killed at Medusa, N. Y., by visiting trees sprayed while in full bloom with an arsenical poison. It was stated that one bee-keeper lost his entire apiary of 100 colonies valued at \$500. The report was investigated, with the following results:

Several men sprayed their fruit-trees on Friday and Saturday, May 18 and 19, the former being a bright day. Trouble was first observed on the 20th. Of the condition of his apiary on that day, Mr. W. P. Makely writes:

"The sight that met my eyes was enough to paralyze any bee-man. In front of each hive lay the full working force of the bees, some in clusters apparently dormant, and others wiggling about as if in great agony. With the appearance of the sun there was a general movement among the bees in an effort to get as far away from the hive as possible. Those that had the strength would try to fly, but could only succeed in making three or four feet before they would drop to the ground. The next day, Monday the 21st, I opened a few hives and found all the workers gone, and a large amount of brood and but a few young bees left. I think that most of the colonies will pull thru, but our honey crop is gone, and we can expect no swarms."

Mr. Makely estimates that practically all the field-workers were lost. Mr. Edwin Snyder claims to have lost between 80 and 95 percent of his workers in his 90 to 100 colonies. Mr. Aaron Jennings has from 200 to 225 colonies, and the first serious consequences were observed on the 23d, when in the vicinity of more than half his hives he could scoop up handfuls of dead or dying bees. Orchards were sprayed on the 21st and 22d, 1½ miles north, and the same distance northwest of this man's place.

A large quantity of dead bees have been received at my office, and they will be analyzed for the presence of arsenic. The destruction was fearful, and there is every reason to think that it was due to poison thrown upon trees in blossom. There is at present a law prohibiting the spraying of

trees while in bloom; and this deplorable experience certainly indicates the wisdom of its remaining on our books and being enforced to the letter.

There is a strong sentiment in some sections of the State in favor of spraying trees while in bloom, but practically every economic entomologist contends that all insects can be controlled just as effectually by spraying just before or after blooming, and in many cases the result is much better.

It has been demonstrated beyond all question by experimental methods that honey-bees can be poisoned by visiting sprayed blossoms; but this is the first case known to me where widespread destruction has resulted under strictly natural conditions, most probably as a result of spraying. This case will be closely watched.

E. P. FELT,
New York State Entomologist.

Certainly, the foregoing illustrates very clearly the importance and necessity of a good law against spraying trees while in bloom, and then a rigid enforcement of such a law. We can hardly believe that any fruit-growers would willfully cause such destruction of their best friends—the honey-bees. Only inexcusable ignorance can be the reason for such conduct.

We hope that in some way the fruit-men may become informed on this subject, which is so vital to their welfare as well as to bee-keepers.

An Important Omission is that of the American Bee-Keeper, where it publishes a very full account of a lawsuit involving a seller of adulterated honey, and then omits the name of the alleged original adulterator. Might as well leave out all personal names as to omit the most important one, we think.

The Weekly Budget

MR. E. S. LOVESY, of Salt Lake Co., Utah, writing us June 6th, says:

"I have just returned from a trip to Northern Utah and Idaho, and as a rule I found the bee-industry in a flourishing condition; the same may be said as to the fruit."

MR. N. E. FRANCE, of Grant Co., Wis., State inspector of apiaries, in a letter dated June 9, writes as follows:

"Prospects are not very good for clover honey, but basswood is well budded all over the State, and if the harvest is a fair one there will likely be a goodly number of Wisconsin bee-keepers at the convention of the National Bee-Keepers' Association in Chicago next August."

MR. WM. A. SELSER—the great honey-man of the East—is just recovering from a very severe attack of typhoid fever. In a letter dated June 12 he says:

"Your letter to hand some time ago while I was in bed. I have had a long siege of it, and without going into details to weary you I will say that the doctor at one time gave me up; and indeed I feel as if I had slept at the edge of the River of Death, and have returned by the mercy of the Great Physician, and am now anxious to seek and fulfill the mission He has spared me for. I am sitting up in my room, and in a few weeks I hope to go out again. Recovery is slow, as my sickness was so severe."

We rejoice with Mr. Selser and his family in his recovery. The world has all too few such men as he. Personally, we can never forget the week we spent in that delightful home when attending the Philadelphia convention last September. Our very best wishes for health, continued happiness, and unusual prosperity, go out to Mr. Selser and his loyal as well as royal family.

H. G. Quirin, the Queen-Breeder,
Is as usual again on hand with his
improved strain of
GOLDEN
ITALIAN QUEENS.

Our largest orders come from old customers, which proves that are stock gives satisfaction. We have 12 years' experience in rearing queens, and if there is any one thing we pride ourselves in, it is in sending all queens promptly **BY RETURN MAIL.** We guarantee safe delivery. Price of queens before July 1st:

	1	6	12
Warranted as queens average	\$.75	\$ 4.25	\$ 8.00
Selected, warranted	1.00	5.00	9.50
Tested	1.50	8.00	15.00
Selected tested	2.00	10.50	
Extra selected tested, the best that money can buy	4.00

GENERAL ITEMS

Bees Doing Well.

My bees are doing well this year, and this week I am going to build a honey-house for which they will more than pay, as altho I have only 15 colonies I can sell all my extracted honey at 8 cents from our door, and the people bring their own utensils.

I got five colonies of black bees to keep on shares for three years, when the whole outfit belongs to me. During swarming, in the early days of May, as soon as they swarmed, I cut out all their own queen-cells and put in two or three good, large cells from my pure Italians, and one of those young queens keeps 8 standard frames plump full of brood from top to bottom-bar. But I am afraid that I injured her last Friday, when I clipped her wings as I cut too close to the thorax, and when she dropt on the top of the frames she bowed herself up. I will look at her next Tuesday, and see if she is all right.

W. H. ALDER.
Callahan Co., Tex., June 4.

Italians on Red Clover.

Today my bees are busy on red clover around my apiary. There is more white clover than red, but they are working on the red clover too. Those who doubt whether Italian bees work on red clover should be here now.

D. J. BLOCHER.
Stephenson Co., Ill., June 7.

The Season—Putting Foundation in Extracting-Frames.

Since my last report we have had extremely fine weather for the bees, very few cold spells, and scarcely any high winds to interfere with the "Hum of the Bees in the Apple-Tree Bloom." Dandelion has been out for some time, and hives are being packed with brood and honey from the yellow heads.

I had 4 colonies become queenless from some cause, the queen being dumpt just off the alighting-board. In each case she had laid the combs pretty full of eggs, with the last laid mostly drone-eggs. They were all from prime swarms (last year), consequently old queens, and died from being worn out, which was indicated by the queen laying drone-eggs (i.e., the seminal fluid being exhausted for fertilizing the eggs.) I have, however, gotten them supplied with a "yellow" (?) Italian queen from my best stock, and all are laying except one, which was too early for drones, and began laying drone-eggs. I had to supply them with another chance. Their queen is out, but not yet laying.

The rest of my 16 colonies are "boiling over" with bees. I have put an extracting-super under the brood-chambers to check their swarming. And now for my experience in putting foundation in the extracting-frames:

First, I cut a board that would just fit inside the frame, and half as thick as the frame is thick. This is nailed onto another board as large as the

Sharples Cream Separators: Profitable Dairying

The Queen Crank

Is before the readers of this Journal with a petition for orders for as fine Queens as he has ever been able to rear. They are being, and have been for some weeks, reared in triple-decker 10-frame bives, from choice Golden and T'ree-Band Mothers, in a Golden yard. The Bee-Keepers' Review, of Flint, Mich., for May (which is a special queen-rearing number) tells how it is done. Ask for a copy. Tested, \$1.00; untested, 75 cents. Yellow Sweet Clover Seed

WE HAVE IT AT LAST!

We have finally succeeded in getting a SMALL quantity of the seed of the YELLOW variety of sweet clover. This kind blooms from two to four weeks earlier than the common or white variety of sweet clover. It also grows much shorter, only about two feet in height. It is as much visited by the bees as the white, and usually comes into bloom ahead of white clover and basswood. We offer the seed as a premium

A QUARTER POUND FOR SENDING ONE NEW SUBSCRIPTION.

So long as it lasts, we will mail a quarter pound of the seed to a regular paid-up subscriber who sends us ONE NEW subscriber for the American Bee Journal one year, with \$1.00; or 1/4 pound by mail for 30 cents.

We have been trying for years to secure this seed, and finally succeeded in getting it. It is new seed, gathered last season by an old personal friend of ours, so we know it is all right. But we have only a small supply. When nearly out we will mention it.

GEORGE W. YORK & CO.,
118 Michigan St., - CHICAGO, ILL.

Queens 5-banded QUEENS

Yellow all over—75 cents each; after June, 50 cents each.

By this my friends will see that I have moved from Falmouth, IND., to Merigold, Bolivar Co., MISS., where I am making a specialty of rearing the BEST Queens from the best strain of bees that can be found in this country.

Remit by postal or express money order, and address all letters to

DANIEL WURTH,

25E2t Merigold, Bolivar Co., Miss.

Langstroth on... The Honey-Bee

Revised by Dadant—1899 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the Ameri-

can Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helpt on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.
118 Michigan Street, CHICAGO, ILL.

19D121 FORT DEPOSIT, ALA.
Please mention Bee Journal when writing.

frame (outside dimensions.) A frame is slipt onto this, a sheet of foundation laid inside, and on the smaller board (that *just* comes up even with the lower side of the groove in the top-bar of the frame), and the edge slid into the groove in the underside of the top-bar. A small wedge-shaped splint with a little flour or starch paste (or some other substance that will stick, and not let loose when it gets warm) put on, and prest into the groove, completes the job, except to give it time to dry before putting the supers on the hive.

I made my splints from old wood separators cut just wide enough to fill the groove in the top-bars just full. By using a sharp knife, a good ruler, or straight-edge, a good, solid cutting-table, and a reasonably straight-grained wood-separator to cut the splints from, they can be made to fit exact, and be made very fast. It helps a good deal in getting the splints to enter the groove readily, and to avoid the sharp edge cutting the foundation, to scrape the sharp edges off from the two edges next to the frame, making it somewhat wedge-shaped.

Now, I presume most of the older heads will say, "O, stucks! any one would know enough to put in foundation," and I presume some have a better way; if so, let's have it, even tho it does knock my way into "smither-eens," and make me feel as if I belong in the A B C class instead of in the X Y Z class, or away up thru the 5th and 6th reader, almost alongside of Langstroth, Huber, Dzierzon, Root, etc.
F. W. HALL.
Sioux Co., Iowa, May 28.

Paste for Labeling New Tin.

Use Demar varnish reduced with alcohol so it will spread easily with a brush, apply to the can, then lay the label on and press down smooth with a damp sponge.

It can be used to mend china and glass, but takes a long time to dry.

This paste *will stick*, is easily prepared, and will not sour.

H. N. CHANDLER.
Langlade Co., Wis.

Prosperous Summer Expected.

We are having an unusual amount of rain for so early in the season, and the alfalfa is coming on finely, fruit also, and I think the bees will have a prosperous summer.

This is the location of the U. S. Marine Hospital Sanitarium for consumptive sailors; there are about 100 men at work repairing the buildings for occupancy, and they have now about 50 patients, and more coming every few days. Most of those who have been here some time are showing wonderful improvement.

ERNEST W. HALSTEAD.
Lincoln Co., N. Mex., June 2.

Some Stinging Experiences.

Prof. Cook's report of a cow being stung to death by bees (see page 147) is different from my experience. When a boy my father used to keep a few bees in old-fashioned gums, that were kept in a row alongside the yard fence. I came up one day with a yoke of young steers, and unyoked them near the bees. They were not well trained, so I

Rocky Mountain Bee-Plant Seed!

(*Cleome integrifolia.*)

...FREE AS A PREMIUM...

The A B C of Bee-Culture says of it: "This is a beautiful plant for the flower-garden, to say nothing of the honey it produces. It grows from two to three feet in height, and bears large clusters of bright pink flowers. It grows naturally on the Rocky Mountains, and in Colorado, where it is said to furnish large quantities of honey."

We have a few pounds of this Cleome seed, and offer to mail a 1/4-pound package as a premium for sending us **ONE NEW** subscriber to the American Bee Journal, with \$1.00; or 1/2 pound by mail for 40 cents.

GEORGE W. YORK & CO.

The Bee-Keeper's Guide

Or, Manual of the Apiary,

—BY—
PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipt, or his library complete, without THE BEE-KEEPERS' GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,
118 Michigan Street, CHICAGO, ILL.

18A4f Please mention the Bee Journal.

tied their heads together to prevent them from jumping from under the yoke when the bows were taken out. They concluded to have a little fun anyway, and when I took off the yoke, they ran up near the bee-gums. The bees did not seem to like oxen, and so proceeded to persuade them to leave. One of the steers jumped the fence. I had no veil, and was somewhat afraid of bees anyway (at that time), so I thought the "jig was up," and that father would soon have more beef on hand than he could dispose of. But the ox did not lose its mind, altho he became rather excited. He jumped back over the fence, and together they ran to the lot about 200 yards away. I suppose they must have received some 30 or 40 stings each.

At another time (and since I have been keeping bees in the modern way), a couple of friends came up one day on horseback. They got down and turned their horses loose. They rambled around and got into the bee-yard, and the result was a very pretty race.

A friend came along one day when I was "robbing," and stooped to eat honey, and see how the extractor worked. He hitched his mule to a tree between the apiary and the house, where I was extracting, the house being some 200 yards from the apiary.

I owned only 40 colonies, at that time, and was pretty green. I had allowed so much honey to be exposed at the house that the bees became excited, and I had a nice case of robbing. While we were in the house the bees attacked the mule. My father happened along and saw they were stinging the mule, and went to his rescue, but the bees stung him so badly that he gave it up and ran to the house for me.

Mr. Wilson (the owner of the mule), saw to him as quickly as possible, while I waited to put on a veil and gloves. When I got out Mr. Wilson

\$5.00 per month will pay for medical treatment for any reader of the American Bee Journal. This offer is good for 3 months ONLY—from May 1 to Aug. 1. Dr. Peiro makes this special offer to test the virtue of small price for best medical services. Reply AT ONCE.

Four Celluloid Queen-Buttons Free AS A PREMIUM.

For sending us **ONE NEW SUBSCRIBER** to the Bee Journal for the balance of this year, with **50 cents**, we will mail you **FOUR** of these pretty buttons for wearing on the coat-lapel. (You can wear one and give the others to the children.) The queen

has a golden tinge. This offer is made only to our present regular subscribers.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate, it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

Prices of Buttons alone, postpaid: One button, 8 cts.; 2 buttons, 6 cts. each; 5 or more, 5 cts. each. (Stamps taken.) Address,

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO.

had unhitch him from the tree, and was trying to drive him away, but he seemed not to care whether he died or not, for he would not go.

Mr. Wilson is a large man, and shaves clean. He was fighting bees with his hat in one hand and whipping the mule with a fishing pole, and twisting his face in more different shapes than a circus clown. I told him to leave the mule to me, and I would take care of him. He seemed very willing, for he ran to the bushes about 100 yards away very quickly; I think his tracks were about 8 feet apart, where he ran across the cotton-patch.

After ruining a buggy-whip on the mule without driving him more than 30 feet, I went to his head and masht the bees as they lit on him, until I got them checkt, when Mr. Wilson returned, and he and I together managed to get the mule to the bushes.

I had got the mule out of the direct line between the house and apiary, so the bees were not increasing in numbers about him, before I tried killing them.

We scraped the stings out with our knives, and bathed the mule with cold water for an hour or two. I also drencht him with alcohol—(some my father had on hand for medicinal purposes; being a physician, he keeps it. I want you to understand I do not keep it.)

The mule was sick for several days, and one of his ears rotted off. Father's face was swollen all out of shape for a couple of days; he must have received a dozen or more stings in the face. The bees were so bad for an hour or two that my mother had to close all the doors and windows, and keep on the inside of the house.

Mr. Wilson will not stop anywhere near an apiary now in daytime; and your humble servant has been very careful since to prevent robbing, also to see that no stock is exposed where bees are liable to attack them.

The tree to which the mule was tied was used every day by my father to hitch his horse to, and of course I never thought of the mule being in danger.

I sincerely hope that I will never have another such experience.

J. M. CUTTS.

Montgomery Co., Ala.

A Point in Handling Honey.—As to placing the shipper's name and address on a case, I repeat the argument that his name should be on the package, so that if any complaint is made to us we will know whose honey it was. The shipper's address should not be on the package; for it is no one's business where the honey comes from; but is a subject only for the jobber who is experienced as to the product. If any shipper wants to advertise his honey, it is his privilege to do so; but when he sells to a wholesaler, he must be satisfied to allow the wholesaler to do his own advertising. Then, again, some customers object to honey from certain localities, and we do not intend

A HANDY TOOL-HOLDER!

Sent by Express, for \$1.50; or with the Bee Journal one year—both for \$2.00.

Every Manufacturer, Miller, Carpenter, Cabinet Maker, Machinist, Wheelwright and Quarryman, Farmer, or any one using a grindstone, should have one of these Tool-Holders. One boy can do the work of two persons, and grind much faster, easier and with perfect accuracy. Will hold any kind of tool, from the smallest chisel to a draw shave or ax. Extra attachment for sharpening scythe blades included in the above price. The work is done without wetting the hands or soiling the clothes, as the water flows from the operator. It can be attached to any size stone for hand or steam power, is always ready for use, nothing to get out of order, and is absolutely worth 100 times its cost.

No farm is well-equipped unless it has a Tool-Holder. Pays for itself in a short time.

How to Use the Holder.

DIRECTIONS.—The Tool is fastened securely in the Holder by a set-screw and can be ground to any desired level by inserting the arm of the Holder into a higher or lower notch of the standard. While turning the crank with the right hand, the left rests on a steady the Holder; the Tool is moved to the right or left across the stone, or examined while grinding, as readily and in the same way as if held in the hands.

For grinding Round-Edge Tools, the holes in the standard are used instead of the notches.

Address, **GEORGE W. YORK & CO.**

CHICAGO, ILL.

to be hampered with the address on the package; and will take care of that part of the business ourselves.—M. H. Mandelbaum (a city honey salesman), in the Bee-Keepers' Review.

Cement-Coating Nails.—The outfit required for preparing the nails is an old frying or stew pan and a little rosin. Place the pan containing the nails on the fire; stir them to get evenly heated. Try a few at first. Have a little powdered rosin, say one tablespoonful to a pound of nails. When the nails begin to turn blue remove from the fire and immediately sift the rosin over the nails, stirring till all are smeared with the molten rosin. Now turn them out on a bench or board and spread out thin. You now have the genuine (so-called) cement-coated nails. One pound of rosin is sufficient to coat 100 pounds of nails. Will some brother bee-keeper tell us how he succeeds with this method?—H. M. Jameson, in the American Bee-Keeper.

Black Brood in New York.—It seems that this disease is breaking out again in the Empire State, for I hear of its having started up in several localities. The following letter will show that the Commissioner of Agriculture, in whose hands rests the responsibility and the power, largely, to eradicate this disease, is very much interested, and is doing and will do all he can to stem the tide of its ravages:

MARQUETTE, ON LAKE SUPERIOR,

is one of the most charming summer resorts reached via the Chicago, Milwaukee & St. Paul Railway.

Its healthful location, beautiful scenery, good hotels and complete immunity from hay fever, make a summer outing at Marquette, Mich., very attractive from the standpoint of health, rest and comfort.

For a copy of "The Lake Superior Country," containing a description of Marquette and the copper country, address, with four (4) cents in stamps to pay postage, Geo. H. Heafford, General Passenger Agent, Chicago, Ill.

MR. ROOT:—I will explain here that last season Mr. West was appointed bee-inspector until a civil-service examination was held, which occurred July 29. He past at 95.2; I at 94.2, and W. D. Wright at 93.6, while M. Stevens stood 85. (I think these figures are correct.) Mr. Stevens, being a veteran, took precedence over all of us, and Mr. West was also appointed.

These inspectors did some very effective work; but the diseased territory was too large to be thoroughly inspected without more help, so W. D. Wright and I were appointed by the New York State Agricultural Commissioner, and ordered to report at the commissioner's office at Albany for work May 1. We accordingly met Mr. Stevens and Mr. West at that time, and spent two days in consultation with the State officials (who, by the way, were very kind and courteous to us), as to how the State should be divided, and ways and methods, etc.

I think it would be well to announce the territory assigned to each inspector, and I enclose a list of alphabetically arranged counties in each inspector's division. All communications in regard to diseased bees should be sent to the inspector in whose division the bees are located.

May 4, 1900. **CHAS. STEWART.**

In this connection perhaps it may be well to state that extracted honey from colonies affected with black brood ought to be boiled at least one hour to be safe. Hives should be scalded or burned out, and bee-keepers in the infected regions would do well not to exchange combs. Tools, smokers, bee-gloves, bee-veils, bee-hats, and even the clothing that is used around diseased colonies, should be disinfected before working on healthy ones. It should be remembered that both foul brood and black brood are very contagious, and the inspectors of the State will do well to urge every precaution.

The most serious difficulty to be encountered will be ignorance as to the nature of this contagious disease; for I learned while in New York that a few bee-keepers who had black brood in the apiary, and knew they had it, took no precaution about exchanging combs, did not wash the hands, much less disinfect smokers or clothing, be-

cause they did not know that it was necessary.

The honey from diseased colonies will do no harm to human beings; but I would suggest that the production of comb honey in disease-infected localities be discontinued, and that extracted only be produced. It may be a hardship to observe all these precautions, now, but it will mean many dollars in the future, even if it is a sacrifice now.

Texas.—The Central Texas Bee-Keepers' Association convenes in seventh annual convention, at Hutto, Tex., July 12 and 13, 1900. All are cordially invited to attend. Excursion rates, and no hotel bills to pay.
Hunter, Tex. LOUIS SCHOLL, Sec.

The Farm as a Factory.—Our modern agriculture demands that the farm shall be something more than a mere producer of raw material to be worked into a finished product by some one else. The times are so rapidly changing in this particular that the best farms all over the country now conform more nearly to this changed order of things. Where it was the custom a few years ago to raise cattle, hogs and sheep, merely that they might be sold as "stockers" to some man who completed the process by fattening and marketing them, they are now fattened and finished at home and by the man who raised them. Farm cheese and farm dairy butter are now taking high rank and serve as other examples of farm manufacture. Farm-cured hams and farm-made sausages may also be referred to. Of course, all these changes and tendencies—and we have only pointed out a few of them—call for better and more business-like methods on the farm. They call, above all else, for a strong, durable and highly efficient power. If the power is portable it possesses many advantages over the stationary power. In many sections it is found advantageous to have a community power—one which is owned jointly by several farmers and which may travel about from farm to farm as needed, supplying power for threshing, cutting ensilage and other feed, grinding grain, sawing wood, etc. Among those powers specially well adapted to this use is the Rumely Traction Engine. The Rumely engines differ from others of their class, in their easy steaming qualities, and they possess unusual actual horse-power. In addition they are very simple and easy to handle. Their traction qualities are excellent and make them fast travelers on the road. It will be well for any farmer, or association of farmers, who think of buying an engine, to look into the merits of the Rumely before buying. Address, The Rumely Company, La Porte, Ind., for handsome free catalog, and mention the American Bee Journal.

BEE=BOOKS

SENT POSTPAID BY

George W. York & Co. 118 Mich. St. Chicago.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in perfect cloth and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopaedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzoz.—This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers, \$1.00.

Bienen-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Bienenzucht und Honiggewinnung, nach der neuesten methode (German) by J. F. Eggers.—This book gives the latest and most approved methods of bee-keeping in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cts.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cts.

Foul Brood Treatment, by Prof. F. R. Che-shire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 20 cents.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about Poultry Business. 64 pages. Price, 20 cents.

ALBINO QUEENS If you want the most prolific Queens—If you want the gentlest Bees—If you want the best honey-gatherers you ever saw—try my Albinos. Untested Queens in April, \$1.00; Tested, \$1.50. 12A26t J. D. GIVENS, LIBBON, TEX.

Please mention Bee Journal when writing.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, June 8.—Not any new comb honey has appeared on the market, but it would sell at 15 cents, as there is a demand for it that can't be supplied for some time hence.

Extracted from the Southern States is coming forward quite freely, but is not active and prices are lower. White sells at 6½@7c; amber, 6@6½c; dark grades, 5@5½. Beeswax, 27c for prime.
R. A. BURNETT & Co.

KANSAS CITY, June 11.—We quote: No. 1 white comb, 14@15c; No. 1 amber, 13@14c; No. 2 white and amber, 13@13½c. Extracted, white, 7½@8c; amber, 7c. Beeswax, 22@25c.

Very little comb honey on the market but what is caudied, which is almost unsalable; stock of extracted, light. No beeswax in the market.
C. C. CLEMONS & Co.

DETROIT, May 24.—Fancy white comb, 15@16c; No. 1, white, 14@15c; amber and dark, 10@12c. Extracted, white, 7c; amber and dark, 5@6c. Beeswax, 25@26c.

Supply and demand for honey both limited.
M. H. HUNT & SON.

NEW YORK, May 21.—Our market is practically bare of comb honey, and there is a good demand for white at from 13@15c per pound, according to quality and style of package. The market on extracted is rather quiet, and inactive. New crop is slow in coming in, and prices have not yet been established. Beeswax holds firm at 27@28c. HILDRETH & SEGELKEN.

SAN FRANCISCO, June 6.—White comb, 11½@12½c; amber, 8@10c. Extracted, white, 6½@7c. light amber, 6@6½c; amber, 5@5½c. Beeswax, 26@27c.

There is not much honey on market, either old or new. Small quantities of new comb and extracted are going to local trade at comparatively stiff values. In some instances, especially for comb, an advance on best figures warranted as a quotation are being realized. To secure export orders, however, of anything like wholesale proportions, prices above noted would have to be materially shaded.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.10, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO., 118 Mich. St., Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

Low-Priced Nuclei.

From July 1st to 15th, we will furnish 3-frame colonies, with young laying Italian Queens, each frame well filled with brood, at \$2.50 each; 3 at \$2.25 each; 10 at \$2.05 each; 20 at \$2.00 each. This is one of the best ways to increase your stock. Catalog free.

[This Prize Article and Illustrations from the Bee-Keepers' Review.]

Commercial Queen-Rearing in all of Its Details.

BY W. H. PRIDGEN.

VERY few queen-breeders now allow the bees to construct their own queen-cells. The cells are dipt and fastened in some way to a stick and then supplied with just-hatched larvæ. If only a few cell-cups are needed they may be dipt by using a single dipping-stick, dipping a single cell at a time; but this is too slow work where there are many cells to be dipt.

The dipping-stick should be not larger than 5-16 of an inch in diameter. The tapering part should be 5-16 of an inch long; reduced rapidly the first 1/8 of an inch, and then gradually reduced to the end. It should slip into a worker-

W. H. PRIDGEN.

A Whole Battery of Dipping-Sticks used in Modern Queen-Rearing—and the Results.

cell one-eighth of an inch before filling the mouth of the cell, and form a sink in the wax-cup that will bear sufficient pressure to make the cocoon fit snugly without touching the bottom. The accompanying illustration shows my first plan for dipping a large number of cups at one time, and attaching them to slats by means of melted wax; but the time has arrived when cell-cups will be on the market, and we need a bar to which they can be attached without melted wax. One, a half-inch square, to fit between the end-bars of a brood-frame, with 18 5-16-of-an-inch holes bored nearly thru, and five-eighths of an inch from center to center, furnishes just such a bar.

Only one round nail should be used at each end when fastening it in the frame, so that the holes can be turned out for the cups to be inserted and the larvæ transferred, with the frame lying on its side. The bars should be immersed in hot wax before put in use, and if the larvæ only are transferred the cups should first be slightly prest into the holes with a peg that fits the bottom; but if the cocoons be transferred with the larvæ, it is only necessary to set them over the holes, and the slight pressure necessary to make the transfer will also tighten the cups.

The bar should be put across the center of the frame, and the space above it, except a bee-space immediately above it, be filled with a thin board nailed in. There will be no necessity of ever taking the bar out of the frame; as, if provided with wire loops, the nursery (see next page) can be slipped over the cells in less time than it takes to count them, and the queens removed as they emerge; or the cells can be detached and used in the usual way, by simply running a knife between them down to the bar, and prying them off.

To dip cell-cups that are smooth inside, the first dip must be full-depth, and the others varied according to the temperature of the room and wax. Usually the second dip should only be half way up, and then the third one will finish it, unless the wax is too hot, and should be nearly full-depth.

The use of the new cell-bar will simplify the dipping of cups wonderfully, as any number of the forming-sticks can be made fast in a board, in rows of suitable distance to admit of conveniently removing the cups, or the sticks can be made fast in the bars, as teeth in a rake, instead of loose, as shown on the first page, and a number of these sets can be fitted into a frame and all dipped at once, by having blocks of varying thicknesses, or some other arrangement, to be adjusted while the wax is cooling, after making a dip, for the frame or board to come down on, to change the depths of the different dips. It is not necessary to make the base of the cups heavy, as is the case when they are to be stuck on slats with wax, and the sticks need not be varied from a perpendicular position, but simply give a little jerk to dislodge the drops as soon as they form on the points, to prevent having long necks to the cups.

The latest machine dips them by turning a crank, and the pins have two motions. They go around like the spokes in a wheel, and they whirl, or slowly revolve, as they go around, which keeps the wax spread evenly around until it sets, and prevents the long points that are so bothersome when dipped by hand. The wax must be the right temperature, and the dipping done by a steady, slow movement. If moved too fast the wax will be forced up too high on the pins, and make the cups with a long side and a short one. Although they are turning while in the wax, they will not turn entirely around while at the deepest point.

The pins are arranged on the circumference of a wheel, but not put on entirely around the wheel, and after all are dipped, and the point reached where no pins touch the wax, all is suddenly raised sufficiently for them to miss the wax, and another revolution given without stopping the wheel, followed by a pause for cups to cool, and then repeated until the cups are sufficiently heavy. Then the wheel is carried over to the water-trough and the cups removed. If the weather is cool, the water should be kept at a temperature of about 100 degrees, Fahr., to make the cups slip off easily.

The machine automatically varies the depth of dip by means of a plate with a thick side and thin one, that is, moved around one notch every time the point is reached where no pegs touch the wax. Over this is arranged a piece of hoop-iron that moves up and down, on which the thumb-screws rest that are used for adjusting the machine to the quantity of wax, and for lowering it as the wax is used up.

As queen-breeders generally will not consider such a machine practical for making cups for their own use—as more simple arrangements can be used for securing satisfactory cups in a wholesale way—I will not go into all of

the particulars, but will add for the benefit of those who want to make them for sale, that the pins should have sharp shoulders the right distance from the points to give the cups the desired depth, which will trim each cup to a uniform depth, and remove the feather edge so liable to be broken off in handling. It should be a square cut in, and the cup made on the head or larger portion. The cells made on pointed sticks are just right for use when the transfer is made by using the cocoon, and there is nothing to do when they are placed over the holes but make the transfer, and they will be fastened in the bar at the same time. If larvæ only are to be transferred, a peg the same size and shape of the transfer-stick, except the end should be round and smooth instead of concave, can be used for pressing the cups in the bar, which will stretch them and make them the right shape inside. No attempt should ever be made to fasten them in unless they are soft enough to mash up without cracking.

Inasmuch as the bees more lavishly supply larval food to royal larvæ than to worker for the first three days, and all agree that the resulting queens are no worse for it, while the experience of many verifies the fact that they are better, I prefer a plan of transferring whereby newly-hatched larvæ can be used. This is done by supplying the breeder with combs so old that the bottoms of the cells have lost their hexagonal shape, and are thick and dark. A piece of such comb may be shaved down with a keen-edged, slightly heated knife, so as to cut it smooth, within one-eighth of an inch of the bottom of the cells; and by bending it back and forth, the cocoons will drop from it, unless it has been sufficiently exposed to moisture to mold.

It will be found that all do not work alike; some seem to be glued in, while others almost fall out, with all degrees between, but usually they can be transferred by taking them up on the transfer-stick, herewith shown, which is sufficiently rounding at the points to slip into them without bruising them; altho they may be stretched a little thereby, which should be the case. The end has a funnel-shaped cavity in it that fits over an egg, or small larva, and takes the cocoon up, fitting like a gun-cap on the tube, which, by a slight pressure and little twist, is transferred to the cup.

It is more satisfactory when the comb is old enough so that the outside of the cocoon is black and glossy, and any adhering thin tissues that are liable to come above the edge of it in the cup can be rubbed from it while it is on the stick. Whenever only a transparent tissue is taken up it is useless to insert it into the cup, as it has not the stability to preserve its form while the transfer is being made. Whenever they loosen up by simply bending the comb back and forth there is nothing to do but insert the transfer-stick and take them up; but, with other pieces of comb, it may be necessary to slightly work the stick back and forth as tho it is to be shoved or pulled out sidewise before it will adhere. After one has been stretched too much to fit the stick it cannot be taken up. Slightly waxing the end of the stick may help in obstinate cases.

I prefer using larvæ too small to be seen, that are surrounded by clear or slightly-milky food; but those larger than the head of a brass pin can be transferred.

When only a small wet spot can be seen in the bottom of the cell the larva will be accepted all right by queenless bees; and one can rely upon being on the right side as to age, as well as certain of the fact that it has been amply fed up to the time of the transfer; especially so if the comb be given to bees anxious for larvæ to feed a few hours before.

The same comb will usually supply larvæ for 3 or 4 days if kept in the breeder's hive as long; and by returning the combs to the breeder after the brood is sealed, there will nearly always be one from which the bees are hatching solidly, which will be filled with eggs just as fast as the bees in the breeder's hive feel the need of brood to feed. In this way only one set of combs need be cut.

Some report better success when transferring larvæ only if no royal jelly be first put into the cups, as the bees begin to feed them as soon as they are transferred. It certainly should be floating in the milky food before it is transferred; and at times when it is sticking to the bottoms of

Transfer-Stick.

the cells with only enough around it to keep it living, good queens need not be expected if such be used. Then it is that the comb from which it is to be used should be given to bees without brood at least 24 hours in advance.

The majority will be more successful in having cups accepted, and attain better results, if they first be given to bees deprived of both queen and all unsealed brood from 6 to 12 hours previously.

Nursing begins the instant they are given, if the bees be long enough queenless to receive them, which is of vital importance, as the larvæ once neglected are slow in development and result in dwarfed queens.

In preparing bees to start cells, it hastens matters wonderfully if they be shaken from the combs, whether it be from the combs of one hive on to those of another, or right into the same hive.

When they are thus disturbed they begin to search for the queen immediately, realizing, I suppose, that she is liable to an accident under such treatment, and they act very much like a swarm when the queen is mist.

If shaken from the combs of a normal colony on to combs minus brood, from 3 to 6 hours is ample time, and sometimes the cups have to be given sooner to quiet them.

At the time when the greatest distress is shown is when they will accept the greatest number, and the chances for the best results lessen as they reconcile themselves to their condition.

If one is making a business of queen-rearing he should keep a colony at work as cell-starters. Fill a body with combs of brood and place it over the colony selected, with an excluder between. Twelve days later place this body on a bottom-board, minus the most of the board, with wire-cloth tacked on as a ventilator; stop the entrance so that no bees can escape; shake the bees from the combs and examine them for cells, removing any that are found.

Substitute a comb $\frac{1}{4}$ full of water, for one in the hive, or pour a little water into one, as they will consume quite a bit when thus shut up, and remove as many more as there are batches of cells wanted, to make places between other combs to receive them.

The bees will cluster in the spaces thus formed, and the cups can be inserted before many bees escape, which they are anxious to do.

Regardless of the kind of hive used, there should be a cloth over the frames before putting on the top, so that it can be gently rolled back and the bees smoked until the spaces are reached, to avoid their escape.

The greatest number of cups I have ever given was 36, and have had as many accepted.

Usually I prepare the bees about 9 o'clock a.m., give them

Cell-Cups, Completed Cells and Queen-Nursery, as used by Mr. W. H. Pridgen, of North Carolina.

the cups at 1 to 3 o'clock p.m., and wait until the next morning to remove them.

Mr. W. S. Pender, of Australia, allows queenless bees to work on one batch 2 or 3 hours, and then gives another, and so on, but, as I know they will accept as many as two batches all right, late in the evening they and adhering bees can be given to cell-builders, and the balance set back over the excluder, ready for the same operation the next day, or whenever desired.

At this date (April 4) I am unable to experiment and ascertain how short a time the allowing of the cups with the cell-starters will suffice, but, of course, Mr. Pender knows.

When this stage is reached another body should be filled with combs of brood and placed over the excluder, and the one just used for the cell-starters put on it when it is returned. Then, when the top one is set off to prepare the bees for accepting cups, some can be shaken from 2 or 3 combs of the one immediately below it, which will be sufficient to start the excitement.

In 10 or 12 days more, all of the bees will have emerged from the top set of combs, and all the brood in the second set given will have been sealed, so that the first set can be disposed of, another set with brood prepared, and the second set come into use in having cups accepted. At these intervals the giving of brood and removing of combs can be kept up during the season, and the bees worked as described daily, or nearly so. Every time a new set is given, those previously given should be examined for cells, and the cells removed.

The brood given keeps up a strong force, altho some bees are removed each day with the cups to the cell-builders. When no honey is being stored the colony should be daily fed a sufficient quantity of syrup to fill the combs as the brood hatches out.

The main point to keep in view is, that whether bees are confined, or made broodless and queenless on their stand with liberty to fly, they will accept cups in a few hours after the queen and all unsealed brood are taken from them.

In preparing a hive to have cells built above an excluder, with a laying queen below, the excluder should be nailed to the top body, and have a bee-space between that and the frames above and below. If the hive is wide enough to take ten frames and a division-board, a tight-fitting-board can be tacked in the center to the excluder, and form two apartments, holding five combs each, thereby doubling the capacity of the colony for cell-building, without ever taxing it to feed more than the usual number at any one time by giving a batch of accepted cups in the center of one apartment between two combs of either sealed or unsealed brood, and as soon as they are sealed, say five days later, place another in the other. This gets it into working order, and one batch can be removed and another given every five days.

Whenever cells are built by queenless bees, if nuclei are to be formed, a sufficient number of combs of brood and the adhering bees should be placed under them as soon as they are sealed, to furnish at least one comb for each cell. Just before the time of hatching the cells should have a nursery slipped over them, and then the nuclei can be formed and queens given as fast as they hatch; or, say twice a day, as all will not hatch at once. No doubt it is better to form the nuclei late in the evening, so that the bees will become accustomed to their changed conditions before they can fly.

Another lot of combs, bees and cells can at once be placed on the same stand to catch the returning bees, and worked in a like manner, to be again and again repeated if necessary; but, of course, in the latter case care should be exercised in selecting all sealed and hatching brood, as the combs will be used within two days for forming nuclei.

When queenless bees are not used as cell-builders a queen can be removed from a colony and other bodies piled on provided in a like manner a few days before nuclei are to be formed, and by allowing the queens to hatch out in a nursery hereinbefore stated, all is ready to form nuclei, without having unsealed brood in the combs to starve as is often the case when drawn from normal colonies; besides, bees thus treated will remain in the nuclei better than those taken from a colony with a queen, even if cells be given, instead of queens.

After getting the bees in shape to be ready for forming nuclei, they should be fed all the syrup they will take every evening, until the divisions are made, except during a flow.

After ascertaining how to have virgins or cells accepted, that is, to bring about the conditions necessary under varying circumstances, it is not only a waste of time,

but often proves to be a loss to open a nucleus from the time a virgin is two days old until the time for her to be laying. Virgins are hard to find, and the bees often act as tho they were queenless while the virgin queens may be present; and, worst of all, often kill them if no honey is being stored, if disturbed.

If virgins are given and not accepted they can often be found near the entrance next morning. A stroll in the evening among those containing queens of mating age will often save time, as there will be considerable distress manifested where a queen has taken her wedding-tour and failed to return, which is sometimes kept up until the next morning, but usually by that time all is quiet. Such cases should be noted, and cells or queens given the *next day*.

The tin divisions in the nursery are $1\frac{1}{4} \times \frac{3}{8}$ inches, are slightly let into saw-kerfs at the bottom, and are $\frac{3}{8}$ of an inch apart, thus forming apartments about $1\frac{1}{2}$ inches deep and $\frac{3}{8}$ square. The pegs have holes in them for holding the candy, and should be dipt in melted wax before being used. If one has them, cartridge-shells can be used instead.

To remove the queens one should be provided with a number of cages, made by rolling up small pieces of wire-cloth into tubes three or four inches long, with one end prest together or closed, while corks or bits of comb make nice stoppers for the other. If the queens are too young to fly, a number of pegs can be withdrawn all along, and the queens allowed to crawl into the cages as they come out, without ever allowing two to clinch, as it almost invariably means death to one. When this is being done the nursery should be lying on its side, and the queens can be distributed by simply allowing them to crawl from the cages down between the combs, or in at the entrance, and give a puff or two of smoke behind them.

If they are to be kept in a nursery very long for any purpose, they should be transferred to one minus cells, as the space is small, and they are liable to get wedged up between the nursery and cells, and perish in attempting to find a way of escape.

In removing those old enough to fly, only one peg should be removed at a time, and the cage should be placed right over the hole. The operation can be hastened by inverting the nursery.

In slipping the nursery over the cells (which is held in place by drawing the wire loops already on the bars over the ends), the tin will cut its way unless an unusual amount of wax has been used in joining them together, as is sometimes the case when the bees are anxious to build comb; and when that is the case they should be separated with a hot, thin knife.

If the cells instead of queens are to be given to nuclei, the nearer the time of hatching the better, and, as they seldom hatch on the orthodox tenth day, if larvæ of the best age are used, it is quite a convenience to attach the nursery and feel easy until they do begin to hatch.

If the division be made when the bees are flying freely all can be shaken from the comb or combs of unsealed brood, and the returning bees will be sufficient to protect it at once.

As soon as virgin queens reach the combs they begin a search for honey, and bees seldom attack a queen while in the act of securing nourishment. No attempt should be made to introduce a virgin by simply releasing her in the hive after she has become very active, whether it be those held in the cells by the bees, as in cases of second swarms, or that have been in a nursery, unless it be to the bees surrounding them.

During a honey-flow the feeble, downy-looking misses can be given the same day the laying queen is removed, with a considerable degree of safety. I have thought that it is safer to give them at once, than any time afterwards, before the bees fully realize and reconcile themselves to their queenless condition. If given to colonies with feeble, old queens they will often be accepted and commence laying with the old queen in the hive, as is the case with super-sedures.

When I have a surplus I often release them in colonies having old queens, and allow the bees to take their choice between the old and the young.

Virgins at the age of two or three days or older can be shipped from the nursery, if escorts from the same hive be used.

Another consideration in the use of so simple and convenient a nursery, is the saving of time with nuclei. A virgin can be given as soon or sooner than a cell, regardless of the conditions, and the time between the giving and hatching of the cells is saved; besides, fine looking cells often

fail to hatch, and it is not uncommon for others equally fine to furnish queens deformed, and that should be discarded instead of consuming valuable time in a nucleus.

While I prefer allowing the bees to have access to the cells until within a day or two of hatching, so as to add to or take wax from them as they see fit, still, if the proper temperature be maintained, and, as they can be inserted without rough handling, or changing their positions, it can be done any time after all are well sealed; and thereby reduce the number of days of queenlessness when built by queenless bees, or allow the giving of a fresh batch oftener to those over an excluder.

In multiplying nuclei the reasons for leaving the queen and unsealed brood on the old stand is that the field-force and enough comparatively young bees return to it to feed the larvæ and keep the queen laying, leaving the others in a better condition to receive a young queen, which will have a field-force by the time she begins to lay, and bees hold more tenaciously to the hive they have for some time occupied, and will sulk when the field-bees quit coming to it, instead of deserting the brood as they often do when given a new hive and location without their queen.

If the queen be carried to the new location she will be comparatively idle until the bees begin field-work, whereas, at the old stand she is kept busy. Warren Co., N. C.

Robber-Bees in the Apiary—What About Them?

BY C. DAVENPORT.

IN the long ago, when I was young in years, and in bee-keeping also, I spent considerable time in anxiously watching hives when young bees were rushing in and out during their exercise or play-spell, wondering if it was not a case of robbing. The subject of robbing was in those days a sort of nightmare affair with me, and I was always dreading and expecting a desperate case of it to commence, and when finally two or three weak, and what I now know to have been queenless colonies, were cleaned out by robbers, I thought I had at last discovered the cause that might prevent me acquiring great wealth with bees, and that it must be this same cause which had prevented old, experienced bee-keepers from becoming rich, for, in those palmy days of youth, it seemed to me that, barring some great unforeseen calamities of this kind, it would be an easy matter to make a great amount of money with bees, besides fully enjoying all those things which we would not sell for money if we could. But if whole colonies were to be wiped out by robbers in such a short time that I hardly knew anything about it until the whole affair was over, it changed the appearance of the prospects.

Now, I do not suppose there are any at present who hold such exaggerated views in regard to our pursuit, or who dread robbing as I did in those days, but possibly some who have not been long engaged in our fascinating, if not wealth-acquiring, pursuit may be interested in what I shall say on the subject of robbing, for I remember how eagerly I then read everything I could find regarding it. This was considerable, but it seemed to me the writers treated the matter in an awed, scared way, giving grave warnings not to do anything to incite it, vaguely hinting at the great danger a bad case entailed. Brief accounts of how bands of frenzied robber-bees had attacked and killed almost all kinds of domestic animals, and in one or two cases they had sacrificed human life itself to their blind, unreasoning rage; and what dismayed me the most, was what was said about the colonies in large yards robbing and fighting until the greater part were destroyed. The subject was not an assuring one as then treated, most particular caution being given not to throw a drop of honey or anything sweet where the bees would have access to it during a time of scarcity, or when no honey was coming in.

Two years ago last fall, at a time when not a drop of honey was to be had in the fields, and as the general expression would be, "bees were just crazy to rob," while shoveling honey out of the cellar one day, I smiled grimly as I thought of this warning, for there were nearly 200 colonies within a few rods. "Shoveling honey out of the cellar" causes a gasp of amazement to a young lady leaning over my shoulder, then follows such a volley of questions that I retreat across the way to my bachelor den, where I am safe from interruptions of this kind. But perhaps I should explain that this honey was stored in a room over the cellar; it was in a large alcohol barrel, about 500 pounds of fine mixt clover and basswood. The barrel got to leaking, and before I knew it the honey was all in the cellar

which had a dirt floor. I shoveled out three or four wagon loads of sand and honey mixt, which the bees industriously worked over, and no trouble with robbing occurred; in fact, if I have any broken comb, sticky frames, or anything else that I want cleaned up, bees are allowed to do the work whether honey is coming in or not, and with me full colonies worth saving protect themselves from all robbers that ever mass together and attack them, and with no precaution taken except in some cases to contract the entrances; that is, after they have had their first cleansing flight in the spring. The only actual trouble and loss I have had on account of robbing has occurred when the hives were first set out in the spring, when the number of colonies wintered in cellars is so large they can not be, or if for any other reason they are not, all put out the same day, there is danger under some conditions, of those set out first robbing the ones put out later.

Bees usually will not make much effort to defend their hive from attack until after they have had their first flight in the spring, and by the time this is over the robbers may be at work in some hives in such force that there is apparently but very little effort made afterwards to repel them.

An old idea, and one still largely believed is, that after bees have concentrated in large numbers to secure any sweet that may have been exposed, or when a queenless colony has been overcome and cleaned out, the whole mass then, if nothing better offers, throw themselves upon some one colony, which even if a strong one may not be able to repel them. This is entirely erroneous, and it is well that it is, for if they did make a determined attack *en masse*, half or more of the colonies in a yard might be destroyed in a short time, but the way they really do, after whatever they have been at work on is about gone, is to scatter or divide up and look for more. Single bees, and in a few cases I have seen about a dozen, attempt at nearly the same time to enter some hive with an unusually large entrance, or one which did not seem to be as well guarded as others; but if they get in at all they are soon dragged out again. Meanwhile, the whole yard may appear to be getting in an uproar, great masses of bees may cluster on the top and around the sides of hives that are tiered up on some colonies, a great number of bees may be flying in and out of the hives which seem so strongly attacked, and many a novice might think the matter was beyond his control, and imagine ruin staring him in the face.

I have seen even old, experienced bee-keepers get excited, and spray and throw water on these hives on which robbers were clustered in a frenzied attack, but if a close observation is made it will be seen that these apparently frenzied bees take good care to keep out of the entrance. If one more venturesome than the rest does get in it is roughly handled. The bees flying in and out so lively are bees that belong to that hive, and they are ready to fight to the death if necessary to defend their stores.

A colony of average strength, if in normal condition, will, before succumbing to robbers, make such a fight that it would always be remembered by one who witness it; and it is something I feel safe in saying, but very few have ever seen, after a whole yard has, as the novice would think, begun robbing, it is in reality only the colonies as a whole becoming waked up to the fact that something unusual is taking place, and they are flying around to find out what it is. Then a general call to repel boarders follows, and in a few days things quiet down, with no harm done.

Still, as a matter of fact, I think it much better to avoid as much as possible all disturbances of this kind in a yard, especially late in the fall, for it excites and worries large numbers of bees, and this may do harm by impairing their vitality to endure the long confinement of winter. But whenever I wish to handle a colony for any purpose, such as taking out or exchanging frames, I always do so without any regard whatever as to robbing, no matter whether a drop of honey is coming in or not. In some cases hundreds of robber-bees will get into the hive and on the combs of the colony being handled, but after the hive is closed up they are soon expelled and others prevented from entering. No precaution is taken except to contract the entrance more or less, depending upon the weather and strength of the colony. I do not advise others to do so, but I have practiced this for years with no bad results. With nuclei the case is different. I have reference to full colonies, tho they may be pretty weak and still repel robbers if in normal condition.

In regard to robbing in the spring when bees are first put out, as before mentioned, there is an easy way to overcome this. Simply smoke the colonies already out enough so the bees will fill themselves with honey. It is very

quickly and easily done, does not harm the bees, and no robbing will be attempted until the honey in their honey-sacs has been put back in the combs, and they will be some time doing this, but it is only under exceptional conditions that robbing in the spring is likely to be started. What these conditions are I would be glad to explain for the benefit of the inexperienced, but I fear I have already gotten outside the space I am allowed in one article.

Southern Minnesota.

The "Old Reliable" seen thru New and Unreliable Glasses.

By E. E. HASTY, Richards, Ohio.

KEEPING TOADS OUT OF HIVES.

Mr. Brown, I fear it will make us tired eventually to put on wire toad-protectors every night and take them off every morn. Lest we should some of us get exasperated and commit the repulsive crime of bufocide, I will suggest to have the toad hitch to the brandy-bottle on which the hive stands, and the string so short he can not quite reach the entrance. Page 315.

BLEACHING SECTION HONEY.

The bleaching of section honey which may from any cause be off color, by direct sunshine, is an attractive idea, but beset with difficulties. The propolis varnish will hardly bleach. Pollen may, one would say. Who knows but that dark honey itself may sometimes bleach? Sunshine will not raise the capping which touches honey—but may it not accomplish a little of the same thing sometimes by lowering the honey beneath till it no longer touches? If there is a bad look which is caused by a microscopic surface fungus, sunshine would be a hopeful thing to try for that. I judge that the danger of getting a big lot of honey melted down would, in some climates, be serious. Outdoor sun would be a little safer than behind glass; but the other danger of robbers would mostly forbid that. On the whole, I guess we must wait for the philanthropic individual to experiment, and bear the experimental losses, and we fall in only after he has reported decided success. Page 311.

GRAPE-VINE SHADE FOR BEES.

The grape-vine shade was a particularly precious fad of A. I. Root's, and it's almost sad to see it ill bespoken on the spot of its birth. Sometimes there is a little of unconscious predisposition to see all the faults and more in our predecessors' pet things—but perhaps nothing of the kind has operated in this individual case. Page 311.

PUTTING SECTIONS ON EARLY.

It is generally supposed that putting on the sections early decreases swarming somewhat—certainly adds room, and the wise heads all say, give 'em room; but I have sometimes had my doubts. Mr. O. O. Belden, page 310, gets in line with these doubts where he thinks that sections that the bees are not ready for encourage swarming if they have any effect.

WAX-EXTRACTOR CLAIMS ALMOST TOO GOOD.

As to the Ferris wax-extractor, I would await reports from those who have bought and used it. It looks a little *too good*—like some of the double-acting and self-righteous hives that used to be offered us. Page 307.

AIKIN'S BEE-BRUSH—BEES TEARING CAPPINGS.

The Aikin bee-brush, size and length of one's arm, for rough-and-ready wholesale brushing of the whole bottom of a super, as nearly as may be all at once, is worthy of a place and a name, I reckon. He would have it made of coarse marsh-grass, not too stemmy, but rank and wild enough to stand weeks of sun and many wettings up with water to put it in condition. It is a golden rule—not only for taking off supers, but also for pretty much all bee-operations—not to let bees either turn back or stagnate after having started them once. Just keep 'em "gittin' furdur" right straight along. I never thought before about there being an impor-

tant difference as to the time of the day in the matter of bees tearing open the cappings of sections. Now he calls our attention to it I can see it. Not likely to tear cappings when they are carrying honey already; and that state of things is more likely to exist well along in the forenoon than at dawn. *Have your supers of sections peel off clean, with no burr-combs and no drip whatever.* Just hear a strong man shouting once as Aikin says that. Page 322.

"MIXT VARIETIES AND THE HONEY-BEE."

This, it seems, is the war cry which Prof. Cook recommends for the horticulturist. The too greedy cultivator has been greatly inclined in the past to find out what one variety had the most money in it (often a showy fruit hardly fit to eat), and then to plant great solid blocks of that one thing. Nature boxt his ear for it. Nature says: Mix your varieties so intimately that comparatively few flowers will have to depend upon the pollen of their own kind. Have this motto printed around your button—and let the bee do the rest. Page 321.

FALL REST FOR QUEENS.

W. A. Pryal's idea of letting queens have a short fall rest and then stimulating them to lay again in December may be valuable for locations with balmy winter climate. The object of course is to have a strong colony of young bees to open spring with. Page 324.

QUEEN-EXCLUDERS, ETC., FROM FOUL-BROODY COLONIES.

Human beings are mostly much alike. Most of us can be worried by hostile blows often repeated into taking a violently contrary kink—*after which we are no longer good authority on that particular point.* McEvoy with wide experience with foul brood, and great abilities in getting it cured, has been pelted for his easy-going notions about its communicability till he seems to have taken just such a kink. I object quite decidedly to our Dr. Miller's abdicating his own judgment in Mr. McEvoy's favor as he does on page 326. Furniture from a smallpox hospital may be used a dozen times outside and no harm result; but still it is not perfectly safe—and it would be an outrage for a leading journal to teach the people editorially that everybody should do so without fear. Same about the queen-excluders from foul-broody colonies.

A NEW NOTE ON INTRODUCING QUEENS.

The Ranson method of safe introduction, on page 329, seems to strike a new note where we hardly expected anything radically new. Get the queen scented with the scent of her prospective home by causing a lot of very young bees to crawl over her. Not a bad idea, perhaps.

INTRODUCING VIRGIN QUEENS.

The fact, apparently proved by Mr. Doolittle, page 329, that any method of introducing virgin queens that keeps them alone for awhile shortens their lives and possibly damages them otherwise—well, that is an important fact, and one not generally in people's minds—therefore, a little "rub it in" in this department is in order. One may suspect that any restraint, for more than a few minutes, of the propensity to scramble around endlessly may be a damage to a virgin queen's development. Where Nature says so emphatically "Exercise, exercise, exercise," it should hardly turn out well to go to the contrary extreme.

DISTANCE BEES GATHER PROFITABLY.

And so a mile-wide river, to-wit the Mississippi, close up to an apiary operates to reduce by about one-half the number of acres within actual foraging oversight of the bees, and cuts down the crop decidedly on that account. Bees *can* go across such a barrier, but mostly don't. Mr. C. P. Dadant very ably handles one side of the problem, how far bees may be depended upon to harvest the honey of a piece of territory. How far bees can (and sometimes do) gather, and how far they habitually do it, are two *very* different questions. Have been known to gather at eight miles; and a radius of that length would include over 200 square miles of territory. With 10 colonies for each mile it should then be possible to run 2,000 colonies in one apiary. That sort of thing does not work—presumably because bees do not *habitually* keep in touch with the honey-yield for any such distances. My own opinion is that finding the honey, and not the journeying for it, is the main difficulty. I even dream that great discoveries in our craft may yet be made in the line of helping our bees find distant honey promptly. On this very important practical problem Mr. D. seems inclined to lead the short-radius end of the class, and to put

the practical radius at less than a mile and a half. Some of the experiences given are remarkable. An apiary only a quarter of a mile nearer to the fall crop on the river bottom always showing in pounds of honey the advantage of that quarter mile. One failure to find, in a bad famine season, a good harvest less than two miles off. And in an extraordinary season two of their own apiaries, only a moderate number of miles apart yielded 140 and 50 pounds, respectively, as averages. Page 323.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Queenless Colony.

I have a queenless colony that I have been trying to build up. I have given them brood three times, as recommended in "A B C of Bee-Culture," but they have no queen-cell yet. They started one, but for some reason tore it down after about six days, and since, tho they take good care of brood given them, they build no more. What can I do with them? NORTHERN IOWA.

ANSWER.—It is just possible that they have a played-out queen, which they hold on to, altho she does not lay. It is also possible that the colony has been long queenless, and the bees very old, and old bees are not good at rearing a queen. But the brood you have given them will be hatching out, and the young bees will rear a queen if you give them young brood or eggs. If you keep right on giving them all the brood they can cover, there is little doubt they will rear a queen. But, as a rule, a colony that has been queenless a long time might about as well be broken up. A queen reared by them is not likely to be satisfactory.

Symptoms Point to Bee-Paralysis.

I wish to ask advice about a disease that seems to be establish in my apiary. I can not find in the standard bee-books, or in back journals, an explanation of it. It originated in a colony of bees whose queen I received from a well-known firm in Ontario last summer. The bees turn a shiny black about one-third up of their abdomens, which are small and pointed. They literally die by the thousands. The queen is very prolific, the frames being always full of brood. When it was confined to one colony I did not care so much, but now I find another of my best colonies going the same way, and I do not know what to do for them. BRITISH COLUMBIA.

ANSWER.—The shiny black appearance points to bee-paralysis, but in that disease the abdomen is not small and pointed, but swollen, and you say nothing about the trembling that accompanies paralysis. It would be well to send a sample of the bees to Dr. Wm. R. Howard, Fort Worth, Tex.

Queenless Colony—Queens Failed to Hatch.

1. About March 1 I bought of a neighbor two box-hives of bees, one very heavy and apparently all right with bees, of course. When I went to bring them home I remarkt to my neighbor on picking up the hive that "I got every bee." and I could not help noticing the absence of roaring in this hive in hauling them home. After getting them home I noticed they were troubled with robbers, and in a day or two, when I transferred them, I found some 50 or 100 old bees with no queen, with plenty of comb and old honey, all the comb containing honey. What was the matter?

2. My favorite old 3-band queen swarmed about May 1, and I divided into nuclei, leaving of course one ripe cell in

the old hive, but not one hatcht a queen. What do you think of that? SOUTH CAROLINA.

ANSWERS.—1. It was in all probability a case of queenlessness of long standing, nearly all the bees having died off from old age.

2. Quite likely the cells were chilled. The bees generally build cells toward the outer or lower edges of the combs, which are kept warm enough in a strong colony, but when divided into nuclei there are not enough bees to cover them, and they are chilled. It is well to see that each nucleus has one or more cells in the center of the cluster of the bees. Cut the cells off the edges, and fasten on the surface of the comb where they will be kept warm. A good way to fasten the cell on the comb is to use a tobacco-staple, such as bee-keepers use for fastening bottoms to hives. Let one leg of the staple be over the queen-cell, and thrust the other into the comb.

Hive to Check Swarming.

What size hive would you advise for a honey-flow of from 2 to 4 pounds per day from the last of March to the last of May? I am using 8-frame, some with two stories. My first swarms came from the two-story ones. I want to check swarming all I can. SOUTH ALABAMA.

ANSWER.—Seeing you already have the 8-frame hives, it is quite likely they will suit you as well as any. Other things being equal, two stories will give you less swarming than one-story hives. It is likely that your two-story colonies swarmed more because they were so much stronger. If you had made two of the colonies change places, it would be pretty sure that the one you changed into the smaller hive would have swarmed first. If you are running for extracted honey, you will find two stories all right, but for some reason I have not been able to make two stories work so well for comb honey. To make more sure against swarming, raise the hive three-fourths of an inch or so on four blocks, and make sure that there is a large entrance between the first and second stories. This last is a great help to prevent swarming.

Carbolic Acid vs. Smoke—Flour in Syrup for Pollen—Feeding to Stimulate Brood-Rearing.

1. How shall I proceed to use carbolic acid instead of smoke among bees?

2. (a.)—Can wheat flour be put into sugar syrup in spring feeding, to answer purposes of pollen? (b.) If so, in what proportion?

3. (a.)—Is it advisable to feed in spring to promote brood-rearing where there is plenty of stores in the hive? (b.) What danger is there in feeding, if not begun too early? (c.) What would be the safe time to begin in latitude 42 degrees, 30 miles west of Boston? MASSACHUSETTS.

ANSWERS.—1. The use of carbolic acid in place of smoke does not seem to meet with much favor in this country, altho some bee-keepers in England are partial to it. Wet a cloth with a solution of the acid, lay the cloth over the frames, and the fumes will drive the bees out of the way in a very short time. You will wonder why I don't tell you how strong to make the solution, and I would gladly tell you, only I don't know. At a guess I should say one part acid to 50 parts water, but that guess may be wild.

2. (a.)—Some use it that way. (b.) I don't know of any fixt proportion, possibly 1 to 20.

3. (a.)—Doubtful. If everything is managed just right, and if the weather is just right, it may be a good thing. (b.) If begun late enough there may be no danger. The chief danger is in stirring up the bees to fly when it is too cold. But if begun late it does little good, for the bees will be then sufficiently stimulated by gathering natural stores. (c.) A skillful and prudent bee-keeper might begin any time when bees fly freely. One who is not very careful better not begin at all, and many of the veterans, perhaps the great majority of them, do not practice it at all.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY,
118 Michigan Street, Chicago, Ill.

[Entered at the Post-Office at Chicago as Second-Class Mail-Matter.]

DEPARTMENT EDITORS:

VOL. 40.

JUNE 28, 1900.

NO. 26

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

The Brosius Pure-Food Bill was before the last session of Congress, but we learn that no action was taken upon it. However, the friends of the measure in both House and Senate, we understand, are very hopeful of its passage early in the next winter session. All bee-keepers will unite in the hope that it may receive prompt attention when Congress reassembles.

The Honey Season for 1900.—It seems from the reports so far the prospects are not very flattering for a good honey crop this year throuth the country generally. Gleanings in Bee-Culture for June 15 contains these editorial paragraphs referring to this matter:

Altho it is a little early to make any predictions as to the honey-flow, owing to the lateness of the season, yet present indications would seem to show that the supply of white clover honey will be rather limited this year. Walter S. Ponder, of Indianapolis, who is in close touch with a large area of country, writes, "There is scarcely any white clover in Indiana, Southern Ohio, and Illinois. The outlook is discouraging, and business is growing lighter." Owing to a lack of rains, H. G. Acklin, of St. Paul, wrote us a rather discouraging letter a week or so ago. Since then there have been good rains, but I fear they are too late to do much good unless with basswoods.

The season in California will be better than was at first expected; and especially is this true for the northern and central portions of the State. The rains finally came in the southern part, but too late for the amount of good they might have done.

Black brood has got such a start in certain portions of

New York that many of the bee-keepers are discouraged; and even if there is a honey-flow I fear there will be but few bees to gather it. F. A. Salisbury, of Syracuse, reports that prospects are not flattering.

In our vicinity I have seen almost no white clover out, altho there are a good many patches of alsike; but these patches are so limited I fear they will not yield much honey.

Altho this is the 13th of June, our bees at the home yard are getting but very little honey, and the same is true of the out-yard about two miles north of us.

While all of this looks very discouraging, yet it must not be forgotten that the season is unusually late, and there is yet a chance for a fair honey-flow, because the greater portion of the country is being visited with frequent and warm rains. These will have a tendency to stimulate clover, resulting possibly in a slow but continuous nectar supply for a considerable length of time. It should also be remembered that it is a little early yet for most places for clover.

By the way orders have been coming in from Colorado, it would seem that indications, at least for that State, are exceptionally good. As the bee-keepers there do not have to depend upon rains, but on irrigation, in all probability they will have another heavy honey-flow; and I would say to the bee-keepers of that State, do not be in a hurry to sell your honey; for if there should be little or no honey in the East you of Colorado will have things largely your own way. With your splendid organization and fine honey, it is evident that the honey-buyers will have to take the honey at *your* price.

If honey will be scarce, those who do get a crop will be able to gauge prices accordingly. In any case, don't sell too low.

Say What You Mean is a good motto, but one not always easily followed. In one of our exchanges is a paragraph beginning with the statement, "Now is a good time to introduce new queens into your apiary," followed by the direction, "Put a queen on top of a hive which is about to swarm, and leave her there until after the swarm issues." Nothing is said as to whether the queen is to be chained on top of the hive, or whether any parasol is to be furnished her in case the sun should be very hot. Neither is anything said as to what is to be done with the new "hive" that issues when the old "hive" swarms, or whether a swarm from the colony may be expected at the same time to keep pace with the increase of "hives."

No, it was not some city scribbler who knows nothing about bees who wrote that sentence. It was a man who is well informed, an expert in bee-keeping, with fine command of the English language, which language would be well handled probably by him to score unmercifully any one else who should be so careless as to write a sentence like the one quoted; and, withal, a good fellow, who will rather enjoy seeing his little failing in this one instance held up to view. It only goes to show that when it comes to the matter of writing in the English language we are all "poor critters," to which this deponent claimeth not to be an exception. But it is also a warning for us all to be just a little more careful.

Art vs. Nature in Queen-Rearing.—Mr. G. M. Doolittle is something of a stickler for following nature, but no one has done more than he toward success in departing from nature in the rearing of queens. It can hardly appear according to nature to have a row of cells made artificially and strung on a stick, all the occupants of the cells emerging as queens at nearly the same time. According to nature, the cells would be scattered about the hive, mostly on the edges of the combs, or on some inequality of the comb, an egg first occupying the cell (instead of a larva as in the artificial plan), the occupants of such varying ages that at the time of the issuing of a prime swarm there will be queen-cells sealed, queen-cells with eggs, and queen-cells at various intermediate stages. Yet, in a certain sense there has been no departing from nature in Mr. Doolittle's plans, and the testimony is that as good or better queens are

reared than can be produced by taking queens reared under the swarming impulse which so many formerly considered the *ne plus ultra* of queens.

Lately there has been a little discussion in the American Bee-Keeper as to the desirability of having queen-cells constantly in the direct care of the bees, that is, having bees constantly in direct contact with them. Mr. Doolittle says that he found from experience that virgin queens kept caged from the bees were short-lived in proportion to the length of time they were kept from the bees, and he now advises the cells and young queens to be constantly in the embrace of bees from start to finish.

W. H. Pridgen favors a short time of caging, and gives some good reasons for it. He says:

"I never did much of this, as I soon learned that I could get a laying queen from one just hatcht about as soon; but as I can gain from one to three days by giving the just hatcht downy misses, with the assurance that as few will be rejected as there are cells that fail to hatch and are torn down, I would be glad for Mr. Doolittle to tell us if he thinks they are really injured at all when allowed to remain caged only a few hours at most, and especially if kept at the temperature of a strong colony.

"I keep my cells in immediate touch of the bees until the time for distribution, and then keep them where the queens emerge sooner than is often the case if given to nuclei, and especially early in the season, and in nuclei newly-formed."

The problem is to keep as near to nature as possible in the line of keeping cell and virgin queen at the best temperature, unless it be that there is some special power resident in the actual touch of the workers—a supposition not to be thrust aside too hastily. According to nature the cell will be kept in a strong colony at a uniform temperature, and if the weather be warm enough, or the nucleus strong enough, there will scarcely be any departure from nature in taking a sealed cell from the upper story of a strong colony and giving it to a nucleus.

Mr. Pridgen makes a point in favor of caging the cell just before the young queen is expected to emerge, by saying that if kept thus till the queen emerges, one can see the queen, whereas when a sealed cell is given to a nucleus there is danger that a defective queen may issue, and possibly that no queen may issue.

Let us be thankful that attention is nowadays so strongly directed to the matter of *good* queens rather than handsome ones.

"Impure Food Must Go."—This is the heading of an item in the Chicago Record for June 18, which reads as follows:

Druggists, grocers, candymakers and packers come under the ban of the new Illinois pure-food law which goes into effect July 1. From that day forward every label on every package of foodstuff must "tell the truth and the whole truth" about the quality of the contents. The man or firm responsible for falsehood will be liable to fine and imprisonment.

July 1 will be a "busy day" for every grocer in the city. Old labels will disappear and new ones take their places. The "pure maple syrup" of yesterday will become plain glucose to-morrow. "Currant jelly" will have a new label, and "apple butter," which never saw an orchard, will have a new name all its own with "apple" excluded. At the breakfast table will be "coffee," and not coffee and chickory mixt, as heretofore. The latter probably will be known as "coffee compound."

Circus lemonade is to suffer, for there is an absolute prohibition of the sale of "lemon extract" which has less than 5 percent of pure lemon-oil. There will be no "honey" unless it is "honey." The present bottled stuff labeled "pure strained honey" will disappear, and "syrup of glucose" will march to the front. There will be pure vanilla, and the druggists will profit thereby.

Next in line among the "interested" people are the baking-powder dealers. After July 1 labels must give a specific statement as to whether the boxes or cans contain

an alum, alum phosphate or cream-of-tartar powder. Vinegar also comes under the ban, and dealers in candy must discover if any impure materials have been used in the manufacture of candies, ice cream or foodstuffs.

When the law was past it gave the wholesale and retail dealers 18 months to dispose of the "adulterated" stock. That time is nearly up, and they are pushing the stuff off to their customers as rapidly as possible.

Bee-keepers will watch with much interest the enforcement of the new Illinois law against adulteration of foods offered to the public. We believe it will be looked after conscientiously by those whose duty it is to see that it is obeyed, as they appear to be men that mean to try to do their duty. We wish them every success, and would be glad to aid them in every way we possibly can.

Those Premium Dr. Miller Queens.—The following letter from Dr. Miller explains itself:

MR. EDITOR:—A correspondent writes requesting a suspension of the rule so that his premium queen be sent at once without waiting its turn. He is probably joking, but there is no doubt that some are feeling that there is unwarranted delay in receiving their queens. And those sending in the last are likely to be among those expecting queens first. It should be remembered, however, that *time* is an essential factor in the rearing of queens, and when there is a large list, those that come at the last end should expect their queens in September rather than in June.

It is only fair to say, however, that the first queens on the list were sent out much later than I had anticipated—a delay which no one regrets more than I. The chief culprit in the matter is that all-prevailing, all-pervading individual, the *weather*. In all my experience in bee-keeping, I think I never knew so much April weather left over for summer consumption. Days have been cold, and nights colder. The first clover blossom was seen May 22, and supers were put on in due season, only to be left unnoticed by the bees till about June 18, when some colonies began work slowly. Ordinarily, when bees store nothing from clover within two or three weeks of its first appearance, it may be considered settled that it is one of the years when white clover doesn't "give down" any honey. This year, however, I suspect the trouble is all due to the weather, and that after waiting four weeks there may yet be a crop of clover honey, if the clerk of the weather only sees fit to allow winter clothing to be laid permanently aside.

If summer really comes, extra effort will be made so that those later on the list will get their queens as early as could have been originally expected, each queen being sent out in order as fast as possible. To those first on the list I can only express my sincere regret—I can not honestly say apology for that for which I am not really to blame—that there has been any delay, the delay probably being more annoying to myself than to any one else.

While I have the floor I may as well say another word as to the character of the queens. Some of them are fine in color, more of them are not handsome at all. As to *worker* progeny, there will probably be very little difference, all being of the same stock. I confess to a real liking for beautiful bees, and would rather have very yellow bees, if at the same time they were the best workers. I prefer utility, however, to beauty, and try to rear the queens that will give me the most honey, and your subscribers will get the kind of queens I rear for my own use.

C. C. MILLER.

Several of those entitled to receive Dr. Miller queens have written us enquiring as to the cause of the delay in mailing them; and one or two have written in a most discourteous manner. Now, it seems to us that all should be willing to believe, by this time, that Dr. Miller would get those queens off at the very first possible moment. Surely, every bee-keeper who is at all acquainted with Dr. Miller would not question his honesty of purpose and effort to do exactly as he agrees, every time.

Please remember that to all will be mailed a postal card notice a day before the queens are mailed, and that they will be gotten off just as rapidly as Dr. Miller can do it, and do it well. But he can't control the weather any more successfully than other people have been able to do.

GENERAL ITEMS

Lovely June.

BY CLARA EMILINE CONVERS.

List to the tinkle of
Bells in the dells;
Each a fond tale of love
Tenderly tells!
Come to me where I wait
Under the vine
Down by the garden gate,
Lover of mine—
Come to me, bring to me
Love's fullest measure:
Fondle me, sing to me,
O my soul's treasure!

List to the coaxing croon
Of the grave dove;
O blissful days of June,
Fragrant with love!
Come to me tenderly,
Lull me to rest:
With thy arms plume me
Close to thy breast—
Come where I wait for thee,
Here in my bower:
Thy lips the honey bee,
My lips the flower.

—Chicago Times-Herald.

Fastening Foundation in Sections.

I meet a great many bee-keepers who dread the job of fastening foundation to sections without a great deal of trouble. To such I will try and explain the easiest and quickest way that it can be done without a press.

First roll the sections in a wet cloth or paper, say over night, as many as you want to use the next day, so they will not break in folding. Take a small piece of beeswax, or ball a piece of foundation the size of a hickorynut, and briskly rub two or three times across the upper part of the section, where you stick the foundation; rub all you intend to use that day, then cut the foundation the size you want to use; place the edge on the section where you rubbed, wet the hammer and tap the edge of the foundation lightly, and rub across the edge, and the foundation is stuck for keeps. Then fold the sections, straighten the foundation, and place in supers. With a little practice you can fold and fasten foundation in more sections than in any other way, and do it right.

CHARLES SMAIL.

Shelby Co., Ohio, June 16.

The Olive as a Honey-Yielder.

What do you think about this olive twig all over blooming? Just so looks the whole tree. And what a fragrance! It is carried for miles. But you perhaps know this Russian olive tree better than I do, so you will have noticed that the flowers appear by-and-by, and that the bees seem to be very much after them. Can you tell me whether the olive blossoms are rich in nectar or not? Are the lilies and roses also of any value to the bees?

C. H. FRIESEN.

Marion Co., Kan., May 28.

[We referred the above to Prof. Cook, who sends the following reply:—EDITOR.]

The letter from Mr. Friesen is of general interest, as there is a principle connected with his question that touches all flowers. The olive, the

The Queen Crank

Is before the readers of this Journal with a petition for orders for as fine Queens as he has ever been able to rear. They are being, and have been for some weeks, reared in triple-decker 10-frame hives, from choice Golden and Three-Band Mothers, in a Golden yard. The Bee-Keepers' Review, of Flint, Mich., for May (which is a special queen-rearing number) tells how it is done. Ask for a copy. Tested, \$1.00; untested, 75 cents. Money order office, Warrenton, N. Yellow Sweet Clover Seed

WE HAVE IT AT LAST!

We have finally succeeded in getting a SMALL quantity of the seed of the YELLOW variety of sweet clover. This kind blooms from two to four weeks earlier than the common or white variety of sweet clover. It also grows much shorter, only about two feet in height. It is as much visited by the bees as the white, and usually comes into bloom ahead of white clover and basswood. We offer the seed as a premium

A QUARTER POUND FOR SENDING ONE NEW SUBSCRIPTION.

So long as it lasts, we will mail a quarter pound of the seed to a regular paid-up subscriber who sends us ONE NEW subscriber for the American Bee Journal one year, with \$1.00; or ¼ pound by mail for 30 cents.

We have been trying for years to secure this seed, and finally succeeded in getting it. It is new seed, gathered last season by an old personal friend of ours, so we know it is all right. But we have only a small supply. When nearly out we will mention it.

is one of the most charming summer resorts reacht via the Chicago, Milwaukee & St. Paul Railway.

Its healthful location, beautiful scenery, good hotels and complete immunity from hay fever, make a summer outing at Marquette, Mich., very attractive from the standpoint of health, rest and comfort.

For a copy of "The Lake Superior Country," containing a description of Marquette and the copper country, address, with four (4) cents in stamps to pay postage, Geo. H. Heafford, General Passenger Agent, Chicago, Ill.

Please mention Bee Journal when writing advertisers.

Mission or any other variety, does furnish nectar whenever it attracts the bees. This is true of any blossom. It may be said truly that when any flower is fragrant it is almost sure to contain nectar. The color of flowers, as also their fragrance, is specially to attract bees and other nectar-loving insects, that they may pollenize the blossoms. We find that the olive in this region is a very shy bearer, and one important reason is that often only one variety was planted, and as this plant or fruit is sterile to its own pollen, it fails to fruit. I have proved by direct experiment, that the olive will not bear fully unless it is cross-pollinated. It is very important, then, that the olive be planted so as to mix varieties that blossom at the same time, and there should be honey-bees in the region to do the work of carrying the pollen from the flowers of one tree to those of another.

We should remember, then—

1st. All showy flowers are nectar-bearing.

2d. All fragrant flowers are honey-plants.

3d. Every bee-keeper is interested in all showy and all fragrant flowers, practically.

4th. In planting orchards, the fruit-grower should mix varieties, and not plant in solid blocks.

5th. As most fruit-trees require cross-pollination, and as the honey-bee is the great agent in this work, every orchardist should see to it that there is a goodly number of colonies of bees near his orchard. A. J. COOK.

Los Angeles Co., Calif., June 16.

Bees Not Doing Well.

Bees are not doing very well here, yet. They wintered well, but the spring was very unfavorable for breeding, and since the white clover blossomed the weather has been bad for the bees about half of the time.

A. W. SMITH.

Sullivan Co., N. Y., June 16.

Very Dry Weather.

It is terrible dry here. Some white clover is in blossom. We must have rain soon if we have any white honey. I had my first swarm today. The cold spring left many colonies weak.

CHAS. B. ALLEN.

Oswego Co., N. Y., June 11.

Report of Early Honey, Etc.

In a former report it had been stated that we were extracting honey on May 16, stored from the early sources, notably the poplar, maple, dandelion and fruit-bloom, all of which are too early for bees to store surplus, managed on the ordinary methods.

The artificial swarms made May 5, from which were taken off, respectively, 52, 48, 46 and 47 pounds gross, we are again (June 7), extracting the surplus stored from raspberry, and other early sources.

The queen that is now entering on her sixth year gives us 33 pounds more, which added to the 52 pounds, as reported May 16, makes 85 pounds for this particular colony. Allowing 32 pounds for supers and combs, leaves 53 pounds of extracted honey, with bees

J. S. TERRAL & CO., Lampasas, Texas.
18Atf Please mention the Bee Journal.

enough, on May 26, to cover 48 frames—32 full-depth, and 16 half-depth frames—because on this date all the brood and eggs were out in the 16-frame nucleus.

May 28 the artificial swarms had quite a notable field-force of two-days-old bees storing honey.

The 16-frame nuclei with fine young queens and several frames of brood and eggs, and honey stored in surplus supers, are very promising.

The aforesaid queen, when 3 years younger, occupying the same kind of hive, and in the same house, managed by the ordinary methods, failed to have a field-force sufficiently strong to store surplus from the above-mentioned early sources. Whereas, by our present system, she gives us 53 pounds of extracted honey and a 16-frame nucleus with honey stored in the super by the first of June. While she is, by a few pounds of honey, ahead of other colonies, yet she is behind some in brood-rearing.
B. J. CHRYSOSTOM.
St. Joseph Co., Ind.

A Report—Alsike Clover, Etc.

My bees went thru the past winter without the loss of a single colony, but two were robbed this spring. I put them in the cellar Dec. 3, and took them out April 5; the next day they were working on soft maple bloom. They built up very fast on willow and fruit-bloom, and 2 weeks ago I found a number of covers filled with honey where the boards had been left off.

Bees all about here are strong in numbers, and if the fields produce the material the prospect is encouraging for a good crop of honey.

White clover bloom is in full blast—10 or 12 days earlier than usual—and the bees are right after it—a proof that it is yielding honey better than for 2 or 3 years; but the crop that has never

\$5.00 per month will pay for medical treatment for any reader of the American Bee Journal. This offer is good for 3 months ONLY—from May 1 to Aug. 1. Dr. Peiro makes this special offer to test the virtue of small price for best medical services. Reply AT ONCE.

DR. PEIRO,
34 Central Music Hall, CHICAGO.

SEND FOR CATALOG.

Four Celluloid Queen-Buttons Free AS A PREMIUM.

For sending us ONE NEW SUBSCRIBER to the Bee Journal for the balance of this year, with 50 cents, we will mail you FOUR of these pretty buttons for wearing on the coat-lapel. (You can wear one and give the others to the children.) The queen has a golden tinge. This offer is made only to our present regular subscribers.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate, it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

Prices of Buttons alone, postpaid: One button, 8 cts.; 2 buttons, 6 cts. each; 5 or more, 5 cts. each. (Stamps taken.) Address,

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO.

I. J. Stringham, 105 Park Place, New York City,

Keeps in stock a full line of POPULAR BEE-KEEPERS' SUPPLIES.

Silk-faced Veils, 35 cents, postpaid.

Tested Italian Queens, \$1.00; Untested Queens, 60 cents. From honey-gathering stock.

We keep in stock a full line of Popular Apiarian Supplies.

Catalog FREE.

Please mention Bee Journal when writing.

A HANDY TOOL-HOLDER!

Sent by Express, for \$1.50; or with the Bee Journal one year—both for \$2.00.

Every Manufacturer, Miller, Carpenter, Cabinet Maker, Machinist, Wheelwright and Quarryman, Farmer, or any one using a grindstone, should have one of these Tool-Holders. One boy can do the work of two persons, and grind much faster, easier and with perfect accuracy. Will hold any kind of tool, from the smallest chisel to a draw shave or ax. Extra attachment for sharpening scythe blades included in the above price. The work is done without wetting the hands or soiling the clothes, as the water flows from the operator. It can be attached to any size stone for hand or steam power, is always ready for use, nothing to get out of order, and is absolutely worth 100 times its cost.

No farm is well-equipped unless it has a Tool-Holder. Pays for itself in a short time.

How to Use the Holder.

DIRECTIONS.—The Tool is fastened securely in the Holder by a set-screw and can be ground to any desired bevel by inserting the arm of the Holder into a higher or lower notch of the standard. While turning the crank with the right hand, the left rests on an steady the Holder; the Tool is moved to the right or left across the stone, or examined while grinding, as readily and in the same way as if held in the hands.

For grinding Round-Edge Tools, the holes in the standard are used instead of the notches.

Address, **GEORGE W. YORK & CO.,**

CHICAGO, ILL.

failed us before in 10 years, since we began raising it, nearly all winter-killed, together with red clover, last winter. I refer to alsike clover. We raise our own seed and usually sow 10 or 12 acres every spring. It not only never fails to yield a goodly amount of honey, but, with a light mixture of timothy to hold it up, it makes the best hay for stock we ever had. There is literally no waste, the cattle consuming every vestige of it if cut in proper season.

It is usually supposed that alsike will not thrive well on dry soils, but we raise large crops on our driest land by first removing the piles of manure that accumulate about the buildings of every stock-farm to the land that needs it most, instead of removing the buildings from the manure piles.

I have been aching for years to get sweet clover started here, but have not done so on account of the undue prejudice against it by the majority of the people; still, there are plenty of farmers of my acquaintance who will allow the dirty asthma-breeding ragweed to grow and flourish along the roads bordering their farms, without a murmur, who, at sight of a little sweet clover, would raise an awful howl.

The writer of "General directions for finding the queen," on page 354, is original if nothing more. Summarized to me, it means—and nothing more—"If at first you don't succeed, try, try again." (I hope the author of "Afterthought" will not accuse me of trespassing on his ground.) A. F. FOOTE.

Mitchell Co., Iowa, June 9.

Removing Honey Early.

I never saw bees doing so well at this time of the year. I have commenced to take off supers already. I never took any off in June before. W. K. BATES.

Winona Co., Minn., June 20.

Selling Granulated Honey.—Bee-keepers generally thruout the country appear to be awaking to the importance of some educational work among the masses in regard to extracted honey. There is indeed a degree of ignorance prevalent in the land regarding the nature, care and use of honey, both comb and extracted, that is amazing; but the particular point that is at present engaging the attention of the producer is that of educating the people to the use of the candied extracted article.

It is quite generally believed that granulated honey is adulterated—that the granules in the liquid are an adulterant—and the majority of retail dealers, sharing this ignorance, are incapable of rendering a true explanation to the prospective buyer, but he will instead most likely apply the force of his argument to the deliverance of his own untarnished name from the menacing stigma, laying particular stress upon his personal good faith and innocence in buying the "stuff." This will, of course, be supplemented with an apology for having offered it to his esteemed

patron. This may appear somewhat overdrawn; but we have witness just such an instance.

It does seem just a trifle strange that in 6,000 years (or 60,000, as the case may be) people have not learned that honey will granulate in cold weather, and that they are yet afraid of this most wholesome, pure and delicious food after the change has taken place.

It behooves producers of extracted honey to work earnestly to disabuse the public mind of this popular error, and to disseminate a knowledge of the ease with which honey may be restored to its liquid state when preferred in that condition. Granulated honey is very much preferred by many to that in liquid form, and some of our Western producers have so educated the trade that their goods are not look for in any other way—indeed, their honey is not put upon the market until after it has granulated. Specific instructions for liquefying the contents goes with each retail package. In this condition there is no spilling and daubing, and the crop is marketed and retailed in the same cleanly and neat manner as an invoice of canned fruits.

The subject is one worthy of serious thought, and the expenditure of some effort on the part of those interested in the development of a permanent and profitable market for extracted honey.—American Bee-Keeper.

Contraction and Its Effect.—The practice of using only five frames in an 8-frame brood-chamber, and filling up the space with dummies for the purpose of forcing what honey does come in into the supers, is called "contraction." This was extensively practiced a few years ago, but is now generally abandoned. It is far better to have the colonies so strong that when the first honey comes, it will be rusht right into the supers. It is better to use a full-sized brood-nest than to putter away with weak colonies with a contracted brood-nest. But if the honey-flow is short, and colonies are not overly strong, then contraction may be practiced sometimes to advantage. But in this case it will be necessary to watch closely for swarms, as contraction has quite a tendency to encourage the swarming propensity, because the bees seem to need more room for brood-rearing.—E. R. Root, in *Gleanings in Bee-Culture*.

Using Soiled Brood-Combs.—We had quite an experience a year ago with soiled combs from colonies having died the winter before, and very many bee-keepers are more or less troubled with such combs every year. The question then arises, "What is the best use we can make of these combs?" I have seen it recommended within a short time to give them to young swarms. In my experience I found that to be the worst use I could put them to, and that in the face of the fact that sometimes young swarms will select for their home a hive that had been previously occupied by a colony, and is filled with soiled combs of the very worst character. Many a time have I hived swarms into hives full of comb, and not very bad comb at that; but in by far the most cases the bees would not stay, and could not be made to stay, not even by caging their queen. With me the bees seem to pre-

Rocky Mountain Bee-Plant Seed!

(Cleome integrifolia.)

...FREE AS A PREMIUM...

The A B C of Bee-Culture says of it: "This is a beautiful plant for the flower-garden, to say nothing of the honey it produces. It grows from two to three feet in height, and bears large clusters of bright pink flowers. It grows natur-

Cleome in Bloom.

ally on the Rocky Mountains, and in Colorado, where it is said to furnish large quantities of honey."

We have a few pounds of this Cleome seed, and offer to mail a 1/4-pound package as a premium for sending us ONE NEW subscriber to the American Bee Journal, with \$1.00; or 1/2 pound by mail for 40 cents.

fer to go back to their old home minus a queen; or if the queen was at liberty the whole company would respectfully bid me good-by. If one really wishes to utilize old combs for his young swarms, as good a way as I know of is to first let them go thru a cleaning process on top of a good, strong colony; and the more honey is stored in them by that colony, the better the result will be. It will nearly all be carried up into the sections, or used up some way. A young swarm hived on solid combs of honey will astonish the owner in the amount of section honey it will produce. A few soiled combs may be given to a young swarm at a time, after the same is well established in a new home, the same as is admissible in case of old colonies.—F. GREINER, in *Gleanings in Bee-Culture*.

Releasing Queens at Night.—Mr. S.

A. Dyke, of West Virginia, writes me of the excellent success he has had in releasing queens at night, when trying to introduce them. He has a cage so arranged that when the slide is withdrawn the opening to the cage is still covered with paper that is saturated with honey. The slide is withdrawn at sundown. By the time the slip of paper is eaten out it is night, and all is quiet. One advantage of releasing a queen in this way, instead of watching her as she leaves the cage, is that there is no danger of her flying away. I once liberated ten queens just at dusk, when it was so dark that a lamp was needed. They had been kept away from the bees and allowed no food for half an hour. This was according to some instructions given by some foreigner—I think it was Mr. Simmins. The whole ten queens were accepted—perhaps they might have been anyway. Whether releasing them at night had anything to do with their acceptance is hard to say. Leaving them without food for half an hour makes them hungry, and they are in a mood to accept any food that is offered them by the workers, which is one factor in their favor.—Bee-Keepers' Review.

Prevention of Drone-Comb.—The

way I manage is to give new swarms which are to build comb, a brood-chamber of only about half the size of the one from which the swarm came, this smaller size being made by contracting it with dummies, while a part of the surplus for section honey is placed over the frames at the time of hiving. Some of the sections in the surplus arrangement should be partly filled with comb left over from the season previous, so as to start work in the sections at the same time the bees start below. This causes the bees to store honey above while they build comb more slowly below, building only as fast as the prolificness of the queen demands it.

As the queen's ability for laying increases, more frames are added, so that at the end of the season I have the hive filled, or very nearly so, with nice worker-comb, and secure lots of section honey. By this plan I secure three important items—much section honey, very little drone-comb, and a hive filled with nice, straight worker-comb, the latter costing less, in my estimation, than it would to buy the foundation,

wire the frames, and fit the foundation into them.—G. M. DOOLITTLE, Gleanings in Bee-Culture.

Admirable Advice to Advertisers from "Agricultural Advertising."

Nothing except the mint can make money without advertising.—Gladstone.

I would as soon think of doing business without clerks as without advertising.—John Wanamaker.

The old mediums, provided they have kept up with the times, are usually good things to stick to.—Advisor.

When you pay more for the rent of your business house than for advertising your business, you are pursuing a false policy. If you can do business, let it be known.—Franklin.

"Let people know where you are and what you have. Use more printer's ink and there will be a demand for your stock such as was never known before."—Hon. John W. Springer, president National Live-Stock Association.

Senator Chauncey Depew, in a recent interview, said that the country is at present suffering not from business stagnation or overproduction, but rather from an "indigestion of prosperity." He might have added that the pepsin of advertising is the best remedy for such indigestion.

De Weddin' Day.

BY FRED H. YAPLE.

Pick de banjo, honey—put in dem ting-a-lings—Keep yo' fingers goin' cross de home-made strings:

For de darkies will be singin';
So keep the banjo ringin';
Like notes de little southern bluebird sings.

Pick de banjo, honey—put in dem ting-a-lings—Beat dem feet so lively, fo' dat's de day dat brings

Back de reckolecksluns dear—
So make de music clear—
Like notes de little southern bluebird sings.

Pick de banjo, honey, fo' de weddin' day am comin';
In de golden summer time, when all de bees am hummin';
So pic dem good and fast,
Fo' dat weddin' may be de last
Dat I'll eber hear dem lubly strings a tummin'.

So pick de banjo, honey—put in dem ting-a-lings—
When de darkies ama-dancin', den finger on dem strings,
"De Mobile Buck" an' "Watermelon Sweet"—
Dey'll hoe 'em down wid lively feet—
To de notes like de little southern bluebird sings. —Chicago Daily News.

BEE=BOOKS

SENT POSTPAID BY

George W. York & Co., 118 Mich. St. Chicago.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers, \$1.00.

Biene-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Bienezucht und Honiggewinnung, nach der neuesten methode (German) by J. F. Eggers.—This book gives the latest and most approved methods of bee-keeping in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condense treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cts.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cts.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 20 cents.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about Poultry Business. 64 pages. Price, 20 cents.

ALBINO QUEENS If you want the most prolific Queens—If you want the gentlest Bees—If you want the best honey-gatherers you ever saw—try my Albinos. Untested Queens in April, \$1.00; Tested, \$1.50.
12A26t J. D. GIVENS, LISBON, TEX.
Please mention Bee Journal when writing.

HONEY AND BEESWAX MARKET QUOTATIONS.

CHICAGO, June 19.—Not any new comb honey on the market with the exception of a little sweet clover, which, owing to the scarcity of comb honey, has sold at 15 cents. Extracted is slow of sale with 7 cents about highest price that can be obtained for white: 6½@7c for best ambers, and 5½@6c for dark grades. Beeswax, 27@28c. R. A. BURNETT & Co.

KANSAS CITY, June 20.—We quote: No. 1 white comb, 14@15c; No. 1 amber, 13@14c; No. 2 white and amber, 13@13½c. Extracted, white, 7½@8c; amber, 7c. No beeswax in the market.

We have a shipment of new comb honey in transit from Florida. The supply of old comb honey is very light, mostly candied. C. C. CLEMONS & Co.

DETROIT, May 24.—Fancy white comb, 15@16c; No. 1, white, 14@15c; amber and dark, 10@12c. Extracted, white, 7c; amber and dark, 5@6c. Beeswax, 25@26c.

Supply and demand for honey both limited. M. H. HUNT & SON.

NEW YORK, May 21.—Our market is practically bare of comb honey, and there is a good demand for white at from 13@15c per pound, according to quality and style of package. The market on extracted is rather quiet, and inactive. New crop is slow in coming in, and prices have not yet been established. Beeswax holds firm at 27@28c. HILDBRETH & SEGELKEN.

SAN FRANCISCO, June 6.—White comb, 11½@12½c; amber, 8@10c. Extracted, white, 6½@7c. light amber, 6@6½c; amber, 5@5½c; Beeswax, 26@27c.

There is not much honey on market, either old or new. Small quantities of new comb and extracted are going to local trade at comparatively stiff values. In some instances, especially for comb, an advance on best figures warranted as a quotation are being realized. To secure export orders, however, of anything like wholesale proportions, prices above noted would have to be materially shaded.

The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.10, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO., 118 Mich. St., Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

CONTRIBUTED ARTICLES

The Yellow Sweet Clover (*Melilotus Officinalis*.)

BY JOHN R. SCHMIDT.

THIS subject has been written up so often in our bee-periodicals during the past two or three years that it is almost impossible to say anything new. But it is such a good thing that those who have had any experience with this queen of honey-plants never tire of seeing it "aired" in the journals from time to time by some enthusiast. This, at least, has been my experience, and it now appears before the readers once more, and I use as an illustration a photograph from nature instead of the usual pen-and-ink drawing. My first intention was to get a picture of the whole patch of clover in bloom, but owing to yellow photographing very dark, the whole beauty of the picture was lost, and undesirable for reproduction. The accompanying picture is a branch in detail, and, taken as a whole, more desirable than a large mass of the same thing.

The yellow variety of sweet clover is much more scarce than the white, but I am pleased to say it has all the good qualities of the white, and some to spare of its own. It may justly be called its own sister, as a description of the white variety answers equally well for the yellow, with a few exceptions as to color, etc.

This plant begins to bloom when the common white clover (*trifolium repens*) first makes its appearance, and sometimes a little sooner—this year about the middle of May, which is at least 4 weeks ahead of the white variety of sweet clover.

The plants do not grow as tall as the white, but it is in my estimation a better bloomer. The stems are thinner and more slender, and the leaves are very small. When a large mass is seen in full bloom it presents a solid, yellow color, the leaves being almost entirely hidden from view by the profuse bloom. This bloom lasts 5 or 6 weeks, and then the white sweet clover forges ahead and claims our attention. Just think of the beautiful appearance these so-called "obnoxious weeds" would present if

they were sown together and allowed to bloom unmolested along our roads and waste lands! White, and golden yellow, how beautifully they harmonize, and how rich and pure! Try a combination of these two colors and see how pleasing they are; or, better still, get some seed of each of these plants and have the plants themselves. Once started they will need no further care, and will spread rapidly.

The honey-producing qualities of the yellow sweet clover cannot be excelled if ever equaled by any other plant, excepting the white sweet clover. The following little instance will serve as a good example:

The past early spring and up to the last of May I practiced uncapping sealed honey and spreading brood almost to an extreme, and as a result the hives were crammed full of brood with little or no honey. Then came a spell of very disagreeably cool, rainy weather, with the bees confined to the hives almost entirely for 5 days. At the end of this time all the honey was consumed, and they were actually beginning to starve. The prospects for buying several dollars' worth of granulated sugar were excellent, but on the sixth day the clouds all cleared away, the weather warmed up, and the bees began to work desperately upon a small patch of this yellow clover along a railroad track. As this was the only thing they were working on I thought the sugar had to be bought anyhow.

But I waited two days longer, trusting to luck that they would at least work upon the profuse bloom of white Dutch clover that was now in bloom; but every bee seemed to make a bee-line for this yellow clover, and it fairly swarmed with them. Late in the afternoon of the second day I took a peep at some queen-cells that I expected to hatch, and you can imagine my surprise on seeing the top part of each comb more or less filled with *new honey*. Now, I know this came from the yellow clover, because it was so black and dirty. I first thought it was stored on top of pollen, but this was the color of the honey, and was caused by the soot and dirt falling on the blossoms from passing trains.

This patch of yellow sweet clover is the only one in reach of my bees, and is about 4 years old, the first plants of which undoubtedly received their start from seed dropping from a passing freight-car. It extends along the railroad track about 200 yards, while all the plants together would probably cover a space about 30 feet square. So you can see it does not take long to spread, and that a small amount will make a good showing in the hives. Everyone should intro-

Yellow Sweet Clover in Bloom.

duce this clover in his neighborhood, if it is not already there, and he will have a plant that never fails (as I know of) to yield nectar, and undoubtedly will have the best and most reliable honey-plant in existence.

Do not spend money on white Dutch clover, as it is unreliable, and in some places does not yield at all. It grows everywhere here, but no matter what kind of weather we have it always fails to yield, and the bees seldom visit it. This year there is an unusually large bloom, but not a bee can be seen on the blossoms, and this is after we have had extensive rains. Both white and alsike clover grow rank here, but it is all the same as far as honey is concerned.

I have said nothing of yellow sweet clover excepting as a honey-plant, and this serves only as an introduction to what some one else may say who grows it more extensively for other purposes. Judging from the growth of the plant I should think stock would accept it more readily than the white variety. I hope some one else will tell us more about it.

Hamilton Co., Ohio.

[We have a small quantity of the seed of the yellow sweet clover which we offer postpaid at these prices: One pound, \$1.00; ½ pound, 60 cents. Or, we will send ½ pound with the American Bee Journal 1 year for \$1.40.—EDITOR.]

Robbing Among Bees—Can It Be Prevented?

BY G. M. DOOLITTLE.

A CORRESPONDENT seems to be in a very anxious state of mind, and writes thus: "Is there any such thing as preventing bees from robbing each other in the spring? If there is, won't you tell us how it can be done? I have had some robbing in my apiary before, but never such persistent attacks as this year, and I fear I shall lose many of my colonies unless something begins to yield honey, or stormy weather occurs so as to keep the bees in the hives for a few days."

Quinby, in his "Mysteries of Bee-Keeping," tells us that there is little excuse for having bees robbed by other colonies at any other time save in early spring, thus admitting that even as great a bee-keeper as he was could not fully prevent robbing at this season of the year. And I doubt if that apiarist lives whose patience has not been severely tried at some time in his bee-keeping life in trying to save weaker colonies from being robbed during the spring of the year.

The first thing to be done by way of preventing robbing is to take every precaution against the possibility of robbing occurring. Right here is where the beginner is the most likely to err. Hive-entrances to weak colonies are often left open full width till robbing is started, when they are shut so closely that the colony seeks to escape from their imprisonment, rather than protect their stores. The hives are opened in the middle of warm days, and the frames of honey left exposed so long that robbing gets started before the hive is closed, the bees of the hive often being smoked from fear of stings till confusion so reigns that the bees are in no condition to defend themselves till the robbers have overpowered them.

Then, hives of honey from which bees have died during the winter are left outside till the bees get to carrying off their contents, when they are suddenly taken away at a time when the bees are fairly crazy for more, and being so suddenly deprived of the "mine" from which to steal, they pounce on unsuspecting colonies in such force that the guards are not able to keep all of them out of the hive, and thus robbing is started where there would have been none had the bee-keeper been very careful to have no exposed sweets about the apiary at any time of the year.

This matter of *not exposing sweets at any time of the year* is one which could be profitably dwelt upon for a whole article, but without carrying it further, I wish to say that the first means looking toward the preventing of robbing is, to know the condition of each colony as regards its numbers before any really warm days come in the spring; for if any colony is weak in numbers that colony is almost sure to be robbed unless some extra precaution is taken.

Again, if a colony is queenless in early spring, that colony is almost sure to be robbed; and if robbing is once started on such colonies, a general row may be expected throuth the apiary. I make it a point to look at each colony some cool day in early spring to see how many spaces between the combs they occupy, the number of which is set down where I can see it at a glance, and the same thing is

done with every colony before taking it from the cellar. Colonies occupying five spaces or above are called good colonies, and to such colonies I allow an entrance during the spring months three inches long by three-eighths deep, such entrance being amply sufficient for any colony (till young bees are hatching plentifully) after they have had their first or cleansing flight. A colony occupying only four spaces is given about two inches in length of entrance, while a colony which only occupies three spaces is closed down to an entrance only three-fourths of an inch in length. We read very often of the entrance being contracted so as to admit only *one* bee at a time, but whoever so contracts will soon find that trouble occurs by way of the dead bees which can not be drawn thru so small a space, thus clogging or stopping the entrance entirely.

If the cluster in any hive does not occupy three spaces, or these to a sufficient amount so I think it can care for what honey it has in the hive, then all the combs are taken away from it except one of honey and those which have brood in them, inserting a division-board and placing the comb of honey next to the side of the hive, and the comb or combs of brood next this. The division-board is now drawn up next to the comb of brood, while the entrance, of about the size of the smallest given above, is placed at the opposite side of the hive, so that the bees in going out and returning must travel over this vacant space between the division-board and the entrance. Fixt in this way a colony must be so weak that it is good for nothing if it does not protect itself from robbers, unless sweets are exposed so a general pilfering is establish; for robber-bees do not like to travel over a long vacant space *inside* of a hive where they are liable to be seized by a sentinel at any time. Even weak nuclei, when fixt in this way, are rarely robbed with me, and the more I use it the better I like it.

If any colony is found queenless supply it with brood from some other colony until you can procure a queen for it, providing it has bees enough to allow it to care for itself. If it does not have plenty of bees, unite it with some small colony having a queen. If thru careless handling, or from any cause, robbing is started, I think the best thing to do first is to throw a sheet over the hive which is being robbed. Leave it for a half an hour, when it is to be suddenly lifted from over the hive so as to let the robbers out which have collected on the underside, and the bees from the colony which have been shut out go in. Replace the sheet for another half an hour, when it can be removed and a handful of dry grass or hay put over the entrance, and a handful of wet hay put over this. This will allow them to dwell in peace the rest of the day, as robbers do not like to crawl down thru wet hay, unless there are some coming out loaded with honey all the time, and you have stopt the loads of honey from coming out with the sheet before the hay was put on.

This course will stop the robbing of any colony that is good for anything where the entrance has been fixt as above; and, with one exception, if a colony will not care for itself the next day after being treated as here given, I would take the combs away from them, allowing the few bees to go with some other colony, rather than to run the risk of having the whole apiary demoralized by the bees taking the honey from the hive at some time when the apiarist was not present. The exception alluded to is where a colony may be very weak, but has a choice queen that we wish to save, but has no place to put her just at this time. Should this be the case, treat the colony to the sheet and hay as given above, and when night comes carry it to the cellar and keep it there till you can use the queen. If you are very anxious to build the colony up, and it is strong enough to live in the cellar till the outside bees can gather pollen or honey, it may then be set out and given some emerging brood to strengthen it; for after the bees secure the first pollen or nectar freely, the disposition to rob seems to leave them, very largely.

Bees, and Spraying Fruit-Bloom with Arsenites.

BY F. GREINER.

I N the States where bee-keepers are awake to their interests they have, I believe, succeeded in having laws past against spraying fruit-trees while in bloom. This they accomplish on the mere strength of their *belief* that bees would be and had been poisoned by visiting sprayed bloom. Positive proof that bees were ever poisoned was really lacking. But, as Prof. A. J. Cook says, "We spray potato-vines with poison, and the bugs disappear. We did not

Home-Apiary of Mr. James M. Hobbs, of Yankton County, South Dakota.

make a post-mortem examination to find out whether the dead bugs have Paris green in their stomachs, but are satisfied with the apparent result of our spraying, and the fact that the bugs are gone."

We have taken the same ground in the case of bees. The trees had been sprayed, and the bees have died as the result. Many scientists, however, have not been satisfied with our opinionative proof. They refuse to accept what bee-keepers thought they had good reason to believe. The Ohio Agricultural Experiment Station has now published the experiments they have made in order to test the matter, and they hereby furnish the missing link in the chain of proof now available. How minutely and extensively the work was carried out may be judged from the few following facts:

Separate analyses were made of thorax, posterior legs, and abdomens of bees which were known (or at least strongly suspected) to have died from arsenical poisoning while working on the sprayed bloom. The bees were first washed in three different ammonia waters to ascertain whether any poison adhered to the bees' exteriors, and to remove such. In some cases slight traces of arsenic were found in the ammonia water. Thoraxes and also posterior legs, with the pollen adhering, analyzed gave no traces of arsenic. This is contrary to my expectations. I should surely expect the pollen to contain poison as well as the honey. In stored honey taken from nearly ruined colonies, no traces of arsenic could be detected; but the abdomens of bees analyzed revealed unmistakable traces of the poison.

In summing up, the station says: "We believe that we have the first conclusive proof of the effect on bees of the use of arsenical poisons in the orchard while trees are in bloom. We can see no other conclusion that can be drawn from the result of our experiments than that bees are liable to be poisoned by spraying the bloom of fruit-trees, the liability increasing in proportion as the weather is favorable for the activity of the bees; that all bloom must have fallen from the trees before the danger will have ceased."

The bee-keepers of our land owe the Experiment Station of Ohio a vote of thanks.

One more point I wish the station had not been silent on. I should like to know the whole truth. It would interest me to know how much of a crop these trees, sprayed while in bloom, bore as compared with the others not so sprayed. Our esteemed friend, E. T. Abbott, said at the Buffalo convention, that a fruit-blossom is so delicate it can not even bear a drenching of water, much less of Bordeaux or Paris-green mixture. If that is true, spraying it would necessarily and totally ruin the fruit crop, and no sensible fruit-grower would try that more than once. I, at the same time, gave expression to my view, that spraying the bloom might not prove to be so damaging to the fruit prospects, as it would be useless and unnecessary work. The Ohio Experiment Station should be in position to decide that point. If the fruit-grower could be made to believe that he would injure his fruit crop by spraying the bloom, then, of course, he would not spray. But I believe it is always best not to exaggerate, but stay within the limits of truth, if we know what that is.—Gleanings in Bee-Culture.

The Premiums offered this week are well worth working for. Look at them.

Wintering Bees—Managing Natural Swarming.

BY J. M. HOBBS.

By referring to the illustration herewith, it will be seen that my hives are all in one continuous line, resting on 2x4 joists, 14 inches apart, and one brick above the ground. These joists are spiked together with a cross-piece every six feet, so they are kept from canting or springing, and are all on a level, but one-half inch higher at the back. Two feet back of the row of hives is a row of posts eight feet apart, three feet in the ground, and five feet above the ground, and in a line with the hives. Then five feet in front of them, and in line both ways is another row six feet above the ground; then a cross-piece is nailed from one post to the other. This makes the pitch for the roof. The roof-boards are put on lengthwise, and shingled the same as any roof.

For the rear side I nail on six-inch fence-boards six inches apart; this lets the air pass thru in hot days in summer. I cut a gate out of the rear side to swing out, having three in the cut referred to. A gate makes it handy to manipulate at all times, as the operator is behind the bees.

My bees face the south, and the front is boarded down from the top just far enough to keep the hot sun from the front of the hives. Each hive has a slanting board in front for the bees to alight on, and the hives are eight inches apart, and each hive-front of a different color, while the hives are in about three different colors, and properly arranged on the stand.

In front of this stand all the ground should be as clean as a floor for a rod or so. I sweep all the dead bees away once a week; this prevents the ants and other pests from accumulating near the hives, and also makes it easy to find defective queens in swarming-time.

Now, as regards wintering: When the season is far enough advanced, say about November, I put the inside packing on, which is an empty super filled with chaff—wheat or oats, and fine and dry. I put a thin cotton cloth on the frames over the bees, then set the super on. I do not press the chaff, but put it in lightly. Under the cloth and on the frames I have a device something like Hill's, made out of barrel staves, which lets the bees pass over the frames, and works nicely. The hive-covers rest down over the hive about an inch. This completes the inside packing.

Then I fill in behind the hives and between them to their tops with dry straw; this leaves only two open spaces in the rear side of the bee-house, and these I stop by putting two more six-inch boards in between those already on; then all are ready for winter.

I have some old strips of carpet which I put in front of the hives, and in very bad, blowing snow-storms I let them down over the front of the hives. I leave a bee-space four inches wide open in front; when the weather is fine and I want the bees to have a flight, I turn up the carpet and put it down again at night.

In the spring I wait until the bees show signs of being well built up with young bees before I remove the packing, and take the inside packing off last, when ready to put on empty supers. I have had very good results by these methods.

Now as to my success with swarming: In the first place, I have, as you can see, nothing in the front of my bees but a very few low plum trees, so close to the hives that the bees will not alight on them when swarming. Everything that they could settle upon is what I improvise

for them, so just before they begin to swarm, and after the leaves have begun to be on the trees, I make four or five holes in the ground about two rods or so along in front of my apiary, and some two rods apart. Then I select as many low, bushy trees with leaves on as I have holes dug. The whole secret comes in selecting and setting these "dummies," as I call them. First get them about three inches thru at the butt, and with as many branches as possible, and set each of them leaning towards the north, in such a manner that the bees will have a branch under which to cluster and hang down, and be in the shade. Now make these so enticing that a swarm can not withstand the temptation. Do not have the dummies over six feet high. Try to make each one a little more tempting than the last, and go as far as to have some one particular spot where you wish them to settle, so that it will be the handiest to sit and hive them.

This may seem all moonshine, but if you will follow the above directions you will find how soon you and your bees will begin to have the same liking.

After you have madet hese cozy little alighting-nooks, keep them up by adding green branches as the old ones wither, and it will be like fresh straw to an old hen's-nest. Leave the old bush, but add green boughs to where you expect to see the swarm settle. Practice makes perfect. I have done this way for many years, and I have had only one swarm to abscond in 20 years. I always endeavor to be around in swarming-time, and sometimes pitch a few handfuls of black coal cinders in towards the dummy I wish them to settle on, and they seem soon to catch my wishes, and down they go. So far this plan has been a perfect success with me.

I always have hives all ready with starters or old comb in the shade for all new swarms. All these hives have loose bottoms, and I have a mortar-board which I set on the ground under where the bees have settled, then put the hive on that with the cover off, lay a few green twigs on top of the cloth on the hive to keep the wind from blowing it off, and take a tin pan, and with a stick, slice a good part of the bees off into it, turn the cover or cloth back and empty the bees into the hive on top of the frames, place the cloth back, and lay the twigs on top, then slice off more bees, and pour them at the front of the hive. It may be well to urge them a little with a twig or a feather, but do what you do gently, and you will soon have them all in the hive. I first get them about all into the new hive, then I pick them up and put them on the stand where I wish them to remain. I always put a few green twigs on top of the new hive, and let them project out in front a little a day or so, until they are accustomed to the new location.

This is about all there is to be said in this direction. Perhaps these few explanations may be of some interest to some amateur bee-keeper, who may be situated similar to myself—inside the limits of a city of 4,000 inhabitants.

Yankton Co., S. Dak.

Advantages of Producing Extracted Honey.

Written for Northeastern Ohio and Northwestern Pennsylvania Convention,

BY B. W. PECK.

I WILL first tell how I manage my bees when working for extracted honey. First, I try to have all colonies strong by the first of June, or at the beginning of white clover bloom I see that all colonies have plenty of stores, leaving them packt until late in the spring, and by taking hatching brood from the strong and giving to the weak, crowding the weak colonies on as few combs as they can cover, etc.

When they are built up strong, and the weather is good, I unpack them. I prefer to have a little honey coming in when unpacking bees, as they are then better natured; also, there will be less fighting when they enter the wrong hive, which they will do more or less when unpackt, by changing the appearance of their home.

I now watch them closely, and as soon as the hive is full of bees and brood, and some honey coming in from white clover, I place a queen-excluder over the frames of the lower story (I use the Simplicity hive, holding 10 Langstroth frames), over which I place the super holding 10 full-depth frames of comb. After the lapse of a few days, if the season is good, some of the best colonies will need another set of combs.

The honey should be left on the hives until it is well ripened before extracting it. When it is extracted the combs are returned to the bees, ready for the fall crop.

I will here give one year's report to show the advantage of producing extracted honey in a good season:

I began the season of 1886 with 56 colonies. My recollection is that I got about 1,000 pounds of comb honey. My whole crop was 7,000 pounds for the season. Fifteen colonies were run for comb honey, and averaged $66\frac{2}{3}$ pounds per colony; at 12 cents per pound it would be \$8.00 per colony. Forty-one colonies were run for extracted honey, and averaged 143 $\frac{2}{11}$ pounds (at 8 cents per pound this would be worth \$11.45 per colony).

Of course, the unfinished sections were extracted, which would change these figures a little, but it will be seen that more than double the amount of extracted honey per colony was produced, or about \$3.00 per colony in favor of the colonies run for extracted honey. But in moderate seasons the difference will not be so great.

When ready to extract, I try to have everything in readiness. I use a 4-frame Cowan extractor, which is placed on a bench about two feet high. I use an uncapping-can for the cappings. I have two ways of keeping hot water on hand for dipping the honey-knife in when uncapping, which is a great help. One way is to have a lighted gasoline stove near the extractor, with water on; and the other way is to have a lighted lamp in a box, with a hole in the top of the box, over which set a basin of water.

I have ready plenty of honey-pails with covers, most of which hold 25 pounds. When all is ready I proceed to the bee-yard with a wheelbarrow and empty super, and one super with empty combs, hive-cover or board, one or two turkey feathers, smoker, bee-veil, some cotton rags, matches, etc. When removing honey I first blow a little smoke in at the hive-entrance, then removing the covering from over the frames I pour a deluge of smoke down between the frames, until many of the bees are driven below. Then with a chisel I pry the super loose from the lower story, and lift it off on the hive-cover, and in its place I put the super of empty combs. I then loosen the frames of honey in the super, lift them one at a time, and give a quick jerk in front of the hive, which dislodges most of the bees; and bees remaining on the combs are brusht off with the turkey-feather.

I then place the combs of honey in the empty super on the wheelbarrow. When these combs are empty they are taken to the next hive to be extracted, and so on thru the yard, unless it induces fighting and robbing, when they are put on just before dark.

My better half usually assists me when extracting, uncapping while I turn the extractor crank, weigh the honey as extracted, etc.

In summing up, then, here are what I consider some of the advantages of producing extracted honey:

- 1st. The apiarist can manage more colonies.
- 2d. There will be less swarming.
- 3d. We will get more honey.
- 4th. Combs once built can be used indefinitely.
- 5th. Bees will work better in large combs than in small combs or sections.
- 6th. Much time is saved the bees in comb-building.
- 7th. It takes less skill to produce extracted honey than comb honey.
- 8th. Colonies that will do little or nothing in the sections many times will produce a fair crop of extracted honey.
- 9th. Extracted honey can be shipt with less damage than comb honey.
- 10th. It can be kept over from year to year with less damage than comb honey.

11. Last but not least, I find extracted honey sells better, being cheaper than comb honey.

In conclusion I will say that I have endeavored to point out some of the advantages of producing extracted honey. Now don't think from what I have said that I would advise all bee-keepers to produce extracted honey, for I would produce what my market demands, and which pays best. It will probably pay most bee-keepers to produce both comb and extracted honey. I always produce some comb honey.

Ashtabula Co., Ohio.

Honey and Some Honey-Plants Considered.

BY DR. G. G. GROFF.

POPULAR ideas are that all flowers alike produce honey, and that bees pass from blossom to blossom indiscriminately collecting the sweet fluid. This, however, is incorrect. By no means all flowers yield honey, and most of them yield it very scantily. Indeed, those plants visited by honey-bees which yield any considerable amount above that

consumed by the bees from day to day are, in any one section of the country, limited to a very small number, and usually not more than one, or at most two, of these plants are in blossom at one time. There are, however, a good many flowers that yield some honey, yet are for various reasons not visited by honey-bees, among which we may name the honey-suckle (visited, however, sometimes for the pollen), and plants of the buttercup family. In some cases the honey-bees can not reach the honey, in others it is probably not palatable to them.

It is also true that there is a great difference in the amount of honey produced in different years by the same species of plants. Sometimes there seems to be almost no honey at all in white clover, while at other times honey is in the blossoms for a few days, and then it suddenly disappears, or, in other seasons, there is honey so long as blossoms of clover are to be found. The secretion of honey does not depend upon the season being moist, for usually the honey-"flow" is greatest in dry seasons. There does seem to be some connection between the amount of honey produced and the character of the soil upon which the plants grow. Thus, clover growing on clayey ground seems to yield more honey than that growing on hillsides where there is but little clay. The same is true of other plants. Often there is honey in one district and none in another not far distant.

The plants which yield "surplus" honey in ordinary seasons are the red and black raspberries, the white clover, the basswood, and the buckwheat. Some other plants may yield small additional quantities, but are hardly of practical importance. There are, however, some early spring flowers giving honey which is useful in stimulating brood-rearing in the hives, without which there is no hope of any surplus. We will first name some of these plants.

The practical bee-keeper knows that his hopes of obtaining honey all depend upon having his hives full of bees when the "flow" comes. Brood is produced in quantity only when some honey can be obtained from flowers then in bloom. Hence, the importance to the apiarist of the early-blooming flowers.

The willows of several species, and the silver and red maples, blossom in March and April, depending upon the season. They yield both honey and pollen, and whenever the days are warm enough the bees constantly visit them. If one is about his apiary on warm days in March and April, he will notice the bees coming in with pollen even at times when no flowers have been observed. At such times they have doubtless found blossoms on some warm bank, and are making good use of them. The poplar trees also bloom in April, a little later than the willows. Reference is here had to the true aspen poplars, not the tulip poplar. The dandelion and strawberry blossoms are much visited by bees. Later, about the first of May, we have the sugar-maple and the blossoms of the fruit-trees—the peach, cherry, plum, apple, pear, quince, and strawberries, etc. These all yield honey and pollen, but, as our seasons average, the honey from our fruit-trees goes altogether to stimulate brood-rearing. The locust trees (both the honey and the black locust) blossom after the fruit-trees and before the white clover. Surplus is seldom stored from these blossoms, tho they are good honey-producers. Their honey goes to produce more brood, or to feed the colony until the clover comes.

We next consider plants which produce surplus honey. These for the Atlantic States are few in number.

Of the plants which produce surplus honey the white clover is first named. This plant grows spontaneously thruout the whole region. In the well cultivated sections it is almost the only honey-producing plant left on which the apiarist can any longer depend. It begins to blossom in June, and continues on into July. The honey from this plant is the whitest and finest produced. It is entirely free from any peculiar or offensive taste or odor, and is a general favorite.

In the more northern States the red raspberry commences to blossom a little later than the white clover. This is a valuable honey-plant of which bee-keepers in the South are deprived. This honey is considered by many to be fully equal to that of the white clover. In July the basswood blossoms. This tree yields a great amount of honey, but unfortunately there are no longer many trees to furnish blossoms and nectar. This honey is darker than that from clover, and has also a peculiar odor, which is unpleasant to many persons.

The last plant of value as a honey-producer is buckwheat, which begins to blossom in August, and continues until frost. The honey from buckwheat is dark, and has a

taste of its own which is not offensive. The honey is very rich, and a taste for it is speedily acquired. The cultivation of this plant is becoming, year by year, more restricted, and is now confined to the newer and more mountainous sections.

Those regions where the land is all under cultivation have only the white clover to depend upon for honey, unless there are a few basswood trees along the streams, while in the mountainous areas will be found clover, basswood, raspberries and buckwheat. It takes but a moment, then, to decide where one could best hope to succeed in bee-keeping.

We place among the plants which produce a small or variable amount of honey the mint and figwort families; also the asters and goldenrods. Of the first families, the mints, we have the hoarhound, the sage, bergamot, the catnip, and the motherwort, all producing considerable honey. Of this group the most remarkable is the motherwort (*Leonurus cardiaca*), which is constantly visited by bees while it is in blossom. The supply of honey is limited only by the number of plants, which at present in most places is small. It has been suggested that this plant be cultivated for the honey it yields. It is now a rather unsightly weed.

The figwort (*Scrophularia nodosa*) is an excellent honey-plant. It has a square stem, and exteriorly a good deal resembles the mints. It is a worthless weed except for its honey-producing flowers. It is not very abundant. The wild mustard, the teasel, the boneset, the wild sunflowers, the Spanish-needles and the snapdragons, as also the smart-weeds produce some honey, tho in most places the total is of little value. In Michigan Prof. A. J. Cook holds the goldenrods in high esteem as honey-producers. In Pennsylvania the writer can not find that they are of any value at all. On newly cleared land the sumac springs up, and it is held by some to be a valuable source of honey, and that considerable amounts are some years collected from it.

The tulip poplar, popularly called "poplar," also produces honey in its beautiful large blossoms, but the tree is too scarce to be of much value to the bee-keeper. The blossoms of the blackberry, like their near relatives, the raspberries, are honey-producers. The milkweeds are also secreters of honey. Curiously, the pollen of these plants often sticks to the feet of the bees and disables them so much that they perish.

Prof. Cook says that at times the blossoms of the Indian corn yield both honey and pollen to the bees, but we think to no great extent. We have never observed the bees working on these blossoms.

The laurel (*Kalmia*) yields honey which is poisonous. Generally the bees do not work on these blossoms, but in some localities they do, and we frequently read of persons poisoned by honey which probably comes from this plant. It is thought that the poisoning of the Greek soldiers under Xenophon, was by honey from this family of plants, in this case from rhododendrons.

The plant-lice (aphides) which infest many plants secrete a sweetish fluid of which bees, ants and other insects are very fond. In season when real nectar is scarce, or altogether lacking, bees will collect and store this material, which is generally known as honey-dew or manna. There is, however, another variety of honey-dew which seems to be secreted by the leaves of plants, and is gathered by the bees. The material is hardly fit for human food, nor is it for bees either, and it is doubtless a principal cause of winter loss of colonies, for it produces in the bees a diarrhea from which they perish if the winter is one of continuous cold, so that they can not take an occasional cleansing flight. Cider, juices of grapes, and all other sweet fluids are collected and stored by bees in seasons of scarcity. The general bad effects of all these are the same as of the honey-dew—they produce intestinal disorders from which the bees die.

The profitable cultivation of plants, otherwise useless, for honey alone, has never yet been demonstrated, and the low price of sugar will probably preclude any such efforts in the near future. Honey will remain a luxury, and as such will be produced in favorable locations—that is, on poor soil, where the honey-plants grow naturally, and where the land can be utilized for nothing else. However, in the planting of shade trees it would be well to plant those which will produce honey as well as shade.

The effort is made by practical bee-keepers to find some plant, like the buckwheat, which may make a useful crop, and at the same time produce honey. Many think alsike clover will do this. Prof. Cook thus speaks of it: "Alsike or Swedish clover (*Trifolium hybridum*) seems to resemble

both the red and the white clover. It is a stronger grower than the white, and has a whitish blossom tinged with pink. This forms excellent pasture and hay for cattle, sheep, etc., and may well be sown by the apiarist. It will often pay apiarists to furnish neighbor farmers with seed as an inducement to grow this par excellent honey-plant. Like white clover, it blooms all thru June into July. It should be sown early in spring with timothy, five or six pounds to the acre, in the same manner that clover is sown."—*Popular Science Monthly*.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Preserving Fruit with Honey.

1. How can I preserve fruit in honey, and not destroy the flavor of the honey? I have a good crop of both, and by putting together in good order it may enable me to find consumers that I would not otherwise. ALABAMA.

ANSWER.—I have seen it stated that all that was necessary was to put the fruit in the honey, making sure than it was entirely covered. A number of reports, however, say it was not a success, and it is a little doubtful whether it would be well for you to try it on a large scale. If any have succeeded, perhaps they will report.

The Empty Hive Above or Below—Which?

In the "ABC of Bee-Culture" it advises putting the new hive at the top and the bees will move up. In a recent issue of the Bee Journal one of the correspondents advised putting the new hive at the bottom, and the bees will move down. Are they both right? If so, which will work the better, and how long a time will it take? ILLINOIS.

ANSWER.—Both are right. I prefer to put the added story under, if it is expected to be occupied as a brood-nest, as that loses less heat, and bees naturally extend downwards. It may take all summer, or only a few days, depending upon the conditions and the strength of the colony.

Questions on Queen-Rearing.

1. If I deprive a strong colony of bees of their queen and all brood, and give them when they show signs of their queenlessness, some hatching eggs on the Alley plan, and feed them for 5 days a pint of honey, will bees prepared thus rear as good queens as under the Doolittle plan of queen-rearing? If not, why not?

2. Is there any other objection to queenless bees rearing inferior queens, than that of selecting too-old larvæ? If there is not, then by giving them just hatching eggs we do the selecting and are on the right side in this point.

3. I have tried the Doolittle plan, and somehow the bees won't do much other than tear up the cells even after started by queenless bees. ILLINOIS.

ANSWERS.—1. I do not know any reason why they should not. But there is a chance also for them to rear some not so good, for they may treat some of the cells as workers till the larvæ are quite cold, then conclude to rear queens of them, while with the Doolittle cups the cells will be treated as queen-cells from the start. They will in no case be treated as workers, for if the bees are not willing to treat them as queens they will empty the cells. Feeding a pint of honey will probably do no good, if the bees are gathering. If you prefer to use the Alley plan, it may be well to guard against poor queens in this way: After giving the cells, and at a time when you think no larva is more

than a day old, take out the cells and destroy the larvæ in any cells that have not already been enlarged by the bees.

2. I think you are mistaken on both points. I do not think bees select larvæ too old when they have younger present. Neither are you "on the right side" if you give just hatching eggs, or even eggs just laid, unless you guard against some of the poor queens you are sure to have. For bees don't start queen-cells only in the first 24 hours, but continue to start them for several days, and some of the last started will be from larvæ too old. You may be on the safe side if you give them just hatching eggs, then 48 hours later stick in a wire-nail over every queen-cell started, and at the last use only the cells you have thus markt. And in my judgment you will be just as safe to give them eggs and brood in all stages, if you take the same precaution.

3. I suppose you mean you have had cells started by queenless bees, and then had them destroyed when put over an excluder over a colony with a laying queen. That would probably have been the case with any kind of cells you gave, even if you had given cells from a swarming colony. The weather may have had something to do with it, and there is a difference in colonies. Some colonies will do better with cells put over an excluder than others. Over some colonies cells will be started if you give them brood, while others at the same time will tear down cells already started. Cells will be more kindly treated over a colony with a queen old enough to be superseded than over one with a vigorous young queen.

Bees Not Working in Supers.

I had 11 colonies in the spring, and have had 9 swarms; 3 of the old colonies have filled 2 supers each, and are working on the third; 2 have filled 1 super each, and others are doing nothing in supers. All are strong, but don't work early nor late. Would you change queens, or what is the trouble? The swarms are doing well. The bees are hybrids except 2 colonies of Italians from brag stock, and they are doing nothing worth speaking of. MARYLAND.

ANSWER.—It is not an easy thing to tell just what is the trouble without being on the ground. It is possible that one colony may have more to do than another in the way of filling up its brood-combs. Try this: Take from one of the colonies at work in supers a section well started or half filled, bees and all, and put in the super where the bees are doing nothing in sections. That will start them if anything will. If a strong colony in bees is doing nothing in supers when others are on their third super, and if they have appeared of equal strength all the time, you may do well to give a different queen.

Italian-Black Bees for Honey.

What race of bees are those you furnish the American Bee Journal as premium queens? TEXAS.

ANSWER.—They are Italian with a mixture of black blood. I prefer beautiful yellow bees, if they do just as good work, but my best honey-storers have proved to be among those having some black blood. There is an objection to breeding from anything but pure stock. A cross of any kind is not so sure to perpetuate itself. Pure Italian stock will furnish queens that vary very little from the mother. A cross will not produce queens so uniform. Some will be better than the mother, some worse. But stock from a cross-bred queen that has given an extra record for honey-storing may average better than that from a pure-bred queen. So, on the whole, I think I get more honey by breeding from a queen that has given a very high record, even if there is some black blood present.

Royal Jelly, Queen-Cups, Etc.

I have failed so far to conceive what royal jelly is, and how it is obtained. How is it inserted in the queen-cells? and what quantity is used? How are cells fastened in the combs? Can we purchase the Doolittle cell-cups ready "primed" for inserting into the combs? KENTUCKY.

ANSWER.—The nurse-bees prepare a concentrated food for the very young larvæ that is fed to them for 3 days, when the larvæ are weaned, as it is called, a coarser food being given them. Larvæ intended for queens, however, receive this highly-organized food during the whole of their larval existence, and receive it in large quantity. The

rations of a worker larva are very carefully measured out, just exactly the right amount, no more, no less. To a larva intended for a queen, the food is given in such large quantity that considerable is left in the cell after the young queen emerges. Royal jelly does not look like jelly at all, when fed to the young queen (more like a mixture of flour and milk boiled together,) but what is left in the cell after the young queen leaves it is dried down and has a somewhat translucent appearance like jelly, hence the name.

Very likely Doolittle cell-cups will be shortly put on the market, as they can be made by wholesale by those who have the proper facilities, but it is not likely you can ever buy them "ready primed," for inserting in the comb. A small quantity of royal jelly (twice the size of a pin-head or more) is put into the cell-cup, then the little larva is put in, and the cell given to a queenless colony, or to a strong colony having a queen, in the latter case in an upper story over an excluder. These cells ready primed could not be kept on sale, for the jelly would dry up and the larvæ die in a short time.

The only way to obtain royal jelly is to get it from queen-cells in which the bees are rearing young queens. These may be found in any colony preparing to swarm, or that has just swarmed. It must be taken from cells not yet sealed. If no swarming colonies are at hand, a colony can be made queenless, and it will then start queen-cells.

For some, it will be easier to get queen-cells from a colony that has swarmed. Cut out the cell with a thin, sharp knife-blade, and fasten it on the side of a comb where it will be right in the center of the cluster of bees. A hole may be cut in the comb and the cell fastened in, but a better way is to use a tobacco-staple. Lay the cell against the comb, point downward or partly so, push in the points of the staple, letting the cell be not in the middle of the staple but at one end, pushing well into the comb the point farthest from the cell.

A tooth-pick may be used to transfer the jelly and the young larva. Use only the smallest larvæ.

Sowing Alsike Clover Seed.

Will alsike clover do well if sown after oats harvest, say in July or after? If so, what time would you advise sowing it, and where can I get seed?

ILLINOIS.

ANSWER.—I have some doubt about it, but ask some farmer in your neighborhood whether it will do well to sow red clover at that time, and act accordingly. You can order seed from George W. York & Co.

Uniting Bees—Ripening Honey—Ants and Bees.

I had 3 swarms from a single colony on the following dates: May 29, June 6, and June 8. All are good-sized swarms, the second especially so. I was a few hours too late with an Alley trap to head off the queen of the third swarm which I wish to prevent. Not having an extra hive, I "hived them" very nicely in a large butter-tub, turned upside down, and they have taken to it and are working well.

1. If I put the tub of bees above the frames of swarm No. 1, with a Porter bee-escape and board between, not having killed the queen, will they probably unite without quarreling, at this season?

2. I have noticed many allusions in the columns of the Bee Journal to the "ripening" of the honey by the bees. Please tell how long it takes them to ripen it, or is it ripened as soon as sealed?

3. In what does this "ripening" by the bees consist?

4. Is there any occasion to fear the depredations of any kinds of ants about bee-hives, or will the bees take care of them?

BOSTON.

ANSWERS.—1. Very likely there will be no quarreling, but whether the bees will all come into the hive in reasonable season is a question. If they do not, you can drum out the remainder, leaving the bees to settle the matter of a queen.

2. The time of ripening is not uniform. In dry, hot weather, with a scant flow, it is ripened almost as fast as gathered. As a rule, honey is ripe when sealed, but there are exceptions.

3. I don't know. It is partly in evaporating the water, but there seems to be a richness gained by allowing honey for some time in the care of the bees that is more than mere thickening.

4. As far North as you are, you have little to fear from ants. If you do not use quilts, and have board covers that allow a bee to go wherever an ant can go, the bees will keep the ants out. There is, however, a large wood ant, which fortunately does not seem to be very plenty, that sometimes honeycombs the bottoms of hives, leaving a mere shell outside—somewhat dangerous in the case of those who move bees to and from out-apiaries.

Eggs of a Virgin Queen.

I got into a little argument with a friend about the question on page 327, in regard to a virgin queen laying eggs which would hatch drones. Will you kindly answer the following:

If, as you state on page 327, eggs of a virgin queen will hatch drones, are we then to infer that the queen-bee is an hermaphrodite? If not, are we to expect that a virgin pullet's eggs will hatch roosters?

ANSWER.—About half a century ago, Dzierzon aroused fierce antagonism by making the startling assertion that an unimpregnated egg laid by a bee could produce a living being. The correctness of his position, however, has been firmly established, and scientists today do not dispute the fact. An unimpregnated egg laid by a queen will produce a bee, but always a drone. An unfertilized queen's eggs and those of a laying-worker can produce only drones. These are the facts that have been proven over and over again (in the case of laying workers much to the sorrow of many a bee-keeper), yet they would hardly justify you in calling the queen a hermaphrodite. Neither are we justified in thinking that the same rule would hold with pullets, any more than we would be in saying that because a single act in meeting the drone is effective for life that the same would hold with a pullet.

Queen-Laying Irregularly—Swarming, Etc.

1. I got two queens from Mississippi the first of May. One is all right and the other looks as nice but has not more than two frames of brood, and she lays from 1 to 6 eggs in a cell—an average of about 3 to the cell. Do you think she will get regular, or would I better dispose of her? She does not deposit the egg every time she goes into a cell, but will drag it about, leaving it on top at times.

2. Yesterday I had two swarms at once; they clustered together, so I put them all in one hive. This morning I lookt in and found one queen balled, so I caught and caged her, the other one was free. Was that proper, or should I have divided them when I hived them?

3. I found two queen-cells in a light colony last week, thinking they meant to supersede the old queen, and as she was dark I went to a hive which had swarmed a few days before, cut out a queen-cell almost ready to hatch, and then cut out the two mentioned, and put this one in place. Today I saw her on one side of the frame and the old one on the other side. Is not that way all right to Italianize, if they dispose of the old queen?

NEBRASKA.

ANSWERS.—1. It is sometimes the case that after being thru the mails a queen is so demoralized as to make bad work in laying, and then straighten out afterward. Give her a fair trial before displacing her.

2. If you want increase, it would have been right to have divided the bees, giving to each division a queen. If you are after honey, and if your harvest closes early, you may get more honey by having all the bees in one hive.

3. You did a good thing.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it.

The American Fruit and Vegetable Journal is just what its name indicates. Tells all about growing fruits and vegetables. It is a fine monthly, at 50 cents a year. We can mail you a free sample copy of it, if you ask for it. We club it with the American Bee Journal—both papers one year for \$1.10.

C. C. MILLER, "Questions and Answers." ** E. E. HASTY, "The Afterthought."

LEADING CONTRIBUTORS:

G. M. DOOLITTLE, F. A. SNELL, C. P. DADANT, R. C. AIKIN, PROF. A. J. COOK, "OLD GRIMES."

IMPORTANT NOTICES:

The Subscription Price of this journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec00" on your label shows that it is paid to the end of December, 1900.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

VOL. 40.

JULY 5, 1900.

NO. 27

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "ed" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

The Need of a Text-Book on Bee-Keeping.—A correspondent, in sending in a number of questions, stipulates that he shall not be referred to a dollar-and-a-quarter text-book, as he reads the American Bee Journal and another good bee-paper. Which is probably equivalent to saying that he has no text-book, and should not be asked to get one. Our good friend is standing very much in his own light. Altho earnest effort is made to send out every week a bee-journal that shall be excelled by none in the world—one which shall be of value to the veteran and the beginner, so good indeed that it shall be felt indispensable—yet there need be no hesitation in saying that one who has no text-book will do well to dispense with its weekly visits for a year or more, if that is the only condition on which he can obtain a text-book.

The department of "Questions and Answers" has its purposes and limitations. It can not be expected to fill the entire place of a text-book. A text-book is supposed to contain answers to all the questions that will be asked by every beginner in bee-keeping, and many of those asked by those of riper experience. Now suppose it should be understood that the purpose of "Questions and Answers" was to give all the information needed by each new subscriber, so that he should need no text-book. Keep in mind that each week new subscribers are added to the list. One who has just begun sends in the question, "Is it the old or the young queen that goes off with the swarm?" A week or two later, a new comer who has not seen previous numbers,

asks the same question, and as each week brings in more recruits, the question appears again and again, "Is it the old or the young queen that goes off with the swarm?" Naturally the one who first asked the question would feel that such a question should have a long vacation, and that the space thus occupied should be filled with something a little more fresh. As there are hundreds of questions that each beginner has a desire to have answered, if all should depend entirely on "Questions and Answers" for the information needed, each number of the American Bee Journal would be crowded with such matter, and after the first year or so each reader would feel there was nothing worth his time to read, after having already read it so many times.

"Of what use then is the department of 'Questions and Answers' if one can not ask for the information he needs?" One can ask for the information he needs, and after having carefully studied a text-book he will still find plenty of questions to which he desires answers. New things are constantly coming up which have not as yet found their way into the text-books. Some things in the text-books may be a little hard to understand, and a little side-light will help. One will have difficulty at one point, another at another. After a careful study of what is contained in the text-book, no one need hesitate to ask any question that troubles him. But if any one should think that he should find answered in "Questions and Answers" everything he desires to know as a beginner, he will himself plead most earnestly to be protected from such questions and answers in the future, after they have become ABC to him.

An Experimental Station has been established by W. Skarytka, in Schletz, Austria, where any one can send bees, hives, etc., for trial and comparison without charge for such trial, providing all are sent prepaid. Here's a chance for several would-be American inventors to have their "ideas" tested.

The Chicago Convention of the National Bee-Keepers' Association meets the last week in August, as will be noted by the following from Secretary Mason:

EDITOR OF AMERICAN BEE JOURNAL:—

Please allow me to remind the readers of the American Bee Journal that the next convention of the National Bee-Keepers' Association is to be held in Chicago, Ill., on the 28th, 29th and 30th of August next, commencing Tuesday evening, the 28th, at 7:30 o'clock.

The sessions will be held in Wellington Hall, No. 70 North Clark St., about a block and a half from the Bee Journal office, and about five blocks directly north of the Court House. The hotel at which members can secure lodging, etc., is the Revere House, southeast corner of Clark and Michigan Sts., only one-half block from the hall. Rates of lodging will be 50 cents per night, and several will have to occupy one room. To many bee-keepers this will be an "added attraction," especially as they will have good beds to sleep on, as Mr. York has been assured by the hotel proprietor. It may be possible that this hotel will not be able to accommodate all of the bee-keepers, altho the proprietor will do his best to see that it does. Each one attending the convention should secure a lodging-place as soon as possible after arriving in the city. There is usually no trouble in getting enough to eat at reasonable rates.

The program for the convention will be different from what it has usually been. There will not be to exceed one paper at each session, and the remainder of the time will be occupied in the asking, answering, and discussion of questions. The question-box will be in charge of such veterans as Dr. C. C. Miller, of Illinois; Rev. E. T. Abbott, of Missouri; D. W. Heise, of Ontario, Canada; C. P. Dadant, of Illinois; R. L. Taylor, of Michigan; O. O. Poppleton, of Florida; and the editor of the American Bee Journal.

On Wednesday evening the editor of Gleanings in Bee-Culture will give an "Illustrated stereopticon talk on bee-keepers I have met, and apiaries I have visited."

The papers will be from such noted ones as Thos. Wm.

Cowan, of London, England; Dr. Wm. R. Howard, of Texas; Mrs. H. G. Acklin, of Minnesota; S. A. Niver, of New York; Herman F. Moore, of Illinois; and R. C. Aikin, of Colorado; and if you want to know what the papers are about, and assist in the discussion and enjoyment of the questions, please report in person at the above mentioned hall at the time indicated.

I have been unable as yet to learn what the railroad rates will be, but they probably will be as heretofore—one fare for the round trip from some localities, one and one-third from others, a cent a mile each way in the Central Passenger Association territory, or one fare for the round trip. The exact rate may be learned by inquiring at any railroad station.
A. B. MASON, Sec.

P. S.—Say, Mr. York, it has occurred to me that you might be willing to help delegates to secure lodging-places, if they would ask you to.
A. B. M.

Yes, we will be glad to do what we can toward securing lodging-places for those who will notify us a sufficient time in advance of the meeting. Already several have requested it. We think the Revere House will be able to care for one hundred or more, and likely the balance of the convention can secure lodging thru their friends and acquaintances residing in Chicago, aside from ourselves. Please do so if you possibly can, as we will likely have all the applications we shall be able to place.

There is an excellent restaurant, with reasonable charges, adjoining the hall, where doubtless most of the members will get their meals. The best part of a convention is the time between sessions if as many as possible can be kept from getting scattered. That is one reason the committee tried to secure hall, hotel and restaurant accommodations all within a half block of each other.

Australian Honey-Plants seem to be largely trees. A list of names of honey-bearing plants or trees in that region sounds strange to American ears. Among them, as recited in the Australian Bee-Bulletin, are bottle-bush, ti-tree, pepper-tree, flooded-gum, mahogany, bloodwood, red-gum, spotted-gum, white-gum, blue-gum, water-gum, black butt, tallow-wood, white-box, and stringy-bark.

Editor Tipper says lucerne (alfalfa) does not yield honey generally till its third year. If that is the case in this country, it has not been reported generally.

The great heat of the sun in Australia is likely to dry up white clover so as to lessen its value as a honey-plant.

California Bee-Men Organize.—Not long ago there appeared in the Pacific Rural Press a report that the bee-keepers of the San Joaquin valley, recognizing the advantage arising from co-operation, met in Selma, Fresno county, March 12, 1900, and formed a State organization under the State law of 1895, whereby each member has but one vote, whether he has 10 or 1,000 colonies.

The qualification for membership is the ownership of 10 or more colonies of bees and a compliance with the constitution and by-laws of the organization. There is a membership fee of \$2.00, and no dues nor assessments. The organization will be known as the California Bee-Keepers' Association. It is hoped to get every bee-keeper in the State to join.

The object is to run the business along the same lines as the raisin-growers, adopting their by-laws as nearly as practicable, and if they can succeed in getting 60 percent of the bees in any county or locality subscribed there will be a district formed in that county, and conducted the same as the prune or raisin growers manage their affairs.

The following were elected temporary officers: J. P. Johnston, president; M. A. Gilstrap, secretary; J. W. Payne, treasurer; J. P. Johnston, J. F. Crowder, J. W. Payne, B. D. Vanderburgh and W. M. Grimes directors. M. A. Gilstrap was chosen secretary of the board, and B. D.

Vanderburgh corresponding secretary. Messrs. Johnston, Payne and Crowder constitute the executive board.

The above information was furnished by Corresponding Secretary B. D. Vanderburgh.

To Our Foreign Subscribers.—It seems to be necessary again to inform our foreign subscribers that any offers we make in the bee-papers of this country do not apply to any country outside of the United States, Canada and Mexico. This will be self-evident to any one who stops a moment to think, on account of the extra postage. For instance, a subscriber in Jamaica sent us \$1.00 for a new subscription, and expected us to send the Bee Journal for one year to the new subscriber, and a Dr. Miller queen to himself as a premium for sending the new subscriber. Our queen offer does not apply to any country outside of the three named, and the Bee Journal sent to Jamaica for one year is \$1.50 alone.

Whenever we receive any money from foreign countries it is *all* applied on subscription to the Bee Journal at the regular foreign rates, so that full value is always given in return for the amount sent us.

DR. A. B. MASON, of Toledo, Ohio, Secretary of the National Bee-Keepers' Association, writing us June 23d, has this to say:

"There has been no surplus honey here since fruit-bloom, and some colonies have had to be fed to keep up brood-rearing. Sweet clover is just beginning to bloom, and white clover is past its prime."

MR. JOHN P. WEIBLER and Miss Marguerite Wehling were married at Glen Ellyn, Ill. (the home of the bride), Tuesday, June 19, 1900. Many of our readers will recognize Mr. Weibler as the young man in our employ who has the principal charge of the bee-supply department and its patrons. He has been with us continuously, in various capacities, since the spring of 1892, and has been faithful, efficient, sober and industrious. All who know "John" will unite with us in hearty congratulations, and wish both him and his wife a long and happy life.

HON. EUGENE SECOR, of Forest City, Iowa, General Manager of the National Bee-Keepers' Association, returned home the latter part of June, after a six-weeks play-spell in the East. No doubt there are many of his correspondents who have been getting anxious to hear from him during his absence. Such undoubtedly have received prompt attention since his return home. Mr. Secor simply dropt all business, and but few letters were forwarded to him while he was away. Of course, he made arrangements before leaving so that nothing should suffer very seriously. He reports that while he was absent from home his bees had it all their own way, and that when he came back to them "they evidently needed a director."

Mr. Secor wrote us, June 22d, that he was all right again, and ready for business at the old stand.

York's Honey Calendar for 1900 is a 16-page pamphlet especially gotten up to create a demand for honey among should-be consumers. The forepart was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample free; 25 copies for 30 cents; 50 for 50 cents; 100 for 90 cents; 250 for \$2.00; 500 for \$3.50. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices

Please mention Bee Journal when writing,

Improvement of Stock is something that almost any bee-keeper, almost anywhere, can work for with fair hopes of success. Much has been said regarding the improvements that have been brought about in cattle, sheep, poultry, plants, etc.; it must not be forgotten, however, that many of these improvements have come about as the result of care, food and shelter. The long horns and sinewy muscles of the ox are no longer needed in defending himself against the attacks of wild beasts. Care, and shelter, and food, eventually make an animal or plant less able to battle for life with the forces of nature. At the same time these changes in the animal or plant make it more desirable for man. The battle with nature made the animal or plant less desirable for man's use. Battling with nature has brought out and developed in the *bee* those very characteristics, hardiness and honey-gathering, that are the most valuable to man. Chaff hives and warm cellars, and the like—this "coddling," so to speak—has not improved the bee. At the same time there is no disputing that there is a difference in bees, and that by crossing and selection, and breeding in the right direction, we can improve them; but we must understand what we are working for, and work intelligently.—Bee-Keepers' Review.

Reformed Spelling seems to be attracting attention on the other side of the globe. In the Australasian Bee-Keeper, Hitter having spoken disparagingly of it, G. R. Harrison comes to the rescue in this vigorous fashion:

That Hittite Hitter falls foul of the Yanks who are trying to get rid of a little confusion in our methods of making language visible, and are adopting reformed methods of spelling. We use in writing the language some 49 sounds, which we represent in a hazy sort of way by 26 signs or letters, two of which can be eliminated, as other signs are also used for the same sounds, one of which (c) is used for two different sounds (k and s), and we are therefore always gloriously uncertain which sound it is intended to stand for.

Over 20 of the 49 are vowel sounds, and are represented by five signs, tho a couple more are occasionally borrowed (a e i o u and sometimes w and y), and these five signs are used on no special principle, thus, not only are there some half-dozen "a" sounds, but the "a" sign stands occasionally for "e, i, o and u," which makes our rules for writing language clear as mud, doesn't it?

We have excellent and easily learnt rules for the use of these signs, but it takes a lifetime to learn the exceptions to these rules, so we don't spell by rules, but have to make the spelling of each word a special effort of memory. *We can't pronounce a word as it is spelled, because there are no rules govern-*

Sharples Cream Separators: Profitable Dairying

The Queen Crank

Is before the readers of this Journal with a petition for orders for as fine Queens as he has ever been able to rear. They are being, and have been for some weeks, reared in triple-decker 10-frame hives, from choice Golden and Three-Band Mothers, in a Golden yard. The Bee-Keepers' Review, of Flint, Mich., for May (which is a special queen-rearing number) tells how it is done. Ask for a copy. Tested, \$1.00; untested, 75 cents. Yellow Sweet Clover Seed

WE HAVE IT AT LAST!

We have finally succeeded in getting a SMALL quantity of the seed of the YELLOW variety of sweet clover. This kind blooms from two to four weeks earlier than the common or white variety of sweet clover. It also grows much shorter, only about two feet in height. It is as much visited by the bees as the white, and usually comes into bloom ahead of white clover and basswood. We offer the seed as a premium

A QUARTER POUND FOR SENDING ONE NEW SUBSCRIPTION.

So long as it lasts, we will mail a quarter pound of the seed to a regular paid-up subscriber who sends us ONE NEW subscriber for the American Bee Journal one year, with \$1.00; or 1/4 pound by mail for 30 cents.

We have been trying for years to secure this seed, and finally succeeded in getting it. It is new seed, gathered last season by an old personal friend of ours, so we know it is all right. But we have only a small supply. When nearly out we will mention it.

GEORGE W. YORK & CO.,
118 Michigan St., - CHICAGO, ILL.

If You Want Bees

That will just "roll" in the honey, try Moore's **Strain of Italians**, the result of 21 years of careful breeding. They have become noted for honey-gathering, whiteness of cappings, etc., throught the United States and Canada.

Warranted Queens, 75c each; 6 for \$4.00; 12 for \$7.50. Select warranted, \$1.00 each; 6 for \$5.00; 12 for \$9.00. Strong 3-frame Nucleus with warranted Queen, \$2.50. Safe arrival and satisfaction guaranteed. Circular free.

Langstroth on... The Honey-Bee

Revised by Dadant—1899 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helpt on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for

one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.
118 Michigan Street, CHICAGO, ILL.

MARQUETTE, ON LAKE SUPERIOR,
is one of the most charming summer resorts reacht via the Chicago, Milwaukee & St. Paul Railway.

Its healthful location, beautiful scenery, good hotels and complete immunity from hay fever, make a summer outing at Marquette, Mich., very attractive from the standpoint of health, rest and comfort.

For a copy of "The Lake Superior Country," containing a description of Marquette and the copper country, address, with four (4) cents in stamps to pay postage, Geo. H. Heafford, General Passenger Agent, Chicago, Ill.

ing the spelling and pronunciation. Therefore, we should go a long way better than our Yankee friends, and adopt a proper code of signs for the language such as is given to us by Mr. Isaac Pitman, in his Phonotype and Phonograph, where the principles of one sign one sound, and one sound one sign are carried out. The English language is very good, and will grow better; it has evolved from inarticulate barks and grunts, and become a means of interchanging abstract ideas of infinite beauty and delicacy; the language will become more perfect yet, but we certainly require an improvement in the means of recording it. I've seen an improvement in my time, and our children and their children will perfect it.

Getting Rid of Ants.—I once purchast a lot of bees that the owner assured me he would brimstone unless I bought them, as they drove him off his place. On examining them I found one of the stands had half of its combs filled with the large black wood ants. As the combs were "fixt and immovable," I turned the hive upside down, dusted Persian insect-powder freely among the ants, and then closed the hive for a few minutes, when I reverst it, and in a few minutes had the pleasure of seeing the bees carrying out the dead ants. I had no further trouble with that colony. I irrigate the ground on which my lives stand, and in consequence the ants are driven to the hives. They never enter the combs, but seek the spaces between the sections where the bees can not reach or glue them out. I have tried placing a ridge of insect-powder around the hive. While the bees do not seem to be affected by it, the ants avoid it for several days until it has lost its strength, when they remove it. A chalk-mark will prevent the passage of ants as effectually as a barb-wire fence will cattle; but the ants will remove the chalk, a particle at a time, until they have a passage thru it, just as rats will pack glass, when placed in their holes, till it is all removed.

The best way to exterminate ants is to make a mixture of arsenic, Paris green, London purple, or strychnine, with syrup or honey. Put this in a dish, and the dish in a box, with the

The Bee-Keeper's Guide

Or, Manual of the Apiary,

—BY—

PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipt, or his library complete, without THE BEE-KEEPERS' GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal with \$2.00, and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

ends covered with wire-screen cloth that will admit ants, but exclude all bees. Place this box on the trail of the ants, and they will carry the poison home, feed it to their young, eat it themselves, and soon the colony will be among the things that were.—E. H. SCHAEFFLE, in Gleanings in Bee-Culture.

Celluloid and Glass Bee-Veils.—

Bee-veils with celluloid and glass fronts are described in our "A B C of Bee-Culture;" but in comparison with the silk tulle, so far as clearness of vision is concerned, they are little if any better, much more expensive, and, on account of their weight, are not apt to hang straight, but will flop back and forth at every movement of the apiarist. The glass, moreover, is liable to break, and get covered with moisture from the breath, to say nothing of getting dirty. I have personally tried these devices myself, and do not consider them anywhere equal to silk tulle.—E. R. ROOT, in Gleanings in Bee-Culture.

Wetting Sections Before Folding.—

F. L. Thompson says in the Progressive Bee-Keeper:

"Being a mechanic, Mr. Rauchfuss has several other devices that would not occur to most of us. That for wetting sections employs a principle that has not occurred to Dr. Miller, hitherto the authority on the section-wetting question—that of letting the water come thru a long tube, reaching from a vessel set on a height. The orifice of the tube being quite small, the stream is fine, but the elevation from which it comes, by a well-known law of hydraulics, causes it to emerge with considerable force, and it dives right down into the holes made by the grooves of sections resting on their

The Modern Remedy Co., Kewanee, Ill.

edges, without any unnecessary overflow or waving. The tube is about three feet long. It is of lead, about one-fourth inch outside diameter, with the lower end drawn to a point, and the upper end provided with a brass fitting that attaches to a faucet in a five-gallon can. If I were rigging up such a thing, I would try a five-foot length of rubber tubing, set a bucket of water on a shelf, tie a stone to one end of the tube to keep it at the bottom, and try the siphon principle—not that it would be any better, but folks who don't understand soldering might compass it better. Then to get the fine orifice at the lower end I would try Dr. Miller's tapered and grooved wooden plug, or possibly a piece of a lead-pencil with the lead removed and the two halves tied together again—tho that might make the stream a little too large."

GENERAL ITEMS

Good Prospect for Honey.

We have every prospect for a large honey harvest. White and alsike clover are in full bloom. Altho linden has been cut to a great extent here, there is much left, and it will bloom abundantly this year.

I. A. TRAVIS.

Wood Co., Wis., June 22.

In Tulare Co., Calif.—Overstocking.

It may not be uninteresting to know how the winter served the bee-keepers here. Last winter came on me with 40 colonies of bees. The same number came thru in fine condition. There were but few days at a time when the bees could not be out and gather honey if there was any.

Orchard bloom began to come the latter part of February, which gave the bees a fine start, and the latter part of March there was every prospect of a prosperous bee-season, when the weather turned cool and dry. The bees at once began to show the effects of the change, working slower than they had been doing, and in April they swarmed lightly—6 swarms, and 4 saved.

Now (June 20) the drones all, or nearly all, are killed, and bees in many hives are gathering barely enough honey to live on from day to day. I have fed some. Alfalfa is beginning to bloom, and in a few days it is hoped we will be in a fine honey-flow. All colonies that wintered are supplied with bees ready for the honey-flow when it comes. Appearances are good, only late in the season.

Last week a gentleman purchast a small piece of land within a mile and a half of me, and has moved 150 colonies of bees on to it. What the effect is going to be is more than we can calculate. If it will be to the disadvantage of any one the gentleman evidently thinks he has the best of the situation.

We are tolerably thickly settled in this vicinity, and nearly everybody has from one to a dozen colonies of bees, which makes our range quite well stocked, without the new comer. We ex-

A HANDY TOOL-HOLDER!

Sent by Express, for \$1.50; or with the Bee Journal one year—both for \$2.00.

Every Manufacturer, Miller, Carpenter, Cabinet Maker, Machinist, Wheelwright and Quarryman, Farmer, or any one using a grindstone, should have one of these Tool-Holders. One boy can do the work of two persons, and grind much faster, easier and with perfect accuracy. Will hold any kind of tool, from the smallest chisel to a draw shave or ax. Extra attachment for sharpening scythe blades included in the above price. The work is done without wetting the hands or soiling the clothes, as the water flows from the operator. It can be attached to any size stone for hand or steam power, is always ready for use, nothing to get out of order, and is absolutely worth 100 times its cost.

No farm is well-equipped unless it has a Tool-Holder. Pays for itself in a short time.

How to Use the Holder.

DIRECTIONS.—The Tool is fastened securely in the Holder by a set-screw and can be ground to any desired bevel by inserting the arm of the Holder into a higher or lower notch of the standard. While turning the crank with the right hand, the left rests on an steadies the Holder; the Tool is moved to the right or left across the stone, or examined while grinding, as readily and in the same way as if held in the hands.

For grinding Round-Edge Tools, the holes in the standard are used instead of the notches.

Address, **GEORGE W. YORK & CO.**

CHICAGO, ILL.

pect to go on the principle that what cannot be cured will have to be endured. I would be pleased to see instructions or a discussion of the situation in American Bee Journal. If there are precautions we can be governed by them in case of overstocking, etc.

SUBSCRIBER.

Tulare Co., Calif., July 20.

Sunshine for Driving Out Moths.

Bees wintered well in this section, and are storing a good deal of honey. There is an abundance of white clover. Yesterday, in cleaning up some old hives with comb where bees had died during the winter, I held the comb up in the doorway towards the sun, looking for moths; the bright sun drove them from their hiding places, and they crawled out on the outside where I could brush them off. From one comb where at first I only saw a few moths the sun drove out a score or more. I don't remember seeing this method of finding moths mentioned before, and thought it might be useful to some of the readers of the American Bee Journal.

J. RIDLEY.

Winneshiek Co., Iowa, June 21.

Some Experiences with Bees Stinging.

Reading the article on page 147, and again on page 395, about bees stinging, I will relate some of my experiences:

About the year 1869 or 1870, in the wild blackberry season I visited an old soldier friend in Crawford Co., Wis. I owned and drove to this friend's a mule team. My friend had no hay at that time of year, but feed being good in the yards we picketed the mules over night in the door-yard, a place of a half acre, more or less. In the morning I moved the mules, which brought one of them close to two colonies of bees kept in box-hives, never dreaming of any trouble from them. We all went into the woods berrying, returning about 11 a.m. We were picking over some of the berries for dinner, when a boy a dozen years old sitting in the door, after looking very steadily in the direction of the mules, said very slowly, "Mr.—, I—guess—the—bees—are—stinging—your—mules." Being quite warm I was in my shirt sleeves, also hatless, I ran out. The mule nearest the hives was literally covered with bees. She was kicking, rolling, pawing, and getting into worse shapes than any mule I ever saw inside of a circus ring. Of course I went to her assistance at once, hatless and coatless. I had all I could do to keep out of her way, for she was wild by this time. The bees fell upon me—not by the dozen but by the hundreds—yes, I think thousands, for both colonies were out in full force.

My friend was out, too, but was unable to assist me for a few moments. They stung me over my body, hands, head and face. When I could get a chance I ground up what were on my head, but finally I got the mule loose in some way, and started for a cornfield near at hand. By hard work I soon got rid of what were following me.

As soon as I was away with the mule they all pitch upon the other one, which was a little further off. My

friend saw a broad-ax lying near, and he severed the rope and let her free. Then the dog, a calf, and all the people near, had to take a look for protection for about 20 minutes, when all was quiet again.

I don't know how many stings I had, but I think not less than 100.

The first mule had more than five times this number. Not knowing what to do I bathed my head and face, and also the mule, with kerosene oil, and that evening drove home a distance of 12 miles—and in a couple of days we were no worse for the experience.

I bought a half dozen colonies of bees in 1895, and put them out in the spring 30 feet from the kitchen door, and one rod from the driveway, where I drove my team every day. I never had but one sting from being so near, and only one on a horse. I was driving in one day when a bee, dropping down while hard at work, struck the horse just over the eye, and not getting free, of course left its stinger in the horse's flesh, which he objected to very much. This was all the trouble we had that year. The next year, just in swarming-time, an old gentleman of 70, and his wife, past my place in a lumber wagon; the road was about 70 feet from the nearest hives, and a swarm of bees were in the air right in or over the road. There was no one at the house or nearer than 40 or 50 rods from the apiary. The old people did not notice, or did not think, and drove right into the swarm. Just as soon as the bees began to sting the horses they would not move, and they attack the people also. The women gave the cry of alarm, and soon brought to their assistance two men who were plowing corn some 50 rods away. The old people had abandoned the team, and retreated to a safe distance. The horses had laid down and were still down when help arrived. The two men went to work bare handed, without veil, unhitch and took the horses to a house one-half mile away, and bathed the horses for two hours with alcohol secured from a town three miles away.

The horses came out all right after about three month's roving in the pasture, but the top of their ears came off.

I keep now from 12 to 20 colonies of bees right along in a little lot of $\frac{3}{4}$ acre. I have a cow which is pastured in this lot; she eats the grass around the hives just the same as tho they were stumps. I have noticed her feeding, standing right in front of two or three hives, switching her tail, and loaded bees coming in and the naughty cow standing right in the way of their getting into the hive. I never saw but one bee sting her; that time she kick up her heels and ran into the barn, as the door stands open. I don't feel any alarm for her safety, for should she trouble them too much and they should resent it, she has a safe retreat.

I believe that bees get used to stock if they are kept around them. I remember years ago, when I knew nothing of bees—only that they had stingers and stored honey—that I could not go among them two minutes before a bee was after me. Now I work among my bees, often hatless, and very seldom have any trouble. I like to work with them, but we have so much trouble of late getting any clover to stay by us, and the basswood is being

all cut off, so that I am afraid we shall have to cut down our bee-yard to about one-third of its present size.

I don't find anything better for beesings than cold water, for man or beast.

L. G. BLAIR.

Grant Co., Wis., June 23.

Poor Prospect for Honey.

Bees in Tulare County are doing very poorly this year. Our main honey-plant—alfalfa—has not bloomed yet. I think the honey crop in this locality will be light. Bees now are bringing in just enough to live on. We generally have 3½ months of honey-flow in June, July and August—and the first half of September. We have now lost the first part of June, and a very poor outlook for the rest of June.

DAN CLUBB.

Tulare Co., Calif., June 19.

Honey Crop to Be Short.

My bees wintered well, and have swarmed very freely since May 4. I have about 100 colonies now. The honey crop will be short this season in my section of the county.

J. P. ORCUTT.

Hardin Co., Iowa, June 22.

What Will the Harvest Be?

My first swarm of bees issued June 14th. There is plenty of clover bloom, but only three good honey days thus far. Yellow sweet clover (*Mellilotus officinalis*) has been in bloom for a month, and the white variety has just begun to bloom. White clover bloom is quite plentiful, but has failed to give down the precious nectar. What will the harvest be? MRS. L. HARRISON.

Peoria Co., Ill., June 21.

Drouth—Fastening Foundation in Sections.

Owing to a drouth, which is quite general in the north half of this State, and vast areas of the Dakotas, the outlook for profit here is very poor this season. Most of the cereal grains—wheat, oats and barley—are almost past being helpt by rain. What is true of the crops is to a great extent true of the honey-flora. Altho in the more shaded places—the timber and brush—white clover is producing some, but so little that the swarming-impulse is very low, and no surplus honey is being stored.

Our early spring with unusually fine weather brought the wild fruit-bloom into its fullest glory; and the bees started with a boom, but their beginings for increase and stores of surplus honey faded away with the last of the bloom. Drouths like this are uncommon here. With a sufficiency of rain white clover and basswood may give us a good honey crop yet.

About fastening starters in sections: If Mr. Lathrop (page 373) will come over I think I can soon convince him that putting foundation in sections is very easy and pleasant work. I have a little apparatus arranged to fit in and over the lamp chimney. On this is fastened a little pan to hold beeswax which is heated by the lamp. The pan is a little to one side, leaving about one-fourth of the open space of the chimney for heating the sections.

Two horizontal projections are arranged to hang the sections on.

When all is ready, hang on a section, leave its edge side against the pan. In five seconds remove and replace with another. Now turn the first with the heated side downward in your hand. Dip one edge of the foundation in the heated wax and apply quickly to the place it is desired to be fastened. If all has been of the proper temperature, and the work done well, it may now be carefully turned and placed for cooling. The next section may now be replaced and used in the same way.

As for speed with small starters, I can put them in at the rate of eight per minute, and do it right. With full-sized sheets the speed is not so rapid, but is quite gratifying. Certainly, it can be "delegated to cheap help." Only get those who take pride in doing their work well.

To use the above plan gives full satisfaction; to others it may serve only as a suggestion to be improved upon.

E. S. ROE.

Rocky Mountain Bee-Plant Seed!

(*Cleome integrifolia*.)

...FREE AS A PREMIUM...

The A B C of Bee-Culture says of it: "This is a beautiful plant for the flower-garden, to say nothing of the honey it produces. It grows from two to three feet in height, and bears large clusters of bright pink flowers. It grows naturally on the Rocky Mountains, and in Colorado, where it is said to furnish large quantities of honey."

We have a few pounds of this Cleome seed, and offer to mail a ¼-pound package as a premium for sending us ONE NEW subscriber to the American Bee Journal, with \$1.00; or ¼ pound by mail for 40 cents.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, June 19.—Not any new comb honey on the market with the exception of a little sweet clover, which, owing to the scarcity of comb honey, has sold at 15 cents. Extracted is slow of sale with 7 cents about highest price that can be obtained for white; 6½¢ for best ambers, and 5½¢ for dark grades. Beeswax, 27@28c. R. A. BURNETT & CO.

KANSAS CITY, June 20.—We quote: No. 1 white comb, 14@15c; No. 1 amber, 13@14c; No. 2 white and amber, 13@13½c. Extracted, white, 7½@8c; amber, 7c. No beeswax in the market.

We have a shipment of new comb honey in transit from Florida. The supply of old comb honey is very light, mostly candied.

C. C. CLEMONS & Co.

DETROIT, May 24.—Fancy white comb, 15@16c; No 1, white, 14@15c; amber and dark, 10@12c. Extracted, white, 7c; amber and dark, 5@6c. Beeswax, 25@26c.

Supply and demand for honey both limited.

M. H. HUNT & SON.

NEW YORK, May 21.—Our market is practically bare of comb honey, and there is a good demand for white at from 13@15c per pound, according to quality and style of package. The market on extracted is rather quiet, and inactive. New crop is slow in coming in, and prices have not yet been established. Beeswax holds firm at 27@28c. HILDRETH & SEGELKEN.

SAN FRANCISCO, June 6.—White comb, 11½@12½c; amber, 8@10c. Extracted, white, 6½@7c. Light amber, 6@6½c; amber, 5@5½c; Beeswax, 26@27c.

There is not much honey on market, either old or new. Small quantities of new comb and extracted are going to local trade at comparatively stiff values. In some instances, especially for comb, an advance on best figures warranted as a quotation are being realized. To secure export orders, however, of anything like wholesale proportions, prices above noted would have to be materially shaded.

WANTED—HONEY AND BEESWAX.

We have a tremendous and growing trade in this line, and would like to hear from all who have such goods to sell in any part of the country, with quality, description, and lowest cash price. THOS. C. STANLEY & SON, Fairfield, Ill.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.10, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO., 118 Mich. St., Chicago, Ill.

Packages for Shipping Extracted Honey.

Written for the Wisconsin Convention at Madison, Feb. 7 and 8, 1900.

BY A. G. WILSON.

MY experience in shipping and selling honey in barrels and kits has been quite satisfactory.

For the past 9 years I have produced and sold, some seasons, over 20,000 pounds in the above-named packages, which reach its destination in good order, except in two instances, where one barrel and one kit evidently had been broken open and robbed of part of their contents.

I use 32-gallon basswood barrels, steel hoops, each holding 350 pounds of honey. The kits are manufactured for holding jelly, but are very convenient and durable for honey, each holding 33½ pounds. I scarcely ever have a package leak.

The barrels are very convenient to handle about the extracting-house, also to load into the wagon, and on the railroad platform. One is not compelled to do much lifting, as they can be rolled quite easily.

The kits are very nice to handle, and are shipped 4th class, the same as barrels; they are also the best selling package I have ever used.

I have never met with an opportunity to sell my honey for a greater price put up in 60-pound tin cans than in barrels. The cost of storage for 100 pounds of honey in barrels is 24 cents; in kits, 34 cents; in 60-pound tin cans, 75 cents.

I am not in any way interested in the manufacture or sale of any of the above-mentioned packages.

Vernon Co., Wis.

[This picture shows one of Mr. Wilson's apiaries that contains 120 colonies, a workshop 12x12 feet, and a bee-cellar with walls and ceiling 3 feet thick, made of sand, with a board roof. The hand-cart has springs under the corners of a platform—a good cart to carry combs on. The hives in this apiary are set in pairs, so that one acts as a bench to put tools on while working with the others. Mr. Wilson is one of Wisconsin's best and largest bee-keepers.—EDITOR.]

Bee-Keepers' Exchange—California's Experience

BY PROF. A. J. COOK.

I AM glad to note that there is increased attention being given to the subject of co-operation among apiarists. I was especially glad to read an article in the American Bee Journal from Mr. C. A. Hatch, who is one of our ablest men, and has had a broad experience, not only in apiculture, but also in general farming. He has also had wide observation, and is a close student of all such lines, and therefore his opinion and advice are well worth attention.

There can be no question about the value of co-operative effort in all lines of agriculture. It has been said that ten men can grow agricultural products successfully where but one can market well. There is no doubt much of truth in this, and no doubt the great handicap to the whole field of agriculture is the fact of isolation and the inability of its patrons to work together. All other businesses are able to combine and act as a unit. This is largely true in all other manual labor classes, and thus the success and value of the labor unions. The remark of one of the leaders of the labor union, recently made before a committee of Congress investigating trusts, to the effect that they feared not the trusts if they themselves could only be thoroughly organized, is certainly significant.

I think there is no subject that better deserves attention of all agriculturists in every line of production than that of acting together. Their product is something that must be had, and were they combined as are the railroads and business men in manufacturing and commerce, they would certainly have a very different report to make in regard to their success and the profits of their business. I have already referred to isolation. This makes it very difficult for farmers to become acquainted and to learn the benefit of the union effort. Thus the farmers are more or

One of the Apiaries of Mr. A. G. Wilson, of Vernon Co., Wis.

less suspicious and distrustful, not to say envious, and are reluctant to trust each other. It is true, then, that it will be absolutely necessary first to commence a general work of education to show not only the value of united effort, but to convince the people that they can trust each other, and that there is no inherent reason why agriculture may not be as greatly served by the most perfect co-operation as are the railroads, or the manufacturing interests.

Southern California has taken the lead in the matter of co-operations, and the results are most gratifying and satisfactory. The raisin industry was entirely prostrate in the hands of the commission men, vineyards were being dug up or sold under mortgages, and the raisin-growers were the most despondent people of all our sunny southland. Two years ago co-operation was suggested as a remedy, and over 75 percent of the raisin-producers were brought into the combination. The result was marvelous. Over a million dollars about Fresno alone mark the increase in price. Mortgages were paid; profits were satisfactory, and despondency was at once replaced by joy and courage. Last year over 90 percent of the raisin-growers of our State came into the combination, and that assured for two years, so that now no other class of people are so full of hope and courage as are the raisin-men.

The Citrus Fruit Exchange of Southern California is another illustration of the great value of co-operations. This organization has agents in the East, and looks after the whole matter of selling, equal distribution and general progress of the business. A great saving has been made in the packing, in the cost of the boxes, etc., as well as in the costs of marketing. One year over two million dollars worth of business was done without any loss at all, and the entire loss for several years has been but a few hundred dollars. And yet the business has been up in the millions.

The Deciduous Fruit Exchange is another organization which is now about two years old, and is already well on its feet, and has a vigorous and gratifying status to-day. This organization has secured better prices in all products which it handles than those outside. In all its business it has yet never lost a cent, while the expense of the organization is almost nothing. We see, then, that we have the value of such organizations fully demonstrated. Southern California was especially well fitted to be the pioneer in such work. A great many of our ranchers (as we call them here) were successful business men of the East, who came here in search of health. Thus, they understood the value of co-operation, and were quick to make use of it. It took less time, too, to convince the general farming public that the value of such organizations was immense, and objections to them almost without foundation.

I doubt if there is as much culture and general business sense among the farmers of any other region as you will find all over Southern California. Is it not true that bee-keepers are more generally readers, and men of intelligence, than are most persons engaged in agricultural pursuits? I think this has always been true, and since the years of bad wintering and honey drouths, owing to repeated dry seasons and other causes, the unintelligent have been more and more weeded out, so that to-day it seems to me a large proportion of the bee-keepers are reading, thoughtful men. If I am right in this conclusion, then certainly apiculture is already ripe for such co-operation as I am advocating in this article.

As I have been a close observer of co-operations in Southern California, and its most earnest advocate ever since I came here, six years ago, I feel that I know something of the difficulties as well as the advantages. I don't believe there are any insuperable difficulties in the way of co-operation among our farmers. The first point to be gained is to convince the people that the project has real merit, and the second to show them that farmers can do this as successfully and extensively as can the railroads. The railroads hire men to do their work. Why, then, can not the farmers? Then, if the farmers have no business ability among themselves, which is certainly not to be believed, they can surely secure the very best of talent, and that at an expense which they can well afford, a thousand times over. I believe that the success of the raisin industry in California, of the Citrus Fruit Exchange, of the Deciduous Fruit Exchange, will speak to the whole country very soon in most persuasive tones. It would seem to me that if the bee-papers would take this matter up with all the energy of their being, they might soon bring the bee-keepers into harmony with these organizations. This is well worth all the energy and effort it will cost, for it will not only be a great advantage to the industry of the honey-producer in securing better prices, cheaper implements, and a constant,

even market, but will also be another example to the country, and to the farmers generally, which will alone place the agricultural interests on a level with all other industries.

Agriculture certainly deserves a higher rank, and it is most deplorable that the industry has been so long look down upon. If the best morality and highest ideal of right living are to be found among the agriculturists—and I think this point can hardly be refuted—then surely anything that exalts this industry is well worth our first attention.

I am a thoro optimist. I believe to-day is the best day the world has ever seen, and I rest in the full conviction that to-morrow will be a better day. I believe a better Christianity is soon to dawn upon us; that better politics are to gratify right-minded men, and that more harmony and general helpfulness are to come upon us as communities. I can not but believe that one of the greatest agents in the production of this better condition of things is to be a more intelligent, refined and successful agricultural class. I am as strongly of the opinion that the strongest lever in producing this last condition of our agricultural classes will be thru co-operations among tillers of the soil.

May I not plead then to the editors of our several bee-papers to enlist heartily in this effort to bring the apiarists of our country to unite in the most thoro co-operation? Already California has led in this matter, and has had an organization for two or three years. It is in good hands, as the officers are not only our best bee-keepers, but are also men of great, good sense, integrity and excellent business ability. It is only to be regretted that the excessive drouths of the last two years have been so disastrous to the bee-keeper that the organization has had no chance to show its value. If better years ever come to the apiculture of Southern California, I believe we shall have another example of the great good that may come thru wise co-operation.

Los Angeles Co., Calif.

Robber-Bees—How to Cure and Prevent.

BY S. T. PETTIT.

THERE are various ways of stopping robbing. The condition of the colony being robbed should always be considered. In any case the first thing to be done is to close the hive so nearly that a single bee can with difficulty squeeze thru, then treat the robbers the same way. There may be several colonies taking a hand in the fracas. If so, look them up and punish them also. When the bees have quit flying toward night, open all up and let the robbers all go home; but watch, or in a few minutes they may go to robbing.

Again, at nightfall put the colony being robbed in a dark cellar, and leave it there for two days. In the meantime set an empty hive in its place. The hive in the cellar should be replaced on the stand in the evening, when all is quiet, and place on entrance-blocks such as is described below. If the hive being robbed is a strong one, leave the entrance three or four inches wide, and cover the entrance with a small armful of hay or straw, and sprinkle liberally and often with cold water, and take it also to the dark cellar for two days. But to prevent robbing is better, and generally easier, than to break it up after it once gets started.

Less robbing will occur if the hives face to the south or west, or anywhere between these points, for the simple reason that the prevailing winds from these quarters will favor the guards in several ways; but the west winds are too strong for best results when the hives face in that direction, so I prefer facing them to the south. Then in the evening of the first day out of the cellar give each hive whose bottom-board is at all loaded with dead bees, or is soiled, a clean, sweet, warm floor. To warm it, it should be kept for an hour or more in a warm room. The change should be carefully and quickly made. Let one lift the hive straight up, and another remove one floor and adjust the other; then adjust the entrance-block. Take a walk around next morning, and see how bright and thankful the little creatures look. Their home floor is so sweet and clean! and their courage will be strong enough to defend it. A dirty hive is more likely to be robbed than a clean one.

The entrance and entrance-blocks are factors that demand our careful consideration in this undertaking. The entrance should be about three-eighths inch high, and no higher.

If any one has much black blood in his yard I believe it will pay him to try entrance-blocks, that is, provided he has not something as good or better. I have a better in the shape of an addition to these blocks for very weak or queen-

less colonies, but there is not room for a description of it here. To make the blocks, cut a piece of lath an inch longer than the entrance. Cut this in two in the middle, then cut the corners back a little so as to form a V next to the hive when placed in position. Now cut another piece one inch shorter than the first. Next, nail this on top of one of the first pieces. Have the outer ends even when nailing. Now place all in position, and the top piece will cover the V space next to the hive. Close the entrance, and draw a mark across the loose piece at the end of the piece above it, by means of which you can tell just how far you can open the entrance when standing behind the hive.

As a rule, bees should have an entrance big enough to satisfy them. A generous entrance encourages them to defend their honey. With it they are more comfortable, and drier and warmer than with one that is too small. How can bees warm and dry themselves in a hive filled with a polluted atmosphere that can not escape? You might as well expect a Jersey to yield lots of good milk from poor hay and sawdust.—Gleanings in Bee-Culture.

Honey—From the Hive to the Table.

(Written for the Wisconsin Convention held at Madison Feb. 7 and 8, 1900.)

BY GEORGE W. YORK.

TO produce a large crop of nice honey requires skill and labor on the part of the bee-keeper. To get that same crop of honey properly on the tables of the consumers who ought to have it, requires skill and labor of an entirely different sort from that used in its production, if satisfactory financial returns are to result.

Perhaps it will be well if the two kinds of honey—comb and extracted—are treated separately, as each must have its own special manner of preparation for marketing. Suppose we take comb honey first, as that is the form in which all honey is first taken from the hive.

THE HANDLING OF COMB HONEY.

Of course, I assume that it is in one-pound sections, be they tall or square, plain or scalloped. In most markets I believe that the form or style has not the slightest to do with its selling. People do not purchase honey because it is surrounded with wood made in a certain form—they buy honey because of its own tempting appearance and delicious flavor, the latter being suggested by the very name—*honey*.

The most popular shipping-cases are the single-tier, no-drip 12 and 24 pound, which, for safe railroad delivery, should be put up say 20 or 10, respectively, in a straw-bottomed crate, with handles so that it must be carried between two men. Then by placing the cases of honey in the crate so that it can be easily seen thru the glass, there is scarcely any danger that a single comb in any of the cases will break down in transit.

After the honey reaches the city dealer (for I am treating the subject on the supposition that the honey goes from the hive to the city table), he will re-sell it to the grocery trade mostly in single-case lots, as the majority of retailers do not purchase honey in large quantities, knowing that they can be supplied on short notice should their supply run out.

I have found that in many instances it pays to furnish the retailer with paper cartons in which to deliver the honey to the consumer. The carton makes a neat and strong package, is very convenient, and, if properly used, it will serve as a good advertising medium for the dealer or producer. But the producer should never put more than his name on shipping-cases or cartons unless he sells direct to consumers, when he should also put on his full post-office address.

At the present time [Feb. 1, 1900] a carton of honey weighing about one pound should be furnished to the retailer at say \$2.00 per dozen, and sold out singly at from 20 to 25 cents.

Perhaps I have said enough on comb honey, so I will now turn to extracted—a more difficult problem, I think you will all agree.

THE HANDLING OF EXTRACTED HONEY.

Having a thick, well-ripened article, of excellent flavor, how shall it be transferred from the hive—or perhaps I would better say, from the extractor—to the table of the hungry consumer? Shall it be liquid or granulated? At present the liquid form seems to be most common. Later on granulated honey may become popular, but likely only

in certain localities where that form has been pushed almost exclusively.

To begin at the extractor, or settling-tank, I would say (if I were not among Wisconsin bee-keepers) put it into 5-gallon tin cans, one or two in a wooden box. My experience with barrels as a honey receptacle for shipping has not been very encouraging, so I trust you will permit me to advise tin cans for holding and shipping even Wisconsin's fine honey.

The tin can has advantages over the barrel. It is easier to manage in reliequifying, as it can be set upon a radiator, a coil of steam-pipes, or may more easily be put into a tank of hot water. The can, when emptied with proper care, may be used again. Of course, it is a lighter package to handle, as it holds less than a barrel. It is easier to sample—simply unscrew the cap, and there you are!

But no matter whether it is shipped in tin cans or wooden barrels, it must be reliequified, and run into small retail packages when it reaches the city, if it is ever to get to the tables of the consuming public.

Now there comes an important question: Shall the retail packages be—not wood or tin, but glass or tin? At present glass seems to be the leader, not only in the far East, but in the central West. Mr. Selser, who annually puts up about 40,000 pounds of extracted honey for retailers, uses glass entirely for quantities under five or six pounds. People are attracted by the clear, sweet liquid, and when they see it in glass they generally want it. Of course, the use of tin avoids breakage, but I believe that the tin package for retailing extracted honey will never be very popular among grocers, unless the time comes when extracted honey is sold in the granulated form.

Supposing, then, that glass is decided upon, what about the size of packages? I would suggest that there be only two—one holding a half pound or trifle over, and the other a pound or trifle less. A glass package larger than the latter I do not think advisable, nor one smaller than the former.

Of course, a neat label will be placed on every retail package of honey, and the contents be absolutely pure and of the finest quality.

These glass packages of honey should then be sold to grocers or retailers by the dozen, and at the price of glass and extracted honey to-day [Feb. 1, 1900] the half-pounds should bring about \$1.40 to \$1.50 per dozen, and the pound size \$1.70 to \$1.90; the former ordinarily retailing at 15 or 16 cents each, and the latter at 18 to 20 cents.

After all, I must confess that I am not an authority on this subject. Who is? But perhaps I have said something that may at least serve to introduce the question. If a good discussion follows, I shall feel repaid for making the effort to "set the ball rolling." Cook Co., Ill.

Queen-Excluders from Foul-Broody Colonies.

BY WM. McEVROY.

MR. EDITOR:—It will greatly oblige me if you will publish at once the following question and my answer to it which appeared in the Canadian Bee Journal for May, 1900:

QUESTION.—Some time ago I bought a number of queen-excluders that had been on bees that had foul brood. Will it in any way affect them for future use? What precaution should I adopt, or should they be discarded altogether? W. E. Y., Tilsburg.

ANSWER.—Queen-excluders that have been used on foul-broody colonies are perfectly safe to use on any hive of bees without disinfecting. The larvae to become diseased must be fed in a CORRUPT CELL or with DISEASED honey, and as queen-excluders have nothing on them for the bees to feed to the brood, they can not disease any colony of bees. Wm. McEvroy.

The above question was sent to Mr. Craig, and he sent it to me to answer thru his journal, which I did. Dr. Miller—a level-headed man, and one of the best bee-keepers in Uncle Sam's domain—agreed with the answer I gave. And now, to my great surprise, I have just read in the American Bee Journal for June 23, 1900, a very strong protest entered there by Mr. Hasty, against the opinions held by Dr. Miller and myself.

In the Province of Ontario I have succeeded in getting thousands of diseased colonies cured of foul brood, and in every case the same old queen-excluders were used on the cured colonies, without being disinfected in any way, and no disease ever appeared after they were again used.

If Mr. Hasty, and the other readers of the American Bee Journal, will read page 12, of Dr. Howard's book on foul brood, they will find that his test cases prove that my

answer was correct. Dr. Howard is by far the best authority in the world on foul brood, and I will leave it to him to say if my answer was not perfectly correct.

Woodburn, Ont., Canada.

Bee-Keepers' Exchanges—Why? Why Not?

(Written for the California State Bee-Keepers' Convention.)

BY C. H. CLAYTON.

I WAS pained lately to read in a prominent bee-paper an article purporting to give the reasons "why bee-keepers' exchanges fail." The article in question was from the pen of a former member of this Association, and was wholly unsatisfactory, in that the writer not only failed utterly to grasp the logic of the situation, but also failed to point out any adequate remedy for the evils complained of.

In daily speech modern men and women pay tribute to the old order—the order which seems to decree that the bee-keeper's existence depended upon brawn and not upon brain. This thoughtless slighting of the bee-keeper's vocation seems curious when one pauses to observe how deeply the bee-keeper of to-day is involved in the meshes of commerce. The successful bee-keeper of this generation must be a business man first, and a keeper of bees afterward. In him must be combined many talents. He must be a capitalist, cautious and crafty; he must be an operator of industrial affairs, daring and resourceful, and he must play labor's part, with patience and humility. He is in business as certainly as the merchant or manufacturer. And until the order changes the bee-keeper's success in business will be governed by the kind and quantity of brains he uses.

From the flower to the ripened nectar—from the first operation in bee-keeping to the last—one is forced to realize how the spirit of the age has made itself felt here. The most desirable bee-keeper is not the fellow who can hit the punching-bag most lustily. He is the man with the cunning brain who can get the most work out of the bees without injuring them for future use. He is in the ranks of skilled labor.

In the bee-farm the investor has the use of labor-saving machinery to increase the output of his establishment; his profits are large or small according to the caprices of his market. He can not estimate with much accuracy what his cost of production is going to be at any season. The rains, the winds, the drouth, may cut his product short 50 percent, or wipe it out altogether.

During the period of time extending back for the last 10 years, the business community in the entire country has suffered from what seemed to have been over-production. The result of this was to bring about excessive competition in all lines of business. Anxious to find purchasers, prices have been cut below the limits of reasonable remuneration. This evil of excessive competition seemed to prevail everywhere. In the effort to obtain relief the wages of labor were reduced. This only led to additional complications. The working-men strove by the only means at their command to save themselves, and strikes and lock-outs were instituted, and these were followed by the usual distressful accompaniments.

The only effective means of overcoming this condition seemed to be in the obvious one of an undertaking among the producers of various lines, as to the prices to be asked for their various commodities. Regulation in this respect was only possible thru a union of interests upon the part of those engaged in the same line of business. Ordinary trade agreements were hard to enforce, and were readily disregarded in the effort to obtain business.

Only a small fraction of humanity can be stirred by considerations of moral or mental advantages. In our greedy modern life the material side is chiefly regarded. By far the greater number challenge all things with the question, "What is there in it for me?" It is but the statement of a simple fact, to say that the present tendency toward combination and co-operation is but the reaction from the keen and excessive competition of the past few years.

Whether this movement for co-operation is justifiable or not depends upon the facts in the case. Whether for good or evil must be determined by the results. An impulse so general, and so wide-spread in the business world, must have cause for its existence.

The rights of the public are not to be ignored in any event; but so long as those rights are respected the individual is certainly at liberty to concentrate his capital and combine his resources with that of his fellows in the same line of business for their mutual benefit.

A practical instance of the good accomplished by co-operation is the decrease cost of production by doing away with the wasteful method of competitive business. By constant study of the conditions of business in all its phases they are enabled to increase the demand for a product, and thus enlarge the consumption. If abuses should arise these organizations are at all times amenable to the law. No combination will ever be able to maintain abnormal prices, for the reason that such a course would call into play practical competition, and this will always operate as a check. Any undue increase in price will lessen the demand.

The co-operative movement is the outgrowth of natural conditions, and opposition to it is based upon a misunderstanding of the fact that it is the application of a great and effectual remedy to the crushing and demoralizing condition which has resulted from unlicenst and excessive competition.

It is curious that we should have had growing up around us for the last 300 years the very co-operative system of which philanthropists dream, and that men should have failed to recognize its features. If the day ever comes when all men shall have obtained a secure competency it will be when co-operation has become universal. There is no other road leading to the abolition of poverty.

Speaking generally, there will be no honesty in the world until men have been taught that all intersocial relations should be reciprocal, due to an interchange of service among equals. Any attempt to crush out or interfere with the proper and reasonable workings of this remedy is utterly hopeless. The movement is bound to continue until all industrial activities are brought into a system of co-operation.

Now a word concerning the opposition to the movement as experienced in the Bee-Keepers' Exchange. I will name some of the reasons, as they occur to me, why the Exchange has found it difficult to attain that measure of success it deserves. I do not intend to be harsh, but I would be untrue to you if I were not plain.

The failure to perfect the organization, leaving out of consideration the failure of two crops in succession just as we were starting, is attributed to:

1st. Selfishness on the part of many who desire to sell at the better terms offered by the great buyers on account of the agitation in favor of organizing. Such men say: "You are all right, but we have a crop of honey to sell, and are now negotiating to that end. *When we have sold we will be with you, heart and soul, and do all we can to aid you in building up an exchange that will protect our interests.* In the meantime, however, do not for the world abandon the effort to bring about a perfect and complete organization of the bee-keepers."

2d. Crop mortgages which prevent independent action on the part of the producers.

3d. Concessions made to the producers in the way of rebate on commission, so much on supplies, or in any way that would be satisfactory to the parties interested. The inevitable result of such an arrangement is the lowering of prices to the producer by just that much, and it is a detriment to the honest buyer when he comes to deal with those who have not made this kind of a deal. So the concession made to one operates to the detriment of all. Men are not in business for their health, and anything of this kind is sure to be found out and taken advantage of.

4th. Intimidation. Many have foolishly tied themselves up, and are given to understand that siding with the movement might impair their personal interests.

5th. Apathy on the part of some who do their thinking by proxy.

6th. Jealousy on the part of some who fear that their neighbors may be as much, or possibly more, benefited thru the Exchange than themselves.

7th. Dissensions, caused by difference of opinion as to how to proceed, and upon what plan the business shall be conducted. We have had our share of these, but, thank the Lord! I think they are a thing of the past. The School of Adversity has taught us to look to results rather than mode or manner.

Our impressions of men and measures are too often superficial, being founded upon imperfect knowledge as to men, and meager experience as to measures. It seems to me to be humanly impossible for any one to arrive at a true solution of the problems involved in the workings of the exchange principle in the short period of one year, which length of time comprises the whole of our ex-president's experience in California. Others who have large interests here, and years of experience also, are not so ready to condemn the movement, even by implication, unless prepared

to suggest something better. Too often we reach down into our minds and bring forth our thoughts, and put our brooding hypotheses into words, and show our acumen, and the searching quality of our discernment, by shaping our conclusions and offering them to be examined. Talk of this kind does not consist of sworn statement. It is merely conversation, where fact is scarce, opinion abundant, and conjecture overflowing.

After years of study I declare to you that I see no other salvation except in some form of co-operation. You may call it a "Combine," an "Association," an "Exchange," or a "Trust," if you will, and try to legislate it out of existence.

Self-preservation is the first law of Nature, and men must and will combine in furtherance of their mutual interest. Mistakes, many mistakes, have been, and doubtless many more will be, made while seeking the best method of organization, but surely these mistakes should not discourage us—should not deter us from profiting by our past experience. There is no half-way place. We are fighting for our very existence, and we must be prepared to meet conditions as we find them.

These conditions are plain to all. Why, even the news-boys on the streets of this city to-day recognize them and are organized—associated together for the protection of their interests. Shall it be said that bee-keepers, who, as a class, are among the most intelligent people of the world, can not, or will not, combine for the good of each other?

I feel deeply, earnestly in this matter. Three years now as secretary of the Exchange I have been in close touch with the commercial world, and have had abundant opportunity to see the inside workings of affairs, and I tell you truly that if you attempt to "go it alone" you will go as a lamb to the slaughter. You will be the legitimate prey of every Harpy that seeks to live off the sweat of honest toil.

Los Angeles Co., Calif.

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Richards, Ohio.

BITTER-SWEET, OR THE BOY'S FIRST STING.

That Italian artist, page 337, certainly knows how to paint a crying boy. Also a straw skep and a rustic bench and roof, he does fairly well on. But did he post himself on the habits of bees before painting his quite successful picture? Alas, no! Without smoke his boy has taken two or three good-sized combs from the hive and got the bees off them, and has just received his first sting.

NATURAL SWARMING.

Mr. C. P. Dadant betrays his residence in a non-swarming locality where he gives as a test between normal swarms and absconders, "A natural swarm issues only in a good honey-producing time." Instead of being absolute verity this is merely a general rule, liable to many exceptions. And it is so common for bees to swarm with little honey in their sacs that it is hardly proper to call full supply a general rule. Page 337.

PROF. LAZENBY'S REPORT.

An unusual supply of "nuts and raisins," both for the critic and the student, is Prof. Lazenby's report, pages 338, 339. It is rather a surprise to me to see pears put at the foot of the list both for pollen and honey, and another one to see the peach rated so low. Takes a good many years to get general rules of this kind settled, and I wonder a little if Mr. Lazenby's years of observation have not been too few. If ask to name the honey-value of the trees off hand, I should have put the order peach, pear, cherry, apple. I see too little of plums to put them in. The nectar in a peach-blossom is often visible to the naked eye—or used to be years ago.

His first table will be handy to keep for comparison with the work of our own colonies when we incline to inspect them. It is plain from the figures that he counted

the pollen-carrying bees, and assumed that all the rest were carrying honey. This will hardly do. Many may have been empty from various causes—and some no doubt carrying water and the nameless juices used in brood-rearing—and for the period between 2:30 and 3:00 p.m. quite likely half of them were merely returning from play.

His weight of strictly empty bees—5,750 to the pound—is lighter than we have mostly been estimating them (4,400 to 4,700), and on the whole I should say the old weights are the more practical, as we seldom have anything to do with bees *en masse* when they are *entirely* empty. Of course, it's well to know what really empty bees do weigh.

In table three I should judge the heaviest weights of much more value than the average. Pretty evident that the attempt to get honey-laden bees was a failure in several instances. Yet it is quite possible that young bees in their first efforts at nectar-gathering sometimes rush home with very small amounts. His two best bees carried 54½ percent of their own weight—wonderful enough to stop and think over—but my own observations in the same line make me think that, if he will keep repeating the trial till he hits the most favorable kind of a day and yield, he will record considerably heavier loads, running up to 70 percent or more.

Guess I shall scold about table four. Weighing the whole man to find out how many silver dollars he has in his pocket is rather crude. There is no serious difficulty in removing and weighing the pollen-pellets themselves, and then we know something about it. I think he is partly right and partly wrong about bees not bringing honey and pollen both at the same trip. When they go expressly for pollen probably he's right; but when they go for honey and *incidentally* get their jackets dusted with pollen, why should they comb it off and throw it away, when they might just about as cheaply pack it in little "pony" pellets and bring it along? (We apparently see them doing this sometimes.)

The most novel idea of the paper is that a pollen-gatherer visits three times as many flowers in the same time as a bee after honey. Guess that's right. The pollen is simply dabbled in—which consumes much less time than the pumping up of the nectar.

ONE OF OLD GRIMES' BEST HELPERS.

And so Old Grimes thinks that that machine on which a fellow sits down to walk is the last, if not the best, of the bee-keeper's helpers. I suppose it never thinks that it "owns the apiary and takes a fatherly interest in the owner." Page 339.

DOUBLING SWARMS IN HIVING.

Mr. Davenport, in his article on hiving swarms two and two, gave us a good Hamlet, but rather left Hamlet out of it. He "did ought" to have told us some way to head off the great difficulty of that oft desirable manipulation—the disposition of mixt bees to ball their queens. Page 340.

SWARM-HIVING APPARATUS.

Wonder if Mr. Snell thought of the Taylor swarm-catcher when he said all but the two he named had gone out of use—may be it's correct, however. Of living bee-keepers I think comparatively few have taken down more swarms than I, and my personal feeling is that any catcher that purports to take down a swarm without getting up where they are is a nuisance—not a little nuisance, but a pretty big one—albeit success can be had with them *sometimes*. Especially may failure be lookt for with a swarm that has a virgin queen. These—at least some of them—are greatly inclined to take wing repeatedly. Page 341.

EARLY SPRING HONEY.

It is worth while to note that the apiary at Notre Dame has again got spring honey enough to extract from several hives notwithstanding the unfavorably spring. One super weighed (in the gross, presumably) 32 pounds, May 16th. Queer. May be our professionals haven't found it all out yet. Page 348.

BLEACHING COMB HONEY.

Queer I didn't think of the obvious way to avoid getting sections melted by the sun in trying to bleach them—cotton cloth instead of glass. A. E. White, page 366, seems to have the thing into practical, commercial shape already. Expose to sulphur fumes *first*; then it only takes a few hours with most sections. And he finds that nearly all will bleach if exposed day after day. A cotton *room* built right over one of the honey-house doors makes the

thing handy. A beat of the drums and a flourish of trumpets for Comrade White.

SUCCESS WITH BEES IN THE FAR NORTHWEST.

It is pleasant to see the success of G. T. Montgomery in the far northwest, where everybody says bees can not be kept. And his neighbor wintered a colony on the summer stand! "Everybody" is a good school-teacher, but he off gets left, just like we uns the nobodies. Half of the matter, I surmise, is that the nectar and pollen of the far north is still uninfected with evil germs, just as it used to be here and everywhere. Page 364.

LATE SECOND SWARMING.

W. T. Stevenson's case of a swarm at 22d day from prime might happen in two or three different ways. Bees might keep queens prisoners in their cells all that time. This, if proven up, would be an interesting addition to our bee-knowledge. Same remark if a lot of virgins loose in the hive for several days neither fought nor got themselves balled. I once found a case in which a lot of surplus queens were secreted under cushions, etc., about the hive, having evidently been driven out "higglety-pigglety" by the workers that didn't want to be bothered with them. A case like this might result in a 22d day swarm. The citizens of the hive (being all women-folks) might change their minds, allow one of the poor outcasts to come in again, and then swarm when the regnant queen began to "say things." Page 363.

BEE-KEEPING IN A FOREIGN LAND.

"Just so as it ought to be" when we hear of bee-keeping in a foreign land from the pen of one of the consuls of the United States. See the interesting account of bee-affairs in the Holy Land by Consul Merrill. Page 356.

GLASS CARTONS FOR HONEY.

So the carton of the future must be partly glass and partly paper, eh? Shouldn't wonder. But I want to put in my parting scowl and kick for the "uplifting" of those brethren who desire such a thing as to sell glass for honey by weight, at more than its cost. Page 353.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Split Bottom-Bar for Brood-Frame.

Would it be advisable to split the bottom-bar of the brood-frame so that foundation might be fastened at the base? I have experienced much trouble in getting the bees to fasten the comb to the bottom-bar. MASS.

ANSWER.—I have many frames in use that have a split bottom-bar, and I like them very much. The only trouble is that if no precaution is taken the comb will be bulged. I prevent bulging by using splints put in perpendicularly.

Foul Brood and the Queen—Introducing Queens—White and Fall Honey-Flow.

1. If I should purchase a queen by mistake taken from a colony that has foul brood, would the queen transmit the disease to my apiary?

2. I received a \$2.00 queen from a queen-breeder June 7, and placed the caged queen in colony No. 40, having previously destroyed carefully every queen-cell. On the 9th I released the queen and on the 11th I opened the hive and found a virgin queen with the drone appendage still adhering, and my \$2.00 queen lying outside dead. Nos. 39 and 40 hives were just alike, and close together, and No. 39 had a

virgin queen that became missing at the time. Now could the virgin queen in No. 39 have come out and met the drone and gone back into No. 40 and killed the laying queen? Would the bees allow a strange virgin queen to enter the wrong hive unmolested?

3. If on account of a poor honey-flow the bees only partly fill the supers, is it best to leave them on the hives till the fall flow, or take the sections off and put them back at the beginning of the fall flow? OHIO.

ANSWERS.—1. At least some of the authorities say the disease is not communicated by the queen, but I should prefer a queen from a healthy colony.

2. The thing probably happened just as you hint. The \$2.00 queen had been in the hive only a day or two, hardly recovered from her journey in the mails, and the bees took up with the stranger. Whether the young queen or the workers killed the queen is a question. Bees are freaky things, and the same thing might not happen with you again in a lifetime.

3. If there is the same difference in price as generally prevails between the early and fall honey, (two cents or more a pound), better take off all finished sections at the close of the white flow.

An Insect That Works on Red Clover.

I enclose an insect. What is it? I have seen them work on red clover for a number of years. I do not know where they come from, and nobody else has them in this neighborhood. IOWA.

ANSWER.—I am not an entomologist, and am acquainted with very few of the many kinds of bees, an acquaintance with them lying outside of bee-keeping proper. The specimen sent looks to me more like some kind of fly. Prof. A. J. Cook, of Claremont, Calif., is an entomologist, to whom should be sent all kinds of "bugs" to be named, not forgetting to put in stamps for reply.

Questions on Swarming.

1. June 7 a prime swarm issued, and I put it on the old stand, and set the old colony beside the new one. June 14 I removed the old colony to a new stand; on the 17th it cast another swarm, but went back into the hive. What was the cause?

On the 17th another colony cast a prime swarm. I put the new swarm on the old stand and the old one beside it. On the 18th the old colony cast another small swarm, and it also went back. I have had bees for 10 years, and never had them act this way before. MINNESOTA.

ANSWER.—1. It is possible that the prime swarm had been delayed by the weather, so that on the 17th the young queen was able to take her wedding-flight, at which time a swarm sometimes come out and returns. It is also possible that the swarm on the 17th was a regular second-swarm, and it returned for some reason that I don't know.

2. It may be that the old queen was killed or lost some time before the 17th, so that a lot of young queens were reared and one of them came out with the swarm on the 17th, and another the next day.

Extracting Honey—Cross Bees, Etc.

1. I am a new hand with frame hives and so I want some advice. I use the 10-frame hive. Will it do to extract all above the honey-board, just leaving the 10-frames?

2. Will it do to extract a frame, say about $\frac{3}{4}$ or $\frac{3}{8}$ sealed?

3. Why is some extracted honey thin on top in a comb or barrel?

4. Will sweet clover grow in red clay land?

5. I have some very cross bees. What is the best way to manage them?

6. Our honey is from poplar, sourwood, etc.; no clover or grain, but a lot of woodland near here. How many colonies will do well in one place? If I build up another apiary how far must I have it from the first?

7. If I use 10 frames for the brood chamber, how many frames should there be in the extracting-super? ALA.

ANSWERS.—1. Yes, all above the honey-board should be extracted, and some extract part that is in the brood-chamber, but generally it is best to let the brood-nest alone.

2. It will be easier to extract before any sealing is done, but the honey will be thin and unsatisfactory. You get a fair body of honey by extracting when $\frac{3}{4}$ sealed, but it will be still better if you wait till all is sealed.

3. When you extract honey that is partly sealed, the unsealed part is thinner and lighter than the rest, and so rises to the top.

4. Yes, it is hard to find any soil on which it will not grow.

5. The very best way to do with very cross bees is to change the stock by killing the queen and giving them a queen that will produce gentler bees. In a month or two the old bees will be all gone, but the change in disposition comes before that, and it almost seems as if the presence of the new queen has some effect upon the tempers of the old bees. You will get along best with the cross bees by being very gentle in your movements with them, making no quick motions, and using only enough smoke to subdue them, but repeating the dose whenever they show fight. Be careful to leave no bits of honey lying around, for a little start at robbing may make very cross bees of those that under ordinary circumstances are gentle.

6. No one can say for certain, but perhaps 75 to 100 colonies may do in one place. Something like 3 or 4 miles is a good distance between apiaries.

7. Some use 9, but more 10.

Marking Bees to Distinguish Them.

How can bees be markt so as to distinguish them from others of the same colony? ILLINOIS.

ANSWER.—A camel's-hair pencil dipt in some bright color may be lightly toucht on the upper part of the thorax.

Forming Increase to Prevent Swarming.

I would like to know what is the best way to form increase to prevent swarming in an out-yard. WIS.

ANSWER.—That's a hard question. One way is to take the queen with a frame of brood, a frame of honey, and the adhering bees, put her in a hive in a new place for 8 or 10 days, then put the hive that contains the queen on the old stand and the old hive in the new place—in other words, let the two hives swap places, brushing the bees off about half the brood-combs into the hive that contains the queen. Another, and perhaps a better way would be this: Take all the brood from the old hive and fill up the hive with foundation. Shake off about half the bees from the frames of brood, or brush off clean half the frames, leaving all the bees on the other half, put this brood with its remaining bees in a hive on a new stand, and in about two days give it a laying queen.

Pollen in Surplus Honey.

We are annoyed very much this year with pollen in our surplus honey—both sections and frames. Can we do any thing to prevent it? KENTUCKY.

ANSWER.—It is possible something might be done if all the conditions were known; but it is hard to guess at the conditions, and equally hard for you to mention conditions that might make a difference. You say pollen troubles in sections "this year." It is somewhat doubtful that the year or the season has much to do with it. More likely there is something a little different about your management. Possibly the brood-chamber is crowded. Some have complained of pollen in sections when brood-frames were very shallow. Thick top-bars, slat honey-boards, queen-excluders, anything that makes greater distance between brood and sections may help to keep pollen out. After all, it is just possible that some peculiarity of the season may have more to do with it than I have suspected.

Colony Perhaps Overheated in Transit.

I have been perplext about the way one of my colonies has been acting the last three or four nights. Each morning I find hundreds of young bees on the alighting-board which are pulled or driven out of the hive, some of them almost able to fly, others having the appearance of having wings eaten off, or not yet developd. These young bees are able to crawl around on the grass during the whole day, but

are driven off or carried away when they try to enter. This colony I had shipt to me about 10 days ago, and the hive seemed too full of bees for the warm weather. None could fly for about 24 hours after arrival, being nearly suffocated. Now they work well and are gathering honey. I have made inquiries from old bee-keepers to explain what is wrong, and what is the remedy, but got no satisfaction. ONT.

ANSWER.—It is quite possible that the overheating on the journey injured these young bees in the way described, and that as soon as the injured ones are disposed of the colony will be all right.

Absconding Swarm—Bees Defending Their Hive.

1. After we had taken in a swarm of bees, we let the hive stand where it was. We watcht the hive during the day, and were to remove it later on. When "later on" came there were only a few bees left. We saw bees flying out but none entering. What was the cause?

2. I have had a number of colonies that fight in front of the entrance. Are they protectng from robber-bees, as they look well? MINNESOTA.

ANSWER.—1. The bees may have absconded, or they may have returned to their own hive. If the hive stood out in the sun, or if it was too close, that favored absconding. Keep a hive open, even to leave the cover partly off the first day after hiving. It is well to put a hive where it is to stand just as soon as the bees are all settled. Scouts may be out looking for a place, and there is a possibility that such scouts may come and take the swarm to the place they have found, if the swarm is still standing where they left it.

2. Yes, when there is fighting in front of a hive, it is likely the bees of the hive are defending their hive against intruders.

Queer Idea of Drones—Uniting a Swarm with a Colony.

1. I received this story from a person who had it from an experienced (?) apiarist; it is only because he askt me as a favor to write you, that I trouble you with such an absurd statement:

The (experienced) apiarist says that the "king-bees" (drones) have a sharp, horny thing in place of a sting, and when it is time to swarm they keep picking at the queen until she leaves the hive, and the bees follow her. What do you think of it?

2. I have a colony of bees I do not think will swarm, which I will call A. I bought a swarm from a neighbor which I call B. Now, if A should swarm, what is the best way of uniting with B?

As I am shortsighted I would not be able to find queens of A or B. Would it do any harm to simply let them fight it out? MINNESOTA.

ANSWERS.—1. Wherever you find drones with that sharp horny prod, they are very vindictive, and resent anything said about them, and if they once learn the name of the "experienced apiarist" that has told about them, they will be sure to prod him to death! As you have suppress his name, his life may be spared.

2. If A swarms within a few days of B, the swarm may be allowed to enter with B. If some days elapse before A swarms, shake all the bees of B from the combs onto the ground in front of the hive, dump the swarm on the ground with them; and after they have run together into the hive, put the brood back. The bees will settle the matter of queens. But you ought to have a pair of glasses that would allow you to recognize a queen easily.

York's Honey Calendar for 1900 is a 16-page pamphlet especially gotten up to create a demand for honey among should-be consumers. The forepart was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample free; 25 copies for 30 cents; 50 for 50 cents; 100 for 90 cents; 250 for \$2.00; 500 for \$3.50. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

The Premiums offered this week are well worth working for. Look at them.

GEORGE W. YORK & COMPANY,
118 Michigan Street, Chicago, Ill.

[Entered at the Post-Office at Chicago as Second-Class Mail-Matter.]

DEPARTMENT EDITORS:

C. C. MILLER, "Questions and Answers." ** E. E. HASTY, "The Afterthought."

LEADING CONTRIBUTORS:

G. M. DOOLITTLE, C. P. DADANT, PROF. A. J. COOK,
F. A. SNELL, R. C. AIKIN, "OLD GRIMES."

IMPORTANT NOTICES:

The Subscription Price of this journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec00" on your label shows that it is paid to the end of December, 1900.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

VOL. 40.

JULY 12, 1900.

NO. 28

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

The National Convention Next Month—don't forget it. The dates are Aug. 28, 29 and 30. Every bee-keeper who can arrange to be present should be on hand early and stay until the end. It promises to be the greatest convention of bee-keepers held since the World's Fair, in 1893. The officers are planning an interesting program.

Ripening Honey Off the Hives.—S. P. Culley, in the Progressive Bee-Keeper, quotes G. M. Doolittle as saying that honey can be ripened in open jars in a warm room, and now saying basswood should be ripened on the hive to get its best flavor. Mr. Culley thinks this is true of sumac, and notably true of Spanish-needle honey. But he thinks white clover honey may be just as good ripened artificially; so it is important to know what kinds of honey need to be left on the hive to ripen.

New Bee-Papers.—The editor of the Progressive Bee-Keeper thinks it selfishness to speak discouragingly of starting new bee-papers. Couldn't our contemporary exercise a little more charity and admit that one might discourage an uncertain venture with other than selfish motives? Knowing that nine out of ten of the new bee-papers have ended only in failure, and that the longer a failing journal continues the struggle the greater the financial loss, is there anything kind in encouraging a new venture when you are morally certain that it will end only in failure, and that

every month the struggle is continued means dollars of loss to the struggler?

As it is not our money that is sunk in new papers, perhaps we should keep quiet and let the starters learn by experience. And yet, it seems to us that it would be just a trifle hard-hearted in us not to offer a warning word to the man of small capital, and less experience, who is thinking of starting on a venture that is practically certain to end in loss and failure. When a child, unless told, doesn't know that fire will burn its fingers, isn't it a kindness to warn it? We think so, no matter what others may say to the contrary.

Hot Water for the Uncapping-Knife is part of R. C. Aikin's outfit for extracting honey. A pan 4 by 8 inches, and 3 inches deep, contains water heated by a small oil stove. G. M. Doolittle thinks with a sharp Bingham knife no heat is needed. This is the gist of two items mentioned in the Progressive Bee-Keeper.

Bee-Eggs by Mail.—J. F. Mundy reports that he received from Editor Pender (Australasian Bee-Keeper) by mail a small frame of eggs, and altho they remained in the post-office two days before he got them, they hatcht out all right, and he reared some good queens from them. The editor says the eggs should be sent the day they are laid.

A Storage-Tank for Extracted Honey is strongly urged by R. C. Aikin in the Progressive Bee-Keeper. He has one of five tons capacity of galvanized steel that cost him about \$40. It saves his keeping on hand cans to the amount of about \$100. Aside from the matter of expense, the tank is desirable to allow the honey to stand long enough for all impurities, such as bits of wax, to settle and be removed.

"A Perfect System for Managing Out-Apiaries in the production of extracted honey" is the somewhat pretentious title of an article by N. E. France in the Bee-Keepers' Review, the editor no doubt being responsible for the heading. After reading the article one is inclined to feel that the heading is not so very far out of the way, at least in so far as concerns the planning of work for the number of workers to the extent of six that go daily to the different out-apiaries, the whole seeming to be something like a daily picnic into the country. Editor Hutchinson was not idle with his camera when last visiting the Frances, so four half-tones illustrate the article.

The Honey-Bee the Horticulturist's Friend.—Prof. S. J. Hunter, entomologist of the Kansas State University, contributes a paper for the annual report of the Colorado Board of Horticulture for 1899, which is just received at this office. Prof. Hunter's subject is, "Some Entomological Problems in Horticulture." After enumerating many of the more injurious insects met by the horticulturist, he pays this worthy tribute to the honey-bee and its value to the fruit-grower:

Let us note a friend, the honey-bee, which visits orchard, vineyard, strawberries, blackberries and raspberries, and brings about great results. It was formerly supposed that plants fertilized themselves, but it has been more recently shown that many plants are so constructed as to prevent self-fertilization. Nature has so constructed the plant itself that it is impossible in some cases for the pollen of its own anthers to fall upon the stigma of its own ovary, but the stigma is fertile to pollen brought from other flowers of the same species. It is the intention of nature that insects shall carry the pollen.

During my field-work this season I had occasion to spend a short time in the vicinity of Rocky Ford, with Senator Swink, who is not only known to you, but to us who live outside of your State. He has been closely identified with

the melon-growing interest of the Arkansas valley in this State. Senator Swink noticed that the first blossoms on the melon-vines did not set, did not bear fruit, but that with the second or third blossoms there came a little wild bee to the blossom, and with its coming came melons also. Now, Senator Swink reasoned to himself, if that little bee can bring fruit to the second blossom, why not secure returns from the first blossoms? He distributed hives of bees among his melon-patches, and these bees have not only been fertilizers of melon-blossoms, doubling the average yield, but likewise they have furnished annually much excellent honey, artistically and skillfully stored, as many of us know who have visited the Colorado horticultural apartments.

Be sure that there are sufficient bees in the neighborhood, or at least within two or three miles, to visit properly the blossoms. When possible, endeavor to favor the bees by selecting a sheltered situation for the orchard, or by planting windbreaks.

About a third of the pamphlet report from which the foregoing is taken, is devoted to a very full report of the last annual meeting of the Colorado State Bee-Keepers' Association.

Nuova Guida Pratica Per L'Apicoltore Novizio is the name of a book received at this office, said book being written by Carlo Perrucci. Lack of a knowledge of the Italian language causes a lack of a suitable notice such as the book no doubt deserves. Names of prominent apicultural writers in other countries than Italy, not omitting some from this country, shows that as a text-book in apiculture it is not intensely local. Figures being the same in Italian as in English, it is interesting to note that the book is up-to-date in giving 15 days instead of a longer time for the development of a queen.

Keeping Bees in India.—Mr. Siaden says in the British Bee Journal that altho Italians have been introduced into India, the climate does not seem adapted to them, and they have disappeared. He says:

The only bee at present admitting of cultivation is *Apis mellifica*, variety *Indica*, various races of which occur in the hills and plains, and in Ceylon. It may be known roughly from honey-bees unsuited to cultivation by its medium size. The large bee, *A. dorsata* (about $\frac{5}{8}$ inch long), and the small bee, *A. florea* (about $\frac{5}{16}$ inch long), both of which build their combs *out in the open* from boughs of trees and shrubs, or from overhanging ledges of rocks, should be avoided except for experiment.

"Say What You Mean."—Mention was made on page 408 of instruction being given by an experienced writer to put a queen on top of a hive to introduce her, in which case it seemed that further particulars ought to have been given. The writer in question sends privately the following desired particulars, for which he will please accept thanks:

EDITOR YORK:—With regard to that queen, I will say for your edification that she should have a bandana parasol held over her by a little girl dressed in blue; and should have at least three pages, or four, who have been properly fed on sweets to fan her—keep her cool. When she issues from the cage she should have one or two of McKinley's Philippine warriors on hand to defend her in case some marauding Boer should conclude to do away with her majesty.

There are a great many other things that might be said with regard to her, but you being a man conversant with bee-lore and various other things connected with the sale of supplies, will fully understand that a busy man has not time to tell all of these things in one letter.

Wishing you success in your attempt to introduce this queen to a "hive," I am, Very truly yours,

We fully endorse the instructions except as to one item—the "bandana parasol." Of course, a "bandana parasol" is all right, but the easy inference is that no other parasol would answer. In this opinion we must dissent. In all

the cases in which we have tried parasols of different material, there seemed to be no advantage whatever in those of bandana. Of course, localities may differ, but we strongly suspect that the advantage of the bandana material is all in the imagination of our good friend.

The Weekly Budget

MR. A. I. ROOT, of The A. I. Root Company, called on us lately when in Chicago. He also went to see Dr. C. C. Miller.

MR. J. O. GRIMSLEY, of Overton Co., Tenn., Secretary of the National Queen-Breeders' Union, wrote us June 16th that they were having the "best honey season for several years. Bee-keepers are much encouraged."

MR. HARRY HOWE, of Cuba, wrote us recently that bees are starving where he is, and that there would be no honey until September. What with foul brood and starvation it would seem that bee-keeping is not all "a bed of posies" in Cuba.

MR. B. S. TAYLOR, of Riverside Co., Calif., dropt in to see us a week or two ago. He had been visiting relatives in Michigan. He keeps about 200 colonies of bees, but the honey prospects are not very flattering in his locality this year. Mr. Taylor went to California about 10 years ago for the good of his health, the doctors saying he could not live long. He has regained his health, and is doing nicely in his new home. California may not always have wonderful floods of honey, but it certainly has been able to do wonders for many in the way of restoring impaired health.

PROF. A. J. COOK, of Los Angeles Co., Calif., writing us June 25th, said this concerning the honey crop and prospects in California:

"Altho this is a very dry season in California, yet we are getting a very good supply of honey. There will be a good deal more than the bees require for their own needs. It seems to depend much on the time the rains come whether a small rainfall brings a honey crop or not. The present season was very early, and the flowers have continued to bloom for a long time.

"It will not be long before there will be large alfalfa fields in many parts of Southern California. This royal crop will be grown by irrigation, the water being pumped. This will make a honey crop independent of the winter rainfall, as is now true in parts of the San Joaquin valley. This is one of the gains from the recent dry years. People have learned of the great and invaluable reservoir beneath the ground."

MR. C. P. DADANT, of Chas. Dadant & Son, leaves for the Paris Exposition July 12th, the very date of this issue of the American Bee Journal. One of his daughters will accompany him. Mr. Dadant bears with him a duly authorized certificate showing his appointment as a delegate to represent our National Bee-Keepers' Association at the congress of bee-keepers to be held in Paris, Sept. 10th, 11th and 12th, or at any other meeting of bee-keepers which he may be able to attend while he is abroad. Certainly no other American bee-keeper could quite so well represent the bee-culture of United States in Paris as can Mr. C. P. Dadant. Being a native of France, and thoroly familiar with everything connected with bee-keeping the past 30 years or more, both in Europe and America, he is eminently qualified to represent the apiarists of his adopted country. And as he pays his own expenses, the National Association can only be the gainer all around.

All will unite with us in wishing Mr. Dadant balmy winds and a waveless sea—a pleasant voyage, and safe return.

H. G. Quirin, the Queen-Breeder,
Is as usual again on hand with his
improved strain of
GOLDEN ITALIAN QUEENS.

Our largest orders come from old customers, which proves that our stock gives satisfaction. We have 12 years' experience in rearing queens, and if there is any one thing we pride ourselves in, it is in sending all queens promptly BY RETURN MAIL. We guarantee safe delivery.

GENERAL ITEMS

Bees Booming.

Bees are booming. I have but four colonies in condition to store surplus, but they are working on the third super.
U. L. PEARSON.
Ford Co., Ill., July 3.

White and Yellow Sweet Clover.

I saw a few stems of white sweet clover in bloom here June 22d. The yellow variety had then been in bloom just 3 weeks. My plat of the yellow is now in full bloom, and some of the seed is in the dough state. I have plants of the white sweet clover 4½ inches high from seed planted by me just a month ago. It is no trouble to make the seed grow all right if planted right.
M. M. BALDRIDGE.
Kane Co., Ill., June 26.

A Notable Bee-Keeper.

Years ago I reared Italian queens. About the year 1862 I paid Mr. Parsons, of Long Island, \$50 for an Italian queen. I was living in California, and imported, in 1860, 66 colonies of bees from New York, by water, and sold to a Mr. Hay, 175 colonies for the same purpose. Of the 66 colonies, 60 arrived safely.

I knew Mr. Quinby quite well. I had in New York about 500 colonies of bees.

I commenced using the Langstroth hive in about 1857 or 1858, and I am using it still. I like it better than any other that I have ever tried. I take 4 bee-papers.
P. V. VEEDER.
Yolo, Co., Calif., June 25.

Introducing Queens—Cockroaches.

About May 15th I transferred an old colony from an old-fashioned hive to a new 9-frame hive. I could see no young brood and no sign of a queen or queen-cells; nothing but a little brood from laying workers.

I decided that there was no queen so I ordered one, which came all right. I examined the colony before introducing the queen and I found the bees all working, and lots of young brood on several frames doing well.

I had one more old colony which I transferred into two new hives, and put the new queen in one colony and the old queen in the other. They all went in with the new queen. Now comes the queer part of it:

Twelve days after they left the hive and brood a swarm issued and I put them in the same hive; three days after I took the sticks off the old brood was hatching out. Where was the queen in the first hive when I divided? Will brood live 12 days without any bees to keep it warm?

I saw an article on page 385 of this journal about enameled cloth. I bought two colonies that had enameled cloth for covering, and the underside of the cloth was just alive with cockroaches. I took the cloth off, did not put on any honey-board, and let them freeze out.

The Porter Spring Honey-House Escape

Shown in use on a window screen, reduced in size one-half, and having a part of the exterior broken away to give a view of the springs, is a perfect device for getting the bees out of extracting-rooms, house-apiaries, piles of supers, etc. It permits the bees to pass out thru it easily and rapidly, yet it absolutely prevents their return or the entrance of the most persistent robbers. Without a trial it is difficult to realize its value to the apiarist.

Mr. Kretschmer says of it: "I hasten to express to you my admiration for an article I have been waiting for so long a time. It is just the thing." And all who have used it similarly commend it.

DIRECTIONS.—Tack the escapes as shown in the engraving over holes punched thru the wire cloth at the upper corners of each window on which they are to be used, or over holes bored wherever convenient, if the enclosure is without windows.

PRICES: Each, 25c; per dozen, \$2.75, postpaid.

The Porter Spring Hive-Escape for getting the bees out of the super automatically before removal from the hive, which is similar to the escape shown above, is one of the most popular and useful apicultural implements of the day, and its friends have been gained by substantial merit alone. At the Columbian Exposition it won the highest and only award given an escape. Leading bee-keepers the world over use these escapes and give them their unqualified endorsement. Directions for use with each escape.

A Few Extracts from Testimonials:

They are perfect in action.—British Bee Journal.

I would not do without them if they cost \$5.00 apiece.—Wm. Muth-Rasmussen, Independence, Calif.

Bee-men are certainly behind the times if they can afford to use them and do not.—M. H. Meadleson, Ventura, Calif.

We cannot too highly recommend them. We intend to use them in all our apiaries hereafter.—Chas. Dadaut & Son, Hamilton, Ill.

I have 85 of them in use and don't see how I could possibly get along without them.—John Nippert, Phoenix, Ariz.

The most sting-proof bee-keeper will appreciate the Porter Bee-Escape with the first attempt and place it among the indispensables of the apiary.—Chas. F. Muth, in American Bee Journal.

The Porter Bee-Escape clears the super of bees so quickly and perfectly and easily that it makes the taking-off of honey a pleasure instead of a dread as in former years.—G. M. Doolittle, Borodino, N. Y.

PRICES: Each, 25c; per dozen, \$2.25, postpaid. Order of your dealer, or of

THE A. I. ROOT CO., Medina, Ohio, General Agents for the U. S.

They wintered well, and this spring when I transferred them not a roach was to be found.

I set each hive on a bench two feet high and two feet square, with a tight board fence on the north and west sides and cover. C. E. MINKLER.

Chemung Co., N. Y., July 1.

Good Prospect for Basswood.

My bees came thru the spring rather weak in numbers, as I lost about one colony in ten during the winter and spring. The past winter was the hardest one on bees for 30 years, with me. It is raining, and the bees can't do anything today, but the honey-flow has been good for 15 or 18 days from locust and poplar, tho there were not half enough bees to collect it all. Bees are in good condition now, and the prospect for the basswood bloom in this county was never better. I hope we will have good weather when it begins to bloom, which will be about the first of July. A. J. MCBRIDE.

Watauga Co., N. C., June 16.

Bees Doing Well.

Bees are doing a very good business at present, but we need rain very badly, as everything is drying up. I have 64 colonies all in good condition, and have already taken off some nice section honey. I have lots more almost capt. JOHN J. COX.

Chippewa Co., Wis., June 29.

A Busy Bee-Keeper.

With 24 colonies of bees that have cast 22 swarms, all successfully hived, besides two from somewhere unknown; putting up all my supplies myself, and running a jewelry store with a good line of repairing done by me, keeps me busy. Bees are doing well.

E. L. DUNHAM.

Weld Co., Colo., July 2.

No Swarms and Little Honey.

I have had no swarms and there is no immediate prospect of any. Bees are getting enough to live on from white clover. We generally get surplus honey here from goldenrod.

O. C. MASTIN, M.D.

Holt Co., Nebr., June 25.

Dry Weather and No Honey.

Bees are in fine condition, very few swarms, and white clover is abundant, but the dry weather has cut us out of a good yield of honey. C. ZOLL.

Marion Co., Ill., July 2.

Finding the Queen.

I read recently an article by Mr. Root telling how he finds queens. I find that the best way for me to find those black queens (the kind that will run all over the hive and hide in the corner or under the bottom-bars), is to put a super on top if the hive has none on, and smoke and drum them up into it; then place an empty super (with perforated zinc nailed to the bottom), on top of the hive, putting the super containing the bees on top of the one with the perforated zinc bottom, and the work is done. I hardly ever miss a queen—always find her on the zinc trying to

Yellow Sweet Clover Seed

WE HAVE IT AT LAST!

We have finally succeeded in getting a SMALL quantity of the seed of the YELLOW variety of sweet clover. This kind blooms from two to four weeks earlier than the common or white variety of sweet clover. It also grows much shorter, only about two feet in height. It is as much visited by the bees as the white, and usually comes into bloom ahead of white clover and basswood. We offer the seed as a premium

A QUARTER POUND FOR SENDING ONE NEW SUBSCRIPTION.

So long as it lasts, we will mail a quarter pound of the seed to a regular paid-up subscriber who sends us ONE NEW subscriber for the American Bee Journal one year, with \$1.00; or ¼ pound by mail for 30 cents.

We have been trying for years to secure this seed, and finally succeeded in getting it. It is

Yellow Sweet Clover in Bloom.

new seed, gathered last season by an old personal friend of ours, so we know it is all right. But we have only a small supply. When nearly out we will mention it.

The Bee-Keeper's Guide

Or, Manual of the Apiary,

—BY—
PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipt, or his library complete, without THE BEE-KEEPERS' GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,
118 Michigan Street, CHICAGO, ILL.

BY RETURN MAIL.

Golden Beauty Italian Queens,

Reared from imported mothers.

get thru. I can get the queen in this way quicker than I can tell by writing. I give them plenty of smoke, using excelsior for fuel as it gives plenty of smoke quickly, and I have no trouble in getting the queens. I usually smoke them up at night and take the queen away in the morning.

We have had dry weather here since fruit-bloom, and it now looks as if we would get little honey this summer. It is not much work to care for the bees, as they get enough to feed themselves, and that is about all. I hope to see some more honey coming in later on.

O. F. SNOW.
Barnstable Co., Mass., July 2.

Severe Drouth—No Clover Honey.

We have had a severe drouth here up to date, but had a nice rain this morning, with the promise of more. We will get no clover honey in this part of the State, but hope for a little basswood. Bees just began to work on it yesterday—July 1st.

Bees are in fine condition. Feed in the pastures is short and brown, and our cows are shrinking in their milk.

B. T. DAVENPORT.
Green Lake Co., Wis., July 2.

"Apis Mellifica" for Bee-Stings.

Several times I have noticed in bee books and papers discussions of remedies for bee-stings, and so far as I can see no one seems to have hit it yet. The homeopathic schools use a medicine called *Apis mellifica*, made from the poison of the bee, and used for swellings, inflammations, etc. I can stand the hurt all right, but I hate to be all swelled up, and if this is taken before a sting begins to swell it never swells at all. I have used this for about a year, and it never fails me when I take it in time:

One tablet of the 2d trituration is a

\$5.00 per month will pay for medical treatment for any reader of the American Bee Journal. This offer is good for 3 months ONLY—from May 1 to Aug. 1. Dr. Peiro makes this special offer to test the virtue of small price for best medical services. Reply AT ONCE.

DR. PEIRO,

If you want health and vigor, good appetite and sound sleep, take LAXATIVE NERVO-

A VITAL TABLETS, the quick and safe cure for Constipation, Nervous Dyspepsia, Insomnia, Nervous Affections, the "Blues" and all attendant evils. It aids digestion, purifies the blood, strengthens the nerves, improves the appetite, induces sweet sleep, tones up the whole system and makes you a new creature. It not only makes you feel well, it makes you really well. It gives you that vim and vigor which makes life worth living.

LAXATIVE

NERVO-VITAL TABLETS

It contains no narcotics nor bromides nor other injurious drugs. We give the formula with every box. You know exactly what you are taking. Originally put up for physicians' use. Ask your druggist for a **FREE SAMPLE.** If he hasn't it, don't take a substitute, but send us a stamp for our

book on "Health" and we will send you a free sample, sufficient for you to try it and test its merits to your own satisfaction. Isn't it worth trying free? It positively cures. Price 10c and 25c per box. Don't delay sending.

The Modern Remedy Co., Kewanee, Ill.

good dose. Repeat in 10 minutes, and again in 20 minutes. After that every half hour for eight or ten doses. When I start to work without a veil I sometimes take a dose, and then my blood is all ready for a sting if it comes.

E. A. LEWIS.

Montcalm Co., Mich.

Yellow Sweet Clover Valuable.

Yellow sweet clover was in bloom here June 1st, and probably several days earlier. The ordinary white variety did not bloom in that neighborhood until June 21st, tho a few blossoms were seen about a mile away June 13th. The bees workt well on it from the start. Basswood bloomed June 21st.

It is safe to say that yellow sweet clover is three weeks earlier than white sweet clover, or than basswood, which in my opinion should make it very valuable to the bee-keeper in a sweet clover country.

J. A. GREEN.

Lasalle Co., Ill., June 25.

Honey a Short Crop.

Honey here is going to be a short crop. There has been lots of white clover, but cool nights and rainy weather kept the bees from storing honey, and they have visited the white clover but very little. All colonies seem to be in good condition, but have stored no surplus.

R. R. RYAN.

Marion Co., Ore., June 26.

Plain Sections and Fences.

Please have a few *responsible* bee-keepers reply to this :

Can more honey be produced with plain sections and fences than with the old style sections? If so, why?

To the point—no hedging around.

Walker Co., Ala. R. V. Goss.

[We should be pleased to publish a few replies to the above from those who really have had sufficient experience to be competent to say.—EDITOR.]

A Report and an Experience.

Last year was such a poor season here that I did not think it worth while to report. Our bees wintered well, with scarcely any loss, and came out in the spring very strong. I now have 24 colonies, two natural and four artificial swarms. I am Italianizing as fast as I can. The bees are storing some honey in the supers. We had a dry spell that almost proved serious for the bees, but the abundance of rain we are now having makes the apiary musical with the joyful hum of the bees.

I have had a little experience that baffles my bee-ology. Some time ago I made a colony queenless with no brood young enough to rear a queen from, so I gave them a good, ripe queen-cell, and a few days later lookt at the cell and thought it was torn down by the bees. I then grafted in a piece of brood-comb three inches square, and they at once commenced three queen-cells, proving that they certainly did tear down the cell.

Then on the 12th day I lookt for results. I found one cell opened by a queen just hatcht, and to my astonishment I found brood in three stages—

SPECIAL NOTICE!

Last winter's cut of basswood is the whitest it has been for many seasons. We are now making sections out of this new stock and therefore are in a position to furnish you with the very finest quality in the market.

Four Celluloid Queen=Buttons Free AS A PREMIUM.

For sending us ONE NEW SUBSCRIBER to the Bee Journal for the balance of this year, with 50 cents, we will mail you FOUR of these pretty buttons for wearing on the coat-lapel. (You can wear one and give the others to the children.) The queen has a golden tinge. This offer is made only to our present regular subscribers.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate, it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

Prices of Buttons alone, postpaid: One button, 8 cts.; 2 buttons, 6 cts. each; 5 or more, 5 cts. each. (Stamps taken.) Address,

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO.

A HANDY TOOL-HOLDER!

Sent by Express, for \$1.50; or with the Bee Journal one year—both for \$2.00.

Every Manufacturer, Miller, Carpenter, Cabinet Maker, Machinist, Wheelwright and Quarryman, Farmer, or any on using a grindstone, should have one of these Tool-Holders. One boy can do the work of two persons, and grind much faster, easier and with perfect accuracy. Will hold any kind of tool, from the smallest chisel to a draw shave or ax. Extra attachment for sharpening scythe blades included in the above price. The work is done without wetting the hands or soiling the clothes, as the water flows from the operator. It can be attached to any size stone for hand or steam power, is always ready for use, nothing to get out of order, and is absolutely worth 100 times its cost. No farm is well-equipped unless it has a Tool-Holder. Pays for itself in a short time.

How to Use the Holder.

DIRECTIONS.—The Tool is fastened securely in the Holder by a set-screw and can be ground to any desired bevel by inserting the arm of the Holder into a higher or lower notch of the standard. While turning the crank with the right hand, the left rests on an steadyie the Holder; the Tool is moved to the right or left across the stone, or examined while grinding, as readily and in the same way as if held in the hands.

For grinding Round-Edge Tools, the holes in the standard are used instead of the notches.

Second-Class Queens,

(What Becomes of Them?)

As to color of progeny there are some tested queens that are second-class, that are equal to any for business. That is, 3-band bees predominate in the offspring of golden mothers. These are sold at 50 cents each. If 5-band bees predominate, and do not exceed 80 percent, they are worth \$1.00; above this and not to exceed 95 percent, \$1.25; all of a higher grade and not uniformly marked, \$1.50 each; while first-class breeders are placed at only \$2.00.

Untested, either 3 or 5-band, 75c each; or 3 for \$2.00. Money order office, Warrenton, N. C.

eggs, larvæ, and sealed. The next day I also found the young queen that had just hatched a day or two before. Now, the conclusion must be this: That the first queen-cell I gave them must have hatched, and the queen was laying, and permitted another queen to be reared. Of course, "I don't know."

H. W. HECHLER.

Keokuk Co., Iowa, June 28.

Smoking Bees Out of Sections.—

The following is given by F. L. Thompson in the Progressive Bee-Keeper, along with which should be the caution that too much smoke affects the taste of the honey:

"To remove the bees from a section super, Mr. R. D. Willis uses a box without a top, on which the super just fits. A hole at one end admits the nozzle of the smoker. When the super is set on and smoke pumped in, nearly all the bees find it impossible to remain, and the few left eventually leave thru the window-escape of the honey-house."

Non-Swarming—The Most Hopeful Field.—

I believe the most hopeful field for commercial bee-keeping lies in the improvement of the stock, in the direction of non-swarmling. There are some strains of bees not so much addicted to swarming as others. Take such a strain and use every means available to prevent swarming, breeding always from colonies that are not inclined to swarm, and I believe you will, in time, have a non-swarmling strain of bees. Bees have, in times past, been bred mostly from the worst swarmers; it is the easiest way to get good queens and increase for those who do not make a business of bee-keeping; but I think the time is coming when those making a business of bee-keeping will reverse this practice, and breed from those that don't swarm. Now, I will have to plead guilty to the charge of breeding from swarming colonies myself. I was, like all beginners, anxious for increase, and glad to have them swarm. I soon saw, however, that the colonies that did not swarm were a good deal the most profitable in honey; so I have reared a few queens from some that did not swarm, and they were away ahead of the average bees. The worst year for swarms that I have seen, about one-third of mine run for comb honey did not swarm. Other years I have had from none to 3 or 10 swarms from 30 to 50 colonies. But each season the bees have to be watched, and this watching is what we want to do away with.

There are many plans of dividing and uniting in the fall, and thus keeping down increase after a fashion, but we want the whole force of one queen to stay together thru the honey-flow in order to get good crops of fancy comb honey.

How to do this without any one on hand to watch for swarms is, in my judgment, the greatest problem now before the bee-keeping fraternity.—E. S. MILES, in Bee-Keepers' Review.

Langstroth on... The Honey-Bee

Revised by Dadant—1899 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroughly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for

one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.

118 Michigan Street, CHICAGO, ILL.

MARQUETTE, ON LAKE SUPERIOR,

is one of the most charming summer resorts reached via the Chicago, Milwaukee & St. Paul Railway.

Its healthful location, beautiful scenery, good hotels and complete immunity from hay fever, make a summer outing at Marquette, Mich., very attractive from the standpoint of health, rest and comfort.

For a copy of "The Lake Superior Country," containing a description of Marquette and the copper country, address, with four (4) cents in stamps to pay postage, Geo. H. Heafford, General Passenger Agent, Chicago, Ill.

Admirable Advice to Advertisers from "Agricultural Advertising."

Business men can not learn too much about advertising. If you are too busy with other branches to attend to your advertising yourself, the more you know about advertising and its methods and results the better you will be able to judge the ability of the advertising man you employ, and the results of his work.—The Ad Writer.

Profit from advertising depends not so much upon the number of inquiries received as upon the way in which they are handled. A hundred inquiries properly followed up are often of more value than a thousand replies which receive no more attention than the mere sending of a booklet, often a poor one at that.—Advertising Experience.

Possibly the best way to place the good qualities of your stock before the public is to get up a neat pamphlet containing sufficient useful information about the stock you are breeding to make it desirable to intending purchasers. This booklet is advertised, and either offered free or a slight charge is placed upon it to cover postage, which keeps away the simply curious. In such a book much more can be said and more cheaply than by writing letters.—E. J. W. DEITZ.

You wouldn't expect to plant a seed, never go near it again and expect it to bear fruit. Yet that's the way a great many people do advertising—simply put in the first copy that comes to them, run it week after week without change, and expect it to accomplish more than all the salesmen. Advertising properly done will work wonders in a business-bringing way, but, like a growing plant, it requires careful attention.—The Wheel.

Rocky Mountain Bee-Plant Seed!

(*Cleome integrifolia*.)

...FREE AS A PREMIUM...

The ABC of Bee-Culture says of it: "This is a beautiful plant for the flower-garden, to say nothing of the honey it produces. It grows from two to three feet in height and bears large, clusters of bright pink flowers. It grows naturally on the Rocky Mountains, and in Colorado, where it is said to furnish large quantities of honey."

We have a few pounds of this Cleome seed, and offer to mail a ¼-pound package as a premium for sending us ONE NEW subscriber to the American Bee Journal, with \$1.00; or ¼ pound by mail for 40 cents.

BEE = BOOKS

SENT POSTPAID BY

George W. York & Co. 118 Mich. St. Chicago.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopaedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers, \$1.00.

Biene-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Bienezucht und Honiggewinnung, nach der neuesten methode (German) by J. F. Eggers.—This book gives the latest and most approved methods of bee-keeping in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cts.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cts.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 20 cents.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, July 7.—Some new white comb honey is selling at 15c; not much offered and not much demand for it. Extracted is slow sale; best white, 7½@7¾c; best amber, 6½@6¾c; dark amber, 5½@5¾c. Beeswax, 27@28c.
R. A. BURNETT & Co.

CINCINNATI, July 2.—This market is completely bare of comb honey. The demand for extracted honey is good. Several good shipments of extracted honey from Mississippi and Arkansas have arrived and found a ready sale at 6½@7¾c. No white clover honey on the market; same would bring about 8c. Beeswax, 25@26c.
C. H. W. WEBER, 2146 Central Ave.

KANSAS CITY, June 20.—We quote: No. 1 white comb, 14@15c; No. 1 amber, 13@14c; No. 2 white and amber, 13@13½c. Extracted, white, 7½@8c; amber, 7c. No beeswax in the market.

We have a shipment of new comb honey in transit from Florida. The supply of old comb honey is very light, mostly caud.

DETROIT, May 24.—Fancy white comb, 15@16c; No. 1, white, 14@15c; amber and dark, 10@12c. Extracted, white, 7c; amber and dark, 5@6c. Beeswax, 25@26c.
Supply and demand for honey both limited.
M. H. HUNT & SON.

NEW YORK, May 21.—Our market is practically bare of comb honey, and there is a good demand for white at from 13@15c per pound, according to quality and style of package. The market on extracted is rather quiet, and inactive. New crop is slow in coming in, and prices have not yet been established. Beeswax holds firm at 27@28c.
HILDRETH & SEGELKEN.

SAN FRANCISCO, June 6.—White comb, 11½@12½c; amber, 8@10c. Extracted, white, 6½@7c; light amber, 6@6½c; amber, 5@5½c; Beeswax, 26@27c.

There is not much honey on market, either old or new. Small quantities of new comb and extracted are going to local trade at comparatively stiff values. In some instances, especially for comb, an advance on best figures warranted as a quotation are being realized. To secure export orders, however, of anything like wholesale proportions, prices above noted would have to be materially shaded.

WANTED—HONEY AND BEESWAX.

We have a tremendous and growing trade in this line, and would like to hear from all who have such goods to sell in any part of the country, with quality, description, and lowest cash price. THOS. C. STANLEY & SON, Fairfield, Ill.

WANTED COMB HONEY AND EXTRACTED HONEY. Will buy your honey, no matter what quantity. Mail sample with your price expected delivered in Cincinnati. 1 yr cash on delivery. C. H. W. WEBER, 2146 Central Ave., CINCINNATI, OHIO.

POULTRY BOOK FREE, 64 pages, illustrated, with 3 mos. trial subscription to our paper, 10c. INLAND POULTRY JOURNAL, Indianapolis, Ind.

Queen-Clipping Device Free...

The MONETTE Queen-Clipping Device is a fine thing for use in catching and clipping Queens' wings. We mail it for 25 cents; or will send it FREE as a premium for sending us ONE NEW subscriber to the Bee Journal for a year at \$1.00; or for \$1.10 we will mail the Bee Journal one year and the Clipping Device. Address,

MADE TO ORDER.

BINGHAM BRASS SMOKERS

made of sheet-brass which does not rust or burn out should last a life-time. You need one, but they cost 25 cents more than tin of the same size. The little peacock shows our brass hinge put on the three larger sizes.

No wonder Bingham's 4-inch Smoke Engine goes without puffing and does not

DROP INKY DROPS.

The perforated steel fire-grate has 381 holes to air the fuel and support the fire.

Prices; Heavy Tin Smoke Engine, four-inch Stove, per mail, \$1.50; 3½-inch, \$1.10; three-inch, \$1.00; 2½-inch, 90 cents; two-inch, 65 cents.

BINGHAM SMOKERS

are the original, and have all the improvements, and have been the STANDARD OF EXCELLENCE for 22 years. Address,

T. F. BINGHAM, Farwell, Mich.

I ARISE DOOLITTLE

To say to the readers of the BEE JOURNAL that

DOOLITTLE

has concluded to sell QUEENS in their season during 1900, at the following prices:

- 1 Untested Queen .. \$1.00
- 3 Untested Queens.. 2.25
- 1 Tested Queen 1.25
- 3 Tested Queens.... 3.00
- 1 select tested queen 1.50
- 3 " " Queens 4.00
- Select Tested Queen, last year's rearing, 2.50
- Extra selected breeding, the very best. .500

Circular free, giving particulars regarding each class of Queens, conditions, etc. Address,

G. M. DOOLITTLE,

11A26t Borodino, Onondaga Co., N. Y.

Please mention Bee Journal when writing Advertisers.

23rd Year Dadant's Foundation. 23rd Year

Why does it sell so well?

Because it has always given better satisfaction than any other. Because in 23 years there have not been any complaints, but thousands of compliments.

We guarantee satisfaction.

What more can anybody do? BEAUTY, PURITY, FIRMNESS, No SAGGING, No LOSS. PATENT WEED PROCESS SHEETING.

Send name for our Catalog, Samples of Foundation and Veil Material. We sell the best Veils, cotton or silk.

BEE-KEEPERS' SUPPLIES OF ALL KINDS.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.10, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO., 118 Mich. St., Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

AMERICAN BEE JOURNAL

ESTABLISHED IN 1861 OLDEST BEE-PAPER IN AMERICA

DEVOTED EXCLUSIVELY TO THE INTERESTS OF HONEY-PRODUCERS.

40th YEAR.

CHICAGO, ILL., JULY 19, 1900.

No. 29.

Mr. and Mrs. J. W. Hubbel and Apiary, of Clark Co., Wis.

Two Clark Co., Wis., Apiaries.

MR. Harry Lathrop, of Green County, about a year ago, visited a number of apiaries in Wisconsin, among them the two shown on this page. Afterward he wrote up his trip for the Wisconsin Agriculturist, from which we take these paragraphs:

"Peter J. Klein has an apiary of about 40 colonies. His principal honey-plants are dandelions, white clover, raspberries, basswood and asters. He informed me that in 1894 he took 900 pounds of comb honey from 3 colonies and increased them to 9. The honey was nearly all taken late in the fall from asters.

"Mr. Klein showed me a building made with double walls which he had constructed for the purpose of wintering his bees, but it was not a success, so he used it for a workroom and used his dwelling-house cellar for a winter repository. I have seen quite a number of such buildings and in most cases they have been put to other uses than that for which they were constructed. It requires very thick walls to make a building that will maintain an even temperature above ground. I saw such a building that is a success as a winter repository. It was built by H. R. Boardman, of Ohio. The walls are about 14 inches thick.

"After a few pleasant hours spent with Mr. Klein, during which time I was taken out in the great forest to examine the various honey-plants, he kindly provided a horse and buggy and together we went on to the home and apiary of John

Hubbel. Mr. and Mrs. Hubbel are both enthusiastic bee-keepers and have an apiary of 110 colonies all in good condition. With them, as with most others, the honey crop for 1899 was quite light, but they, like most bee-keepers, are of a hopeful turn, always seeing golden harvests in the future. For a short time we had a real lively bee-keepers' convention and then enjoyed a good farm dinner, prepared by the skillful hands of the bee-keeper's wife."

The Home Honey Market.

BY C. DAVENPORT.

ONE day last fall, while at work in the shop and honey-house combined, a stranger stepped in the door and greeted me with, "How do you do, Mr. Bee-keeper? Have you any nice white comb honey to sell this fine day?" He was the buyer for, and part owner of, a large grocery in a city some 20 miles distant. He bought and carried back in the light spring-wagon he came in, \$67 worth of honey, for which he paid 15 cents a pound. I mention this because it so well illustrates what I wish to emphasize in regard to developing the home market; and that old saying, "Rome was not built in a day," can aptly be applied here, for it takes time, a number of years, to discover and fully develop its full possibilities, in perhaps I may say the average locality; that is, it does when a strong, vigorous effort is made to do so.

Some bee-keepers might reside in the same locality un-

Apiary and Daughters of Mr. Peter J. Klein, of Clark Co., Wis.

til time had whitened their once black or red hair, without making much progress in this line; in fact, many imagine they have no home market to develop.

Again, let me cite something that will make my meaning in this respect clear. Some time ago Mr. F. L. Thompson, who, altho not engaged in our pursuit long, is a well educated, intelligent man, and a ready—indeed, I think, owing to the many remarks he has made about what I have said, he should be willing to allow me to say that he is almost a *too ready*—writer, told me in the American Bee Journal some time ago in a very interesting way how he attempted to develop his home market. Probably most of those who read this also read what he said, so I will only say that his plan was peddling or canvassing from house to house. He met with such poor success that he decided that in his locality there was no home market worth developing, at least for him.

Now note the case of Mr. R. C. Aikin, of the same State (Colorado); he has in time developed a home demand which I believe takes thousands of pounds more to supply than he produces, and if I am right he is engaged more extensively and produces much more honey than Mr. Thompson does; and from reading what both have said in regard to their localities, I judge that in Mr. Thompson's locality the possibilities for creating a large home demand were much better than in Mr. Aikin's. It is my belief that the only localities in which a large home demand can not be created are those in which lack of population prevents. But even in sparsely inhabited localities the chances are far greater than many would think.

Let us imagine a territory embracing 20 miles in each direction from a bee-keeper. Suppose it has only 10,000 inhabitants; this, counting the residents of the towns and villages it might contain, would be a very sparsely settled region, indeed, but if each person, on an average, consumed five pounds of honey yearly, tho it would mean only a small fraction of an ounce per day for each, and they could consume this much by taking it in the form of pills, the way Mr. Thompson has suggested, still it would take 50,000 pounds to supply their annual demand.

Of course, I am fully aware that there are many persons in all localities who do not, and who probably could not be induced to, use any honey at all; on the other hand, tho, there are many who consume more than five pounds annually, and a great many more that could without much difficulty be induced to do so.

Now, the only way that the consumption and demand for honey can be increased is by advertising. At first this seems like a strange assertion. I can imagine some one saying, "Cut the price down say one-half, and see if it does not increase its consumption and demand." My friend, that would be advertising in one of its most effective forms, but an unprofitable way to the producer.

Another might say, "I never advertise, but I produce a first-class article, and my sales are increasing each year." This is another and more profitable form of advertising; that is, in this case the goods advertise themselves, owing to their merit. But this form may under many conditions be far too slow to secure the practical results that would be attained in combination with other forms. Advertising combined with merit is the secret of success in almost all forms of business, and sometimes advertising alone brings great success in a financial way when merit is nearly, if not entirely, lacking; and the number of effective ways or forms of advertising are great and varied.

For instance, P. T. Barnum used elephants to plow with, not because the work could be done cheaper with them than with horses, but simply as an advertisement, and he took good care to see that the plowing done with these ponderous beasts was where it would be daily seen—not only by a great number, but also great numbers of different people. But it must be borne in mind that Barnum was too shrewd a man to expect any full or adequate immediate returns for this expensive work with animals that cost more money in those days than many of us can accumulate with bees in a lifetime, and no immediate returns could be expected from the large sums of money he spent to have long lines of railroad cleared. But again he took great care that the anxious, delayed passengers should know that they could not proceed because the road was cleared for Barnum, who was coming thru on a special train.

Now, many forms of advertising I have practiced to increase the local demand for our product have brought in far less immediate returns than the effort expended justified me in expecting, but, as with Barnum, it has all told in the long run, and the success I have achieved in this respect is due to advertising in varied ways the fact that I am a pro-

ducer of honey that is first-class of its kind. And in our pursuit no really permanent success can be obtained unless we produce first-class goods, but it is advertising that enables me to annually dispose of thousands of pounds in my local market, and which brings people from 20, and even 30, miles distant.

As I mentioned at the beginning, peddling from house to house I consider a poor method of advertising, at least so far as immediate returns are concerned, but it can be done in such a way that it will result in much future benefit. Of course, tho, locality and the man will make a great difference in the sales that can be made in a house to house canvass; this was my first method of trying to develop my home market, and it was persistently followed for some time, but this work was to me so disagreeable, and the results so far from what I desired, that it was long ago entirely abandoned for easier but much more effective methods of advertising, and altho I have perhaps already said more in relation to this matter than many will care to read, there is so much more I would like to say that I shall, if the editor permits, continue the subject in my next, in which will be described more in detail the most practical form of advertising that I have practiced.

Southern Minnesota.

Improvement in Stock the Most Hopeful Field in Commercial Bee-Keeping.

BY J. E. CRANE.

I DO not suppose that all of the honey secreted by the flowers will ever be gathered, even by the best of bees, still less will the best or most productive bees it is possible for man to produce ever get honey where none is to be had; but, if we can breed from our strongest and most industrious colonies till 50 or 75 such shall gather what 100 are now required to do, we shall at least save what it requires to keep the extra number of colonies. I believe we would better, for a time, look for *Apis dorsata in our own yards*. If we fail to find it, we may, perchance, find something even better.

I will not give in proof what a few isolated individuals have done, who are far away where distance lends enchantment, altho I might safely do so, but rather give a few facts from my own experience.

I became disgusted with the superior qualities of breeds as a whole. I had found some colonies of black bees greatly superior to the average Italian; while the qualities of the 3-banded Italians I had found, from many years experience, to be exceedingly variable. I advanced the theory that great improvements might be made by careful breeding for this purpose. That I might know what had already been accomplished I bought as good a queen as money would buy from a queen-breeder who I had reason to believe had for many years been trying to improve the productions of his bees. I was unprejudiced, and seeking for the truth. During the summer of 1898 I reared some 35 young queens from this purchast queen. Of course, these mated with my own drones, or drones from my old stock.

The spring of 1899 found me with enough of this cross to judge somewhat of its value. The colonies of this stock were scattered thru two yards, and had the same care as my old stock.

I did not have long to wait, however, to note a difference after the flowers began to bloom; for I could tell the hives containing these young queens about as readily by the extra amount of early honey gathered as by their color, which was quite distinct from my own. The season proved one of the poorest I have ever known, yet these bees showed their superior working qualities during the entire season.

In September, when I came to look my hives over to see how much honey each one had for winter, I found my old stock to average 10 or 12 pounds in their brood-chamber, while the new stock averaged not far from 25 pounds, nearly or quite enough to winter on.

Later (in November or December), I wisht to get rid of some honey in some old drone-combs, and placed them in the sun on the south side of the barn out of the wind, as the weather was quite cool, to see if perhaps the bees would take it out. I was surprised to notice that almost every bee that worked on it (and they were numerous) was the descendant of this purchast queen, as could easily be told by the color, while I had yet in my yard some 25 colonies of my old stock of bees. Whether trying to gather honey at so unseasonable a time of the year is a virtue, or otherwise, I will not attempt to decide, but it shows at least their vigor,

energy, and determination to get honey under adverse conditions.

Another point in favor of these bees, altho only a cross between superior stock and my own, was that they run very evenly; *i. e.*, what seemed to be true of one seemed to be true of all; showing that the queen I had purchast had come from stock bred for productiveness for many generations; and was capable of transmitting her good qualities in a very markt degree.

To accomplish such improvements in bees as I have outlined, the honey-producer should be able to rear all of his queens from the most productive colonies in his own yard, or from the best queens to be purchast; and this involves the necessary intelligence and skill for rearing artificially, with ease and rapidity, all his young queens from year to year.

In closing, let me say that however it may be with others, I am satisfied that, for myself, there is no direction in which I can make such decided and paying improvements in the production of honey as in the rearing of all my queens from the best and most productive stock to be found in my own apiaries, or that can be purchast for a reasonable sum of money.

To this end I shall devote my energies as never before, that the present season may show a large advance over the past in improving my bees.—Bee-Keepers' Review.

From the Freshly Laid Egg to the Fully Developpt Queen.

BY DR. C. C. MILLER.

ON page 199, Vol. I., of the American Bee Journal, the Baron of Berlepsch gives details of an experiment he made, in which queen-cells were sealed nearly ten days after the eggs were laid, and the queen emerged from the cell fully 18 days after the laying of the egg. In another experiment the time was 17 days. "These experiments," he says, "show that the opinion generally entertained, that the queens emerge between the 17th and 18th day after the eggs are laid, is correct." This was 40 years ago. Later, 16 days came to be accepted as the orthodox length of time for a queen, and still later some have called the time 15 days. T. W. Cowan says that queens mature "in from 14 to 17 days from the day the egg is laid." In a table of "Metamorphoses of Bees," British Bee-Keepers' Guide-Book, page 10, he gives what is probably meant to be the average, as follows:

1. Time of incubation of egg.....3 days.
2. Time of feeding the larvæ.....5 "
3. Spinning cocoon by larvæ.....1 "
4. Period of rest.....2 "
5. Transformation of larvæ into nymphs...1 "
6. Time in nymph state.....3 "

Total.....15 "

It is probable that a principal reason for the formerly accepted longer time, and for the considerable variation allowed by so good an authority as Mr. Cowan, comes from the fact that nuclei instead of full colonies were used in some of the cases for observation. Berlepsch used "a small forced swarm" in the experiment which gave him 18 days. Possibly if observations were always made with full colonies under favorable conditions, Mr. Cowan's 15 days might never be exceeded. It will be noted that Mr. Cowan has the larva fed 5 days, and Berlepsch nearly 7, Cowan's queen being sealed when 8 days old, and Berlepsch's when nearly 10, counting from the laying of the egg.

Incidentally, I made some observations last summer as to dates of sealing and hatching, while experimenting as related on page 834 of Gleanings in Bee-Culture for last year. It may be remembered that the five combs, *a, b, c, d, e*, were given in succession to the same queen to be laid in, so that every egg in any comb was older than all the eggs of any comb coming later in the list. I rather expected to find that the cells, both worker and queen, would be sealed in the order of their ages, all the cells of *a* being sealed before any cells in *b*, and so on. Such was not the case, for July 7 I found six worker-cells sealed in *b* while some cells were still unsealed in *a*. It might be supposed that the position might have something to do with it, the bees being more slow to seal cells in the outside comb, *a*. But this argument could not apply at the other side of the brood-nest, for July 12 I found 4 worker-cells sealed in *e*, while

there were cells still unsealed in *d*. It seems clear that in this case cells were not sealed strictly in the order of ages.

July 6 I found about 10 square inches of sealed worker-brood in *a* when the oldest larva was less than 8 days and 30 minutes old (I count always from the laying of the egg). This agrees with Cowan's table, "time of feeding the larvæ, 5 days." As some little time should probably be allowed for the sealing of 10 square inches, it is likely that some of the cells were sealed when the inmates were less than 8 days old. Next day at 4 p.m. some cells were still unsealed when all had past the age of 5 days 4 hours.

Comb *b* gave much the same testimony: Six worker-cells were sealed when none had past the age of 8 days 4 hours (they might have been considerably short of that), and a few cells were left unsealed when all had past the age of 8 days 2 hours.

On comb *e* four worker-cells were sealed when the oldest lackt 45 minutes or more of being 8 days old. On this same comb the last queen-cell started (with too old larva) was not sealed till it was 9 days 3 hours old or older.

July 5 I started an experiment for the sole purpose of deciding something about the times and seasons of development. At noon I gave to No. 84 an empty comb for the queen to lay in, and took it away 4 hours later, with about 80 eggs in it, putting it over an excluder on 51. This upper story was strong in bees, and it was no doubt well cared for. July 8, 4 p.m., only 5 eggs were hatcht. At this time all the eggs were at least three days' old, showing that most of them did not hatch till after 3 days old. I think others have reported considerably less than this, showing that the bees are not uniform in their proceedings, but very likely Mr. Cowan is right in giving 3 days as the time for eggs to hatch.

At this time, July 8, 4 p.m., the comb was given to No. 18, its queen, all its brood, and some of its bees being taken away at this time, leaving it a fair colony, but not strong. July 10, 6 a.m., larvæ were lavishly fed, several slightly enlarged as for queen-cells, and one hooded. One or several observations were made daily, but it is not necessary to recite all.

July 13, 6 a.m., one queen-cell sealed and one worker-cell. These were somewhere from 7 days 14 hours to 7 days 18 hours old. At 9 a.m. no change. At noon a few more worker-cells sealed. At 6:15 p.m. another queen-cell sealed. This cell must have been sealed when not more than 4 hours under 8 days old, and not more than 6 hours 15 minutes over 8 days old. These were perhaps the only queen-cells started with larvæ of proper age, for the age limit was reacht July 11, 4 p.m. But the bees continued to start queen-cells, and seemed especially desperate in the matter when the age limit had been past some two days, for 16 fresh queen-cells were started between July 13, 6:15 p.m., and 4:30 the next morning. It should be remarkt, however, that 4 other cells had been started soon after the age limit was past.

It would seem as if the attempt to make queens of too old larvæ had the effect to prolong the time of sealing beyond what it would have been if the larvæ had been treated thruout as workers. Notice what follows, and you will see that this is so. When the 8 days from the laying of the last egg had been past 12 hours 30 minutes, there were 16 queen-cells unsealed. At 17 hours past the 8 days, 9 were still unsealed. At 21 hours past the 8 days, 3 were still unsealed. At 25 hours past the 8 days, 2 were still unsealed. I am sorry to say there is no note when these last were sealed.

July 20, 6 a.m., no queen had yet emerged. At 10:25 a.m. one was out of the cell and was removed. This queen emerged from the cell in not less than 14 days and 14 hours, and not more than 14 days 22 hours 25 minutes after the laying of the egg.

There seems nothing in these observations to throw discredit on the table of Mr. Cowan, and it may not be an unfair inference that he drew his conclusions from colonies of fair strength while others used nuclei.

A practical consideration is that those who count upon 16 days from the laying of the egg to the emerging of the queen may have a fine batch of queen-cells destroyed by a queen emerging inside of 15 days.

It appears quite plain that bees are not uniform in their performances, and it would be nothing strange that the next experiment should give different results.

I am quite strongly of the opinion that there is much more variation as to the time of sealing queen-cells than there is in the time of sealing worker-cells. I have been surprised, sometimes, upon opening a sealed queen-cell, to find it occupied by so small a larva, and this with everything in prosperous condition. The bees can afford to vary no little with queen-cells, while such variation with worker

would be disastrous. As a rule the rations of the worker are carefully measured out, not an iota remaining unused; and if the larva should be sealed up a day or two before the usual time, the worker would be dwarfed if not starved. With a royal larva it is different. From first to last it has an excess of food, and if sealed up while quite small it has a sufficient supply to last. McHenry Co., Ill., Jan. 12.

[This article, as will be seen by the date, was written about the first of the year; but I have held it till now so that the interesting conclusions can be verified or disproved in the apiary. I should like to have our readers, especially queen-breeders, go into the matter carefully; for in a practical way it involves the matter of choice queens, and that means honey.

What surprised me is that in one of the experiments conducted the bees should have apparently waited so long before starting the bulk of the cells; for Dr. Miller says that 16 fresh queen-cells were started on the 13th of July, just 8 days after the eggs were laid, or 5 days after the larvæ were hatched. We have heretofore assumed that larvæ just hatched, or larvæ not more than three days old, was the preferred age; but here is a case where the bees evidently had a preference for the five-day limit. Now, the question is, was this exceptional with this colony, or is it the common average? Now, don't you see a great deal of importance attaches to this?—ED.]—Gleanings in Bee-Culture.

Moving Bees Short Distances.

BY I. W. BECKWITH.

UNDER the above heading G. M. Doolittle, on page 291, makes some statements that are likely to do mischief.

In the first place, he moves his bees with as little jar as possible; why, he does not say. It can hardly be on account of the danger of breaking down the combs, for unless they are new and full of honey, there is no such danger loaded in a wagon without any protection. Neither can it be that he thinks it necessary to avoid disturbing the bees with so much jarring, for when he gets them home he finds it necessary to pound on the hives and disturb them for a considerable time.

But the more important error that he makes is in the statement that the bees will not find the hive that is left to catch the returning bees, provided it is moved more than five feet from where their hive had formerly stood. If the hives had stood more than five feet apart it would be necessary to leave at least every other hive, which would allow very little choice in the strength of the colonies to be left; and then, when these were taken home there would nearly as many bees return and be lost as tho he had moved all at once; since those that returned from the first lot moved are the field-bees that would be liable to return again. And if the distance between hives should be more than ten feet, there would be no use in leaving any.

He says: "If you move the weaker colonies more than five feet you lose all the bees that fly from that;" and a little further along on the same page he says: "But after careful watching for many years I am satisfied that all such bees finally go back to their new location, if they have been treated as here given." I would like to ask Mr. D. which of these two statements is correct? I might report cases to show that neither is true, but will only relate one case, and I think the universal experience of observing bee-keepers is the same as mine.

On May 5th I bought nine colonies of bees from a neighbor living about 40 rods from my place, and that evening I moved seven of them home, leaving two very weak ones to catch those that should return. Four of the hives were scattered, having been left where the swarms were hived last summer, and two of them were 50 feet or more from where I left the "catcher." The other five were on a stand together. The next day I went there to see how they were getting along, and found that those two were catching the bees all right, the one where the five had been catching most of the bees.

After two days I brought home the one that had caught the most bees, and set the other in its place. Again, after two days, I brought this one home also, and took a very weak colony from home to put in its place, which caught quite a number of bees. The bees were working vigorously at this time.

Fremont Co., Wyo.

The Premiums offered this week are well worth working for. Look at them.

The National Queen-Breeders' Union.

BY J. O. GRIMSLEY.

AFTER reading the editorial on page 360, relative to the National Queen-Breeders' Union, I am convinced that Mr. York, like many others, has formed a wrong idea—probably from not being informed as to the real object of the organization. One thing leading to this conclusion is this, that he says: "Suppose the supply-dealers should form a union, telling how honest they are," etc. This has no bearing whatever on such an organization as the union of queen-breeders, and proves that he does not understand us. His reference to the "free advertising" is still further evidence that he misunderstands us—and my editorial in *The Rur-alist*.

I can not accuse Mr. York of being so selfish and short-sighted as wilfully putting an error before his readers; in fact, I must say he is a clean editor, always looking to the interest of his readers. Had I any other opinion of him I could not write for his columns at this time, or any other. I believe him sincere when he says: "We bear not the slightest ill-will toward the National Queen-Breeders' Union, or its members." Really, I believe a mutual friendship exists between Mr. York and each member of the Union. I make these remarks to show to the readers of the "Old Reliable" that no ill-will exists—his comment was timely, and, barring his lack of information regarding the Union, nothing can be said against it.

He says: "The National Bee-Keepers' Association is an organization of which every one at all interested in bees should be a member. It is not restricted to a half dozen or so people who have something to sell to bee-keepers, but it is in the interest of all who keep bees." Every word of that is true, and I might add further that bee-keepers everywhere stand in their own light by not joining the Association. I keep the card of the Association standing at the head of my column in *The Rur-alist*, and give it all the "free advertising" I can. The "half dozen or so people who have something to sell to bee-keepers" has an indirect reference to the National Queen-Breeders' Union. Of course the Union can't number up into the hundreds like the National Bee-Keepers' Association, for every bee-keeper can't be a queen-breeder, neither, indeed, will such ever be the case, but a majority of the bee-keepers are dependent upon the queen-breeders for just such stock as they need. Mr. Root recognized the fact that queen-breeders were not numerous when he wrote to me that "the queen-breeders can be counted on the fingers of your hands." I can hardly think they are so scarce as that, but the real, honest, up-to-date breeders may be—I can't say.

The National Queen-Breeders' Union blows its horn of "honesty" because no dishonest breeder can remain a member, and in case a member "beats" a customer, the Union is bound to make the loss good. That is no bad feature, is it? We number but few, I admit—always will, for there are few breeders—but we want every honest breeder in our ranks—they belong there, the bee-keepers are interested, and will be benefited.

"Free advertising" of the Union is like "free advertising" of the Association. The members of the Union are individual advertisers of queens, while the members of the Association are individual advertisers of honey, queens and supplies—in each case, of course, so far as advertising is required.

The fact that the Union guarantees honest and square dealings upon the part of individual members will make breeders slow to join, but we will number all honest breeders in our ranks when they fully understand what we are doing.

The Union fixes a standard for Italians, Golden Italians, Carniolans and Albinos, and will, as occasion requires, add others. In this we settle the name Golden Italian, and show what each class of queens must produce. Heretofore no standard was recognized, except as individuals might fix.

An application for membership must show how the surroundings are, as regards neighboring bees, and chances for pure mating—everything, in fact, tends to encourage every possible improvement, both in stock and methods of rearing. The organization is looking to something more than individual interests. It wants to benefit all, and is exactly the same class of organization as the National Bee-Keepers' Association, except it is composed exclusively of queen-breeders, and the members must be received by a vote. If its rules were not strict in that regard unscrupulous breeders would soon outnumber the honest, and the organization would be a farce.

Of course, it will take time to perfect the organization, and get its objects and good features properly before the

bee-keepers, but with the addition of most of the best breeders we will prove that our "pet scheme" is of as much worth to American bee-keepers as the National Bee-keepers' Association is.

The Boardman Feeder—Rendering Wax.

BY G. H. FREY.

NOT long since I saw the question asked as to what to do with Boardman entrance feeders to keep the feed from running out faster than the bees would take it. A few years ago I commenced keeping bees, and after reading books and papers on bee-keeping, and talking with experienced bee-keepers, I concluded it would be a good plan to feed, especially in the spring up to the time of the honey-flow. So I began to look for a good feeder, and after studying all kinds I decided to try the Boardman entrance feeder, as did some other bee-keepers here, one to the extent of getting 100 feeders, which he has not used yet.

After getting my feeders (20 in number), I found that no matter how level, or how careful I might be, the feed would run out as fast as possible, taking about five minutes to empty a quart jar. I worked and fussed with them until I became almost disgusted. At last I tried putting a piece of thin cloth over each jar before putting the cap on. Sometimes I would punch holes thru the cloth if it didn't let feed thru fast enough; but I found this unsatisfactory. Then I put my thinker at work again, and finally came to the conclusion that the hole cut in the cap was too large, so I tried some with a $\frac{3}{8}$ -inch hole cut in the center of the old cap, using both caps. This gave the best of satisfaction. Then I fixed all I had, which I use right along now, but I find in putting the special cap on the other cap they must be soldered as tight together as possible all around (not fastened all around, but just in three or four places).

I have had some experience in rendering wax from old combs. At first I tried melting and straining, but got very little wax. The past spring I made a press by taking two planks (hard wood) $5\frac{1}{2}$ feet long and 14 inches wide, hinged together at one end with three of the largest size strap hinges, the hinges being bent to fit over the ends of the planks, after putting a $\frac{3}{8}$ -inch thick strip of wood between the planks after the hinges are bolted on. There is a 3-inch square hole cut about 12 inches from the hinged end in the bottom plank, with heavy screen over it, such as is used in sand-sieves, nailed solid with small staples. The ends of the planks opposite the hinged ends are hewed off so as to be used as handles.

I use a large tin boiler to boil the combs in. They should be allowed to boil up well, so as to get all the wax melted. I also use a large size wooden tub, with a strip nailed across one side, down about 6 inches from the top, for the hinged end of the press to rest on. I also have a box for the handle end to rest on to keep the weight off the tub. Then, taking about half a grain sack, I put in $\frac{1}{2}$ gallon of the melted combs, and folding the sack as much as possible, I proceed to press it out, folding the sack until all the wax is prest out.

The press will need a strip of cloth on each side, and ckt on the top plank. Also, a piece across the top plank in front of the portion used as a press. Extracting wax is a job with all common methods, and this plan is no fun.

After all is prest out and cooled, take off the wax and melt it again in some water, and if very dirty it might be best to melt a couple of times, but in melting two and three times don't let it boil; just let it come to a boil, so as to have all the wax melted.

Linn Co., Iowa.

Candied Comb Honey—How Profitably Utilized.

BY A. M. APPLGATE.

THIS question has been frequently discussed thru the journals, and all the best methods given for saving the honey and wax; but in all these you destroy the comb and leave the honey so inferior in quality that you hardly realize enough out of it and the wax to compensate for the nice straight combs you sometimes have to melt in order to get the honey.

The method I will attempt to describe preserves the combs as nice as new, and instead of the second-class honey you have first-class vinegar, which will bring you as much money and be as easily disposed of. Besides, you are all aware that inferior honey should not be put on the market at any price.

Having provided a barrel with one head out, take the frames containing the candied honey, and where they are sealed comb them with the edge of a wire-cloth just enough to expose the honey. Sometimes there will be enough honey in the combs that can be thrown out to pay for uncapping and running them thru the extractor first. Then pack the frames containing the combs as snugly as you can in the barrel, noting at the time about how much honey they contain so that you will know how much water to add. Having the frames secured in the bottom of the barrel so they can not float, pour in water enough to cover them. You can hurry fermentation by adding a little yeast; or should you already have some fermenting, add a little of it to the one just prepared.

Two pounds of honey to one gallon of water makes very good vinegar; but you should keep it as much stronger as possible so that the water used to rinse the combs after they are thru fermenting and thoroly soured, may be added, making in all about one gallon of water to every two pounds of honey. The honey, and even the pollen that contains some honey, or has absorbed some of the sweetened water, will be fermented out of the cells. What is not removed in this way will shrink from the cell walls, when dry, and will jar out or be removed by the bees. To remove the vinegar from the combs turn the frames, with the top down, supporting them between the thumbs and fingers, let them drop onto some strips across the top of the barrel, gently at first, until the comb is relieved of some of the vinegar; then immerse them a few times in water, jar the water out in the same way, and use it to dilute the vinegar. Any additional rinsing will do no harm, neither is it necessary to have the combs entirely free from the vinegar.

I treated black-brood combs in the same way last summer, and thought what little vinegar adhered to the combs was an advantage.—American Bee-Keeper.

Value of Bees to Farmers, Fruit-Growers, Etc.

BY DANIEL WYSS.

FARMERS, fruit-growers, and gardeners should keep more bees. Will it pay? will probably be the first thought of the reader. Yes, it will pay to keep bees. We do a great deal of work every day for which we are not rewarded immediately, and for which we do not receive direct pay, but expect to be benefited later in an indirect way for such labor. The only profit most people could see in keeping bees would be the surplus honey obtained for family consumption or to put on the market. Bees are the best agents in fertilizing fruits. When fruit-trees bloom, bees visit the blossoms in quest of honey (nectar). This nectar is secreted in a basin in the lower part of the blossom. Around this basin are the stamens terminating at the top into anthers, which contain the pollen. Webster defines pollen as being the fecundating dustlike cells of the anthers of the flowers. The pistil is the female organ, and stands in the center of the flower. It consists of the ovary at its base, which contains the rudiments of the seeds. On the top of the pistil is the stigma which receives the fertilizing powder (pollen) from the anthers.

The two sexual organs—stamens and pistils—are, in certain species, united on the same flower, and in others on different flowers, and even on different trees. Some plants and trees are sterile to their own pollen. Quite a number of species of trees and plants are fruitless when only pollen from the same tree or plant is applied to their flowers; altho the same trees and plants mature fine fruits and seeds when pollen from other trees or plants is applied. This goes to show that it is absolutely necessary in order to raise perfect fruit and an abundance thereof from trees and plants that are sterile to their own pollen, that pollen from other plants or trees of different varieties of the same species be transmitted or carried to the flowers of these self-sterile varieties.

If any reader doubts the above statement, let him make an experiment with two Brighton grape-vines, planted 100 yards or more apart, and that distance from any other grape-vine. Then plant a Concord grape-vine within three feet of one of the Brighton vines, and none to the other. When these vines come into bloom probably as many bees will be found on the blossoms of the isolated vine as on the other two planted closely together. Some of the bees that will visit these two vines, will probably climb over every blossom thereon, and thus intermingle the pollen of the Concord vine with the blossoms of the Brighton, producing perfect fertilization by cross-pollination. This Brighton vine will bear large bunches, well and closely filled with

fine, well-developed berries of the best quality, while the isolated one will yield but few bunches of scattered berries.

A great many varieties of apples, plums and pears are self-sterile, and in order to bear perfect fruit must be cross-pollinated with pollen of other varieties of the same species. Cross-fertilization is strictly necessary for small fruits, such as raspberries, gooseberries, etc. In some seasons, when apples, plums, pears and cherries bloom, the weather is often unfavorable for pollination. It may be too cold and too wet, and the pollen remains too moist and too sticky. If during such seasons there would be but a few hours of sunshine, while the bees in great numbers would visit the blossoms, fruit would set abundantly, and a good crop would be the result. If, however, during the few hours of sunshine no bees would visit the bloom, very little fruit would set.

The honey-bee was wisely created to perform the transmission of pollen, its body being covered, especially on the underside, with many fine hairs of a compound, feather-like nature. When a bee alights on a flower, and whirls around on the same, its hairy body is soon loaded with pollen. Arriving on the next blossom some of the pollen comes in contact with the stigma of that flower, and is fertilized.

Thirty to 35 years ago fruits were more perfect and abundant. At that time there were ten colonies of bees to one at present, in this locality. In those days fruit-trees when in bloom fairly swarmed with bees. Mark the change in the spring when trees are blooming. Compare the number of bees you may see among the blossoms with those of former days.

Thirty-five years ago almost everybody kept bees. Our forests were then full of hollow trees where runaway swarms found lodging-places. From there they would swarm the next season. Runaway swarms from the apiaries, and swarms from the woods, were caught and put in common boxes, nail-kegs, etc. In the fall of the year when honey was wanted a colony or two would be slaughtered by "brimstoning" them. Admit that 35 years ago bees had a better range for gathering nectar (honey) than now. At that time our forests abounded in yellow poplar, linden, or basswood, and other nectar-yielding trees that are getting very scarce now. On the other hand, there is a better range of field flowers, white clover, etc. Three years ago this locality produced more white clover honey per colony than at any other time in 30 years.

Bees are not hard or difficult to winter if you give them some attention in the fall of the year. The writer has wintered from 12 to 25 colonies for 12 years without the loss of a single colony. Bees have other values than here set forth. Their stings are said to be sure cure for a great many cases of rheumatism. Cases have been reported in which the cure was almost instantaneous.

Bees, like stock, have been greatly improved by breeding. They are more docile, not so apt to sting as those of former days, and there is not much danger of getting involuntary treatment for rheumatism from them. Try it a few years, farmers and fruit-growers. Keep more bees, and you will be surprised to learn what a benefit they will be to you.—Tuscarawas Co., O., Weekly.

Belgian Hare Breeding is the title of a pamphlet just published, containing 10 chapters on "Breeding the Belgian Hare." Price, 25 cents, postpaid. It covers the subjects of Breeding, Feeding, Houses and Hutches, Diseases, Methods of Serving for the Table, etc. It is a practical and helpful treatise for the amateur breeder. (See Prof. Cook's article on page 292.) For sale at the office of the American Bee Journal. For \$1.10 we will send the Bee Journal for a year and the 32-page pamphlet on "Belgian Hare Breeding."

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it.

The American Fruit and Vegetable Journal is just what its name indicates. Tells all about growing fruits and vegetables. It is a fine monthly, at 50 cents a year. We can mail you a free sample copy of it, if you ask for it. We club it with the American Bee Journal—both papers one year for \$1.10.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Keeping Extra Queens Over Winter.

Can one keep extra queens over winter, that is, in a box—so that in case of a queenless colony one can resort to them?

ILLINOIS.

ANSWER.—The only way to keep queens successfully thru the winter is in a colony of bees or a nucleus. The trouble is to bring a nucleus thru the winter, unless it be pretty strong.

Colonies Killing Bees.

I have 16 colonies of bees, and today I lookt thru hive No. 5 at 1 p.m., and, finding them in a normal condition, went away. At 4 p.m. I lookt thru No. 11, that had one queen-cell capt. I noticed before I had closed it that they were fighting on the frames. I closed it up, and at 7:30 I saw at least a half gallon of bees dead at the entrance, about an equal amount at each, No. 5 and No. 11, which are about 3 feet apart, and are black bees. What is the probable cause of this trouble? I have been reading the Bee Journal nearly two years and don't recall a like case askt or answered.

I used planer shavings and a little tobacco in the smoker. The bees were still fighting at nightfall, and I gave them a good smoking. I must wait till morning to see the result.

KENTUCKY.

ANSWER.—A stray swarm may have tried to force entrance. Sometimes such a swarm will be kindly received, and at other times every one of the intruders will be killed.

Some Swarming-Troubles.

1. I have a colony of bees that has attempted to swarm several times; the queen being clipt she did not go with them upon the first swarming, so the bees returned. I then placed a perforated-zinc entrance-guard on the hive and have left it there ever since. The colony has attempted to swarm several times since putting on the guard, but of course in each case the bees have returned. I do not care for increase, and so have put entrance-guards on all my hives. What will be the result? Will not the swarms return each time they attempt to leave, and finally get to work all right. I have two supers on the first colony mentioned, and the bees are working in both. I prefer to have them store honey, instead of wasting their time attempting to swarm.

2. I have been thinking of trying the following experiment with the above colony:

Remove the hive from the stand and put on the brood-chamber a shallow extracting-super filled with frames of comb foundation. Then on top of it put a queen-excluder, and on that the two supers with the bees in them. After putting the queen in the shallow brood-chamber place the old brood-chamber beside the old stand, facing in the opposite direction. This would throw practically all the working-force of the bees back on the old stand, causing them, according to my idea, to fill the supers rapidly, and thus also prevent all further attempts to swarm. After two or three days I would remove the old brood-chamber to a new stand, letting them rear a queen. What do you think of this latter scheme as a method for preventing swarming, and also getting a honey crop? Later on the two colonies could be united for winter, and thus do away with increase that is not wanted.

A. B. S.

ANSWERS.—1. The entrance-guard will hold the queen, so that the swarm will be obliged to return, unless it hap-

pens to fall in company with a small after-swarm or some other colony having a flying queen, when it will leave you without ceremony. As soon, however, as the first young queen emerges, the frenzy to swarm will be redoubled, and there will very likely be cases (I had a number of them) in which the queen will get thru the excluder or thru some crevice, and away go the bees. In some cases the young queens will be successfully held, but exit for the queen must be allowed for the wedding-flight, or you will have a drone-laying queen.

2. I cannot clearly make out just what your plan is, but I think you mean to have the queen without brood in the lower chamber, and eventually all the old brood taken away. If rightly carried out, this will prevent swarming, and may result in a satisfactory crop.

Inside Measure of a 10-Frame Hive.

On page 374 Dr. Miller says the 10-frame dovetailed hive is $14\frac{7}{8}$ inches, inside measure. Is that right? I wrote the A. I. Root Co. last winter for their measure, and they said $14\frac{1}{4}$ inches inside. NEW YORK.

ANSWER.—I was wrong and the A. I. Root Co. right. I was a victim of misplaced confidence in the maxim that figures cannot lie. The 8-frame dovetail is $12\frac{1}{8}$ inside, and two more frames spaced $1\frac{3}{8}$ adds $2\frac{3}{4}$ to the $12\frac{1}{8}$, making $14\frac{7}{8}$. That's the way I figured it out, and I felt quite safe in those figures, not thinking that I had a 10-frame hive that I could measure. I have, however, three of the Draper barns, which are 10-frame, and I have just measured one, and find it $14\frac{1}{4}$. It seems that in the 10-framers no room is left for a dummy as in the 8-frame; hence the discrepancy. I certainly would not like to do without the dummy space in the 8-frames, and it would probably be an improvement in the 10-frames, but that wasn't the question, and I ought to have answered $14\frac{1}{4}$. As a spite shot at the A. I. Root Co. for getting me into this trouble, I may say that it is a difficult thing at present to get a frame out of the 10-frame hive, and after being in use two or three years in any locality where bee-glue is plenty, it will be simply unendurable.

Bitter Honey—Italianizing—Swarming.

1. I send you by this mail two vials of honey, numbered 1 and 2.

The honey in vial No. 2 I know whence it came, but vial No. 1, I am not so sure about. Can you tell me thru the columns of the American Bee Journal the plants it was gathered from? It is honey that was gathered early, say thru April and up to May 20, or thereabout. You will discover it is very bitter—in fact, so bitter we can't eat it, nor do we undertake to put it on the market.

The honey in vial No. 2 is (or will be when thoroly ripe) *very fine*, both in quality and body, as when well ripened it is very thick; in fact, so thick it will hardly run, and you notice from the sample it is real clear. This No. 2 vial, which is the large one, is sumac honey. If it doesn't rain too much my 34 colonies will store lots of sumac honey.

2. Did I do right in swapping frames of bitter honey stored in extracting-frames, for empty combs on the outside of the brood-chamber? thus, you might say, making 10 frames for queens to lay in.

3. Are 10 frames $13\frac{3}{4} \times 8\frac{3}{8}$ inches, inside measure, as much as ordinary queens will keep filled? My hives hold 12 of these frames, and I have seen every one chock-full of brood.

4. I ordered two golden Italian queens a few weeks ago, expecting to try to Italianize my entire apiary this fall after black drones were "done doing." Now, what do you think of this? I am quite sure I could accomplish it a great deal easier early in the spring, yet I prefer to do the Italianizing in the fall, that I may have laying queens ready for business early in the spring.

Will you give me your ideas about what you would do if in my shoes?

5. I have had only 4 swarms in 3 years that I am aware of. How's that? Lonoke Co., Ark.

ANSWERS.—I. I can't tell the source of the bitter honey. It reminds one of hoarhound, and in spite of its bitterness some might like it. It is not impossible that a demand might be created for it on account of medicinal qualities.

The sumac honey is not very heavy in body (possibly not well ripened), light in color, with a peculiar flavor

which is by no means unpleasant. If well ripened it is not hard to imagine it might be very fine.

2. Probably you could do no wiser thing than to give the bees frames of bitter honey in place of empty combs, thus getting the honey changed into bees.

3. There is a great difference in the capacity of queens. Some would not keep 12 frames like yours filled, and some would need more; 10 such frames are equal to about $8\frac{1}{2}$ Langstroth frames, and many queens find 8 Langstroth frames enough, while others need more.

4. I should certainly Italianize this fall rather than to wait for spring, having just that much the start, but if it were spring I don't think I should wait for fall.

5. If you have for 3 years kept from 10 to 30 colonies, and in that time have had only 4 swarms, you are very much to be envied. Please tell us what you think is the reason you have had so little swarming. The non-swarming question is a live one. J. O. Grimsley goes as far as any one can go in that direction, believing that the swarming propensity can be bred out entirely.

The Chicago Convention of the National Bee-Keepers' Association meets the last week in August, as will be noted by the following from Secretary Mason:

EDITOR OF AMERICAN BEE JOURNAL:—

Please allow me to remind the readers of the American Bee Journal that the next convention of the National Bee-Keepers' Association is to be held in Chicago, Ill., on the 28th, 29th and 30th of August next, commencing Tuesday evening, the 28th, at 7:30 o'clock.

The sessions will be held in Wellington Hall, No. 70 North Clark St., about a block and a half from the Bee Journal office, and about five blocks directly north of the Court House. The hotel at which members can secure lodging, etc., is the Revere House, southeast corner of Clark and Michigan St., only one-half block from the hall. Rates of lodging will be 50 cents per night, and several will have to occupy one room. To many bee-keepers this will be an "added attraction," especially as they will have good beds to sleep on, as Mr. York has been assured by the hotel proprietor. It may be possible that this hotel will not be able to accommodate all of the bee-keepers, altho the proprietor will do his best to see that it does. Each one attending the convention should secure a lodging-place as soon as possible after arriving in the city. There is usually no trouble in getting enough to eat at reasonable rates.

The program for the convention will be different from what it has usually been. There will not be to exceed one paper at each session, and the remainder of the time will be occupied in the asking, answering, and discussion of questions. The question-box will be in charge of such veterans as Dr. C. C. Miller, of Illinois; Rev. E. T. Abbott, of Missouri; D. W. Heise, of Ontario, Canada; C. P. Dadant, of Illinois; R. L. Taylor, of Michigan; O. O. Poppleton, of Florida; and the editor of the American Bee Journal.

On Wednesday evening the editor of Gleanings in Bee-Culture will give an "Illustrated stereopticon talk on bee-keepers I have met, and apiaries I have visited."

The papers will be from such noted ones as Thos. Wm. Cowan, of London, England; Dr. Wm. R. Howard, of Texas; Mrs. H. G. Acklin, of Minnesota; S. A. Niver, of New York; Herman F. Moore, of Illinois; and R. C. Aikin, of Colorado; and if you want to know what the papers are about, and assist in the discussion and enjoyment of the questions, please report in person at the above mentioned hall at the time indicated.

I have been unable as yet to learn what the railroad rates will be, but they probably will be as heretofore—one fare for the round trip from some localities, one and one-third from others, or a cent a mile each way in the Central Passenger Association territory. The exact rate may be learned by inquiring at any railroad station.

A. B. MASON, Sec.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us *one new* yearly subscription to the American Bee Journal at \$1.00.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY,
118 Michigan Street, Chicago, Ill.

[Entered at the Post-Office at Chicago as Second-Class Mail-Matter.]

DEPARTMENT EDITORS:

C. C. MILLER, "Questions and Answers." * * E. E. HASTY, "The Afterthought."

LEADING CONTRIBUTORS:

G. M. DOOLITTLE, C. P. DADANT, PROF. A. J. COOK,
F. A. SNELL, R. C. AIKIN, "OLD GRIMES."

IMPORTANT NOTICES:

The Subscription Price of this journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec00" on your label shows that it is paid to the end of December, 1900.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

VOL. 40.

JULY 19, 1900.

NO. 29.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

The National Queen-Breeders' Union.—Mr. J. O. Grimsley, the secretary of this organization, has an article on another page of this issue of the Bee Journal. He sets forth quite ably and fully the objects of the Union in which it is desired to invite all honest queen-breeders. Undoubtedly its aims are worthy, and it might be a good thing for the few queen-breeders in the country to get into the organization. And yet, we fail to see very clearly just why any of the bee-papers should devote much space to advertising it, any more than they should push the claims of the Carriage Manufacturers' Union, because bee-keepers need carriages, and ought to be told who are the honest makers. Or, to bring it nearer home, why should the bee-papers push a Bee-Supply Dealers' Union, if there were one in existence?

There are doubtless just as honest queen-breeders outside of the Union as there are in it. Shall the bee-papers, by devoting space to the Union, favor those breeders who have paid their \$10 membership fees, rather than those who are just as worthy outside of it, and who perhaps are more inclined to patronize the advertising columns of the bee-papers, than are the members of the Union?

By the way, for what purpose is the \$10 membership fee used? But perhaps that is none of our affair.

A Ventilated Double Gable Cover is the one that H. L. Jones says in the Australasian Bee-Keeper he has settled upon as the only satisfactory one, altho he has tried many

kinds, including flat, "Danzy," painted canvas, oilcloth, and tin roofs. A double cover has been somewhat called for in this country, but manufacturers have not seemed inclined to supply it, such a cover, however, having been mentioned in the Canadian Bee Journal as on the market in Canada. The advantage of a double over a single board cover is claimed to be that a hive with a dead-air space between its two parts acts as a non-conductor—warmer in winter, cooler in summer. One objection to the flat board cover is that when it doesn't warp it twists, so that as soon as it acquires a little age disagreeable cracks will be found between the hive and the cover. With the double cover the upper part may have the grain running one way and the lower part the other, such a cover allowing a close fit even when cold. The want for a satisfactory cover is yet to be supplied.

Colorado and Wax-Moths.—F. L. Thompson quotes in the Progressive Bee-Keeper the letter of Prof. Gillette, given on page 200 of this journal, which letter, and the words introducing it, Mr. Thompson thinks might be misleading. As the larva of the moth mentioned by Prof. Gillette does not feed upon wax and honey, he thinks it should not be said to infest honey-combs, but only pollen-combs.

Be Careful in Packing Bees for Shipment.—The British Bee Journal gives particulars of a distressing mishap in which the cover came off a hive prepared to be sent by train, and many persons were severely stung, the bees holding possession of the grounds till dark. The very greatest care should be exercised to see that by no possibility a single bee can escape in case of shipment, and even when hauling to an out-apiary for the first time it is very likely to be the case that some little leak has been overlooked, and a stinging reproof teaches more caution for the future. In case of shipment on the railroad, a safe rule would be to accept no bees from one who has had no previous experience in shipping, and that is practically the rule with railroads in this country.

Small vs. Large Bottoms for Queen-Cell Cups.—Since the production of cell-cups "by the peck," thus popularizing their use, there comes to the surface a difference of opinion as to whether the bottoms of the cell-cups should be of the same shape as the bottoms of queen-cells that bees prepare for swarming, or for a short distance the same size as the bottom of a worker-cell. As originally made by Mr. Doolittle, the cells had large bottoms, a portion of royal jelly was put in the cell, and the little larva placed thereon.

Then Willie Atchley conceived the idea of transferring part of the cocoon with the larva, paring down the comb containing the larva to be transferred, then lifting with tweezers the little cup of cocoon containing the larva, and placing both cocoon and larva in the cell-cup. To make this work more satisfactorily, he made the dipping-sticks upon which the cell-cups were formed somewhat pointed, so that for a little way the bottom of the cell was the size of worker-cells, then suddenly enlarging to the full size of the queen-cell.

Then W. H. Pridgen took up the matter, and took two long strides in advance. He conceived an arrangement for making the cells by wholesale, whether with large or small bottoms, and devised an ingenious arrangement to take the place of the tweezers. This latter consists of what he calls a "transfer," or transfer-stick. The end of this transfer is of such size as to fit snugly into the shallow cocoon, hollowed out at the extreme end, so that the larva is unharmed by the transfer. Pressing the transfer into the shallow cocoon, he lifts the latter and places it in the bottom of the

cell-cup, then after a little pressure withdraws the transfer, and the cocoon with its larva is left in the cell-cup ready for the acceptance of the bees.

The question now is, Which is better, the large bottomed cell-cup with its ration of royal jelly, or the smaller bottom with its transferred cocoon? The large bottom has on its side the advantage of priority, with a possible tendency toward preference for a plan already familiar. With the small bottoms, a piece of the comb must be cut out, care must be taken to have comb of sufficient age to make the cocoons sufficiently tough, and in cutting out the comb a lot of larvæ and young bees may be wasted. On the other hand it is replied that with proper care a piece of comb can be cut out containing larvæ all of the right age, and an inch square of such comb will furnish 50 larvæ, and a patch of dry comb can be put in to fill up the hole; that there is no trouble getting royal jelly and stirring it up to get it of the right consistency, but each cocoon carries with it its ration of food of just the right sort, and that such cells are more readily accepted by the bees.

Each side claims its plan as that of least labor, and it will probably take time to decide which is right, if indeed each is not right from its own stand-point.

Improvement in Stock is a topic that has sprung into prominence as never before during the past year. Mr. J. E. Crane has been working upon it in several successive numbers of *Gleanings in Bee-Culture*, and now discusses it in the *Bee-Keepers' Review*. Mr. Crane thinks it would be well if some of the energy displayed in getting up improvements in fixtures had been devoted to the bee itself. "If half the efforts," says he, "that have been spent in producing a non-swarming hive had been spent in producing a non-swarming breed of bees, I believe we should now have been far in advance of our present position."

In working for improvement, it should be not merely for gentleness, color, or purity of breed, but rather for best results in storing.

The best part of his article appears on another page this week.

Needs Laxative Nervo-Vital Tablets.—Editor Leahy is in "pain" because the advertisement of the Modern Remedy Co. is running in this journal, and says "the 'Old Reliable' gives space to a 'quack.'" Mr. Leahy, if you will read carefully the advertisement, you will find in it the following words: "We give the formula with every box. You know exactly what you are taking." When the ingredients of a remedy are given in full, it is not customary to denominate such remedies as "quack" remedies, nor the compounder as a "quack." If it were, then no physician or druggist would be free from the title of "quack." Better send for a free sample of the remedy, Mr. Leahy, and perhaps it will relieve you of some surplus bile.

Editor Leahy closes his painful editorial with these strange words:

"I do not believe I should enjoy paying \$200 a year for an advertisement in a publication that would sell some one else three times the space for only \$50 to ask me each week if I was full of ginger, or had the blues."

Editor Leahy, in the words quoted, does not say in plain terms that he would have to pay twelve times as much for advertising as do the Modern Remedy Co., but it can so easily be understood to bear that meaning, that we commend to our contemporary an ancient injunction which reads: "Thou shalt not bear false witness against thy neighbor."

The National Convention Next Month—don't forget it. The dates are Aug. 28, 29 and 30. The place—Chicago.

The Weekly Budget

MR. HARRY LATHROP, of Green Co., Wis., writing us July 8th, said:

"Our honey-yield has been fair, and is still coming, but basswood was cut short by storms."

CLOSED SATURDAY AFTERNOONS.—Those who might desire to call at the office of the *American Bee Journal* on Saturday afternoons during July, August, and September, will please remember that the office will be closed then. It is the custom of this office to close up during the time mentioned. We all need a little fresh air, and decided that there is no better time to take it in the whole year. So please call at any other time than that mentioned above.

MR. JOHN CALVERT, business manager of The A. I. Root Co., sailed for Europe July 3, going with the Christian Endeavor hosts to the International convention in London. Here is what he said further about his trip across the water:

"After spending ten days in London and vicinity we sail to Antwerp, and spend three weeks on the continent, visiting points of interest in Belgium, Germany, Switzerland, and the World's Fair in Paris. Returning to Great Britain we spend about three weeks longer visiting business acquaintances and friends, and may also attend the International Bee-Keepers' Congress in Paris in September."

AN ERROR CORRECTED.—Some time ago we published an item from a California newspaper which said that a Mr. Crowder, in that State, had 3,000 colonies of bees. Editor Root questioned the correctness of the statement, and so Mr. John H. Martin investigated the matter, reporting his finding in this paragraph in *Gleanings in Bee-Culture*:

"About that Mr. Crowder and his 3,000 colonies of bees, the statement of which was published in the *American Bee Journal*, and quoted from a Tulare paper. I am informed by parties who live near Mr. Crowder, that he has only about 800 colonies. The 3,000 story was a sensational and gross exaggeration."

We are glad to be able to make the correction, and can only regret having published the erroneous figures in the first place. However, as doubtless no real harm has resulted, perhaps we may be forgiven this time—provided we promise not to do it again.

ONE ON HASTY.—Like Bro. Doolittle's old Dutchman, I should like to "arise and ask" what's the matter with E. E. Hasty? Let me quote what he says on page 343, *American Bee Journal*: "Your best girl, if rescued from the ruins of a house wreckt by a tornado." That's a whole romance in a nutshell. When a staid old bachelor like Hasty gets to raving about best girls and tornadoes, there's something worse than a tornado behind it. Yes, sir; it is a strong indication of matrimony. Didn't think that of you, Bro. Hasty (tears, onions in my handkerchief).—J. H. MARTIN, in *Gleanings in Bee-Culture*.

Now, that's a pretty how d' ye do. First thing we know, both of them—Hasty and Martin—will be "taken in" by "best girls." Then there *will be* tornadoes and sich like. But, then, any man—or two men—that will persist in going it alone as long as Hasty and Martin have been at it, deserves a good shake up. And if it takes two "best girls" to do it—and they do it well—we'll hurrah for the "best girls." (Please signal us when it's time to hurrah.)

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

H. G. Quirin, the Queen-Breeder,
Is as usual again on hand with his improved strain of
GOLDEN ITALIAN QUEENS.

Our largest orders come from old customers, which proves that our stock gives satisfaction. We have 12 years' experience in rearing queens, and if there is any one thing we pride ourselves in, it is in sending all queens promptly BY RETURN MAIL. We guarantee safe delivery.

GENERAL ITEMS

There's Music in the Air To-Day.
BY DAVID HALL.

Oh! there's music in the air to-day, for in the forest near,
The lindens are in blossom and the bees
Are making that glad murmur so delightful to the ear—
Dear as the sweetest choral symphonies.

From each hive they're rushing wildly in their eagerness to win
The wealth within those nectar-laden flowers;
And toiling home with weary wing, just see them tumble in—
From early morn till twilight's golden hours.

How it warms the heart and stirs the pulse, at such a scene as this,
And the bee-keeper who has not felt its power Has not yet attained that eminence in earthly bliss
Which the buoyant heart demands in such an hour.

Then, woodman, spare the linden-tree, preserve its generous shade,
Its beauteous form now waving in the breeze;
For memories dear come back to me, how I in childhood played
There, listening to the humming of the bees.
Wyoming Co., N. Y., July 8.

Alfalfa as a Honey-Plant.

Referring to Australian honey-plants, on page 425, lucerne or alfalfa is mentioned as not yielding any honey until the third year. That is true for this (Atchison) county. Three years ago I sowed some alfalfa south of my apiary, but I have not at any time seen on it over 10 bees to the acre, and I have kept close watch, too, because this field is where I pass along several times very nearly every day, if I am at home. Alfalfa is on both sides the road, but this year, from the second crop of alfalfa the air is scented and full of bees humming going from and to the patch.

There was much white clover here this year, in my bee-range, there being about 1,000 acres, counting 1½ miles each way. This is a good honey-year for my bees.
ALBERT WILTZ.
Atchison Co., Kan., July 9.

Light White Honey Crop.

The white honey crop is going to be quite light in this vicinity. Basswood was full of bloom, but yielded little nectar. White clover is coming up quite profusely since the heavy rains, and may yield some honey. I am looking for a good fall flow.
C. H. STORDOCK.
Winnebago Co., Ill., July 11.

Introducing a Capt Queen-Cell.

Often the question is askt, how can I introduce to a queenless colony a capt queen-cell, and protect it from being torn down? The best plan that I know of, and I've tried more than one, is to take a wire-cloth cone—such as is used in bee-escapes—and carefully insert the queen-cell, so that the capping shall just protrude thru the apex of the cone; then carefully fold the corners together and give the points a twist so that they will not separate, and you have a protector that is complete.

Place the cell thus protected between Sharples Cream Separators: Profitable Dairying

The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

GEORGE W YORK & CO.
118 Michigan Street, CHICAGO, ILL.

The Porter Spring Honen-House Escape

Shown in use on a window screen, reduced in size one-half, and having a part of the exterior broken away to give a view of the springs, is a perfect device for getting the bees out of extracting-rooms, house-apiaries, piles of supers, etc. It permits the bees to pass out thru it easily and rapidly, yet it absolutely prevents their return to the entrance of the most persistent robbers. Without a trial it is difficult to realize its value to the apiarist.

Mr. Kretschmer says of it: "I hasten to express to you my admiration for an article I have been waiting for so long a time. It is just the thing." And all who have used it similarly commend it.

DIRECTIONS.—Tack the escapes as shown in the engraving over holes punched thru the wire cloth at the upper corners of each window on which they are to be used, or over holes bored wherever convenient, if the enclosure is without windows.

PRICES: Each, 25c; per dozen, \$2.75, postpaid.

The Porter Spring Hive-Escape for getting the bees out of the super automatically before removal from the hive, which is similar to the escape shown above, is one of the most popular and useful apicultural implements of the day, and its friends have been gained by substantial merit alone. At the Columbian Exposition it won the highest and only award given an escape. Leading bee-keepers the world over use these escapes and give them their unqualified endorsement. Directions for use with each escape.

A Few Extracts from Testimonials:

They are perfect in action.—British Bee Journal.

I would not do without them if they cost \$5.00 apiece.—Wm. Nuth-Rasmussen, Independence, Calif.

Bee-men are certainly behind the times if they can afford to use them and do not.—M. H. Mendleson, Ventura, Calif.

We cannot too highly recommend them. We intend to use them in all our apiaries hereafter.—Chas. Dadant & Son, Hamilton, Ill.

I have 85 of them in use and don't see how I could possibly get along without them.—John Nippert, Phoenix, Ariz.

The most sting-proof bee-keeper will appreciate the Porter Bee-Escape with the first attempt and place it among the indispensables of the apiary.—Chas. F. Muth, in American Bee Journal.

The Porter Bee-Escape clears the super of bees so quickly and perfectly and easily that it makes the taking-off of honey a pleasure instead of a dread as in former years.—G. M. Doolittle, Brodino, N. Y.

PRICES: Each, 20c; per dozen, \$2.25, postpaid. Order of your dealer, or of

THE A. I. ROOT CO., Medina, Ohio, General Agents for the U. S.

the top-bars in the center of the colony, properly cover it up, and in due time the young queen will emerge and be accepted. I've introduced many in this manner, and have yet to record a failure. The cones can be made by any one, about as fast as he can count, if he is a little slow in counting.

We have a bee-keeper in this town who told me a few days ago that he once ate 3 pounds and 8 ounces of honey at a sitting. Next.

WM. M. WHITNEY.

Kankakee Co., Ill.

Not Much Surplus Honey.

There has not been much surplus honey gathered in this neighborhood. Bees swarmed freely the last of May and the first part of June. We had no rain for about a month, so there has been no nectar for them to find of late. The first growth of alfalfa the bees did not work on, and the second growth with rain does not seem to yield much, but on buckwheat bloom the bees are very busy. But how the supers will be is hard to tell.

Comb honey sells from 15 to 20 cents a pound, and very little found at those prices.

R. C. SUPPE.

Woodson Co., Kans., July 10.

Not a Fourth of a Crop.

I am sorry to say that the honey harvest is over here, and we have not harvested $\frac{1}{4}$ of a crop. The last week of hot weather with high wind has dried up all white clover, and there are no prospects for any fall honey of any kind. Bees swarmed very little—out of 215 colonies I had only about 20 swarms. Bees are idle now.

N. STAININGER.

Cedar Co., Iowa, July 9.

Severe Drouth in Minnesota.

We have past thru the severest drouth Minnesota has ever experienced. The rains have come now, and will help us out in a good many things, but is too late for wheat and oats, also for honey. Basswood is nearly over, and it yielded very little honey. The most

If You Want Bees

The Bee-Keeper's Guide

Or, Manual of the Apiary,

—BY—
PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without **THE BEE-KEEPERS' GUIDE**.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

of the fall honey-plants are dead. If the bees get enough for their own use I will be thankful. **E. B. LANGDON.**
 Douglas Co., Minn., July 7.

May Have to Feed for Winter.

Up to June 12 bees flourished well, and stored a large amount of honey. As sourwood is not yielding nectar I am thinking that bee-keepers in tide-water Virginia will be compelled to feed for the coming winter, as I have to do when that source fails, and that has failed for the past 3 years.

I think that my bees are thru swarming, as I have not had any issue to-day. My spring count was 29 colonies, increased to 87, and I had several swarms go to the woods.

J. H. ALLEN.
 Nansmond Co., Va., July 2.

A Queer Season for Bees.

This is a queer season. In early spring the bees gathered considerable honey, and they gather some yet, but it is rainy nearly every day, so the hives do not fill up very fast. The willow-herb is in full bloom now, fully a month earlier than usual.

HANS CHRISTENSEN.
 Skagit Co., Wash., July 6.

Not a Favorable Season.

The season has not turned out as favorably as the early spring promised. June came first cool and dry, then hot, dry and windy. This pushed the bloom ahead rapidly, and while the season was short it did not yield heavy either, as is sometimes the case under such circumstances. Sweet clover, which usually begins to bloom about June 20th, is now almost ripe, the earliest I ever knew it to dry up. Basswood was

\$5.00 per month will pay for medical treatment for any reader of the American Bee Journal. This offer is good for 3 months ONLY—from May 1 to Aug. 1. Dr. Peiro makes this special offer to test the virtue of small price for best medical services. Reply AT ONCE.

Hardly Making a Living.

Bees are hardly making a living with basswood in bloom. They are working on over-ripe strawberries and red raspberries.
J. W. PARKER.
Onondaga Co., N. Y., July 7.

Basswood Almost a Failure.

Bees are doing well here on white clover, but basswood bloom has been almost a failure, on account of the cold and wet weather during its blooming time, which was of short duration this year.
N. YOUNG.
Hardin Co., Iowa, July 9.

A Short Report.

I started in the spring with 6 colonies in 8-frame single-story hives, and one colony in a two-story one. I divided them so as to give each hive four combs of brood and honey, or simply took one-half out, and put it into another hive, making 16 colonies in all. I have 16 strong colonies, and have taken 112 pounds of salable section honey; 14 colonies work in the sections well, but 2 won't work in them at all. I have baited them with partly filled sections, and the bees carry the honey down in the brood-chamber. The combs there seem to have plenty of honey in them.
FRED TYLER.
Mason Co., Ill., July 9.

A Thankful Bee-Keeper.

This report is a little premature, as our honey-flow is not over yet, but I am so thankful for what I have got so far that I could not wait any longer. The season here in fruit-bloom was perfect for the bees, and they filled the hives to overflowing, and increast wonderfully fast: but after that, until June 23d, they did nothing. On June 21st I found 3 colonies that had not one bit of honey in their hives, so I fed them on that date and the day after. There was no white clover here. On June 24th I found that there was some honey coming in, and on that date I put a hive on the scales, the record being as follows:

June 25.....	gain	5¾	pounds
" 26.....	"	5½	"
" 27.....	"	5¼	"
" 28.....	"	6	"
" 29.....	"	4	"
" 30.....	"	3¾	"
July 2.....	"	5	"
" 3.....	"	4	"
" 4.....	"	5½	"
" 5.....	"	5	"
Total.....		50¾	"

While this is no great yield, I think it is pretty good when the sugar-barrel in the fall was staring me in the face, for we have no fall flow in this vicinity. Basswood did a little here, and there was some alsike a mile or so away, but 2½ miles from here there is 17 acres of white clover that I am told the owner is going to let go to seed, and then cut it. It is a new venture with him, but he thinks it will yield between four and five bushels of seed to the acre. I think

SPECIAL NOTICE!

Last winter's cut of basswood is the whitest it has been for many seasons. We are now making sections out of this new stock and therefore are in a position to furnish you with the very finest quality in the market.

LEWIS WHITE-POLISHT SECTIONS

Are perfect in workmanship and color. Orders shipt immediately upon receipt. A complete line of everything needed in the apiary. Five different styles of Bee-Hives. Lewis Foundation Fastener simplest and best machine for the purpose. Price, ONE DOLLAR, without Lamp.

SEND FOR CATALOG.

Four Celluloid Queen-Buttons Free AS A PREMIUM.

For sending us ONE NEW SUBSCRIBER to the Bee Journal for the balance of this year, with 50 cents, we will mail you FOUR of these pretty buttons for wearing on the coat-lapel. (You can wear one and give the others to the children.) The queen has a golden tinge. This offer is made only to our present regular subscribers.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate, it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

Prices of Buttons alone, postpaid: One button, 8 cts.; 2 buttons, 6 cts. each; 5 or more, 5 cts. each. (Stamps taken.) Address,

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO.

QUEENS!

Untested Queens, Italian, 60 cents. Tested, \$1.00.

A HANDY TOOL-HOLDER!

Sent by Express, for \$1.50; or with the Bee Journal one year—both for \$2.00.

Every Manufacturer, Miller, Carpenter, Cabinet Maker, Machinist, Wheelwright and Quarryman, Farmer, or any one using a grindstone, should have one of these Tool-Holders. One boy can do the work of two persons, and grind much faster, easier and with perfect accuracy. Will hold any kind of tool, from the smallest chisel to a draw shave or ax. Extra attachment for sharpening scythe blades included in the above price. The work is done without wetting the hands or soiling the clothes, as the water flows from the operator. It can be attached to any size stone for hand or steam power, is always ready for use, nothing to get out of order, and is absolutely worth 100 times its cost.

No farm is well-equipped unless it has a Tool-Holder. Pays for itself in a short time.

How to Use the Holder.

DIRECTIONS.—The Tool is fastened securely in the Holder by a set-screw and can be ground to any desired level by inserting the arm of the Holder into a higher or lower notch of the standard. While turning the crank with the right hand, the left rests on a steady the Holder; the Tool is moved to the right or left across the stone, or examined while grinding, as readily and in the same way as if held in the hands.

For grinding Round-Edge Tools, the holes in the standard are used instead of the notches.

Address, **GEORGE W. YORK & CO.,**

Second-Class Queens.

(What Becomes of Them?)

As to color of progeny there are some tested queens that are second-class, that are equal to any for business. That is, 3-band bees predominate in the offspring of golden mothers. These are sold at 50 cents each. If 5-band bees predominate, and do not exceed 80 percent, they are worth \$1.00; above this and not to exceed 95 percent, \$1.25; all of a higher grade and not uniformly marked, \$1.50 each; while first-class breeders are placed at only \$2.00.

Untested, either 3 or 5-band, 75c each; or 3 for \$2.00. Money order office, Warrenton, N. C.

Yellow Sweet Clover Seed

WE HAVE IT AT LAST!

We have finally succeeded in getting a SMALL quantity of the seed of the YELLOW variety of sweet clover. This kind blooms from two to four weeks earlier than the common or white variety of sweet clover. It also grows much shorter, only about two feet in height. It is as much visited by the bees as the white, and usually comes into bloom ahead of white clover and basswood. We offer the seed as a premium

A QUARTER POUND FOR SENDING ONE NEW SUBSCRIPTION.

So long as it lasts, we will mail a quarter pound of the seed to a regular paid-up subscriber who sends us ONE NEW subscriber for the American Bee Journal one year, with \$1.00; or ¼ pound by mail for 30 cents.

We have been trying for years to secure this seed, and finally succeeded in getting it. It is new seed, gathered last season by an old personal friend of ours, so we know it is all right. But we have only a small supply. When nearly out we will mention it.

GEORGE W. YORK & CO.,

118 Michigan St., - CHICAGO, ILL.

Please mention Bee Journal when writing advertisers.

it will be a paying crop. The owner is not a bee-keeper, but he tells me the field is perfectly alive with bees, and when a storm comes up here, and the bees come home in a hurry, it seems they nearly all come from his direction, and as I know there is no beepasturage between my apiary and his field of white clover, I presume there is where some of my honey has come from.

I have been bothered with only a couple of swarms so far, and do not now expect any more. In fact, I am never bothered much with swarming for some reason. Altho I run for comb honey, my experience is at variance with others who have excessive swarming.

Well, I am thankful for what honey I have secured, and I do not have to feed this fall, as the prospect for so doing was so fair for the last month before the flow came.

The omission of weight on July 1st was caused by adding another case of 30 sections, it being a 10-frame hive.

One thing I have found out is, that it is as Mr. E. R. Root says, the double-deckers are not so good for comb honey until the deck is taken off at the commencement of the flow.

CHAUNCEY REYNOLDS.
 Sandusky Co., Ohio, July 6.

Bees Hatching Hens' Eggs.

I have been using the plan of having the bees hatch hens' eggs all spring, and it is all that I have claimed for it. Out of 100, and perhaps a dozen more fertile eggs, every one hatcht a good, strong chick, no crooked legs or half-dead ones. I have applied, and shall have the plan before the public before next spring. It will be very cheap, and any bee-keeper can use it without much extra expense, as the bees are not interrupted in the least. I use a chaff hive for the purpose, with chaff cushions, which act as a hen, and the eggs are placed above the bees, where they are kept warm from Feb. 15th till late in the fall. I think after a person tries this plan he will have no use for complicated incubators or cross sitting-hens. I have had the plan in mind for three or four years, but this is the first time I have tested it, and I have never heard of it being used by any one before.

JOHN G. NORTON.

McDonough Co., Ill., July 5.

The Glucose Yarn Still Going.

I clipt the following from a paper, it having been written by J. S. Trigg, Iowa's most noted agricultural writer:

"Now here is a sweet, mean trick if ever there was one. A man in an eastern town keeps a lot of bees, and has discovered that if the bees can get glucose to eat they will not bother to forage for the sweets of the flowers, but will work most industriously filling the ready-made comb furnisht with glucose honey!"

Of course, Mr. Trigg got the idea from the article referred to several times in the American Bee Journal.

**25 cents Cash
 paid for Beeswax.**

This is a good time to send in your Beeswax. We are paying 25 cents a pound—CASH—for best yellow, upon its receipt, or 28 cents in trade. Impure wax not taken at any price.

Address as follows, very plainly,

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO.

Langstroth on... The Honey-Bee

Revised by Dadant—1899 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helpt on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for

one year—both for \$1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.

118 Michigan Street, - CHICAGO, ILL.

Queens

UNTESTED ITALIAN, 50 cents each; tested, \$1 each. Queens large, yellow and profitable. Circular free.

21Atf Address, E. W. HAAG, Canton, Ohio.
 Please mention Bee Journal when writing.

The tone of the clipping indicates that he is credulous in regard to the new discovery (?), and is intent upon giving it wide circulation. I have explained the matter the best I could in one of our county papers, but the lie is traveling fast.

Last week, when I was delivering some honey to one of my customers (a country merchant), the dealer said: "I hear a new method has been discovered for making honey so that the bees do not have to depend upon the flowers."

Suspecting what was coming, I askt, "Is that so? Why, how is it done? I am anxious to keep up with the times, and learn all the new methods."

He replied, "Why, J. S. Trigg says all you have to do is to feed the bees plenty of glucose, and they won't go near a flower."

Of course, I told him I had read Mr. Trigg's article, and explained how the story originated, etc.

But that is only one out of thousands who will read and believe the falsehood. I think all bee-keepers should take particular pains to set the matter right, not only by talking it to their customers, but thru their local newspapers.

My bees are doing fairly well on white clover yet. I am trying to keep down swarming, but I have 11 new swarms, the most of them issuing before the middle of June, from 25 old colonies. Nearly all are working in the sections, and quite a number are filling their third super of 24 sections.

Not long since I saw the statement (I am unable just now to find the page) that a good-sized swarm of 30,000 bees should weigh about 5½ pounds. I have weighed a number of prime swarms this season, and the lightest was 5 pounds, and they run from that to 8 pounds and 2 ounces. I use the 8-frame hive.

A. F. FOOTE.

Mitchell Co., Iowa, July 2.

American Enterprise at Paris.—Among the striking and original exhibits at the Paris Exposition of 1900 few have occasioned more favorable comment than the great map of the United States, 18x15 feet, exhibited by the well known advertising agency of Lord & Thomas, Chicago and New York. This map is constructed to show at a glance the various details concerning state areas and population, number of publications in each, circulation per issue, percentage of circulation to population, value of publishing plants, number of employes, average hours of labor, average wages paid and average cost per inch for yearly advertising. Information of this nature is of especial value to advertisers, showing as it does the best locations in which to place advertising to reach the greatest number of people and secure best results.

The firm of Lord & Thomas has been engaged in the general advertising business for over 30 years, and ranks among the largest in its line. They prepare advertisements for all classes of advertisers and place them in publications.

Copies of this valuable map will be sent free on request to all advertisers who address Lord & Thomas, Trade Building, Chicago.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, July 7.—Some new white comb honey is selling at 15c; not much offered and not much demand for it. Extracted is slow sale; best white, 7@7½c; best amber, 6½@6¾c; dark amber, 5@5½c. Beeswax, 27@28c.

R. A. BURNETT & Co.

CINCINNATI, July 2.—This market is completely bare of comb honey. The demand for extracted honey is good. Several good shipments of extracted honey from Mississippi and Arkansas have arrived and found a ready sale at 6½@7½c. No white clover honey on the market; same would bring about 8c. Beeswax, 25@26c.

C. H. W. WEBER, 2146 Central Ave.

BUFFALO, June 20.—For strictly fancy white one-pound comb honey we are getting 16@17c. Any grade sells high—10@15c, as to grade.

BATTERSON & Co.

KANSAS CITY, June 20.—We quote: No. 1 white comb, 14@15c; No. 1 amber, 13@14c; No. 2 white and amber, 13@13½c. Extracted, white, 7½@8c; amber, 7c. No beeswax in the market.

We have a shipment of new comb honey in transit from Florida. The supply of old comb honey is very light, mostly caudled.

C. C. CLEMONS & Co.

DETROIT, May 24.—Fancy white comb, 15@16c; No. 1, white, 14@15c; amber and dark, 10@12c. Extracted, white, 7c; amber and dark, 5@6c. Beeswax, 25@26c.

Supply and demand for honey both limited.

M. H. HUNT & SON.

NEW YORK, May 21.—Our market is practically bare of comb honey, and there is a good demand for white at from 13@15c per pound, according to quality and style of package. The market on extracted is rather quiet, and inactive. New crop is slow in coming in, and prices have not yet been established. Beeswax holds firm at 27@28c. HILDRETH & SEGELKEN.

SAN FRANCISCO, July 3.—White comb, 12@12½c; amber, 8@10c. Extracted, white, 6½@7c. Light amber, 5½@6¼c; amber, 5¼@5½c; Beeswax, 26@27c.

The market is fairly supplied with amber extracted, which is arriving mainly from the San Joaquin section, and is meeting with a moderate demand at current rates, both for shipment and local use. Water white honey is scarce, either comb or extracted. Choice comb is inquired for; and in a small way is salable over figures warranted as a regular quotation.

WANTED—HONEY AND BEESWAX.

We have a tremendous and growing trade in this line, and would like to hear from all who have such goods to sell in any part of the country, with quality, description, and lowest cash price. THOS. C. STANLEY & SON, Fairfield, Ill.

WANTED COMB HONEY AND EXTRACTED HONEY.

Will buy your honey, no matter what quantity. Mail sample with your price expected delivered in Cincinnati. I pay cash on delivery. C. H. W. WEBER, 2146 Central Ave., CINCINNATI, OHIO.

WOOL MARKETS AND SHEEP, CHICAGO, ILL.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.10, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO., 118 Mich. St., Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

CONTRIBUTED ARTICLES

Growing Crimson Clover as a Honey-Plant.

BY F. GREINER, ONTARIO CO., N. Y.

BEFORE long it will be time to sow crimson clover again, and I would like to say a few words in regard to this clover as a honey-plant, with that end in view of interesting the bee-keeping fraternity in it so as to induce them to grow it more extensively not only to furnish pasture for their bees, but also to enrich their land.

My experience is as follows: A year ago (in July) I sowed my plum orchard of two acres or more to crimson clover, sowing about 15 quarts per acre—perhaps 12 quarts might have answered. It came up nicely, and tho we had an unprecedented drouth, it made fine growth and soon covered the ground. It was a gratifying sight even during the winter, for it retained that beautiful green color we so admire in our meadows and pastures when the grass first starts in the spring. In the most bleak places the clover winter-killed, but outside of that it started nicely in the spring.

It commenced blooming the last of May, and continued to June 10, during which time it was freely visited by the bees.

It may be observed that this span of time—from the last of May to June 10—is just exactly that dull time occurring every year between the fading of the apple-bloom and the beginning of the raspberry and white clover honey-season. The crimson clover is therefore all the more valuable as a honey-plant.

I notice it had a most beneficial effect on the land, plowing up quite mellow where formerly it had been quite hard. Some grape-growers in this and adjoining vicinities sow crimson clover in their vineyards, let the seed get about ripe, then plow the crop under. They tell me it will thus seed itself.

I am not able to give exact data as to the amount of honey crimson clover yields, but judging from the number of bees engaged all day long gathering the honey, I should say it would excel the white clover and buckwheat for the time it lasts, and might be considered a close rival of the basswood. In fact, I have but few times seen as many bees at work at a time as I had occasion to observe in my clover field. At times I counted 20 bees to the square foot, of which three out of every four were gathering honey.

Supposing the bees would evenly distribute at that rate over an acre of crimson clover while in bloom, 861,200 bees would find room and employment on the same at one time. If I now assume that every colony of bees has 20,000 workers to spare for outdoor labor at this time of the year, that would perhaps be an estimate fully high enough. By dividing the former number by the latter we find that it would require 43 colonies to furnish the workers necessary for one acre of crimson clover; 100 colonies would need about 2½ acres at the same ratio. It would perhaps be unreasonable to assume that 100 colonies of bees could be fully employed on 2½ acres of ground; but it would seem as tho 25 acres might be sufficient, providing there is an even stand of clover all over the field.

Now, perhaps my figures are not very reliable, and prove nothing, still the fact cannot be dodged that I found from 10 to 20 honey-bees per square foot busy in my clover, not counting the bumble-bees and other insects. Therefore it seems to me by providing a few acres of crimson clover, blooming as it does at a time when other bloom is scarce, we could greatly benefit our bees. It would, of course, be necessary to allow the clover to form seed and not plow it under too soon.

The seed of this clover finds a ready sale at a fair price, and it would seem that even the farmers who are not bee-keepers might be induced to grow it just for the seed, if nothing more. Bee-keepers might even pay a premium to farmers in their vicinities. I believe I could afford to pay 75 cents or \$1.00 for every acre sown within one mile of my apiaries.

In consideration of the fact that the majority of bee-keepers are also engaged in farming, some of them quite extensively so, would it not be a wise thing for them to devote a portion of their farms to crimson clover?

Managing Out-Apiaries for Extracted Honey.

BY N. E. FRANCE.

EACH bee-keeper should study the various ways of others, and then apply such methods as will best suit his location and circumstances. With us, bees wintered in the cellar would often be weaker in numbers the last of April and May than when taken out of the cellar, while those wintered in large chaff hives on the summer stands would be strong and by far the more profitable. So that, for the last 20 years, our bees have been mostly in these chaff hives, which are simply four standard Langstroth hives inside, combined into one hive or house, with a 2-inch space on the outside for chaff filling. Each colony is separate from the others, one entrance on a side, but in winter weather the bees cluster near the center of the hive, and thus help to keep each other warm. See the picture herewith of an empty hive, showing brood-frames in hive-body, button over upper entrance turned to one side as in summer; second story by the side of the hive; top and side next to the stack showing chaff wall with a strip of tin on two upper stories of the hive to prevent any chance for bees to pass from one colony to another. When two sets of extracting-combs are to be used, the cover is raised in place by use of the board band, which is hooked together and set on the hive proper. One-half of this band is laid on the grass, with the queen-excluding zinc leaning against the hive by it. The hinged cover is turned back one way while working two colonies, and reversed when working the others—so that there is no need of lifting any covers. A plain band made of common fencing forms the stand for the hive, and is leveled before the hive is put on it.

If the bees have plenty of good honey and a young fertile queen early in the fall, we seldom have any loss. On an average, not over three to five percent. I do not recommend this hive, nor advise those having single hives, and who can winter bees successfully in the cellar, to change to our method or kind of hive. The bees consume a little more food in chaff hives than in a cellar, so, if you can, keep the cellar dry, well ventilated, of uniform temperature, about 45 degrees with strong colonies and good feed, and don't be in too great a hurry to get the bees out in the spring.

In warm weather in the spring I examine each colony, and see if they need any feed or help; and, if so, give them next to the brood a comb of honey that I may find in some queenless colony that has lost its queen during the winter; or, perhaps, exchange an empty comb for a comb of honey from some colony that can spare it. When dandelion bloom appears, I again examine each colony, clipping the queen's wings, putting the brood from the second story down below, and putting empty combs above. If a colony has a good queen, but the colony itself is not as good as desired, I take from the strongest colonies one or two brood-combs covered with bees, and give them to the weaker.

When there is nothing for the bees to gather in the spring, we use a hive-tent; for by its use we can work in the apiary all day and not have any colony of bees disturbed by robber-bees. Our tent is made of a light frame, and covered with cheese-cloth, with an outlet at the top to let out bees that may alight on the inside while we are at work. If I were to make a tent in which to work single-colony hives, I would use three light frames covered with wire-cloth and hinged together, so it could be folded and easily stored away when not in use.

From the best colony in the apiary I select choice worker-combs full of eggs to rear my queens for that apiary; buying new queens, one or two each year, to introduce new blood. As my bees are mostly in out-apiaries, from three to five miles from home, and no one there to look after them when we are away, I do not allow natural swarming, but divide as occasion requires.

When white clover begins to yield honey we extract all the store-combs to get out this amber grade from fruit-bloom and dandelions, as its color and flavor should not be mixed with the better grades. Great care is taken to keep each grade separate, and to see that each package is marked, showing the weights and the source from which the honey is gathered. No honey is allowed to be extracted until fully ripened; and, generally, all capt over. If unripened honey is put on the market it will soon spoil and ruin the market. Good, ripened honey, if kept in a dry room, will keep for years. I have some good honey in common glass jars that I extracted 22 years ago, and it promises to remain good so long as not sampled too often.

Towards the close of the honey-flow we make sure to save enough good combs of honey to feed the bees until dandelion bloom next season. I am often asked, "How much

honey is necessary to winter a colony of bees?" My reply is, "A little too much feed in the fall will be just enough next spring." Wisconsin bee-keepers lost 70 percent of their bees last winter, not all for want of honey, but in many places in the State, in May, I found dead or weak colonies without honey.

When our honey season is over the extra combs, after being cleaned up by the bees, are stored in racks in the bee-house, the hive-entrance nearly closed up by the large button, and the little space over the bees, under the roof, filled with dry oats chaff or straw. This is all the work we do to fit our bees for winter.

Allow me to describe some of the methods of handling the six or seven hired, inexperienced boys from 15 to 20 years of age. I board them for the days they help me, about four weeks, and pay from \$12 to \$20 per month. Each one, by number, has duties assigned, and will take special interest in his work, and soon become an expert in his department. Each is furnished a good straw hat and bee-veil to take care of and return at the close of the season.

As we near an out-apiary, each man gets his trousers adjusted bee-tight at the ankles, and veil on his hat ready for business. Each apiary is located on a gentle slope to the south, with a heavy timber wind-break on the north and west, and a private road from the upper side of the apiary, thru the yard by the side of the extracting-house that is in the center of the yard. This road leads on down the slope below the apiary, so that the wagons, when loaded, can be run by hand easily to a safe distance in the grove to hitch on the teams. There is a freight wagon for barrels, uncapping-box, etc., and a canopy-top four-seated rig much like a stage. Having but one team, I hire a team for a few days to haul one of my wagons. We generally arrive at an out-apiary about 8:30 a. m., three to five miles from home. Each man is ready for duty, and they soon change the scene in the apiary. All are a jolly set; and if one should get a sting he is quiet about it, for fear the other boys may laugh at him. I will call them by number to be better understood.

Nos. 1 and 2 each have a team to care for and drive; so on arrival near the apiary they unhitch and put the teams in the farm-barn near by; then bring to the apiary the extractor that was stored in some dry farm-building.

No. 3 being the smallest boy, brings two pails of spring water, one for drinking and the other for wash-water. No. 4 leads the wagons into the apiary by the side of the bee-house; then puts the barrels, etc., in place in the house. No. 5 lights the smokers, gets fuel in the open box near the house, and each set of tools in place ready. No. 6 puts the cloth roof and siding on the house, and with a couple of nails fastens the board in place with the screen-door attached with spring hinges. This bee-house has simply four corner posts seven feet above the ground. The sides of the house are each ten feet, with a foot-wide board around the top and bottom. Cheese-cloth two yards wide and 40 feet long forms the entire siding, and a heavy ducking cloth, 10x12, forms the gable roof, which gives plenty of shade in hot days, and sheds water if caught in a shower. Small strips of leather are sewed to the edges of these cloths thru which to drive the wire nails to hold them in place.

All this takes only from five to eight minutes after arrival; then No. 5, with a sharp Bingham knife, will uncap the honey-combs, while No. 6 attends to the extracting, straining, and filling of the barrels holding 360 pounds each. I usually take the place as No. 6, as I can better take that place, and at the same time have a chance to see each hand and give orders. No. 1, with No. 2 as assistant, and No. 3, with No. 4 as assistant, open hives, take out honey-combs, brush off what bees do not run off by two or three strokes of a very thin and wide brush-broom, that is made specially for the purpose, at a broom factory, of select, fine stock. Nos. 2 and 4 bring these honey-combs, a set at a time, to the house, and return with a set of extracted ones to fill up and close the hive. The first hive in the morning has to be closed up without upper combs, so as to have combs ready for use in others, and the last set is returned to the first worked colony. To save time and keep out of each other's way, the honey-combs are set just inside of the door of the extracting-house, to the left side of the door, so that No. 5 can get the combs, uncap them over a box made for the purpose, and set them close by the side of the extractor without taking time for one or two steps. No. 6 puts the honey-combs in the extractor, which is a Cowan 4-frame reversible, with ball bearings and lever brake—in short, the best extractor on the market.

The empty combs are set by the right side of the door, and without taking more than one step. The field-boys,

The France Quadruple Chaff-Hive.

Nos. 2 and 4, get rid of their honey-combs, and empty ones for exchange, by simply going to the shop-door. The little time saved in these few steps may seem of little importance, but it saves me daily the cost of one more man.

Every one as busy and happy as the little pets we are working with, time passes so swiftly that it seems but an hour after our arrival when the alarm is sounded from the house—dinner.

We all quit work as soon as possible and not leave hives open. These boys are active and hearty eaters, but even this laborious task is done in order. Nos. 1 and 2 feed the team; No. 3 gets a pail of fresh spring-water; No. 4 takes the baskets of dinner to a shady spot near by; No. 5 spreads the cloth and sets the table—picnic style. No. 6 cuts the loaves of bread and carves the meat. Dinner over, each has a duty in packing up and getting to work. The same is true at the close of the day's work, which comes when the entire apiary of 100 to 150 colonies have been treated.

The light-covered wagon with the boys in arrives at home in time for them to do the few chores common around a farm-house; so they are ready, as the freight-wagon backs up to the warehouse, to roll the barrels in the house, the floor being on a level with the wagon-bed, carefully weigh each barrel, and mark its gross and net weight on the label.

The honey is stored in these barrels until sold, without any other care—except a few dozen cases of 60-pound square cans for farmer trade. If barrels are made of a good quality of staves, kiln-dried and iron-hooped, the barrels then stored a short time in a dry, airy room, and the hoops driven the day the barrel is filled, they will never leak. That is our experience for the past 20 years; sending barrels thousands of miles, and to nearly every State east of the Rockies. We must use such packages for extracted honey as our markets demand. The next best package is the 60-pound tin can, cased; and where good cooperage can not be had, and at cheap figures, the box tin can package is perhaps as good as any. Our home market consumes about 10,000 to 12,000 pounds of extracted honey, and 500 pounds of comb honey per year.

The extracted honey is sold in common tin pails, holding three, five and ten pounds each. We furnish every grocery-store with the honey in these pails; and, to catch some customers that do not want to buy the pails, they are allowed to pay for pail and honey, and when the pail is empty and clean, they can return it to the store and get pay for it, the same as it cost.

Almost all kinds of gummed labels will not stick to new tin cans or pails, but they will stick for all time and not wash off if put on with a paste made of demar varnish reduced with alcohol.—Bee-Keepers' Review. Grant Co., Wis.

What to Do With Unfinisht Sections.

BY S. A. DEACON.

IT has often been remarkt in print that "bee-keeping is a business of details." It is all that; and the many little operations to be performed in the economic production of honey, and in fitting it for sale, are considerably eased and expedited by the numerous little dodges and devices which we owe to the skill and inventive genius of members of our fraternity; nor can we have too many of these aids.

The late Mr. Allen Pringle, in his entertaining essay on "Bee-Keepers' Mistakes," said a good deal to discourage us from giving rein to our inventive faculties, asserting that, as a rule, we shall find that we have only been wasting valuable time going over old ground—"digging up that which has been dug up before." But with all due respect to the memory of the author of this doubtfully sage advice, I rather think we should go on delving, and tho we may not strike a bonanza, there is no reason why we should not turn up a valuable little nugget or two that have not hitherto seen the light of day. So much for the preamble; now to the point.

Few questions have been more frequently askt and answered in the columns of this journal than that heading these remarks, viz.: "What shall we do with unfinisht sections?" and somewhat varied have been the replies. Emerson T. Abbott says, "Throw 'em in the sty"—to the little piggy. But I think very few of us can afford to "cast our pearls before swine;" I, for one, can not, and have to exert my ingenuity to fit them for use again. To that end I have just been looking over, and "fettling up," some 2,000 such sections, in readiness for another expected flow. They were a disheartening sight, a hopeless looking lot, nearly all the bottom starters nibbled away, combs all sorts of odd shapes and patterns, like the bits of a child's puzzle-map, and in many cases the sections so stained and dirty that I was more than once inclined to the opinion that Mr. Abbott's advice was about right after all. But "Needs must," says the proverb, "when a certain old gentleman drives," and the necessity for exercising strict economy in our very precarious pursuit, urged me to try what I could do to fit them for another campaign.

In the majority of cases I found it best to boldly whip out the whole comb—after having first leveled them down with a Taylor comb-leveler. Then, with a little tact and economic carving, with here and there a little artistic patching and joining, I got them into shape. The eye soon learns to see where the knife must go, and with a little practice it all goes very quickly. Of course, it takes time and patience; and tho I have no doubt but that many, like Mr. Abbott, will ridicule the idea as entailing a waste of time, there are, on the other hand, many who will find it anything but a tedious or unpleasant occupation during the long winter evenings; and it is a work in which the help of the juniors of both sexes can be enlisted. I find that, unaided, I can get thru about 250 a day; and seeing that in this shape they are almost, if not quite, equal to full sheets of the new drawn foundation, I consider the time and labor expended on them amply repaid.

And now for the *modus operandi*: The only tools required are a small "straight edge" (or a little square piece of ½-inch stuff 4x4 inches), and an old thin-bladed table-knife—if the point be broken off square and this square top sharpened a bit, all the better, for it facilitates cutting out the corners and pop-holes. At the operator's right hand must be placed a lamp on a chair, so that he can easily hold the blade just over the chimney. After holding it so for a second or two, he passes it rapidly between the wood and the comb wherever they are connected, when out falls the latter unharmed. He then passes the empty sections to his assistant, if he has one, who scrapes off the wax still adher

ing to them, and places them in the scraping-box—of which more anon. The operator having a pile of combs before him, with the knife occasionally held for a second or two over the lamp, sets to work carving them up as economically as he can. Of course, there will be some waste, lots of odds and ends falling away, and which, together with the scrapings of the sections, will give about three pounds of nice, light colored wax per 1,000 sections thus treated.

Fixing the pieces in the renovated sections goes very rapidly once one gets in the way of it, and it is done thus:

Place the piece of comb in position, and with a piece of section held in the left hand, bear gently and evenly down on it. Having held the knife for two or three seconds over the lamp, slip it smartly in between the piece of comb and section, move it rapidly backwards and forwards, bearing down gently all the time with the bit of section in the left hand, when heigh, presto! it is fixt as firm as a rock. Perhaps the "Daisy" may be made to do it.

To adults who may find the work too "niggling" and tedious, and who, in their want of patience may be apt to deem the game not worth the candle, I would suggest handing the job over to the junior members of the family, especially where there are intelligent, light-handed lassies; reward them at the rate of, say, twocents per dozen, and they will delight in the task. It is better than throwing them in the pig-sty, the opinion of such millionaire (?) members of our fraternity as Mr. E. T. Abbott to the contrary notwithstanding.

The hopelessly dirty sections I discard, and, in some cases fit the combs into quite new ones. But by using what I may term my "Handy Scraping-Box," I manage, and that with very little labor, to restore the dirtiest looking sections to their pristine whiteness, or so nearly so that there is no question about putting them on the hives again. Indeed, the use, or success, of this box has far exceeded my expectations. Its construction is too simple to need much explanation thereof. It is made of stoutish stuff and holds six sections, which are rigidly fixt by means of a follower and a wooden thumb-screw. Where a "screw-box" is not available, a very good iron thumb-screw may be made by beating out flat the head of a big ordinary screw, after having made it white hot; the sharp point must be filed down a bit.

Having placed six sections in the box, and screwed them up, scrape the surface with an ordinary clasp-knife, having a round or dagger-shaped blade; then give them a brisk rub over with No. 1 sandpaper, followed up with No. 0, which restores the original polish. Turn the box over and do the other side. If the sides require it, which they seldom do, do them, too, by altering the position of the sections in the box. I find I can turn them out "like hot-cakes." I have not yet had an opportunity of testing the utility of this simple device for scraping and cleaning up full sections, but I fancy it will be found very useful where such are more than ordinarily dirty or stained. The sections being held rigidly they can be scraped, and if requisite, touched up a bit with No. 1 or No. 0 sandpaper far more vigorously and efficiently, and with less fear of damage than when held loosely in the hand and done one by one. As it costs, so to say, nothing to make it, and there is no patent on it, I would advise every one to try this arrangement, and those who don't like it can simply tack a top and bottom on the box, with a slit in the top, and make a money-box of it—tho I fear in that shape it will be found, nowadays, just about as useless. Well, then, kindle the fire with it, or give it to mother-in-law to keep her cottonspools in. South Africa.

Distance Between Center to Center of Frames.

BY G. M. DOOLITTLE.

A CORRESPONDENT writes that he has an apiary of 100 colonies, and thinks of adopting a space of one and 5/16 inches from center to center, as the right frame-space for the future in his apiary, he having formerly used a space of 1 1/2 inches. He asks, "What do you think of the venture?" and wishes me to give my "think" in the matter in the columns of the American Bee Journal.

Well, to be candid, it is a venture I should not want to go into. If I thought I could see some gain in such close spacing I would try it on, say five, or not to exceed ten, of the 100 colonies for a year or two, and then if it pleased me I would fix the remainder in that way.

Here is something that so many lose sight of, and rush headlong into any project which seems good to them, using

the whole apiary to experiment with, when any feasible looking experiment could be just as well tried with half a dozen colonies as with 100, and if the pet project proved a failure but little loss would result, as against five to ten times as much where the whole apiary is tried, which latter is something hard to be borne, generally resulting in sending the experimenter from the ranks of apiculture with the idea that "bee-keeping does not pay."

I really wish some one competent would tell us, in a logical way, just what there is to be gained in a real, practical dollar-and-cent way, by the close spacing of frames which is recommended every now and then. I have carefully experimented for several years to find out whether I was wrong in sticking to a spacing of 1 1/2 inches from center to center of frames. That is the average, as I have found by measuring many times, which the combs are apart, when built by bees in box-hives where they have their own way in the matter, and so far I see no practical reason for departing to a closer spacing than Nature taught the bees to use.

During early spring a greater space is needed between frames to keep up sufficient heat for brood-rearing than later on when the weather is warm. If there could be artificial heat used so that the hive could be kept warm enough for brood-rearing in any part of it during the spring months, then a closer spacing than 1 1/2 inches might answer; but where the bees are obliged to create a heat sufficient for brood-rearing *inside of the cluster of bees*, and not inside of the hive, then the case is different. To thus create and preserve heat inside of the cluster, the bees must have more space than for a single tier of bees between each range of comb, this single tier being all that can congregate there where the close spacing of one and 5/16 inches is used.

In my experiments I have found that far more brood will be brought to perfection during the cool days of April and May with a 1 3/4 spacing than with the spacing proposed by the correspondent; but when we come to July and August weather his spacing will work fully as well as the 1 1/2-inch spacing. If it were not for the fact that one square inch of brood in April and May is worth more than ten times that amount in July and August; and also that, do the best we can, it is hard work to secure the necessary number of bees to work to advantage on the early flow of honey coming from white clover, this close spacing might come into general use. But as it is I can only look on so close a spacing as that proposed by our correspondent as a move in the wrong direction.

TRANSFERRING BEES.

Another correspondent writes that he wishes to transfer some bees from box-hives to movable-frame hives during fruit-bloom, and asks, "Which is the better way to do it? By the old way of cutting combs out and fitting them into frames, or by what is known as the 'Heddon plan?'"

The old plan is the only one I would use at the time of fruit-bloom, and, in fact, it is the way I prefer at any time of the year, unless the colony to be transferred has such crooked combs that it will cost much labor in fitting them into frames. The Heddon plan of transferring, as I understand it, is to drive the bees from their combs, leaving only a few bees to care for the brood, and hiving those driven on frames filled with comb foundation. In 21 days the old hive is driven again, taking *all* the bees this time, these last being hived on frames of foundation, the same as the first "drive." The combs from the old hive, now free from brood and bees, are to be rendered into wax. But, if I am correct, Mr. Heddon never advised this way of transferring where the same was to be done in early spring or in fruit-bloom, before the hives were filled with bees and brood.

With me, the time of fruit-bloom is just the time for the bees to get under good headway rearing brood, and making a general preparation for the main honey harvest from white clover and basswood; and should we transfer by the Heddon plan at this time, we would break up all of these plans of the bees just at a time when we wish every egg possible laid by the queen, so the bees from them can come on the stage of action when the honey harvest is on. Hence, by using the Heddon plan at this time of the year, we would so shorten our "crop" of bees that it might make all the difference between a good crop of honey and no surplus at all. One hundred and twenty-five dollars would not tempt me to allow any person to transfer 25 colonies of bees for me in such a way in fruit-bloom; as I should calculate that I would lose that much or more by so doing in an average season.

Then, the Heddon plan involves the melting up of all

combs in the old hive, which is a thing I object to. I never could understand the logic which calls for the destroying of good, straight worker-combs for the sake of making the wax which comes from them into foundation, fitting the same into frames, obliging the bees to draw it out, and add more wax to it in the process, that we might have only good, straight worker-combs again. If any wish to go thru this process, of course I have no objections; but I want them to understand what they are doing before they start in the matter, and not do it ignorantly, because some one recommended the plan without giving the whole logical outcome of the matter.

Fruit-bloom is a good time to transfer bees by the old way; in fact, so transferring at that time, where their own combs are fitted into frames, seems to give the bees renewed vigor, so that the colonies become better fitted for gathering surplus honey than do those of the same strength that are left undisturbed. In case any colony has very crooked combs I should leave them until just after the honey harvest, when it would be well to use the Heddon plan, feeding if necessary to prepare them properly for winter. Or, if the old hive is not suited for obtaining surplus honey from it, this transferring could be done at the commencement of the harvest, when, by using the Heddon plan of preventing after-swarms, the first "drive" might store some surplus honey. Onondaga Co., N. Y.

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Richards, Ohio.

BEE-STOMACHS—HONEY VS. SUGAR FOR INVALIDS.

An apparent slip occurs in the able article of Prof. Cook, page 370, where he says that the true stomach of the bee is larger than the honey-stomach. Very likely this is the visible appearance, when both are empty; but the fact that the latter when full is more than half the weight of an unloaded bee, rather makes it impossible that the former should have the greater capacity.

Say, Prof. Cook, I'm getting weak in the faith about honey being *practically* better food for invalids than granulated sugar. After a long period of valetudinarianism, intentionally consuming much sweet, and with my prejudice (if I had any prejudice) in favor of honey, you will see me eating sugar as a horse eats oats, and not much honey. Sad case of backsliding, isn't it? And Gleanings in Bee-Culture, not very long ago, holding me up to the world as its champion honey-eater!

LOCUST BLOOM AND TREE.

That spray of locust bloom, page 369, is very lifelike. One disadvantage of the locust that Mr. Schmidt left out is its creeping roots, which infest sandy soil somewhat in the style of an arboreal Canada thistle.

SALTING BEES.

The man who lets cattle get at his home-apiary till they find out that salt can be had by licking at the hive-entrances—I rather guess he's a gone case, as a bee-keeper, and that we need not waste sympathy on his woes. Possibly in some out-apiaries the matter may stand somewhat differently. Somebody else's hired men may have to be depended upon to shut the gaps they open. Better omit salt in such situations—and perhaps Editor Root is too penny-wise in objecting to the cost of sulphate of copper for them. A barrel of salt to serve 400 colonies for two years—a quarter of a cent per colony per year is "too awfully cheap." Page 376.

HAULING HOME EXTRACTING-COMBS OF HONEY.

Aikin's new style of hauling the combs of honey home from the out-apiary before extracting seems to have just one drawback—needs 300 extra combs to work it. The full double set of combs are supposed to be sufficiently hard to get—and keep—without these extras. Where there's a will there's a way, however. His Ku-klux horse with canvass all over him, head and ears—well, if the horse doesn't ob-

ject to it the rest of us needn't. May perhaps be the best way to deal with a serious difficulty. Page 377.

A NON-SWARMING METHOD.

The Blakely non-swarming method seems to be a practical one—don't tell us to use a great lot of combs of brood without bees "wherever they are needed," as I was getting ready to hear as I read it. The objection is that the extracted-honey part of the business is boomed, and the section-honey part deprest. With good runs of honey at the right time it might prove quite satisfactory. Page 381.

CLEANING BEESWAX OFF TIN.

A jet of hot steam for cleaning the beeswax off bright tin is probably an excellent idea—except for the large section of us who haven't got the jet of steam. My working idea, in this regard, is to devote certain tin utensils to use in beeswax and *absolutely nothing else*, and then let the films of wax remain on. Keep 'em bottom up when not in use, to avoid adhering dust. Page 381.

THE MIDDLE SECTIONS IN A SUPER.

The question is raised, page 382, whether sections stored directly over the middle of the brood do not incline to have a more sodden appearance than those at the edges. Worth wrestling with. I'll guess off hand that it's mainly accident. They don't store at all at the far edges excepting when the honey-flow is quite good; and a good flow favors fine appearance.

AVERAGE AGE OF QUEEN-MATING.

Thirty German queens mated at an average age of six days. The range was from four days to nine. The result with a lot of American queens nearly the same—average a little older. We should refresh our memories with these fundamental facts once in awhile. And let's see, I believe we are taught that the time between mating and commencing to lay is very short, so that the total time from emerging to laying is usually a little over a week, but sometimes less. Page 382.

THOSE TWO "WEST"-ERN WOMEN.

And what have we here, page 385? Mrs. West, and a daughter bigger than herself, and the plump statement underneath that Mrs. W. does all the work. Guess that's a slip of some sort—notwithstanding that our observations in this lazy, butterfly world prepare us to believe just that. Too honest and resolute a look on the younger woman's face—and printed on her costume. The ladies have a beautiful spot. They believe in porticos (which more than half of us have discarded.) And they manifestly believe in having things snug. None of your spread-all-round-for-a-mile tactics in their lemonade.

TOO SCIENTIFIC TERMS IN QUEEN-REARING.

Glad Doolittle didn't stop with saying the bulk of a B shot in royal jelly for cells. Some of us, like myself, don't know "B" from "bull's foot" in the terms of a sport which we care not a fig for. But four turnip seeds, ah, that's coming to terms of precision! And the jelly, it seems, is to be well shaken before being taken—careful there not to break the bottle! Seal up the natural cell yourself (with no queen in it), and keep the jelly for use for two weeks if you need. None but the experienced hand could have told us that. Hardly expected Doolittle to aver so decidedly the uselessness of meal and flour as pollen substitutes—but I have no protests to put in. Page 386.

THE APPLE AND EVOLUTION.

Mr. Jolley is a little extreme in his evolution teachings, page 386. We can hardly depend upon seedlings from cross-fertilized seed bearing fruit "in all probability" better than the parents. "Occasionally" is all that can be truthfully said there. And about the apple being develop from the wild rose, I guess none of the great masters of evolution would quite consent to back him there. If we can stand the evolutionary millions of years, it comes to this, that the apple and the rose were both develop from a common parent (not now in existence at all), not that the apple was develop from the rose, or the rose from the apple. Better say the apple sprang from one or more of the crabs of the eastern continent—and not try to unwind the evolutionary ball any further than that.

BROOD-CHAMBERS FOR EXTRACTING AND FOR SECTIONS.

And so Aikin thinks a hive for extracting should have a larger brood-chamber than if run for section honey. May

be he's right; but somehow it doesn't hit me yet, at least does not hit me *effectively*. I use about the same chamber for both, and *intend* to put heavy combs enough below in the fall to make wintering safe. But, then, my field excels in late fall flows. It does look as if the handling of half-stories, which Mr. A. tells of, was excellent for an out-apiary where swarming must be fought to the utmost. Page 387.

BEE-PARALYSIS—"SWEET-CLOVERING" WORN-OUT LAND.

Adrian Getaz is of interest on the subject of paralysis, page 389. Camphor checking it, but also giving flavor to the surplus, and as one has to keep intermitting his remedy. Especially noteworthy is his opinion that old queens will eventually get to lay infected eggs, to the utter ruin of the colony. Of course, the natural remedy in that case would be to keep the colonies supplied with young queens. If guesses were allowable in such serious investigation I should guess that *some* young queens would get their ovaries affected, and that some old ones would escape. However, "All young queens" is not a bad motto, even where paralysis does not prevail.

His scheme of buying worn-out land for a trifle, getting it set in sweet clover, and then selling it at a rise looks fascinating. But there used to be a fable the moral of which began—

"All ye who would your trades forsake,
Take warning from my sad mistake."

No doubt the buying of the land would go merrily.

WINTER EXTRACTING OF HONEY.

H. D. Burrell sounds rather extreme on winter extracting 90 degrees of temperature for 48 hours; but may be it's practical. Page 390.

ACTION AND NON-ACTION OF STUNG ANIMALS.

We seem likely to find in the end that animals of various kinds, under very severe stinging, will sometimes run violently, and sometimes refuse to stir at all. Page 395.

CEMENT-COATING WIRE-NAILS.

Some will be quite glad to know that they can cement-coat their own wire-nails by such a simple process as that on page 398—just a snuff of finely powdered rosin sprinkled on them when they are hot enough to begin to look blue.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Sweet Clover as Hog Pasture—Salting Bees.

1. What do you know about sweet clover for hog pasture? I note what Mr. Boardman says about it in "A B C of Bee-Culture."

2. I have two watering devices for bees as prescribed in "A B C of Bee-Culture." These are kept supplied with fresh water, and each morning I sprinkle salt over the boards. The bees are there thick. Is there any danger of overdoing the salting? IOWA JOE.

ANSWERS.—1. I have no personal knowledge as to the value of sweet clover as hog-pasture, and will cheerfully yield the floor to any one who has. I suspect, however, that it may be a matter somewhat of training with hogs, as it is with horses and cattle. There are places where I've seen sweet clover growing along the roadside unmolested, while stock had eaten down all the grass about it. Yesterday I saw some places of that kind in a drive of 5 miles, but I saw more places where cows had eaten the sweet clover close to the ground. One fact about sweet clover I do not remember to have seen mentioned often. It is that stock seem to learn to eat the *dry* sweet clover hay more readily than the

green plant. My horses eat the green plant very sparingly, but will come at call out of green pasture and munch down the dry hay greedily. Possibly if conditions were reversed, and plenty of sweet clover were growing in their pasture instead of almost none, they might show a different preference. About a ton of pure, sweet, clover hay was put into my barn this summer, and most of it is gone already. I wish I could have the mow filled with it.

2. It is not likely that you can get bees to take more salt than is good for them.

Questions on Swarming.

I had a swarm of bees July 5, and hived it all right, and the next day (July 6) I had another from the same hive. Is that a simple occurrence, or something extraordinary? Both swarms had a queen, and another was left in the cell in the hive. ILLINOIS.

ANSWER.—In the great majority of cases, the first after-swarm will not issue till more than a week after the prime swarm. Then the after-swarms, if more than one, will follow in quick succession. In your case the two swarms were practically after-swarms, altho there may have been no prime swarm. About June 27 was the time for the prime swarm, and it may have issued and the queen was lost, or something may have happened to the queen at the time the prime swarm issued, and the swarm may have returned. Or, there may have been no preparation for swarming at all, and by some means the old queen was killed. In that case there would be several queens reared, and if everything were favorable for swarming you would have just what happened in your case.

Wants Queen-Rearing Directions Explained.

On page 408 is an editorial beginning with heavy type, "Say what you mean." If Mr. Pridgen had done this in all parts of his prize article on queen-rearing published in the same number, so that a novice could get clearly his intended meaning, it would not have been necessary to have troubled you to make one particularly obscure passage clear. I have read it, and re-read it, perhaps 25 times, hoping it would clear up, but it is still Greek. The passage I refer to is on page 403, viz:

"If one is making a business of queen-rearing he should keep a colony at work as cell-starters [Is this colony to be queenless?] Fill a body [hive I suppose] with combs of brood [any bees? or a queen?] and place it *over* [Italics mine] the colony selected [for cell-starting, I presume] with an excluder between. [Where is the queen which is to be excluded, above or below?] Twelve days later [why 12 days?] place this body on a bottom-board [which body, the top or bottom one?] minus the most of the board, with wire cloth tacked on as a ventilator. [That's certainly lucid enough.] Stop the entrance so that no bees can escape." [What becomes of the excluder, which was below this body, when it was on top of the other? Neither are any directions given for the disposal of the other body.]

I will thank you to rewrite the above paragraph, if it will not be regarded as a breach of etiquette on the part of the Bee Journal, which I presume is under obligations of courtesy to the author for the privilege of publishing the article referred to.

In conclusion, I beg to say that it is the plain duty of those who, being familiar with a subject, and undertaking to enlighten the reading public by publishing treatises, should gravely weigh every item of the subject-matter, eliminate all obscurities, and make it so plain to the way-faring man that he might go and do the thing taught.

APIS MELLIFICA.

ANSWER.—It is no breach of etiquette whatever to try to make clear anything not fully understood in the columns of this journal, and Mr. Pridgen would be one of the last to find fault with anything of the kind. He has shown a very commendable inclination to make known to others the things he has learned no doubt after much hard thinking and experimenting, and has made no light contribution toward progress in queen-rearing. It should be remembered, however, that it is much easier to find fault than to give the remedy, and many a one who might find some cloudiness about Mr. Pridgen's instructions might not be able to write with greater clearness. It should also be remembered that Mr. Pridgen is an expert in the line of queen-rearing, and the matters about which he writes are

all ABC to him, on which account he may not go into minutiae sometimes as much as might be desired by the rest of us who do not know so much about queen-rearing. Mr. Pridgen should not be held accountable, probably, for what is most likely a printer's error in a passage you mention, "minus most of the board." That "board" should read "brood."

Answering your questions, I understand Mr. Pridgen to say that a colony is to be selected from which bees are to be taken to act as starters of cells. Put an excluder over the hive containing this colony, and on this excluder put a hive body. Fill this hive body with combs of brood obtained from other colonies. No queen is to be given to this upper story, and no bees need be given, for the bees will come up from the lower story thru the excluder to care for the brood. I do not know for certain why Mr. Pridgen would leave matters in this condition for 12 days, but can imagine two reasons—one, that there may be no unsealed brood from which to rear queens; another, that a force of bees may have time to hatch out. It is quite possible he may have some different reason, and we'll be glad to have him tell us.

The queen remains all the time in her own hive. At the end of 12 days the upper story is taken from over the excluder, still leaving the queen in the lower story, and the upper story with its now queenless bees is placed in any convenient place on a bottom-board with wire-cloth tacked on as a ventilator, so that no bees can escape and yet the bees have abundance of air. This may be accomplished by having a very deep bottom-board with the entrance closed with wire-cloth, or a frame the size of the bottom of the hive may be entirely covered with wire-cloth, and the hive placed thereon, hive and wire-cloth both being raised by means of a block under each corner.

No directions are given for the disposal of the other body in which is the queen, nor of the excluder over it, for nothing is to be done with them. They are left on their own stand where they were at the beginning.

The substance of the whole story is that this removed upper story contains a lot of bees shut up with no queen, and with nothing from which to rear one, and just crazy for the cells you will give them.

Perhaps Superseding the Queens.

I have two colonies of bees each of which has a young laying queen. Their first brood is just capt over—good worker-brood. Now they both have started queen-cells with larvæ already in them. What causes that? They are not very strong yet. They have each 3 or 4 frames of eggs, larvæ and sealed brood. One of the queens seems very prolific.

ILLINOIS.

ANSWERS.—I don't know, but I suspect the bees are trying to supersede their queen. Those who do not clip their queens are hardly aware how often a queen is superseded when only a few weeks, and sometimes only a few days, old. The queens seem all right, appear to lay well and all that, but for some reason the bees are not satisfied with them, and supersede them. If they are thwarted by having the cells torn down, the queens are likely to fail rather suddenly, and it looks as if the bees could foresee their coming failure.

Brood-Frame Cover—Absconding Swarm.

1. What is the proper material to cover brood-frames to keep bees from going into the super when there are no sections on?

2. I hived a swarm in a new dovetailed hive, and set it in the shade of an apple-tree, but had the brood-frames covered with a new table oil-cloth; but after they were in the hive a few hours they all went out and left. I had arrived just as the last bees were coming out of the hive, and I tried to make them cluster, but they would not stop. I tried to stop them with a spray pump, by spraying water on them. Why did they leave the new hive? MICH.

ANSWERS.—1. The proper way is to have no supers on when you don't want the bees to enter them. Don't think of having a super of sections on with something to prevent bees getting into them. Put it down as a fixt rule that sections are never to be put on except during a flow of honey, or just before one is expected. Possibly you may refer to having a super on a hive without any sections in it, the super being filled with planer-shavings, leaves, or something of the sort for winter. In that case it is desirable to have some covering over the brood-frames so the bees cannot get

up into the packing. Probably nothing is better for the purpose than burlap, altho cotton-cloth or almost any kind of cloth will answer.

2. That "new table oil-cloth" was no doubt somewhat to blame. Oil-cloth, when new, has an objectionable smell, and bees are fastidious in that respect. You might put it over an established colony, and they would stay all right, because unwilling to desert their brood and stores, but when first hived they have not sufficient inducement to stay in an objectionable place. Even if there were no smell about the oil-cloth it is not a good thing to put over a newly-hived swarm. It is too close and warm. One of the things of most importance to look after in the case of a newly-hived swarm is to see that they have *unlimited* ventilation. Raise the hive on blocks, and for at least the first day or two leave the cover partly off or partly raised. Hardly any danger of leaving the hive too open for the first two or three days.

Diagnosing Pickled and Black Brood.—I never have any difficulty in diagnosing a sample of real *foul* brood. The symptoms of that disease are so marked that it is very easy for one who is at all acquainted with its characteristics to determine whether or not it is a case of *Bacillus alvei* (foul brood); but to decide between a case of black and pickled brood is not so easy, for the two look very much alike, and under some conditions they are alike so far as external appearances are concerned. Knowing that a good many bee-keepers had sent samples of diseased brood to Dr. Howard, I felt that we could hardly ask him to make such diagnoses without compensation, for he is not in any way connected with an experiment station or any government work; and a man of his attainments as a bacteriologist ought not to be asked to perform a difficult service of this kind, requiring years of preparation and study, for nothing. As yet, I know of no one in this country who has been able to discriminate between one and the other absolutely. Black brood, as we know, is decidedly contagious—perhaps more so than foul brood, and quite as destructive. Pickled brood is a mild form of disease; but so far as I know it is not very destructive. Very often it will disappear of itself, and in any event a mild treatment will eradicate it entirely.

We will suppose that a bee-keeper discovers something in one of his colonies that looks suspicious to say the least. If he can know absolutely, by sending a sample to some competent expert, that he has neither black brood nor foul brood, this knowledge may be worth to him hundreds and possibly thousands of dollars.

Very recently a queen-breeder, who has some 500 nuclei, and who is carrying on the business of queen-rearing very extensively, sent a sample of diseased brood, desiring us to wire him at once what it was. The sample came duly to hand, and I immediately wired back, "Not foul brood—possibly black or pickled brood." At the time of sending a sample to me he sent one to Dr. Howard also, and the latter very promptly wired him that it was nothing worse than pickled brood. This information was worth to him hundreds of dollars; otherwise he would have withdrawn his advertising, broken up his nuclei, practically throwing away a splendid trade in queens, at the same time ruining his business perhaps for all time to come. He had only one case in his yard, and that was promptly disposed of.

While we are perfectly willing to perform such services so far as we are able, Dr. Howard can not afford to do them for the mere love of the pursuit. I wrote him, asking him what it would be worth to diagnose diseased samples of brood, and he replied that he thought he could afford to do it for \$2.00; and this I regard as very reasonable, considering that he may have to spend hours with the microscope; so I would suggest that doubtful samples be sent to Dr. W. R. Howard, Fort Worth, Tex., with a letter of explanation, and don't forget to send the money.

In a letter recently received from Dr. Howard, he gives specific directions by which every bee-keeper can diagnose to some extent for himself. Of the three particular brood diseases he gives the following diagnostic signs:

FOUL BROOD.

GLUE-LIKE consistence of the mass, and the offensive smell.

BLACK BROOD.

JELLY-LIKE consistence of the mass, the absence of ropiness noticed in foul brood, and the peculiar sour-like smell.

PICKLED BROOD.

ALWAYS WATERY, turning black after being attacked with the mucor fungus—a black mold—and by placing the larvae in a sterilized chamber, keeping warm and dark, in three or four days the white fungus of pickled brood appears. I nearly always place a few larvae of every specimen of all kinds of dead brood. Foul brood and black brood are attacked with a fungus, tho kept for months.

WM. R. HOWARD.

—Gleanings in Bee-Culture.

GEORGE W. YORK & COMPANY,
118 Michigan Street, Chicago, Ill.

[Entered at the Post-Office at Chicago as Second-Class Mail-Matter.]

DEPARTMENT EDITORS:

C. C. MILLER, "Questions and Answers." ** E. E. HASTY, "The Afterthought."

LEADING CONTRIBUTORS:

G. M. DOOLITTLE, F. A. SNELL, C. P. DADANT, R. C. AIKIN, PROF. A. J. COOK, "OLD GRIMES."

IMPORTANT NOTICES:

The Subscription Price of this journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec00" on your label shows that it is paid to the end of December, 1900.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

VOL. 40.

JULY 26, 1900.

NO. 30

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

Why a Bee-Keepers' Exchange?—Prof. Cook seems insistent that every bee-keeper should be a member of something like a Bee-Keepers' Exchange. What need? Bee-keepers have heretofore gotten along without anything of the kind, and they can get along now. Their attention has been chiefly given to the best means of securing a crop of honey, and that can be done without any such thing as an Exchange. A man can produce just as much honey, whether he is to get 5 or 15 cents a pound for it. He can produce the same amount if he has no market quotations, and takes his snow-white section honey to the grocery and gets for it just the same price as the grocer paid for some dirty black stuff not fit to put on the table.

And yet no intelligent bee-keeper would be satisfied not to inform himself as fully as possible, so as to get something like a fair price for his product. He watches the bee-papers to see whether the crop is large or small, to see what the prices are in the market reports, informs himself as to his own particular locality, and makes some effort to get the most he can for his honey. If it be admitted that he is right in doing this, it is hard to stop short of the logical conclusion that a bee-keepers' exchange is something almost in the line of a necessity.

When a man, who has shown himself for so many years unselfishly interested in the advancement of bee-keepers' interests as has Prof. Cook, urges any measure for the general good, it is well to give heed. The illustrations

he gives in the line of fruit-growers are strong, especially that of the raisin-growers, with an increase of a million dollars that seems to be credited to the account of co-operation. A significant fact is that the 75 percent that entered the movement at its beginning increased to 90 percent after trial.

It would not be amiss to quote what has been already done by organization on the part of bee-keepers. A pitifully small percent of the bee-keepers of the country banded together for a few years, mainly with the idea of resisting the invasion of their rights as to location, yet that small band has made it safe for every bee-keeper in the country to locate where he pleases, with no fear that some crotchety neighbor may have an ordinance past telling him to "move on."

Adulterators of honey have boldly flaunted their wares in the faces of honest bee-keepers all over the land, and the first show of weakening on their part has come from the organized effort of a comparatively small number of men acting as one body.

If Exchanges are good for others, why not for bee-keepers? If bee-keepers combined have secured advantages against invaders of their rights, and against adulterators, why may not combination be a good thing for them in the way of buying and selling? At any rate, the question is a live one, and these columns are open for its full and free discussion. Objections and advantages will be equally welcomed.

Queen-Excluders When Working for Extracted Honey are in common use, the reason given for their use generally being that the queen is prevented from going up to lay in the extracting-combs. J. B. Hall, the Canadian veteran, gives in the Canadian Bee Journal another as his chief reason. By having an excluder between the brood-chamber and the extracting-super he is never in any anxiety for fear the queen will be injured, and can thus work much more rapidly. A few workers may be killed as the result of rapid handling, and it matters little, but it would matter a good deal if hasty setting a super on should mash a queen. If an excluder is on, there is no queen to be considered; she is safe below the excluder.

An Improvement in Queen-Cages that seems to have originated in Medina or vicinity, seems likely to be of real service. As sent out heretofore, the Benton shipping-cage has at one end a cork closing a hole that leads thru the candy to the queen. The cork is pulled out, and as soon as the candy is eaten out the queen is liberated. The longer the journey the more candy eaten out by the attendant bees in the cage, and if a very small portion is left the introduction may be too sudden for best results. By the new plan no cork is used. Instead thereof a bit of pasteboard is nailed over the hole, three or four small perforations being in the pasteboard. The candy comes close up against the pasteboard, and the bees must gnaw away the pasteboard before they can eat the candy. This avoids the possibility of too sudden introduction, assuring greater safety in every case. When a customer receives a queen, there is no cork to withdraw; all he has to do is to pry off the cover and put the cage in the hive. The bees do the rest.

Some Things Proved.—Mrs. A. J. Barber, of Montezuma Co., Colo., has this to say, in Gleanings in Bee-Culture, about the things she has proven at least to her own satisfaction:

Since the beginning of the new year I have been looking back over the nine years that I have been with the bees, and taking stock, so to speak, of the points that I have proved to my own satisfaction. I have been in the bee-

business, first, because it was necessary that I should have some money-making business that I could attend to while caring for my home and family; and, second, because I loved the work, and felt sure that I could do better in it than anything else that would not require more capital to begin with.

In the nine years I have never had a failure. Last year was a short crop. There was a long drouth, and water failed for irrigation. We had not quite 9,000 pounds of both comb and extracted honey from 130 colonies spring count.

Now, the points that I have proved to myself are these:

That careful, patient work and management are essential to success.

That comb and extracted honey can be produced with profit from the same apiary at the same time.

That the wax and vinegar may be made to pay the cash expenses of such an apiary.

That with the exercise of a little ingenuity and forethought two apiaries of from 150 to 200 colonies of bees can be managed by a woman and a little boy, with but very little other help except in hive-making or nailing up fixtures.

That one who makes a business of bee-keeping should take all the best bee-papers, and keep up with the times.

That the person who depends upon luck generally has bad luck.

I have proved, in an experience of six years as inspector of bees for this county that the treatment of foul brood can not be made too thoro, and that the best use to make of honey from infected colonies is to burn it or bury it very deeply.

I have also settled the hive question, for myself at least. The 8-frame dovetailed is my choice.

Stingless Bees are of several kinds, all small, and too tender for anything but a warm climate. The small amount of honey they produce, and that of poor quality, makes it doubtful that they will ever have commercial value, but the following description of the nest of *Melipona togoensis*, from the British Bee Journal, may be of some interest:

The nest was in a hollow branch of a tree. It consisted of three parts (1) the nest proper, with the brood-combs; (2) the pollen and honey-pots; and (3) the entrance-hole and passage. The nest proper was 24 cm. long. In shape and structure it was apparently very similar to an ordinary wasp's nest, for there were twelve horizontal slabs of comb, of which the middle one was the largest, and the cells were constructed on one side only of the comb. The combs were connected to one another by pillar-like supports, the whole being encircled by a paper covering. The material was not, however, the familiar grey "papier mache" of the wasp, but a dark brown kind of wax. The cells were circular or irregularly hexagonal, not regularly hexagonal as in the comb of the honey-bee.

The honey-pots, which occurred in a separate part of the nest, were egg-shaped, and of a much larger size than the brood-cells. They were used for the storage of honey and pollen.

Stimulative Feeding is practiced by W. O. Victor, as told in *Gleanings in Bee-Culture*, not to furnish directly bees for the harvest, but to furnish the bees that may rear the bees for the harvest. So he feeds six or seven weeks in advance of the expected flow. Of course, it must be remembered that experience and care is necessary that stimulative feeding may not work the wrong way.

For Smoker-Fuel cotton waste is highly recommended in *Gleanings in Bee-Culture*. Not dry cotton, but that which is soaked in oil and is thrown away along railroad tracks after having been used as grease for the wheels. Mr. L. Highbarger, of Ogle Co., Ill., is the discoverer of this new smoker-fuel which is said to light easily, makes a good smoke, and lasts well.

Weed Comb Foundation, according to F. L. Thompson, in the *Progressive Bee-Keeper*, is more brittle than other foundation. Unless made very warm, it crumbles in cutting, thus wasting. A pound of it made full sheets and bottom starters for 118 sections.

The Weekly Budget

DR. A. B. MASON, writing us July 14th, reported that he was getting very little surplus honey so far this year. He also refers to a very pleasant visit from Mr. C. P. Dandant and his daughter who were on their way to Paris. He says: "We had a good visit, and we got acquainted with a very nice young lady."

MR. E. E. HASTY—our inimitable "afterthinker"—writing from Lucas Co., Ohio, July 18, says:

"The season now is largely spent, and not much to show for it in the way of honey; but in the 20 years I have run this apiary there always has been some surplus (location rather strong on late flows, and weak on early ones), so I'll just cheerfully hope I'll have some honey yet."

MR. H. D. CUTTING, an ex-president of the National Bee-Keepers' Association, expects to be at the Chicago convention next month. Mr. Cutting has been partially blind for several years. We can assure him of a hearty welcome and a good time generally. Mr. Cutting had charge of the Michigan apiarian exhibit at the World's Fair, and so was in Chicago several months during 1893. All will be glad to see Mr. Cutting at the annual convention once more.

MR. G. M. DOOLITTLE, of Onondaga Co., N. Y., wrote us July 17:

"There has been positively no honey here since apple-bloom, and I am feeding bees. This makes queen-rearing up hill work. I do not expect to be at the Chicago convention next month."

Surely, Mr. Doolittle sends a discouraging report. And there will be a big hole in the Chicago convention if he is not there.

QUEEN VICTORIA, as everybody knows, has, for the first time in 40 years, made a trip over to Ireland. In commemoration of the event a box of one dozen sections of honey from the four provinces of Ireland was presented to her Majesty. The box containing the honey was specially made of Irish bog oak, by the Abbott Bros., with glass sides, and bore on the lid the letters V. R. in a silver shamrock pattern. It is a pity there has not been a little more mutual exchange of honey between those two nations during the last century. By the way, the Queen is just 81 as this is written. Her reign has now extended over a period of 63 years, exceeding by three years that of any other English monarch. Every fourth person in the world is one of her subjects.—*Gleanings in Bee-Culture*.

THE YEAR BOOK FOR 1899 is a cloth-bound volume of 880 pages, 6x9 inches, issued by the Department of Agriculture at Washington, D. C. The law under which the Year Book is published says that it shall contain reports of bureaus and divisions of the Department of Agriculture, and such papers by experts, and such statistics and illustrations as the Secretary of Agriculture shall believe to be specially suited to interest and instruct the farmers of the country, and include a general report of the work of the department. Also, that there shall be printed 110,000 copies for the use of the Senate, 360,000 copies for the use of the House of Representatives, and 30,000 copies for the use of the Department of Agriculture, all for free distribution, postage paid, among the farmers, the only class specially interested. Each intelligent farmer who desires a copy of this very valuable book should write to his Representative in Congress, or to his Senator if he fails with the former. Each Representative has 1,000 books to distribute, and each Senator about 1,200. Send for a copy of it. It is the best "something for nothing" investment for the farmer that we know of.

The National Convention Next Month—don't forget it. The dates are Aug. 28, 29 and 30. The place—Chicago.

The Chicago Convention of the National Bee-Keepers' Association meets the last week in August, as will be noted by the following from Secretary Mason:

EDITOR OF AMERICAN BEE JOURNAL:—

Please allow me to remind the readers of the American Bee Journal that the next convention of the National Bee-Keepers' Association is to be held in Chicago, Ill., on the 28th, 29th and 30th of August next, commencing Tuesday evening, the 28th, at 7:30 o'clock.

The sessions will be held in Wellington Hall, No. 70 North Clark St., about a block and a half from the Bee Journal office, and about five blocks directly north of the Court House. The hotel at which members can secure lodging, etc., is the Revere House, southeast corner of Clark and Michigan St., only one-half block from the hall. Rates of lodging will be 50 cents per night, and several will have to occupy one room. To many bee-keepers this will be an "added attraction," especially as they will have good beds to sleep on, as Mr. York has been assured by the hotel proprietor. It may be possible that this hotel will not be able to accommodate all of the bee-keepers, altho the proprietor will do his best to see that it does. Each one attending the convention should secure a lodging-place as soon as possible after arriving in the city. There is usually no trouble in getting enough to eat at reasonable rates.

The program for the convention will be different from what it has usually been. There will not be to exceed one paper at each session, and the remainder of the time will be occupied in the asking, answering, and discussion of questions. The question-box will be in charge of such veterans as Dr. C. C. Miller, of Illinois; Rev. E. T. Abbott, of Missouri; D. W. Heise, of Ontario, Canada; C. P. Dadant, of Illinois; R. L. Taylor, of Michigan; O. O. Poppleton, of Florida; and the editor of the American Bee Journal.

On Wednesday evening the editor of Gleanings in Bee-Culture will give an "Illustrated stereopticon talk on bee-keepers I have met, and apiaries I have visited."

The papers will be from such noted ones as Thos. Wm. Cowan, of London, England; Dr. Wm. R. Howard, of Texas; Mrs. H. G. Acklin, of Minnesota; S. A. Niver, of New York; Herman F. Moore, of Illinois; and R. C. Aikin, of Colorado; and if you want to know what the papers are about, and assist in the discussion and enjoyment of the questions, please report in person at the above mentioned hall at the time indicated.

I have been unable as yet to learn what the railroad rates will be, but they probably will be as heretofore—one fare for the round trip from some localities, one and one-third from others, or a cent a mile each way in the Central Passenger Association territory. The exact rate may be learned by inquiring at any railroad station.

A. B. MASON, Sec.

York's Honey Calendar for 1900 is a 16-page pamphlet especially gotten up to create a demand for honey among should-be consumers. The forepart was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample free; 25 copies for 30 cents; 50 for 50 cents; 100 for 90 cents; 250 for \$2.00; 500 for \$3.50. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

Belgian Hare Breeding is the title of a pamphlet just published, containing 10 chapters on "Breeding the Belgian Hare." Price, 25 cents, postpaid. It covers the subjects of Breeding, Feeding, Houses and Hutches, Diseases, Methods of Serving for the Table, etc. It is a practical and helpful treatise for the amateur breeder. (See Prof. Cook's article on page 292.) For sale at the office of the American Bee Journal. For \$1.10 we will send the Bee Journal for a year and the 32-page pamphlet on "Belgian Hare Breeding."

"**The Hum of the Bees in the Apple-Tree Bloom**" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us *one new* yearly subscription to the American Bee Journal at \$1.00.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription *a full year in advance*, we will mail you a Wood Binder free—if you will mention it.

The American Fruit and Vegetable Journal is just what its name indicates. Tells all about growing fruits and vegetables. It is a fine monthly, at 50 cents a year. We can mail you a free sample copy of it, if you ask for it. We club it with the American Bee Journal—both papers one year for \$1.10.

The Premiums offered this week are well worth working for. Look at them.

Exceptionally Good Season.

The season has been exceptionally good here so far, and it has kept me busy to keep my 265 colonies supplied with surplus room, with the help of one man.

ERWIN WILLIAMS.

Otero Co., Colo., July 12.

Catnip as a Honey-Plant.

I have been experimenting with various honey-plants for 15 years, and am now convinced that in southeastern Nebraska catnip excels all others in the secretion of nectar. In communities where it grows in abundance bee-keepers never fail to get a crop of honey. Wm. Burow, a German bee-keeper living 12 miles north, first called my attention to it 10 years ago, he having secured 250 pounds per colony of fine white comb honey from it in years when my bees only gathered sufficient to winter on. He has since

DITTMER'S FOUNDATION

Wholesale and Retail

Langstroth on... The Honey-Bee

Revised by Dadant—1899 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroughly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for

one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

gathered seed for me which I have sown on waste vacant land and the highways, so that now I have quite a good stand of it. I have my bee-yard sown to it and it helps shade the hives. When once sown, that is sufficient, as it will stand drouth and does not freeze out, spreads rapidly, and secretes nectar every year after the first. It grows about 3 feet high, commences to bloom about June 15, and blooms until frost. The honey is white, very much resembling white clover honey, and I have failed to detect any unpleasant taste in eating it.

The seed can be sown in the spring or fall, and will do well on almost any kind of ground, but I find it does best along fences and in stump ground not too much shaded. I find that farmers do not object to having it sown on the highway as they do sweet clover.

If catnip is plenty by the side of sweet clover the bees will visit the clover very sparingly. From my observations I am convinced that it secretes in this community four times as much honey as sweet clover, which I regard as the next best honey-plant.

Our bees wintered poorly last winter. We lost from spring dwindling 20 to 40 percent. This caused a rush to get out of the bee-business, but those of us who remained have nothing to regret; notwithstanding we had a hail-storm that destroyed our basswood flow and greatly damaged sweet clover.

J. L. GANDY.

Richardson Co., Nebr., July 16.

Expects Little Surplus Honey.

Bees are lightly brooded, and working occasionally today, swarming some, but are not gathering much honey, and of poor quality. Josephus' famine cycle—5 years past and 2 to come—after that I expect some good honey seasons. My health is poor and I am in no other business but bee-keeping. I am 67 years old, but I have patience to wait for that cycle to pass. I had no surplus last year, and expect but little this year. Just now there is plenty of rain, and a moderate honey-flow.

E. H. STURTEVANT.

Washington Co., N. Y., July 14.

Third Poor Honey Season.

Bees have done nearly nothing so far this season. Prospects are gone for surplus. There is lots of clover but no honey, and the third season of it.

J. C. KELLY.

Tama Co., Iowa, July 14.

A Lively Hiving Experience.

Last fall my brother (Glen) was given a swarm of bees, and then purchast 3 more. Then I traded with him for one of them, and this spring he subscribed for the American Bee Journal. The bees wintered as nicely as could be, and the first swarm, the biggest of the season, came out May 15th, and went right straight off. He followed them for a mile on the run, and they went out of sight.

To-day my swarm came out. (Whew!) I had just bought an old hive with combs to put them in, and there was a lot of candied honey in it, so I wet the combs to dissolve it so the bees could use it. I guess that made them mad,

The Bee-Keeper's Guide

Or, Manual of the Apiary,

—BY—
PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPERS' GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

for they staid just about an hour and then came out again.

Then I got stung in the hair, and my troubles began. The animals couldn't reach thru, so left the poison in my hair, and every bee I came near after that thought I had been into some meanness, and needed a popping. I dared not go within a rod of the flying bees on penalty of getting one or more in my hair.

They went back to the same place they clustered in the first time. I didn't have any more hives, so I tried to drive them back to the old hive by sprinkling them with water with the spray pump, and gave them an awful ducking. But they didn't go back worth a cent, and I got a stick and jarred them off. Didn't go back then, either. And some of them were so wet that they fell plump into the grass, and it took a full hour for them to get out and go back to the cluster.

When they got settled, Glen and a neighbor, Thompson by name, went up to cut off the limb. The bees had settled on one limb and a twig of another, so when they went to take it down the twig pulled out and pulled about half the cluster off. Thompson was holding the limb until Glen should get on the ladder. But the bees began to pop, pop, bang! and said neighbor jump and shook off half of the remaining bees, and Glen jump on the ladder real quick. Then he took the limb and walkt down without a sting, while Thompson solemnly affirms that he got a dozen. I had to get a pail of water and wash my hair out before they would let me alone.

The flying bees came down and began to cluster again, so Glen took them up on an old chicken-coop, and sat there for about an hour while they settled again. In the meantime—and a mean time it was—I got a frame of unsealed brood and put into the hive with the old combs.

\$5.00 per month will pay for medical treatment for any reader of the American Bee Journal. This offer is good for 3 months ONLY—from May 1 to Aug. 1. Dr. Peiro makes this special offer to test the virtue of small price for best medical services. Reply AT ONCE.

The Modern Remedy Co., Kewanee, Ill.

Then Glen handed down the bees, and they let me alone as long as my hair was wet, and I shook them down in front of the hive. They went in all right that time, and have staid. I am proud of them now.

I suppose it is such things that give a fellow experience, but the going thru—O my!

If anybody wants minute directions about hiving bees without getting stung, apply to Glen Lewis.

E. A. LEWIS.

Montcalm Co., Mich., June 29.

Good Year for Bees.

This is a pretty good year for bees. I started with 31 colonies in the spring, and now have about 50, and about 1,500 pounds of section honey. Last year I had 38 colonies, but 7 died last winter.

ALBERT EVERDING.

Marshall Co., Ill., July 17.

Have Stored Some Honey.

My bees wintered without any loss, and have stored some honey. I have had only one swarm so far. They are on a town lot, so I can not increase them much. In fact, I do not want increase, so you see I have succeeded very well in this respect. A. SHAW.

Grant Co., Wis., July 12.

Season a Failure—Sweet Clover—Fruit Kept With Honey.

Our bees have made a complete failure this season. It has been so dry that white clover dried up in June. We have had two little showers lately, but they can do the bees no good. I think they stored a little honey-dew or red clover honey for a few days, but I don't know where they got it.

We shall have to commence feeding soon to keep them alive, and in a condition to fill up for winter. They are hunting everywhere for a little nectar, and the raspberry patch is just swarming with bees. A few colonies stored a little honey in fruit-bloom, but they carried that all down into the brood-nest with the exception of one colony from which I took about 16 pounds.

In our neighborhood the farmers try very hard to keep the sweet clover mowed down along the roadsides, as they seem to have a great fear of it. Sometimes we see that mowed and all other weeds left. Bees do not visit it much here, not like they do raspberry and other fruit bloom, nor even so much as strawberry bloom. I believe much depends upon the weather whether plants secrete nectar or not. In years when it is very dry nothing seems to yield much nectar.

When we get nothing in the spring we are apt to get a fall flow of honey. I think it is because we generally have more rain in the summer or fall if we don't get but little in the spring, and for that reason it pays to see to it that our bees have enough honey in July and August to keep the colonies in good condition to gather the fall honey. As a rule smartweed and Spanish-needle spring up abundantly when summer rains come on, but much of the smartweed, or rather heartsease, which looks very much like smartweed on oat-stubble ground, is plowed by the farmers early in the fall, so the bees do not get near as much honey as

SPECIAL NOTICE!

BEE-BOOKS

SENT POSTPAID BY

George W. York & Co. 118 Mich. St. Chicago.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apisary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. J. Root.—A cyclopaedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers. \$1.00.

Bienen-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Bienenzucht und Honiggewinnung, nach der neuesten methode (German) by J. F. Eggers.—This book gives the latest and most approved methods of bee-keeping in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condense treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cts.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb of extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cts.

Foul Brood Treatment, by Prof. F. R. Che- shire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Care. 64 pages. Price, 20 cents.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about Poultry Business. 64 pages. Price, 20 cents.

they would if the stubble ground could be left unplowed.

Fruit put up uncooked in honey always sours for me. I have tried it several times. Possibly if the fruit could be cooked and the honey poured into it and just brought to a scald, and then canned, it would not injure the taste of the honey very much, and would keep. Peaches are better sweetened with honey than sugar before canning.

MRS. L. C. AXTELL.
Warren Co., Ill., July 10.

Slow Sealing of Honey--Sweet Clover in Mississippi.

I have taken very little honey so far. My bees are mostly in three stories, two of which are filled with brood and honey, but they don't seem to be in any hurry about sealing the honey. I rather fear I have been rearing bees at the expense of honey. I would like to ask Dr. Miller whether I am allowing them too much liberty, or whether I should have confined the queens to one story by excluders.

Generally, when I want to learn anything about bees, I watch Dr. Miller's department, as some "greenhorn" is sure to ask what I want to know; but I have watcht in vain for some sure sign to tell when bees are preparing to swarm (some outward sign) without having to pry into their private apartments (brood-nest).

Will Mr. M. M. Baldrige tell us what his experience is with sweet clover in Mississippi? Is it best to sow in the fall or early spring, or will

any old wet spell do? I have a road, but little used, about 1¼ miles long, 23 feet wide, running thru my place. If I plow this up mud-pike fashion, and sow to sweet clover, would it likely cut much of a figure toward the support of 100 colonies? ALBERT VOUGHT.
East Carroll Co., La., July 13.

Not an Encouraging Report.

Last fall I put my 43 colonies into the cellar, and all came thru the winter in fair condition. They built up fine on the willow bloom, but when apple-blossoms came they died at a fearful rate, so that hardly any but young bees were left; but they had recovered again when white clover came into bloom, and did some good work until basswood opened, which was loaded with bloom, but the weather clerk was against us, so they had only about two days to make use of the basswood—it was too rough and windy. Our only hope now is the king of all—sweet clover—of which we have a great amount, if the people will let it stand long enough to give the bees a chance. I have as yet taken only about 1,000 pounds of honey. A. WICHERTS.
Cook Co., Ill., July 16.

Long Drouth in Minnesota.

This is a poor season for honey in this vicinity. There was no rain from the first of April to the first of July—dry weather and cool nights, no honey, and bees bred but little. Some bee-keepers had to feed thru the month of

"The New Voice" Free for Five Months!

Everybody knows of THE NEW VOICE as the greatest temperance and prohibition weekly newspaper on earth. We have made arrangements with its publishers, so that we can offer it for the 5 months beginning with July 1,

Free as a Premium for sending us one New Subscriber for one year to the American Bee Journal (with \$1.00.)

If you would like to see a sample copy first, write a postal card to THE NEW VOICE, 315 Dearborn St., Chicago, Ill., and ask for it.

THE NEW VOICE is \$1.00 a year; but to any one who will send us 30 cents, we will have it mailed for the 5 months mentioned above; or for \$1.20 we will send any one the American Bee Journal for one year and THE NEW VOICE for the 5 months—July, August, September, October and November.

All who get THE NEW VOICE on these offers must be new subscribers to that paper, and not renewals.

**25 cents Cash
paid for Beeswax.**

This is a good time to send in your Beeswax. We are paying 25 cents a pound—CASH—for best yellow, upon its receipt, or 28 cents in trade. Impure wax not taken at any price.

Address as follows, very plainly,

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO.

May to keep their bees alive. I have not heard of any honey being taken off yet, and but very few swarms. There is not as much white clover this year as usual. Basswood is just coming into bloom, and the bees are in a rush. There has been plenty of rain for the last two weeks, and we are hoping for a better flow of honey the balance of the season. My bees have made a good beginning in the sections. I have had only one swarm to issue, but I am looking for more every day.

S. B. SMITH.

Millelacs Co., Minn., July 14.

A Defense of Sweet Clover.

I notice on page 413, A. F. Foote says he wants sweet clover started in his locality but the farmers object. I would say they object to one of the greatest fertilizers that grows; also, cattle and horses can be taught to eat it, and when they do there is no better hay grows. It produces an abundant crop of fine-flavored white honey, the flow lasting for about three to three and a half months. In this locality about three-fourths of our honey comes from sweet clover.

I had as much opposition when I planted my first seed, but I planted the seed just the same; now nearly all the farmers see the value of it.

We also have cleome here with a yellow blossom. It is generally a little earlier than the pink. I would not favor planting it in this locality, as it is good only for bees, so far as I know; while some claim it pays to raise the seed for poultry. Sweet clover feeds my bees in summer and my cows in winter, and it produces good milk and honey.

I divide my bees, and have none fly off and leave me. C. W. SNYDER.
Garfield Co., Utah, July 13.

P. S.—I extracted honey the last week in June, this being the first year that such a thing has happened earlier than July 15. C. W. S.

The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, July 7.—Some new white comb honey is selling at 15c; not much offered and not much demand for it. Extracted is slow sale; best white, 7½@7¾c; best amber, 6½@6¾c; dark amber, 5@5¼c. Beeswax, 27@28c.
R. A. BURNETT & Co.

CINCINNATI, July 20.—White extracted honey, 7@7½c; southern extracted, 5½@6½c, owing to quality. No comb honey on market. Good demand for beeswax at 25@27c.

Shipments of extracted honey from the South are more numerous than a few weeks ago, but we find it hard to make sales, owing to a slow demand. C. H. W. WEBER, 2146 Central Ave.

BUFFALO, July 20.—For strictly fancy white one-pound comb honey we are getting 16@17c. Any grade sells high—10@15c, as to grade.
BATTERSON & Co.

KANSAS CITY, July 20.—We quote: New No. 1 white comb, 14@15c; No. 1 amber, 14c; dark, 13c. Extracted, old, 6@6½; no new in market. Beeswax, 22@25c.
C. C. CLEMONS & Co.

DETROIT, July 24.—Fancy white comb, 15@16c; No 1, white, 14@15c; amber and dark, 10@12c. Extracted, white, 7c; amber and dark, 5@6c. Beeswax, 25@26c.

Supply and demand for honey both limited.
M. H. HUNT & SON,

NEW YORK, July 21.—Our market is practically bare of comb honey, and there is a good demand for white at from 13@15c per pound, according to quality and style of package. The market on extracted is rather quiet, and inactive. New crop is slow in coming in, and prices have not yet been established. Beeswax holds firm at 27@28c. HILDRETH & SEGELKEN.

SAN FRANCISCO, July 3.—White comb, 12@12½c; amber, 8@10c. Extracted, white, 6½@7c. Light amber, 5½@6¼c; amber, 5¼@5¾c; Beeswax, 26@27c.

The market is fairly supplied with amber extracted, which is arriving mainly from the San Joaquin section, and is meeting with a moderate demand at current rates, both for shipment and local use. Water white honey is scarce, either comb or extracted. Choice comb is inquired for, and in a small way is salable over figures warranted as a regular quotation.

WANTED—HONEY AND BEESWAX.

We have a tremendous and growing trade in this line, and would like to hear from all who have such goods to sell in any part of the country, with quality, description, and lowest cash price. THOS. C. STANLEY & SON, Fairfield, Ill.

WANTED COMB HONEY AND EXTRACTED HONEY. Will buy your honey, no matter what quantity. Mail sample with your price expected delivered in Cincinnati. I pay cash on delivery. C. H. W. WEBER, 2146 Central Ave. CINCINNATI, OHIO.

WOOL MARKETS AND SHEEP, CHICAGO, ILL.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.10, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO., 118 Mich. St., Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

Benefits of Organization Among Bee-Keepers.

BY F. L. MURRAY.

(Read at the Wisconsin Convention at Madison, Feb. 7 and 8, 1900.)

IN my opinion there is only one way to accomplish any purpose for the benefit of a community, and that is to combine our forces and work together. No matter to what industry we belong it is up-hill work for any individual to reach the top of the ladder without the help and co-operation of his fellow laborers. And it is just as essential for bee-keepers to unite their forces, that is, join a good society or societies, both local and national, as it is for any other industry to combine.

In this age of strife and competition (or "dog eat dog") the unorganized forces soon give up the day and are at the mercy of the unscrupulous organized faction who live on the fat of the land at our expense.

A Chicago lady informed me that all during the last two years when we were getting 10 or 12 cents for our fancy comb honey, they had to pay 20 cents per pound for every pound they bought in Chicago, and a friend of mine informed me that he went thru a wholesale grocery store in Chicago last spring where they were making more "honey" every month than a good many of us bee-keepers could produce with our bees, and without a doubt there are a great many such establishments in every large city.

Now, don't infer from what I have said that I favor trusts and monopolies, for I think they are the curse of the present age; but I do believe in organization to protect our own interests and enforce laws for our benefit.

For instance, would we ever have had a foul brood law in the State of Wisconsin if it were not for the bee-societies in our State, especially the Southwestern Bee-Keepers' Association? If it had not been for that association it is very doubtful if we would have had the law yet. I joined this association at Montfort, Wis., in 1894, and have attended every meeting since. At Wauzeka, in 1896, our present foul brood law

was framed and adopted, and by the hard work and hearty co-operation of its members—especially our present foul brood inspector, Mr. N. E. France, who is a whole society in himself in his unbounded enthusiasm and untiring zeal for the bee-keepers at large—it was put thru. Of course, we will have to give the State society the credit of having the winning name which we had to use to get the State law thru, but outside of the name the Southwestern Bee-Keepers' Association has done almost everything that has been done so far for the benefit of the bee-keepers in the State of Wisconsin.

The present convention is one of the largest and most interesting I have attended in the State, and as a member of the State association I am pleased to note that thru the energy of its present officers it has again been "resurrected," as it were, and thru it and co-operation with the Southwestern and the other local societies of the State we should be able to accomplish a great deal more in the future than we have in the past.

There are a great many things that could be accomplished by thoro organization. The first duty of a bee-keeper is to get his or her bee-keeping friends interested in the local or State societies, for in this way it is easier to get them interested in the National society, and it is to the National Bee-Keepers' Association that we can look for assistance and support in the greatest evil our fraternity has to contend with—adulteration. I think it is of vital importance that every bee-keeper here today should join the National Bee-Keepers' Association, and whether we fight adulteration thru that society direct, or thru legislation for

Mr. and Mrs. F. P. White and Apiary, of Lafayette Co., Wis.

honey alone, or for a general pure-food bill including honey (which I think would be better, for then we could co-operate with other sufferers from adulteration, and would get the combined influence of several branches of industry), it matters not, for, anyway, it can be done *only* by organization.

I am not going to give here a plan of operation—I will leave that to older and wiser heads than mine—but I merely wish to try to show some of the good that could be done thru thoro organization. We should also have a systematized method of marketing the honey crop. We have no trouble about marketing any other farm product, why honey?

There are a great many other things that could be accomplished by uniting our forces, and I wish to say again that it is the duty of every honey-producer to belong to the local bee-society nearest to him, to the State society, and to the National. This rule should stand good in every State in the Union.

Get into line, fellow bee-keepers, in this day of progress and improvement, and let us show the people that we are fully able to take care of ourselves and the interests of our beloved pursuit.

Lafayette Co., Wis.

The Importance of Water for Bees.

BY PROF. A. J. COOK.

I HAVE been reading that splendid work on bee-keeping, Root's "A B C of Bee-Culture"—a work of which every American bee-keeper may well be proud—and the comments in that, with what I read in the journals, leads me to wonder if we all know all that is to be known regarding the use of water in the apiary. Mr. Doolittle has said in the American Bee Journal that bees need large quantities of water when breeding, implying that water is used to feed the young bees.

In the higher animals, water, next to oxygen, is the largest food factor in the animal physiology. When we consider the work that water does in the animal economy, we do not wonder at this. Water makes up the large proportion of all the tissues of the body. I have seen the statement that water makes up one-twelfth of the teeth, and it is true that some of the liquids of the body, like the saliva, are almost entirely made up of this liquid—995 parts of every 1,000 of the saliva are water. The animal, then, needs water to form its very substance.

Again, all the functional activity of the body—as absorption, circulation, assimilation—requires that all the elements concerned in the operations be in solution. We all know that water is nature's great solvent. Water is what keeps all the nutrient substances of the body in solution. Water serves plants also in the same way. Plants are not only composed largely of water, but water holds the food elements of the plant in solution, and so we see why plant and animal alike thirst for water.

Animals possess another function that requires much water to carry it on. As this function is very essential, even necessary to life itself, we see another reason why water must never be stinted if good vigor is to be maintained. I refer to perspiration. We know just how much heat is generated in the body in an hour, and we know that a rise of a few degrees of heat is fatal. Both of these differ in different animals. It is found that on an average man generates heat enough to kill him in between three and four hours, were there not some way to cool him off. Perspiration is the way that this cooling off is done. There is a tremendous heat-producing engine in the body. The heat comes from what is called destructive metabolism, or katabolism. These terms refer to the tearing down of tissue, consequent upon the work of the body.

Most animals get the water in all of the food, much of which, as is true of many fruits and vegetables, may contain over 90 percent of water in their composition. Bees are less fortunate in this respect than are most animals, as there is not a very large amount of water in either honey or pollen. It is probable that bees need a very large amount of water. They have tissues like other animals, which, as we have seen, are largely composed of water. Their food, like that of other animals, must be in solution to be available. They are very active, and this implies very rapid metabolism. We have seen that metabolism is the source of animal heat, and we do not wonder that bees soon warm up when anything disturbs the heat equilibrium of the body.

Is it not more than probable that bees must profit by the mechanical aid which comes from evaporation of water from their bodies? I see no reason to doubt the truth of this. Who of us has not seen the wet, sticky mass when

the hives have been shut up on a hot day so that the water could not pass off. The bees can not ventilate the hive, and the water of respiration, which at such times becomes very rapid, and of perspiration, can not pass off, and we soon have a forbidding mass of dead bees and water, which becomes more and more gruesome, until death ends all.

We know how we suffer on a hot day in case the air is loaded with moisture. This moisture in the air is unfavorable to evaporation, and the cooling process is stayed. We are very much favored in this matter in Southern California. The air is almost always dry when it is hot, and the evaporation from the body is so rapid that we do not feel even intense heat. I have known men to shingle houses when the mercury was over 100 degrees, and they seemed to feel no inconvenience. At such times a person may plunge into an irrigating ditch, and in a very short time his clothing will be entirely dry. Dry air must be around us to permit this grateful evaporation. Do not bees ventilate the hives on a hot day as we fan ourselves, and as the dog extends its tongue to promote this evaporation and so cool off? As bees do not get as much water in their food as do many other animals, and as they are very active animals, and must be cooled off by excessive evaporation, we readily see why they need much water, and why they repair to the rill and pool when work is great, and weather is warm.

Of course, bees are most active in warm weather, and then for two reasons they need much water. When the weather is very warm we are usually more quiet, and so do not need to do so much cooling off, and do not evaporate so much water from respiration and perspiration. If the weather is very hot, and we must perforce work hard, then we breathe fast, sweat much, and must drink great drafts of water to supply the needs of the blood. The water is passing very rapidly from the blood, and must be as rapidly supplied. Bees are hard at work on the hottest days, as then is their harvest, and so they must have great quantities of water to supply their pressing needs.

I doubt, then, if it is correct to say that bees need water to aid in brood-rearing. When they are very busy gathering from the field, then brood-rearing is very active, and as the bees are at hardest work they need to do very great cooling off, both because of the heat and the activity, and so must have much water. In case we have a protracted rain-storm, the bees do not stop brood-rearing, but do stop the active gathering in the field. They stop gathering water perforce. If water was directly necessary in the work of brood-rearing, then rearing brood would stop at all such times, which is not the case. Pollen or bee-bread is necessary to brood-rearing, and when there is no pollen then brood-rearing ceases.

I think that we are safe, then, in holding that water is necessary in the nutrition of the bees, and in regulating the bodily heat. It is more important when the bees are very active, and so in hot weather, when bees are most active in the field, then it is that they need most water. It is not likely that they use the water directly in rearing brood, but as brood-rearing is usually most active when the bees are at full work, it is a pretty sure indication of the amount of water needed by the bees. Water is, without doubt, very necessary, and so should always be supplied when the bees can not get it near the apiary. In winter the bees are so quiet that this need is fully met by the water in the honey, which is the main, if not the entire, food of winter.

Los Angeles Co., Calif.

Beeswax and How It is Bleached.

(Taken from the Chicago Record, in its department of "Shop-Talk on the Wonders of the Crafts.")

EVERY little while the commission men on South Water street receive round, flat cakes of beeswax. Some of them are dark brown, and others are light yellow, and the man who hails from New Jersey can tell where the beeswax came from by its color.

"That dark-brown cake," he said, "came from Wisconsin, for the bees up there are fond of the tobacco-plant and wild grapes, but that pretty yellow cake came from Iowa or central Illinois, and the bees that made it tapt nothing but clover blossoms. Most of the beeswax goes to the East, if it isn't too dark in color, for the biggest bleacheries are there. Cobblers, harnessmakers and tailors use the dark-brown beeswax. They seem to think it is the best for their work. So it is in one respect, for the wax thread then is nearer the color of the leather, but shoemakers who make fine hand-sewed shoes use the bleached wax. Down

East, where I came from, the wax is light yellow, and I have seen some of the same color which came from Africa, but the Cuban bees love tobacco as much as the Badger State bees do, and their wax is darker brown—too brown sometimes to be whitened. You don't know what beeswax is? I know it comes from honey-bees, but where they get it from is more than I can tell, and I guess there is no man on the street who can tell for sure.

It is supposed that beeswax in its original form is a sort of scale on the stomach of honey-bees. When the little busy bee thinks of storing up honey, it begins working its legs energetically, patting its stomach and carrying the scales to its mouth, where it mixes them with a frothy liquid until the scales are soft and plastic. When the scales are kneaded enough the bee makes the hexagonal cells of the honey-comb in which it places its gathered sweets, for it knows that unless the honey is kept from the light it will change, and will not be fit for its food in winter. When the man who owns the bee-hive is ready to rob it of its honey, he removes the comb, and either sends to market the little glass-faced box with the honey-comb in it, or else he puts the comb in a centrifugal machine and whirls the honey out of it. He then puts the comb in boiling water and melts it down, running the melted beeswax into little cakes.

It is estimated that for every pound of honey there is one pound of comb, and that over 1,000,000 pounds of beeswax are used in this country every year. Since chemists and refiners went into active competition with the honey-bees and made a pure, white wax, or paraffin, out of petroleum, the use of beeswax in the manufacture of sperm can-

is carried around into the water. The roller turns once every second, and when the chilled ribbons of beeswax are carried around into the cooler water they fly off of the roller into the water-bed.

From the cooling bed the wax is lifted on wooden forks placed in boxes and carried outside to the bleaching-beds. These are called frames, and stand about three feet above the ground. Each frame is about 100 feet long, 15 feet wide and a foot deep. In each frame half a ton of wax is spread, and there it stays for a month or five weeks, depending upon the number of sunny days, for the wax is exposed to the full light of the sun. Several times a day the wax is sprinkled with water to keep the sun from melting it, and once each day two men harrow it with a rake which extends across the frame, so that in the month of bleaching every bit of wax has all of its sides exposed to the sun several times.

At the end of a month the yellow wax has turned a creamy white, and it is then taken back to the melting vat and remelted, run thru the screen over the wooden roller and brought back to the bleaching-frames for another stay, this time, however, for only two weeks. By this time the beeswax is pure white, and is ready to be put into marketable shape. The boys take about 500 pounds of wax and melt it in a small tub. Near the tub is a table on which stands a large number of pans about four inches in diameter, and a quarter of an inch deep. The pans are arranged in rows, for the melted wax is poured into one row at a time. Above the pans and across the full width of the table is a movable copper cylinder. It is really a double

Running Off the Beeswax.

The Bleaching-Frames.

Molding the Beeswax.

dles, wax flowers and carbon papers has gone down, but the cobblers, tailors, and harnessmakers still stick by the honey-bee, and declare that no petroleum wax can equal beeswax when it comes to wax-ends for slipping thru awl-holes. Chemists, artificial flower-makers, laundries, and other users of wax have not all gone over to the enemy, as the 500 tons of beeswax consumed annually indicate that the honey-bees have hosts of friends left.

But many of these friends require white, or nearly white, wax, and the yellow wax made by the bee must first be whitened or bleached before it is put on the market. The sun is the bleacher, so all bleacheries are in the country away from the dirt and smoke of cities, and usually in the center of large honey-districts. The beeswax is sent to the bleaching-house in the shape of loaf-shaped cakes, each weighing about 25 pounds. These cakes are broken into small pieces and put into a vat or tub made of cedar, about five feet high and three feet across. In the bottom of this vat are two square wooden pipes, crossing each other at right angles. The tops of these pipes have a number of holes bored in them, and both are connected with a steam pipe which brings the steam to them at a pressure of about 60 pounds to the square inch. From 1,200 to 1,800 pounds is placed into the vat at a time, and enough water is run in to float the wax. Then the steam is turned on, and it jets up thru the holes in the wooden pipes, melting the wax. The dirt in the wax falls to the bottom of the vat, and the melted wax, about three hours after the steam is turned on, is ready to be drawn from the vat.

Not far from the vat in which the wax is melted is a wooden roller about five feet long and a foot and a half in diameter. This roller revolves in cool water, and when the melted wax, after first passing thru a sieve, falls upon it in narrow ribbons it chills at once, and, sticking to the roller,

cylinder, one inside of the other, and the space between the two is filled with hot water. The melted wax is poured into the inside cylinder, and is kept in a liquid shape by the hot water-jacket.

A number of small tubes lead from the inner cylinder thru the water-jacket, and one valve turns the melted wax into all the tubes, so that the boy who is filling the little pans can move the cylinder along until it is over a row of pans, and then can turn the valve and fill the entire row at once. In an hour the wax in the pan-molds is cold, and is ready to be shipt.

[In the Chicago Record, about a week later, appeared the following :—EDITOR.]

LETTERS OF CORRECTION FROM BEE-KEEPERS.

In a recent "Shop Talk" on the preparation and bleaching of beeswax for use, a typographical error placed the proportion of comb to honey as "one pound of honey to one pound of comb." The error was such a palpable one that probably the great majority of readers charged it against the compositor. Among the correspondents who have noticed the error are the following, who, besides correcting the mistake, add some interesting information on bees and honey, which subjects were but slightly touched upon in the Record, because the article in question related to the bleaching of beeswax, and not the bee-keeping industry:

Dr. C. C. Miller, of McHenry Co., Ill., writes:

"I have been much interested in the series of articles, 'Shop-talks on the Wonders of the Crafts.' I suppose they are in the main reliable, but when it comes to talking about anything connected with bee-craft the general rule holds

that everything found in print in that line outside of bee-books and bee-journals may be counted on to abound in errors. The beginning of the fourth paragraph contains this statement: 'It is estimated that for every pound of honey there is a pound of comb.' Without asking faith in any statement of mine I think any one will be able to see that this statement is wrong. Take a piece of comb honey and look at it. Does it seem that the wax in it weighs as much as the honey? It may be you haven't a piece of comb honey on your desk, but you may have market reports. A report before me gives: 'Dark comb honey, 10 to 13 cents per pound; beeswax, 27 to 30 cents; extracted honey, 5 to 7 cents.'

"Now suppose a man sends to Chicago a consignment of dark comb honey for which he gets 10 cents a pound, I suppose you know that all that is necessary to get the beeswax out of that comb honey is merely to melt the whole mass, and on cooling the cake of wax will be on top.

"He takes two pounds of that comb honey, melts it, and has one pound beeswax, say 27 cents; one pound extracted honey, 5 cents; total 32 cents, or 16 cents a pound, as against 10 cents that it will bring as comb honey. At that rate do you suppose there would ever be a pound of dark 10-cent honey on the market?

"Instead of saying for every pound of honey a pound of comb, it would not be far out of the way to say half an ounce of comb to a pound of honey.

The idea expressed about black beeswax coming from tobacco, and light yellow wax from clover is all nonsense. Very dark wax and very light wax comes from clover, as I suppose it does from tobacco; but I doubt if a pound of wax can be produced that can be proved to have come from tobacco. There are lots of things about bees of real interest to the general public, concerning which the public ought to be informed, at least it seems so to me, but I may not be a fair judge in the matter.

"If you will write me next summer I'll take pleasure in sending you some scales of wax just as they come from the bee, and I never saw them of any color but white, no matter what plant the bees work on. The color came afterward.—C. C. MILLER."

M. M. Baldrige, of Kane Co., Ill., writes:

"Every bee-keeper knows, in case he knows anything worth knowing about his specialty, that no one can tell by its color simply from what locality beeswax comes, nor from what class of flowers it is made. The color of wax depends almost entirely upon the age and condition of the comb from which it is made, and sometimes upon the vessel used in melting the comb. Honey-comb from which beeswax is made is secreted from honey, and dark honey will make just as white comb as light-colored honey. For instance, buckwheat honey is what is known to bee-keepers as dark honey, but its color depends somewhat on the soil upon which the buckwheat is grown, sandy soil producing a lighter-colored honey than our rich, black prairie land. Now, buckwheat honey, when converted into wax by the bees, makes the very whitest of comb, and consequently makes white or light-yellow beeswax. When the comb becomes old and dark by being left in the hives for a term of years, and is used by the bees for breeding purposes, it then makes, when melted, what is known as dark-yellow or dark-brown beeswax. And it matters not whether it comes from the East, West, North or South. Again, if the combs be melted in bright tin it will be of lighter color than when melted in iron vessels, as iron always discolors hot wax. For this reason no one should use iron in which to melt either wax or comb, in case a product of the lightest possible color be desired.

"Now, it is barely possible that bees may work to some extent on the blossoms of tobacco, but that they gather much honey therefrom, or that they are 'fond of the tobacco-plant,' needs stronger proof than simply an assertion. The honey-comb is made chiefly from honey; the bees have the power at will to change or convert the same into fat. The fat is exuded by the bees, and appears between the abdominal rings on the underside of the abdomen, and in the shape of thin, narrow ribbons of wax, and is then taken therefrom by the comb-builders and made into comb. That is the explanation given by the majority of practical bee-keepers and scientists of the present day. There are, however, a few who dispute the foregoing explanation in part; who claim that the bees have the power at will to change the honey into fat, but that while the fat is an oil, or in the liquid condition, the wax-producers being also the comb-builders, have also the power to disgorge the oil thru the mouth, or honey-tube, directly upon the edge of the cell,

and that the wax-scales sometimes found between the abdominal rings are simply congregated oil or the refuse fat of the bee. Their claim is that no one has ever yet reported seeing an incomplete cell in a ragged or imperfect condition upon the edge, which would often be the case if the scales of wax were used instead of the oil in its construction.

"Honey is now generally thrown out of the comb, whether the comb be old or new, by a machine operated by centrifugal force, but it is an error to suppose that new comb is melted into wax as soon as the honey is thus extracted. As a rule, such comb is given back to the bees, so they can refill it with honey, and in good seasons as many as three, four, or even five times. Such comb, if cared for properly, may be thus used from year to year, and for a period of 10, 15, or 20 years.

"Oh, no; there is no such estimate among bee-keepers as one pound of honey to each pound of comb, nor *vice versa*. What you probably refer to, as 'estimated,' is that it takes about 20 pounds of honey to secrete wax enough to make a pound of comb, but that is one of the old and now obsolete estimates.—M. M. BALDRIDGE."

No. 11.—How to Get the Most Out of Yourself.

BY "OLD GRIMES."

IF we were to solve the problem of how to get the most out of a horse, a yoke of oxen, or a steam-engine, we have books without number that will give full instructions respecting the course to pursue.

With some men—"the man with the hoe," for instance—the rule you would apply to the oxen would work well. Then there are some to whom the rules for the horse would apply, and others the steam-engine.

But I am supposed to be treating a higher development, found in the intelligent bee-keeper—an animal, of course, but combining the intelligence of all animals, a machine of all machines—a universe, something infinite. That is the reason why books can not compass the subject, and it would be far from the ability of Old Grimes to approach a thousandth part of the subject.

But in trying to get the most out of ourselves there are some thoughts perhaps worth repeating, that will find a responsive chord in some weary heart, and that will give hope for the toils of to-day, and to-morrow, and the next day.

Dear fellow worker, "Did you ever see angels in the opening flower, and hear angel songs in the night-winds? Of course, you did when you were a pure, confiding child. But, alas, the years come and go, the eye becomes dimmed with worldly aims, and the beautiful side of life is lost. The flower is ruthlessly trodden under foot, and the whispering evening winds caress an unresponsive and careworn brow." And who is to blame? Has the world been too much for you? Have self-seeking men abused your confidence? Are you in debt, and is the load heavy and grievous to bear? Well, you are to blame for placing this leaven into your life, but you can gain some consolation by teaching your children never to get into debt. Tell them that interest and the law to enforce its payment are as merciless as a buzz-saw. Has the pressure been so great that you see demons in your fellow men? Beware! the man who sees demons in others has the demon in himself.

Get back the faith of childhood, see the angel in the flower, see the angel in your fellow man, and the angel will also abide with you.

Are you a church member? It is well. O, you are not? Well, I believe it is the proper thing, but in these days of toleration probably you and I believe that no church has an exclusive patent on the gate into heaven. Of course, you believe in Christ and His teachings. Every well-rounded man does. He works upon a broad-gauge plan, and there is hope for you. Get the angel in our heart, and we are one with the Infinite.

Well, now, it seems to me I hear some one say, "Old Grimes is trying to preach a sermon." Oh, no, I am only pointing out the bed-rock upon which to build character—something that will bring the greatest results—faith that this is but the threshold to a grand future life. This faith brings content with our lot, peace of mind when the storm breaks, and more precious than silver and gold.

But if our soul is right how is it with the body? You certainly can not get much out of yourself if you abuse "the house you live in." Have you the blues? Then look at the stomach, the liver, and the kidneys, and work to get

them right. You ask how? Well, there are many ways. There is the doctor with his pills, powders, and plasters. That is about the handiest, but not the best. Old Grimes and the boys keep themselves right thru physical culture. This cures the whole body. Of course, the exercise takes time, but it pays. If you go no further than the exercise of deep breathing, that pays. Not one person in ten breathes properly, and there is a world of health in the development of lung-power. The Grimes family are free from colds, malaria, and various ills, and all from bathing and massage every morning.

If you feel well—if the angel is in your heart—you will think well of every one you meet. Yes, you must love all animate creation, and send forth helpful thoughts.

If a bee-keeper comes to you for information do not be churlish and unduly secretive, for the seeker after knowledge, if bent upon gaining it, will find it somewhere else, and he will think better of the man who gives it, and not much of the man who withholds. Remember that the man who freely imparts information with word or pen receives more than he gives.

Don't cross bridges until you come to them. Ten chances to one there is no bridge to cross, and the worry has been useless. Worry brings on disease and premature old age; it drives out noble thoughts, shrivels, and kills.

To get the most out of himself the bee-keeper should saturate himself with bee-keeping lore. When Old Grimes was a boy books on bee-culture were scarce, and of journals there were none. But at present there is no excuse for ignorance on any feature of bee-keeping. Books and papers are plentiful, and one paper you can tie to with confidence that it will benefit you, is the "old reliable" American Bee Journal.

If a book or paper is purchased it should be read. How do you read a paper, anyway? While your eyes are on the page is your mind on neighbor Jones' high-stepping team of horses? Or do you just look at the headings and then throw down the paper and think there is nothing in it that will hold your thoughts?

Oh, no, friend, the nut is not worth much unless the meat is carefully pickt out and digested. And, yes, there are bee-men who will not even crack the nut, that is, the paper is thrown aside without even removing the wrapper. Such persons may win success, but the yare not up-to-date. Their knowledge comes to them by reflection from some brighter luminary in their neighborhood. Yes, friend, it is far better to be a sun than a moon—very bright and up-to-date.

Now, there are a number of thoughts crowding down to my pen-point to get expression, but they would better be checked, and left to be exprest at some future time, or exprest not at all, for here we have the whole thing in a nutshell:

"Let each man think himself an act of God,
His mind a thought, his life a breath of God;
And let each try, by great thoughts and good deeds,
To show the most of Heaven he hath in him."

Managing Late Swarms—Partly Filled Sections.

BY G. M. DOOLITTLE.

AS soon as a swarm is seen issuing I take six frames filled with foundation, and two wide frames of sections, putting the same in a box or hive which is convenient to carry; and when I arrive at the hive from which the swarm is coming, I take the frames from the box and place them down by the hive. As soon as the swarm has mostly ceased coming out the hive is opened, and all of the frames of brood and honey, with the adhering bees, taken out and placed in the box, after which the two wide frames of sections are placed, one at each side of the hive, and the six brood-frames put between them. The hive is now arranged and closed.

"Will the bees stay on these combs all right in that open box? I should think they would fly out after the swarm."

There is no trouble about the bees leaving the combs. If the weather is warm, and there are many bees on the frames, about a third of them are shaken off in front of the hive, when the box is placed in the shade a rod or two away, so the bees from the swarm will not find it when being hived, which is the next thing to do; hiving them in the rearranged hive on the old stand.

"Is there no danger of having too few bees on these combs should the weather be cold?"

If the weather is cool, or but a few bees are on the combs of brood, omit the shaking off, for it will want all of the bees to keep the brood in good condition.

"Yes, but what do you do with these combs of bees and brood?"

They are taken to a hive which has been placed where I wish a colony to stand, and arranged in it the same as they were in the old hive; and after tucking them up all warm and nice they are left till the next morning. At any time during the forenoon of the next day they are given a virgin queen, or a queen-cell just ready to hatch, and in this way we have no trouble with after-swarming, for the bees feel so poor at this time that they are glad of anything in the shape of a queen, the flying bees that were taken with the combs of brood having gone back to the old stand with the swarm.

"Must this giving of the queen be done at just such a time? Why not wait three or four days?"

If the delay is longer than 18 hours, this formed colony often becomes so strengthened by the rapidly hatching brood that they will destroy the queen-cell, or kill the virgin queen, and after-swarming will be the result.

"Would it not be well to give this formed colony a laying queen?"

Do not give them a laying queen unless you wish a prime swarm from the colony in from 18 days to three weeks, for the bees will surely use her for such swarming if the honey harvest continues for that length of time.

"What do you claim for this plan over the old one used by the many?"

By this plan I get a powerful colony on the old stand, which will do as much in the sections, if not more, than they would if they had not swarmed; for the *new* swarm will work with a vigor rarely known to bees under any other circumstances.

"Do you do anything further with the colony made from the combs of brood?"

In ten days, if the honey harvest continues, sections are given to this colony, which has rapidly increased to such from the combs of brood carried in the box; and as the young queen has now commenced to lay, the bees will at once go into the sections, often giving a fair yield of honey; yet the main yield will come from the new swarm, as they have at least one-third more bees than they would had they been hived on a new stand, all of the field-bees returning to this place.

"Do the bees returning from the combs of brood and the fields catch the inspiration of the swarm?"

Yes, they all work with a will together; and as the harvest is at its hight also, and the brood-chamber contracted, the storing of honey goes on in the sections at a rapid pace, such colonies often giving from 50 to 100 pounds of "fancy" honey to their keeper, while, if hived on the old plan, little save partly filled or empty sections would be the result.

If the hive is left as we now have it until winter the bees are not liable to have sufficient stores; so when the harvest of white honey begins to draw to a close, the sections are taken from the sides, which were placed there at the time of hiving (if they have not been taken out filled before), and the combs necessary to fill out the hive are used to take their places. In this way the bees will fill these last for winter; and should a fall yield occur they will often have some extra stores to spare to help out any weak colony that may be short.

"What is done with the partly filled sections which may thus come from the sides?"

These are taken from the wide frames and placed with those which are on top, when the bee will finish them, if the honey season does not drop off too suddenly; or they can be kept and used for "bait" sections the following year.

"How are these best kept over so that they can be nice and clean, ready for use when wanted?"

There are various ways, such as extracting the honey from them and then placing a lot over some strong colony for the bees to lick the remaining honey off, when they are stored away in a clean, dry place till wanted. Or they can be uncapt and set over some colony short of stores till the honey is carried below. But I generally use the plan given by Dr. Miller, I think, of setting the whole lot in the cellar or some dark room, when on a pleasant day the door is opened, giving the bees of the apiary access to them, when, at night, I find them all cleaned up, with very few combs gnawed, provided we give the bees access to them at the right time, so that night comes at about the time the bees have the honey carried away.—Gleanings in Bee-Culture.

How a Swarm Was Lost—A Confession and Warning.

BY HARRY LATHROP.

I WANT to tell about a blunder I made the other day at the Browntown yard, whereby I lost a large swarm of bees, the result of over-confidence, growing out of a long experience with clipt queens. For years we have not known of a swarm leaving our yards for the woods; but to the woods away went the swarm above mentioned, right before the gaping, astonished bee-keeper. It was thus:

The Browntown yard is run, to all practical purposes, as an out-yard. I have a helper who works there during the forenoon, and I go down on the train at noon and remain on duty until evening. My home, be it known, is at the Monroe yard, eight miles east, at present. It was just 3:15 p.m., and I was thinking that all swarming was over for the day, when out came No. 46. They were strong, and were working in two supers, the top one of which was full of nice, white honey nearly ready to come off. As my custom is, I pick up a queen-cage and went over to the hive and watch for the queen, but I did not see her. I supposed that perhaps she had failed to come out, as is often the case, and that the bees would soon come back. But as they clustered and hung quietly in a tree near by, I thought I would better investigate a little. I first turned to the record of No. 46 in the book; it read, "April 28, queen clipt, probably '98."

I next went to the hive, thinking that perhaps they had superseded the old queen, and had swarmed out with a newly hatched virgin. But when I went into the brood-chamber I found it in a normal condition, but full of brood in all stages, including newly-laid eggs. Now, I was positive that the queen of this hive was a clipt queen when the record was made in the spring. So I concluded that the old queen was yet present, and knowing that she could not fly I expected that the bees would hang in the tree awhile, then uncluster and go back to the hive.

I was busy in another part of the yard (when I ought to have been getting that swarm down), and after awhile I heard something. Looking up I saw my swarm high in the air, and starting for some eastern point. No use trying to stop them—might just as well save your strength and time on as hot a day as that was. I stood there disgusted and ashamed of myself for such blundering work. If one of my men had done so—well, there was no one to scold me. A woman in a neighboring house came out with a tin pan and gave it a few taps, but saw that it was useless work trying to stop those bees. She called, asking if they were mine. Mine! Alas, they were once, but now they belong to whoever may find them. They are gone, and so is the five to ten dollars worth of fancy comb honey they would have produced had I saved them. Let them go.

But why did they go? I will tell you what I think. That colony had superseded their old queen rather early—soon after the record was made; the young queen had mated and gone on laying without my discovery of the fact. When I saw them hanging so contentedly in the tree I should have taken no chances, altho I have seen them cluster and hang quite awhile, the queen in the meantime being caged at the entrance of a prepared hive on the old stand ready for the return of the swarm.

Working as I have with clipt queens so long, and having such an easy time of it, made me too confident, and you know on a hot day a fellow doesn't like to climb trees to get swarms. But the fellow who neglects to do so when he doesn't know he knows, ought to have a club.—Wisconsin Agriculturist. Green Co., Wis.

York's Honey Calendar for 1900 is a 16-page pamphlet especially gotten up to create a demand for honey among should-be consumers. The forepart was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample free; 25 copies for 30 cents; 50 for 50 cents; 100 for 90 cents; 250 for \$2.00; 500 for \$3.50. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

The Prelims offered this week are well worth working for. Look at them.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Queen With a Leg Off.

A queen sent me arrived in a feeble condition, with one leg torn off. Will such a queen be of any value if successfully introduced?

ILLINOIS.

ANSWER.—A queen so badly maltreated by the bees as to have her leg torn off might do good work afterward, but the chances would be against it. You do not say so, but I suppose the ill treatment was received in the attempt to introduce her, for a queen would hardly receive such treatment from her own bees in the cage.

Altho I would not think it proper to send out a queen lacking a leg, yet I have had several such queens that did excellent work. The leg, however, was probably lacking from birth, and was not torn off by the bees in these cases.

A Queen Question.

I received a Dr. Miller queen and succeeded in introducing her into a colony which had just swarmed four days before. I pulled down all queen-cells I found, and more on Friday last. The queen never stopt piping from the time she was released until to-day, when the colony swarmed and went away. I opened the hive and found some worker and drone brood about hatched, and two queen-cells not sealed, with the larvæ in them; also one cell sealed, but not an egg or sign of young brood of any description other than the two queen-cells. Did the queen not lay any, or did the bees destroy her eggs? I feel sore about losing the queen, as I intended to divide the colony to-day.

ONTARIO.

ANSWER.—It was not the introduced queen that did the piping and left with the swarm, but a virgin queen that was free in the hive. The queen sent you could not have gone off with the swarm, for both wings on one side were clipt so she could not fly. It is a very unusual thing for a second swarm to leave 20 days after the prime swarm; and in this case it looks a little as if there were two factions in the hive, one insisting that the stranger should rule, and the other insisting that the virgin should be mistress, the strife delaying the swarming. It is possible that the introduced queen may have been allowed to lay a few eggs, for it sometimes occurs that a queen is allowed to lay a very few eggs, perhaps in queen-cells, and is still rejected.

Perhaps Bee-Paralysis.

I have one colony of bees that in June, 1899, cast a good-sized swarm, which I hived, and it did and is doing all right, but the parent colony, after the young queen got to laying, and the young bees had hatched out and commenced playing, there would be scores of bees that would come out on the alighting-board, rub their abdomens and wings with their hind legs, but would be unable to take a flight, and so they would crawl away from the hive, continuing to make the effort to fly, but could not; and the same was true of them all last spring and summer. These bees come out at the time the young bees take their play-spell. I can not see any difference between them and those that can fly.

What is the probable reason why they can not fly? Is it possible that the queen may be at fault in some way? I

can not think that they are old, worn-out bees coming out to die, because their wings are not ragged and broken. Some of them seem to be somewhat less than others.

Can you tell me a remedy? The colony is not any stronger now than it ought to have been the first of May, if as strong.

Perhaps I should have said that there have been drones until the last three or four days, and they are too feeble to fly.

OHIO.

ANSWER.—I don't know, unless it be a case of bee-paralysis. In that case there should be seen a trembling of the diseased bees, some of them having a shiny-black appearance. If paralysis is the trouble, no satisfactory remedy has yet been found. As far north as Ohio, however, it is not likely to be very bad, and will likely disappear of itself. In the South it is a severe scourge.

Bare-Headed Bees—Feeding Back.

1. Some time ago I received a queen from one of the queen-breeders, and when looking thru the hive in which I introduced her I found one or more frames with brood uneven, some drawn out farther than level, and not capt; some looks dark. What is the trouble? My opinion is that they haven't enough bees to nurse the brood.

2. Do you think it pays to feed to finish sections nearly all capt? I have a number of supers nearly finish of bass-wood honey, and have some colonies I run for extracted honey, which I was thinking of using to feed to finish with now, as I don't expect honey enough from the fields to finish until buckwheat.

IOWA.

ANSWERS.—1. It is a case of "bare-headed bees." The young bees are not sealed over at all, but they hatch out all right, and no harm comes from it. It is a matter of frequent occurrence, and it is uncertain what is the cause, but I suspect it is caused by worms eating the capping.

2. A few bee-keepers think they can profitably feed extracted honey to have sections finish, but most of those who have tried it think it does not pay.

Should the Public Be Encouraged to Keep Bees?—

In answer to this question, J. B. Hall says in the Canadian Bee Journal :

"Yes—no. I would like to encourage all those that have natural tact to keep bees, and are in a locality where it would pay them to keep them, but indiscriminately to advise every one to keep bees for a living would be to do a great injury. We should be very cautious how we encourage people to keep bees. I may be a rather peculiar temperament; I think a bee-keeper, like a fiddler, is born. If a man can look after ten thousand little things, and do everything right, and do them at the proper time and in the proper way, and is desirous of keeping bees, and is willing to live in a new country, encourage him."

Dr. Miller's "Goback" Sections.—While I was visiting Dr. C. C. Miller at his home, he and his sister Emma quite incidentally made reference to their "goback" colonies and "goback sections."

It seems that, in taking off their comb honey, they remove the supers when most of the sections are completed. These are taken to the house, and the filled sections are set to one side, to be scraped and cased; but the unfinished ones "go back" into the same or another super. There may be one or a dozen or perhaps a hundred or so of supers with partly filled sections, and these are all designated as "gobacks." They are either placed on top of other supers that are being built out from foundation, or upon colonies that seem to show a special aptitude for finishing up gobacks.

In looking over Dr. Miller's hive-record book I found there were certain colonies that had produced so many filled

sections and finish up so many gobacks. These gobacks are all placed on the hives *before the honey-flow ceases*; so when the season is over, Dr. Miller has nothing but No. 1 filled sections without any unfinished ones, or practically none, to be extracted, to be sold for less money, or to be filled out after the honey-flow by feeding back—a wasteful, laborious, and disagreeable job, because all has to be done during the robbing season.

Of course, there is nothing particularly new about placing unfinished sections on the hives, to be filled out; but, if I mistake not, the general practice is to place such sections on the colonies *after* the honey-flow.

Another interesting fact to me was that some colonies are much better for finishing gobacks than for filling sections from the foundation—that is to say, when work is apparently *started* or almost finish, those colonies show a special aptitude for *completing* work, but they are not as much inclined to *start* on raw foundation as some other colonies in the yard.

It seems that the Miller family have a way of finding out the peculiarities of each colony, and those peculiarities are recorded in the record-book; and if the queen is still in the hive next year, that queen and her bees are devoted to a special kind of work—it may be to filling out gobacks, to running for extracted honey, if the honey is travel-stained, water-soaked, or discolored, or to producing comb honey from foundation at the start. The colony that is good both at producing honey and finishing gobacks is given light work, and its queen is used for a breeder.

Emma also gave me an interesting fact; and that was, when one has sections that from any cause have tiny drops of honey oozing from the cappings, to put them in a super, place the super on a hive for a few hours, when the sections will all be licked up clean and nice. It appears that the Millerites so manage that their crop shall be *practically all of it* No. 1 honey; and yet I suspect that over half of the producers of comb honey have anywhere from 10 to 25 percent of it No. 2. A word to the wise is sufficient.—Gleanings in Bee-Culture.

A Swarm of Bees on the March.—I thought it probable that the following may possess some interest for you or your readers: When cycling this morning on my usual professional "round" I was not a little astonished to see a swarm of bees *walking* in procession, like a long, brown snake, along the narrow footpath bordering the main road from here to Newark. The resemblance to what one could suppose Lord Robert's army on the march would appear like at once struck me. There were some few bees flying ahead, representing the "cavalry scouts;" then came the main army in serried ranks, extending to a length of several yards, all marching on foot—these were the "infantry," of course; and, finally, separated from the main body by about two feet, but with "scouts" passing to and fro, came a considerable cluster forming the indispensable "rear-guard." A man working on the road informed me that the whole swarm had thus advanced about 20 yards since he had first observed them some time before.

I at once rode back to the house of a bee-keeper I knew who lived near, and failing to obtain a skep, got a box of shallow frames with comb built out and an old newspaper. Returning, I placed this "Pretoria" directly in front of the advancing army, covering the box with the newspaper and propping it up in front with a stone. I then continued my journey, and on my return found, as I had expected, that "the army" had "taken possession of the town," and that "all was quiet." This evening I drove over and took possession of the swarm, which I have now safely established in my apiary at home. Knowing, as we bee-keepers do, the loyalty of bees to their queen, it almost look as if these little wanderers had caught up the patriotic spirit of the day. Anyway, I have seen many swarms, but this is the first time I ever saw one *walk*.—(DR.) PERCY SHARP.

[The above is not only interesting, but our correspondent's simile is a very happy one, there being little doubt that the queen's inability to fly kept the bees loyally marching on foot rather than take wing and desert her.—EDS.]—British Bee Journal.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY,
118 Michigan Street, Chicago, Ill.

[Entered at the Post-Office at Chicago as Second-Class Mail-Matter.]

DEPARTMENT EDITORS:

DR. C. C. MILLER, "Questions and Answers." ** E. E. HASTY, "The Afterthought."

LEADING CONTRIBUTORS:

G. M. DOOLITTLE, C. P. DADANT, PROF. A. J. COOK,
F. A. SNELL, R. C. AIKIN, "OLD GRIMES."

IMPORTANT NOTICES:

The Subscription Price of this journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec00" on your label shows that it is paid to the end of December, 1900.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

VOL. 40. AUGUST 2, 1900. NO. 31.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

The Chicago Convention Program appears on the next page. It will be noticed that the stereopticon will be a prominent feature at this convention; that both Messrs. Hutchinson and Root will throw on the screen pictures they have taken of the bee-keepers and the apiaries they have visited on their travels over the country. A powerful electric light and a fine stereopticon will be used. Indeed, it will be practically an apiarian trip over the whole United States, and even a run over into England.

This picture-and-travel feature of the next convention will be something unusually fine and attractive, and will be well worth going a long way to see. And, then, to meet the old-time friends, and form many new-time friendships—can such pleasures be valued in dollars and cents?

The Honey Crop for 1900.—Reports concerning the honey season and crop are always so very conflicting that it is practically impossible to get even a fair estimate of the quantity of honey harvested thruout the country. But, as we were recently told by one of the oldest and most experienced honey commission men, there will likely be plenty of honey this year as in other years. He said he has not known the year in the past twenty, that he could not get all the honey he wanted. There is honey somewhere in this great country of ours every year; and we believe that the bee-keeper who sells his crop early, and at a fair price, will be the gainer this year.

"A fair price" may be a rather indefinite statement. Perhaps we should say that whenever the bee-keeper can realize a net wholesale price of say 14 cents a pound for the best grade of white comb honey he would better take it; and 7 cents for best white extracted honey. Prices on other grades should be in proportion.

Now, understand, we are not advising any one to sell at these prices, but we will simply say that if we had a quantity of honey to sell, and could get those prices net this year, we should count ourselves very fortunate indeed.

Editor Root had the following to say in reference to the honey-crop outlook, in Gleanings in Bee-Culture for July 15:

Reports are still coming in from all sections of the country; and so far the revised outlook stands about as follows:

Michigan seems to be having a good honey-flow—at least I do not remember seeing an unfavorable report, while we have on file a large number of good ones. Colorado, Arizona, and other of the Western States depending upon alfalfa, will have their usual honey-flows. In California the reports range all the way from one-third or one-half a crop down to total failures. In New York the reports are unfavorable as a rule—no clover or basswood to speak of. From Pennsylvania there are a few favorable reports. From New Jersey come quite a number of good reports. Reports from Florida vary greatly. Some show a third of a crop; others a total failure. Texas will have a good deal of honey from some sections, and almost none from others. Some of the Southern States will have very little honey. Missouri, that had a crop of honey all over the State last year, has nothing to report this year to speak of. The season in Wisconsin is practically a total failure; a little better in Minnesota. In Iowa and Illinois it is fair to poor. Dr. C. C. Miller is getting his usual crop of honey; or at least he reports he is doing as well as he did last year; but he does not know where the honey is coming from.

Notwithstanding the season seems to be generally unfavorable, we have a large number of good reports from all over the country.

So far no large amount of honey has found its way to the centers of honey distribution. At present it is a little too early; but there will be considerable alfalfa honey this year to dispose of, both comb and extracted; a very scant supply of ordinary white clover, and a light supply of red clover and of basswood.

Taking it all in all, the supply of white clover honey and basswood will be very light this year. Honey, if any is sold at all, will be principally alfalfa, with some mountain sage from California, perhaps. There will be on the market, as usual, Southern honeys; and, in all probability, from the large amount of warm rains that seem to be general over the country, there will be a good fall crop; that is to say, the bees will probably gather enough from fall flowers to fill their hives and save feeding. If they will do this much, bee-keepers will probably feel fortunate.

A Warning to Honey-Shippers.—While it may not be as necessary now as it was several years ago, to warn bee-keepers to be careful to whom they ship honey, yet it is well enough to permit a gentle reminder. It is fast coming to be the proper thing to agree on a cash price before the honey leaves the producer for the city buyer. It may not be paid for in advance, however, but in case it is not, the shipper should exercise great care as to the financial responsibility of the buyer.

There may yet be a few concerns who think they can persuade bee-keepers to say good-by to their honey, by sending out eloquent letters in which they claim to be about "the whole thing" in their particular city, and give every assurance that they can realize a cent or two above the market price for all the honey that bee-keepers could possibly ship them. Don't be fooled by any such "bait." It is better to donate your honey to your good neighbors rather than to risk it in the hands of such over-confident concerns.

Verily, what shall it profit a bee-keeper if he shall produce a large crop of honey, and then lose it thru some fraudulent city dealer?

Chicago Convention Program.—The following is the program of the 31st annual convention of the National Bee-Keepers' Association, to be held at Chicago, Ill., Tuesday, Wednesday, and Thursday, Aug. 28, 29, and 30, 1900, the sessions to be held in Wellington Hall, 70 North Clark St.:

FIRST SESSION—TUESDAY EVENING.

Call to order at 7 o'clock.

Song—Dr. C. C. Miller, of Illinois.

"How to Sell Honey"—S. A. Niver, of New York.

"Keeping Bees in a City"—L. Kreutzinger, of Illinois.

Question-Box.

SECOND SESSION—WEDNESDAY MORNING, 9:30.

Song.

Invocation.

President's Address—E. R. Root, of Ohio.

"Queen-Rearing by the Doolittle Method"—Mrs. H. G. Acklin, of Minnesota.

Question-Box.

THIRD SESSION—WEDNESDAY AFTERNOON, 1:30.

Song.

"Bee-Keepers' Rights and Protection by Law"—Herman F. Moore, of Illinois.

"Trials of the Commission Man"—R. A. Burnett, of Illinois.

Question-Box.

FOURTH SESSION—WEDNESDAY EVENING, 7:30.

"Breeding for Longer-Tongued Bees"—J. M. Rankin, of the Michigan Experiment Station.

"Bee-Keepers I Have Met and Apiaries I Have Visited"—E. R. Root, of Ohio, assisted by Dr. C. C. Miller, Dr. A. B. Mason, E. T. Abbott, and others. Illustrated by a stereopticon.

FIFTH SESSION—THURSDAY MORNING, 9:30.

Song.

"Various Forms of Diseases Among Bees; Cause and Cure"—Dr. Wm. R. Howard, of Texas.

Report of the General Manager—Hon. Eugene Secor, of Iowa.

"Pure-Food Legislation"—Rev. Emerson T. Abbott, of Missouri.

Question-Box.

SIXTH SESSION—THURSDAY AFTERNOON, 1:30.

Song.

"Chemistry of Honey and How to Detect Its Adulteration"—Thos. Wm. Cowan, of California.

"How to Ship Honey to Market, and in What Kind of Packages"—George W. York, of Illinois.

Question-Box.

SEVENTH SESSION—THURSDAY EVENING, 7:30

"Co-operative Organization Among Bee-Keepers"—R. C. Aikin, of Colorado.

"My Trip Thru Wisconsin and Minnesota"—W. Z. Hutchinson, of Michigan. Illustrated by a stereopticon.

Unfinisht Business.

Adjournment.

One prominent feature of the next convention will be the stereopticon work. Messrs. Root and Hutchinson, with a powerful stereopticon, will project upon the screen some photos they have taken of apiaries they have visited in various portions of the United States. The convention will be held in Wellington Hall, 70 North Clark Street, about a block and a half from the office of the American Bee Journal, and about five blocks directly north of the Court-house. The hotel at which delegates may secure lodging is the Revere House, about half a block from the convention hall. The rate for lodging will be 50 cents per night, and the proprietor has assured Mr. York that good beds are provided, but that several will have to occupy the same room. But when any one desires a room with a single bed, the charge will be \$2.00 per night. If two men wish to take a single room in that way they can do it, sharing the expense between them. Some G. A. R. people will pay 75 cents per night for a single bed, so bee-keepers are specially favored at 50 cents. The hotel is almost within a stone's throw of the convention hall, and right near the hall are first-class restaurants, where meals can be secured at reasonable rates.

It is a little too early yet to announce what the railroad rates will be during G. A. R. week; but it is assumed that they will be low, probably a cent a mile each.

Chicago is a central point, and there will undoubtedly be a large attendance; and, considering the attractions, it is earnestly hoped that bee-keepers will turn out in good, strong force.

E. R. ROOT, *President*.
DR. A. B. MASON, *Secretary*.

It will be noticed in this program ample time is allowed for the question-box. This is usually the best feature of a bee-keepers' convention, particularly if Dr. Miller holds the box and keeps the people talking. You see, it gives everybody who has had experience such a good chance to tell what they know, especially when there are so many questions to which Dr. Miller says he has to answer "I don't know."

We are looking forward to a large gathering of bee-keepers, and a royal time for all who attend. As there are something like 200 bee-keepers in this county alone, there would be a fair sized convention if only they came. But we are hearing nearly every day from some far-away bee-keeper who expects to be here.

There will be two "grand armies" in Chicago, then—one of good ex-soldiers and the other of ex(tra)-good bee-keepers.

The Weekly Budget

MR. J. T. CALVERT, of The A. I. Root Co., was delayed about two weeks in starting for Europe, on account of a disastrous fire at Hoboken, which, destroyed ships and shipping interests at that point. He sailed July 18th from Boston.

MR. LOUIS SCHOLL, secretary of the Central Texas Bee-Keepers' Association, writes us that their recent convention, held at Hutto, July 12 and 13, "was one of the best meetings" of their State, 115 persons being present, representing 5,808 colonies of bees. We have attended national conventions that did not number as many in attendance. Texas seems to be coming up.

We expect to begin publishing a report of the above meeting next week.

THE WISCONSIN APIARY shown on the first page this week is that of Mr. and Mrs. F. P. White. The hives are 8-frame dovetailed. Mrs. White is near the center of the end of the apiary, and Mr. White near the end. They started with two colonies in 1894, and increased to 89 in 1899.

Mrs. White was taken ill a year ago last April, and was advised by the family doctor to go to Chicago for an operation, which we regret to record proved unsuccessful. She remained at the hospital for two months, then returned home, and lived nine weeks, up to which time she was as enthusiastic over the bee-work as any one could be, and took a great interest in it. In a letter from Mr. White, he says: "She was a tender-hearted, loving wife, and a thoughtful sister and daughter."

MR. HERMAN F. MOORE, secretary of the Chicago Bee-Keepers' Association, lives about 14 miles northwest of Chicago. He has nearly 30 colonies of bees, which he is running for extracted honey. We called on him early in July. He was just beginning to extract. Some colonies occupied three 10-frame Langstroth hive-bodies, with much brood in all three stories. He allows the queen free access thruout the hive, and extracts from frames of honey that are practically all filled and sealed, taking them out of any part of the hive where they may be. His principal source of honey is sweet clover.

Mr. Moore has a fine city retail trade, which he looks after carefully all the year. He is an energetic young man, educated as a lawyer, but loving bees and outdoor life more than his legal profession, he devotes his whole time to bee-keeping, and to keeping his many customers sweet.

Yellow Sweet Clover Seed

WE HAVE IT AT LAST!

We have finally succeeded in getting a SMALL quantity of the seed of the YELLOW variety of sweet clover. This kind blooms from two to four weeks earlier than the common or white variety of sweet clover. It also grows much shorter, only about two feet in height. It is as much visited by the bees as the white, and usually comes into bloom ahead of white clover and basswood. We offer the seed as a premium

A QUARTER POUND FOR SENDING ONE NEW SUBSCRIPTION.

So long as it lasts, we will mail a quarter pound of the seed to a regular paid-up subscri-

The Unstriven Fail.

Build as thou wilt, and as thy light is given;
Then, if at last the airy structure fall,
Dissolve, and vanish, take to thyself no shame;
They fail, and they alone, who have not striven.
—T. B. ALDRICH.

Best Prospect in Four Years.

Bees are storing honey very fast. The main honey-flow has just set in, but we are having considerable rain. My bees are in fine shape to gather the sweets. The prospect is better than it has been in four years. We had considerable swarming thru April, May and June, but I never saw swarms build up faster. I had one albino colony 15 days after casting the prime swarm to cast its first after-swarm, then five days later another after-swarm, making 20 days between the prime swarm and the last after-swarm.

J. R. SCOTT.

Lamar Co., Tex., July 16.

Hoping for a Fall Crop.

I have 29 colonies of very fine Italians. The season has been too wet, so no surplus up to this date. I am hoping for a fall crop from heartsease and Spanish-needle, as the creek bottoms could not be cultivated. I am working for section honey. A. S. GRIFFITH.
Saint Clair Co., Ill., July 24.

Some Interesting Cuban Notes.

Several years ago I was a subscriber to the most valuable American Bee Journal, which I counted as a most excellent aid to bee-keeping, and quite often short articles from my pen on bees and bee-keeping in Louisiana appeared in it; but changes in position of life caused me to drop it. At times I did well with my bees, but only after many failures, and many valuable lessons of experience. It has been over two years since I have had anything to do with the sharp little "critters," but I never lose an opportunity to see a bee-hive or to try to learn something about them.

Cuba is an excellent place in which to produce honey. I saw one place here, out in the country, where there were about 150 hives, apparently 10-frame Langstroth, all neatly painted, and each one on a neat stand, with a different device on the front of each. The majority of them were two or three stories, and many of them going up to four and a half. They were placed in an excellent location, and amid a large grove of palms and bananas, and presented a beautiful sight from the train.

There are many beautiful wild flowers here that bloom and give place to others, thus furnishing a supply nearly all the year around.

I was speaking with a commission merchant here on the outlook for honey, and he said that it appeared to be very good. He sells on commission and said that, as a rule, extracted honey brought 55 or 60 cents (Spanish silver) here at wholesale—about 45 or

Langstroth on... The Honey-Bee

Revised by Dadant—1899 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroughly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for

one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

48 cents in American gold—and at times was very plentiful. He also told me that he was trying to have improved lives, and material for the same, brought into the country free of duty.

□ In this climate one may wear summer clothing all the year around, but in the cool nights of January and February one needs blankets to sleep under, the same as at home.

This is a great place for high prices. Vegetables average from 8 to 10 cents per pound; bread, 6 to 8 cents; meat, from 20 to 45 cents; chickens, from 90 cents to \$1.10; eggs, from 40 to 72 cents per dozen; and nearly all other commodities in like prices.

The country is rather hilly, with few levels between, and the land very fertile as well as of all colors. I have seen on a hillside land from coal black to clear white, with all the shades of brown, red, blue and yellow between, and this in an acre, too.

Milk is very high here, and it is almost impossible to get it pure, even tho they drive the cows around the streets and milk them at your door; and in addition, charge you from 60 to 90 cents for a gallon.

Nearly all the people here have the fever of "manana," and many of the Americans who have been here since the war have it, too. The people, as a rule, are not overclean—I mean the natives. I have seen them very often use a wash-basin to wash their head, face and socks in, and then (using other water, of course) take the same basin and have one sponge and some water for washing table-cloths, chairs and paved yards. Their kitchens are right alongside their cesspools, and they very often leave their dishes from one meal to another before washing them. While they cook they nearly always have a cigarette in their mouths. It is a common thing to see little tots without any clothing other than nature gave them, with a stump of a cigarette or cigar in their mouths; and, in fact, whole families smoke, even to the old women.

JAMES B. DRURY.

Province of Habana, Cuba, July 4.

Favors the "Fence"—Fair Crop.

I have 13 colonies of bees. The "fence" system of procuring comb honey is the best extant. I have tried nearly every other kind, including tin separators, but the "fence" beats them all.

The honey crop here is fair to middling. Bees now are working white and sweet clover, the latter abounding in great profusion.

D. B. GIVLER.

Dupage Co., Ill., July 24.

Plain Sections and Fences.

In reply to R. V. Goss' question, on page 445, whether or not more honey can be produced with plain sections and fences than with the old-style sections, I would say that we have been using both styles for two years, and positively can not tell any difference, so far, in the quantity of honey stored, tho possibly the bees will fill them a little better than the old-style section. But we find one serious objection to the plain section and fences, that is, the bees will build more bur-combs than in the old-style sections, even if the hive is "level." And then, again,

CRIMSON CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

	5lb	10lb	25lb	50lb
Crimson Clover	70c	1.20	2.75	5.00
Alsike Clover	80c	1.50	3.50	6.50
White Clover	90c	1.70	3.75	6.50
Alfalfa Clover	80c	1.40	3.25	6.00

Prices subject to market changes. Add 25 cents to your order, for cartage, if wanted by freight.

The Bee-Keeper's Guide

Or, Manual of the Apiary,

—BY—
PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPERS' GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,

in a good honey-flow the bees will draw out the comb to the edge of the section and fasten it to the cleats on the fences, thereby causing a row of cells to be uncap in removing the sections. However, we would like to hear the experience of others.

KINZEL & EMERT,
Sevier Co., Tenn.

Cider Brandy for Bee-Stings.

Here is an incident I was told by an old bee-keeper the other day; there may be something in it, but I do not say there is:

While talking with a bee-keeper the other day about bee-stings, he said he once witnessed a very severe case which occurred to a person who started to hive another swarm of bees, having hived one that same day. It had clustered on a limb of a pear-tree, and he had advanced within about two rods of the cluster when they came for him, posthaste, and he was nearly covered in less time than it takes to tell it. He retreated toward his home, which was a little distance away. On reaching it he found himself completely blind from the effects of the stings. His wife went to the cellar for a pitcher of cider brandy, as they used to keep it handy. She returned with it and put it on the table by the patient, and went to get a glass, but he was suffering so much that he took the pitcher and drank its contents, which was enough to intoxicate five men, tho he failed to feel its strength when in that condition; but the poison from the bee-stings came out from the wounds like gum from a tree, and he recovered in a few days.

Now, Mr. Editor, what do you think of that?

The honey crop is fair from basswood and sumac, with a good prospect for a fall flow. White clover failed. If

\$5.00 per month will pay for medical treatment for any reader of the American Bee Journal. This offer is good for 3 months ONLY—from May 1 to Aug. 1. Dr. Peiro makes this special offer to test the virtue of small price for best medical services. Reply AT ONCE.

The Modern Remedy Co., Kewanee, Ill.

we can improve our stock so as to make them red clover workers, we may look for better success. ROBT. J. CARY, - Fairfield Co., Conn., July 21.

[Tis said, Mr. Cary, that it takes one poison to kill or counteract another poison. Now, if cider brandy or any other kind of brandy or whisky, were taken only under circumstances similar to those mentioned, we think there would be few people who would object to their use. But it is just possible that with the cold water treatment the unfortunate victim referred to would have recovered just the same, so it isn't necessary always to recommend intoxicating liquors as a medicine. There is a hospital here in Chicago which has had a better record in the successful treatment of cases which have come under its care since they have dispenst entirely with the use of liquors.—EDITOR.]

A Report—Swarming Management—Honey-Dew—Bees as Pollinators.

Bees are working hard at present on both white and alsike clover. The last named seems to be the better of the two. June 15th my scales colony gained two pounds, and have been gaining ever since.

Last year my bees did not do anything up to July 7th. We did not get any clover honey, but I got about 3,000 pounds of light-colored honey, which was gathered from mint and blue vervain, both of which are plentiful here, and the prospects are good for a crop of honey from them again this year, and I think if the weather keeps dry I will get some clover honey.

I have 81 colonies, and have had no natural swarms, tho I have made 3 artificial swarms, but I like natural swarms better, as they seem to go to work as tho nothing had happened; but when you divide a colony the one that has no queen almost always lies idle for a few days, which means quite a loss in a good honey-flow. I hived some natural swarms on full-drawn combs in the forenoon, and gave them an extracting-super, and by night I found considerable honey in the extracting-combs. In a week I extracted from those colonies and they workt

Four Celluloid Queen=Buttons Free AS A PREMIUM.

For sending us ONE NEW SUBSCRIBER to the Bee Journal for the balance of this year, with 50 cents, we will mail you FOUR of these pretty buttons for wearing on the coat-lapel. (You can wear one and give the others to the children.) The queen has a golden tinge. This offer is made only to our present regular subscribers.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate, it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

Prices of Buttons alone, postpaid: One button, 8 cts.; 2 buttons, 6 cts. each; 5 or more, 5 cts. each. (Stamps taken.) Address,

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO.

25 cents Cash paid for Beeswax.

This is a good time to send in your Beeswax. We are paying 25 cents a pound—CASH—for best yellow, upon its receipt, or 28 cents in trade. Impure wax not taken at any price.

Address as follows, very plainly,

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO.

A HANDY TOOL-HOLDER!

Sent by Express, for \$1.50; or with the Bee Journal one year—both for \$2.00.

Every Manufacturer, Miller, Carpenter, Cabinet Maker, Machinist, Wheelwright and Quarryman, Farmer, or any one using a grindstone, should have one of these Tool-Holders. One boy can do the work of two persons, and grind much faster, easier and with perfect accuracy. Will hold any kind of tool, from the smallest chisel to a draw shave or ax. Extra attachment for sharpening scythe blades included in the above price. The work is done without wetting the hands or soiling the clothes, as the water flows from the operator. It can be attached to any size stone for hand or steam power, is always ready for use, nothing to get out of order, and is absolutely worth 100 times its cost.

No farm is well-equipped unless it has a Tool-Holder. Pays for itself in a short time.

How to Use the Holder.

DIRECTIONS.—The Tool is fastened securely in the Holder by a set-screw and can be ground to any desired level by inserting the arm of the Holder into a higher or lower notch of the standard. While turning the crank with the right hand, the left rests on an steady the Holder; the Tool is moved to the right or left across the stone, or examined while grinding, as readily and in the same way as if held in the hands.

For grinding Round-Edge Tools, the holes in the standard are used instead of the notches.

The Fannie Field Poultry Pamphlets Cheap.

We will mail you your choice of any of the following 64-page poultry pamphlets at 10 cents each, or all 3 for only 25 cents—while they last:

POULTRY FOR MARKET.—It is written for those who wish to make poultry-raising profitable.

CAPONS AND CAPONIZING.—It shows in clear language and by illustrations all the particulars about caponizing fowls, and thus how to make the most money out of them. Every up-to-date poultry-keeper should have it.

OUR POULTRY DOCTOR, or, Health in the Poultry Yard, and How to Cure Sick Fowls. All about poultry diseases and their cure.

Remember, we mail the above at 10 cents each, or all three for 25 cents; or for \$1.10 we will mail the three pamphlets and credit your subscription to the American Bee Journal for one year. Address,

GEORGE W. YORK & CO.,

118 Michigan Street, CHICAGO, ILL.

right along. When I make artificial swarms I take about half of the bees and half of the brood, and the queen, and put them into a new hive, and fill both hives with combs. Then I take the new hive that contains the queen and set it on a new stand. This works quite well for me, but sometimes the colony that was left will build a lot of queen-cells, and swarm, tho I almost always go thru them and cut out all but two cells. That stops swarming.

When my bees swarm, and I don't want them to swarm but once, I get the swarm on a swarming-box that I have used for some time, which is made of half-inch lumber. It is about 18 inches long and 8 inches square with a lot of holes bored in it, and one end left open. It is attach to a long pole, so I can get them to cluster there. When they are all in and on the box, I move the hive that the swarm issued from to a new stand; then I get the swarming-box that contains the swarm, and dump them on the alighting-board. In so doing I have never lost a single swarm, and this plan of moving the old hive weakens it to such an extent that it does not swarm any more that year; while the new swarm being placed on the old stand catches all the field-bees that were out during the time the swarm issued. Having the new swarm on full-drawn combs works a little like giving a newly-married couple a full outfit to start in house-keeping with.

I have seen bees gathering honey-dew from oak leaves, and on examination found a kind of wedge-shaped insect on the bottom of the leaves and branches. I found this same kind of insect on the hedge fences a few years ago. This honey-dew was of a very light color, and was very abundant, so it could be seen in small drops on the stems of the new leaves. When these drops get so large that they fall on the leaves below they look like real dew, as some people think it is. I think if they would examine the matter very closely, they would almost always find the insects that produce honey-dew. Bees will work on these oak-leaves early in the morning and late in the afternoon. This stuff was used by the bees for brood-rearing, which is about all it is fit for. But it is a good thing that we get some honey-dew in this locality, because it generally comes when there is nothing else for the bees to get any honey from.

I have wondered for some time why it is that farmers do not pay more attention to bees, when the bees are their best friends. If they have any fruit-trees bees of some kind are needed to fertilize the blossoms, and the honey-bee seems to be the best for this purpose. I think bee-keepers could do a great deal along this line by talking to their neighbors that keep bees, and telling them the real good that bees do for them in getting their fruit, and telling them the real value bees are in getting fruit-trees to bear; and it will not do any harm to tell them a little about honey, because most people think that all bees are good for is to store honey and sting. It would be a good thing if we could have a little of this nature study taught in our public schools.

Rocky Mountain Bee-Plant Seed!

(*Cleome integrifolia*.)

...FREE AS A PREMIUM...

The A B C of Bee-Culture says of it: "This is a beautiful plant for the flower-garden, to say nothing of the honey it produces. It grows from two to three feet in height and bears large, clusters of bright pink flowers. It grows naturally on the Rocky Mountains, and in Colorado, where it is said to furnish large quantities of honey."

We have a few pounds of this *Cleome* seed, and offer to mail a ¼-pound package as a premium for sending us ONE NEW subscriber to the American Bee Journal, with \$1.00; or ½ pound by mail for 40 cents.

GEORGE W. YORK & CO.

118 Michigan St. CHICAGO ILL.

Second-Class Queens,

(What Becomes of Them?)

As to color of progeny there are some tested queens that are second-class, that are equal to any for business. That is, 3-band bees predominate in the offspring of golden mothers. These are sold at 50 cents each. If 5-band bees predominate, and do not exceed 80 percent, they are worth \$1.00; above this and not to exceed 95 percent, \$1.25; all of a higher grade and not uniformly marked, \$1.50 each; while first-class breeders are placed at only \$2.00.

Untested, either 3 or 5-band, 75c each; or 3 for \$2.00. Money order office, Warrenton, N. C.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, July 7.—Some new white comb honey is selling at 15c; not much offered and not much demand for it. Extracted is slow sale; best white, 7@7½c; best amber, 6½@6¾c; dark amber, 5@5½c. Beeswax, 27@28c.
R. A. BURNETT & Co.

CINCINNATI, July 20.—White extracted honey, 7@7½c; southern extracted, 5½@6½c, owing to quality. No comb honey on market. Good demand for beeswax at 25@27c. Shipments of extracted honey from the South are more numerous than a few weeks ago, but we find it hard to make sales, owing to a slow demand. C. H. W. WEBER, 2146 Central Ave.

BUFFALO, July 20.—For strictly fancy white one-pound comb honey we are getting 16@17c. Any grade sells high—10@15c, as to grade.
BATTERSON & Co.

KANSAS CITY, July 20.—We quote: New No. 1 white comb, 14@15c; No. 1 amber, 14c; dark, 13c. Extracted, old, 6@6½c; no new in market. Beeswax, 22@25c.
C. C. CLEMONS & Co.

DETROIT, July 24.—Fancy white comb, 15@16c; No. 1 white, 14@15c; amber and dark, 10@12c. Extracted, white, 7c; amber and dark, 5@6c. Beeswax, 25@26c.
Supply and demand for honey both limited.
M. H. HUNT & SON.

NEW YORK, July 26.—There is a fair demand for white comb honey, and enough arriving from the South to supply the demand. Fancy white sells at 15c; No. 1 white, 13@14c; No. 2 white, 11@12c. Extracted remains rather quiet, and the market is sufficiently stocked to meet the demand. Beeswax very firm at 28@29c.
HILDRETH & SEGELKEN.

SAN FRANCISCO, July 18.—White comb, 12@12½c; amber, 9@11; dark, 6½@7½c. Extracted, white, 7½@8c; light amber, 7@7½c; amber, 6@6½c. Beeswax, 26@27c.

Amber grades are in fair supply, both comb and extracted, and there is a moderate business doing in the same at prevailing figures, mostly in a small jobbing way and on local account. Large dealers are purchasing only to fill immediate orders, not caring to stock up at present prices. Water-white honey is scarce and in a limited way is salable at tolerably stiff figures.

WANTED—HONEY AND BEESWAX.

We have a tremendous and growing trade in this line, and would like to hear from all who have such goods to sell in any part of the country, with quality, description, and lowest cash price. THOS. C. STANLEY & SON, Fairfield, Ill.

WANTED COMB HONEY AND EXTRACTED HONEY.

Will buy your honey, no matter what quantity. Mail sample with your price expected delivered in Cincinnati. I pay cash on delivery. C. H. W. WEBER, 2146 Central Ave., CINCINNATI, OHIO.

We have a Large Stock on hand and can ship promptly.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

HOWARD M. MELBEE, HONEYVILLE, O.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.10, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO., 118 Mich. St., Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

CONTRIBUTED ARTICLES

Selling Honey by Local Newspaper Advertising.

BY C. DAVENPORT.

IN my previous article I called attention to the fact that all efforts of whatever kind made to increase the sale and demand for our product is advertising in some form, and as before intimated, I have tried it in many different ways,

and expense; besides, it requires a certain kind of skill or ability, as well as experience, to make them a success; for these reasons they are far less practicable than newspaper advertising.

But, my friends, this is not so simple a matter as it appears. Whole books have been written on the subject, and shrewd, intelligent men are making a life work of learning the methods or ways in which the most returns for the money expended can be secured by newspaper advertising so the few words I say in the small space I am necessarily allowed, can only treat the subject in a general way.

In any locality where the demand is not what it should or might be, the first thing to be determined is, Why isn't the demand and consumption greater? There may be many

Mr. Anton G. Anderson and Apiary, of Pottawattamie Co., Iowa.—See page 505.

and by far the most effective way I have tried, all things considered, is advertising in the local papers. There are, tho. other ways in which more immediate returns, or, in other words, there are quicker ways by which large quantities of honey can be sold, but they entail much more work

reasons why it is not, but I can take space to mention only the two which usually either singly or combined are the cause. One of these is the fear of adulteration. This adulteration business has got to be one of the greatest curses of modern times; it not only injures the health of millions

who thru ignorance or necessity eat adulterated food products, but it works great harm to many producers by creating a prejudice in the minds of the people against their product. This is the case in our pursuit. There is no use in our trying to dodge the fact that our product is looked upon with more or less suspicion by the general public. Many people really believe that bee-keepers feed their bees sugar, glucose, cane-syrup, and the like, in order to have them "make" honey from it. In fact, I myself, a few years ago, accused one of the bee-keepers in this State of producing and selling comb honey made from sugar, but I now know I was in error, and that it can not be done. Yes, I tried it; gave it a most thorough trial, not because I intended to practice it if it was profitable—no, I intended that if sugar-honey could be produced for 10 and 12 cents a pound at wholesale, to pull right out of the whole business; but I have no fears of any actual adulteration of this kind ever being done, even if the wholesale price of honey should be double what it has been the last few years. Not because I think there are none who might not practice it, but simply because it could not be done with profit.

But the belief in my locality became so strong, that bee-keepers were selling honey made from sugar and cane-syrup, that it seemed impossible to increase its sales. As a matter of fact, I lost considerable trade already worked up. When this feeling was at its height, the following notice appeared in one of the local papers:

\$500 REWARD.

Five hundred dollars will be paid by us to any one who proves by analysis or otherwise that any honey sold by C. Davenport or his agents is adulterated in any way or manner; or, in other words, if it is not pure nectar gathered by bees from flowers. This offer holds good a year from date. _____ & Co., Bankers.

This notice appeared only once, but that was sufficient, for I secured a large number of the papers. One old lady, to whom I showed the notice, said: "Of course that settles it, and I am glad you have quit feeding your bees stuff. Genuine honey from flowers is what I want." She was one of my regular customers, but had previously that year refused to take any, saying frankly that she was afraid it was adulterated; and I could not convince her that it was not, but a guarantee of \$500 did, as it did almost all others. Of course, there are always a few that nothing can convince. But suspicion gradually died out, until some time ago, when it began to revive again. This distrust of honey was not confined to my immediate neighborhood by any means, but extended over a wide extent of territory.

A less amount of money as a guarantee of purity will answer, as I found when working up trade in other towns, but in a locality where no suspicion about the purity of honey locally produced exists, it would be folly to bring up the subject and offer any reward at all.

This brings us to the other reason to be discussed, why the local demand is not greater. This is on account of indifference, and general ignorance of its worth. As a means of overcoming this cause or reason, short but numerous paragraphs should appear in a local paper, calling attention to its great value as a daily article of food on account of its healthfulness; that, besides being one of the most delicious sweets known, it possesses great medicinal virtues in many forms of throat, lung, and stomach troubles; how some of our most eminent physicians attribute many forms of kidney diseases which so often terminate fatally, to the free use of cane-sugars; and that some of these patients are forbidden any form of sweet food except honey.

Call attention to the remarkable fact that when man lived to be 300 or 400 years old, honey was the only form of sweet known; how bees and their product have from these

earliest times descended to us of the present time unchanged by the evolution of ages.

I have emphasized the fact and explained why some honey may be much inferior to others; that on account of devoting my whole attention to its production, with the most modern hives and appliances, what I sell is warranted to be the best of its kind; that the great improvements in hives, a better understanding of bees, and the increase in numbers in which they are kept, have caused honey of late to be sold at such a price that its use is no longer a luxury to be enjoyed only by the rich, but that it can now be used by all classes, even as a matter of economy under some conditions.

All the short paragraphs I have caused to appear relating to the subject have been put at the head and sandwiched in between paragraphs relating to local events. Small notices of this kind put among regular advertisements are apt to be overlooked, but all who take a paper carefully read the local notes, because otherwise they might miss something of great importance, said either about themselves or their neighbors. So, just after reading how Miss Jones wore her new bonnet to church last Sunday, the next paragraph may inform them that C. Davenport, while it lasts, is offering choice mixt clover and basswood extracted honey for 8 cents a pound.

Tho every one does not take the local paper, those who do not may borrow it of their neighbors.

A person who formerly lived here but who is now a resident of Dakota, had the local paper from here, his old home, sent to him, and saw these notices. He wrote in regard to honey, and has since been a large customer, buying on an average about 500 pounds a year, part of which he probably retails at a profit amongst neighbors; and from this one customer that I secured by this means, I have received a number of times the amount above what I could in the city markets, to pay what my newspaper advertising has cost me, all told. A single announcement in a paper merely offering honey for sale, stating its price and telling where it can be obtained direct from the producer, will under some conditions bring results that could not by some be obtained in a week's work of peddling. Local newspaper advertising rates are very low, and I have been able to pay most of these bills with honey.

And if the immediate returns from this form of advertising are not what is expected, it should not be hastily condemned or abandoned, for its later effects are often far greater. I am acquainted with a bee-keeper who has, in a comparatively short time, almost entirely by this means, worked up such a trade that altho he keeps 200 or 300 colonies himself, he has to buy thousands of pounds annually to supply the demand. His advertising, tho, is not limited or confined to his local paper; much of his trade is in other States. Besides receiving a much better price than could be obtained in the general wholesale markets, he gets the cash before the goods are shipped.

Southern Minnesota.

Mountain Honey-Dew—Eucalyptus Honey.

BY PROF. A. J. COOK.

A FEW days ago I did what I wish every bee-keeper in America could do—visited the far-famed Yosemite Valley. Think of a valley seven miles long and one mile wide, surrounded on all sides by rocks which rise almost vertically to a height of nearly one mile! Think of the Yosemite Falls, 2,600 feet high, and with one leap of 1,600 feet! Try to picture to other falls on the larger Merced River, the Nevada Falls and the Vernal Falls, near

each other, so that both are visible at the same time, one over 300 and the other over 600 feet high!

Imagine, if you can, great glacier-worn domes looking like so many bald heads, crowning the lofty heights which surround this valley. Well, we surrounded, carried by faithful horses, one of these great domes, called the south or half dome, and ascended to the top of Cloud Rest beyond it, when we were over 10,000 feet above the sea. For the last mile of our ascent the pine trees were just dripping with honey-dew, and the chaparral beneath was also shining with the great drops of nectar. The bees have evidently not reached as high as this in the mountains, as we saw no bees on the honey-dew.

Some of my students who were with me, who had already been enlightened on the subject, were quick to seek for the authors of this secretion, and found them in the great hosts of plant-lice which everywhere infested the great pines. So thick was the nectar that we could easily collect it in sufficient quantities to test. We found, as I have almost always found it from plant-lice or aphids, exceedingly delicious. I express the wish to my student companions that I wished I had an apiary on this grand old mountain summit. I should be sure of a great harvest of most excellent honey.

Myself, wife, and daughter are now spending a few days in the unique little town of Avalon, situated on Catalina Island. The beautiful town is nestled at the foot of high hills—almost mountains—and faces a placid little bay of the same name as the town. The whole place comprises but a few acres, and the streets are lined on both sides by fine eucalyptus trees. There are many of them now in full blossom, and they are musical with the hum of hosts of bees. Thus Catalina has its bees if Yosemite Mountains have not.

It will be remembered that Mr. Wood proposed to come here to rear queens in hopes to secure pure mating. He gave it up upon finding that there were bees already in abundance on the island.

Catalina Island, Calif., July 23.

Feed Value of Bokhara Clover—A Comparison.

BY T. F. A. CONNELLY.

THINKING it might be of interest to some bee-keepers, and as I have never seen it published, I will send the analysis of bokhara clover hay, and accompany it with the analysis of wheat and alfalfa hay for comparison, that they may learn the feed value of the bokhara hay. Any one can see by the chemical ingredients that bokhara is the equal of either in value as a forage-plant.

	Amount digestible in 100 pounds.				Potential Energy in 1 pound (calories)	Nutritive Ratio
	Crude Protein	Crude Fat	Crude Fiber	Nitrogen, Free Extract		
Wheat hay.....	3.14	1.20	9.81	37.40	987	1:15.8
Alfalfa hay....	12.41	1.57	10.40	26.73	985	1: 3.4
Bokhara hay...	8.68	1.92	9.96	29.42	976	1: 5.0

This analysis was made at the California Agricultural Experiment Station (see page 146, report for 1896). In this part of the State no one has yet made any hay from sweet clover. I have now 10 acres seeded to the plant, and will try it, but it is surely a good honey-plant, for last summer near me there was a small piece in bloom, and the bees worked on the bloom from June 10th till Nov. 13th, and I long since learned that bees do not visit flowers unless they contain nectar. I have also learned that no matter what plant the bloom always contains nectar. Within three miles of my apiary there are 1,000 acres of alfalfa, and gen-

erally the bloom is profuse, but the amount of surplus varies greatly, and altho I never have to feed, the amount of surplus in 1895 was, on an average, 120 pounds. One colony filled 420 sections. My yield of comb honey was 12 tons, while for 1896 my surplus was less than 70 pounds per colony. The conditions were precisely the same, as everything here is grown by irrigation. Our rainfall averages about four inches per summer.

The condition of the atmosphere has more to do with the flow of nectar than many suppose. I have seen the alfalfa meadows an ocean of blossoms, and not a bee visit them. Then it may be but a few days when the entire meadow will be alive with the industrious little workers. Or, the change may be the other way—from a busy scene to a holiday. One would think it was Sunday, or a circus, as there would be no work going on.

Some report that the rain washes the nectar out; that could not be the case here, for we have no rain.

There is no doubt but that with me the electric condition of the atmosphere governs the flow of nectar.

Inyo Co., Calif.

Directions for Dipping Cell-Cups or Goblets for Commercial Queen-Rearing.

BY W. H. PRIDGEN.

AS the latest freak in dipping receptacles for larvæ to be converted into queens is to make goblets instead of cups, I will explain how it is done.

The dipping-sticks illustrated again here (and which, by the way, were shown inverted, on page 401), were used to dip a whole batch at a time, and when heavy enough, and while the wax about the base was still in a liquid state,

Dipping-Tank for Queen-Cell Cups.

the whole set was touched to the bar, which would adhere, and then the bar, or rather a thin slat, cups and all were dipped again, which fixed all to the slat at once. At this stage the slat and base only of the cups were touched to cold water, and the dipping-sticks withdrawn one at a time, and is shown by one or two of the pegs being elevated in the picture, thus leaving the cups properly arranged on the slat ready to slip in the frame, as Mr. Doolittle tells us to do it.

The dipping-tank shown herewith was used with this outfit, which is long enough to admit a bar or slat that fits between the end-bars of a brood-frame, and this outfit is still very serviceable for making cups for one's own use; but the pegs must be rigidly fixed for dipping the commercial article, for convenience in removing the goblets as well as forming them.

Two lamps are used, one near each end, to keep the wax

at a uniform temperature, which should be just above the melting-point.

Now that the cups are no longer attached to a bar, a piece of tin has been fitted into the bottom of the tank, having the ends perforated and turned up to a level with the top of the tank, just under the rests or gauges, allowing pieces of wax to be added as the liquid is used out, without its interfering with the work. The wax is added over the lamps, thus causing it to melt without raising the temperature elsewhere, and serves the purpose of keeping the depth of dip regulated without having continually to adjust the gauges, which can be raised or lowered according to circumstances.

The bevels at the ends of the forming-stick holder both incline the same way, which admits of varying the depth

again full depth, and set on the board, by shaking the drops off, if the bases are large enough, before placing them on the board, or, failing to shake them off, if the size of base is to be increased.

The main body of the cups should be made heavy enough at first to prevent the contraction in cooling to cause the water that can not be shaken from the sticks to burst thru and make water-bubbles or knots on them; and then increase the weight of the bases, as that part has to remain longer in the wax, altho the dipping is done quickly, and therefore is inclined to melt off; while the last dip should be full depth to make the cups smooth outside, and also to warm the whole up so they will slip off of the pegs easily.

When completed, touch the bases to cold water, but not

A Whole Battery of Dipping-Sticks used in Modern Queen-Rearing—and the Results.

(Both engravings in this article kindly loaned by the Bee-Keepers' Review.)

of each alternate dip, by an endwise movement, and still use the gauges as a rest, so as to dip the pegs from end to end alike.

To make the cups with flat bottoms or goblet shape, one must have a board on the table that has been thoroly soaked in water, and keep it wet by occasionally dipping it, or else touch the dipping-sticks to it every time they are taken from the water.

Make two dips the same depth in rapid succession, then touch the bases of the cups to the melted wax, and immediately set them on the wet board, to remain until the wax "sets." Then dip them half way up, and set them on the wet board as before. The next time dip three-fourths up, and go back to the wet board. At this stage the base may or may not be heavy enough, but the cups should be dipt

deeper than the necks. This is done to harden the bases so that they can be handled; while the main body should remain warm to be easily removed. If allowed to contract too much they fit the pegs too tightly for easy removal.

If they are to be inserted in a bar as described in the issue of June 28, simply shake the drops of wax from them instead of placing them on the wet board, which will leave the bases pointed.

The goblet-shaped or flat-bottom cups are either stuck on the bar with melted wax, or else use a bar with two headless small nails projecting $1/16$ of an inch, driven $1/4$ inch apart, where every cup is to stand, and simply press the cups down on them. Arrange the nails in pairs, forming two rows up and down the bar, and have the pairs $5/8$ of an inch apart.

Warren Co., N. C.

CONVENTION PROCEEDINGS

Report of the Central Texas Convention.

BY LOUIS SCHOLL.

The sixth annual meeting of the Central Texas Bee-Keepers' Association was held at Hutto, July 12 and 13, 1900.

The convention was called to order by Pres. E. R. Jones at 10 a. m., July 12th. Rev. L. L. Lusk, of Hutto, offered prayer.

Mr. A. W. Carpenter delivered an address of welcome in behalf of the citizens of Hutto, to which Judge E. Y. Terral responded.

Secretary Scholl read the minutes of the last meeting, which were adopted. After calling the roll, new members were enrolled and dues collected.

A motion was made and carried that ladies (members) be exempt from dues.

It was moved and carried that any bee-keeper can join the Association at any time by writing to the secretary, and enclosing the regular membership fee of 50 cents for a year.

Another motion prevailed, "That any member who fails to attend, or fails to pay his dues for *three* consecutive meetings without a suitable excuse, be stricken from the list." Of course, when any one pays his yearly dues he is a member, whether he attends the annual meetings or not, as above.

The president's annual address was delivered by Pres. E. R. Jones. The election of officers for the next term resulted as follows:

O. P. Hyde, president; J. B. Salyer, vice-president; and Louis Scholl, of Hunter, secretary and treasurer.

HONEY-RESOURCES OF TEXAS.

On this subject Mr. Stachelhausen said he could not say much, as he had been over but a very small portion of Texas, and therefore could not know much about the honey-resources outside of his own locality. His main honey-plants are Indian-head, hoarhound, and horsemint, but he does not expect much from late horsemint. Mustard is another important one. In dry years mesquite is his main source; otherwise it is horsemint that gives the crop. Then cotton yields, while some years it does not, and he has not yet found what causes it. Broom-weed is sometimes good in the fall.

Judge Terral's experience was almost like that of Mr. Stachelhausen, not knowing much about other sources in other localities. He commenced by mentioning corn-tassels, and does not believe that bees ever get honey from them. His bees get some honey from turnip patches, and some other minor plants, followed by horsemint. He thought he could improve the yielding of horsemint by watering it, but failed. He believes that it grew too rank. He talked about the old-fashioned buckwheat in Kentucky, where it just bent down to the ground loaded with bees, but the other sort was no good. He does not believe that cotton yields honey. He saw the bees work on the leaves just as they work on oak leaves, and believes that they only get "bug-juice."

Here F. L. Aten said that black bees do not work on cotton. He told of a man who had nothing but blacks that did not get any cotton honey; but as soon as he Italianized his bees they gathered cotton honey.

F. J. R. Davenport says that cotton on light land does not yield as well, and that the honey is different from the

whiter honey of cotton on the black land. He also spoke about sweet clover as a good honey-yielding plant, and the different changes of the atmosphere and the effect upon the yield and secretion of nectar of the sweet clover blossoms.

D. C. Milam gave a list of the main honey-yielders of his locality (Uvalde County). First, is wild peach, a sort of evergreen, blooming in February; wild tan in March; also buffalo clover. Prickly pear and others help along the list. The wa-he-ah (gua-ella) is a wondrous honey-yielder, as bees store from this source faster and more honey in less time than anything else (in April). He depends upon catclaw for the main surplus, but this season it was a failure; in summer and fall horsemint, with other minor plants and "bug-juice" to finish.

M. M. Faust has other minor early plants for brood-rearing. Catclaw, mesquite, cactus and white brush, which blooms after every rain during its season only a short time.

B. A. Guss, of Bell County, locality and sources similar to other northern localities as mentioned by Messrs. Terral, Davenport, and others.

E. J. Atchley, of Bee County, almost like Uvalde County, mentioned as follows: Live-oak honey, if a good season, is very early and very valuable for brood-rearing; the quality, tho, is an inferior yellow honey. Wa-he-ah from March 1st to April 1st, is sometimes cut short by north winds. Catclaw is very thick, but on account of rain it failed this year, but horsemint was fine, and gave lots of honey. As horsemint is quite strong flavored, all combs are emptied for the mesquite flow which follows. Sometimes they have a second spring in the fall and get much honey; otherwise not. Sometimes this causes a bad spring following. He said that all colonies ought to be strong in the fall, and thus wintered over with plenty of stores will be in good shape to gather, and be ready for any early flow that might come. In answer to a question, he said it is best to feed in the fall and rear plenty of young bees. It would be too late in the spring.

FIRST DAY—EVENING SESSION.

College Station was selected as the place of the next meeting, at the same time as the Texas State Farmers' Congress.

The regular program was again taken up, and Louis Scholl tried to handle "Balks, Blunders and Difficulties in the Way of Beginners." "This subject must have been given to me by mistake, for I have always been too careful and went too slow to make any balks and blunders. But difficulties—I have had very many; but as they are all of private affairs, I would not like to tell about them. May be I was to tell about the balks, blunders and difficulties of others; but as I do not attend much to other people's business, I can not say anything on this subject at all."

Mr. Davenport said he did not even have to tell about other people's balks and blunders, as he had made some himself. But he told about a bee-keeper who hived a swarm of bees, and late in the fall he found that the "gum" was full of honey, so he *robbed* 'em. He took out all they had, and to make a good job of it he ordered his boy to get some biscuits, with which he daubed up clean every bit of honey. Of course, the bees got "rattled," swarmed out, and starved. Another man took some honey from his bees and unknowingly set fire to something in the bee-yard. Discovering it later, he found his bees and everything burned. He, himself, tho, has everything nice, neat and clean, nothing lying around, and puts all bits of comb, wax and honey away at once. He has his hives eight feet square, and keeps them clean, too, inside and outside.

A Member—Say, tell us about your wax and your wife's cook-stove.

Mr. Davenport said he melted wax on his wife's stove in a wash-boiler, and upset it.

G. F. Davidson arose to ask how Mr. Davenport manages to keep his big hives, which are eight feet square, clean. He said he could not do so.

Mr. Davenport explained that his hives are the regular size, but that they are set eight feet square or apart each way.

Mr. Davidson's first balks and blunders were made when he moved his first bees. After moving, the bees would swarm out. They were hived back only to have them come out again. To keep them from doing this he wanted to fix them, so he nailed up their entrances. He found out later that this was a serious mistake, for all melted down, and he lost the bees. He said he was once like many who think they know all about bees, and if they have success one year they are not slow to report it in some bee-paper; but next year it does not work at all.

M. M. Faust said that he was not like the first two gentlemen. Perhaps they were not real bee-keepers, or what they said was only complimentary of themselves. Lookt a little "fishy." He said he makes blunders all the time, and it sometimes seems as if all was blunders.

W. H. Laws never heard of any bee-keepers who balk. They never balk, but go ahead. They make blunders, tho, and he has heard plenty of such, just as he once clipt virgin queens.

E. R. Jones made two bad blunders. The first was to try to keep bees in his locality (Milam County), and his second was in not getting away from there.

MANAGEMENT OF OUT-APIARIES.

F. L. Aten gave his experience. He uses the 10-frame hive, three or four stories high, and has strong colonies. He does not work them the same hight every year, and by four stories high he does not mean an empty box and bees, but full of comb and bees to the top. He prevents swarming by giving plenty of room, spreading the brood-combs, and putting frames filled with comb foundation in between. He puts the rest of the combs above in the super, and fills up with frames of foundation. One must study this well, and use good judgment, or he will not succeed.

E. R. Jones has not had experience with out-apiaries, but his first object would be to manage successfully colonies to prevent swarming. This would be plenty of room in such shape and way as it can be best occupied. But it all depends upon circumstances. Sometimes comb foundation is almost useless when much wax is secreted during a fast flow. During a slower flow foundation is better.

E. J. Atchley would use 10-frame hives, 3-banded Italians, and prevent swarming on Mr. Aten's plan. He would extract honey, and see to them once in awhile, and would likely not lose many swarms. He would use frames all filled with comb, which is better. Sometimes colonies would have their brood-nest above, and plenty of room below, and would swarm; sometimes just the reverse; but when given room above and below, and also plenty of drone-comb in the hive, there is very little swarming. Swarming can not always be prevented.

ESSENTIAL QUALITIES OF A SUCCESSFUL BEE-KEEPER.

Udo Toepperwein advised first reading and taking all of the bee-papers; study the bee-books, and go to the bee-conventions. Then don't rush into the business, but go slow; and the farther he gets into it the less he sees and knows about it.

Mr. Stachelhausen—Work, read and think, and after awhile you will be a good bee-keeper.

D. C. Milam thinks that one who is successful at other things ought to be successful at keeping bees. Ought to stick to it thru thick and thin, and a bad year generally

proves the successfulness of a bee-keeper, either when he lets his bees starve during such a year, or when he feeds them and helps them thru.

Mr. McClure thinks only those with a genuine bee-head are successful, and that those without such a head ought not to fool with bees, but apply themselves to something else for which they have a head.

But Mr. Davidson does not believe that it is the head alone, but that one must study to be successful. There are some who have kept bees in box-hives and gums, and never read a bee-paper. Such never succeed. This is the class of bee-men who are always asking such questions, "How do you keep web-worms out of the hives?" Others who get lots of honey from a few colonies, imagine that they will get rich by keeping more bees, and then not spend one dollar for a bee-paper; they are not successful.

W. H. Laws—It is the natural fitness for the business to make a successful bee-keeper, and such a man will make money out of bees, and also find pleasure in bee-keeping. Such he also thought would be successful at other pursuits.

E. J. Atchley says that experience is one thing necessary to be successful, as all those who rush into a thing big are never so.

R. B. Leahy told how he succeeded in bee-culture. He started with books first, read them thru and thru again; took the bee-papers and read them, and studied everything he could find on the subject. So he started with books and journals first, and succeeded with his bees afterwards.

SECOND DAY—FORENOON SESSION.

BEST METHOD OF COMB-HONEY PRODUCTION.

L. Stachelhausen says the production of comb honey in sections is more difficult than producing extracted honey. He described different methods that he uses. The most important is very strong, rousing colonies, with the brood-chamber crowded full of brood. This leaves no room for honey there, and the only place is in the sections in the supers above. One way of having strong colonies and plenty of room, by letting the queen breed in two stories, is unfit for producing section honey, as there are some empty combs in which the bees store the honey that ought to go into the sections. Large colonies in a small brood-chamber are better, and by splitting the brood all the time to keep from swarming. He told about Doolittle's method. Hiving swarms as per Hutchinson's method is a good way. His own way is similar to it. He changes hives as in swarming, by putting one of his shallow cases with starters only in the frames, in place of the colony just removed. Then he brushes all the bees from that colony into the new hive, and sets the section supers on top. Sometimes a queen-excluder is necessary, and to keep the bees quiet he gives them a frame of young brood, which has to be removed the next day or the bees will swarm out. First use another empty case below the one with frames and starters for a few days. Use the comb and brood for various purposes in the yard—combs on extracted-honey colonies, etc., and the brood can be given to nuclei. Or the Heddon method can be practiced. He never tried to put the brood-cases above the sections when all the colonies are run for comb honey exclusively.

Mr. Laws spoke on the plan as recommended by Mr. Demaree. Mr. Jones also told about several good experiments he had made, something similar to the Golden method.

[Concluded next week.]

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

Chicago Convention Program.—The following is the program of the 31st annual convention of the National Bee-Keepers' Association, to be held at Chicago, Ill., Tuesday, Wednesday, and Thursday, Aug. 28, 29, and 30, 1900, the sessions to be held in Wellington Hall, 70 North Clark St.:

FIRST SESSION—TUESDAY EVENING.

Call to order at 7 o'clock.
 Song—Dr. C. C. Miller, of Illinois.
 "How to Sell Honey"—S. A. Niver, of New York.
 "Keeping Bees in a City"—L. Kreutzinger, of Illinois.
 Question-Box.

SECOND SESSION—WEDNESDAY MORNING, 9:30.

Song.
 Invocation.
 President's Address—E. R. Root, of Ohio.
 "Queen-Rearing by the Doolittle Method"—Mrs. H. G. Acklin, of Minnesota.
 Question-Box.

THIRD SESSION—WEDNESDAY AFTERNOON, 1:30.

Song.
 "Bee-Keepers' Rights and Protection by Law"—Herman F. Moore, of Illinois.
 "Trials of the Commission Man"—R. A. Burnett, of Illinois.
 Question-Box.

FOURTH SESSION—WEDNESDAY EVENING, 7:30.

"Breeding for Longer-Tongued Bees"—J. M. Rankin, of the Michigan Experiment Station.
 "Bee-Keepers I Have Met and Apiaries I Have Visited"—E. R. Root, of Ohio, assisted by Dr. C. C. Miller, Dr. A. B. Mason, E. T. Abbott, and others. Illustrated by a stereopticon.

FIFTH SESSION—THURSDAY MORNING, 9:30.

Song.
 "Various Forms of Diseases Among Bees; Cause and Cure"—Dr. Wm. R. Howard, of Texas.
 Report of the General Manager—Hon. Eugene Secor, of Iowa.
 "Pure-Food Legislation"—Rev. Emerson T. Abbott, of Missouri.
 Question-Box.

SIXTH SESSION—THURSDAY AFTERNOON, 1:30.

Song.
 "Chemistry of Honey and How to Detect Its Adulteration"—Thos. Wm. Cowan, of California.
 "How to Ship Honey to Market, and in What Kind of Packages"—George W. York, of Illinois.
 Question-Box.

SEVENTH SESSION—THURSDAY EVENING, 7:30

"Co-operative Organization Among Bee-Keepers"—R. C. Aikin, of Colorado.
 "My Trip Thru Wisconsin and Minnesota"—W. Z. Hutchinson, of Michigan. Illustrated by a stereopticon.
 Unfinished Business.
 Adjournment.

One prominent feature of the next convention will be the stereopticon work. Messrs. Root and Hutchinson, with a powerful stereopticon, will project upon the screen some photos they have taken of apiaries they have visited in various portions of the United States. The convention will be held in Wellington Hall, 70 North Clark Street, about a block and a half from the office of the American Bee Journal, and about five blocks directly north of the Court-house. The hotel at which delegates may secure lodging is the Revere House, about half a block from the convention hall. The rate for lodging will be 50 cents per night, and the proprietor has assured Mr. York that good beds are provided, but that several will have to occupy the same room. But when any one desires a room with a single bed, the charge will be \$2.00 per night. If two men wish to take a single room in that way they can do it, sharing the expense between them. Some G. A. R. people will pay 75 cents per night for a single bed, so bee-keepers are specially favored at 50 cents. The hotel is almost within a stone's throw of the convention hall, and right near the hall are first-class restaurants, where meals can be secured at reasonable rates.

It is a little too early yet to announce what the railroad

rates will be during G. A. R. week; but it is assumed that they will be low, probably a cent a mile each way.

Chicago is a central point, and there will undoubtedly be a large attendance; and, considering the attractions, it is earnestly hoped that bee-keepers will turn out in good, strong force.

E. R. Root, *President*.
 Dr. A. B. Mason, *Secretary*.

"JOSIAH AND I GO A-VISITIN'" is the title of Josiah Allen's Wife's new humorous serial which is begun in the Midsummer Story Number (August) of *The Ladies' Home Journal*. There are also four short stories—"Catharine of Arrogance," "Grandmother Winslow's Precious Plates," "From a Far Country," "The Story of a Song"—and the conclusion of Julia Magruder's serial, "The Voice in the Choir." "College Girls' Larks and Pranks" reflects the wit and shows the love of fun of the American girl. There is also a group of stories full of interest and mystery about "The Haunted Houses of New England," and others in quite the opposite vein are related by Rev. Cyrus Townsend Brady in describing his experiences as "A Missionary in the Great West." "My Summer with Some Chipmunks" gives some exceedingly interesting glimpses of the coy, brown-coated little rodents. Of interest to every girl aspiring to a higher education is an article detailing "How a Girl Can Work Her Way Thru College," by a Cornell graduate. Mrs. Burton Kingsland writes on "Conversation and Good Form in Public Places," and Mrs. S. T. Rorer explains "Why I am Opposed to Pies." The August Journal takes its readers on another stage of the pictorial journey "Thru Picturesque America," gives some views of "An Entire House on a Single Floor," and on the cover presents Howard Chandler Christy's "American Girl in Society." "Golden Poppies," a waltz by B. H. Janssen, is sure to find abundant favor with music lovers. The departments are as varied and complete as usual, and the pictorial features numerous and of commanding excellence. By the Curtis Publishing Company, Philadelphia. One dollar a year; 10 cents a copy.

York's Honey Calendar for 1900 is a 16-page pamphlet especially gotten up to create a demand for honey among should-be consumers. The forepart was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample free; 25 copies for 30 cents; 50 for 50 cents; 100 for 90 cents; 250 for \$2.00; 500 for \$3.50. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

Belgian Hare Breeding is the title of a pamphlet just published, containing 10 chapters on "Breeding the Belgian Hare." Price, 25 cents, postpaid. It covers the subjects of Breeding, Feeding, Houses and Hutches, Diseases, Methods of Serving for the Table, etc. It is a practical and helpful treatise for the amateur breeder. (See Prof. Cook's article on page 292.) For sale at the office of the American Bee Journal. For \$1.10 we will send the Bee Journal for a year and the 32-page pamphlet on "Belgian Hare Breeding."

"**The Hum of the Bees in the Apple-Tree Bloom**" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us *one new* yearly subscription to the American Bee Journal at \$1.00.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription *a full year in advance*, we will mail you a Wood Binder free—if you will mention it.

The Premiums offered this week are well worth working for. Look at them.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY,
118 Michigan Street, Chicago, Ill.

[Entered at the Post-Office at Chicago as Second-Class Mail-Matter.]

DEPARTMENT EDITORS:

DR. C. C. MILLER, "Questions and Answers." * * E. E. HASTY, "The Afterthought."

LEADING CONTRIBUTORS:

G. M. DOOLITTLE, F. A. SNELL, C. P. DADANT, R. C. AIKIN, PROF. A. J. COOK, "OLD GRIMES."

IMPORTANT NOTICES:

The Subscription Price of this journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec 00" on your label shows that it is paid to the end of December, 1900.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

VOL. 40. AUGUST 9, 1900. NO. 32

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

Dr. Miller Premium Honey-Queens.—As Dr. Miller is about caught up with orders now, he will likely be able to send queens quite promptly from now on. So we renew the offer of one of his queens as a premium for sending us one new subscriber to the American Bee Journal with \$1.00. See the last page of this number.

Candied vs. Liquid Honey at Retail.—There seems to be an irrepressible conflict between those who advocate selling honey in liquid form and those who advocate training customers to accept it in the granulated condition. Among the chief advocates for selling honey in the granulated state have been R. C. Aikin, G. M. Doolittle, and Dr. C. C. Miller, altho the last-named might do well to keep his finger out of the pie, seeing he is a producer of comb honey, and can hardly have had much experience peddling extracted honey to customers. In one respect, Mr. Doolittle stands somewhat alone, for he preaches putting candied honey in wooden packages, filling up just before the honey is too solid to run. Two special advantages are claimed for this, and at least for some cases they are well worth considering. One is that the cost is less than for any other package. The other is that there is little danger of breakage, and practically none of leakage.

Mr. Chalon Fowls steps into the arena as a "liquid" champion, altho the blows he strikes in Gleanings in Bee-Culture are by no means liquid, but very solid. In reply to

the claim that C. F. Muth had his customers trained to desire candied honey, he produces a letter from Fred Muth, a son of C. F., who says the bulk of his father's trade was to manufacturers, and it appears that those who demanded candied honey were those with whom Mr. Muth came in contact with personally as consumers, and could talk to, and he always made it his business to talk candied honey.

The strongest argument, however, in favor of selling honey in the liquid form is that given by Editor Root, in a foot-note, when he says that Mr. Fowls has been and is now getting double prices for his honey. Surely that is good pay for putting on the market a first-class article and replacing any that candies, and Mr. Fowls may well laugh at Dr. Miller's "straw" arguments. Editor Root says, however, referring to the great success of Mr. Fowls and W. A. Selser in selling liquid honey:

"Yet if either one of them were in Mr. Aikin's locality he might find it more convenient to put out his honey in the candied form, and that the profits would be just as great; or, what is more probable, the people of Colorado would not pay the prices obtained by Mr. Selser and Mr. Fowls for their bottled goods."

Reporting Convention Proceedings.—There are very few people who understand getting up reports of conventions for publication. Some seem to think that the editor of the paper in which the report is wanted, must publish *everything* just as written or sent in by the secretary or the one who writes out the report. Of course, those papers that are mostly local, and have small circulations, must fill up their space in some way, and having little of value to put in, will likely publish a whole lot of things of no interest to any but those who were at the particular convention reported.

For instance, in one report sent for publication there were over two pages of the manuscript devoted to what different ones said as to where the next place of meeting should be. It was then decided to go, for instance, to Podunk. Then at the next session of the same convention, on the same day, the place selected was reconsidered, and it was decided to hold the next meeting at Honeyville. Now, what sense would there be in publishing a whole lot of talk that is of no interest or benefit to any one? Why waste time in writing it out? Why not say that it was decided to hold the next meeting at Honeyville, and let it go at that? That is all any one cares about.

We might multiply illustrations like the above, but it is hardly necessary. What a journal that circulates all over the whole world should publish is simply the *facts* as brought out at a convention. There is necessarily much talk at every convention—talk that, however, is perfectly proper at the time and place, but that is not worth the space it would occupy in print.

In these busy times everything must be boiled down. Sugar-makers don't put maple sap on the market—they first boil it down, and then offer the rich syrup and sugar. And so with convention reports, they need to be boiled down for the busy, up-to-date business man.

Fumigating Combs or Honey.—Bisulphide of carbon has been used to some extent in place of sulphur to fumigate combs more or less infested with worms, and it is likely that its use will become more common. C. Davenport discourses about it in Gleanings in Bee-Culture in such manner as to impress one that he knows whereof he affirms. It is well to have it fully understood that bisulphide of carbon is a dangerous explosive, but Mr. Davenport says there is a great difference in the explosiveness of different samples. Either there are two kinds, or there is a difference in its preparation. What he first had would explode on the approach of a lighted match always before the flame

actually touch the liquid itself. What he obtained later in pound cans at the higher price of 40 cents a pound, altho it seemed equally effective in destroying worms, would only burn slowly without explosion when a lighted match was dropt into it.

Bisulphide of carbon is far ahead of sulphur, in that it destroys eggs and worms of all ages, and apparently with equal facility, for when you find one worm dead you may count all dead, whereas with sulphur it is very difficult to kill other than the smaller worms, and eggs are apparently unaffected by it. But it is important that the bisulphide be rightly used. The combs to be treated must be put in something that can be closed perfectly tight. Then a considerable quantity—say a small tumblerful—must be used; no danger of using too much, for as soon as any of the larvae are found dead, the bisulphide can be poured back—that is, what is left unevaporated—and it will be as good as ever. The bisulphide is simply left to evaporate in an open dish in the tightly confined space. This better grade of bisulphide seems to have no bad effect upon section honey, and may prove a boon to those who find it necessary to fumigate section honey.

The Weekly Budget

MR. JAMES A. STONE, of Bradforton, Ill., secretary of the Illinois State Bee-Keepers' Association, has been nominated for the office of State Auditor, on the prohibition ticket. Here's a chance for Illinois bee-keepers, and all others in this State who wish to do so, to vote for a candidate who is not owned or controlled by the liquor crowd—who dares to speak out against that terrible curse—the American saloon—army canteen and all.

MR. CHAS. CLARKE is a bee-keeper located about 14 miles south of Chicago. We called on him Friday, July 20. He has some 30 colonies right in the midst of a fine sweet clover region, and his bees were putting up as fine white comb honey as could be found anywhere. He has since taken off 54 sections of beautiful honey from one colony that had the third super about half full besides. He will get a good crop.

Mr. Clarke is a splendid florist as well as careful bee-keeper. His flower-garden is worth going a long way to see. We may have the privilege of showing a picture of it in these columns soon.

Mr. Clarke's father is a justice of the peace, and has been occupying that honorable position for many years. His parents built the house they live in, about 30 years ago, and the three are living together as cosily and happily as can be, the good father and mother nearly 70 years of age, we should judge, yet retaining their youthfulness and vigor to a remarkable degree. That many more happy years may be theirs is our wish.

DR. C. C. MILLER, of McHenry Co., Ill., writing us Aug. 1st, says:

"In this 'locality' the season is anything but a satisfactory one for bee-keepers. It isn't as bad as with Mr. Doolittle, who reports no honey since apple-bloom, which many of us, I am sure, will hear with sincere regret, but the storing has been fitful and unsatisfactory. For once, I think it may be fair to lay the trouble largely to the cool weather. A hot day will come, and bees will work busily, then will come two or three days so cool that winter cloth-

ing feels comfortable in the morning and evening. As a rule, I don't believe you can expect much storing when nights threaten frost. When nights are so hot and sultry that you go about trying one spot after another to find a place cool enough to sleep, then is the time you may expect honey to 'give down.' I mean the next day, for of course bees can't be expected to gather much at night, no matter how hot. Clover is the main dependence here, and the usual season for white clover honey is now over, altho much of it is still in blossom, but I don't know whether the bees are getting anything from it. I have taken off less than 500 pounds of honey, all told, and perhaps 20 to 25 pounds to the colony may remain on the hives nearly ready to remove. Whether more is to follow remains to be seen."

MR. THOMAS G. NEWMAN, of San Francisco, Calif., one of the directors of the National Bee-Keepers' Association, wrote us July 23d as follows concerning his inability to attend the Chicago convention, and also in regard to his sadly unfortunate blindness:

FRIEND YORK:—I should be delighted to attend the next National convention at Chicago, but the fates are against it, and I must be reconciled to the surrounding conditions, so will dismiss the matter from my mind. I wish you would say to any inquiring friends, at the convention, that I should have been present had it been possible. With my vision so much impaired, it is difficult for me to go around, and unsafe for me to be away from home without some one to guide me. Hence I very seldom go out without my wife, unless it be to cross the street to the postoffice, or something of that kind. I hope that the convention will be a great success. Yours truly, THOMAS G. NEWMAN.

Mr. Newman's many old friends will regret very much to learn of his continued affliction, and also that he cannot be at the Chicago convention the last of the present month. All would be glad to take him by the hand once more, and express to him their heartfelt sympathy in his sad affliction. It should be some consolation to Mr. Newman, however, to know that tho far away, and with darkened vision, yet there are many who often think of him with kindly feeling, and wish down deep in their hearts that he might soon have his sight fully restored.

MR. ANTON G. ANDERSON AND HIS APIARY are shown on the first page this week. He furnishes us with the following:

EDITOR YORK:—I was born in Denmark, 27 years ago, and came here when but five years old. Ten or eleven years ago I caught the bee-fever from a farm journal, and of course I was anxious to "try my luck." I think it was in the spring of 1890 that I bought my first colony of bees for which I paid \$5.00. It cast two swarms the first season, and they left for parts unknown, which, however, was my own fault.

A year or two after that I purchast three or four colonies, and got hold of "A B C of Bee-Culture," when I studied the habits of the busy bee.

My apiary now consists of 27 colonies in dovetail hives, and a few 12-frame Gallup hives. The dovetail hive is best adapted for comb honey.

There has seldom been a total failure here, as we have always gotten some surplus honey. There is a good market for honey in Council Bluffs and Omaha. The retail grocery men pay 10 to 14 cents per section. These two cities are only 12 or 14 miles from here.

I was successful in wintering my bees in the cellar, till the winter of 1898-99, when two or three of the colonies died. Last winter I did not lose a single colony.

The main honey crop here is from sweet clover, which grows in great abundance on the public highway.

Besides the bees, I also take care of about 50 acres of corn, which keeps me quite busy during the summer months.

The American Fruit and Vegetable Journal is just what its name indicates. Tells all about growing fruits and vegetables. It is a fine monthly, at 50 cents a year. We can mail you a free sample copy of it, if you ask for it. We club it with the American Bee Journal—both papers one year for \$1.10.

Yellow Sweet Clover Seed

WE HAVE IT AT LAST!

We have finally succeeded in getting a SMALL quantity of the seed of the YELLOW variety of sweet clover. This kind blooms from two to four weeks earlier than the common or white variety of sweet clover. It also grows much shorter, only about two feet in height. It is as much visited by the bees as the white, and usually comes into bloom ahead of white clover and basswood. We offer the seed as a premium

A QUARTER POUND FOR SENDING ONE NEW SUBSCRIPTION.

So long as it lasts, we will mail a quarter pound of the seed to a regular paid-up subscri-

Yellow Sweet Clover in Bloom.

ber who sends us ONE NEW subscriber for the American Bee Journal one year, with \$1.00; or ¼ pound by mail for 30 cents.

We have been trying for years to secure this seed, and finally succeeded in getting it. It is new seed, gathered last season by an old personal friend of ours, so we know it is all right. But we have only a small supply. When nearly out we will mention it.

GEORGE W. YORK & CO.,

Please mention the Bee Journal.

If You Want Bees

That will just "roll" in the honey, try Moore's Strain of Italians, the result of 21 years of careful breeding. They have become noted for honey-gathering, whiteness of cappings, etc., thruout the United States and Canada.

Warranted Queens, 75c each; 6 for \$4.00; 12 for \$7.50. Select warranted, \$1.00 each; 6 for \$5.00; 12 for \$9.00. Strong 3-frame Nucleus with warranted Queen, \$2.50. Safe arrival and satisfaction guaranteed. Circular free.

27Dt J. P. MOORE (lock box 1) Morgan, Ky.

Please mention Bee Journal when writing.

A Swarm of B's.

B hopeful, B happy, B cheerful, B kind,
B busy of body, B modest of mind,
B earnest, B truthful, B firm and B fair,
Of all Miss B Haviour B sure to B ware.
B think ere you stumble for what may B fall,
B true to yourself and B faithful to all;
B brave to B ware of the sins that B set,
B sure that one sin will another B get,
B watchful, B ready, B open, B frank,
B mauly to all men, whate'er B their rank;
B just and B generous, B honest, B wise,
B mindful of time and B certain it flies.
B prudent, B liberal, of order B fond,
B ay less than you need B fore B aying B yond;
B careful, but yet B the first to B stow,
B temperate, B steadfast, to anger B slow.
B thoughtful, B thankful, whate'er may B tide,
B just and B joyful, B cleanly B side;
B pleasant, B patient, B fervent to all,
B best if you can, but B humble withal.
B prompt and B dutiful, and still B polite;
B reverent, B quiet, B sure to be right;
B calm be retiring, B ne'er led astray,
B grateful, B cautious of those who B tray.
B tender, B loving, B good and B nign,
B loved thou shalt B, and all else B thine.

—Truth.

Bees Doing Fairly Well.

Bees are doing only fairly well. I expect something better later. What a hopeful set of old cranks bee-keepers are, aren't they? W. M. M. WHITNEY.
Kankakee Co., Ill.

Poorest Season for Years.

This has been the poorest season known in this locality for years for white honey, and the prospects are not very flattering for buckwheat.

C. B. HOWARD.

Seneca Co., N. Y., July 28.

Very Light Honey Crop.

The honey crop is very light at points from which I have received a report.

Ontario, Canada, July 25.

There Are Others.

EDITOR YORK:—I note your editorial on "Trials of a Bee-Supply Dealer," on page 361. Of course, you meet cranks, and some souls smaller than a grain of mustard seed. Long ago I gave up the belief that every individual has a soul. I frequently meet men who have none—not even a trace of a soul. Don't you? But I want to furnish a counterpart to your article—to note some of the trials of a purchaser of supplies.

The beginning of every transaction is in part wrong. I part with the price of the supplies in clean cash, without opportunity to see them, or count them. I don't like this, but we can't do better. It is a pleasure to me to pay for an article on delivery. But to pay days, or weeks, beforehand, and then be at the mercy of the shop-boy to count, to pack, to address, etc., I do not like.

I am now using 1,000 brood-frames cut half an inch too short in the top-bar. The frames, and the brood-chambers I am using them in, came from the same manufacturer, in the same shipment. There is no reasonable excuse for such blundering.

In 1897 I remitted cash with order for 2,000 sections of special size in the month of July, stating I needed them

DITTMER'S FOUNDATION

Wholesale and Retail

This foundation is made by an absolutely non-dipping process, thereby producing a perfectly clear and pliable foundation that retains the odor and color of beeswax, and is free from dirt.

Working wax into foundation for cash, a specialty. Write for samples and prices.

A full line of Supplies at the very lowest prices, and in any quantity. Best quality and prompt shipment. Send for large, illustrated catalog.

ALL THE ADVANTAGES

of a low down wagon, such as ease of loading, saving of heavy lifting, saving the land from cutting up and rutting, are derived from using a set of

Electric Steel Wheels

They convert your old wagon into a low down handy wagon at the lowest possible cost. They are made of steel with either direct or staggered oval steel spokes. They are made in sizes to fit any wagon. A set of these wheels means

that you have practically two wagons.—A low one for the farm and a high one for the roads. Any height you want, and all wide, non-rutting, easy draft tires. Write at once for catalogue, prices, etc.

Langstroth on... The Honey-Bee

Revised by Dadant—1899 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for

one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.
118 Michigan Street, CHICAGO, ILL.

PATENT WIRED COMB FOUNDATION

Has no Sag in Brood-Frames.

Thin Flat-Bottom Foundation Has no Fishbone in the Surplus Honey.

Being the cleanest is usually workt the quickest of any foundation made.

quickly, and would appreciate a prompt shipment. The firm kept my money, made no explanation, and at the end of 3 weeks sent the sections. Had they been manly enough to say, "We can't fill your order," this would have been honest. The other course was not.

I often deal with a firm that sends out first-class goods as a rule. Once in a while something snide turns up. But they never send a bill of the articles purchast, whether the order be for 10 dollars or a hundred. And their count is, in a majority of instances, at fault, tho not seriously. This proves that the counting and packing is done by a careless subordinate. The goods are not checkt up in a business way. Often a weak box is used, good enough for a 50-mile shipment, but inadequate for 500 miles of handling. A business man would not permit such things to occur. I could lengthen the list, but you don't want long articles.

The cranks you complain of will always be with us. We can't get rid of them. But the class of little wrongs I complain of can easily be corrected. There are only a few supply dealers. They have more than average intelligence. A little proper criticism would cure them. I believe all of them have souls, and a cure is therefore possible.

F. W. DEBUSK.

Las Animas Co., Colo.

[Mr. DeBusk, do you ever make mistakes? And are any of them wholly inexcusable? We believe they are, for we make just such mistakes ourselves—perfectly inexcusable. So does everybody else. But, like all should do, we are trying to get them down to a minimum—always "going on to perfection." And we don't expect to arrive at the destination called Perfection, in this life.

We know that many of the errors committed by bee-supply dealers are very annoying to the customer, and they are just as provoking to the honest, conscientious dealer when brought to his notice.

We would not attempt to shield the wilfully negligent and careless dealer or his subordinates, but we do bespeak the exercise of charity for the man or firm who tries to do right and yet occasionally makes mistakes. We are all human.—EDITOR.]

Sweet Clover in Ontario, Canada.

People can call sweet clover a weed if they like, but up in this country it's a blessing to have it. We have only a little of it, but cattle eat it as readily as the best of grasses. Do you suppose it would cure for hay?

Ontario, Canada. W. D. HARRIS.

[Yes, of course it is cured for hay. On page 470 Dr. Miller mentions it.—EDITOR.]

White Clover a Failure.

There is no linden in our locality, and as white clover (which is our main dependence) has been a total failure this season, progress at queen-rearing has been very materially interrupted.

CRIMSON CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

	5lb	10lb	25lb	50lb
Crimson Clover	70c	1.20	2.75	5.00
Alsike Clover	80c	1.50	3.50	6.50
White Clover	90c	1.70	3.75	6.50
Alfalfa Clover	80c	1.40	3.25	6.00

Prices subject to market changes. Add 25 cents to your order, for cartage, if wanted by freight.

The Bee-Keeper's Guide

Or, Manual of the Apiary,

—BY—
PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPERS' GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,

Hancock Co., Ind., July 22.

Some Hints—Wise and Otherwise.

If It Is So that in the city of Santa Fe, New Mexico, there are no rats, mice or cats, because of the too rarified air of that locality, the pertinent question would be, How, then, is it possible for people and other animals to live there?

THOSE ZULUS in Africa have a fine sense of propriety. It is said they decorate the graves of their dead with the empty and partly-filled bottles of medicines the doctors supply. It is a covert suggestion that requires no X-rays to make clear.

PRINTERS' INK contains some deleterious elements—just what it is I don't know. But this is an established fact, that newspapers and other printed matter, when used for toilet purposes, is one of the greatest factors in the production of piles.

And while on this subject, I wish to note the result of an accident to my

The Modern Remedy Co., Kewanee, Ill.

bees. I placed some broken combs on a newspaper, and there being considerable honey left on it after removing the combs to another place, I concluded to let the bees eat the honey rather than waste it. They soon devoured the nectar, but lo! and behold, when all the honey was gone, some bees were left—quite a few of them—dead as a doornail! Now, what killed them so quickly if not the printer's ink with which the newspaper was printed?

ENLARGED TONSILS, especially if they have been diseased for a year or more, should be removed. No possible harm can occur if properly excised, and great permanent good is certain to result. The fear of pain is the cause of greatest objection, but in reality the danger or suffering is not as great as that of having a tooth extracted, if done by an experienced surgeon.

RUNNING OF THE EARS is not the harmless occurrence that some people think, but quite unfortunate in results. It is usually due to suppuration and destruction of the contents of the internal, or middle ear, involving the drum and three little bones that connect with the drum to produce sound. Scarlet fever, measles and whooping-cough are the three greatest factors of this condition. Continued neglect of this discharge is absolutely certain to result in permanent deafness.

WHY IS IT the breath becomes shorter as we ascend high altitudes? Because but an insufficient amount of oxygen can be inhaled. The carbonic acid generated from our waste tissues remains to maintain the blood sluggish, thus impairing the circulation. It is this state of affairs that causes what we experience as shortness of breath. If this condition is continued the carbonic acid retained in the system transforms the muscles into fat to an extent sufficient to prevent their natural elasticity, and the result is a form of affliction termed "mountain rheumatism." The muscles of the heart, also, become sandwiched, as it were—"fatty infiltration," doctors term it—producing insufficient force of the heart to pump the blood thruout the body. The lungs are, therefore, not promptly relieved, and the short breathing ensues. In time the heart enlarges by dilation, because of its own weak action, and finally the end comes.

DR. PEIRO.

Workers Laying Eggs at Will.—There has been much discussion as to whether worker-bees could lay eggs at will, or whether they were enabled to perform this act from the kind or quantity of food furnished them while in the larval state. To aid in the solution of this problem, Mr. Arthur C. Miller, of Rhode Island, made the following experiment: He formed a nucleus of bees sufficient to cover four Langstroth combs. Three of these combs were dry, empty combs, while the fourth contained honey and pollen alone. This

BEE-BOOKS

SENT POSTPAID BY

George W. York & Co. 118 Mich. St. Chicago.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiculture, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopaedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers, \$1.00.

Bienen-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Bienenzucht und Honiggewinnung, nach der neuesten methode (German) by J. P. Eggers.—This book gives the latest and most approved methods of bee-keeping in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cts.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cts.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohake.—Origin, Development and Cure. Price, 10 cents.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field. Everything about Poultry Diseases and their Cure. 64 pages. Price, 20 cents.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about Poultry Business. 64 pages. Price, 20 cents.

and all Apian supplies cheap. Send for FREE Catalogue. E. T. FLANAGAN, Belleisle, Ill.
Please mention Bee Journal when writing.

was done on the 5th of May. On the 12th the first eggs appeared; on the 15th they were abundant; three days later they had all of the symptoms of a colony badly afflicted with laying-workers. Unless some of the bees from which the nucleus was stocked had been reared in a colony where queens were being reared, it would seem that this experiment proved that workers would lay eggs at will.—Bee-Keepers' Review.

Using Tobacco-Smoke on Bees.—Tobacco-smoke for the purpose of handling bees should be used very sparingly and carefully. It is hardly safe to advise beginners to use it, for its effect is to stupefy the whole colony; and if the fumes are administered during the day there will be an hour, or two hours, perhaps, when the bees, slightly intoxicated, would put up no defense whatever at the entrances. If, during the robbing season, they would allow robbers to come right in pellmell and help themselves; hence tobacco-smoke is recommended for use only at night. But even then I suspect the introduction of queens could be accomplished almost as well without the weed.

The best time to introduce queens is toward night. We once reared two dozen queens right among the bees, and every one was accepted. The queens in this case were some that came thru the mails, badly daubed, and

Rocky Mountain Bee-Plant Seed!

(*Cleome integrifolia*.)

...FREE AS A PREMIUM...

The ABC of Bee-Culture says of it: "This is a beautiful plant for the flower-garden, to say nothing of the honey it produces. It grows from two to three feet in height and bears large,

clusters of bright pink flowers. It grows naturally on the Rocky Mountains, and in Colorado, where it is said to furnish large quantities of honey."

We have a few pounds of this Cleome seed, and offer to mail a 1/4-pound package as a premium for sending us ONE NEW subscriber to the American Bee Journal, with \$1.00; or 1/4 pound by mail for 40 cents.

GEORGE W. YORK & CO.
118 Michigan St. CHICAGO ILL.

reacht us just at nightfall. Nothing remained but to let the queens run loose and take their chances, and we were very greatly surprised the next morning to find all of them apparently nicely accepted.

In peculiarly stubborn cases tobacco-smoke may be used, especially where the bees are determined to ball the queen, and we have positive evidence that the bees are queenless. I have made a colony so "beastly drunk" (pardon the expression) that when the bees finally recovered from their spree they accepted the queen, when before that they would ball her on sight.

Our practice now is to use tobacco-smoke only during fair-time, for, unfortunately, our county fair-grounds are within an eighth of a mile of our apiary; and during the time the stands are making taffy, selling watermelons, lemonade, and the like, our bees would prove to be a great nuisance unless we went around to all the hives and gave a smudging of tobacco-smoke. This is done in the morning, about 8 o'clock, and another dose is given about 1 o'clock. Half a dozen puffs of smoke are blown in at the entrances, all over the hives. If the colonies are all stupefied there will be no danger from robbing. This smudging keeps the bees at home. But care should be exercised, as there is danger of overdoing it, and also danger of not doing enough of it; for if they have once got a taste of the sweets over at the fair-ground it takes a great deal of stupefying to keep them at home.—E. R. Root, in Gleanings in Bee-Culture.

Boiling Honey to Disinfect.—Honey, to be boiled and disinfected, should have a little water added to it, so that when it has been boiled an hour or so it will still have the same consistency it did before it was boiled. Ordinary thick honey placed on the stove would be apt to boil all over, and it should be thinned down very materially before any attempt at heating has been made. No, there would be danger, I think, of bees getting foul brood at an ordinary drinking-trough. So far as I know, the disease is conveyed only thru the honey or the old combs that have been in diseased hives. It may be carried on the clothing of bee-keepers, but nine times out of ten it is carried by robber-bees from infected honey.—Gleanings in Bee-Culture.

The Novelty Pocket=Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.10, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO., 118 Mich. St., Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, July 7.—Some new white comb honey is selling at 15c; not much offered and not much demand for it. Extracted is slow sale; best white, 7@7½c; best amber, 6½@6¾c; dark amber, 5@5½c. Beeswax, 27@28c. R. A. BURNETT & Co.

CINCINNATI, July 20.—White extracted honey, 7@7½c; southern extracted, 5½@6½c, owing to quality. No comb honey on market. Good demand for beeswax at 25@27c.

Shipments of extracted honey from the South are more numerous than a few weeks ago, but we find it hard to make sales, owing to a slow demand. C. H. W. WEBER, 2146 Central Ave.]

BUFFALO, July 20.—For strictly fancy white one-pound comb honey we are getting 16@17c. Any grade sells high—10@15c, as to grade. BATTERSON & Co.

KANSAS CITY, July 20.—We quote: New No. 1 white comb, 14@15c; No. 1 amber, 14c; dark, 13c. Extracted, old, 6@6½c; no new in market. Beeswax, 22@25c. C. C. CLEMONS & Co

DETROIT, July 24.—Fancy white comb, 15@16c; No. 1, white, 14@15c; amber and dark, 10@12c. Extracted, white, 7c; amber and dark, 5@6c. Beeswax, 25@26c. Supply and demand for honey both limited. M. H. HUNT & SON.

NEW YORK, July 26.—There is a fair demand for white comb honey, and enough arriving from the South to supply the demand. Fancy white sells at 15c; No. 1 white, 13@14c; No. 2 white, 11@12c. Extracted remains rather quiet, and the market is sufficiently stocked to meet the demand. Beeswax very firm at 28@29c. HILDRETH & SEGELKEN.

SAN FRANCISCO, July 18.—White comb, 12@12½c; amber, 9@11; dark, 6½@7½c. Extracted, white, 7½@8c; light amber, 7@7½c; amber, 6@6½c. Beeswax, 26@27c.

Amber grades are in fair supply, both comb and extracted, and there is a moderate business doing in the same at prevailing figures, mostly in a small jobbing way and on local account. Large dealers are purchasing only to fill immediate orders, not caring to stock up at present prices. Water-white honey is scarce and in a limited way is salable at tolerably stiff figures.

WANTED—HONEY AND BEESWAX.

We have a tremendous and growing trade in this line, and would like to hear from all who have such goods to sell in any part of the country, with quality, description, and lowest cash price. THOS. C. STANLEY & SON, Fairfield, Ill.

WANTED COMB HONEY AND EXTRACTED HONEY. Will buy your honey, no matter what quantity. Mail sample with your price expected delivered in Cincinnati. I pay cash on delivery. C. H. W. WEBER, 2146 Central Ave., CINCINNATI, OHIO.

DR. MILLER'S Honey Queens

One Untested Queen Free as a Premium for sending ONE New Subscriber to the American Bee Journal for one year.

We have been fortunate in making an arrangement with DR. C. C. MILLER—the well-known honey-specialist—to rear queens EXCLUSIVELY FOR US DURING THE

SEASON OF 1900. These Queens will be mailed in rotation, so "first come first served."

The Queens Dr. Miller will send out on our orders will be precisely the same as those he rears for his own use, so of course they will be from his best stock. His best colony in 1899 had a queen reared in 1898; May 5, 1899, it had brood in 4 frames, and he gave it at that time a frame of brood without bees. It had no other help, but May 25 a frame of brood with adhering bees was taken from it, and the same thing was repeated June 3, leaving it at that time 5 frames of brood. It stored 178 sections of honey, weighing 159 pounds (and that after July 20, in a poor season), being 2½ times the average yield of all his colonies. A point of importance is the fact this colony did not swarm, and an inspection every week or 10 days showed that at no time during the entire season was there even so much as an egg in a queen-cell. Dr. Miller rears queens from this one.

The demand nowadays is for BEES THAT GET THE HONEY when there is any to get, and Dr. Miller has such bees. You will want to have a queen from his best, we are sure, even if she is not pure Italian.

Do not send any orders to Dr. Miller, as all orders MUST come thru us, according to our agreement.

Remember, send us \$1.00 for ONE NEW SUBSCRIBER to the American Bee Journal for one year, and YOU will get ONE OF DR. MILLER'S UNTESTED HONEY-QUEENS FREE AS A PREMIUM. This offer is made only to our present regular subscribers. Orders for queens are to be filled in rotation.

Address all orders to GEORGE W. YORK & CO., 118 Michigan Street, CHICAGO, ILL.

CONTRIBUTED ARTICLES

Preserving Combs from Moths—Caging Queens.

BY G. M. DOOLITTLE.

WILL you please tell us thru the columns of the American Bee Journal how to keep combs during the summer months from being eaten up by the larvæ of the wax-moth, when we wish to preserve those from which the bees have died during the winter? I have several hundred such, so I am anxious to know.

ANSWER.—In the March number of the American Bee-Keeper I find the following, which was given by Frank Benton at the December meeting of the Ontario County (N. Y.) Bee-Keepers' Association, held at Canandaigua:

Place an empty brood-chamber on top of a stack of combs, and there-in place a dish with a little bisulphide of carbon, then cover up tight; the liquid will transform into gas and kill every living thing within the stack of hives.

I have this down in my reference book, and whenever I have any combs to preserve in the future I shall try it, but as I have none not covered with bees the present summer, I could not vouch for the truth in the matter, further than that it comes from good authority.

Fumigation with burning sulphur has been the former way, and as this has worked well with me I will give it, together with some other ways of working, so the questioner can try it by the side of the Benton plan, and thus find out which he likes best. If he wishes to keep his combs for an indefinite period, they should be fumigated and stored away afterward where the female moth can not have access to them. But where such combs can be used during June and the forepart of July fumigation may not be necessary.

For storing combs from which the bees have died during the previous winter, my plan is to store them in some dry, airy room, where they can be hung two or more inches apart. In storing them I select out all that contain much bee-bread or pollen, and place them by themselves where I can use these first, then I select all having but little pollen in them, and place these where they will come to hand next after those first named; then I select all which are old and black, but with no pollen, and have these next at hand, while those having been used but little by the bees for breeding purposes, and having no pollen in them, are left to be used last or latest in the season.

All white combs in which no brood has ever been reared, the same having no pollen in them, whether containing

honey or not, and that have been taken from the hives during the fall, winter, or early spring, are almost moth-proof, or, at least, I have never, to my remembrance, had such combs disturbed by the larvæ of the wax-moth, where kept as above for any term of years; but when such combs are taken from the brood-chamber of the hive during hot summer weather, and stored away as above, then they may be troubled some.

Combs stored two or more inches apart, with those having the most pollen in them to the front, need not be looked after in this locality till June, when they should be examined; and if any fine webs are noticed about the cells containing pollen, these should be given to the bees as soon thereafter as possible. By about the 10th to the 15th look after those having a little pollen in them, and by the 25th look after the old, tough combs; while those which the bees have used but little for breeding purposes will rarely need looking after before July 4th to 10th.

In this way I have no difficulty in using all the spare combs I may chance to have before the moth troubles them to an extent sufficient to injure them, unless my losses have been exceedingly heavy during the winter.

But if we wish to keep combs during a whole season or more, they must be fumigated in some way, or else have been exposed to a temperature as low as zero during the previous winter. Where this latter has been the case, pack them away in early spring in some box or closet which you know to be absolutely moth-proof, and they will keep for ever, or as long as the box or closet keeps, providing no female moth is ever allowed to deposit eggs on them.

To fumigate by the old way, place them in a tight room, or in hives which will sit closely together, one on the other, without bottoms, when sulphur is to be burned to the amount of a pound to every 400 cubic feet contained in the hives or room. In sulphuring combs there is little fear of using too much sulphur; for should a deposit of sulphur occur on the combs, thereby giving them a greenish tinge, it will not harm as it does on comb honey.

In sulphuring honey or combs, too much care can not be taken guarding against the possibility of fire; for a room filled with the fumes of burning sulphur, together with many inflammable combs, is a poor place to go to extinguish what may prove to be a conflagration, unless found in time. For this reason an iron kettle, partly filled with ashes, with live coals on the ashes, with the combs so hung that none of them can melt and fall in the fire in the kettle, is the best thing to use to pour the sulphur on. If you wish the combustion of the sulphur to be complete, too much must

not be poured on too small a surface of coals, otherwise a part of the sulphur will not burn as it should.

LENGTHY CAGING OF VIRGIN QUEENS.

I am about going into the queen-rearing business. I am led to believe that if I can introduce old virgin queens when I take out a laying queen from a nucleus, that a gain in time can be made, as these old virgins will get to laying sooner than would those hatched in the nuclei. Therefore, I wish to know how long a virgin queen may be kept confined in a nursery-cage, or otherwise, before she becomes too old to be fertilized?

ANSWER.—So far as my experience goes, all perfect queens will fly out to meet the drones when from five to nine days old, during the months of June, July and August if the weather is favorable to such flight; and any contrivance which prevents their doing so is an injury to the future value of the queen, in my opinion. If the weather is unsuitable, this same queen will have no desire to go out till such a day comes; hence, there is no uneasiness, consequently no injury to her value. But confine her once on a nice day, when she has a desire to go out, and she is injured to the extent of the efforts put forth to accomplish her purpose. I do not believe it possible for any queen to be just as good after being kept confined so she can not fly out to meet the drone, when nature prompts, as she would be if she had her liberty to do as she pleased.

As said above, the rule is for a queen to go out when from five to nine days old; but during the months of April and May, also of September and October, in this locality, queens frequently do not become fertile till they are from two to four weeks old; yet these queens have proved as good as any, as far as I can see. Having this in mind, I once argued that if I kept virgin queens confined till they were three or four weeks old, they would be as good as any. So I kept queens in nursery-cages and otherwise till from two to four weeks old, then introduced them to frames of hatching brood, but not one of these queens which were confined past the time when they had a desire to fly proved to be nearly as valuable as queens allowed to do as they pleased. Some which were kept confined nearly four weeks never were capable of keeping as many as four Langstroth frames full of brood at their very best.

After an experience covering a period of nearly 20 years in trying nearly every kind of "short-cut plans," as they are called, to secure laying queens often from nuclei, by using virgin queens of advanced age to take the place of laying queens taken from nuclei, I have settled down to the conclusion that the giving of a mature cell, in all cases where a queen is removed in such a way that we desire a virgin queen to take her place, is much the best plan of any, taking all things into consideration; good queens being thus obtained every time, providing the queen-cells are reared in such a way that they will give good virgin queens.

Onondaga Co., N. Y.

Naturally-Built Comb vs. Comb Foundation.

BY S. A. DEACON.

IN the American Bee Journal for Nov. 4, 1897, Mr. C. P. Dadant has a rejoinder to my contention (for it is certainly no *refutation* of it), viz.: that the advantage of using costly comb foundation over that of allowing the bees to construct their own combs has been hitherto somewhat overestimated; and in which contention I am borne out by the practical experience of a California contributor, who signs himself "Sage-Brush."

Mr. Dadant's reply, which, I confess, I had awaited with fear and trembling, is hardly so scathing, and certainly not so conclusive as some doubtless expected it to have been; and as I have not been utterly annihilated by him, I have cancelled the order for my funeral. In upholding the value of foundation, he stood on very delicate ground, and with the true modesty and gentlemanly instincts so conspicuous

in the composition of the Dadants, he was no doubt hampered with a desire to avoid extolling too exuberantly the use of a commodity in whose consumption he is pecuniarily interested.

Mr. Dadant has certainly by no means disproved, in fact he has not even disputed, my contention that the term "drawing out the foundation" is altogether a misnomer, or dispelled the idea which it is so likely to induce, viz.: that when, upon opening a hive, we see a long string of bees all clinging to each others' "coat-tails" (like a lot of school-boys playing at "tug-of-war"), they are necessarily engaged in pulling or "drawing" out the foundation; nor has he by any means disproved my statement that the use of foundation is, in a great measure, wasteful; in fact, he has, if anything, confirmed my assertion that the bees do not "draw out" the side-walls, tho they may utilize the wax in them to extend or increase the depth of the cells as far as it goes; for he says that "after the bees have worked on foundation, any little boy can see that the base and side-walls are very perceptibly thinner."

Now, as nobody has hitherto had the rashness to assert that the bees "draw out" the *base*, it is reasonable to conclude that this thinning down of it is effected by their removing a lot of surplus wax with their mandibles, and which means a waste of the bees' time and of their owner's money; for they could more rapidly secrete and use their own wax, costing the bee-keeper nothing, as against 50 cents a pound for foundation. And is it not reasonable to conclude that if the bees thin down the base—by digging out and removing the surplus wax—the side-walls are thinned down in precisely the same laborious and time-wasting manner, and that they do not therefore "draw them out" at all? Indeed, such mode of construction would be quite opposed to their natural instincts. Hence, I have no hesitation in repeating my statement, viz.: that to imagine that the bees "draw out" the thick side-walls—presumably after the material composing them has become plastic by the heat of the atmosphere and of the crowded hive—is a silly and unreasonable belief, in spite of Mr. Dadant's rather discourteous remark that, in asserting that the bees do not "draw out the foundation" Mr. Deacon does not know what he is talking about.

Mr. Dadant tells us that the bees "remodel the side-walls" and complete the cells by adding some of their own wax. This is tantamount to saying that they break down the costly material that we supply them with, and re-construct after their own manner—a totally different thing to their "drawing out" the side-walls! Yes, Mr. Dadant emphatically says "they remodel them, Mr. Deacon to the contrary notwithstanding." Why, that's exactly my argument, and on this point Mr. Dadant and myself are perfectly agreed! *Votez main, Monsieur. Shake!*

And will Mr. Dadant, or any other man, venture to deny that this demolishing and rebuilding by the bees is just as much a waste of labor and time, as tho, in arranging for the building of a long wall one foot wide and six feet high, one were to furnish the masons with bricks previously cemented together in the shape of a stumpy wall three feet thick and two feet high, necessitating the demolition of the same ere they can go on building, and that, too, when they are quite willing to supply their own bricks, all loose and handy, gratis, and which bricks must be otherwise wasted? The cases are identical. If the bees must needs first gnaw away the wax and then "remodel"—as Mr. Dadant plainly affirms they do—no sane person can possibly deny that furnishing them with material in a shape they find useless for their purpose, and that at 50 cents a pound, constitutes a waste. There is no getting over it—it is too self-evident.

I do not say that there is *no* advantage in using founda-

tion; my former remarks were by no means intended as a wholesale disparagement of it; I merely asserted, and now unhesitatingly re-assert, that we are deluded in assuming that the bees rapidly stretch, or elongate, presumably by tugging at or "drawing out" the side-walls; and as Mr. Dadant's own evidence incontestably proves that they do no such thing, but that they break the thick, stubby walls down and "remodel" them, I consider my contention unassailable. If the bees first break down the thick, stubby side-walls we give them—as so great an English authority as Mr. Samuel Simmins affirms they do—and reconstruct the walls with the same wax—as so great a French and American authority as Mr. Dadant says they do—I fail to see how my contention can otherwise than hold good, viz.: that we are deceived in our estimate of the economic value of foundation, *i. e.*, as affording a saving of time and labor to the bees, and also, consequently as to its pecuniary value. Carefully and intelligently conducted experiments, such as made by "Sage-Brush," are bound to prove that the saving, or gain, by its use is not proportionate to its cost. One would reasonably suppose that as well as the bees utilize the wax, which they have laboriously to detach first from the stubby walls (and which costs us 50 cents per pound) for building out their comb, they would be prepared to use plain, unembost wax, placed in handy shape within easy reach (and costing only 25 cents per pound) for the same purpose; in that case all we would need to furnish them with would be the septum, or base, but the benefit would really be so slight compared with even the smaller cost of this, that it would be preferable to leave them to find *all* their own material.

While expressing "great regard" for that patient, careful, and highly intelligent observer, Mr. Simmins, Mr. Dadant sneers at statements of mine, which are really only re-echoes of those made by the same Mr. Simmins. For instance, in allusion to my remark that "careful experiments have conclusively demonstrated that it takes less than six pounds of honey to make a pound of wax," Mr. Dadant contemptuously asks, "Pray who made those *careful* experiments?" Well, the gentleman for whom he professes a great regard made some of them. And as his observations, which decided the ratio of honey consumed by the bees to the production of a pound of wax, will, I am sure, be found highly interesting to the majority of our readers, I shall make no apology for giving in full a recital of the method whereby Mr. Simmins arrived at the conclusion above stated.

"My experiment," says Mr. Simmins, "was conducted in a large flight-room, 50 feet by 10 feet. A swarm of nearly three pounds weight was made up and given frames, with a line of wax as a starter to each. I determined to avoid the complication that would arise if brood were produced, but at the same time it was necessary to have a fertile queen presiding, or the bees would not work to the best advantage. The new combs were therefore removed every three days, and the occasionally eggs were to be seen, no food was consumed in their production other than that fed to the queen. The removed combs were placed behind the division-board, and were emptied of their contents by the bees, again to be used in filling fresh frames. Thus, without extracting, the combs were taken away perfectly dry, with the exception of the three last built; and to make sure of wasting none of this remaining honey, the combs containing it were run down in a vessel with no added water. The bees had access to both pollen and water while building, and from six pounds of honey fed to them they gave 6¼ ounces of clear wax, with a balance of 15 ounces of honey left over. If I say an even pound left I shall be nearer the mark, as the bees had the means of loading themselves much more heavily than when the swarm was made, as they were then forced to consume what they had before commencing to build. Five pounds, therefore, giving that quantity of wax, it would be supposed that it takes 12 4/5 pounds of honey to give a pound.

"But our experiment is not yet completed; the bees had

to live during the 20 days taken to carry it out. Being in a confined area during autumn, when the weather was far from being as warm as could be desired, the expense of production would be very much more than when new combs are built in the height of the season. The bees did not get on so fast, especially as the best combs were removed in time to prevent the production of brood, and towards the last the supply of honey became very limited.

"To get at the cost of living, after removing the last of the combs and balance of the honey, the bees were given just one pound of honey in a feeder arranged so that they would not get it fast enough to go on building. After the fourth day there were six ounces left; but here is a little difficulty: They could not require 10 ounces in that time, and on removing the feeder with balance of honey, and giving four empty combs, they put about two ounces into the cells. This would still leave eight ounces consumed, or two ounces per day while in active flight. Then for the 20 days we have 40 ounces consumed to preserve life, which deducted from the five pounds leaves two pounds eight ounces actually used in producing the 6¼ ounces of wax; thus, to produce one pound of wax 6 2-5 pounds of honey would be consumed.

"When the cost of living was carried out, the bees were reduced about one-third, so that two ounces per day should be within the mark. In the height of the season, with everything favorable, it is only reasonable to say that the cost of production is really much less, and probably less than five pounds of honey are consumed in actually producing one pound of wax."

Is not that sufficiently satisfactory, Mr. Dadant? It certainly does not agree with your statement that "it takes from 7 to 15 pounds of honey to produce a pound of comb in the very best circumstances." But let us hear what Mr. Simmins has further to say about "comparative cost," *i. e.*, of natural and artificial comb:

"In the course of the experiment," continues Mr. Simmins, "I found that about eight standard frames (14 inches by 8½ inches) of new comb will give one pound of refined wax. It is surprising what a large amount of refuse is left after melting the most beautifully white combs, so that the actual weight of wax obtained is much less than that of the original combs. *Observe this:* One pound of wax costing the producer less than one shilling and sixpence [36 cents] fills eight frames with finish comb. To do this with foundation 1½ pounds of that article is required, costing in hard cash at the least two shillings and sixpence [say 60 cents] for the base only; to this the bees add considerable of their own production before the combs can be completed; making the total cost much over three shillings [say 75 cents]. Facts are stubborn things, and can not be ignored."

So much for the very careful experiments of Mr. Simmins.

In regard to my assumption (really that of Mr. Simmins, from whose book I learnt it) that the secretion of wax goes on in the hive, and that the scales are therefore wasted where foundation is used, Mr. Dadant emphatically states that "this is not so, as there is always a necessity of wax for lengthening the comb." It is rather difficult to know whether he herein denies that the secretion of wax goes on, or only denies that "it is wasted." If he admits that the secretion of wax goes on, then—in the case, at least, of the Nebraska man's foundation, which is warranted to have "enough wax in the side-walls to enable the bees to finish the combs without any additional wax"—there is bound to be a waste; and it was really the advertised claim of this foundation maker that, in the first place, set my thoughts and my pen agoing.

Mr. Dadant concludes his very lame attempt to refute my statements by suggesting that I should first make experiments, and not write until I have done so. But why should I masquerade as an expert and make experiments, when far abler men than myself, such as Mr. Simmins, of England, and Mr. "Sage-Brush"—whatever his proper patronymic may be—in California, and scores of others have already done so? And what would be the good, as far as trying to convince Mr. Dadant goes, when he, rather

superciliously, pooh-poohs the experience of such authorities as Mr. Simmins, suggesting that he has not used the proper kind of foundation in his experiments, or the bees would not have scraped away the side-walls. Is it likely that an expert of Mr. Simmins' standing would make experiments with adulterated or inferior material? This is not very complimentary to Mr. Simmins' intelligence! Mr. Dadant, while denying that the bees scrape off the side-walls, informs us that they "remodel" them. Will he kindly explain the bees' *modus operandi*, how they can remodel or reconstruct without first demolishing?

Mr. Bevins quotes from "Langstroth Revised" in connection with this argument, a passage which reads: "It is a remarkable fact that the bees thin out their foundation to a certain extent and make it considerably deeper out of the same material." So far from opposing my contention, this—like all of Mr. Dadant's statements—goes to confirm it, *i. e.*, to prove that the bees' time and labor are wasted in having to "thin down" the side-walls (as well as the base) by excavating the wax where it is not wanted, and putting it where it is wanted, in other words, demolishing and reconstructing—or "remodeling"—for they can no more stretch, pull, or "draw out" the side-walls than the masons can stretch, pull, or "draw out" the stubby wall of cemented bricks three feet wide by two feet high into one a foot thick and six feet high.

Mr. Bevins quotes yet another passage from "Langstroth Revised," viz.: "When foundation has been made with a thin base and a heavy wall the bees draw it out more readily into comb." And why? Simply because they have more 50-cent material on hand to quarry into, but whose intrinsic value is 25 cents only. With all proper respect for Father Langstroth's memory, and with all due respect for the revisers of his work, I maintain that the bees do *not* "draw out" the walls, and I hereby challenge any one to prove that they do! South Africa.

(Concluded next week.)

Report of the Central Texas Convention.

BY LOUIS SCHOLL.

(Continued from page 502.)

CHUNK HONEY VS. SECTION HONEY FOR THE SOUTH.

E. J. Atchley says that both are good. He used to think that section honey was the best and nicest thing, and for many years did not produce any other, and advocated the production of comb honey in sections. Of course, section honey is very nice, but he thinks the dollar is nicer. As chunk honey brings more money in the South, there are no more sections for him now. In the first place, he can produce at least one-third more chunk honey in frames, then, when put in cans, it can be shipped at a less freight rate, going as fourth-class. Section honey, in glass-front shipping-cases, goes at first-class rate, and *at owner's risk*; while honey put up in two 60-pound cans to a case, if damaged *en route*, will be settled for by the railroad companies. This is greatly in favor of comb honey put up in cans, and Mr. Atchley has had enough section honey smashed to bring down the price as low as that of chunk honey. Some object to such a mess, but are sections ever set on the table? And when the section is cut, it is just that way, too. If cut out of the section it is chunk honey, too, but nothing like a

chunk out of a can, with nice honey all over and around it; and, indeed, there is nothing more inviting when hungry, and nothing nicer. If everything is favorable to produce section honey, it is all right; but two supers of chunk honey can be produced to one of section honey.

O. P. Hyde thought there never was anything nicer than comb honey in one-pound sections, and he was slow about changing his mind, as he was against such a mussy way of putting up honey. Now he knows that the new way of putting up nice comb honey in cans and putting in extracted honey to fill up the cracks and crevices, to prevent the nice, tender combs from mashing, is *the* honey for the South. Also, as he has always kept bees from a dollar-and-cent standpoint, he must produce what is in demand. He read a number of letters received in a few days from a firm in Ft. Worth, asking them to ship honey. Out of a large lot of this honey, amounting to over several hundred dollars, only *two* cases was extracted, and the rest all *chunk comb* honey in 60-pound and 12-pound cans. This gave a good idea of the large demand for this kind of honey. The proper name will be *bulk comb honey* from now on.

R. B. Leahy asked what percent Mr. Hyde produced over section honey.

Mr. Hyde—About one-third more bulk, besides adding about 15 pounds of extracted to fill up the 60-pound cans, which sells at the same price as the comb honey. When filling the cans with comb first, it is only possible to get in from about 40 to 45 pounds. Sometimes double the amount of bulk comb honey may be produced in frames, while it is impossible to produce good section honey during a bad flow.

B. A. Guess has produced such comb honey almost exclusively ever since he kept bees, while the majority went over to produce comb honey in sections; and while they were all discussing section honey he thought his comb honey was good enough, and he built a trade on such, and now the demand is so great with that he can't supply it. Producing section honey always seemed too scientific for him, and is the reason why he did not attempt it. Now he is glad to see the bee-keepers come back again.

Mr. Davenport says that such honey does not work with him in his market at Waxahachie. He gets the fancy trade, and has fancy section honey.

J. J. Waldrip has produced extracted honey. For many years he produced section honey, which paid very well. For shipping honey, sections go as first-class freight, and as the other goes as fourth-class, there is a saving of freight in favor of bulk comb over section honey, which goes at owner's risk. It gets smashed up, and is lost, while bulk comb honey in cans saves honey, besides freight.

Mr. Faust is for the dollar, and gave the same evidence as did Pres. Hyde.

Mr. Leahy explained why he thought the production of bulk comb honey was not such a great thing, and for bee-keepers to be convinced he told them just to ship some of it to the North. But if it is to the benefit of the producer, then it is a move in the right direction. As it can not be sold in the North, it remains only for Texas, and therefore there may be danger of an overproduction. Then, too, it seems to him that bee-keepers were going backward to 30 years ago, when he first started with bees, the only difference being in better hives, foundation, and more scientific methods. He also said that it was hard work to produce fine section honey.

QUEEN-REARING.

Mrs. Jennie Atchley described her methods. As they are largely queen-rearers their methods are based on a large scale. Ten or 15 of their best cell-building colonies are dequeened and made ready. Before doing this, an old comb is put in some of the breeders' hives for young larvæ

to graft cells. The cells are then attached to the under edge of a comb, and cut out rainbow shape, which is preferred to Doolittle's stick for the cells. About 50 cells are used to a colony to build out. On the seventh or eighth day go around and pinch off all small cells that are started on the combs. On the ninth day (nuclei are formed beforehand) one cell is given to each. Sometimes two cells are built too close together to be cut apart, when both are put in.

H. H. Hyde said a good breeder to start with is a prolific, gentle, honey-hustler, and one that will keep a strong colony of bees during the time of scarcity. For securing cells and large queens the Doolittle is the best plan. Prepare colonies in early spring. He has not found any difference between Italians and hybrids for cell-building, but prefers a queen of year before last. He gets his colonies running over with bees, using a division-board feeder to stimulate. He makes Doolittle cell-cups with the Pridgen cell-dipping arrangement. This he exhibited and explained. He next takes the dipt cells and fastens them to a stick, 18 on each; then secures larvæ from 26 to 48 hours old to graft cells. Larvæ must not be too old, as also queens from such hatch too early. He uses royal jelly for grafting, and a little spoon like a cane to dip larvæ out with, in which great care has to be taken. The little larvæ should not even be turned over, or the bees will not accept the cells. He next cuts out half of a comb and inserts the stick containing the cells below this, and gives to cell-builders in the upper story, above an excluder. Here he puts combs of young brood on both sides of the cell-comb, so as to draw up a lot of young bees. He says by putting unsealed brood up above, and with a lot of young bees to feed it, and no queen there, makes the same condition as that of a colony at the time of superseding their queen, as there is a small amount of larvæ in proportion to young bees present at the time. When the cells are ready they are removed to nuclei, one in each. If he has a surplus of cells he inserts them in introduction-cages, filled with candy, and then puts these in a frame and hangs it in the hive to keep over until he has places for them. He uses this same cage when introducing virgin queens. When he has a valuable queen he uses the wire-cloth comb-cage, by taking a piece of screen wire-cloth about six by eight inches; about one inch around the edge is then raveled off and the edges bent over, so as to form a sort of shallow box. The sharp, pointed walls are then stuck into a side of a brood-comb containing hatching brood; the queen is to be put into this cage, and after awhile she will be found laying, and a lot of young bees to protect her. But don't make the mistake and stick this cage on a comb of honey, or a newly built comb, for it will not work; besides, the bees will undermine the edges of the cage and kill that valuable queen. As he rears queens quite extensively, he runs a large number of nuclei. One must be careful or he will soon run his nuclei down. Never take out a queen except you have a cell or a virgin to give them, and then it is best to let the young queen lay a few days to strengthen the nucleus. In this way he has his nuclei strong, and during cotton bloom he gets quite an amount of extracted honey from them. He also touched upon laying workers—those pests of queen-rearing—and told how he gets rid of them. He says that no matter how careful one is, he will have trouble with such, but when he has he simply takes a frame with bees, queen and brood, and gives to a colony containing the pests, and it soon stops it.

Mr. Faust prefers medium-sized queens to extra large and very small ones, which latter are no good. With the Doolittle plan almost all are good, and none small.

Mr. Atchley does not question about the methods used when wanting good queens, for if any of the plans are used

rightly good queens can be reared. He says that all the methods are good.

But Mr. Davidson does not agree with him, as he prefers the Alley method, which he believes to be better than any other. He repeated his description of this plan as given at the meeting at Milano last year, on account of some not having understood him then. The plan is to use narrow strips of comb, only one row of cells containing eggs. With an unlighted match he destroys every other egg, and attaches this to the bottom of a comb that has been cut away about half.

Mr. Atchley then asked Mr. Davidson if there was any difference between the Atchley plan and Alley's plan, as the Atchleys move the little larvæ, cocoon and all, into dipt cells, which does not make any difference.

Mr. Laws said it is not methods that make good queens, as all plans produce some good queens. With the Doolittle plan he secures all good queens, and, as told by Mr. Hyde, above an excluder, with conditions in superseding.

Judge Terral was requested to deliver a speech on apiculture in the assembly hall at College Station next year.

Mr. Salyer was appointed a committee to prepare a program for the next meeting. He requested the secretary to have badges printed for the next meeting, and to mail them to members at least 15 days before the meeting, with a request to the members to attend.

SECOND DAY—AFTERNOON SESSION.

Among the resolutions introduced and passed, were these:
Resolved, That the thanks of this Association are hereby tendered to the people of the city of Hutto, for their unstinted hospitality extended to us during our stay among them; to Mr. O. P. Hyde and family for their unceasing efforts to care for each and every member of the Association. We will each retain kindly memories of this meeting.

Resolved, That this Association tender our ex-President, E. R. Jones, our sincere thanks for his kind and efficient services in behalf of this Association.

Resolved, (by Central Texas Bee-Keepers' Association, in convention assembled) That we petition the next legislature, thru Prof. Connell, of the A. & M. College, Bryan, Tex., for an appropriation for the establishment of a State bee-keeping experiment station at College Station; and also for a sufficient appropriation to pay a man to manage and experiment at this station.

All of the resolutions were considered and adopted unanimously, except the last, as it was deemed best first to go down to College Station and meet there before taking this step, and so it was thought best to wait, as it was yet quite early.

QUESTION-BOX.

The question-box was next taken up, as follows:

QUES.—Does it pay you to rear your own queens? ANS.—Yes, and no. It depends upon circumstances. When during swarming season it is good, but otherwise not, and it is preferable to buy them from breeders who are prepared for it. Then, queens are cheap now.

QUES.—What is best to do with weak third swarms? ANS.—Hunt out the queens and put them back. If a valuable queen put her in a nucleus.

QUES.—Which is the best size super and frame for bulk comb honey?—ANS.—After a long discussion, the shallow super and frame were greatly in preference. Especially the 5¼-inch deep supers and 5⅝-inch frames.

QUES.—Can any one tell why so many virgin queens sometimes disappear? ANS.—Many are caught by birds or insect-loving animals, when they take their wedding flight. Many are balled by their own bees; and there are other ways by which they are lost, but mostly during bad weather when it seems as if the bees wanted to force the virgin

queen out to perform her duties, as more are balled on this account, and it does not happen often when the weather is favorable. Some are balled when returning from their bridal trip.

There were many other questions answered and discussed by all, and the list of about 40 members present showed that 5,808 colonies of bees were represented.

The apiarian exhibit at the hall consisted of many useful tools, implements and appliances, besides fine honey and bees. Next year a grand exhibit is expected at College Station, when the Association meets there. Prizes will be offered for the different exhibits, many of which have already been donated, to be awarded by a committee of four, appointed by the convention, viz.: Louis Scholl, W. H. Laws, J. B. Salyer and O. P. Hyde. The secretary was requested to solicit donations for prizes, and a list will be given later.

This was indeed a grand meeting of bee-keepers.

LOUIS SCHOLL, *Sec.*

O. P. HYDE, *Pres.*

CONDUCTED BY

DR. C. C. MILLER, *Marengo, Ill.*

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Prices of Queens.

Please quote me prices on both tested and untested Italian queens?
ILLINOIS.

ANSWER.—To this and to others who have sent inquiries, the only answer I can make is that I have no queens for sale, only as the orders come from the publishers of the American Bee Journal.
C. C. M.

Keeping Candied Extracted Honey.

I have my last year's crop of extracted honey yet, and it has candied solid, and I want to sell it in my home market, but haven't the time to work at it yet. How long will it keep in the candied state? I keep it in my honey-house where it is very warm in the summer, but very cold in the winter.
INDIANA.

ANSWER.—It ought to keep all right for a number of years, unless your wife takes your honey-house to do a washing in, so as to make steam.

Entrance-Guards—Pumpkins as a Honey-Plant.

1. Was not the perforated zinc used in entrance-guards intended for hybrid as well as Italian bees? I tried a guard on a hybrid colony and not $\frac{1}{4}$ of the bees were able to pass thru.

2. How do pumpkins rank as a honey-plant? I have not yet studied botany in my school work, but I thought by the way the bees work on the blossoms they must get something from them, as there were two or three bees on every flower in the morning.
ILLINOIS.

ANSWERS.—1. There is supposed to be no difference between hybrids and Italians as to passing thru perforated zinc. There must be something exceptional about your bees, or your entrance-guards, that allow only $\frac{1}{4}$ of the bees to pass thru.

2. Pumpkins are quite rich in nectar.

Giving a Swarm Ventilation.

In giving a swarm in a new hive, is it always necessary to give ventilation? If so, how would you give ventilation?
MICHIGAN.

ANSWER.—To say the least, it is very important, if you want the swarm to stay. For the first two or three days you can hardly give too much ventilation. Raise the hive an inch or more from the floor-board, and raise the cover $\frac{1}{4}$ to $\frac{1}{2}$ inch at one end, or leave the cover partly off. After the first two or three days, when work has been fairly begun, the cover may be closed.

Keeping Bees on a Balcony.

There is a man living in our city who would like to keep bees on his balcony, as he has no other room for them. Is this a possibility? If so, please explain how the hives can be arranged so he can manage them from the back.
MICHIGAN.

ANSWER.—There is no special trick in the matter, but it would be easier to give specific instructions on seeing the lay of the land. The main thing is to face the hives so that there shall be the least interference by passers-by as the bees enter or leave their hives. If the hives are of the ordinary pattern, it will not be easy to manipulate them other than at the side, but the hives can be in pairs, two hives close together, then a space, then two hives close together.

Starting in Bee-Keeping.

1. Do you recommend bee-culture as a means of money-making for boys in school (college), who want to help defray their expenses?

2. What variety of bees are best or most profitable?

3. What would a colony of bees cost for starting?
CITY MAN.

ANSWERS.—1. If it be merely the matter of money, there might be other kinds of employment more advisable. But if a young man has some taste for bee-keeping, it would be hard to find anything better, for the care of bees to a student with such taste would be recreation rather than toil, and if well cared for a few colonies of bees would make substantial returns. But it requires some knowledge of the business.

2. Italians, or those with a large proportion of Italian blood.

3. Prices vary much, perhaps from \$5 to \$7, generally.

Introducing Queens.

I received the queen you sent me in good order, but she is *non est* now. I would like to write you the way I introduced her, and if you will tell me what my mistake was, you will greatly oblige one of your readers.

I did not have any queenless colonies, so I took two frames of sealed brood with adhering bees, and two frames of honey, and shut them in a hive, putting the cage between the top-bars. In two days, as the bees seemed friendly towards the queen, I let her run on the frames of brood, and the next day, altho I did not see her, I found eggs in the frame. Yesterday the bees commenced to rob the colony, and I could do nothing with them. I lookt at them this afternoon, and they had taken every drop of honey, and I should think had had a free fight, from the dead bees on the bottom-board, but no queen living or dead could be found.

This is only my second year at bee-keeping, and as yet, altho I have a great many theories, I have not had much practice, but I hope in time to be more successful.

MRS. FLORENCE.

ANSWER.—It would have been a safer thing to have left to the bees the job of releasing the queen, instead of letting her out of the cage yourself. Still, that had nothing to do with the loss in your case, for your finding eggs was good

evidence that the queen was received all right, providing this was three days or more after the bees and brood had been taken from the mother colony. The only trouble in the case was that the nucleus was overpowered by robbers, and I'm afraid that a certain woman was a wee bit to blame in the matter, altho that may be an unwarranted suspicion on my part. What I am afraid of is that the hive was opened to see what was going on, and a frame left standing out of the hive for a time let the robbers have a taste that aroused them. At a time when robbers are likely to be troublesome, the greatest care should be exercised about opening a hive with a weak colony, not to expose anything to robbers, and there is some advantage in doing the work rather late in the day, for in that case if robbers do attempt to enter, the coming on of night will stop them and give the weakling a chance to rally. The entrance should be only large enough for one or two bees to pass at a time.

Queenless Colony Gathering Honey and Pollen.

Do bees gather honey and pollen when they are queenless?
MICHIGAN.

ANSWER.—Yes, as you can easily tell by watching a queenless colony. If you look inside when a colony has been queenless for some time, you may think they gather more pollen than others, but that's because they store without using what they gather, which is really less than others gather.

Observatory Hive.

1. Please give directions for making an observatory hive.
2. If I put frames of brood and honey in, with a sealed queen-cell, how many bees will it take to make a fair colony in an observatory hive?
3. What is the best way to get a colony in the observatory hive? I have no extra queens.

ANSWERS.—1. An observatory hive may contain only one frame, or it may contain 10 frames. It is built on the same general principles as another hive, only the two side-walls should contain a pane of glass, with a shutter to cover the glass.

2. Just the same as in any other hive, depending on the number of frames, each frame being well covered with bees.
3. One way is to pen them in for 24 hours, taking care that they do not smother.

Honey Granulated in Brood-Combs.

About one-half of my surplus honey, also the same percent of honey stored in brood-frames, that which was gathered thru the month of June, is candied. The sources from which the honey was gathered thru the month of June are as follows: White clover, poplar, black-gum, and the largest percent of the total is honey-dew. From all these sources my bees have gathered honey year after year, but never have I seen a drop of candied honey in combs. Why did this honey granulate? Will the candied honey in the brood-frames be all right for wintering bees, since some of it is quite hard and dry? If not, what would I better do?

WEST VIRGINIA.

ANSWER.—I cannot tell why your honey should act so differently this year. It might be well for you to feed to each colony five pounds of sugar with the same weight of water, removing some of the honey for that purpose. A larger amount of sugar might be still safer.

The American Fruit and Vegetable Journal is just what its name indicates. Tells all about growing fruits and vegetables. It is a fine monthly, at 50 cents a year. We can mail you a free sample copy of it, if you ask for it. We club it with the American Bee Journal—both papers one year for \$1.10.

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Richards, Ohio.

QUEEN-REARING IMPROVEMENTS.

I am rather "the day after the fair" in commenting on Mr. Pridgen's splendid article on queen-rearing, as copied from the Bee-Keepers' Review on pages 401 to 405. It has already been commented on by those who know something about rearing queens for market, which I do not. I know that in the opening picture those cell-cups give a singularly vivid impression of the delicate waxiness of wax. I should guess that a very great labor-saver was that queen-nursery to slip over 18 cells at once—and give each princess a boudoir of her own—and release her thru a hole with a wooden peg. I wonder how many readers blunderingly thought from looks that the transfer-stick and a dipping-stick were all the same thing. And many of the little paragraphs might be profitably enlarged to a considerable article—just to get the thing more effectively thru a dull fellow's wool.

When A. I. Root called for a sheet of foundation a mile long he didn't think how soon some one would distance him by grinding out a peck of young queen-cells with a few turns of a crank! (And some might say that W. H. P. is the more significant crank.)

And it seems it isn't worth while to try off-hand introduction with virgin queens which have reached that extremely active state characteristic of them when many hours old. I judge that one of the best general directions is: Observe at eventide all colonies from which queens are likely to mate—and if one has failed to return from flight there will be panic and distress manifest at the door.

ROBBER-BEES AND THEIR WAYS.

And so Mr. Davenport also "got left" by 500 pounds of honey which was once in a barrel. And I will admit that sometimes—many times—anything and everything can be given to bees to clean up without putting any dangerous mischief into their heads; still I incline to maintain that the robber-bee is not altogether a figment of the imagination, like grave-yard ghosts. It's perfectly true that robbers will form squirming bunches, and act as if in a frenzy of desire to get into that hive, when they are taking good care to keep away from the entrance, for fear of consequences. It is a helpful suggestion that an apiary often gets in a roar when there are not many robbers—mainly the roar of bees trying to find out what's going on. Page 405.

FASTENING FOUNDATION IN SECTIONS.

As to fastening foundation in sections, Charles Smail, page 410, evidently does it, and in an unusual way—still I think he might profitably meditate on the way Dr. Miller does it, and on the methods of some of the other brethren. You see if a type-setting youth should entirely ignore the efforts of others in the same line, he would be pretty sure to think that 30 cents' worth of type-setting was a rousing day's work.

SHOWY AND FRAGRANT FLOWERS AS HONEY-YIELDERS.

Thanks to Prof. Cook for his general principles (page 411) that all showy flowers and all fragrant ones are nectar-bearing. I think, however, there is room for warning against riding these principles too hard. The "nigger-head" and the ox-eye daisy and the mayweed are showy, but they hardly count much to our profit. The flowers of basswood are not showy, yet they count heavily. Our heaviest yielder, white clover, is but very faintly fragrant, and no more showy than the mayweed is. So we can not judge conclusively offhand by either beauty or fragrance. I wonder if it wouldn't do to make another general rule, to the effect that flowers of ill odor are mostly of no account for honey.

SUNSHINE TO MOVE WORMS OUT OF COMBS.

Yes, Mr. Ridley, your accidental discovery is likely to be of some use. Instead of the tedious work (seldom fully complete) of picking worms out of combs, set the combs up in the hot sunshine and make the worms crawl out. Page 430.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

The National Convention This Month—don't forget it. The dates are Aug. 28, 29 and 30. The place—Chicago.

Apiary Experiments; by Prof. Clarence P. Gillette, being Bulletin 54 of the Agricultural Experiment Station of the Agricultural College of Colorado, is a very interesting pamphlet, for which this office is indebted to the courtesy of the author. The problems discuss in this pamphlet relate mostly to comb foundation. Space is also given to the advantages of separators, proportion of wax in comb honey, and substitutes for pollen. The first question for settlement was:

DO BEES USE WAX FROM ARTIFICIAL FOUNDATIONS TO EXTEND THE CELL-WALLS AND THE COMB MIDRIB?

Black foundation was made by mixing lamp-black with the melted wax from which the foundation was made. Starters an inch wide were given in sections, and the bees built down an inch or more below the starter before the black entirely disappeared. Full sheets were given in sections, and the cell-walls were deep black at the bottom, gradually becoming lighter until the color hardly showed at the outer edge of the cell-wall. This proves clearly that bees freely use the wax in the foundation in extending the midrib, and also in drawing out the cell-walls, freshly secreted wax being mixed with that furnished in the foundation.

Then Prof. Gillette tackled this very practical and important question:

IS THE WAX OF THE MIDRIB OF THE FOUNDATION USED IN COMB BUILDING, AND, IF SO, WILL IT BE CUT DOWN TO THE THINNESS OF THE MIDRIB IN 'NATURAL COMB'?

Samples of foundation, of midribs of the same after being worked by the bees, and also midribs of natural comb were weighed, the weight of a square inch being taken in grains. A square inch of midrib of natural worker-comb weighed from 1.65 to 3.2 grains, showing that the bees are by no means constant in their measurements. The average of a number of specimens was 2.1 grains. "Very heavy foundation gave a comb midrib weighing 5.90 grains more to the square inch than the midrib of natural comb. Medium brood foundation gave a midrib 3.08 grains heavier to the square inch, or almost 2½ times the weight of natural midrib. The lightest midribs were obtained by the use of extra-thin and thin super foundations, averaging but .85 to .90 grains to the square inch more than natural midrib."

While all midribs thicker than natural were thinned by the bees, none of them were thinned to the natural weight. Deep-cell foundation with very thin base, and with high cell-walls, was actually made thicker by the bees, possibly because some parts were so thin as to have perforations.

Besides weighing the different samples, a large number of measurements were taken by means of plaster casts. The common range in thickness of the midrib in naturally-built worker-comb was found to be between .0032 and .0064 of an inch, and in drone-comb between .0048 and .008 of an inch.

In natural comb, the upper part, near its attachment, had a heavier midrib than the lower part. The midrib of thin and extra-thin foundation was scarcely thinned at all by the bees, and both were about alike, the difference in weight between thin and extra-thin being mainly in the incipient cell-walls. Measurements showed the same thing that had been shown by weighing, that the midrib of heavy foundation was thinned much, and that of light foundation little. Unless the midrib was thicker than about .0068 of an inch, the bees seemed to think it needed no thinning.

Prof. Gillette next turned his attention to

THE THICKNESS OF CELL-WALLS BUILT ON FOUNDATION.

The natural cell-wall is much thinner than the midrib, varying from .0018 to .0028 of an inch, the average being not more than .0024. On heavy foundation the cell-walls were thick for some distance from the midrib, none having cell-walls so thin as the natural except thin and extra-thin foundation, and the deep-cell foundation sent out by The A. I. Root Co. in 1899. Of these, Prof. Gillette says: "I was not able in many cases to detect by measurements that the cell-walls on these foundations exceeded the average thickness in natural comb."

Taking three samples of comb each .9 of an inch thick, it was found that natural drone-comb was distinctly heavier than worker, and scarcely lighter than comb built on thin super foundation. The natural worker took 5.40 square feet to the pound, drone 4.32, and the comb on thin foundation 4.23. Of course, this involves the weight of both cell-wall and midrib, but the cell-wall plays the more important part, as it is estimated that in comb an inch thick the area of cell-wall is about ten times that of the midrib.

Bees seem to make heavier cell-walls when heavy foundation is used, but extra-thin foundation produces much the same result as thin, the principal difference being the less amount of cell-wall in the extra-thin. To get anything approximating natural comb, there must not be a large amount of wax either in the base or cell-walls of foundation.

Prof. Gillette's experiments do not agree with the be-

lief that all the weight of wax given in foundation will be utilized to the best advantage and save the bees secreting just that amount of wax. When foundation containing an abundance of wax to build the entire comb is used, the bees still add much more wax, sometimes nearly enough to build the comb without the help of the wax in the foundation. It is best economy to have the midrib of the foundation as thin as that in natural comb, and only a moderate amount of wax in the cell-walls.

If natural comb an inch thick is filled with honey, the weight of the honey will be 20 to 25 times as much as the weight of the wax. The proportion of wax, as might be expected, is greater in thin than in thick combs.

Bottom-Board Feeding has been practiced more or less for many years. A deep bottom-board, already water-tight, or made so by filling the cracks with wax, is placed under the hive, the whole being raised in front, the feed is poured into the entrance at dusk, and by morning all is cleared up, if the weather is suitable. It has been reported in some cases that too many dead bees have been found carried out the next day. W. O. Victor describes a plan in *Gleanings in Bee-Culture* that seems to be an improvement. He uses the shallow bottom-board under the dovetailed hive, not more than half an inch deep, the hive is raised half an inch in front, the feed is poured in thru a funnel flattened and bent at the end, and the bees reach the food from the bottom-bars without the danger of tumbling into it.

Bees and Red Clover.—Some time ago Dr. Miller advocated in *Gleanings in Bee-Culture* with some earnestness the importance of breeding bees for length of tongue, but the editor seemed inclined to throw cold water on the project. Now Editor Root seems to be taking the lead in the matter, and has offered a prize for the longest-tongued bees. In France something has been done in this line, and several instruments called glossometers have been devised for measuring the length of bees' tongues by getting them to take feed thru some kind of a grating or opening, the depth to which the feed is emptied showing the length of tongue. Breeding persistently from bees showing the greatest length of tongue might be expected to result in obtaining a strain that would be able to do good service on red clover.

Prof. E. C. Green, of the Ohio Experiment Station, advocates the advisability of beginning at the other end of the line, and breeding a strain of red clover with tubes short enough for common bees to work on. Editor Root says:

"I hope this matter may be taken up at the Ohio Experiment Station, under Prof. Green's direction, and in the meantime I hope our bee-keepers will be on the watch for red-clover heads with short tubes. Mark these in some way so that they can be distinguished when they go to seed. Preserve the seed carefully, and sow them in a small patch next year. From this patch select again the shortest tubes, and thus continue on until a short-tubed clover is developed. If this kind of clover could be secured, the bee-keepers could well afford to furnish the farmers the seed free, and the result would be that such seed would be disseminated all over the country."

The Koran on Bees.—If we are to judge from samples given from the Koran in the *British Bee Journal*, it must be rather difficult for a Mahomedan to remain faithful to his religious guide after he becomes an up-to-date bee-keeper. Here is a specimen that is rich:

"In the hives there are males and females, but all alike in appearance, so that man can not distinguish them. The work is done by both sexes. The brood is hatched when the season arrives; chiefly in spring the germ is spit out into the cells, as is the case with other flies—the life of the bee is not known.

"Death takes place either once or twice a year from fatigue or that the old bees over-eat themselves, and returning to the hives are suddenly killed and thrown out by their comrades. European bee-keepers call them drones.

"Swarms are groups of young bees which leave their cells and rush out to hive alone and at their ease.

"Bees spend their nights out-of-doors, except Thursday evening, when all return home, because of Friday the holiday.

"Honey is gathered from all flowers and sweetened by the bee, who swallows it as nourishment—it ripens in the stomach and is deposited later on in the combs as excrement; the sap of flowers and juice of fruits being the only nourishment taken by the bee, their excrements are very clean for our consumption.

"Wax is collected from flowers sticking to their feet, carried into the hive, and kneaded to a dough for the construction of comb."

MR. G. M. DOOLITTLE, of Onondaga Co., N. Y., wrote us Aug. 1, as follows:

"No such bee-year ever known here since I began keeping bees—31 years ago. No honey—not a cell since fruit-bloom. No swarms. Have had to feed. Queen-rearing is up-hill business. Dry weather spoiled the clover, and forest worms ate up the basswood. If buckwheat does not yield, the sugar-barrel is our only salvation."

BEE-KEEPING IN URUGUAY.—It seems they are having trouble with bees in Uruguay in the public scientific schools. The following item in *El Siglo*, dated April 3, from Palmira, Uruguay, is translated from the Spanish, and it certainly constitutes good reading:

"There is much comment ament the disposition of the Auxiliary Commission, which has ordered the removal of apiaries from agricultural stations, alleging that the bees are prejudicial to agriculture, while the scientific stations are of entirely the opposite opinion. There is now in vogue in the Uruguay station the North American system of apiculture, which is of much importance. It is the first one installed in Uruguay."

This is followed by a most vigorous and able defense of the bee as the best friend of the farmer and orchardist.—*Gleanings in Bee-Culture*.

THE DUKE OF YORK, in England, is taking some interest in bees and honey. "Stenog," in *Gleanings in Bee-Culture*, gives this paragraph in reference to the matter:

"An interesting feature of the *British Bee Journal* is a fine view every week of an English apiary. At the Royal show of bees and honey at York, the Prince of Wales and the Duke of York were interested spectators. Mr. Carr laid a section-case containing the queen on the top of a frame hive near at hand, while the driven bees were shown in the hive, and their subjugation and disinclination to sting were demonstrated by the bees being taken up in handfuls. The Duke of York having inquired in what way the bees were removed from the hands, and being shown the usual method of jerking them off by a downward shake, the Prince of Wales jocosely observed, 'And a very good way, too.' It would be a rare sight in the United States to see one so high in rank as the Prince taking any interest in such things."

We are glad to learn that our English "cousin" shows an interest in bee-keeping.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40-cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

ROOT COMPANY'S PAGE.

SHIPPING-CASES.

Our No-Drip Cases are still in the lead. We keep constantly on hand a large assortment from 12-pound size up. We also make special sizes to order.

That Root's Cases are in demand is shown by the fact that one dealer alone has ordered 16,000 this season.

WINTER-CASES.

Our Winter-Cases are made of thin lumber dovetailed at the corners, with a telescope cover.

The cost is only 75 cents each singly, yet for convenience they are unsurpassed, and only excelled by the chaff hive in the protection afforded. Don't let your bees winter-kill or spring-dwindle when you can avoid it by using our Winter-Cases.

RUBBER GLOVES.

This is the time of the year when you need gloves, for robbers are about the bees and they are harder to handle than earlier. Take comfort with a pair of our gloves.

Ladies' sizes, Nos. 6, 7, 8 and 9, \$1.35; postage, 5c
Gents' sizes, Nos. 10, 11 and 12, \$1.45; " " 5c
Extra long driving, Nos. 13, 14, \$1.70; " " 10c

Mark size of hand on sheet of paper when ordering. If you order by number, remember that in rubber you need two sizes larger than you wear in kid; i. e., if you wear No. 6 in kid you will need No. 8 rubber.

BICYCLES

In trade for honey at market prices.

Having sold a carload of bicycle crates, we took in trade a quantity of machines which, so long as they last, we will sell **AT COST**.

A \$30.00 bicycle—"Pathfinder"—made by the National American Cycle Company, Akron, O., for \$17.00 cash or \$20.00 in trade for honey of good quality at market prices. Catalog and further particulars will be sent on application. Send a sample of your honey and we will give you price we will allow.

COMB FOUNDATION.

□ Not too late yet to order Comb Foundation for the fall flow. If you order Root's Weed Process you may be sure you will be pleased with the result. We keep in stock the four grades in boxes of 1, 2, 3, 5, 10 or 25 pounds.

A small order has the same attention as an order for a ton.

SPECIAL GOODS.

This is the time when you should order odd size or special goods. Our busy season is over and we can do almost any work in wood you want, either for bee-keepers or others.

□ We make a specialty of packing-boxes, from the size of a section-box up. Let us figure with you.

FEEDERS.

How about your winter stores? Are you sure your bees have enough? Should it be necessary to feed you can't do it easier than with our Division-Board Feeder. This is made to hang like a frame in a Langstroth hive. Price, 20 cents each, complete. Less in quantities.

Honey-Labels.

Do you use labels for your honey? Are they really ATTRACTIVE labels? If you do not you may be losing many sales because your honey lacks attractiveness. You can't expect to market your honey at the best price unless you use every care in putting it up. Send for our label catalog and see our 1, 2, and 3 color labels.

Tin Packages for Honey.

If you are one of the people who market extracted honey in small lots you will find our pails just what you want. A dozen sizes and kinds to select from. We also furnish square cans—1-quart, 2-quart; 1-gallon and 5-gallons. A single can or carload, as you wish. Write for prices.

Gleanings in Bee-Culture.

When our advertisers write us that their advertisements have paid them well, we know GLEANINGS IN BEE-CULTURE must be read by the best bee-keepers. We know, too, that GLEANINGS is appreciated, for our circulation is increasing all the time. Send 25c for a six months' trial and get A. I. R.'s Notes of Travel and hundreds of other interesting things.

Comb-Foundation Mills.

Perhaps you are so far from us and rates are so high that you want to make your own foundation.

Our mills are being improved constantly. If you want to purchase a foundation mill, send for package of samples showing different styles we can furnish. Send 2c stamp for these.

Bushel Boxes.

Bee-keepers are always looking for labor-saving ideas. Have you ever read our 16-page pamphlet, "Handling Farm Produce?" It is full of information and gives prices of bushel boxes and other things. Free for the asking.

HONEY-EXTRACTORS.

"Operator No. 6 puts the honey-combs in the extractors, which is a Cowan 4-frame reversible, with ball-bearings and lever-brake—in short, the best extractor on the market."

Extract from article of N. E. France, of Wisconsin, in June Review. No one is better qualified to judge the worth of an extractor than Mr. France. He says the ROOT COWAN IS THE BEST.

Thousands of others say so.

Glass Honey-Packages.

We have all sizes of Mason Jars with aluminum or porcelain-lined caps. Also Jelly Tumblers, two sizes; Glass Pails, four sizes; and Self-Sealing Jam Jars. Besides these we still have the four sizes square jars, which have long been on the market. Don't forget us when you need glass packages for honey.

RUBBER STAMPS.

Have you ever thought how handy it would be to use a rubber stamp to mark your honey-cases, showing the grade? Then, too, if you sell in the home market you ought to have your name on the case so it would be returned. We make stamps of all kinds for all sorts of purposes. Let us send you our rubber stamp circular.

QUEENS.

We don't say much about our queens, do we? I suppose some of our friends wonder why. Let us tell you: We began selling queens many years ago. We know all about the business from A to Z. We have the best breeding queens to be found in this country or Italy, and the best apiarist to be had. The result is our 400 colonies do not begin to furnish enough queens for our orders. Our queens are unsurpassed. You will find it so if you buy them.

HONEY.

We buy a number of carloads of comb and extracted honey each year. If you have secured a good crop send us your offer. You don't have to worry about the return if you sell to us.

If you have extracted honey send sample. If you have failed to secure enough for your home market, let us supply you. We have honey engaged all over the country, and can ship direct from the producer, many times.

AGENCIES.

A list of our principal agencies will be mailed you on request. We can ship from stock such items as our regular Hives, Sections, Foundation, Extractors, etc., from these agencies.

Send your order direct to us, if you prefer, and request that we ship from nearest point, and we will do so, saving you freight charges and giving you quick delivery.

Chicago Convention Program.—The following is the program of the 31st annual convention of the National Bee-Keepers' Association, to be held at Chicago, Ill., Tuesday, Wednesday, and Thursday, Aug. 28, 29, and 30, 1900, the sessions to be held in Wellington Hall, 70 North Clark St.:

FIRST SESSION—TUESDAY EVENING.

Call to order at 7 o'clock.
 Song—Dr. C. C. Miller, of Illinois.
 "How to Sell Honey"—S. A. Niver, of New York.
 "Keeping Bees in a City"—L. Kreutzinger, of Illinois.
 Question-Box.

SECOND SESSION—WEDNESDAY MORNING, 9:30.

Song.
 Invocation.
 President's Address—E. R. Root, of Ohio.
 "Queen-Rearing by the Doolittle Method"—Mrs. H. G. Acklin, of Minnesota.
 Question-Box.

THIRD SESSION—WEDNESDAY AFTERNOON, 1:30.

Song.
 "Bee-Keepers' Rights and Protection by Law,"—Her- man F. Moore, of Illinois.
 "Trials of the Commission Man"—R. A. Burnett, of Illinois.
 Question-Box.

FOURTH SESSION—WEDNESDAY EVENING, 7:30.

"Breeding for Longer-Tongued Bees"—J. M. Rankin, of the Michigan Experiment Station.
 "Bee-Keepers I Have Met and Apiaries I Have Visited"—E. R. Root, of Ohio, assisted by Dr. C. C. Miller, Dr. A. B. Mason, E. T. Abbott, and others. Illustrated by a stereopticon.

FIFTH SESSION—THURSDAY MORNING, 9:30.

Song.
 "Various Forms of Diseases Among Bees; Cause and Cure"—Dr. Wm. R. Howard, of Texas.
 Report of the General Manager—Hon. Eugene Secor, of Iowa.
 "Pure-Food Legislation"—Rev. Emerson T. Abbott, of Missouri.
 Question-Box.

SIXTH SESSION—THURSDAY AFTERNOON, 1:30.

Song.
 "Chemistry of Honey and How to Detect Its Adultera- tion"—Thos. Wm. Cowan, of California.
 "How to Ship Honey to Market, and in What Kind of Packages"—George W. York, of Illinois.
 Question-Box.

SEVENTH SESSION—THURSDAY EVENING, 7:30

"Co-operative Organization Among Bee-Keepers"—R. C. Aikin, of Colorado.
 "My Trip Thru Wisconsin and Minnesota"—W. Z. Hutchinson, of Michigan. Illustrated by a stereopticon.
 Unfinished Business.
 Adjournment.

One prominent feature of the next convention will be the stereopticon work. Messrs. Root and Hutchinson, with a powerful stereopticon, will project upon the screen some photos they have taken of apiaries they have visited in various portions of the United States. The convention will be held in Wellington Hall, 70 North Clark Street, about a block and a half from the office of the American Bee Journal, and about five blocks directly north of the Court-house. The hotel at which delegates may secure lodging is the Revere House, about half a block from the convention hall. The rate for lodging will be 50 cents per night, and the proprietor has assured Mr. York that good beds are provided, but that several will have to occupy the same room. But when any one desires a room with a single bed, the charge will be \$2.00 per night. If two men wish to take a single room in that way they can do it, sharing the expense between them. Some G. A. R. people will pay 75 cents per night for a single bed, so bee-keepers are specially favored at 50 cents. The hotel is almost within a stone's throw of the convention hall, and right near the hall are first-class restaurants, where meals can be secured at reasonable rates.

It is a little too early yet to announce what the railroad rates will be during G. A. R. week; but it is assumed that they will be low, probably a cent a mile each way.

Chicago is a central point, and there will undoubtedly be a large attendance; and, considering the attractions, it is earnestly hoped that bee-keepers will turn out in good, strong force.

E. R. Root, *President*.
 DR. A. B. MASON, *Secretary*.

If You Want Bees

That will just "roll" in the honey, try Moore's *Strain of Italians*, the result of 21 years of careful breeding. They have become noted for honey-gathering, whiteness of cappings, etc., thruout the United States and Canada.

Warranted Queens, 75c each; 6 for \$4.00; 12 for \$7.50. Select warranted, \$1.00 each; 6 for \$5.00; 12 for \$9.00. Strong 3-frame Nucleus with warranted Queen, \$2.50. Safe arrival and satisfaction guaranteed. Circular free.

27 Dct J. P. MOORE (lock box 1) Morgan, Ky.
 Please mention Bee Journal when writing.

Italian Queens!

reared from the best 3-band honey-gatherers, by the Doolittle method. Untested, 45 cents each; 1 dozen, \$4.50. Tested, 75 cents each; 2-frame Nucleus, with tested queen, \$1.75 each. No disease. Safe arrival.

W. J. FOREHAND,
 19D12t FORT DEPOSIT, ALA.

Albino Queens by return mail. Untested, 75 cts.; warranted, \$1.00; tested, \$1.25.
 12A26t J. D. GIVENS, LISBON, TEX.
 Please mention Bee Journal when writing.

Italian Queens.

	1	3	6
Untested Queens.....	\$0.90	\$2.50	\$4.50
Select Untested Queens.....	1.25	3.25	6.00
Tested Queens.....	1.25	3.50	7.00
Select Tested Queens.....	2.00	5.00	9.00

These Queens are reared from honey-gatherers. Orders filled in rotation. Nothing sent out but beautiful Queens.

27A9t D. J. BLOCHER, Pearl City, Ill.
 Please mention Bee Journal when writing.

Cleome and Its Honey.

I merely scatter cleome seed any and everywhere soon after gathering, and Nature does the rest. With us it produces the whitest and best-flavored honey of any plant that grows here.

Bees are doing fairly well, but they swarmed a little too much. We expect considerable late flow from cleome.

W. H. HOUGH.
 Santa Fe Co., N. Mex., July 30.

White Clover and Basswood Failed.

Bees have done very poorly so far. White clover and basswood were complete failures. It has rained nearly every day this month, and I think fall flowers will be all right.

H. H. PORTER.
 Sauk Co., Wis., July 30.

A Very Deceptive Season.

This has been a very deceptive season (I suppose that would be the proper word for it), as it has been holding out inducements for a good season almost, or in fact all, of the time since it commenced raining, about the middle of

Sharples Cream Separators; Profitable Dairying

DITTMER'S FOUNDATION

Wholesale and Retail

This foundation is made by an absolutely non-dipping process, thereby producing a perfectly clear and pliable foundation that retains the odor and color of beeswax, and is free from dirt.

Working wax into foundation for cash, a specialty. Write for samples and prices.

A full line of Supplies at the very lowest prices, and in any quantity. Best quality and prompt shipment. Send for large, illustrated catalog.

GUS. DITTMER, Augusta, Wis.
 Beeswax Wanted.

Please mention Bee Journal when writing.

ELECTRIC HANDY WAGONS

excel in quality, strength, durability. Carry 4000 lbs. They are Low priced but not cheap.
 Electric Steel Wheels—straight on staggered oval spokes. Any height, any width of tire to fit any wagon. Catalogue FREE.
 ELECTRIC WHEEL CO., Box 16. Quincey, Ills.
 Please mention Bee Journal when writing.

The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

GEORGE W YORK & CO.
 118 Michigan Street, CHICAGO, ILL

The Bee-Keeper's Guide

Or, Manual of the Apiary,

—BY—
PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipt, or his library complete, without THE BEE-KEEPERS' GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,
118 Michigan Street, CHICAGO, ILL.

BY RETURN MAIL.

Golden Beauty Italian Queens,
Rearred from imported mothers.

Untested, 50 cts.; 12 Untested, \$5.50; Tested, \$1.
J. S. TERRAL & CO., Lampasas, Texas.
18Atf Please mention the Bee Journal.

June; but there has been but very little nectar in anything, it seems, so we will have to chronicle another poor season. A few good honey-days would give me a nice crop of honey, as my bees are in nice shape to gather it. The pastures are eaten off too close in this country. Perhaps we will get enough honey this fall for them to fix up for winter. I certainly hope so.

W. C. NUTT.
Hardin Co., Iowa, July 28.

Half a Crop of Honey.

We have harvested a big wheat crop and a good half crop of honey—far better than expected. We had one of the worst drouths in May and June for many years, and now we are having plenty of rains, and it looks as if we will have a good corn crop.

I expect to attend the Chicago convention Aug. 28, 29 and 30.

L. A. HAMMOND.
Washington Co., Md., July 30.

Bees Starving—No Honey.

Our bees are starving—a state of affairs that I have never seen or heard of in this part of the country at this time of the year. We have had no honey since fruit-blossoms to amount to anything. This makes three poor years here in succession. I think that we are overstocked with bees. It does not take many bees to overstock here in a poor season.

GEO. W. STINEBRING.
Wayne Co., Ohio, July 23.

No Rain for Over Three Years.

Three and a half years have gone by since we have had a good rain here, yet I am now growing nice watermelons, and these without irrigation, with well-water 60 feet below the surface. Bees on the great ranges are weak or dead.

DR. PEIRO,

34 Central Music Hall, CHICAGO.

Please mention Bee Journal when writing.

The Mississippi Valley Democrat —AND— Journal of Agriculture, ST. LOUIS MO.

A wide-awake, practical Western paper for wide-awake, practical Western farmers, stock-raisers, poultry people and fruit-growers, to learn the science of breeding, feeding and management. Special departments for horses, cattle, hogs, sheep, poultry and dairy. No farmer can afford to do without it.

It stands for American farmers and producers. It is the leading exponent of agriculture as a business, and at the same time the champion of the Agricultural States and the producer in politics. Subscription, One Dollar a Year.

FREE SAMPLE.

If he hasn't it, don't take a substitute, but send us a stamp for our

book on "Health" and we will send you a free sample, sufficient for you to try it and test its merits to your own satisfaction. Isn't it worth trying free? It positively cures. Price 10c and 25c per box. Don't delay sending.

The Modern Remedy Co., Kewanee, Ill.

Here, orange and alfalfa bloom carry them over. H. M. JAMESON.
Riverside Co., Calif., July 28.

Prospect for a Fall Crop.

There is not much white clover honey here. It was cut short by drouth. Basswood was ruined by hot weather. There is a splendid prospect for a fall flow, now commencing.

I expect to attend the Chicago convention. F. M. BOWDISH.
Ingham Co., Mich.

Keeping Things in Place.—I have investigated quite thoroly, and find that it is a very rare thing for any man or woman who "has a place for everything and everything in its place," to make a failure in anything they turn their hand to. And in nothing is this more applicable than in bee-keeping. Many times have I been to the places of those who told me "bee-keeping did not pay," only to find the greatest disorder. When askt for the smoker to use in looking at a colony of bees, the proprietor did not know just where he left it last, and after a search it was found just where he had dropt it after using it the last time. Hives were leaning in every direction, grass uncut, combs thrown about, being destroyed by the moth, and tools and utensils lying out in the weather going to decay. Ah, no wonder there is no money in such bee-keeping.—G. M. Doolittle, in Progressive Bee-Keeper.

Best Smoker-Fuel—How Used.—All things considered, I have come to the opinion that planer-shavings or hand-hole sawdust—a stringy kind of excelsior made by means of a wabbling saw—makes the best kind of smoker-fuel—the most lasting and the densest smoke; but in order to get good results one must throw in but a very little of the shavings, light a match, and work the bellows until the fuel is reduced to live embers. Throw in some more, and treat them in the same way. It is then possible to cram in the planer-shavings, pushing them down hard. Next fill the nozzle, in the same way, snap it back into place, and we are ready for an hour or two hours' work. If the smoker is kept full there is no blowing of sparks into the hive. This treatment is especially adapted to the Crane smoker, for it has a powerful direct blast. It may also be used for the Bingham and Corneil; but with either of these less crammng of the fuel is advisable.—Gleanings in Bee-Culture.

Points in Peddling Honey.—Mr. J. C. Stewart, of Missouri, has had quite a little experience in peddling honey. In a letter he gives a few interesting points, some of which are as follows: When he goes to a town he goes prepared to stay two weeks, if necessary; taking along a change of clothing. Instead of stopping at a hotel, he hunts up some boarding-house where he can get board at about \$3.00 a week, and pay for the same in honey. In canvass-

SPECIAL NOTICE!

Last winter's cut of basswood is the whitest it has been for many seasons. We are now making sections out of this new stock and therefore are in a position to furnish you with the very finest quality in the market.

LEWIS WHITE-POLISHT SECTIONS

SEND FOR CATALOG.

Four Celluloid Queen-Buttons Free AS A PREMIUM.

For sending us ONE NEW SUBSCRIBER to the Bee Journal for the balance of this year, with 50 cents, we will mail you FOUR of these pretty buttons for wearing on the coat-lapel. (You can wear one and give the others to the children.) The queen has a golden tinge. This offer is made only to our present regular subscribers.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate, it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

Prices of Buttons alone, postpaid: One button, 8 cts.; 2 buttons, 6 cts. each; 5 or more, 5 cts. each. (Stamps taken.) Address,

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO.

BEE-BOOKS

SENT POSTPAID BY

George W. York & Co. 118 Mich. St. Chicago.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopaedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers, \$1.00.

Bienen-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Bienenzucht und Honiggewinnung, nach der neuesten methode (German) by J. F. Eggers.—This book gives the latest and most approved methods of bee-keeping in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cts.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cts.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kolnake.—Origin, Development and Cure. Price, 10 cents.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 20 cents.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about Poultry Business. 64 pages. Price, 20 cents.

ing for orders he offers his prospective customer a taste of honey. If there is any hesitancy in getting a spoon, he takes a square of paper from a pad that he carries, and pours a small quantity upon the square of paper. He also carries a damp cloth in his pocket to clean the jar if it becomes sticky. If they begin to talk about adulteration and imitation honey, he draws from his pocket a photograph of his apiary, showing himself in the yard, which seems to create an impression that he must be a "sure-enough" bee-man. In taking orders he writes down simply the street and number, not bothering to get names. He canvasses two days, and then delivers. Before starting out to deliver he takes a piece of paste-board and draws a map of the district in which he has to deliver, marking out the streets and numbers where he has to call and the amounts to deliver, thus being able to lay out a route to the best advantage.—Bee-Keepers' Review.

The Globe Bee-Veil.—One can wear any kind of hat with it except a plug, and his face will be absolutely protected. Besides the convenience of wearing the every-day head-gear that always feels comfortable, one has the added security, real as well as fancied, of having the veil held clear away from the neck, face and head by means of the skeleton-like globe steel springs.

Yesterday at our out-yard, when two or three of the crossst bees made a dive for the back of my neck, I did not have the feeling that *perhaps* the veil was touching me at some spot where the rascals could get in a good jab. No, I had the satisfaction of knowing that those parts were invulnerable. At another time, when I received an onslaught from a hive of cross bees, and which stand as guardians over the whole apiary against the intrusions of thieves, I had the pleasure of seeing (even tho at close range) that my nose was a good big inch from the mesh of the veil.

I am not sure but if I were to work in the apiary day in and day out that I would use it exclusively; for one of the things I do like is to wear a hat I am used to. The ordinary cap will not support the average veil in a way that protects one properly, and I very often wear a cap, and with that the globe is just the thing.—E. R. Root, in Gleanings in Bee-Culture.

Introducing Queens.—The best possible plan for an expert may be a very poor one for a novice. To illustrate: I have for the past two years guaranteed the safe introduction of the queens that I have sold. Last year I advised the caging of the queen against the side of a comb of hatching brood. There were some failures; mostly, I believe, thru lack of thoroughness in details—the management was such that the bees burrowed under the cage and released the queen too soon. This year I am advising purchasers to let the bees release the queen by eating out the candy from the end of the shipping-cage; taking the extra precaution to have all of the brood removed from the colony until the queen begins laying. The failures are very few, indeed. I think, however, that the only really infallible method is to release the queen upon combs of hatching

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

	5lb	10lb	25lb	50lb
Sweet Clover (white)	70c	\$1.20	\$2.75	\$5.00
Crimson Clover	70c	1.20	2.75	5.00
Alsike Clover	80c	1.50	3.50	6.50
White Clover	90c	1.70	3.75	6.50
Alfalfa Clover	80c	1.40	3.25	6.00

Prices subject to market changes. Add 25 cents to your order, for cartage, if wanted by freight.

Rocky Mountain Bee-Plant Seed!

(*Cleome integrifolia*.)

...FREE AS A PREMIUM...

The A B C of Bee-Culture says of it: "This is a beautiful plant for the flower-garden, to say nothing of the honey it produces. It grows from two to three feet in height and bears large, clusters of bright pink flowers. It grows naturally on the Rocky Mountains, and in Colorado, where it is said to furnish large quantities of honey."

We have a few pounds of this Cleome seed, and offer to mail a ¼-pound package as a premium for sending us ONE NEW subscriber to the American Bee Journal, with \$1.00; or ¼ pound by mail for 40 cents.

GEORGE W. YORK & CO.
118 Michigan St. CHICAGO ILL.

brood, with no bees present except the young bees that hatch from the combs.—Bee-Keepers' Review.

Speaking of Robbing, many times the very best thing is to do nothing. When robbers get started on a weak queenless colony, it is about as well to let them finish up first as last. If there is much honey in the hive it can be taken out, leaving just a little for the robbers to finish up. If the colony is strong enough to be worth saving, giving it a queen will make it pluck up courage to defend itself.—Gleanings in Bee-Culture.

Preventing the Biting of Cappings.—Mr. Hairston, of Indian Territory, writes that he finds the bees more loth to leave the supers after the harvest is over than during the honey-flow. It is at this time, that is, after the harvest, that they are inclined to bite the cappings when disturbed. He says that he noticed that they did not bite cappings so long as there was unsealed honey for them to fill up on: taking a hint from this, he pours a little extracted honey on the escape-board, near the escape, when putting the board in place, and in this way he entirely prevents the biting of cappings. Another thing: For some reason the bees leave the super more readily when the honey is used.—Bee-Keepers' Review.

Yellow Sweet Clover Seed

WE HAVE IT AT LAST!

We have finally succeeded in getting a SMALL quantity of the seed of the YELLOW variety of sweet clover. This kind blooms from two to four weeks earlier than the common or white variety of sweet clover. It also grows much shorter, only about two feet in height. It is as much visited by the bees as the white, and usually comes into bloom ahead of white clover and basswood. We offer the seed as a premium

A QUARTER POUND FOR SENDING ONE NEW SUBSCRIPTION.

So long as it lasts, we will mail a quarter pound of the seed to a regular paid-up subscriber who sends us ONE NEW subscriber for the American Bee Journal one year, with \$1.00; or ¼ pound by mail for 30 cents.

We have been trying for years to secure this seed, and finally succeeded in getting it. It is new seed, gathered last season by an old personal friend of ours, so we know it is all right. But we have only a small supply. When nearly out we will mention it.

THE BOXERS OF CHINA

are attempting to solve a gigantic problem, but they are going about it in the wrong way, and will never succeed. Some people, in this country, seem to think that they have as great a puzzle on their hands in selecting a location for a home. They will certainly go about it in the wrong way unless they inspect the beautiful farming country on the line of the Chicago, Milwaukee & St. Paul Railway, in Marinette County, Wisconsin, where the crops are of the best, work plenty, fine markets, excellent climate, pure, soft water; land sold cheap and on long time. Why rent a farm when you can buy one for less than you pay for rent? Address C. E. Rollins, Land Agent, 161 La Salle St., Chicago, Ill.

ELECTRIC

"The Wheels of Progress."

Now that a political campaign is on, we may expect to hear a good deal from the spell-binders of all parties about the "wheels of progress." One cannot always be sure what the political orator thinks he means, but if he is really interested in the "wheels of progress," we might take him into almost any farmyard and show him the real article.

We say "almost any" farmyard—because the use of the Handy low-down farm wagon is becoming almost universal, and it is on these wagons that we find the real wheels of progress. The truth is that no progressive farmer is content, now, to use one of the old high-wheeled wagons when he can get a "Handy" for less money.

This is a question every farmer should consider before his fall hauling is on hand. One man with a "Handy" will do nearly as much work as two men with a high wagon, and the broad tires of the "Handy" prevent rutting, and roll easily over ground where a narrow-tired wagon would mire.

The Handy wagon with broad tires has come to stay. The leaders in their manufacture are the Electric Wheel Co., of Quincy, Ill. They make also, low steel wheels, with any width tire, to fit any wagon. Send for descriptive catalog and prices. You will be surprised to learn how cheaply you can get a set of wheels for your old wagon. Mention the Bee Journal.

WOOL MARKETS AND SHEEP, CHICAGO, ILL.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Aug. 7.—Fancy white comb honey is selling at 15c per pound, with No. 1 grades bringing 14@15c. There is not much demand at present, and will not be until this hot spell shall pass. Very few amber grades on the market and yet what there is does not sell. Extracted white, 7@7½c; amber, 6½@6¾c; dark, 6@6½c. Beeswax, 28c. **R. A. BURNETT & Co.**

CINCINNATI, Aug. 8.—The demand for extracted honey is slow, while the shipments are many. I quote as follows: White clover, 8@8½c; Southern and amber, 6½@7c. Comb honey sells as fast as it arrives at the following prices: Fancy, 16@16½c; No. 1, 15c. Beeswax, good demand, 25c. **C. H. W. WEBER.**

BOSTON, Aug. 8.—Fancy 1-pound cartons, 17c; A 1, 15@16c; No. 1, 15c; No. 2, 12@13c. Extracted honey from 7½@8½c, as to quality.

It is too early in the season and too warm for any inquiry on honey, so prices named are only nominal. The prospects in this vicinity seem to be for a light crop. **BLAKE, SCOTT & LEE.**

BUFFALO, July 20.—For strictly fancy white one-pound comb honey we are getting 16@17c. Any grade sells high—10@15c, as to grade. **BATTERSON & Co.**

KANSAS CITY, July 20.—We quote: New No. 1 white comb, 14@15c; No. 1 amber, 14c; dark, 13c. Extracted, old, 6@6½; no new in market. Beeswax, 22@25c. **C. C. CLEMONS & Co.**

DETROIT, Aug. 10.—Fancy white comb, 14@15c; No. 1, 13@14c; no amber or dark to quote. White extracted, 6½@7c. **M. H. HUNT & SON.**

NEW YORK, July 26.—There is a fair demand for white comb honey, and enough arriving from the South to supply the demand. Fancy white sells at 15c; No. 1 white, 13@14c; No. 2 white, 11@12c. Extracted remains rather quiet, and the market is sufficiently stocked to meet the demand. Beeswax very firm at 28@29c. **HILDRETH & SEGELKEN.**

SAN FRANCISCO, July 18.—White comb, 12@12½c; amber, 9@11; dark, 6½@7½c. Extracted, white, 7½@8c; light amber, 7@7½c; amber, 6@6½c. Beeswax, 26@27c.

Amber grades are in fair supply, both comb and extracted, and there is a moderate business doing in the same at prevailing figures, mostly in a small jobbing way and on local account. Large dealers are purchasing only to fill immediate orders, not caring to stock up at present prices. Water-white honey is scarce and in a limited way is salable at tolerably stiff figures.

WANTED—HONEY AND BEESWAX.

We have a tremendous and growing trade in this line, and would like to hear from all who have such goods to sell in any part of the country, with quality, description, and lowest cash price. **THOS. C. STANLEY & SON, Fairfield, Ill.**

WANTED COMB HONEY AND EXTRACTED HONEY. Will buy your honey, no matter what quantity. Mail sample with your price expected delivered in Cincinnati. I pay cash on delivery. **C. H. W. WEBER, 2146 Central Ave., CINCINNATI, OHIO.**

DR. MILLER'S Honey Queens

One Untested Queen Free as a Premium for sending ONE New Subscriber to the American Bee Journal for one year.

We have been fortunate in making an arrangement with DR. C. C. MILLER—the well-known honey-specialist—to rear queens EXCLUSIVELY FOR US DURING THE

SEASON OF 1900. These Queens will be mailed in rotation, so "first come first served."

The Queens Dr. Miller will send out on our orders will be precisely the same as those he rears for his own use, so of course they will be from his best stock. His best colony in 1899 had a queen reared in 1898; May 5, 1899, it had brood in 4 frames, and he gave it at that time a frame of brood without bees. It had no other help, but May 25 a frame of brood with adhering bees was taken from it, and the same thing was repeated June 3, leaving it at that time 5 frames of brood. It stored 178 sections of honey, weighing 159 pounds (and that after July 20, in a poor season), being 2½ times the average yield of all his colonies. A point of importance is the fact this colony did not swarm, and an inspection every week or 10 days showed that at no time during the entire season was there even so much as an egg in a queen-cell. Dr. Miller rears queens from this one.

The demand nowadays is for BEES THAT GET THE HONEY when there is any to get, and Dr. Miller has such bees. You will want to have a queen from his best, we are sure, even if she is not pure Italian.

Do not send any orders to Dr. Miller, as all orders MUST come thru us, according to our agreement.

Remember, send us \$1.00 for ONE NEW SUBSCRIBER to the American Bee Journal for one year, and YOU will get ONE OF DR. MILLER'S UNTESTED HONEY-QUEENS FREE AS A PREMIUM. This offer is made only to our present regular subscribers. Orders for queens are to be filled in rotation.

Address all orders to GEORGE W. YORK & CO., 118 Michigan Street, CHICAGO, ILL.

CONTRIBUTED ARTICLES

The Bee-Hive Incubator and How It Works.

BY J. G. NORTON.

THE picture herewith shows only a few of my 55 hives, but will represent my new incubator in a way. The hives, as will be seen, are two-story chaff, that I adopted about 15 years ago, and have been a success for honey and also to hatch chickens. The first story is chaff-packet, four inches back and front, and two inches on the sides. Over the brood-chamber I place a piece of oilcloth or canvas—either will do. I use for the eggs a cushion with hollow center which is the shape of a hen's nest, and will hold from 16 to 50 eggs. The cushion is eight inches thick, and fills the top of the second story within two inches of the top.

Mr. J. G. Norton and His Bee-Hive Incubators.

After the eggs are placed in the nest, or incubator, another small cushion is prest over the eggs, and all are kept warm. The temperature outside may drop 20 to 40 degrees, but that in the nest is kept about the same. I find in this latitude eggs can be set any time after Feb. 15, and as we very seldom get surplus honey here before June 10, all this time can be used to advantage. The eggs need turning only every two or three days, in this way, so it does not need very close watching.

I am entirely satisfied with the plan, and to show how sure I am of the results, I have all spring been setting pure

Buff Cochin eggs worth \$5.00 a sitting, and have not lost a fertile egg; and the chicks are the best and strongest I ever had.

Be sure to use the strongest colonies as incubators, having at least six combs well filled with brood; then your test will result satisfactorily. McDonough Co., Ill.

Swarming of Bees—A Review of the Subject.

BY PROF. A. J. COOK.

IN looking over several of the bee-books I have been led to wonder if we had all the wisdom regarding the swarming of bees that was desirable. Before starting on the

subject proper, I wish to say that I am proud of our bee-books. Dadant's Langstroth is a splendid book. I feel very happy that it is so. Several years ago Mr. Langstroth (who may be called most appropriately "the grand old man," for like all great men, he died not with death) honored us, as he did on several occasions, with a good long visit. He told me that he wished some one to rewrite his book, and askt me to suggest some one to do the work. I told him that I did not believe that he could do better than to get the Dadants to do it. He followed my advice, and I am sure that neither he nor any other bee-keeper is sorry for the decision.

It is excellently well done. A·B·C of Bee-Culture is also a splendid work of which we may all feel very proud. I have just given it a very thoro reading, and I feel like congratulating the authors and all apiarists the world over for the splendid treatise.

The third work that I have reviewed is that of Thos. W. Cowan. I am likewise very pleased with Mr. Cowan's work, and do not wonder that it is regarded as the most authorita-

tive work of Europe. I think it is remarkably reliable as it is fair and honest. The scientific part is especially able, full and correct. I think all our American bee-keepers, who feel able to do so, would profit by a careful reading of Mr. Cowan's excellent work.

In reading these works it has been suggested to me that an article on swarming might well be written. I find several points with which my experience does not tally. I write the article in no dogmatic spirit, and shall be glad to have the points I make criticised by any one who thinks they deserve criticism.

WHY DO BEES SWARM ?

I think without doubt bees are incited to swarm because of something disturbing their peace. This is most commonly a crowded condition of the hive just at the dawn of the honey harvest. The combs are full of brood, the hive filled with bees, and the bees feel uncomfortably crowded and thus are impelled to divide up or swarm. That this is not the only cause is certain. Bees often swarm when they are not crowded at all. I think the most common cause, other than crowded condition of the hive, is from lack of honey. I have often known starvation to cause bees to swarm out and push for a new home. Here it would seem that they could not improve their condition by swarming, and we must conclude that a disturbed state impels them to act. An untidy condition of the hive also drives bees out, or causes them to swarm. Nearly all bee-keepers in the Northeastern part of the United States have not infrequently had early spring swarms after a cold, disastrous winter. With spring came serious dysentery, and bees, queen and all rusht forth for a new home. While this does not seem so unreasoning as the last, the final result could not be greatly different.

When bees swarm naturally, that is, because of an overcrowded condition of the hive, nearly all the bees that are mature enough to fly, including drones and queen, push out from the hive in the event of swarming. It is not true, however, that the queen leads the swarm, as has often been stated. As early as 1870, I commenced the practice of clipping the queen's wings, and would advise all bee-keepers to do so to-day. Thus I have many times watcht the swarm as it issued from the hive, and likewise noticed the egress of the queen.

I find the queen rarely goes out until the last of the swarming out of the bees. Again, it is often stated that in case the queen does not join the bees in their swarming, either because she cannot or will not; then the bees do not cluster, but return to the hive. The last part of this statement, I think, is invariably true, that the bees will not go off without the queen, but will always return to the hive. It is not true, however, that they will not generally cluster. In my experience they will almost always cluster, I think, indeed, almost as often as the queen goes with them. For I have known, very rarely, however, the bees to go forth with the queen and yet return to the hive without clustering at all.

The time of swarming is generally from eleven to two, or near the midday period; yet I have known the time to vary not a little from this. I have known swarms to come forth at five or six in the afternoon. The late Mr. Moon once told me that he once knew a colony to swarm at the time of full moon, in the moonlight. This erratic swarming as to time, I think is almost always limited to after-swarms, where a young queen goes out with the bees.

The place of clustering is a matter of some interest. A tree or bush seems to be preferred, probably because it is convenient for the bees to cluster on them. I have known a post or fence to serve them in such way. The hight, too,

at which the cluster is formed is a matter of interest. It is usual for the first swarm with the old queen to cluster low; while after-swarms, which of course are attended by young queens, may cluster far up in tall trees. I believe I have known clusters as high as 30 feet, in tall trees.

Why do bees cluster at all? is often askt. We must remember that the old queen may not have tried her wings in flight for over a year. That she is able to use her wing-muscles at all is hard to understand. I believe that the clustering is to give her a rest after her first exercise as she flies out, before she takes her long journey perhaps of one or two miles. It has been reported that bees sometimes do swarm and not cluster at all. I have known one case of this kind, myself. It was an after-swarm, and, of course, a young queen went with the swarm.

When do the bees select their new home? is a question of interest. It has been suggested that the bees cluster so that scouts may go forth in search of a new home. I have had positive evidence on several occasions that scouts go forth one, two, or three days before, to look out and, clean out their prospective home. Once it was in the side of a house. The bees were noticed just before the dinner hour, busily going in and out high up by the cornice. It was supposed a colony had entered and taken possession. After dinner, we were surprised to find that the bees had all gone. We supposed that they had found their new home obnoxious. The next day a large swarm came and took possession of the place. I have since known a number of such cases. I have little doubt but that this is always true, and that the bees cluster simply to rest the queen.

The rate of flight of the swarm is very various. I once knew a swarm to fly nearly a mile, and one of my students followed it on foot the whole distance and located its new home. I have known other cases where one would need to be well mounted to keep up with a colony. After-swarms fly with more speed.

We all know that there may be many queen-cells in the old hive when a colony goes forth. I think that a first swarm rarely if ever issues until one of these cells is captured. Some bees, especially the Carniolans, form an excessive number of such cells. We know that often all these queen-cells are destroyed after the queen emerges from the first one. In case of such destruction the cells are always cut open on the sides. If, on the other hand, the queen liberates herself and comes out to fly forth, the cell is open at the end. In case several swarms are to issue—I have known five swarms to come out one after another from a single colony—the bees guard the queen-cells so that the first hatcht queen cannot destroy the others. As many bee-keepers have observed, rarely several queens go forth with a new swarm. Some of our ablest bee-keepers think that, in such case, the queens have been held for some time in the cells, and in the excitement of swarming, the guards have lost their vigilance, and so several queens rush out with the new swarm. Much more rarely two queens will dwell together in a colony, for a time, both laying eggs.

This article is quite long enough; but I wish to give a few rules which I think every bee-keeper will do well to observe. I believe under ordinary circumstances that we would better be content with but one swarm per colony, each year.

I believe, too, that it is better always to clip the wings of all the queens, as this saves labor, and very likely may save loss, as no swarm will ever go off without a queen.

If, then, we wish only one swarm per colony, it is well worth while to study the most convenient method to limit swarming. I believe by far the best method is the so-called Heddon method.

Los Angeles Co., Calif.

Queen-Rearing—Some Things to Remember.

BY G. M. DOOLITTLE.

IT was with more than usual interest I read what was said by Dr. Miller and the editor, on page 409, regarding "Those Premium Dr. Miller Queens," for I have past thru all those experiences myself, and, like Dr. Miller, can truly say, "The chief culprit in the matter [queen-rearing] is that all-prevailing, all-pervading individual, the *weather*." Yes, the weather has all to do with queen-rearing, and the weather has been unusually bad all this season so far here in central New York. But while this has been so, yet *all* should understand, as do Dr. Miller and myself, that not much headway can be made rearing queens north of latitude 42 degrees before about June 1st. Knowing this, is why I keep standing in my advertisement all the time, "Queens in their *season*." By that word "season" is meant the season of central New York; yet many seem to think that Dr. Miller, and other queen-breeders here at the North, can "grind out" queens at pleasure during April and May, no matter whether we have frozen ground, snow or frosts.

And when we tell them they will have to wait, a few are unkind enough to write in "a most discourteous manner," as Editor York tells us about. Others write jokingly, or more often otherwise, if they can not come in just a little ahead of some one else, on account of a queenless colony, or something of the kind, and use such nice words, and express such a kind spirit, that one is almost persuaded to do as they request, to please them.

Dr. Miller well says, "Those sending in last are likely to be among those expecting queens first. It should be remembered, however, that *time* is an essential factor in the rearing of queens, and when there is a large list those that come at the last end should expect their queens in September rather than in June." Dr. Miller seems to have an adaptability to "catching on" in a short time to what it takes other persons years to find out. This is his first season, I believe, at queen-rearing as a business. However that may be, there is an item connected with this matter which he has not touched upon, and one which is very important with those who have been in the business for years; also one which has a very important bearing regarding early orders. That item is, orders carried over from the previous season, and those which accumulate during the winter and spring months, these very often amounting to as many as can be turned off before the first to middle of July. Of course, the ones carried over must come first, then those received during November, December, January, February, March, April and May, in their order. And so it often comes about that an order received on the first of June for a select tested queen can not possibly be filled much before August. That factor—time—plays an especial part in queens of this class.

Let us look at the matter for a moment so as to save hard feelings all around. Suppose we start the cells for those queens on the first day of June; 11 to 12 days in the cell form is the rule, so we count the latter; 10 days from emerging from the cell to laying; 21 days from the time of laying until the first worker-bee emerges from its cell, and five days is short enough time in which to make the selection. Thus, we have 48 days later as the time to send out the first queen of this class, or the 18th day of July. Yet many seem to think such queens can be sent out promptly to meet an order coming in May, say nothing about orders being filled in rotation.

I have written on this matter so that those purchasing queens may use a little more patience and charity toward the nearly "swampy-with-orders" queen-breeder, who is doing his level best to get queens *of the best grade* out as fast as possible to please his customers.

Naturally-Built Comb vs. Comb Foundation.

BY S. A. DEACON.

(Continued from page 516.)

OF course, I fully expect to be told that my arguments are only of the specious kind, and that we are all very well aware that the term "drawing out the foundation" is merely a *facon de parler*, and is not intended to convey the meaning that the bees elongate or extend the side-walls by stretching them. But I don't know so much about that, and believe that seven bee-keepers out of ten are misled by the expression into the belief that the bees have only to, and *do* only, stretch the side-walls out; it disguises from them the real truth, viz.: that the "thinning out" is a laborious and time-consuming process, and during which the scales of wax which the bees are all the time secreting, fall unused to the ground, and thus causing many to overestimate the value of foundation to the bee-keeper.

I hereby repeat—Mr. Dadant's objection to the expression notwithstanding—that it is "ridiculous nonsense" for any maker of foundation to claim an advantage for that having such heavy side-walls as necessitates no addition from the bees in order to complete the comb; for the heavier the side-walls the more costly the foundation (buying wax at 50 cents worth only 25!), and the more labor for the bees to break down and "remodel," while, all the time, the wax they are secreting is being wasted!

Mr. Dadant, by-the-by, says, *in effect*, that it is as natural for the bees to secrete wax in a flow as it is for fed stock to lay on fat. This (tho not stated in those exact terms, yet distinctly implied) is equivalent to an admission that while engaged in breaking down and remodeling the foundation, the bees *are* secreting (and *wasting*) their own wax. Here Mr. Dadant is at one with Mr. Simmins, tho he won't admit it in as many words. But he is at variance, I see, with Mr. E. T. Abbott, who says that "foundation saves the time of the bees in secreting wax." Is Mr. Abbott quite sure that while the bees are "remodeling" the foundation they are *not* at the same time secreting wax? Has he, in accordance with Mr. Dadant's advice to myself, experimented before writing? Mr. Simmins *has* experimented; he is a notably careful and observant experimenter; and he asserts, or at least with much reason assumes, that the bees during a flow are secreting wax all the time, and are prepared to give it to us free gratis, for nothing. But no, we prefer furnishing them with foundation at 50 cents per pound and allowing them to drop their own wax on the floor-board, or outside, thus adding the market value of the honey consumed by the bees in making this lost wax (say 40 cents) to the cost of every pound of embossed wax we so extravagantly purchase for them! There is more in this matter of naturally built comb *vs.* foundation than at first sight appears; and it would be interesting to know the result of experiments made at Lapeer, Mich., along this line.

Mr. Dadant says, or implies, that only by the use of foundation can we hope to secure straight combs. Now, this means using full sheets, and for the practical honey-producer the times won't run to it. Personally, I find I get perfectly straight combs built from starters, built, too, on wired frames, and it is very seldom that the bees do not include the wires right in the septum; and even tho they should be now and then a trifle out, and not exactly "as level as a board," what does it matter? They are good enough for all practical purposes, and times are too hard to humor the eye at the cost of the pocket.

On page 719 (1897) we find Rev. Mahin and Mr. J. E. Pond both favoring full sheets in sections in order, as they say, to secure straight combs. But Mr. Secor very sensibly remarks, on the same page, that straight combs are not so much the result of using full sheets as of using separa-

tors. The only "practical" man of the three I consider to be Mr. Secor. It is surely better economy to buy separators once than full sheets every year. I don't think Mr. Dadant will deny that the late Mr. Allen Pringle was a "practical American bee-keeper," and he included the use of full sheets in his list of the mistakes we make; tho opposed to him in this particular was that other "practical American bee-keeper," the late Mr. B. Taylor, who favored the use of full sheets. So you see, Mr. Dadant, that practicalness has nothing whatever to do with it, for we see the most practical men differing greatly in opinion concerning many matters connected with the conduct of our pursuit.

Mr. Dadant advances, as evidence of value, the "enormous sale" of foundation. Yes, it may be *relatively* enormous, but I doubt if it is really so enormous as compared with the enormous number of apiaries in Canada and the United States. This number is being largely augmented every year, and the new hands, the novices, no doubt use a vast deal more than they really need to, even as they take care to supply themselves with every fad and useless article so enticingly brought to their notice via the supply dealers' illustrated catalogs; but I very much doubt if the old, settled, practical bee-keepers use it to anything like the extent which they formerly did, and that they sell considerably more wax than they buy.

In speaking of the enormous sale of foundation, Mr. Dadant assures us that "the American bee-keepers do not foolishly throw their money away." A man need not necessarily be foolish, and yet be induced to invest immense sums which bring him in no proportionate return; and tho not foolish in most things, some men like a long time to benefit by experience. The same class of men who buy to-day unnecessarily large quantities of foundation—because most of the bee-books gammon them that "they can not use it too freely" (right enough, perhaps, for those who keep a dozen or so colonies for recreation)—have, in the past, spent millions of dollars on the once greatly extolled "Golden Beauties," patent double brood-chamber hives, and on endless appliances and contrivances now obsolete, without which, they were at one time under the impression, they could not profitably carry on their pursuit. The wheel is always agoing round; that which is a-top to-day is at the bottom to-morrow.

Several years ago the American Bee Journal was chock-full of advertisements belauding the virtues of the aforementioned "Golden Beauties." Their sale must have been "enormous." Are they wanted to-day? Undoubtedly not, seeing they are no longer advertised; so that "enormous sales" are by no means always a criterion of an article's actual and permanent worth.

According to Mr. Dadant's dictum, American bee-keepers never waste their money on things they can do without, *i. e.*, they "never foolishly throw their money away," these Golden Beauties must be all that was claimed for them, and the demand for them ought to be as brisk to-day as ever; but as it is not, Mr. Dadant must excuse me for opining that American bee-keepers can no more claim freedom from the charge of occasionally foolishly throwing away their money than can any other class of people; we are all liable to be misled, no matter what our nationality or calling.

However, the wheel has turned, and these "Golden Beauties" are now at the bottom, along with the quilts, which every one is now discarding as a big nuisance and utterly useless, and yet of which it would have been rank heresy to say, several years ago, that we could have done without them. The "enormous sale" which enameled cloth had, when quilts were in vogue, did not prove their necessity for all time, any more than will the present enor-

mous sale of foundation go to prove it as indispensable a necessity as many imagine.

Yes, the wheel turns slowly, indicating gradually formed changes of opinions, and awakening us to the necessity of accepting new contrivances and discarding some old ones; and while it was bringing up the drawn super foundation on the one side who will say it is not carrying down into desuetude, or consigning to limbo, the use, or at least, the too lavish use, of ordinary brood foundation on the other—carrying up to us the conviction that, with low prices for our product, foundation is by no means so indispensable as we have hitherto somewhat apathetically allowed ourselves to believe it to be, and that it is a wasteful luxury in which we have been indulging more in the past than we can any longer afford to do?

I have been harping a good deal on the phrase "practical American bee-keepers." Ere this is in print some months will have elapsed since Mr. Dadant was commissioned by you, Mr. Editor, to contest my statement that the worth to the honey-producer of foundation is somewhat overestimated, and the majority of your readers will by that time probably have lost recollection of the discussion's details. I will, therefore, recall one remark of Mr. Dadant, viz.: that "the average American is about as practical a man as can be found on the face of the earth." This was supplementary to his claim for the economic value of foundation on the score that "the American bee-keeper" who purchases enormous quantities of it "does not foolishly throw his money away." Altho the expression does not verbally claim for the American a greater measure of practicalness than for the members of any other nationality, it nevertheless implies that, for practicalness, the citizen of every other country may take a back seat. Now, as a cosmopolitan, whose life has been spent in many climes, and among many peoples, including England, Germany, France, Australia, India and the Cape, I have had ample opportunity of convincing myself of the correctness of Paddy's assertion, that "One man's as good as another, if not, indeed, much better."

I should be very loath to say anything that might be calculated to give the very leastest offense to Americans, or, for the matter of that, to any other man, for I like to get along pleasantly with every one; moreover, many of my nearest and dearest relations are citizens of the Great Union, whose institutions and people I greatly admire; but I can not help telling Mr. Dadant that I have frequently heard in connection with our pursuit, such remarks as the following, viz.:

"Those Yankees, with all their claim for cuteness and smartness, do take an amazingly long time to realize the value or the uselessness of a thing or to know when they are on the right or on the wrong track. They are slow in adopting a really good thing, and equally so in discarding a useless one, and seem to get taken in about as easily and as often as the denizens of most other lands."

"Yes," says another, "to read the American Bee Journal one would think that the bee-escapes were quite a new invention. There seems still to be a great difference of opinion as to their merits, or as to whether they have any at all; yet Simmins says they were used and discarded in England, under the name of 'super clearer,' 20 years or more ago. There are positively some leaders in the industry, too, men who used to answer the Question-Box queries, who have not yet been able to convince themselves that separators are necessary for the production of first-class comb honey." "And here's Ernest Root," says a third, reading from *Gleanings in Bee-Culture*, "who made a great fuss and hubbub over his fancied new notion of end-staples in the top-bar, and yet I see here are two Johnnies

who rise up and say they've been using 'em any time for the last 10 years! They do move terribly slow, do those 'smart Yanks;' but once earn the name of being an early riser, you know, and you may sleep till mid-day."

"Yes," says another, "Ernest Root is getting, I see, to be quite an inventive genius in his way; and he has found out at last, and is cackling over his discovery like a hen that has just laid its first egg—that narrow sections, used with cleated separators, need no openings or scallops—the way Jimmy Topham has been using 'em for years, by planing down his 2-inch sections, you know (the only size you can get from those wretched English supply men). It is a mystery to me that the plan was not long ago conceived and adopted by that smart, practical bee-keeper, Mr. B. Taylor, who first gave us the idea of the cleated separator."

"Again," chips in another, "look at their score or two of complicated, fussy, bee-irritating feeding-devices—especially Golden's; and compare any one of them with your own simple device, Mr. Deacon, of the drawer under the flight-board, why—." But I didn't hear any more, for modesty compelled me to leave the room. Anyhow, I don't think that the average American is one jot more practical than is the average Englishman, or the average German, or the average Frenchman. Nor, I am sure, will any intelligent American put forth such a boastful claim. There are practical and non-practical, wise and foolish, good and bad, pretty and ugly, nice and nasty, men and women among all nations.

I hope I have given no offense; if I thought I should be doing so I would rather have left the above sentences in the ink-pot. And, now, as the said ink-pot is about dried up, I must perforce dry up, too, and conclude with the opinion that the time is near at hand when economic management will open bee-keepers' eyes, first, to the necessity, and, secondly, to the positive advantage, of using very much less foundation than they at present use. South Africa.

Care of Honey—Seasonable Suggestions.

BY MORLEY PETTIT.

EVERY one aims, or should aim, at excellence in whatever he or she undertakes. The adage, "There is always room at the top," is true in every trade and profession. To this rule apiculture is no exception, and those devoted to the production of honey will excel by supplying the very best comb and extracted on the market. Extracted honey is judged by color, flavor, and specific gravity, or "thickness." In saying "color," we might say *lack of color or transparency*. This may be maintained by carefully excluding all darker varieties from the white. The other two qualities are secured by leaving it with the bees as long as possible or convenient. Some of our best men do not extract until the close of the honey-flow. By this, however, basswood and clover are not separated, and in opening hives after the close of the honey-flow, there is danger to the inexperienced of robbing.

As soon as possible after extracting put up the honey in the packages in which it is to be sold, leaving it exposed to the air as little as possible. Not that it will "work" or spoil, but it has great affinity for water, and the exposed surface soon becomes quite thin from contact with atmospheric moisture. Then, if left in a deep tin, holding, say 400 or 500 pounds, the thicker portions sink and the thinner rise until it becomes graded from very thick at the bottom to quite thin on top, and is difficult to secure a uniform sample without a great deal of stirring. Stirring, again, hastens candying, and candied honey, altogether quite as good as, and by many preferred to, the liquid article, will not pour, and is much more difficult to dip into vessels for sale.

There is even yet some doubt among the uninitiated about the question of candied honey, many regarding it with suspicion. Impress upon all buyers the fact that candying, or becoming white and solid similar to lard, in cool or changeable weather, is a proof of purity, altho in rare cases the best extracted honey, in its natural state,

does not candy even under these conditions. To reliquify, set the can on wooden blocks in water over a slow fire. Remember that honey that has been slightly overheated has a burnt taste, is darkened in color, and will not candy again. On the other hand, if the granules are not all melted it candies again very soon. This suggests a point, in the case of extracting-combs, bearing on the subject. Before they are stored for winter have them thoroly cleaned by the bees, so there may be no adhering honey to granulate and set the next season's honey candying early.

For the very reason that all honey becomes hard in cold weather, the best package for retailing is one having a wide, open top, to allow the honey to be dug out, and that may be heated in water if it is to be liquefied. Glass makes a very attractive package, as it shows up the transparency of the contents to good advantage. Altho not quite the handsomest shapes, fruit sealers are the best sellers, as every housekeeper has use for them when empty. Less expensive and more convenient vessels are tin pails of 3-pound, 5-pound, and 10-pound capacity. They may be secured with slip covers for the home market, or self-sealing covers for shipment. The most popular package for shipping large quantities is the 60-pound tin, crated singly. It is about the right weight for one man to handle, and being square, does not waste space. Have a supply of labels which are distinctly your own, and not like those of everybody else, and put them like a trade-mark on every package of first-class honey. Do not injure your reputation by selling dark honey with your label on it, for many will not understand that it is not your best.

With comb honey, carefully scrape all wax or stain from the sections, leaving the wood smooth and white. Grade the sections into two or three classes, according to whiteness of capping and honey, and extent to which the sections are filled and capt. Do not spoil the market with poorly-filled or uncapt sections, but extract them and give to the bees next season. They will be filled much more quickly than sections containing foundation. Very neat and attractive show-cases of whitewood with glass front may be obtained from dealers in bee-keepers' supplies.

Now, as to the best way of disposing of honey, I would say do not be in a hurry to sell at a low figure. Stimulate the home market in every way. Supply your grocers and get them to work up a good trade among their customers. Many never buy honey because it is not brought before their notice. Invite any friends who call to sample your honey, and get them to bring their neighbors and buy. After you have sold all you can at home, sell to those whose business it is to find larger markets elsewhere.—Farmer's Advocate (Canada).

Relationship of Bee-Life to Agriculture.

BY F. GREINER.

I WILL give in the following a synopsis of an address delivered before the Australasian Association for the Advancement of Science, by Prof. Albert Gale, on the subject of "Color of Flowers, and Its Influence on Bee-Life." As far as practical and advisable I will give the Professor's own words. Some things may not be new to the readers, but it will help to show them the state of affairs over there:

"As I proceed I think I shall be able to show that bee-life and blossoms are so closely associated that, to interfere injuriously with either will at the same time injure both. Animal life can not exist without the vegetable kingdom. Some forms of vegetable life *can* exist without the presence or animal life, but others would cease to exist without the presence of some forms of insect life. Nearly all insects aid more or less in fertilizing the vegetable kingdom.

"Pollen is the fertilizing and vitalizing agent in reproducing all classes of vegetables. It is produced in abundance by all flowering plants, both by those of conspicuous and inconspicuous blossoms. *As a rule, inconspicuous flowers are wind-lovers, and those of more gaudy tints are insect-lovers.* It may not be generally understood that there are male and female elements in the vegetable organism just as in the animal organism. Agriculturists and those engaged in vegetable culture do not as a rule know that plants are reproduced on precisely similar lines as animals. Not one out of a thousand has sufficient knowledge of his occupation to understand that there exists a sexuality in plants, and that fertilization is as necessary

in plants as in animals. The one great aim of all vegetable and animal life is to reproduce its species. Both sexes in all the higher orders of animal life possess locomotive powers to enable them to come together for procreative purposes. Locomotive powers in plant-life are very rare.

"The higher orders of animals are uni-sexual; occasionally there are malformations termed hermaphrodites; but in the plant world the higher orders are uni-sexual, bi-sexual, or hermaphrodites—uni-sexual when the male and female organs are on separate plants; bi-sexual when male and female organs are in separate flowers, but on the same plant; hermaphrodite when the procreative organs are both on the same blossom. Yet, nevertheless, *no true flower is hermaphrodite*. To make it clearer, the réceptive and distributive organs do not mature at one and the same time in the same flower. From this it will be seen how utterly impossible it is in the great majority of cases for the anther to fertilize its associated stigma.

"In nearly every case the pollen of insect-loving plants is not dry and powdery, as in the case of wind-loving flowers, but is heavy and adhesive. Its adhesive nature prevents it from being blown about by winds, and it becomes necessary for an outside agent to transmit it from the male to the female organs."

Now comes the question, Are bees attracted to blossoms by their color? and are certain bright colors—red, blue, purple, etc., more attractive to them than paler tints, such as white-yellow? This my experience most certainly contradicts, altho it has so been stated by high authority. I quote from Sir John Lubbock's work on "Bees, Ants, and Wasps:—"

"I brought a bee to some honey which I placed on blue paper, and about three feet from it I placed a similar quantity of honey on orange paper."

Why he needed to place a similar quantity I can not tell; and why he should have *brought* a bee instead of allowing one to find it, is a problem I can not solve.

"The question now is, 'Was the bee attracted by the color of the paper or by the honey?' Last summer in my garden I had a scarlet dahlia in bloom. When it first flowered there was not a stamen present. No bees ever visited it" [to the Professor's knowledge]. "The plant was afterward neglected by me, and this neglect caused the stamens to appear and the pollen to mature. With this change in the flower it soon became a foraging-ground for the bees. Why did they not visit the early blooms? Because there was no bee-food present. Why did they visit it after the stamens appeared? The flowers were not nearly so conspicuous as the earlier bloom. But in passing over they saw there was a reward for their labor. Early last spring the white arum lily was in bloom, and its white pollen was eagerly sought for by the bees. At the same time the broad beans were in full flower. These, too, were an attractive foraging-ground for the same insects. A little later the peach-tree burst into flower, with the result that the first named was entirely forsaken, and the latter receiving only an occasional visit. Did the bees go to the peach-blossoms on account of their attractive colors? Not a bit of it. While the peach-trees were in flower the willows were just showing their catkins. During the bloom of peach and willow my bees were bringing pollen of the two colors only—creamy-white and orange tint. At the same time were roses, marigolds, arum lilies, and other attractive flowers in bloom, but few bees visited them. The pollen was coming from the peach and the willows. The catkins of the willows are so inconspicuous that a large number of people are ignorant of the fact that they are blossoms; yet they were as attractive to the bees as the gaudy peach.

"During the same spring I visited the botanical gardens. There were then beds of English daisies, pansies, anemones, and the turban ranunculus, in full bloom. Nothing in the garden was more showy than the two latter, yet not a bee visited them. Near these was a shrub (*Buxus sempervirens*) in which there was a constant hum of bees. What was the cause? Hidden among the dark-green foliage were hundreds of small greenish flowers supplying abundance of food. If color had been the attractive agent, bees would never have discovered their food in the shrub, but would have sought the showy beds of anemones, etc., in vain; they were double, and therefore there was no bee-food. A short time afterward I saw the bougainvilleas aglow with their showy bracts. They could be seen hun-

dreds of yards away. At the same time the pittosporums were in flower, which were most inconspicuous. In the former there were no bees to be seen, notwithstanding their fiery glow, whilst in the latter there was a sound as tho a swarm of bees had taken possession of it. Watch a large bed of poppies of mixt colors. No one color is neglected by the bees. Poppies are great pollen-producers."

* * * * *

"Darwin tells us that it took ages on the other side of the world for flowers to develop, and the bees centuries to adapt themselves to the flowers. The chief honey-yielding plants of this continent are the encalyptus, pittosporum, and tea-tree families. All these bear whitish flowers. Our introduced fruit-trees and ornamental flowering plants bear brightly colored blooms. In springtime our introduced fruit-trees are conspicuous by the multiplicity of their flowers, and our little native bees as readily find the nectar in them as our introduced bees, and they can not have had ages of experience to guide them. And does it not seem very strange that our hive-bees, upon their introduction here, should have forsaken the bright-colored flowers of the old land that were introduced here at the same time they were? The hive-bee, on its arrival here, after having been educated to the high standard it is said to have attained in the Old World, works upon, not our introduced flowers, red, blue, purple, so much as upon our simple white and yellow ones, so unlike what they ought to have done according to the education they received at our antipodes. Is it not queer that our bees should have gone back in their tastes for color when they crost over the equatorial line and came to this side of the world?"

With due impartiality I have in the foregoing now made the reader acquainted with the essentials of Prof. Gale's observations and conclusions. I can not deny myself the privilege of making some comments, and also to post the reader on what others have done in a similar line, so he may be in a position to judge for himself. Of course, we are agreed that the honey-bee plays a very important part in agriculture, and I am glad the Professor holds this view. In regard to the question, "Are certain colors more sympathetic to bees?" opinions differ. All the observations Prof. G. cites fail to prove that color does not attract bees. He seems to labor under the impression that others had so misconceived the nature of our industrious little friends as to think they would ever stand around admiring the beauty of the flowers. I can assure the Professor we *all* have a better conception of the business qualification of our bee. We are well satisfied they do not visit ever so gaudy flowers if those flowers have nothing to offer. To find out whether a certain color is more attractive to the bee than another we must allow the bee to choose between the colors, *and we must adjust all other conditions so as to be exactly alike*. If one blossom, inconspicuous as it may be, hides in the depths of its corolla delicious nectar, that blossom will be visited by the bees. A highly colored flower, but yielding neither pollen nor honey, will receive no attention from bees. What reasonable person would expect anything else?

The bee has two sets of eyes, one set calculated for long range, the other for short distance. It can, therefore, see. Its antennæ are excellent olfactory organs, and it can probably scent nectar in flowers for a longer or shorter distance. I judge that it does not require much time for a bee to ascertain whether a blossom, even a strange flower, is worth visiting or not.

Dr. Herm. Muller, of Germany, conducted a long series of experiments some 15 years ago, which seem to show that gaudy colors are not preferred by the bee. Light-yellow, white, light-blue, violet, purple, bright-yellow, fiery red—that seems to be the order of their choice. Dr. M. took different colored plates upon which he placed food, and then he noted the behavior of the bees, spending a great deal of time. Generally but two colors were submitted to choose from. The result was as stated.

An observation he made, which is not exactly in line

with our subject, "Influence of color," etc., I will make mention of here, as it is very interesting:

Watching a single bee he found it would get its fill of honey in 2½ minutes. In 3½ minutes it had made the home trip, had unloaded and returned. On the whole, it made 70 trips in seven hours. All bees observed were marked with oil color on the thorax; every other bee a different color. Thus he was enabled to distinguish between the different bees, and to note their individual behavior to the colors and otherwise. The different bees behaved differently in many ways. Finally an average was taken. In this way the conclusions arrived at had some foundation. It would have led too far to give these experiments in detail, and for that reason I have only briefly mentioned them. It will seem to me they prove more than Prof. Gale's observations.

Color exercises a pleasurable observation upon the human eye, and why not upon the eye of the bee? Prof. G. says, in the beginning of his address, "As a rule, inconspicuous flowers are wind-lovers, and those of gaudy tints are insect-lovers." It would be reasonable to suppose that the color was given these latter flowers so as to attract the bees and insects. Of course, that does not yet prove that one color may have more attraction than another. I leave the reader to draw his conclusion.—Gleanings in Bee-Culture. Ontario Co., N. Y.

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Richards, Ohio.

IMPORTANCE OF AN EARLY FORCE OF FIELD-BEES.

Naturally I feel interested in the further report of B. J. Chrysostom, page 412. The teaching seems to be that a tremendous force of field-bees in a colony will get surplus any time of year when the weather is good. Many of us failed to find this out—perhaps mainly because we never had that force of field-bees except in what we called "the season."

HIVING SWARMS ON FULL COMBS OF HONEY.

F. Greiner (page 414) speaks of hiving a swarm on solid combs of honey as if it were good practice. Without positive knowledge as to how it would work, I nevertheless should consider it quite risky, especially in a heavy honey-flow. A swarm wants elbow-room, and a chance to build lots of comb, and rear lots of young brood, all of which would be cut off by solid combs of honey. It is also unsafe to have a swarm on any honey at all in *famine times*. Put in the honey at nightfall, and then they have time before morn to get over the disposition to fill up and "light out" immediately.

CARE IN HAVING OTHER ANIMALS AROUND BEES.

L. G. Blair, page 430, gives us one of the most instructive talks we have ever had about bees stinging animals. It's rather singular how many people incline to drive right into the midst of swarming bees. A little of the John Bullish assertion of "my rights," I fear. If so, the punishment looks rather over-sized for the crime. It doesn't always pay to claim all our rights—either from bees or Boers. That was a curious circumstance that the tips of the horses' ears came off. Probably stings were very numerous on the ears.

Don't tie an animal and go off and leave it anywhere near bees. Bees come in reach, animal snuffs and thrashes at it. Bee gets dander up, dashes back to the hive, and with excited noise and tearing around induces two or three more to follow it in an attack on the beast. All divide their time between the beast and the hive—worrying the beast awhile and drumming for recruits awhile. Naturally after the first few dozen have enlisted, the thing grows with

startling rapidity—until nearly every idle old bee about the hive is out and singing, "Hurrah for the sound of a cannon!" Were the beast loose it would generally stop this cumulative process at an early stage by running away. Comparatively few, even of bee-men, seem to comprehend just *how* bees get into a distant scurrage in such great numbers. I specially commend the above to their attention, hoping it may lead to more care in hitching horses.

YELLOW SWEET CLOVER.

Yellow sweet clover—what a pity it didn't come before the white instead of afterward! The public will now say, All sweet clover coons look alike to us. I am not familiar with the yellow variety, but my idea is that, on account of its smaller size, it does not block up territory so nobody can pass. I judge also from what I hear that it is less self-assertive in forcing itself in (except perhaps in wet soils), and that is an improvement, from the public's point of view. That it is four weeks earlier than the white variety, and quits off before the season is over, are points I had not in mind previously. Likely both kinds are more or less progressive in adapting themselves to locations. This year I find the white kind more troublesome as a weed in the garden than heretofore. Page 417.

THOSE ARTICLES ON ROBBING.

Mr. Doolittle's robbing article, page 418, may profitably be read after Mr. Davenport's on page 405, and between the two the reader will get things about right—and be cured of any incipient itch to go and scatter coals over his straw-stack, which he may have contracted from the former article.

DUMMY SWARM-CATCHERS.
