AMERICAN
 ESTABLISHED IN 1861 OLDEST BEE-PAPER IN AMERICA
BEE JOURNAL.
 DEVOTED EXCLUSIVELY TO THE INTERESTS OF HONEY-PRODUCERS.

40th YEAR.

CHICAGO, ILL., JANUARY 4, 1900.

No. 1.

CONTRIBUTED ARTICLES

A Lovely Apiary in Kankakee Co., Ill.

BY WM. M. WHITNEY.

I MAIL you photographs of my bee-yard, but beg to be excused from giving my experience as a bee-keeper at this time. I'll admit that it would be amusing reading-matter, were it possible for me to give an unbiased, unvarnished account of all my operations in the few years I've been studying the honey-bee.

You see, it would set the whole fraternity to laughing

at me, especially the veterans, and it is so near cold weather we are likely to have a sudden freeze-up, and if any of them were caught in the freeze, no one can tell what the consequences might be; and I do not court being defendant in a suit for damages for personal injury; therefore, I will simply explain in as few words as I can, the yard and surroundings.

In viewing the first picture we are looking nearly north-west, consequently the yard fronts southeast, and the rows of hives and the alleys of course run in the same direction.

The hives are placed diagonally in the rows, and in each pair of rows the hives in one front east and in the other south, making every alternate alley entirely free from bees as a passage-way, and from which the hives can be manipulated without the least annoyance. The rows are seven feet from center to center, and the hives four feet from center to center in the row. The hives are so placed that a line drawn along the rear of the first one will touch the front of that immediately behind it; making it very easy

"Golden-Band Apiary" of Mr. Wm. M. Whitney, of Kankakee Co., Ill.

for the operator to occupy the space at the rear of one hive, and have ample opportunity to examine the front of any other.

There is one wide alley crosswise thru the center to facilitate operations, and, if the apiary were a large one, I would think others at convenient distances advisable.

The hives are placed on stands fully four inches high, but if the ground were liable to become very damp, and to remain so any considerable time, I should recommend at least six inches elevation.

The shrubbery seen in front is currant bushes, and between them and the hives is a portion of a strawberry-patch, which, because of the proximity to the little clump of elms, has become of little or no value. The yard is kept well mowed with a lawn-mower, like the lawn shown in the distance. The shadow of the foliage of a half-dozen little elms sweeps around over the yard by the movement of the sun, so that all get the benefit of it; thus none of the hives are in the sunshine, nor in the shade, all of the time.

You will notice the hive that is open in the second picture is made of 3/4-inch stuff. There are but few such, and they were made by myself in an emergency. I do not recommend them. The balance are of thin stuff, and are as easily handled as any hive I've ever had, or know of.

You will notice a sled standing against a tree. This is of the same height as the stand, and when I wish to move a hive the sled is backed up to the rear, the hive easily pulled on to it, and is hauled away. I prefer the sled to any other method of hauling, as it moves over the uneven ground with less liability to jostle or jar the hive.

You will also notice in the same picture a frame of bees being held for a "time photograph." No veil, no smoke (but smoker ready if needed); bees literally covering both sides of the frame, and running all over my hands—one, you will notice, stopt long enough to have her photograph taken—and all this is done when my suit from head to foot was black, excepting the hat. (The word "black" is italicized for the benefit of those who say bees cannot be handled by persons dressed in such a suit.)

Now, on looking over my description I believe it could have been told in half the words had I taken time and had done a little thinking. "Aye, there's the rub!" How few do any real, hard thinking.

I have tried various plans for arranging hives for convenience, but I like this best for all practical purposes. I do not think I've lost a single queen by its returning to the wrong hive.

Kankakee Co., Ill.

Characteristics of a Successful Bee-Keeper.

BY C. P. DADANT.

BEE-KEEPING is a business that requires the greatest amount of attention to small details or minutiae to carry it on successfully. The good bee-keeper is generally more or less cranky, but he is most extraordinarily so on the attention he pays to his bees, in the very smallest particulars. Everything must be arranged methodically (en papier de musique), and it is only the man who is thus particular who may be depended upon for as great success with bees as can possibly be achieved in the locality where he lives.

In every season, at every turn, the apiarist is confronted with the need of attention to details. In early spring he is to notice the signs of approaching starvation in occasional colonies. By their behavior at the entrance he will recognize the queenless colonies, and it is another detail to furnish them with necessary larvæ to enable them to rear a queen again. The success and prolificness of this queen depend upon the prolificness of the colony out of which the brood has been taken, and that is still another detail.

When the crop comes it is a nice point to detect at a glance the signs of approaching harvest, to furnish supers at the proper moment, so the lack of them may not induce the colony to swarm, and not to furnish them too soon and have them stained by the unnecessary travel of the bees over them.

When the swarm is harvested there are a thousand little things to look after—to recognize whether the queen has been hived without having actually seen her; set the hive up properly so the combs may be built perpendicularly; fasten the guides in the frames correctly; shelter the hive against the too direct rays of the sun; see that the grass is kept down, that the bees are supplied with a watering-trough, if no natural stream is close at hand, etc.

To remove the honey properly without damaging it, to cleanse the sections and have them in attractive appearance, to remove the traces of propolis, to keep the hive supplied with sufficient room, and to put up the honey in shape to make it most readily salable, are all nice points, and require minutiae.

But the greatest vigilance is necessary, and the practical apiarist best shows himself when any robbing is going on. And the man who does not give the robbers a chance, who always has his colonies supplied with queens; who always keeps the entrances of his hives sufficiently open to allow of free entrance and exit, and yet reduces them to the absolute necessities of the colony according to its strength; who manages to handle his bees with so much speed, dexterity and care as to avoid undue excitement—that man is a bee-man indeed. This picture looks overdrawn, and yet I have in mind a dozen men who, to my knowledge, have just this much care of their bees, who do things in the apiary as we say they should be done, but not as we do them ourselves, for I regret to say I lack in many of these particulars, and I cannot refrain from admiring these men, however I may laugh at their too exact notions in ordinary things of life.

For the exact bee-keeper shows himself exact in all the details of life. I have in mind a little incident that will fully illustrate the precise method of the careful bee-keeper. The hero I will not name, but if he reads this he will readily recognize himself, even tho the incident happened years ago:

I was extracting honey for him, and while I extracted the first bucketful of honey he was in his cellar preparing a barrel to receive the honey. The head had been removed, and he had the barrel set upon blocks when I came down to see whether all was ready. By that time I had one bucket about full, and as soon as I found that all was right I went upstairs to get the honey. He came up behind me. In a short time I again descended the stairs with my pailful and cautiously stepping to the spot where the barrel was placed (it was a little dark) I poured my entire bucketful—on the lid. I don't believe a drop of it got into the barrel. Fearing that I might delay a little in bringing the honey, his exactness and exceeding neatness had prompted him to cover the barrel with its lid, for fear some little speck of dust might fall in. A few hot words past. You might have heard one man mutter something about other people's recklessness, while the other was cursing the precise ways of some people. But the quiet man had the best of it, for he went right to work cleaning up that barrel, and it was a job I can assure you, for I had evidently struck the center, and the honey was evenly spread over the entire surface of the lid, and over every stave from top to bottom!

The careful and successful bee-keeper has a neat home, his wood-pile is arranged symmetrically; if he has sawed the wood himself you may be sure that not a single stick is an inch longer than any other stick, and you may venture to assert that every stick of that wood will fit inside of his stove without having to be broken across somebody's knee. His tool-shed is a model of order, his agricultural implements are kept in good repair, and his live stock is healthy and well fed. If these things are not as I represent then he is not as successful a bee-keeper as he might be, for bee-keeping is, as Mr. Heddon once said, "a business of details." Hancock Co., Ill.

First Symptoms of Bee-Diarrhea in the Cellar.

BY G. M. DOOLITTLE.

A CORRESPONDENT writes: "Last winter my bees contracted what is known as 'bee-diarrhea' quite early in the winter, and I wish to know what can be done with a colony of bees in winter quarters when the first symptoms of the disease appears. Please answer thru the columns of the American Bee Journal."

If the bees were in the cellar, and the temperature of the cellar was above 50 degrees, Fahr., I would try cooling the cellar. On the other hand, if the temperature was 38 degrees, or cooler, I would try warming it up to the temperature first given, or a little higher. When the temperature of any cellar is just right it may be known by the quietness of the bees. The air of any room is always the warmest at the top, where any warmth-producing material is in such room, and for this reason I always place the strongest colonies as to bees or numbers in the bottom tier, when putting them in the cellar; the colonies of medium strength in the next tier, while all of the colonies having

the smallest number of bees are placed in the upper tier, or at the top.

I have found by years of experience that if a strong colony becomes uneasy while in the top tier, it may be quieted by putting it on the cellar bottom; and that a small colony, which is in a roar of disturbance, can be caused to become as "still as death" by raising it from the bottom of the cellar to the top. Also closing most of the ventilation from the hive having the small colony will cause it to become quiet; and removing the whole top from an uneasy strong colony will cause them to quiet down and cluster compactly together for the rest of the winter.

But all this should be attended to when the bees are put in the cellar, by putting them in their proper places, and ventilating each hive as we believe it may require. If, in spite of all this precaution, some of them begin to spot the hive, I will say that, after trying all plans of cure, I now let them alone, for I consider it only a waste of time to fuss with them.

If the reader does not agree, he can try giving them a flight in a warm room. Fix a box to set on top of the hive, the same having a glass top; or should a warm day occur carry the bees out for a flight; but after all this has been done the bees will generally be dead before June, if they have the diarrhea badly enough to spot their combs and the inside of the hive during midwinter or earlier.

One thing which is always against this fussing with single colonies of bees wintering in the cellar which have become diseased, is that by "doctoring" these, the disturbance required is apt to cause the other colonies to become uneasy, and cause them to become diseased also, while otherwise they would have gone thru the winter quiet and all right.

A change of food is sometimes beneficial; but, as I said before, the greatest success comes by using the precaution named when putting them in the cellar, and then letting them entirely alone, as far as individual colonies are concerned after they are once prepared for winter.

It is well to enter the cellar where the bees are wintering as often as once in two weeks to a month, to see that everything is all right as to no mice, rats, and the temperature, which should be kept as nearly as possible from 40 to 48 degrees, Fahr. A cellar in which the temperature can be kept from 43 to 45 degrees is as nearly perfect along the line of temperature as can possibly be according to an experience of nearly 30 years with myself and others here in central New York. If the bees are wintering outdoors on the summer stands, and they contract the diarrhea, I am positive nothing can help them short of a warm day in which they can fly freely. And even this will not save them if they become very badly diseased before such a warm day comes. But if such a day occurs at about the time they become uneasy enough to break the winter cluster, then they will generally come thru all right, especially if they can have a chance to fly every two or three weeks thereafter.

I have tried all sorts of plans to cure colonies having the bee-diarrhea that were on the summer stand, such as making a box to fit the hives at the top, the same having the front and top sides covered with glass; placing said box on the hive on sunny days, and if the rays of the sun did not give heat enough, putting inside heated bricks wrapped in cloth, till the bees would come out in the box, making everything black and nasty thru their voiding excrement, when the whole was allowed to cool gradually down, and at night the box was taken off and the hive fixed as snug and warm as possible; but in the spring I could not see that such colonies were any better than others which had the disease equally bad, but were left entirely alone, as death generally was the fate of all.

Then I have tried a change of food, taking away all their stores and substituting that from other colonies or combs of honey stored away in the honey-house, or giving them stores of candy or sugar syrup, but in none of these trials could I feel sure that they were any better off than were the diseased ones which were left entirely without any "doctoring."

Bees, to be perfectly healthy when wintered on the summer stands, should have a chance to fly as often as once

Mr. Whitney holding a frame of Comb and Bees for a Photograph.

in every four weeks, but they will usually be in good order if they have no chance to fly from Nov. 15 to Feb. 1. But if this time is lengthened from Oct. 22 to April 7, as we once had it here, very few colonies will be alive at the end of the last-named date. This year I had bees alive in 15 hives out of 93 wintered outside on the first day of May; but there were not enough bees in the 15 hives to make three good colonies. But that very same year I put out of the cellar, on May 5th to 7th, 52 good, strong colonies out of 54 put in the first of the previous November, with cellar and bees fixed as given above. Onondaga Co., N. Y.

No. 3.—An Apiary—How to Make the Most Out of It.

BY "OLD GRIMES."

THERE are four sources of revenue from an apiary—honey, wax, queens and bees. The great majority of bee-keepers work their colonies for honey, while the wax is an incidental product, and queen-rearing is worked by the specialist. If the sale of colonies is depended upon for revenue, the demand is generally limited, and the demand in that direction is soon supplied.

It is a foregone conclusion that the bee-keeper who wishes to get revenue out of his colonies will not only have many of them, but many apiaries. A business that is worth running upon a small scale will pay proportionately well upon a large scale, provided the bee-keeper's ability rounds out so as to keep the balance.

It certainly would be folly to expect success from an apiary located where there are few honey-plants; the field should be carefully looked over, and the apiary located with as much care as would be exercised in providing pasturage for a herd of cattle or a flock of fatting sheep.

Having located properly, the next thing is to lay out the apiary upon a systematic and labor-saving plan. Wherever the lay of the land will admit of it—and it will admit if it is sought for—the apiary should be laid out according to the Grimes plan—in circles.

The center circle is 12 feet in diameter, and the hives face to the center. The next circle faces out, leaving an operating lane five feet wide. The next circle six feet away facing in, and in like manner additional circles and lanes for one or two hundred colonies. As the hives face differ-

ent points in the circle, more colonies can be placed in a given area than by any other plan, when working with the bees, and a start is made upon a row of hives, the work is ended where it commenced, and presumably near the entrance to the honey-house.

Where the location is subject to winds, and even if it is not, a wind-break should be provided; cold winds are disastrous upon an apiary in the early spring.

The orthodox methods of securing the honey crop have been recommended and practiced so long that they have become really old-fashioned, and, being satisfied that there is a better way, the Grimes family are seeking in that direction and upon the following lines:

The leading endeavor of the wide-awake bee-keeper is to get his colonies into a most populous condition before the honey-flow commences, and to this end the queen is given unlimited room; and it makes but little difference whether the colony is in a barn-hive, or any style that can be properly examined, the queen can occupy only about so much room, and will rear bees to the extent of her prolificness; and when the field-bees are in a great preponderance over the nurse-bees, and the honey-storing capacity of the hive seems to be restricted, the colony is thrown out of balance and a swarm issues, and a large first swarm early in a good honey season can be depended upon for a large yield of surplus honey.

A non-swarmling strain of bees seems to be the desideratum with some of the leading apicultural lights, but there is no reliable method yet discovered whereby this impulse can be prevented when working for comb honey, or, if it is held down, it is to a sacrifice of queens, working-force and honey. Swarming can be prevented in a great measure by the free use of the honey-extractor, but somehow even in this case a colony that has been prevented from carrying out the instincts of nature, altho it may do well for a time, soon gets out of balance, swarms, and thereafter works in a sluggish fashion.

The Grimes family can get the most out of an apiary by working it for both comb and extracted honey. If there are any weak colonies when the bees are placed upon the summer stands, they should be moved alongside a strong colony and worked as a nucleus. If the colonies should all happen to be strong, and they are liable to be when wintered according to the Grimes plan, then as early as possible nuclei should be formed for at least two-thirds of the colonies, or, better still, for all of them, and a laying queen secured even if she must be purchased from breeders further south. This nucleus colony beside the strong one is kept in a semi-nucleus condition by drawing brood from it and giving to the larger colony, the object being to throw that colony out of balance, and to cause an immense swarm to issue at the commencement of the white clover season.

This immense swarm is placed in a hive with only starters in the brood-frames, a queen-excluder adjusted, and upon this two supers of sections, the latter filled with foundation, and the hive is placed in a new location. Nature demands several days' rest for a queen after the issue of a swarm, and she gets what Nature calls for while the bees are building new comb; at the same time the hive is so crowded with bees that the sections are rapidly filled. We prefer to give the bees all new work at first. After a good start has been made, or after the removal of the first case of comb honey, sections with drawn combs can be given to advantage if the bee-keeper should chance to have any on hand. In working for comb honey the Grimes family use the 4¼ section and separators. The new tall section and fence separators may be the thing, but we think that when everybody else gets to using the new form, ours will be so unique that we will get the fancy price for our honey.

The hive and bees upon the old stand are united with the strong nucleus and its laying queen. As the old hive is well supplied with extracting-combs it is worked during the season for that kind of honey. It can be worked for comb honey, but we think it gives a greater profit with the first named.

If a further increase is desired, a nucleus is started with one or two frames of brood and a cell from the parent hive, otherwise the cells are all destroyed. The bee-keeper is troubled with no after-swarms, unless it happens much later in the season during a copious flow from buckwheat or other fall flowers.

It is the plan of the Grimes family so to construct the colonies and the nuclei that they can be wintered in one hive—we then have our nucleus colonies with laying queens ready for the spring campaign.

Before the yield of white honey ends, all filled sections

are removed, and the unfinished ones are concentrated upon the strongest colonies, and there will be but few unfinished sections at the close of the season. We aim to secure all of comb honey as a No. 1 article; all of the dark honey is secured with the extractor.

The Grimes family are aware that the above plans require a good amount of work, but so does any plan of modern bee-keeping require more skill than it did 60 years ago, when old Grimes was a boy and straw-skeps and box-hives were used.

Bob Burdette says that when he was a boy he always loaded his gun by putting the powder in before he did the bullet; but now they put the bullet in before the powder, and that is the difference between a muzzle and a breach loader; and in like manner with our bee-management. Sixty years from date the improvements will be greater than in the past, and the Grimes family believe in adding their mite to hasten the millennial day.

The American Bee Journal—Historical.

BY DR. E. GALLUP.

THE first volume of the American Bee Journal was published before the War of the Rebellion, by Samuel Wagner, a man in every sense of the word. It was then suspended until after the Rebellion was over; or, for five years, if I remember rightly, I knew nothing of its publication, or the first volume, but heard of it in some manner, and subscribed and commenced writing for it on its resumption.

The first national bee-keepers' convention was held at Indianapolis, Ind., Dec. 21 and 22, 1870. At that time H. A. King was publishing the Bee-Keepers' Magazine in New York city. It advocated H. A. King & Co. and the American hive exclusively. It ignored the American Bee Journal and the Langstroth hive—they were never mentioned, and if in writing an article for his paper either the American Bee Journal or the Langstroth hive were mentioned, it would invariably be expunged or dropt out before publication in his paper.

About that time N. C. Mitchell was publishing the National Bee Journal at Indianapolis, in the interest of N. C. M. and his hive. Well, both King and Mitchell tried their soft soap on a man about my size and build, but their pipes failed to connect, altho each offered a handsome bonus to write exclusively for his journal and advocate his hive, etc. But both journals went where the woodbine twineth, as they deserved.

Mr. Wagner was a very quiet, reserved man, so far as blowing his own horn was concerned. He expected and did publish a journal that would, or ought to succeed on its own merits, but came very nearly failing financially. King became frantic about the Indianapolis convention, and was afraid his scheme of keeping the mass of bee-keepers in ignorance of the American Bee Journal and the Langstroth hive would fail, so he got up a rival convention at Cincinnati.

In February, 1871, just after the Indianapolis convention, I received a private letter from Mr. Wagner, stating that he should be compelled to discontinue the American Bee Journal, as he had already sunk nearly \$1,500 in the venture, etc. I replied that some 20 old substantial subscribers had a private meeting at Indianapolis, and had canvast or talkt the matter over among themselves, as he had written to one or two others on the subject. We found a large proportion of those that attended the convention had never heard of the American Bee Journal or the Langstroth hive, and did not even know they had an existence, so I replied as follows to Mr. Wagner:

"Now, Friend Wagner, I do not wish to advise, but if you can hold on until after the Cincinnati convention, we, the old subscribers, are bound to make a tremendous effort to increase your subscription list, and place the 'Old Reliable' on a firmer foundation," etc.

Well, we got subscribers at Cincinnati, obtained all the names of bee-keepers we could get hold of, and sent each a copy of the American Bee Journal. Some time after, I do not remember how long, I received another letter from Mr. Wagner, thanking me very kindly, and saying that the American Bee Journal was fairly and squarely standing on its own feet, that it had fully paid up its loss, and more.

Now the readers will see how very near we came to losing the old stand-by, and first in the field.

When I first commenced writing for the American Bee Journal I wrote a series of articles on the subject of bee-

keeping, and mentioned that I had never seen the subject touch on in any writings, etc. Mr. Wagner then sent me the first volume of the journal, in which he had explained the same theory, almost word for word. I felt badly worked up, and asked why he allowed me to go on making such a fool of myself, etc. His reply was, that it was a great satisfaction for him to know that we were both making the same discovery, and at the same time, and each living in different parts of the world—he in Germany and I in America.

I find on reading Mr. Langstroth's book that many of my articles read as if I had copied them from that book, but that could not be, as I never had the book until about two years ago, as a present from Mr. Dadant.

Orange Co., Calif.

CONVENTION PROCEEDINGS

Report of the Chicago Bee-Keepers' Convention.

BY HERMAN F. MOORE.

The fifth meeting of the Chicago Bee-Keepers' Association held Nov. 2, 1899, was one of the most interesting ever held in Chicago. The day was stormy and the attendance small, every one who came was chock-full of enthusiasm and ideas.

Mr. George W. York was elected president for the ensuing year, and Mrs. Stow and Mr. Moore were re-elected vice-president and secretary, respectively.

Mr. York, Mrs. Stow and Mr. Moore were appointed a committee on the entertainment of the United States Bee-Keepers' Association when holding their annual convention in Chicago in 1900.

The committee on resolutions reported the following:

Resolved, That good work has been done in Chicago by the associated bee-keepers in beginning prosecutions of adulterators of honey.

Resolved, That the said prosecutions should be pushed vigorously until there is no fraudulent and illegal sale of bogus honey in Illinois.

Resolved, That we hereby invite all bee-keepers and others interested in pure honey to subscribe to a fund for the prosecution of the aforesaid offenses.

Resolved, That we invite the public to aid us by submitting samples of impure honey, and reporting to the Chicago Bee-Keepers' Association violations of the law.

GEORGE W. YORK,
CHARLES CLARKE, } *Committee.*
H. S. JONES,

Mr. G. S. Crego, of this (Cook) county, not being able to be present, the secretary read his paper, as follows:

Wintering Bees in Northern Illinois.

As I have been asked to present this subject before the Association for discussion, I will briefly describe the method which, so far, has carried my bees thru with the loss of only one colony in four winters.

Not having cellar-room for storing bees, I have adopted the following scheme for taking care of them on the summer stands: Packing-cases are provided, in size some three inches larger on all sides than the hives they are to cover, a slot sawed in the front extending clear across the hive. The passage-way between the cases and hive is carefully bridged over to allow the bees to go and come freely. The space between the hive and case is closely packed with dry leaves raked up on the lawn. In preparing the hives for packing, I remove the cover and replace it with a pine board $\frac{1}{4}$ inch in thickness, thru which a few half-inch holes have been bored for convenience in fall or spring feeding. These holes are carefully covered with a small piece of thin board at packing-time, then an empty super placed on the board and packed as closely as possible with leaves, in fact, heaped up and running over, and the regular hive-cover laid loosely on top. This thin pine cover next to the frames seems to act as a free conductor to the moisture of the cluster while conserving the heat of the hive very fully. The hand thrust into the leaves in the super in cold weather can instantly locate the cluster by the slight moisture and warmth of the leaves.

When the entire hive, super and all, has been closely

packed, a sloping cover of boards covered with tarred roofing-paper is fitted over all, and the bees are left to enjoy their stores in peace.

So much for out-door wintering.

But I have one colony which has been kept in the basement of my house for three winters, and which has been mentioned in the American Bee Journal once or twice. This colony, kept in a temperature which never approaches frost, and which is frequently maintained at 70 degrees for days at a time, has been the most profitable of any colony in the yard. The bees seem to keep up more or less breeding nearly all winter, inspection on a warm day early in March showing large patches of sealed brood, and, by the time the soft maple and elm blossoms are out, the hive is boiling over with bees.

This colony has never attempted to swarm, and has not yielded less than 150 sections of honey any summer since being placed in the basement. The hive is located near a west window, thru the bottom rail of which a slot is cut to allow the bees to fly whenever the weather will permit, and which is taken out entirely as soon as warm weather has come to stay. It is probable that the quality of the queen is largely responsible for the large yields from this colony, but I am inclined to give a large share of the credit to the fact that the bees are always warm—very warm—in winter, and reasonably cool during the hot weather of summer. The consumption of stores is very small, as they are ready to store surplus honey as soon as the dandelions are out plentifully, having had cases of sections ready to remove as early as June 20.

My hives are all dovetailed 10-frames, and, for my locality, are hardly large enough. The only colony I have ever lost was last winter—one which I attempted to carry thru in a 2-story 8-frame hive, the bees being all dead in the spring with at least 30 pounds of sealed honey left in the hive. No more 8-frame hives for me, thank you.

My success in wintering one colony in a warm place has given me an idea which I hope some time to put into practice. I hope to construct one or more greenhouses, and when I do I shall make a bee-repository under at least one of them, placing the hives about level with the surface of the ground, each hive being connected with the outer air by a bridged passage-way, and the interior of the repository being heated with one or more runs of hot-water pipes. It may not work successfully, but at present I believe it will.

G. S. CREGO.

A very interesting discussion followed the reading of Mr. Crego's paper, in which all present participated. Nearly three hours was devoted to this topic, and justly so, for wintering our bees troubles us more than all else.

A number of those present took lunch at the Briggs House cafe, where they divided their time between ideas and food products.

In the afternoon the following paper by W. C. Lyman, of Dupage Co., Ill., was read and discussed:

The Best Hive for Northern Illinois.

That hive is best which will produce the best results in honey and the health of the bees, and which is also convenient for manipulation.

Since honey in the flowers must precede honey in the hive, it follows that the apiarist must first know the resources of his location thoroughly in order to know what course of management to pursue during the season. The management to be given applies principally to the brood-chamber, for the apiarist can select that form of super which suits him best, either for comb or extracted honey, without any material difference in regard to the quantity or quality of honey obtained, except that separators in some form should be used for comb honey.

The brood-chamber should be large enough to contain honey to carry the bees thru the winter and spring without having to fuss with or feed them in the spring. One of 10-Langstroth-frame capacity will not be too large, but my experience leads me to think that one of 10-Langstroth-frame capacity, and yet not wider or longer than an 8-Langstroth-frame, but deeper, is better than the 10-frame Langstroth hive. This is partly because the supers of an 8-frame Langstroth hive are full large enough to practice the tiering-up method to the best advantage.

I have never been able to obtain better results than where the bees are allowed to swarm once; but I want to hive the swarms in brood-chambers of about half the capacity of those from which they issued, until the close of the white honey harvest, at which time I would give them the same amount of room they had in the spring, and run them

the rest of the season for extracted honey, or for winter stores if enough is not obtained for extracting.

By thus using a small brood-chamber at swarming-time, I find that I can use in it combs fully drawn, or the brood-combs which I have in stock, by giving abundant bottom ventilation, and that no pollen will be placed in the section-boxes, altho the supers are removed from the old hive and placed on the new one before the swarm is run in. Of course, a queen-excluding honey-board should be used, and its advantages are so many that I am not yet ready to discard it.

To contract the brood-chamber with division-boards or dummies would not suit me at all, for a number of reasons.

I have taken this subject from the comb-honey standpoint, for I believe the test of successful bee-keeping is in the production of beautiful comb honey.

I have never seen a hive without faults, and the user must select for himself; but, for results, I believe there is none better than some form of the divisible brood-chamber hive.

W. C. LYMAN.

Then a multitude of questions were answered by Dr. C. C. Miller and others present. This part of our meeting is always interesting, and many new ideas go floating around for assimilation.

The convention was much entertained by Dr. Miller and Pres. George W. York with music. Dr. Miller presided at the piano, and Mr. York sang the new bee-keepers' song, entitled, "The Hum of the Bees in the Apple-Tree Bloom."

(Concluded next week.)

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Leaving Honey in the Hives Outdoors in Winter.

Do frames with honey get spoiled by leaving them in the winter-time in the hives, with the bees in the first and second stories? Or is it better to take the honey out? Here in the South we do not put the hives inside in winter. The bees sometimes work here in winter on certain flowers.

LOUISIANA.

ANSWER.—Have no fear about leaving the honey in the hives. In the North there might be some danger of the honey granulating if the quantity were so large that the heat of the bees would have no effect upon it, but in your latitude there is not that danger.

Feeding Bees in Box-Hives in Winter.

I have two colonies of bees in box-hives that need feeding. How can I feed them this winter? I have made a feeder 14x14 inches, the same size as the hive, and nailed strips around the outer edges, and strips thru the center about two inches apart. Do you think this will work? If not, how can I make one? How would it be to take the bees into the house where it is warm, when I feed them. I can shut them up so they can't get out. I have a Miller feeder for feeding in 8-frame dovetailed hives, but I want one for feeding in box-hives.

NEW JERSEY.

ANSWER.—If I understand you correctly, the feeder you contemplate is to be set under the hive, and you intend to feed liquid feed. At this time of year you must not think of feeding liquid at all. Take your box-hives in the cellar and turn them upside down—don't be afraid of making them dizzy—and lay chunks of comb honey on the brood-combs. If you haven't comb honey make cakes of sugar candy an inch or so thick. Heat water and put into it about three times as much sugar (either by weight or measure.) Set it

on the top of the stove and not in the fire, and be exceedingly careful not to burn it, for burnt candy is poison to bees in winter. Try it from time to time, and when a little of it dropt in water breaks like a pipe-stem, take it off. When it begins to harden around the edges stir it well till it is so thick it will just pour, and pour it into great dishes. If you can get some good extracted honey, you may prefer to make a different candy. Heat the honey till it is very thin, but don't boil it. Take from the stove, and stir into it all the pulverized sugar it will take. Then knead it and put in more sugar till it becomes a stiff dough.

After giving your bees the honey or the candy, let them remain in the cellar, the hives upside down and uncovered, until it is warm enough to put them out in the spring.

Has the Bee an Extra Sense?

1. How does a bee know how to get back home after gathering a load of nectar from a great number of different flowers two or three miles from her hive?

2. Why does a bee, taken from a flower, we will say, south of the hive or tree, and carried north and beyond its home, circle and still go north and away from its home when liberated? The next time it will, after filling its honey-sac, go direct home.

MASSACHUSETTS.

ANSWERS.—I. I see no reason why a bee after roaming about after a load of nectar might not find its way home in exactly the same way that you might find your way back home after roaming about two or three miles picking blackberries (on the supposition that blackberries grow wild in your part of Massachusetts.) It is quite possible also that a bee could find its way back home where you or I would be hopelessly lost. A bee may be able to see long distances, and it is not entirely certain that a bee may not have some additional sense that enables it to find its way home. Take a cat that has never been a quarter of a mile from home, shut it up where it cannot possibly see, take it two miles away and release it, and we are told that when you get back home you may find it complacently waiting for you on the doorstep. Certainly, no human being could perform that feat. Has the cat an extra sense? If so, may not the bee have the same?

2. I don't know; and before believing a bee will do as you say I should want reliable testimony to that effect.

Growing Alfalfa in New York State.

There is some talk in the American Bee Journal that alfalfa is a great honey-plant, also a good pasture for stock, but in the 1896 American Agriculturist Almanac I saw an account of alfalfa as an injury to sheep and cattle as a pasture, claiming that sheep and cattle will feed on it for days without ill effects, but sooner or later trouble arises. Under certain conditions sheep become inflated like balloons, and die suddenly from eating moist alfalfa. What about the plant, both as a pasturage for bees and stock? And on what kind of soil will it do best? Will it grow on limestone ridges? Is it grown in this (Jefferson) county?

I shall be very thankful to see a full account, given from actual experience, if possible. If advisable, I would like to try the plant.

NEW YORK.

ANSWER.—Alfalfa is very largely used as a forage-plant, both in the green and dry state, and if it were true that such ill results would sooner or later come from its use, many would know of it and so report. It is probable that damage may be done by allowing cattle not accustomed to it to overfeed, as is the case with red clover. It has been grown here and there in different places in the East, but I do not remember ever to have seen a single report saying it was of value as a honey-plant, except a report from Michigan in a late number of Gleanings in Bee-Culture. It is just possible that alsike instead of alfalfa was the plant in that case. Alfalfa grows in two or more places in this county, and I have visited it two or three different years when in bloom at a time when bees might be expected to be working on it, but never could I find bees there. Of course, it is a very valuable honey-plant in the West, as in Colorado, but it is probably not worth your while to try it as a honey-plant in the State of New York.

The Premiums offered on page 13 are well worth working for. Look at them.

THE AFTER THOUGHT

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Richards, Ohio.

BEEES AND HONEY OF THE ANCIENTS.

Prof. Wiley, page 740, seems to me to build far too much on the mere phrase, "ethereal honey," in Virgil. The ancients were not such fools as to be unaware that bees, *some of the time*, visited flowers for sweet. It was when they saw them gathering dew, and when they saw them gathering—we even now know not what—from the surface of fresh or newly-thawed soil, and when they saw them at work on what we now call "honey-dew," that they concluded that another, and perhaps larger source, of sweet direct from the air was open to them direct from the air. And some persons stick to that opinion yet. Virgil, in the same poem Mr. Wiley quotes, directed not to plant an apiary on a cattle-range or sheep-walk, and gave at least one correct reason—because stock destroyed the flowers. This shows clearly that Virgil thought flowers a material source of supply, and not a mere trifling one. In fact, Prof. Wiley heedlessly upsets his own position by quoting the ancient yarn about \$650 worth of honey from an acre of flower-garden.

DEMOCRITUS AND DEMOCRATS.

I thank the Professor for the name of that fellow who said, "oil without, honey within," when asked how to live a hundred-and-odd years in vigor. Democritus his name was, it seems, and 450 B. C. Have been looking for him for some time. If I go to forget again I'll think of Democrats. The Democrats are living out their first hundred years in vigor, and are likely to go in for another century—but not on oil and honey—"loam without, gall within," would be the way the Republicans would state it.

DAKOTAN METHODS AND APIARY.

I laugh when I read Comrade Hobbs' boast that he could sit in a chair and take his swarms. Let's send for some of his queens—or, perchance, if we had a Dakotan or South African veldt to keep bees on, our present stock might fail to cluster on nothing 30 feet up. His apiary plan seems to be excellent in some respects, and not so good in others—badly lacking in *location points*. If he would move that chicken-coop we see at the right, to the center front, and then take a shovel and throw up a couple of mounds of dirt midway between coop and wings—well, the aspect would not be improved, but the apiary would be a better apiary. The endless single row, every hive just alike, does have a certain impressiveness poetically considered.

DOOLITTLE ON WINTER BREEDING.

Doolittle puts it well about winter breeding, on page 738—two old bees lost for each young one reared, while in proper season two young are reared for each old one worn out.

STRAINING AT GNATS AND SWALLOWING CAMELS.

Editor Leahy's a good fellow, but he deserves the clip the editor gave him, page 745—would strain out the national convention essays (which are not even gnats at all), and swallow the camel of five pages of romance. What an appetite for camels most of us have! Note how our not-so-bad-as-it-might-be government abolishes the national cock-fight the minute it got to Manila—and introduced the American saloon!

A QUEEN-REARING SUGGESTION.

And so the largest queen-breeder in Australia says bees do remove all royal jelly given them with larvæ—yet he gets more accepted that way, and thinks it works as a suggestion. Page 747. Why not give them the suggestion on a chip, and save the babies from being tumbled about?

A NICE HOUSE-APIARY.

On page 753, Mr. Goudge gives us something out of the ordinary line in a nice house-apiary built to accommodate only five colonies. He did well to keep the cash cost down to \$3.00 a colony, he doing and not counting the carpenter

work. At the very antipodes of Mr. Hobbs, just reviewed, Mr. G. seems to be almost excessive in his painstaking efforts to enable bees and queens to locate. He doesn't explain what the curious round-spottedness about the entrances is—possibly that also is location-marking of a fancy sort.

PROPOLIS AS GRAFTING-WAX.

Proper glad to see our Deacon again, page 754. Thought we'd lost him. Quite interesting to see that he made a success of using simple, unmixt propolis for grafting-wax. I think climate must have something to do with it. It is indeed Nature's own grafting-wax; but I suspect that the wax Nature makes in our July, and the average weather in our grafting-time, are a little too unwilling to yield to each other.

SOUTH AFRICAN HONEY-GUIDE—A SOLILOQUISM.

Of course, information concerning that little wise-head (or lunatic), the African honey-guide can hardly be else than interesting. Very few things in animate Nature seem more worthy of careful study than the psychology of that little chap. Early reports gave us the idea that he always led to honey, and that his object was to get a share of the plunder himself. The first, it seems, is false, and the last at least very doubtful. Bees are not usually taken immediately on being found; so the guide gets nothing, unless he happens around weeks later. Theories have to be reconstructed, apparently. I feel as tho I have evidence that wild squirrels, and at least a few wild birds, are aware that man is a higher creature than themselves, and that occasionally they feel a strong desire to open communications with him somehow (as our astronomers burn to open communication with Mars). Honey-guide simply an extreme example of the same sort—intense and excitable, and chock-full of big thoughts and curiosity, he often wants the *companionship* of some other wise being, wiser than himself, in the contemplation of some of his *problems*. Alas, like children asking questions, he sometimes oversizes us! And one of his commonest problems is, it seems, Why (in a world generally nice) should there be such disgusting creatures as big snakes? And at least once (many thanks to Mr. Deacon for the evidence), Why should a human being lie drunk on the ground? The problem whether tiger would eat Deacon, or Deacon eat tiger, is so-so, altho not so deep. What the problem is in regard to bees is not so plain as one could wish. We don't know from what point of view he regards them. I *guess* he regards insects simply as provender, and that the problem is, Why should provender have such sharp tails, and get together in such armies that a fellow has to stand off and let them alone?

NON-SEPARATED HONEY.

Mr. Stone rather threw—himself—in the eye of the non-separator fellows, when he said that only about 20 pounds of the entire lot of non-separator honey at the World's Fair was fit to ship and sell. Page 758.

FERMENTED HONEY FOR BAKING.

If Chalou Fowls, indorst by Gleanings in Bee-Culture, says some bakers prefer fermented honey to sound—well, that militates pretty strongly against some recent "After-thinks;" but let's have the whole evidence without fear or favor. May there not be an adjustment possible, like this: Slightly tart honey giving the better *flavor* to some cookery, and sound honey giving the more of the moisture-attracting quality? The latter quality is all that a baking trust would ever buy a carload of honey for, I take it.

DON'T "MONKEY" WITH FOUL BROOD.

Some of us were not aware that young queenless bees, and young bees with a virgin queen, were more persevering and thoro in cleaning filth from combs than normal colonies are; but it's not altogether unreasonable, and if Editor Simmins says it, it's pretty likely there's *something* in it—a something which the bee-man who wants his general-knowledge box fully equipt would better make a note of. But, on the whole, this critic would say, Dangerous business for the boys to get at—these foul-brood experiments on pages 762 and 764. Say, let the foul brood alone, and monkey with a toy cannon.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

VOL. 40. JANUARY 4, 1900. NO. 1.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

1900. How does it seem to write it?

The Last Year of the Nineteenth Century! Let us all try to make it the best year we have yet known.

Volume XL, or the Fortieth Year, of the American Bee Journal, is begun with this number. As almost every one knows, it was founded by Samuel Wagner, in 1861. He died Feb. 17, 1872, now nearly 30 years ago. His son "George" conducted the journal until Jan. 1, 1873, when Rev. W. F. Clarke secured control of it, and removed it from Washington to Chicago. In 1874 Thomas G. Newman took hold, and continued its publication uninterruptedly until June 1, 1892, when the present management was installed and has since that time been able to make the old American Bee Journal what it is to-day.

Many have been the changes in matters apicultural during the past nearly 40 years, but with the exception of a few years during the Civil War, the American Bee Journal has gone steadily on, increasing in power and usefulness until to-day it is said by those who are best able to judge that it has never before been so good in every way. We do not take all the credit for this ourselves, as we know that it has been accomplished only by the loyal support of subscribers, advertisers and contributors, who, together with

our own efforts, have been able to build up a weekly journal that fairly represents the great and ever-growing industry of bee-keeping on the American continent.

On another page we give an historical article written by Dr. Elisha Gallup, who is one of the oldest contributors to the columns of the American Bee Journal. He now resides in Southern California, and is somewhere near 80 years of age. The article was written by him several years ago, but we have kept it until now. We think it is very appropriate at this time, and will be read with much interest and profit by all, especially by those of our readers who doubtless were intimately acquainted with the historical matters mentioned by Dr. Gallup.

It will be our highest aim, in the future as in the past, to make the old American Bee Journal just as good as the support given it will allow. Our main object in life is not to accumulate great wealth—if it were we would go into some other business. We desire, above all things, to be helpful, to live for some noble purpose, and believe that in devoting our best energies to publishing a strong, clean and useful journal for bee-keepers, we shall feel, when life's end shall have come, that we have not lived in vain.

We trust that during the coming years the American Bee Journal may merit even larger support, and ever maintain the position which we believe it has rightfully won in the hearts of its readers and in the field of apicultural journalism.

The Bee-Keeper's Best Reading-Time will likely be during the next two or three months. It would be a splendid thing if all who are not already expert in the business would get together their last year's bee-papers and re-read them. Then study that bee-book, too. Oh, you haven't any? Well, that's a great mistake.

No young bee-keeper worthy the name will likely make a very great success with bees if he tries to get along without a good bee-book. And we don't say this because we have such books to sell, but because we know it is the truth. Every good bee-keeper has the best bee-books and the best bee-papers he can find.

It pays to read the methods and experiences of others. Life is too short for one lone person to attempt to find out everything for himself these days. You might as well try to succeed in producing wheat now by cutting it with a sickle instead of a self-binder, as to try to be successful with bees and still use the box-hive and old-time methods.

Short cuts are the order of the day. Read up and learn how others succeed, and then follow in their footsteps unless you can do better than they do.

Honey from Mount Hymettus.—It seems from the following that our good friend, Hon. Eugene Secor, has been receiving a novel Christmas present:

EDITOR YORK:—One of the mementoes I received at Christmas is a tin can of Attican honey, put up in Athens, and said to be "Veritable Miel Du Mont D'Mymette," which I suppose means "genuine Mount Hymettus honey."

The gift was from a young friend, B. J. Thompson, who returned last spring from a tour around the world, and visited Greece.

Sentiment and story cluster around the sweet product of Mount Hymettus, and, I suppose, a money value to the overworked bees of that world-famed region.

I found the flavor peculiar. It is hardly fair to compare it to our best product in fresh condition, but if the tastes of the family are worth anything, it will not supplant the delicious nectar of our own beloved country.

Yours truly,

EUGENE SECOR.

Mr. Secor will have to bring that famous sample to the next national convention, and let his friends have a taste of it. Perhaps few of our bee-keepers ever tasted honey from the famous region of Mount Hymettus.

The Hive Question will not down. Nor need it so long as it is an important one and not fully understood. L. Stachelhausen discusses it in *Gleanings in Bee-Culture* in what appears to be an able, philosophical manner. He is led to the conclusion that for extracted honey a large hive is best, and for comb honey a small one. The aim is to have as many gatherers as possible for the harvest, and as few consumers as possible when no honey is coming in. From the time the queen begins laying, whether it be Feb. 1 or later, up to the time of the harvest, with him the last of May, there is a gradual increase of laying, reaching some 3,000 by the last of April. That allows more than 100,000 workers to begin on the harvest. If the room be so restricted that the queen can lay only 1,600 eggs in a day, then there will be only some 50,000 workers at the beginning of the harvest.

During the honey-flow it is desirable to have the laying restricted, and it is probable that the queen in the larger hive will lay less than the other, for she has become more exhausted by the larger number of eggs already laid. By the close of the harvest there will be the same number of bees to support in the small as in the large hive. The main point of difference is that in the small hive the queen reaches her maximum of laying three weeks before the harvest, and the queen in the large hive increases up to the harvest. That makes the big difference in the number of harvesters.

Somewhat different conditions prevail in working for comb honey. It is desirable that when the harvest begins the brood-combs shall be as full as possible of brood, and kept full. This is more easily accomplished if the queen has been somewhat restricted in her laying by a small hive, for in that case her laying powers will not be exhausted, and the brood-combs will be occupied with brood, forcing the honey into the sections.

Australia vs. America.—American bee-keepers sometimes envy the bee-keepers of Australia when they read of the big yields obtained; but Australian bee-keepers have troubles of their own. The honey-yielding trees that bear so conspicuous a part are being cut down or ruthlessly killed by ring-barking; the London market does not take kindly to Australian honey; and prices in the home market are very low. The *Australian Bee-Bulletin* says:

"We know a bee-keeper whose word may be relied on, and he tells us he has been out of pocket £100 a year for five years."

It seems to us that the bee-keeper mentioned must have had to draw pretty heavily on what has been called in this country "the bee-keeper's bank account"—Hope.

Jamaica, we learn from the *American Bee-Keeper*, contains 4,207 square miles, and is located only 90 miles south of Cuba. The census gave the population as 14,692 whites; 121,955 hybrids; 488,624 blacks; 110,116 coolies; and 481 Chinese.

Mr. E. M. Storer, the correspondent furnishing the above information, says he thinks bee-keepers in the United States need not fear Jamaican competition, as the country is too small for its honey product to be of sufficient importance in the world's markets.

Have Italians Longer Tongues?—An editorial in the *British Bee Journal* says:

"Regarding the supposed longer tongue of the Ligurian bee, most bee-keepers of experience now look on it as an exploded fable."

"**Honey Calendar**" in place of Almanac—Sample free.

The Weekly Budget

MR. W. J. CRAIG, as previously announced in these columns, is the new editor of the *Canadian Bee Journal*. We

are permitted to show herewith a picture of our new editorial friend. Londonderry, Ireland, was his birth-place. He went to Canada some ten years ago, and there met Mr. R. F. Holtermann, who taught him bee-keeping. He has been employed for some years by the Goold, Shapley & Muir Co., and naturally falls into the editorial chair. We bespeak for Mr. Craig a royal welcome among the Canadian readers of bee-literature, and also a successful career as a bee-paper editor.

MR. G. M. DOOLITTLE is offered the following suggestion by Mr. John Suter—a bee-keeper in New York State:

"EDITOR YORK:—Please tell Mr. Doolittle to keep a few bees; they are good for rheumatism."

Mr. Doolittle, we believe, has been suffering from rheumatism, so Mr. Suter's hint ought to be acted upon!

LATER.—Here comes another good friend, from the State of Washington, Mr. R. G. Haun, who also wishes to do Mr. Doolittle a "good turn":

"By the by, tell that 'boy' Doolittle to buy 25 cents' worth of oil of wintergreen, take three drops on sugar four times a day for eight or ten days, and it will do him more good than any amount of bee-stings."

Mr. Doolittle might act on both of the above suggestions—take the oil of wintergreen internally and the bee-stings externally. Still, the concussion caused by their meeting might not be so beneficial to the patient. But Mr. D. can experiment "along that line" and find out.

GLEANINGS IN BEE-CULTURE has just given us a kind notice, as well as a place among its collection of illustrations. We appreciate the courtesy and honor, especially the following paragraph, which appeared in connection with the picture of this pencil-pusher:

"The 'Old Reliable' was purchased by Mr. York of Thos. G. Newman at a time when the latter was steadily declining in health, and found it necessary to seek a change of occupation and location. While the *American Bee Journal* has always been a standard publication, it now stands head and shoulders higher than it ever did before. Always typographically neat, always punctual, a practical, up-to-date weekly, it fills a niche by itself, for no other bee-paper has 'sand' enough to make weekly visits."

HON. GEO. W. WILLIAMS, while on a visit recently to Higginsville, Mo., gave a lecture on bees to the school children. The *Progressive Bee-Keeper* says: "Mr. Williams is a pleasing and gifted lecturer, and we hope other localities will try to secure him for giving bee-talks to the school children."

Getting Bees Out of Box-Hives.
—An old plan given years ago is brought freshly to light in the German bee-journals: Invert the hive in a tub; then pour in water slowly.

Face all Hives the Same Direction.
—F. J. Davis prefers hives facing west for winter, and especially prefers to have all hives face in the same direction. He says that if part face east and part face west, the bees of the hives facing east are attracted by the afternoon sun to play with their western neighbors, resulting in their remaining altogether, thus strengthening the western ones to the damage of the easterns.—Canadian Bee Journal.

Lace-Edging of Sections is much practiced in England. The lace paper hides the edge of the comb, so that it cannot be seen whether the cells next the wood are sealed or not. The amount of paper is sometimes carried to such extent that a rule has been made for exhibitions that 3 1/4 inches square must be left uncovered by the paper. W. Woodley says an exhibit of his was disqualified by an encroachment of 1-16 inch on the 3 1/4 inch space.—British Bee Journal.

Does the Size of Hive Influence Swarming? is a question asked by the editor of the Australasian Bee-Keeper. He says, "I am rather inclined to believe locality, surroundings, and manipulation have more to do with it than size of hive," and calls for the experience of others. Some one lately in this country—wasn't it Critic Taylor?—advanced the idea that there was more swarming with large hives, because they had larger populations, and large population was an important cause of swarming.

A New Kind of Honey-Dew. F. Greiner thinks he found last August, as he reports in Cleanings in Bee-Culture. The bees were roaring on honey-dew from chestnut, oak, and hickory, which seemed to be of the ordinary kind, with abundance of aphides present, while another kind of better quality and less quantity was found on pear trees. For some reason the bees paid less attention to this latter. Aphides were absent, and the honey-dew seemed to be in drops at the point where the stems of the leaves joined the stock. That looks as if the honey-dew exuded at that point, only the drops had a concave instead of a convex surface.

The Munday Frame is described in Australasian Bee-Keeper. It has the same depth as the Langstroth, and is about 3/4 as long. The top-bars are 1/4 inch thick and 1-7-16 wide, fitting closely together, frames running parallel to the entrance, the only place for the bees to get from the lower to the upper story being between the front wall of the hive and the first top-bar, and also between the back wall and the last top-bar, besides at the ends of the frames. Ten frames are used in a hive. Among the advantages claimed are these: No brace or bur combs; no pollen and no discolored comb in the honey-chamber; no draft thru the brood, but plenty of ventilation by way of the sides of the hive; if the cover is blown off, the bees will be all right for days without it, as the tight-fitting top-bars answer for a cover.

Badly Masht Comb Honey.—We lately received a shipment of comb honey, and in this was a lot that was about as badly masht as it could be. Some of it was so jammed and mangled, if I may use that word, that it was not even fit to put out for chunk honey. The better part of it we

SWEET CLOVER

And Several Other Clover Seeds.

Root's Column

GLEANINGS IN BEE-CULTURE.

Our NEW YEAR'S NUMBER is not behind those that have lately appeared. Among the special features is an illustrated poem by Alice Lena Cole, from the Century Magazine; also SUB-EARTH VENTILATION AND OUT-DOOR WINTERING.

COLORADO AS A BEE-COUNTRY. SUPPLIES FROM THE STANDPOINT OF COLORADO BEE-KEEPERS.

SUPERIOR BREEDING-QUEENS, by J. F. McINTYRE, of California.

TALL SECTIONS, Etc., by J. E. CRANE, of Vermont. A VISIT TO A CUBAN APIARY.

G. M. Doolittle, of New York, will continue, as heretofore, to give us the best from his pen on "Answers to Seasonable Questions." The illustrations will be of the same high order as in the past.

We have a few special offers to make to NEW SUBSCRIBERS ONLY, and with these conditions: You will mention this paper when you make your order, and specify the OFFER NUMBER as we indicate below:

Offer No. 11—All for \$1.00.

Gleanings in Bee-Culture, one year.....\$1.00
The Prairie Farmer, one year.....1.00
The Poultry-Keeper, one year......50

Regular price for all.....\$2.50
(If you wish we will substitute the Reliable Poultry Journal.)

Offer No. 12—All for \$1.25.

Gleanings in Bee-Culture, one year.....\$1.00
The Prairie Farmer, one year.....1.00
Maple Sugar and the Sugar Bush, 1 copy......30

Regular price for all.....\$2.30
(If you wish we will substitute Winter Care of Horses and Cattle.)

Offer No. 13—All for \$1.75.

Gleanings in Bee-Culture, one year.....\$1.00
McClure's Magazine, one year.....1.00
The Prairie Farmer, one year.....1.00

Regular price for all.....\$3.00
(If you wish we will substitute the Cosmopolitan for McClure's Magazine.)

Offer No. 14—All for \$2.00.

Gleanings in Bee-Culture, one year.....\$1.00
The Prairie Farmer, one year.....1.00
The A B C of Bee-Culture, one copy.....1.20

Regular price of all.....\$3.20

THE PRAIRIE FARMER is one of the leading agricultural weeklies of the West and gives a vast amount of reliable information, and while we are able to offer it at a low price there is nothing cheap about it. If you are not familiar with the paper, write at once to the Prairie Farmer, Chicago, Ill., for a sample copy.

RELIABLE POULTRY JOURNAL, of Quincy, Ill., and the POULTRY KEEPER, of Parkersburg, Pa. (both monthlies) are leading poultry journals, and you will make no mistake in selecting either of these.

McCLURE'S MAGAZINE and the COSMOPOLITAN are too well known to need any comment. WINTER CARE OF HORSES AND CATTLE is T. B. Terry's second book in regard to farm matters; but it is so intimately connected with the potato book that it reads almost like a sequel to it. If you have only a horse or a cow it will surely pay you to invest in the book. It has 44 pages and 4 cuts.

MAPLE SUGAR AND THE SUGAR BUSH is a most valuable book to all who are interested in the product of our sugar-maples. No one who makes maple sugar or syrup should be without it; 44 pages, fully illustrated.

THE ABC OF BEE-CULTURE, the only encyclopedia on bees, has already been described in this column. About 2,600 copies of the last edition have been sold since it came from the press late in September. Specimen pages of this free.

Watch for our announcement in this column next week.

THE A. I. ROOT CO.,
MEDINA, OHIO.

placed in wooden butter-dishes, and sold for chunk honey. The rest we put into a large cheese-cloth bag and then suspended it over a tub. It hung thus over night, and the next morning the liquid portion of the honey had all run out, leaving practically nothing but dry combs and pieces of combs in the sack. Of course, if there had been sealed honey it would not have drained; but that to which I refer was so badly smashed there were no cappings over the cells. The particles of wax floated on the surface of the honey, leaving the clear liquid portion of it to settle at the bottom, and strain thru the cheese cloth. In the morning, we had a bag of dry bits of comb, or almost dry, and a tub of clear extracted honey.—Gleanings in Bee-Culture.

How do Worms Get Into Sections?—When worms are found on sections that are sealed up tight immediately upon being taken from the hive, it is said the bees carried the eggs there on their feet. Does that look reasonable? Are the eggs in places where the feet would touch them? Would they stick to the feet? Pull the head off a moth, and almost immediately it begins to feel around with its ovipositor for an angle or a crack, not laying till it finds one. Are not the little worms on the sections first found at an angle? Considering what an artful dodger the moth is, how swift in its movements, and how constantly trying to get into a hive, is it not more reasonable to suppose that it has dodged its way thru the hive and made its way into the super?—Gleanings in Bee-Culture.

Getting Unfinished Sections Cleaned Up.—D. W. Heise says in the Canadian Bee Journal:

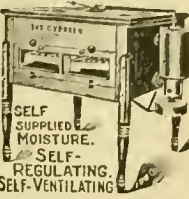

"What I have found the most rapid plan of getting such cleaned up, is to set the supers containing the sections or frames right out in the open, 'with certain precautions,' and let the bees rush into them pell-mell. The precautions are, place the combs or sections at least 1½ inches apart in the supers, place the supers about 100 yards from the hives about 4 o'clock p.m., and then only as many as you think the bees will clean up that day. Don't remove those cleaned supers until you replace them with others at 4 p.m. of the following day, and so on until all have been treated by the bees. After all are clean don't remove the empties suddenly, but gradually decrease them day by day until the last one disappears, and you will find the whole job expeditiously completed without any violence having been done to the most delicate comb, unless perchance some should contain candied honey. Neither will you find any robbing, nor excitement after the job is completed. The only thing that bee-keepers have to fear by any of the 'let at plans,' is the spreading of disease. If any of the deadly germs should be lurking in the honey, and it is for this reason that I would strongly advocate setting out along towards evening, thereby decreasing the chances of bees coming from other apiaries. As to the theory of 'once a robber always a robber,' I take no stock in that whatever."

Colonies Differ as to kinds of Honey and Wax.—Speaking as to this, W. Hessel Hall says in the Australian Agriculturist:

"If clover and dandelion are both out and secreting honey at the same time, the bees do not flit from one to the other, but the bee that starts to work on clover continues to visit clover as long as the supply of clover honey lasts; and the bee that starts on dandelion, sticks to dandelion. The legs of the one will always be found covered with the dull greenish pollen of the clover, and the legs of the other with the bright yellow of the dandelion. This peculiarity usually applies to the hive as well as to the individual bee, and it is quite a common thing in the apiary to find one hive filled with one type of honey, another alongside it filled with a totally different honey, and a third with yet another kind, all gathered within the same period. Indeed, the preference

shown by certain colonies for certain flowers is often very markt. In the writer's apiary, at Lapstone, when the maize crops and the (red) bloodwood are in bloom at the same time, certain colonies can be relied upon to fill their hives with the pale, mild, sweet maize honey, and others with the rich yellow, glutinous honey of the bloodwood; and in this case it is remarkable that even the wax secreted by the bees after eating the two types of honey will be different. The new comb wax from the colony working on maize will be pure white, and tender and crumbly to the touch; while the wax in the hive of the colony working on bloodwood will be a bright yellow, and tougher in texture."

Report for the Past Season.

Bees did poorly in this locality the past season. I had eight colonies, spring count, increased to 10, and got only 150 pounds of comb honey, which sold for 15 and 20 cents per pound. Quite a few bees are kept here, but most of them in a go-as-you-please way and no surplus is gotten by such management.
M. P. LOWRY.
Armstrong Co., Pa., Dec. 18, 1899.

Honey Crop Short.

I commenced keeping bees in frame hives in 1895, and subscribed for the Bee Journal also. I then had 13 colonies, but I have increased to 70 now. I could have had more, but I have been keeping down increase by giving them shade, room, ventilation, etc., honey being my chief object. The honey crop was short here the past season. I obtained only 1,600 pounds, in one pound sections from 47 colonies, spring count. I use the tall sections and like them better than the square ones.

What I have learned thru the columns of the American Bee Journal the last five years has been worth a great deal more than I paid for it, so here is my \$1.00 for 1900. May the year 1900, be the most prosperous year on record for the American Bee Journal, is my wish.
V. V. ROUSH.
Adams Co., Ohio, Dec. 16, 1899.

Pretty Well for a Side-Issue.

My bees did very well this year. I use the 8-frame Langstroth hive, and run them entirely for comb honey. I have 35 colonies that produced 4,000 pounds of honey, which brought 14 cents a pound in the St. Louis market. This does very well for a side issue, and I attribute my success to the American Bee Journal.
JOHN FLEMING.
Calhoun Co., Ill., Dec. 12, 1899.

A Pennsylvania Report.

Last spring we had every reason to expect a large yield of honey, especially those who had taken proper care of their apiaries. Of course, there were some losses in wintering, and in apiaries where there are many losses the bees that do get thru are generally in a weak condition, and so much is not expected. Tho the winter had been severe, cared-for colonies came thru strong, and the early blossoms were abundant, and never in the more than 15 years of my bee-keeping have the bees done quite so well in building up as last spring. Never, to my recollection, was there such an abundance of elm and maple bloom. Fruit-bloom was not so profuse. But, alas, white clover bloomed abundantly, but no honey. Basswood bloomed well, but it was too cold and wet.
What white honey there is brings 14 to 16

24 cents Cash paid for Beeswax.

This is a good time to send in your Beeswax. We are paying 24 cents a pound—CASH—for best yellow, upon its receipt. Now, if you want the money PROMPTLY, send us your beeswax. Impure wax not taken at any price. Address as follows, very plainly,

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO.

cents wholesale; fall honey 12 cents, and in demand. Extracted honey, that is strictly fine, sells for 12 cents to customers who appreciate a good article. The yield per colony was from nothing, in some apiaries, to about one-third of an average crop. There was but little strictly first-class white honey. One thing encouraging about the "luck" is that bees have gone into winter quarters with plenty of good stores.

GEO. SPITLER.
Crawford Co., Pa., Dec. 13, 1899.

Her First Year of Bee-Keeping.

This is my first year at keeping bees. I bought one colony last spring, and I got 48 pounds of comb honey from it, and built up another little colony that we bought Aug. 1, so there are two good colonies now. The first colony I paid \$8 for; the second, \$2. Sept. 11 I bought three colonies for \$18. I had to feed some in October. I bought another colony for \$6; it is very small, so I took out three of the brood frames and packed woolen carpet on each side, and fed syrup until it filled the five combs about four-fifths full.

We have had a dry, warm fall, and my bees are flying to-day. They are on the summer stands yet, but I will put them in a frame house when the weather turns cold. I have all the hives covered with carpet.

We have 36 acres of alfalfa clover. I want to sow all kinds for the bees. We are ten miles from town, and five miles from other bees.

I planted some mignonette in the garden, and the bees work on it until frost, which was Oct. 22. I saved a pound of seed to sow next spring. MRS. BEN. FERGOUSON.

Ford Co., Kan., Dec. 1, 1899.

Last Winter Cold for Bees.

My bees are getting along first rate so far. They averaged 75 pounds of honey per colony. I had only four colonies. I am wintering only two colonies, as one died, and the other I killed and sold the honey for 15 cents per pound.

All the bees in this neighborhood froze out last winter. I had seven colonies packed with two feet of straw all around them, still they froze. They all had honey left. I saved two colonies out of seven. I think packing is a humbug. It was so cold here last winter that if you would take a bucket of water and spill it, it would freeze just as soon as it touched the ground. It was 40 degrees below zero for about a week. The ground was cracked and everybody's potatoes froze. It was the coldest known here in 45 years. B. F. SCHMIDT.

Clayton Co., Iowa, Dec. 8, 1899

Introducing Queens, Etc.

We are having pretty nice weather here. The bees are still flying a great deal of the time. Sept. 2 I got a premium queen which I caged for eight days on a one-pound section of honey on which I put wire screen on each side so she was secured safely. I then took out a center brood-frame, cut out a piece of the comb in one corner of the frame as big as the section, and then inserted the section on the bottom-bar; I then tightened a piece of wire around the frame to have it all secure, as the bees kept on building queen-cells. I left her that way till the seventh day, then took the queen, put her into the old Peet cage, as the bees showed anger every time I opened them, and left the job for the bees to release her themselves. The next day they had her released and accepted her all right. I tell you, she is the finest breeder I ever saw, and her bees are just yellow all over. They are just like queens themselves. I would not take \$2.00 for her.

How is this? Some years ago I had my bees away from home. I was down looking at them the latter part of August, and found, to my surprise, an after-swarm hatching perfect workers except the heads, which were just like drones' heads. The

THE 20TH CENTURY POULTRY BOOK

is undeniably the best and most instructive publication of its kind ever issued. It opens up with a resume on the size and magnitude of the poultry industry and follows with "Poultry Raisings on the Farm," "Poultry and Incubators on the Farm," "Feeding Specially for Eggs," "Raising Broilers for Market," "Successful Egg Farming," "Cups for Profit," "The Pekin Duck Industry," etc., etc. It tells incidentally about the old standard **RELIABLE INCUBATORS AND BROODERS** and the results their use have produced, the success to which they have helped their users, etc. Tells all about the new "wrinkles," new improvements, new machines, etc. We send the 20th Century Book to all

inquirers on receipt of 10 cents to cover postage. **RELIABLE INCUBATOR & BROODER CO., BOX B-2 QUINCY, ILL.**

Experience the Best Teacher.

But a wise man profits by the experience of others. Every farmer and dairyman needs a practical, helpful paper like

Dairy and Creamery

PUBLISHED AT CHICAGO, ILL.

filled with information gathered from the actual experience of practical and scientific breeders and feeders of cattle and pigs. He wants to know how other men get the best results; how to feed to the best profit; how best to utilize his skim milk; how to build up a first-class dairy from the resources he has; what crops to grow to keep up the flow of milk at all seasons.

Last year a patron of a Kansas creamery who read a dairy paper and kept good cows, made \$36.00 per cow more than the poorest patron of the same creamery who did not read a dairy paper. That means something; it shows the value of an up-to-date, reliable adviser like **DAIRY AND CREAMERY**. (Subscription 50 cts. per year.)

FREE!

We will send **DAIRY AND CREAMERY**, the best semi-monthly paper published for farmers and dairymen, absolutely FREE for one year to all new subscribers to this paper, and to all old subscribers paying their subscription one year in advance. Both papers for the price of one. Send your subscription to this office while this offer is open. Both Papers \$1.00.

AMERICAN BEE JOURNAL, CHICAGO, ILL.

A Further Offer: We will give Dairy and Creamery for one year as a premium to any one of our readers who sends us one new subscriber to the American Bee Journal for one year at \$1.00. Unless these offers appear again after March 1, in these columns, they will be withdrawn at that date; so you would better take advantage of them at once. Address,

1D4t **GEORGE W. YORK & CO., 118 Mich. St., Chicago, Ill.**

Save Half Your Feed

by cooking the other half. Experienced feeders know that this problem works out to a surety. This is not the only gain in cooking feed however. **All cooked feed is digested** by the animal economy, and none of it passes through whole. Young things grow more rapidly and mature stock fatten more quickly on cooked feed.

The ELECTRIC FEED COOKERS
are undoubtedly the best for preparing the feed. Made from the best gray iron castings, lined with steel plates, with peccol galvanized steel boilers. Three styles, five sizes, 25 to 100 gal. capacity. We publish a **FREE BOOK ON FEED COOKING** which tells all about these and deals extensively with the subject of stock feeding. Send for it.
ELECTRIC WHEEL CO., BOX 1c, QUINCY, ILLINOIS.

Please mention Bee Journal when writing.

bees were then carrying them out of the hive about as soon as they hatcht, as they were then killing off their drones. They were crawling in front of the hive all over on the ground, as they were too young to fly. I lost that colony in the winter, so I had no experience as to what that kind of a bee with a drone head would amount to. Besides the head, they had stings, and were perfect in every way, like the workers. I should say one-third of them were bees like that. Has anyone ever seen bees like that? If so, please let us hear from them, and what the cause is. I was led to think the queen had been detained from her wedding-trip too long for perfect workers.

JOHN PEDERSON.

Chautauqua Co., N. Y., Nov. 30, 1899.

A Beginner's Experience.

Let me give my experience as a beginner in bee-keeping. I am of mature age now. My father kept bees when I was young—I think that's the reason why I always had a liking for bees, and to have some pastime I bought, in 1898, 7 colonies of black bees, and I got "sold" badly. They were in old, homemade boxes, and non-movable frames. I could look in on top and that was all.

Well, I took the hives home and put them on stands, and they were ready for business. By May 1 two had taken French leave; two more were robbed out and followed suit. By this time I got a bee-book and studied it, and found I had made a bad mess of it so far. I got new, modern, 8-frame hives, with full sheets of foundation,

to put new swarms in. I had two prime swarms and four after-swarms, the after-swarms coming out close together. I united them in two hives; this gave me four strong colonies in modern hives. Two I gave Italian queens. I was unable to find the old queens myself, so I got a doctor who also keeps bees to find them for me.

Fall came, but no honey for me; but all except one were well supplied for winter, and the one I fed. My cellar is cold but dry, the south wall being above ground. I put Hill's devices and chaff cushions over the bees, in a super, and raised the hives about 1½ inches from the bottom-board. When the cold snaps came, and the thermometer went down to the freezing point, I put a large kerosene lamp in the cellar, and this raised the temperature five or six degrees, but the thermometer was never above 40.

April 10 I took the bees out; they were all alive and strong, all having plenty of honey except one, and three days afterwards they had from two to three frames well filled with eggs.

Bee-keepers in this neighborhood lost heavily last winter—one lost all, and others from one-third to a half. None read a bee-paper but the doctor.

My bees went to work in fine shape. About May 1 I transferred the three old colonies to modern hives, and thereby lost one queen. I gave them a frame with eggs from my Italians, and they soon had a hybrid queen. By June 9 the first swarms came. After the black bees had swarmed I cut out all queen-cells and gave them one

of my Italian queen-cells in a cell-protector. Thus I have all but five Italians or hybrids. One Italian colony gave me four supers full of honey, but had little honey below. Seven colonies, spring count, gave me 300 pounds of comb honey, and I increased to 16. No other bees have done as well here. My bees are now in the cellar, packed the same as last winter.

This success I attribute to reading the American Bee Journal and bee-books. The old bee-keepers around here are surprised at my success, and are asking me now for advice. But to take a bee-paper in order to be informed on this matter is above their comprehension! H. G. WALKER.

Stearns Co., Minn., Dec. 7, 1899.

Two Young Laying Queens in Hive.

Has anyone ever found two young, laying queens in one hive? I found two such in one hive, and they had been there long enough to have eggs and hatching brood in the hive. The hive had 14 frames, and the queens were settled in the opposite ends of the hive. I know they were both young queens, because the old one was clipped, and there was plenty of evidence that she had been superseded.

I started in with 43 colonies, spring count, and got 700 pounds of comb honey, which I sold at 12½ cents, and could have sold 10 times as much. I also increased to 58 colonies, all in splendid condition for winter. I winter bees on the summer stands. I lost eight colonies last winter, three being queenless, and the balance from bad feed (honey-dew). By the way, it looks as if the "bug-juice" theory is getting a black eye. I never could believe in that theory. It certainly could not be the natural product of the body, and, if not, then they must gather it from some source like bees do.

I am nearly 67 years old, and it won't be long until I will have to give up my bees, and none of my family can take my place with them. R. R. STOKESBERRY.

Vermillion Co., Ind., Dec. 12, 1899.

TO MAKE BROILERS GROW
 feed them on Green Cut Bone. It is the greatest flesh forming food known. Fed in combination with freshly cut clover it produces both growth and that fine flavor so much sought by epicures. Quick growth, large size and fine flavor mean good prices.
MANN'S NEW BONE CUTTER
 prepares Green Cut Bone in the best form for broilers. They cut fast, fine and easy and last long. Many sizes. Mann's Clover Cutters, Mann's Granite Crystal Grit and Swinging Feed Trays make success sure. Catalogue Free.
 F. W. MANN CO., Box 77, Millford, Mass.

 SURE HATCH INCUBATOR COMPANY, Clay Center, Nebr.

Comb Foundation
 made by a new sheeting process of my own, which produces a clear, transparent and pliable foundation, that retains the smell and color of wax.
Working Wax into Foundation for Cash a Specialty.
 I also carry a full line of SUPPLIES, and can furnish anything in any quantity at bottom prices—wholesale and retail. 1900 Catalog will be ready soon. Send me your name and let me know your wants.
 GUS. DITTMER, Augusta, Wis.
 Beeswax Wanted.

ELECTRIC
 WE PRESENT herewith a cut of the Electric Sweep Feed-Mill which is manufactured by the Electric Wheel Co., of Quincy, Ill. This Mill, introduced this season for the first time, is the direct result of repeated demands made upon the manufacturers by the many farmers all over the country who are using other Electric goods, and who, finding those so entirely satisfactory, urged the manufacture of a mill also. The "Electric" embodies in its plan and construction all the latest principles, modern, economical grinding of feed for stock. It is without gears of any kind and does not absorb or waste any power by that method. It is equipped with a double set of brakes, which effectually break up and reduce the ear-corn before passing it on to the burrs. The burrs are made of specially hardened white metal, smooth and sharp, and capable of long-continued service. The mill is easily adjusted to grind coarse or fine, and besides grinding ear-corn, will also grind all small grains singly or mixt. For very fine work an extra set of burrs are provided. Write the Electric Wheel Company for booklet on Feed Grinders, and say you saw their advertisement in the American Bee Journal.

Queen-Clipping Device Free...
 The MONETTE Queen-Clipping Device is a fine thing for use in catching and clipping Queens' wings. We mail it for 25 cents; or will send it FREE as a premium for sending us ONE NEW subscriber to the Bee Journal for a year at \$1.00; or for \$1.10 we will mail the Bee Journal one year and the Clipping Device. Address,
 GEORGE W. YORK & COMPANY,
 118 Michigan St., Chicago, Ill.

Convention Notices.

New York.—The annual meeting of the New York State Association of Bee-Keepers' Societies will be held in the parlors of the Kirkwood, at Geneva, N. Y., Jan. 10, 1900, at 11 o'clock a.m. All bee-keepers' societies in the State are hereby notified and requested to send delegates. An urgent invitation to attend is also extended to everybody interested in apiculture.
Chapinville, N. Y. W. F. MARKS, Pres.

N. E. Ohio, N. W. Pa.—The Northeastern Ohio and N. W. Pennsylvania Bee-Keepers' Association will hold their 19th annual convention at Andover, Ohio, in Chapman's Hall, Jan. 17 and 18, 1900. Boarding rates of \$1.00 per day have been secured for those attending the convention. All bee-keepers invited. Send to the Secretary for programs.
Franklin, Pa. ED JOLLEY, Sec.

California.—The tenth annual convention of the California State Bee-Keepers' Association will be held in the Chamber of Commerce, at Los Angeles, Feb. 21 and 22, 1900. It will be called to order at 1:30 p.m., Feb. 21. At this time the railroads will sell round-trip tickets to Los Angeles and return for one and one-third fare, on account of the Industrial, Mining, and Citrus Exposition, which will be held in Los Angeles. Tickets good for 10 days. Let every bee-keeper bring some hive, tool or experience that he has found valuable, and we will have a good convention.
J. F. MCINTYRE, Sec.
Sespe, Calif.

Minnesota.—The Southern Minnesota Bee-Keepers' Association will meet in Winona, Jan. 23 and 24, 1900. The program will be as follows: Opening address, by Pres. E. B. Huffman; "Best Strain of Bees for this Locality," by John Turbull; "Bee-Pasturage," by Peter Oech; "Managing Swarming," S. W. Judge; "Best Size of Hives," Wm. Berthe; "Production of Comb Honey," Frank Yahuke; "Extracted Honey," E. C. Cornwall; "Tall Sections vs. the Square," W. K. Bates; "Marketing Honey," Fred Oech; "Rearing Queens," C. A. Gile; "Cause of Loss of Bees in 1898 and 1899," J. A. Gates; "Bee-Supplies," W. H. Bright; "Lady Bee-Keepers," Mrs. P. Dickson; "Wintering Bees," C. Theilmann.
Homer, Minn. E. B. HUFFMAN, Pres.

Wisconsin.—There will be a joint convention of all Wisconsin bee-keepers' societies at the 16th annual meeting of the State Bee-Keepers' Association, Feb. 7 and 8, 1900, in the State Capitol, at Madison, Wis. Many prominent bee-keepers will be there and take part, among them: Jennie Towle, of Clarke Co.; Miss Ada Pickard, of Richland Co., who alone in 1898 had 16,000 pounds of honey from 100 colonies of bees; George W. York, editor of the American Bee Journal, will deliver an address on "Honey, from the Hive to the Table;" Herbert Clute will show the advantages of Clark County for bee-keeping; "Dots by the Wayside," by J. Hoffman; "The Section-Box for Wisconsin Honey," by J. J. Ochsner; the State Inspector of Apiaries will report, and there will be a lively debate on "Spring Management of Bees," by the Vice-President and Treasurer of the State Association. The free-to-all question-box and answers will be a prominent feature, and valuable. There will be a big display of supplies of all kinds, several new and valuable. The American Biscuit Co. use tons of honey in their bakings, and will have a full line of such bakings there on exhibit.

Excursion rates of a fare and one-third for the round-trip, for railroad tickets purchasable in the State, for over 50 cents each. Be sure to bring a certificate of each ticket purchasable so it can be signed Feb. 8, in Madison, and entitle the holder to a third fare return.

The State Horticultural and State Cheese-makers' Associations will meet on the same date in the Capitol.

Don't forget the date—Feb. 7 and 8. It will pay you to attend.
N. E. FRANCE, Sec.
Platteville, Wis.

Bee-Keepers' Photograph.—We have now on hand a limited number of excellent photographs of prominent bee-keepers—a number of pictures on one card. The likeness of 49 of them are shown on one of the photographs, and 121 on the other. We will send them, postpaid, for 30 cts. a card, mailing from the 121 kind first; then after they are all gone, we will send the 49 kind. So those who order first will get the most "faces" for their money. Send orders to the Bee Journal office.

BEE = BOOKS

SENT POSTPAID BY

George W. York & Co. 118 Mich. St. Chicago.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopaedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers, \$1.00.

Bienen-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey," 100-page pamphlet. Price, 25 cents.

Bienenzucht und Honiggewinnung, nach der neuesten methode (German) by J. F. Eggers.—This book gives the latest and most approved methods of bee-keeping in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cts.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cts.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 20 cents.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about Poultry Business. 64 pages. Price, 20 cents.

York's Honey Almanac is a neat little 24-page pamphlet especially gotten up with a view to creating a demand for honey. A very effective helper in working up a home market for honey. Prices: A sample for a stamp; 25 copies for 40c; 50 for 60c; 100 for \$1.00; 250 for \$2.25; 500 for \$4.00. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, Dec. 12.—We quote best white comb at 15c; an occasional small lot of fancy sells at 16c; off grades of white, 12@14c; ambers, 10@12c. Extracted, 8@9c for fancy white; 7@8c for amber; 6@7c for dark grades.

Receipts are larger and the demand is not as good as it has been; most of the retailers have laid in a supply to carry them over the Christmas time.
R. A. BURNETT & Co.

CINCINNATI, Dec. 7.—There is a good demand for all kinds of extracted honey. White clover and basswood sell at 8@8½c; amber and Southern, 6@7c, according to quality and package. Fancy comb honey in no-drip shipping-cases sells at 15@16c; darker grades hard to sell at any price. Beeswax, 26c. C. H. W. WEBER, Successor to Chas. F. Muth & Son and A. Muth

KANSAS CITY, Dec. 9.—We quote No. 1 white comb, 13½@14c; No. 2, 13@13½c; No. 1 amber, 13@13½c; No. 2, 12@13c. Extracted, white, 7½@8c; amber, 7@7½c; dark, 5½@6c. Beeswax, 20@22c.
C. C. CLEMONS & Co.

NEW YORK, Dec. 10.—Demand is very good for all grades of comb honey. Receipts are somewhat light and not up to former years. We quote:

Fancy white, 15 cents; No. 1, white, 13@14c; amber, 11@12c; and buckwheat, 9@11c., as to quality. Extracted remains firm at following prices: California white, 8½c; light amber, 8c; white clover and basswood, 8c; amber, 7½c. Very little trade for extracted buckwheat as yet. Southern, fancy, 7½c per pound; other grades, as to quality, from 70c to 75c gallon. Beeswax quiet at 26@27c. HILDRETH & SEGELKEN.

SAN FRANCISCO, Dec. 20.—White comb, 11½@12½c; amber, 8@10c. Extracted, white, 7½@8c. Light amber, 7@7½c; amber, 5@5½c; Beeswax, 26@27c.

There is no chance for extensive trading in this commodity at present, supplies having been reduced to small proportions. A sailing vessel clearing the past week for England carried 125 cases extracted. Prospects for coming season's yield are considered very good for this early date.

CLEVELAND, Dec. 1.—Fancy white, 16@17c; No. 1 white, 15@16c; No. 1 amber, 13@14c; No. 2 amber, 12@13c; buckwheat, 9@10c. White extracted, 8@9c.
A. B. WILLIAMS & Co.

BOSTON, Dec. 8.—We quote as follows: Fancy white, 16c; A No. 1, 15c; No. 1, 13@14c; buckwheat will not sell in this city. Extracted, light amber, 7@8c.

There is very little now to report in the line of our honey market. The retail trade are loath to pay the higher prices and are buying in a very small way, still the demand is fully equal to the supply.
BLAKE, SCOTT & LEE.

ALBANY, Dec. 10.—We quote: Fancy white comb, 15c; No. 1 white, 13@14c; mixt, 11@13c; buckwheat, 10@11c. Extracted, white, 8@9c; mixt, 6½@7c; dark, 6. Beeswax, 26@28c.
MACDOUGAL & Co.

Successors to Chas. McCulloch & Co.

OMAHA, Dec. 11.—The November trade has up to the present not been as good as was expected, and shows a falling off from October. It seems that the somewhat higher prices this fall are affecting the consumptive demand to some extent, still the warm weather yet prevailing in this part of the country may also be partly responsible for it. While trade has been light, prices have been well maintained, nobody being burdened with stock to such an amount as to become oppressive.

Fancy white still going at 14@14½c, and light amber 1 cent less. Extracted, white, 8@8½c.
PEYCKE BROS.

DETROIT, Dec. 11.—Fancy white, 15@16c; No. 1, white, 14@15c; dark grades, 10@12c. Demand good and supply light. No extracted in market. White would sell for 8@8½c. Beeswax, 23@24c.
M. H. HUNT & SON.

WANTED.—Extracted honey all kinds; mail sample and price expected delivered at Cincinnati. I pay spot cash on delivery.
C. H. W. WEBER,

Successor to Chas. Muth & Son and A. Muth.
404½ 2146-48 Central Ave., Cincinnati, O.

CONTRIBUTED ARTICLES

Keeping Bees as in the Old Country—Ventilating Langstroth Hives.

BY JOHN R. SCHMIDT.

THIS article is the result of a stroll with my camera out among some of the bee-keepers of Cincinnati. The desire generally strikes me about the time of the year when our honey season is over. No special route is laid out, but just to go out and find some one who keeps bees, and to learn his ideas of bee-keeping, and what result was obtained under his management. Most bee-keepers generally have some hobby, or special way of managing their bees, which they think is the best and only correct way of getting a good crop of honey. No doubt many of these ideas are good, for just such ideas finding their way into our bee-literature are combined either wholly or partly by some bright bee-keepers, and as a result we have as to-day the advanced methods of modern bee-keeping.

Two of these ideas, which I am about to describe here, attracted my attention more than usual, so I promptly adjusted my camera and "fired away."

One pleasant Saturday afternoon, being inclined to take one of these trips, I packt my camera, and as it was only a few hours until dark, my trip necessarily had to be a short one, so I decided to call upon Mr. C. H. W. Weber. As Mr. Weber carries on quite an extensive business it is necessary for him to be located in the city—yes, "right in it"—that expresses it exactly, and he is "in it" in more ways than one, for he also has his apiary of 32 colonies in the city on the roof of his store.

After talking bees for some time, Mr. Weber said: "Come up, and I will show you my bees now"—having seen them a few weeks before. So we started to climb stairs, and after climbing three flights we turned to our right, and there we could view that "city roof-apiary," which has been mentioned so often in our bee-literature, as it was formerly owned by the late Chas. F. Muth.

After keeping bees on this roof for many years with perfect success, Mr. Weber says he is going to arrange them all differently, and has a plan which will protect his bees from the extremes of heat and cold, to which they are subject.

Taking me to one side of the apiary, he showed me a row of hives which he has just completed in arranging according to his plan (see photograph). This row is composed of regular dovetailed hives about five inches apart. They are securely incased, excepting the front, with 7/8-inch boards up to the top of the brood-chambers, a space of about five inches being left all around the hives, and this space is tightly packt with chaff or planer-shavings. After they

are packt, boards are fitted in the space between the hives even with the top of the brood-chambers, to keep the packing dry, and make them all rain and snow proof. So far this is nothing more than chaff hives, only on a different plan, but you will notice in the photograph that there is an additional roof over the hives, and is also boarded up in the rear.

The top part of the rear is hinged, and may be raised to allow the sun to shine on the top of the hives in early springtime. During winter, when the cold, unbroken western winds sweep over the house-tops, this arrangement is closed down securely, and the hives are thoroly protected. Weak colonies with plenty of stores will winter just as well as strong ones, and, in fact, every hive in the row will be of uniform temperature, as the heat radiates from one to another thru the chaff between the brood-chambers. The additional roof over the hives is to protect them during the middle of hot summer days.

After explaining the advantages of such an arrangement, Mr. Weber said, in his good-natured German way,

Portion of a Cincinnati Roof-Apiary.

"That's the way they keep bees in the old country." (With emphasis on "that's"). I askt him if he wouldn't have trouble with queens entering wrong hives, as they were all built and lookt exactly alike. He said that as he has only 32 colonies, he can easily know the exact condition of each

colony at all times, and thereby replace any queen which begins to fail. This objection being overcome, I think the plan is worth considering by those who keep bees on roofs, or where chaff hives are considered the best to use.

VENTILATING LANGSTROTH HIVES.

The proper ventilation of regular Langstroth hives with tight bottom-boards during the hot summer days is something which bee-keepers using this style of hive have thought of more or less. This is the way a Cincinnati bee-keeper does it—another idea caught on a different occasion. This also did not escape my camera, but it was a close call—cloudy day, 4 p.m., moving bees, quick exposure, and, as a result, trouble in the dark-room—understand, amateurs? Well, to get down to my subject.

You will notice that the front of the brood-chamber (see photograph) is made of two separate boards, the top one being permanent and coming down to within three inches of the bottom-board. The lower half is movable, and slides up and down just in front of the top one. The stick fastened to this movable board is used to regulate the height of the entrance. When warm weather approaches, and the bees begin to hang out and loaf, this movable lower half is raised somewhat, and the stick acts as a prop, and holds it in place. If the bees still continue to hang out, it is raised still higher, until the desired amount of ventilation is obtained, which seldom requires the full height. The entrance can be completely closed by turning the stick slightly, which allows the lower half to come down and rest on the bottom-board.

This arrangement has been used for a number of years, and the bee-keeper says it gives complete satisfaction, as it ventilates the brood-chamber without allowing the heat to escape from the supers, which is of such vital importance in the production of comb honey.

One objection which may arise from using this method of ventilation is this: If it is used in a locality where the temperature is subject to sudden changes, the bee-keeper may be troubled somewhat with chilled brood if the entrance is left open the full height during a cool night. But there are bee-keepers who say "useless consumers" are reared at this time of the year, when ventilation is needed the most, and, even if the brood is chilled, nothing would be lost. Well, I am not going to start an argument by saying there is no such thing as a "useless consumer," as applied to the worker-bee, but I will say I have often noticed that the hives containing queens which rear the most of these so-called "useless consumers" always come thru the winter strong in bees, and have more honey to their credit at the end of the season.

But coming back to our subject again, we should, nevertheless (even if these bees are considered useless), choose the lesser of the two evils caused by ventilation, and undoubtedly the greater of the two is upward ventilation thru the supers, which method often leaves us with little or no surplus at all. Bees need a uniform heat in the supers for

Simple Device for Ventilating Hives.

the production of fancy comb honey, and it is impossible to get such an article with a draft passing thru or directly beneath the supers—a fact which is being acknowledged by more and more bee-keepers every year.

One more thing I would like to mention before closing,

and that is, I noticed that this entrance saves the bees lots of time, for the incoming bees would alight on the ends of the frames and then pass quickly between them, while the bees in hives having the ordinary entrance spent several seconds before reaching the combs.

Marketing Extracted Honey—Making It a Staple.

BY R. C. AIKIN.

PERHAPS the readers of the bee-papers will think me cranky on the marketing question—I have written so much on this topic. A crank is a very useful thing.

"Oh, we are the cranks to turn the earth
Into the ways of peace and mirth;
Happy side up, sunny side up—
We will ever turn till it's right side up."

That the marketing of extracted honey is yet in its infancy is true, at least as a table sweet. Recently a buyer who handles much honey told me the great bulk of the extracted honey they handled went to manufacturers. If this is true—and I believe it is—is there not a big field for operation in placing extracted honey on the tables of the masses? We have but to recall that when we eat at restaurants, and such places, we do not find honey on the table, and rarely do we find it on the tables of private families outside of bee-keepers. Honey is indeed a luxury, and *extracted honey more so than comb*.

Must we acknowledge that there is by all odds more of comb honey eaten as a sweet than of extracted? It surely looks that way. Mr. E. R. Root, in a paper before the Philadelphia convention, *estimated* that the annual product of comb honey was perhaps 50,000,000 pounds, and that of extracted probably twice as much, or 100,000,000. I also glean from the bee-papers of late, that there are single firms that consume from 200,000 to 300,000 pounds. If such large quantities be used by single manufacturers, surely the great number of firms consuming in baking, and the many other uses to which honey is put in the arts, there must be but a small portion of the 100,000,000 pounds that gets to the table as a syrup. Knowing that the great bulk of comb honey is used on the table, and yet it is a very rare article among the masses, we must conclude that extracted is comparatively unknown to the great bulk of consumers of sweets.

I began here about eight years ago to sell extracted honey, and a few hundred pounds was all that was sold in the community, but now I can sell almost as many thousands as I then did of hundreds. My local trade has increased year by year, until now I can sell almost a carload a year to a village of less than 2,000, together with the surrounding farm community. Even at this rate there are many families who do not use honey, and many others that use it only as a luxury now and then.

That there is a very large percent—yes, the great majority—of our population who do not use honey, is a fact. Those people who do not would use it if it were as *accessible* as other sweets, and compared favorably in price. I make this statement without fear of successful contradiction. I have proven it right here, and others have done the same thing in other localities.

WHY IS HONEY NOT USED?

A business man who is always out of certain goods can not expect a good trade in that line. Honey is *not* kept by even the majority of stores, either comb or extracted, *regularly* and at prices to compare with other sweets of the same grade, while the other sweets are in *all* stores. How long would a store do business if sugar and syrup were not kept in stock, except in cities large enough to run with a limited line in any one store—the various stores making a specialty of certain goods? A common country or village store, and as well the greater part of city stores, could not hold their customers if they did not keep staple sweets. Honey must be kept in stock and offered *regularly* as other goods to be regularly used. These are self-evident truths. Any one who attempts to make a staple sweet of honey, and not keep it in stock, will surely fail. Failure along this line is common—very common—with grocers as well as with bee-keepers, in working up a honey-trade.

Another reason why people do not buy extracted honey is because it is too expensive—there is too much expense between production and consumption. From here to Chicago the present rate on extracted honey is 97 cents per hundred pounds. Suppose I ship 10 cases of honey to any dealer there, and charge him 6 cents f. o. b. here, he pays

97 cents per 100 *gross* weight, which is just about even \$13 on the lot. A lot of 1,200 pounds at 6 cents is \$72; plus \$13 freight, and the honey costs on the car at Chicago 7½ cents per pound.

If the buyer in the city puts his money into the honey he will not want to sell again for a bit less than 10 percent advance, perhaps usually not less than 20 percent. If he were selling to manufacturers in original packages and in large lots the margin may be quite small; but if it goes for table use, and he sells in the original package to go into families by the 60-pound can, there can not be less than 30 percent added—the wholesale dealer 10, and the retailer 20. Cost of honey—10 cases—on car in Chicago, \$85; plus 30 percent for dealers, total \$110.50; or about 9 1/5 cents per pound it costs the consumer.

To repack this honey would cost quite a little, but I scarcely know how much to estimate, much depending upon the equipment for doing the work; we will drop that item and see about cost of packages. The very cheapest tin package will cost at least one cent per pound, while glass packages cost from 3 to 4 cents per pound. This makes the cost of the honey about an average of 12½ cents per pound when it gets to the consumer.

Extracted honey shipt to market in 60-pound cans and repacked for retail trade costs the consumer at least 12½ cents, many times considerably over this—12½ is very conservative. Now buy 6 cents worth of granulated sugar and make a syrup by adding a little water, then place this beside 12 cents worth of honey and see how many customers will buy the sugar rather than the honey. Sugar competes with extracted honey, and there is no use in ignoring the fact.

THE REMEDY IN THE MATTER.

The *producer* must pack his honey in *retail packages* and case it in some way that it may be handled cheaply. One great trouble with apiarists themselves is, first putting up honey in barrels or 60-pound cans, then later repacking it for retail, melting when candied, and also taking back that which candies in stores. All this is piling up cost on the consumer, or reducing the profits of the producer. The producer of extracted honey needs a storage-tank between the extractor and the marketing-package in all cases. After settling, draw from the tank into retail packages, and let it candy as quickly as it will, then sell in the candied condition.

Consumers will buy it candied, and liquefy for themselves, and many want it candied when spread on their bread. People buy new things because they are always wanting "something new," and if 'tis new to buy candied honey they will do it and soon learn to melt it. I sell my extracted honey in lard-pails nicely painted and stenciled—that is, I used to—now our pails are lithographed. This is the cheapest package, and nice, and with the honey candied there is no drip or leak. In my home market the prices are very close to that of granulated sugar, the honey being sold when candied. *I do not put liquid honey in stores*, and my honey sells right along, and is fast becoming a staple.

Larimer Co., Colo.

The Season of 1899—Other Matters.

BY G. W. DEMAREE.

THE past season has been so disappointing to the bee-interest in these parts that one must make a distinction between the "science" and the "practical" in bee-literature and bee-culture in order to feel enough interest in the matter to talk or write on bees.

Last spring, after the Arctic blast of February, the white clover crop showed up more than an average prospect, and bloomed in season in great profusion, and the bees made a splendid start in the section-cases as well as in the extracting-supers; but a wave of heat in the absence of moisture dried up the clover bloom right in the midst of the beginning harvest. And the result was few finished sections, and a great lot partly filled or not touched.

In the past ten years the little white aster—"last rose of summer"—has gained a foothold here in waste places and on old pasture-lands, and the bees store a surplus in the late autumn, if the weather is propitious.

For the last few years I have adopted the plan of leaving the fall surplus on the hives during the winter months, and extract what the bees do not need just before the white honey harvest begins to show a surplus, the following season. In our climate the honey in sealed combs does not granulate in quantity to hinder the work of extracting in

warm weather. This plan carried out in a climate that will permit extracting of carried-over sealed combs insures strictly *clast* honey. The dark honey—fall and spring—is brought together by this management, and the white clover surplus of June and July is strictly pure, after its class. My dark honey is sold as "fall and spring honey" at a reduced price, and all of it is taken by the home trade. The past fall was even too dry and hot for the dronth-proof white aster, and the flow from this source was below the average.

GETTING UNFINISHT SECTIONS CLEANED.

Bee-keepers are still asking how to get unfinished sections emptied and cleaned by the bees. With me it is only a matter of work and proper management. Prepare the section-cases by clipping the capping from any sections that may have been partly sealed; place a bee-escape board on the hive, or hives, that are selected to do the cleaning; remove the escape from its place, and this will leave a pass-way for the bees to enter the section-case of unfinished sections, while the board practically disconnects the case from the hive below. If the work is done just after the honey-flow has past, it will work like a charm.

TIME BETWEEN FIRST AND SECOND SWARMS.

I was of the impression that the question as to the time that intervenes between the first, or prime swarm, and the first after-swarm, under normal conditions, was settled long ago, but it seems that it doesn't stay settled. In the first place, it should be remembered that changeable weather, cloudy, rain-storms, etc., and in the rare cases when bees under sudden excitement swarm before any preparation has begun, does not enter into the question as to the habit of bees under normal conditions in respect of swarming. According to my experience of a quarter of a century in the apiary, the time between the first and second swarms is about ten days.

No cause, or causes, to interfere with regularity; if you open the hive just after the first swarm issues, you will find at least one queen-cell sealed over, indicating that the oldest of the royal developing family is about eight days old, counting from the time the egg was laid, and in eight more days she will leave her cell, and in about two more days she will be strong enough to bring on the excitement resulting in the first after-swarm.

CLIPPING THE WINGS OF QUEENS.

It seems to be looked upon by many bee-keepers as a manipulation difficult to perform. To me it is a very easy and simple operation. Find the frame that contains the queen, adjust it in your revolving frame-holder, lift the queen from the comb by clasping her wings between the thumb and forefinger of the right hand; now place her legs between the thumb and forefinger of the left hand, and with the scissors clip off about half of one pair of her wings, and let her run back on the comb. Restore the frame in the place it was taken from, and close up the hive carefully, so as to excite the bees as little as possible.

QUEENS FROM ADVANCED LARVÆ.

There are exceptions to all rules, perhaps, and it is not safe to say that queens reared from advanced larvæ are always inferior. I once had a queen hatched in just eight days from the time the cell was started. The case being an exceptional one, I kept a close watch over this queen, and she showed up as good as the average of the best queens in the apiary. Some of the best queens I ever owned were hatched in ten days after the cells were started.

Shelby Co., Ky.

No. 4.—An Apiary—How to Get the Most Out of It in Beeswax, Queens, Etc.

BY "OLD GRIMES."

ALTHO it is looked upon as an incidental, beeswax is a very important product, and in the markets of the world it has a more standard value than honey. There is no substitute that can take the place of beeswax in the many uses to which it is put in the industrial arts, and when we have a pound of wax we know there is more gold in it to the square inch than there is in an equal amount of honey.

Bee-keeping is an industry full of little details, and the neglect of them will have an effect upon the earnings of the apiary, and the detail that seems to receive a little more than its share of neglect is the saving of wax. Old Grimes, in his early days, lived near an honest German bee-keeper,

and he was always saving every little bit of comb, brace-combs, little spurs from the covers, etc., and all thrown into a box kept in a convenient place for the purpose. It is said that example is more lasting than counsel, and in this case it seems to be verified, for I have faithfully followed his example, while if he had given it to me in the form of advice, I would have forgotten it the next day.

Altho some people at the present day put their old combs into a sack, the sack into a washboiler, and the boiler upon the kitchen stove, and boil, the majority of them resort to more improved methods.

The solar wax-extractor seems to be in the line of progression, and improvements are reported from Florida and Colorado. Further improvements may be expected, until there will be nothing for boilers or presses to do.

There is at present a revival of the press method. It is right and proper to make improvements, but the press was in use in the Grimes apiary 15 years ago. If it will get out another pellet of wax it is well to use sunshine, water and pressure; the pellets make ounces, the ounces pounds, pounds dollars, and dollars clothing and food for our person.

The Grimes family are pleased to observe that the old steam-stove wax-extractor is relegated to the relic heap, for of all slow-working vexations, and utterly useless things for an extensive bee-keeper, it was the worst.

To get the most wax from an apiary, it pays occasionally to scrape the frames, honey-boards, and the inside of the hives, and when old frames are broken up, to be sure they make fine kindling wood, but before using them for that purpose they should be boiled—there is much wax sticking to old frames even after they are scraped seemingly clean.

And here one of the boys at my elbow irreverently remarks that I had better advise bee-keepers to boil all the dead bees. That might be a good plan for certain specific purposes, but as we have worked the dear little bee for all her dear life is worth, it is time we should exclaim, "Requiescat in pace!"

To get the most out of an apiary in working it for queens needs special talents. If a person is a proficient honey-producer it is no sign that he could succeed in queen-rearing. The qualifications for a queen-breeder can be summed up briefly in the following: Order, patience, neatness, application.

We were told some months ago, in one of our bee-papers, how a certain honey-producer, when he wanted to open a hive, kicked the top off, and when extracting the honey allowed the bees by the million to drown in it. In order for such a fellow to succeed in queen-rearing, there would have to be a grand reformation of his feet, his hands, and his head, and probably the latter would be a hopeless task if he is over 25 years of age.

The economical home-rule applied in the Grimes apiary is to secure good queen-cells, and eventually queens, thru the swarming season when it requires but little order, patience, etc. At other times, queens are purchased from well-known, reliable dealers, and it is a waste of honey to buy cheap queens, or to patronize a queen-breeder whose reputation is not established.

Judging of the scarcity of advertisements in that line, the sale of colonies of bees is not a very extensive business. In trying to get the most out of an apiary by this means, Old Grimes has had some experience. The desire to buy was not equal to the anxiety to sell, and the anxiety of the buyer to bear the price down created a desire to hold, and after quite a little advertising only a few colonies were sold.

Probably the best method of selling colonies for profit was practiced a few years ago by Mrs. Lizzie Cotton, of Maine. Her plan was to sell a fortune-making hive with the bees, and all for the modest sum of \$20! As she catered mostly to a class commonly known as "suckers," the field was in due time supplied, and Lizzie went out of business. There is probably a new crop of "suckers" by this time, but when one is tempted to work the field it is found that the American Bee Journal has such a watchful eye upon the verdant ones that it is doubtful if the scheme would work. The best time to sell bees is upon special occasions, such as stocking a new field, or replenishing a country after a great loss.

The shipping and sale of nuclei from the South to the North ought to be worked up into a good, paying business.

If the bee-keeper desires to sell bees and at the same time hold enough to make the honey-production profitable, he should never sell bees to his nearest neighbor, for every colony the neighbor owns takes just so much from your apiary. The bee-keeper who wishes to make the most out of his apiary should have no rivals within 8 or 10 miles.

CONVENTION PROCEEDINGS

Report of the Chicago Bee-Keepers' Convention.

BY HERMAN F. MOORE.

[Continued from page 6.]

Next on the program was a paper by Mr. H. M. Arnd, of Dupage Co., Ill., on

Marketing Honey and Creating a Demand for It.

Marketing honey is one of the most essential parts of bee-keeping. A failure in the honey crop means the loss of part of your year's labor, but if you sell your product at a loss your entire year's labor is in vain.

I understand that this year's honey-production is less than one-half, but of a superior quality, and yet some bee-keepers have sold their product at the 1897 prices, when there seemed to be an overproduction, times were hard, and all food could be bought at very low prices. Whereas, this year, all kinds of food products—in fact everything, has advanced greatly, and honey should doubly have a big advance, on account of scarcity, quality, and rise in values of goods in general. And yet, these very same men complain that there is no money in honey!

From my short experience I find that it is not difficult to sell A No. 1 honey direct to the consumer at a good price, if you go at it in the right way. A man should be neatly but plainly dressed, as his appearance goes far in impressing the purchaser that he has the genuine article from his own apiary. He must be "up in his business," always willing and ready to answer the hundred and one questions that are apt to be asked. I do not know of anything that will get a person quicker, and more interested, than the bee-subject; nearly all seem to know that the science is full of the miraculous, and are not at all backward in asking all sorts of questions, some of which would stump Dr. Miller or Mr. Doolittle to answer. If you once get people interested you will have no trouble in making sales. Do not hesitate to answer questions, even if at times you have to guess at the answer.

The public in general believes, and some of them think they know, that an imitation comb honey is manufactured, and as I make extracted honey a specialty, I do not argue the point, but sell them the extracted with the understanding that if it is not pure and satisfactory, they can either exchange or return it at my expense. I have had only one lot returned, and that was not even opened, the lady of the house contending that her husband had no right to make the purchase without her consent—that she was the "boss," and I think she was, because the honey came back.

You must send out only superior goods. If you have an inferior article, either sell it to some of your neighbors, or to bakers, at a discount, and tell them that it is not first-class; feed it back to the bees in the fall, or put it in the vinegar-barrel, but never put it on the market as fancy honey.

You must study your trade, and know when to approach certain customers. Some you can sell to at any time of the year, whereas the indifferent honey-purchaser can only be reached successfully after a pay-day, or when the thermometer is down to zero.

If your competitor has good goods, always have a good word for him.

Most of my product goes to Chicago, and by a careful study of my customers, giving them just what they want, and when they want it, I am able to get magnificent prices.

I always sell direct to the consumer, and get all that there is in it. I sell my goods on their own merits, not on the defects of my competitors'. I do not try to compete with South Water street, or the corner grocery, but sell as independently as if I were a "trust." I do most of my business in the down-town district, as I have a large acquaintance there, and can meet them personally. I usually go to such places where I am either known, or I might know their forty-second cousin's aunt; if I am not acquainted I will tell them that I know their relative, and explain my business. I usually have a few sample bottles of honey, and some of my circulars, and place them where I think they

will be most effective. If I do not then make a sale and get some encouragement, I will call again later. Politeness, appearance, and modesty do a great deal in getting a proper interview, which is one-half in getting them interested and making a new customer, who, with proper treatment, will be instrumental in getting some of his friends.

I put up my product in one-gallon and five-gallon tin cans, which I deliver by wagon-express direct to their residences. I also use one-quart and two-quart glass jars, which I deliver direct to their place of business if centrally located. A short time after shipment to a new customer I call on him to find out if everything is satisfactory. I make it a point always to give full-size cans, and filled up to the brim; 12 pounds of honey is considered a gallon, but my customers get nearly 13 pounds. You will find it pays to be liberal with your customers. Always rectify any mistakes, even if you lose at the time, for it will pay in the end, as a reputation for square dealing is worth money to any man.

To create a demand for honey at high prices, you should not sell anything but first-class goods, as such invariably bring new orders. I have as a customer a family that has bought of me \$40 worth of honey within the last two years, and yet I have never seen one of them. Nothing will advertise your goods more than the goods themselves.

The public must be educated as to the uses and benefits of pure honey; there is not one person in fifty but thinks that it is only a luxury of no particular value. If we only could get the people to read and believe our circulars and honey literature, and get the newspapers to print well-written and true articles on the bee, and on honey as a food, I have no doubt that the demand would increase tenfold in a year. I believe that nearly one-half of my customers have lately been convinced that it is not only a delicious but beneficial food.

We have this problem to solve: How can we get our brother bee-keepers to sell their crop for living prices, and at what it is worth, and thus not break down the honey market? In answer, I would suggest that they invest at least \$2.00 per year for information—\$1.00 for the best bee-paper, and the other dollar as dues to some good bee-keepers' association, where he could and would attend the meetings and get the much-needed information.

In these times of monopolies and trusts, when the rich are getting richer, and the poor poorer, we poor bee-keepers will find that the greatest problem for us to solve is, How can the pure-food law be enforced effectively, and drive out of business permanently those mixers of poisons, who for mere gain are not only robbing the public of their hard-earned money, but, more than that, are gradually undermining their constitutions and shortening their lives? If such laws could be enforced, it would greatly improve the demand for our goods, and we would have no trouble to market them at good prices. I believe that every one of us can assist in helping to crush this great wrong by joining the United States Bee-Keepers' Association, and swell its treasury to such an extent that it will enable them to fight the adulteration demons, and use their influence with Congress to put a stop to this great injustice to humanity.

H. M. ARND.

This topic was considered at great length, nearly every one present being personally interested. Many and diverse views were expressed on candied honey and its relation to a honey-trade.

The Hon. A. H. Jones, of Robinson, the newly appointed Illinois Pure Food Commissioner, was introduced to the convention. He made an interesting address, pledging himself to co-operate with all good citizens to prevent adulteration of foods. The bee-keepers congratulated themselves on the presence of Mr. Jones at their meeting, and his evident friendliness to their aims and objects.

Following Mr. Jones, Pres. York and Dr. Miller made a few well chosen remarks on the importance of the work to be undertaken by Mr. Jones, and pledging the hearty co-operation of bee-keepers.

Mr. Jones said that 16 States now have pure food laws. He asked the bee-keepers to aid him in enforcing the laws.

Prof. E. N. Eaton, of Chicago, an analytical chemist, read the following paper:

Honey as Food.

Honey has ever been regarded one of the good things in life. To the Hebrew fathers a land flowing with milk and honey was symbolic of peace and plenty. Thus they pictured their promised land. The ancient Greeks fed their fabled gods with nectar, even to-day generally considered

synonymous with honey. Virgil wrote pastorals in its praise. The American African, always extravagant in language, can conceive of no sweeter name for his love than "My Honey." The black mamma lulls her pickaninnies to sleep with the same sweet refrain.

In English-speaking nations the newly-wedded celebrate their "honeymoon." By the way, that term has a derivation not commonly known. It was a custom of the Goths to celebrate the marriage relation by drinking diluted honey, sometimes called "hydromel," for one month or one moon's age hence the name "honeymoon." It was this drink, fermented I fear, which caused the death, thru suffocation, of the notorious vandal, "Attila."

In speaking of honey as food it will be necessary to name the three great classes of food material—the proteids (or nitrogenous foods), the carbohydrates, and the fats, both of the latter being carbonaceous foods. The nitrogenous foods are, in the main, flesh formers, while the carbohydrates and fats are fuel foods. Honey belongs to the sugar group, a large division of the carbohydrate family. All carbohydrates consist chemically of the elements carbon, hydrogen and oxygen, the latter two in the proportion to form water, that is, eight times as much oxygen as hydrogen.

Honey consists largely of the two sugars—dextrose and levulose—in equal molecular proportions. These sugars occur in Nature in fruits and vegetables. When coffee A sugar, or damp brown sugar, stands for some time it becomes changed into these same sugars. The same change in cane-sugar is brought about by action of diluted acids, neutral salts and ferments. These sugars, when obtained from cane or white sugar by any agency, are invariably formed in equal quantities, and when so existing are termed invert-sugar. Levulose is sweeter, and dextrose not nearly as sweet, as cane-sugar. Invert-sugar is perhaps a trifle less sweet than cane-sugar.

Cane-sugar is usually present in honey, and may exist in considerable quantity in unripened honey, or in the product obtained by feeding bees with that sugar.

Dextrin also occurs in honey in small and variable quantity. It belongs to the carbohydrates group, but is not a sugar. It forms an intermediate product between the sugars and the starches. Dextrin is more commonly known under the name of "British gum," and constitutes the adhesive on postage stamps. It also occurs in the crust on bread.

Formic acid is a constant component of honey. This acid is said to be the irritating agent in the sting of bees and other belligerent insects. Formic acid, like its relative, formic aldehyde, is an excellent antiseptic, but the statement that it exists in sufficient quantity in honey to act as a preservative or intestinal antiseptic, should be taken with a grain of allowance—perhaps two grains.

It will not do to leave the subject of the composition of honey without referring to the least prominent constituent from the standpoint of the scales, but the most important from the standpoint of the purse—the flavors carried from the flowers furnishing nectar. These flowers give to different honeys their individuality. They also add to its value as a delicacy. A solution of sugars without them, even in the proportion existing in honey, could no more justly be sold as honey than could a mixture of acetic acid and water be sold for cider vinegar, or a concoction of water and alcohol for wine. It therefore follows that invert-sugar, or any syrup obtained by artificial feeding, is not honey, and when sold as such is as much a violation of the moral law as selling "white-clover glucose."

In studying the food value of honey from the standpoint of nutrition, we may disregard the flavor and minor constituents, and consider the relations of the main constituent—invert-sugar—in the upbuilding of the animal organism. In the absence of any proof we must give levulose the same value as dextrose as a food, and there seems little doubt that the two sugars follow the same course to the blood.

Sugars are not found in abundance in the body. The blood contains a little dextrose, and the muscles inosite. The liver is stored with glycogen, an isomer of starch, but unquestionably derived from sugar. The generally accepted theory of sugar digestion and assimilation is that sucrose and starch are changed into dextrose by ptyalin and pancreatic ferments. The dextrose and levulose are carried to the liver and converted into glycogen. The glycogen is held in reserve to be reconverted into dextrose to replenish the blood when depleted in that constituent. By this means the circulating sugar is kept constant in quantity.

The food value of sugar has been underestimated in the past. Children are even to-day discouraged from eating candy, which their system craves, and are usually obliged to content themselves with penny goods and other cheap and inferior sweets. And this in the face of the fact that Nature has given her most emphatic approval of sugar as food by placing it in almost all animal secretions for the young. It occurs in predominant quantity in the milk of all mammalia; in human kind, constituting over one-half of the entire solids, and double the amount of any other constituent.

The sugars are the most available of the heat and energy producers. Recent investigations in Germany, France and Italy have shown that sugar acts as an immediate invigorator when fed to persons in extreme fatigue. People at extremely hard work immediately feel the recuperating effect of a sugar diet. The governments of Germany and the United States have added sugar to the rations of their soldiers. In this country the sugar is supplied in the shape of candy. Candies usually consist of mixtures of sucrose, dextrose and dextrin. There can be little doubt that if honey were substituted in part for candy in the soldier's dietary, even more favorable results would be obtained, because, first, honey is in a sense a predigested sugar, and the demand on the digestive forces is lessened; second, honey consists of almost pure invert-sugar, while candies contain dextrin of unknown food value, but certainly not as immediately available as sugar; third, honey is produced by bees unskilled in the art of sophistication, and above the practice of artificially flavoring and coloring, while candy is a product of human ingenuity, and may contain unwholesome constituents; candy usually contains glucose, a product not above suspicion; honey is made in Nature's laboratory; and, fourth, honey can more easily be used as Nature intended, and as experience has proven best—that is, in connection with other foods, as upon bread or hardtack. Candies, when eaten in excess, are unwholesome and cloy upon the palate.

In favor of candy it may be said that adulteration is becoming less and less prevalent, and in the higher-priced candies deleterious adulteration is almost unknown. This is largely due to the wisely directed efforts of the National Confectioners' Association.

Again, candy has an obvious advantage over honey in ease of transportation and distribution. Candy is possibly a trifle cheaper than honey in this country, but certainly not a luxury in the Philippines.

It is an interesting fact that the consumption of no other commodity, unless it be soap, so accurately measures the civilization of peoples as sugar, judged, of course, by our own standards. Great Britain consumes more sugar per capita than any other nation; next comes the United States, then in order follow Switzerland, Denmark, Sweden and Norway, Holland, France, Germany, Austria, Russia, Turkey and Italy. Some allowance must be made for Sweden and Norway, whose cold climate predisposes them to the use of the more concentrated fuels—the oils and fats.

I wish to say one word, in closing, for the dignity of the bee as a manufacturer rather than a collector or common carrier. It is indeed true that the bee may invade the sanctity of more than a million flowers to produce one pound of honey, but she has not gathered honey, only the raw material, which, by working over, she manufactures into honey. She then puts it up in her unique and inimitable original package, and marks each cell with her seal.

E. N. EATON.

The Association tendered Prof. Eaton a vote of thanks for his excellent and instructive paper.

After supper the convention continued their labors. Some hilarity was also interspersed.

The following resolution was read and unanimously adopted, recommending Prof. E. N. Eaton for the position of State analyst:

Resolved, That we congratulate the consumers of the State of Illinois upon the enactment of pure-food laws, and the appointment of a pure-food commissioner. We urge upon Commissioner Jones the necessity of securing honest, energetic and capable assistants to aid in carrying on the work.

"We would endorse Prof. E. N. Eaton for State Analyst, knowing his ability to properly carry out that branch of the work."

The question-box was then taken up. One question, "How to Increase the Attendance," was considered at length. As our first evening session was such a big suc-

cess, it was considered best to hold the next meeting in the afternoon and evening, beginning at 1:30 p.m. and continuing until the members are tired. It was suggested that a lunch be served at 5 p.m., so as to "let no guilty man escape."

The convention adjourned to meet at 1:30 p.m., April 5, 1900.

HERMAN F. MOORE, Sec.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Looking for a Text-Book on Bees.

I saw in a recent answer to a question you refer to a text-book. Kindly tell me what book it is, and where I can get it.

CANADA.

ANSWER.—You are on the right track when you inquire after a text-book. No bee-keeper should be without one. It is even more important than to have a bee-paper, and that's putting it very strong. There are several excellent text-books, any or all of which are good. By sending to the office of the American Bee Journal you can obtain, postpaid, any of the books mentioned on page 15, at the prices named.

Bee-Keeping as a Rural Pursuit.

Here are two sentences taken from Farmers' Bulletin No. 59, of the U. S. Department of Agriculture, which I want explained thru the columns of the American Bee Journal. The sentences read as follows:

1. "On the whole, there should be expected from the raising of bees for any purpose whatever, only fair pay for one's time, good interest on the money invested, and a sufficient margin to cover contingencies."

2. "With no greater expectations than this from it, and where intelligence directs the work, apiculture will be found, in the long run, to rank among the best and safest of rural industries."

Does the second sentence mean that bee-keeping is better, or safer, than all other rural industries? Or, does it mean that it is placed on an equality with other good rural industries, viz: Stock-raising, dairying, poultry-raising, etc?

In explaining the foregoing, I want only the sentences explained as they read, and not as to your opinion whether bee-keeping is better or equal to the others named.

KANSAS.

ANSWER.—Taking the sentences as they read, they seem to mean that when the whole line of rural industries is considered, bee-keeping will be found one of the safest from risks, and among those yielding the largest pay for capital and labor.

Granulated Honey—Feeding Bees—Fertilization in Confinement—Foul Brood.

Altho not a beginner in bee-keeping, there is much in this trying year where I am at a loss to know what to do. Southern California was unfortunately visited by two successive dry years (1898-99), with insufficient winter rains and dry, hot winds, and in consequence the farmers and bee-keepers have a hard time of it. This season was, so to speak, a total failure.

My apiary is situated in a sheltered nook at the base of San Jacinto Mountain. I bought 80 colonies last spring, of which I workt 70 for extracted honey.

1. The early part of this season my bees did fairly well on alfillaree clover and fruit-tree bloom, from the adjoining fruit colony, but the first honey, altho it was by no means

too ripe when I extracted, would candy or granulate within a day or two in the tank. What was the probable cause? I never have noticed this occurring with the early honey for years. It is very annoying and laborious to have to spade the honey out of the tank and dissolve it by heat or the solar extractor, in order to fill it in tin cans for market. I presume the extreme dryness of vegetation is the immediate cause. How would you remedy it?

2. Please illustrate the safest and cheapest method of feeding needy colonies without exciting robbing or drowning?

3. Do you think fertilization of queens in confinement is a possibility to produce a certain variety of bees? Or, is it best to import a tested queen?

4. Foul brood has done its ravages in Southern California apiaries. A treatise on this subject, and remedy, if there is any except extermination, would be welcome.

I think that 60 colonies of mine are safe to winter thru, and we all hope, with sufficient winter rains, that next spring will refund us for our severe losses. CALIF.

ANSWERS.—1. There is a great difference in the granulating of honey from different plants. Some kinds yield honey that will continue liquid a year or years; the honey from most plants will granulate in the course of the following winter; while some kinds will begin to granulate a few days after being gathered. I don't know the reason for it, and never heard of any reason. Neither do I know of any remedy.

2. I know of no safer nor more satisfactory method than to use the Miller feeder. The feeder is put on the hive the same as a super, and putting on the one will no sooner start robbing than putting on the other. When your feeders are all on and left uncovered, you can go around and put in each the amount of dry sugar you desire up to 15 pounds, and the dry granulated sugar will no more start robbing than so much sand. Then you can go around and pour on cold water without danger of robbing and cover up the feeders. After the sugar has been dissolved by the water, then the robbers will get in their work if the feeder is not carefully covered.

A cheaper way is by the crock-and-plate plan. Take a common stone crock (a gallon crock is a good size), fill it $\frac{3}{4}$ full of sugar, or less, as you desire. Put in as many pints or pounds of water as of sugar, cover the crock with a single thickness of flannel or woolen cloth, or with 5 or 6 thicknesses of cheese-cloth; lay over this a dinner-plate upside down, put one hand under the crock and one over the plate, quickly turn the whole thing upside down, and place over the frames of the hive with an empty hive-body about it, and covered up so no robbers can get in from outside. With either of these plans the feeding must be done before cold weather; better not later than September. If you are so unfortunate as to need to feed in winter, and have no combs of honey, lay cakes of candy over the frames, and cover up warm.

3. I have no faith in fertilization in confinement. At different times in the past there were reports of success, but the reports lack confirmation in the way of having the thing repeated in the same way afterward. Get a good queen to start with, and run your chances of pure fertilization, altho it would be better to have one choice queen for drones and another from which to rear queens.

4. Such a treatise is already on the market in Dr. Howard's pamphlet on foul brood, which can be had from the office of the American Bee Journal for 25 cents.

Apartment and Department—Alfalfa.

1. How do you tell the two different apartments—the brood apartment and the surplus apartment?

2. Does alfalfa bloom make good honey? CALIF.

ANSWERS.—1. It is not strange that there should be some uncertainty as to the proper meaning of the word "apartment" as used in bee-culture. In the first place the words "apartment" and "department" are not infrequently confused. An apartment is a separate room or place, usually separated by some sort of a partition from other apartments. A department is something separate as to character rather than place; as the dry goods department and the grocery department of a country store, or of a department store. The two departments may be in one apartment, and one department may fill several apartments. Everything pertaining to the brood in any way may be said to belong to the brood department, no matter in what part of the hive it is; and what pertains to the sur-

plus may be said to belong to the surplus department, no matter in what apartment it may be.

The word "apartment" is the one most commonly used in bee-keeping, and it is not easy to keep it exactly straight. There is generally no difficulty in distinguishing a pig-pen from a bed-chamber, but in an Irishman's shanty with the pig sleeping under the bed (as reported) the distinction is not so clear. So the brood apartment may be sharply separate from the surplus apartment; as in the case of a box-hive with glass boxes for surplus on top, in which case the top of the hive separates the brood apartment below from the surplus apartment above. Or, there may be no such thing as two separate apartments, the brood and the surplus being all in the same apartment; as was the case with the old-fashioned straw-skeps, or even a box-hive with no surplus boxes on top.

The general rule is that the lower story is the brood apartment, everything above constituting the surplus apartment. There may be little or no real partition between the two apartments, just as in the case of two rooms in a house with large folding-doors or portieres between, there can scarcely be said to be a partition, still the apartments are considered separate.

2. In many parts of the West, as Utah, Colorado, etc., alfalfa is one of the best honey-plants. In the East reports seem to give it no standing whatever as a honey-plant. In at least some parts of California its reputation is good. Wherever it does yield honey, the character of the honey is excellent, with many being considered as having no equal.

Preparing Bees for Moving.

I have 48 colonies of bees that I have to move not later than March 1. They are in a cellar, bottom-boards off, covers sealed down. How can I best succeed in moving them about 7 miles? How ventilate, and how fasten the bottoms on?

Would a strip nailed on each corner of the hives, and also nailed into the edge of the bottom-board, be a good way? I have thought so—what do you say to that?

IOWA.

ANSWER.—The first thing is to let the bees have a flight after being taken from the cellar before any attempt at moving them. To take them directly from the cellar to their new place would be somewhat disastrous, in all probability. The weather is usually so cool on the first of March that very little ventilation is needed. Wirecloth at the regular entrance will be sufficient. The particular way of fastening it on depends upon the kind of hive and entrance you have. One way lately given in *Gleanings in Bee-Culture* is probably as easy as any: Cut a piece of wirecloth as long as the entrance is wide, and two or three times as wide as the entrance is deep. Bend it V-shape the entire length; push the sharp end of the V into the entrance and drive in a nail near each end to prevent the wirecloth from springing out again.

Your plan of fastening the bottoms to the hives will be all right. You may like better to use staples. What are called tobacco-staples are all right—a staple about $1\frac{1}{2}$ inches wide with legs $\frac{3}{4}$ inch long. Drive one leg of a staple into the hive and the other into the bottom-board.

Sweet Clover in Canada.

When is the best time to sow sweet or white clover, and the kind of soil best suited to it? Also, will sweet clover suit this northern climate? There is none here. ONT.

ANSWER.—Any time from fall to spring will do. So long as you didn't sow it in the fall, wait till the ground is open in the spring, then roll it into compact soil. One of the best ways is to let stock tread in sweet clover seed. Any soil will do, especially poor lime soil. Sweet clover does well in Canada.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the new bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY,

[Entered at the Post-Office at Chicago as Second-Class Mail-Matter.]

EDITOR:

GEORGE W. YORK.

DEPARTMENT EDITORS:

DR. C. C. MILLER, "Questions and Answers." * * E. E. HASTY, "The Afterthought."

LEADING CONTRIBUTORS:

G. M. DOOLITTLE, C. P. DADANT, PROF. A. J. COOK,
F. A. SNELL, R. C. AIKIN, "OLD GRIMES."

IMPORTANT NOTICES:

The Subscription Price of this journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec00" on your label shows that it is paid to the end of December, 1900.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

VOL. 40. JANUARY 11, 1900. NO. 2.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

Careless Correspondents.—Dec. 30 we received a one-dollar bill for renewing subscription, with a sheet of note-paper in an envelope, but no name or address given so we could tell who sent it. The postmark on the envelope was "Treadwell, N. Y." We can hardly understand how any one could be so careless. It is very annoying to us to receive such letters, and no doubt is the cause of much loss to the careless people who make such mistakes.

Everybody who pretends to do any business whatever should have at least a rubber stamp with their correct name and address on it, and then with it stamp at the top of every sheet of paper they use. This would help out all right when they are so forgetful as to write a letter and then not sign it.

"The Coal-Tar Products."—Mr. Thos. Wm. Cowan, editor of the British Bee Journal, but now in California, wrote us as follows, Dec. 26, 1899:

On page 786 (1899), Prof. Cook writes under the above heading, and from what I can gather he thinks naphthalene would act more surely in destroying foul-brood germs if given to bees in their food.

Allow me to caution bee-keepers in doing so, as otherwise the result may be as disastrous as they have been where the error has been made in giving naphthalene in place of naphthol beta.

Naphthalene, when placed in a hive, does not destroy the germs, but, until it has evaporated, prevents the devel-

opment and growth of bacteria. The constant presence of naphthalene in a hive tends to prevent the disease from gaining ground. Of course, too much in a hive is obnoxious to bees, and they leave it, and in some cases brood has been found damaged. That is why the amount recommended does not exceed two balls at one time in a hive.

For giving in food, naphthol beta (usually written "Naphthol B.," to distinguish it from the Naphthol A. series) only is used. I do not know what naphtha beta is, or what its effect on bees would be. Naphthol beta, in the dilution generally used, does not destroy the spores or bacillus of foul brood, and its efficacy depends upon its preventing the spores from germinating or killing the bacilli, when the spores have turned into these. This is the reason why it is recommended to have it always in the food given to bees. There is no known chemical substance that could be given in sufficient strength to kill the spores but what would also destroy the bees.

THOS. WM. COWAN.
Monterey Co., Calif.

The United States Bee-Keepers' Association.—General Manager Secor's annual report for 1899 was received at this office the last week in December, and reads as follows:

REPORT OF THE GENERAL MANAGER FOR 1899.

To the Members of United States Bee-Keepers' Association:

The chief work of the Association during the year 1899 has been the attempt to stop the sale of adulterated extracted honey.

The place chosen to begin operations was Chicago. This was agreed on because it was thought that the laws of Illinois were explicit enough and severe enough to warrant an attempt to enforce them in the interest of pure food.

Attorney Herman F. Moore, a bee-keeper and member of this Association, assisted by George W. York, editor and publisher of the American Bee Journal, proceeded to collect samples of so-called extracted honey with the intention of prosecuting the offenders, if on analysis they should prove to be adulterated. Nine samples were selected out of a dozen or more bought at different groceries. Out of the nine, five were selected, and a complete analysis made for use in court. That some of them were adulterated was clearly proved by the chemical analysis.

Suit was brought in Justice court against one of the retail grocers where one of the jars was bought, which on trial was proved to contain 90 percent glucose. Notwithstanding that fact, and notwithstanding the law and evidence were clearly on the side of the prosecution, the Justice discharged the prisoner. It was a surprise to everybody connected with the case, except possibly to the judge and lawyer for the defence.

Altho the bee-keepers lost the case in court, the trial elicited so much interest, and was so widely advertised in the daily papers, the result was that one of the leading wholesale grocery houses (and the one, by the way, where the very bogus honey in court was obtained) put out the following circular to the trade:

"PURE FOODS.—We believe the tendency of the buying public in the future will be in the direction of strictly pure foods; and in our opinion the result of this will undoubtedly prove highly beneficial to the health of the consuming public, and unquestionably more satisfactory to the jobber, retailer, and everybody concerned in selling this quality of goods.

"Adulterated articles in the food line are still on the market. . . . but we believe it will be to the best interests of all concerned to advocate the purchase of pure foods as speedily as possible. Unless you know it to be a positive fact that the article you are selling is absolutely pure, do not sell it as such. If you are in doubt, make it known that way."

The above circular was dated and sent out the day of final trial. It looked very much as if the notoriety which Chicago houses were getting thru the papers awakened them to the need of doing something to hold their trade.

Therefore, altho the first drawn battle in the interest of pure extracted honey was an apparent defeat, it seems to have aroused public opinion sufficiently to do good.

No further prosecutions were ordered against the sellers of the other adulterated samples gathered, partly for the reason that not sufficient funds were left in the treasury to continue the fight; and for the further reason that Illinois will soon have a Pure Food Commissioner who, it is to be hoped, will assist, if not take the lead, in the enforcement of the pure food laws, including adulterated honey.

It is the duty of the States Attorney to prosecute for the people all violators of the criminal code, but unless some one stands at his back and insists, and assists, he evidently does very little. We found it was necessary to

help prepare the papers and to produce numerous witnesses. Mr. Moore and Mr. York spent a good deal of time, and did faithful and valuable work for the Association, the latter without any compensation whatever.

I have written 95 letters on a variety of subjects pertaining to the work of the Association, besides the receipts for membership fees. Among these have been articles for the press, trying to correct erroneous impressions regarding the manufacture of comb honey; letters in the interest of pure-food legislation; advice to bee-keepers who were likely to suffer by the untimely spraying of orchards; advice to other bee-keepers who had been ordered to remove their bees from town, or from the proximity of fruit-farms; legal advice regarding the ownership of absconding swarms; the settlement of disputed accounts, bad debts, etc. None of these matters have required legal procedure or defense at the expense of the Association. It has been the aim of the General Manager to avoid litigation whenever possible to effect an honorable settlement.

It seems our Canadian brethren have the same troubles that we of the States do. G. A. Deadman, of Ontario, was annoyed by a quarrelsome neighbor who brought suit to compel him to move his bees. On my advice he employed an able attorney and resisted the suit, promising to write me if anything unusual developed. As I heard nothing from him I infer that his touchy neighbor has not succeeded in getting the court to declare bees a nuisance. With my letter of advice in this case, I sent him a copy of the decision in the celebrated "Arkadelphia case," which Mr. Newman defended and won with such signal ability.

At the annual meeting of the United States Bee-keepers' Association held at Philadelphia last September, Mr. Newman, General Manager of the National Bee-keepers' Union, and Dr. Mason, representing our society, submitted a new constitution to be voted on by both societies with a view to unite the two if the members of both societies so vote. There will be mailed, therefore, with this report the new constitution to be voted upon by all persons who are eligible to vote. It is to be hoped that the project so favorably started may be carried thru, thus uniting all the bee-keepers in one strong organization.

Mr. Newman has exercised a large influence in building up an organization of bee-keepers, and has done much valuable service in their behalf. The relations between him and the writer hereof have been most pleasant. The appreciation for his good work can not be too cordially expressed.

The financial statement herewith submitted shows a small balance in the treasury, but if we carry forward the work which we are expected to do another year toward enforcing the laws against the adulteration of honey, it is needful that all bee-keepers cast in their mite to aid in the good work.

Faternally yours,
EUGENE SECOR, *General Manager.*

The new constitution referred to by Mr. Secor was published on page 707 of this journal for 1899.

The treasurer's statement shows a balance in the treasury of \$131.22.

The present list of members, the names of whom accompanied the annual report, shows 400. There ought to be at least five times that number. Why can't there be? Surely, bee-keepers cannot expect their national organization to do much for them and their industry when they give it so small support. With a membership of 2,000, and the consequent enlarged treasury fund, there is no telling what good things might be accomplished. We wish the officers might have the opportunity to show what they could do with ample funds and large membership.

Lace-Paper Edgings for Sections of honey are much used in England. Any imperfections about the outer part of the comb are thus hidden from view. The British Bee Journal, in order to show to what extent this matter is carried, gives a fine picture of a section bought in a store out of a large lot similarly gotten up. The actual surface left uncovered by the paper is $2\frac{1}{2}$ inches square; that is, the purchaser is able to see a little more than one-fourth of the surface. No wonder the British Bee Journal calls a halt.

The Premiums offered on page 27 are well worth working for. Look at them.

Your Bee-Keeping Experiences Wanted.—We are always glad to publish the good things that our subscribers send in, drawn from their actual work with the bees. Many a little short cut or kink that you use would help some other bee-keeper if you would write it out and send it in for your bee-paper to publish.

We do not ask this as would a beggar, but simply suggest that as you have been helped by the writings and experiences of others, it is no more than fair that you should contribute your share as a slight token of your appreciation of the aid you have received from those who have been glad to give what they could to make your efforts more successful in the apiary.

Taking Care of Things.—Somnambulist, of the Progressive Bee-keeper, has had his dreams disturbed by the reckless way in which some bee-keepers let apicultural apurtenances go to waste. Hive-bottoms are allowed to rest immediately upon the ground; wax-extractors have the glass exposed to accident all the year round; and then he goes out of his way to shy a stone at Farmer Shiftless who allows all his farm implements to become toughened by exposure to the weather.

The Weekly Budget

MR. M. H. MENDLESON, of Ventura Co., Calif., writing us Dec. 16, said: "At present we are having a good rain, but it is the late rains that decide the season."

A NEW ORGANIZATION among the bee-keepers of South Dakota will be formed at Yankton, Jan. 25. We hope it will have the support of all the bee-keepers in that region.

"A CERTAIN CHINESE FLOWER," it is said, "is red in the sunlight and white in the moonlight." If it yields nectar, we presume it would have to be gathered by the bees at night in order to produce white honey.

MR. ALBERT GRISE, of Idaho, sends us a newspaper clipping telling of a swarm of bees that settled on a bicyclist, and when the wheeler retreated the bees located on the saddle of his wheel. They were then scooped in a box by a colored man—about a peck of bees.

MR. A. L. MCFARLANE, of Wallawalla Co., Wash., wrote us recently expressing the wish that some Western bee-supply dealer would advertise in the Bee Journal, as the freight rates from the East are very high to that State. We should think it would pay some Pacific Coast dealer to keep a standing advertisement in these columns.

MRS. THOS. S. WALLACE, of Adams Co., Ill., died with consumption Dec. 31, 1899. She was nearly 61 years of age. Mr. Wallace has been an exhibitor of bees at the Illinois State Fair the past few years, and one of our subscribers for a long time. We extend to him sincerest sympathy in his bereavement, and are glad to know that he mourns not as those who have no hope of a reunion by-and-by.

EDITOR ERNEST R. ROOT attended the annual convention of the Colorado bee-keepers, held in Denver last month. He says it was a success in every way, with an attendance of from 50 to 80. Those Colorado bee-folks know how. They generally have one of the very best State bee-keepers' meetings that can possibly be gotten up. But, then, they are always "Akin" for the best of everything, or else "Rauchfussing" around after it. Hurrah for those get-there Coloradoans!

Cellulosid for Quilts and Excluders is used in England. For quilts, cellulosid has the advantage (whatever that may be) that one can lift the cover and look down upon the bees without taking off the quilt, as the cellulosid is almost as transparent as glass.

Necessity of Covering Apiaries in Cuba is the heading of an article in the American Bee-Keeper, by Col. G. Garcia Vieta. Before the war he had 500 colonies in one apiary and 1,200 in another, and he felt that a roof was an actual necessity. He is again building up his apiaries destroyed by war, having 200 colonies under roof and as many more under available shade. He can examine those under roof in two or three days, while it requires more than a week to look over those out-of-doors. The heat of the sun melts foundation in an hour in exposed hives, but it will not do to keep hives in groves on account of malaria. After the very heavy rains of several days, the bee-keeper cannot work at hives without roof for several days on account of mud. The roof must be strong to withstand the fierce winds.

Disposition of Combs with a Little Honey.—In the report of the Brant County convention reported in Canadian Bee Journal, appears the following:

"What would you do with combs having small quantities of honey in them in the fall? was the next question. Some members advocated setting them out in the yard and allowing the bees to clean them out. Mr. Pepper said that he preferred to extract them even tho the work seemed tedious and unprofitable; leaving honey around the yard has a tendency to excite the bees and often leads to no end of trouble by their robbing. Mr. Edmonson said that he did not favor the idea, for the same reasons, and, besides, they tear and destroy the combs. Mr. S. T. Pettit's plan of placing the super of each hive in front of the colony it belongs to, in order to clean out the combs, after the last extraction, was dwelt upon; some could not see how this would be practical in a yard of 70 or 80 colonies, as it would take some time to do the extracting, and all could not be placed at the same time. J. H. Shaver and W. J. Craig observed that the moth will not attack combs left moist with honey, as they are after extracting, so readily as they will dry combs. The combs will keep better, are not nearly so easily broken, and, besides, the bees will take to them more readily when placed in the hive next season."

Black Bees and Foul Brood.—Editor Simmins makes this statement:

"Native bees are decidedly more subject to the disease of foul brood than either Carniolans or Italians; while the latter more readily respond to treatment when affected, and will quite frequently dispose of the malady without aid from the owner."

He quotes W. Symes, from the Australian Bee-Bulletin, as saying that in his earlier experience he kept black bees and was almost in despair with foul brood, but since keeping Italians the disease had gradually disappeared and now ceast to trouble him. In an experience of 25 years, Editor Simmins has had plenty of proof come under his own observation. He says:

"Our first terrible experience with foul brood occurred over 20 years ago. The bees attacked were, with two or three exceptions, so-called black bees, and these could not keep the disease under. The Italians soon disposed of it with a little assistance, and upon removal of the queen, every vestige of the complaint disappeared from the combs. On later occasions, in buying black bees from a distance, the disease has come

Yellow Sweet Clover Seed

WE HAVE IT AT LAST!

We have finally succeeded in getting a SMALL quantity of the seed of the **YELLOW** variety of sweet clover. This kind blooms from two to four weeks earlier than the common or white variety of sweet clover. It also grows much shorter, only about two feet in height. It is as much visited by the bees as the white, and usually comes into bloom ahead of white clover and basswood. We offer the seed as a premium

A QUARTER POUND FOR SENDING ONE NEW SUBSCRIPTION.

So long as it lasts, we will mail a quarter pound of the seed to a regular paid-up subscriber who sends us **ONE NEW** subscriber for the American Bee Journal one year, with \$1.00.

We have been trying for years to secure this seed, and finally succeeded in getting it. It is new seed, gathered last season by an old personal friend of ours, so we know it is all right. But we have only a small supply. When nearly out we will mention it.

Root's Column

The ABC of Bee-Culture!

Revised in 1899

Three thousand sold in three months.....

67,000 copies published.....

Root's A B C—the 67th thousand! Who ever could have imagined it? But then, this is a book which requires to be known before the fact of its enormous circulation can be realized. And when once known it is a book to be prized beyond many others, for its complete, interesting and practical nature. "A cyclopaedia of everything pertaining to the care of the honey-bee" in very truth; a book of fine views and photographs, almost; illustrations of all the noble machinery used in one of the largest bee-supply factories in the world. Almost every thing a bee-man wants to know is given in precise alphabetical order, while its exceptionally clear type is brought out in the true American style of excellence. If there is any book on apiculture that may be thoroly recommended, it is this of The A. I. Root Co., Medina, Ohio.—BEE-CHAT, LONDON, ENG.

For Sale by all dealers in Bee-Keepers' Supplies, or sent by us for \$1.20, or clubbed with Gleanings in Bee-Culture one year for \$1.75.

Watch this column next week.....

upon us again, but at no time have we had any difficulty in keeping our foreign colonies clean, while those bought were readily treated as soon as the queens were changed and the foreign varieties hatching out.

"On one occasion we bought a number of colonies from (we then found) an infected source. Half were native, the rest Italian. The former were diseased, but none of the Italians.

"In another instance we bought 8 colonies of black bees. At the time, and even for several weeks after transferring, these bees appeared quite healthy. Presently, one after the other showed evident signs of disease, and tho we gave medicated food and otherwise treated them, thus restraining the malady, there was no disposing of the scattered foul cells until the queens were superseded by Carniolans and Italians. During the whole time these were the only colonies diseased among an apiary of foreign bees many times their number."

Wiring Frames with Thread.

—It is somewhat doubtful whether anything can be better for wiring frames than the fine wire usually used, but it seems that in England some prefer thread. If thread is used without preparation, the bees tear it down. A. H. Miller gives in the British Bee Journal, his method as follows:

"I got some tailor's 'yellow twist,' then melted some beeswax in a jam-pot, leaving it upon the stove till the wax came to the boil. I then put in the twist and boiled the wax well into it, then removed and run it round a reel. I then used the wax thread upon about a dozen frames, and not one was gnawed off by the bees. The combs also stood the extractor well. In fixing foundation in frames, I use a small bradawl to make two holes at each side or end of frames on the outside; these two holes are made to run into one on the inside, so as to have the two threads quite close together at about 2 inches from the bottom-bar. I never use more than that amount of support, and never had one break down after using it with some hundreds of combs last season with the wax twist in the extractor.

"The bees seemed rather to like the wax thread, for they imbedded it so that you can scarcely see it in the combs. It is also much nicer to use than wire, besides being so simple."

Getting Queen-Cells Started.

—One of the live topics of the day is the improved methods of queen-rearing, new points being brought out every now and then, showing that some little thing has made all the difference between success and failure. Editor Pender, of the Australasian Bee Keeper, says that when he gives royal jelly, it too often occurs that it dries up in a condition unfit for the larvæ, and he gets better results not to use jelly. He proceeds as follows:

"I have a colony queenless in which there are one or more frames of *young* unsealed brood—the younger the better. When I arrive at the apiary in the morning, I remove these frames of brood for which the bees are busy preparing milk food, and so cause them to accumulate it in their stomachs. When leaving the hive I leave an empty space between two combs for the prepared frame; in this space the bees will cluster in large numbers. From two to four hours later, I take a frame of prepared cell-cups and transfer, as rapidly as possible, the larvæ selected for queens and place this frame in the vacant space, so great is the cluster of bees that time has to be allowed for the frame to settle into position, or if the frame is forced down bees will be crushed. I now have my prepared cells immediately surrounded by bees having plenty of food prepared to feed the royal larvæ, and if this frame is examined in an hour, not only do we find the larvæ well fed, but the cups shaped into true queen-cups. The cups are hardly given before the bees start feeding the larvæ. These larvæ receive only the freshly-prepared food.

"To obtain larvæ suitable for grafting, I

Langstroth on... The Honey-Bee

Revised by Dadant—1899 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the Ameri-

can Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

ELECTRIC FEED MILL

We have put out this mill to meet the demand of the patrons of the famous Electric tools for a good mill at fair price. It is a direct grinder and absorbs or wastes no power in useless and expensive gearings. Cuts, crushes and grades corn, and all small grain, sorgho, or mixed. Adjustable—grinds coarse or fine. Free law. Circulars and prices free. ELECTRIC WHEEL CO., Box 6, Oshtemo, Ill.

keep my breeder-queen well supplied with bees and with but few larvae, so that they are abundantly fed. If you look into your hives you will always find that colony having but little unsealed brood, has the larvae for the first few days floating in an extra abundance of white milk food, which is the royal jelly of the queen, and, when transferring, the larvae are floated upon the transfer-stick without touching them, and sufficient of the jelly transferred with them to surround them in their new cradle. If the cups, as now worked on by the bees, are placed in an upper story of a strong colony, having frames of unsealed brood, a queen-excluder over the brood-chamber, and an old queen laying below, the cells will be completed by the bees, and good cells will be the result if not more than a dozen be given at one time. When removing this frame of cells from the queenless colony, take what bees are hanging to the frame, and a second frame of prepared cups can be given the queenless bees, and I should say it was far more certain to have the cells started by queenless bees than placing the prepared cups at once in the super over the queen-excluder, at least I have found it so, as my bees always refused to accept the cups unless worked on by the queenless bees. If a large number of queen-cells are required, the queenless bees will start several prepared lots in one day."

The Novelty Pocket-Knife

A heavier and stronger knife than the one we offered heretofore.)

(THIS CUT IS THE FULL SIZE OF THE KNIFE.)

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the Subscriber.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a lifetime, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the Novelty is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the Novelties, your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be apprised of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00), and we will also send to each new name a copy of the Premium Edition of the book, BEES AND HONEY. We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO., 118 MICHIGAN STREET, CHICAGO, ILL.

A Fair Yield of Honey.

The past season was not a very good one here. The honey crop was generally light in quantity, but not in quality. I had a fair yield—nearly 1,500 pounds from 40 colonies, mostly buckwheat honey. I think that nearly all the bees in this part of the country went into winter quarters with an abundance of good buckwheat honey, which I consider is the very best for outdoor wintering. ED. JOLLEY.
Venango Co., Pa., Dec. 14, 1899.

Bees Did No Good.

My bees have done no good this season, but I enjoy the Bee Journal and hope for better success next year. I bought some golden Italian bees and have sown some sweet clover seed. My bees are in good condition for winter, as they loaded up pretty well on goldenrod and wild aster.

WILL C. GRUBER.
Martin Co., Ind., Dec. 25, 1899.

Total Failure—No Clover Honey.

Bees were a total failure here the past season. There was no clover. Where there was basswood they did fairly well; it lasted about 12 days. D. E. WHITING.
Dodge Co., Minn., Dec. 23, 1899.

A Young Beginner's Experience.

I commenced keeping bees for a man that I work for, but he never read about bees, and wouldn't let me manage them the way others' experience had taught me, so we didn't have much success. I bought him out last spring—five colonies for \$20. They increased to 12 colonies, and I got 50 or 60 pounds of honey from three. It was a very poor season for bees here—too dry. I was away two weeks in September, and the moth-millers got into one colony and destroyed about half of the combs, so they became discouraged and went away. I now have 11 colonies packed with wheat straw and chaff.

I have always been very much interested in bees, and since I have taken the American Bee Journal I like the business better than ever. I get so much information out

of it that I wouldn't do without it under any condition.

I think this is a good location for bees. I am 19 years old, and have been farming.

I saw an article about bees working on strawberry blossoms. I don't think I ever saw any honey-bees working on these blossoms.

JACOB STINE.

Barry Co., Mich., Dec. 20, 1899.

Bees Didn't Do Well.

I put 180 colonies of bees into winter quarters—90 in a shed and 90 in the cellar. Bees did not do very well here the past summer. From 130 colonies, spring count, I got 3,000 pounds of nice section honey. The new swarms did not do anything. The bees I put in the shed last winter came out all right.

WM. J. HEALY.

Iowa Co., Wis., Dec. 19, 1899.

Half a Crop—Smoker-Drops.

We got only half a crop of honey here the past year, with large winter loss.

I would suggest to Dr. Miller (concerning smokers dripping) to use chips of soft wood, which do not contain any tar when pickt up in the spring after lying all winter on the ground. With these I have had no trouble from black drops.

L. A. SYVERUD.

Lincoln Co., S. Dak., Dec. 19, 1899.

Bees Did Fairly Well.

My bees did fairly well the past season, as they averaged about 60 pounds to the colony. They did well in fruit-bloom, but the forepart of June they were short of food, and if I had not fed them I should have lost some by starvation. Our main supply is from sweet clover, catnip and buckwheat.

M. BEST.

Lucas Co., Ohio, Dec. 18, 1899.

Looking for a Good Season.

The bees did not do any good here this year, but they are wintering well up to the present. They have plenty of honey to winter on. We are looking for a good honey season.

The American Bee Journal is certainly up to the times; I could not keep bees without it.

B. F. BEHELER.

Summers Co., W. Va., Dec. 25, 1899.

A Poor Year, But Prices Good.

I lost only one colony last winter, and that died of starvation. I started in the spring of 1899 with 54 colonies, and increased to 58. It has been quite a poor year. I obtained a trifle over 1,500 pounds of honey but prices have greatly helped to make up for the small crop.

J. L. HAIGHT.

Delaware Co., N. Y., Dec. 19, 1899.

A First Season's Report.

This has been my first season with bees, and it was a poor one. I got two colonies June 15, and lost one queen from some cause, but by June 27 I found five young queens hatching, so I made a division and saved two of them, and by so doing I increased to five colonies. But I had to feed to July 1; and then in October I had to feed again, so they would have enough to winter.

TAYLOR BISER.

Buffalo Co., Nebr., Dec. 13, 1899.

Reports from Two Apiaries.

In the apiary I had in charge for 1899, I began with 21 colonies, spring count, in fair condition, but only increased, by natural swarming, four colonies. The total number of pounds of honey taken was 1,996, mostly extracted, or a general average of 95 pounds per colony. Our season was not anything to brag of, as the clover did not do as well as I expected.

The following is the report of my own

MAULE'S Seeds

Lead all, as thousands of successful gardeners in all sections of the country can attest. If you want the finest garden you have ever had, you must plant Maule's Seeds.

BUY THE BEST.

If you want the best low-down wagon you should buy the Electric Handy Wagon. It is the best because it is made of the best material; the best broad-tired Electric Wheels; best seasoned white hickory axles; all other wood parts of the best seasoned white oak. The front and

ELECTRIC

rear hounds are made from the best angle steel, which is neater, stronger and in every way better than wood. Well painted in red and varnish. Extra length of reach and extra long standards supplied without additional cost when requested. This wagon is guaranteed to carry 4,000 pounds anywhere. Write the Electric Wheel Co., Box 16, Quincy, Ill., for their new catalog, which fully describes this wagon, their famous Electric Wheels, and Electric Feed Cookers. Please mention the Bee Journal.

WE TRUST THE PUBLIC

and send our Incubators to any responsible person. No one should buy an incubator and pay for it before giving it a trial. It is made so that nobody can fall with it. A child can run it. 16c. worth of oil will make a batch. It beats all others at World's Fair, Nashville and Omaha Expositions. We are sole manufacturers of the celebrated New Premier and Simplicity Incubators. Catalogue 5c. Plans for Poultry Houses, etc., 25c.

Columbia Incubator Co., 5 Adams St., Delaware City, Del. Please mention Bee Journal when writing.

bees for the season: I began with two colonies, spring count, and had no increase, but got 156 pounds of extracted honey. The cause of falling off as compared with the above report was as follows: One colony I transferred from a box-hive to a movable-frame one, and for the other I bought a new queen, and let them run down while I was waiting for the queen. Nearly half of the honey was from asters.

J. WILEY MOUNTJOY.

Anderson Co., Ky., Dec. 21, 1899.

A "Too-Too" Season for Bees.

The past season was a poor one for bees here. I got only about 300 pounds from 43 colonies. The weather was too cold, too hot, too wet, and too dry. This is the nearest I can come to explaining why. I had five colonies robbed out, and I put 40 into the cellar Dec. 14, rather light in bees and stores, but I think most of them will come out all right. The wild or bee aster (wire-weed we call it) was the salvation of the bees here the last season. It never fails to yield more or less honey every season, during September and October, wet or dry.

RUFUS WILLIAMS.

Lawrence Co., Ind., Dec. 21, 1899.

A Rather Late Swarm.

I had a fair-sized swarm of bees come to my apiary Nov. 23, and settle on a willow-tree near the ground a few feet from the hives. I got an empty hive and put in full combs of honey, leaving a couple of empty combs in the center. They marched in with their queen at a lively rate, and seem in fine condition at present. My bees have been gathering pollen from some source every day up to the present writing. Brood-rearing is in progress all the time, and the hives are full of fine alfalfa honey. I have 200 colonies of hybrids.

L. E. REDDEN.

Maricopa Co., Ariz., Dec. 18, 1899.

Bees Did Fairly Well.

My bees were put into winter quarters Dec. 4. The temperature dropt then to 30 degrees above zero. Last spring was cold and backward for bees, and it took quite long for them to build up, but under the circumstances they did fairly well. I got about 1,300 pounds of honey, and I am now living in hopes for a better crop next year.

C. H. VOIGT.

Manitowoc Co., Wis., Dec. 26, 1899.

Report for the Season of 1899.

I began in the spring with 22 colonies, increased to 32, and produced 1,000 pounds of honey, which I sold at home for 10 and 12 1/2 cents a pound.

O. B. MONTFORT.

Shelby Co., Ky., Dec. 25, 1899.

Color of Combs and Color of Honey.

I noticed in the discussions at the Philadelphia convention (page 805, 1899) Dr. A. B. Mason askt the question, "Does the color of combs have any influence on the color of honey?" I desire to make a reply to that question in the affirmative. Old combs that have had brood reared in them for any considerable length of time become about the color of dark plug tobacco, and honey, let it be ever so clear, will, after being stored in such combs, become very much discolored by actual test. But such combs are tough and make the very best of extracting-combs, if properly treated; and here is how I do it:

Lay them out in the rain, turning them over occasionally to get both sides filled. After letting them soak for a while, lay them one at a time on a division-board, and with a quick, downward motion the water can nearly all be thrown out of the upper side, then reverse and go thru with the same motion. The water from such combs will be about the color and flavor of tobacco-juice. Keep on with this filling

and throwing out of water until the water is clear, and your honey will show no stain whatever. Of course, I have city water, and in lieu of rain I fill the combs under the hydrant, and lay them on the grass to soak. I have a great many such combs, some with considerable drone comb in them, but that's no difference, as such combs will be filled by the bees in preference to new, white combs. I had none filled the past season, however.

Portage Co., Ohio. L. G. REED.

Not a Satisfactory Season.

The past year was not a satisfactory as last year, for bee-keeping, but we are not discouraged yet. I had 40 colonies in early spring, but only two swarms, and harvested 800 pounds of extracted honey, white clover and buckwheat. The shortness of the crop of clover was due to the severe drouth that lasted nearly two months. At the end of the month of June it began to rain at a pretty good rate, which resulted in the clover ceasing to blossom, and growing instead.

I have put into the cellar 41 colonies, with good, heavy stores. The winter is not hard so far.

I like the American Bee Journal as much as ever, and propose to subscribe for it as long as it continues to be published at the same high standard. JOS. BEAUDRY, Prov. of Quebec, Canada, Dec. 23, 1899.

"Taking Care" of Bees and Honey.

This has been a poor season in this locality. Some of my neighbors got hardly any honey. Bee-keeping is about 40 years behind the times in this neighborhood. No one takes any bee-literature of any kind. They say there were bees before there were books, but it did not work that way with me, for I commenced the bee-business in 1896 with one colony, and increased to eight. These were the first bees I ever handled, so that winter I lost 6 colonies. The two remaining I increased to eight, and subscribed for the Bee Journal. I now have 48 colonies in good condition. There is nothing I like to take care of so well as bees, with the exception of honey, which I can take care of at the rate of about 3 pounds a day.

NELSON S. BARBOUR.

Wadena Co., Minn., Dec. 21, 1899.

Didn't Pay Expenses.

Bees did not pay expenses this year, but are in good condition for next year. I hope to have better success with them next season. W. BISHOP.

Otero Co., Colo., Dec. 23, 1899.

Had Hard Luck in Texas.

Some of us Texas fellows have had hard luck this year—not much honey and a great many bees dead. I have now 75 colonies in fine condition for winter, and with the rain we have had, and horsemint now up and growing, we look for a better honey yield in 1900. Some of my neighbors who keep a few colonies of black bees have lost all they had. Of course, I can't get along without the American Bee Journal.

J. A. ROSSON.

Ellis Co., Tex., Dec. 23, 1899.

Having Abundant Rain.

I was over at the old place a week ago and took a look thru some of the hives. I found that they were not as well stocked with winter stores as I could have wisht. Some of them were on the point of starving. I fed them as far as I could during the limited time at my disposal.

Tho this has not been a cold winter, still it is being a hard one on the bees. This is owing mostly to the fact that there were few fall flowers, and to the early and continuous rains which have kept back certain flowers that yield nectar during November and December. The rains in this portion of

the State have been very abundant, and there is every assurance that there will be a heavy rainfall before the coming spring is over. Those who have bees next summer will get large quantities of honey, I feel sure.

I have noticed by telegraphic reports from the Southern portion of the State, that the rainfall there, while far from being as plentiful as that of the more northern portion, is very assuring. This I am glad to know, as it will help to make more prosperous times in the State. The rainfall here has been 15 inches—more than we had the whole of last season, I believe.

The past few days here have been cold and frosty, yet I have not been able to find in my rounds thru the city, one tender plant injured by the cold. Heliotropes, potato-vines and such other tender plants have escaped, as intimated, I presume, tho we shall have a heavy frost about the last day of the year, that will get in its work on tender vegetation. Just think of great big beds of calla lilies in full bloom at this time of the year! They are as common as weeds here. W. A. PRYAL, Alameda Co., Calif., Dec. 21, 1899.

A Beginner's Report.

This was my first season with bees. I have 21 colonies of hybrids and Italians. I bought 15 colonies and a lot of hives, etc., in June, and brought them home 18 miles on a wagon without springs, over a rough road, on Jan. 28. I handled them as well as I knew how, but lost one colony by being smothered. The combs broke down. The bees stored very little surplus honey this year. They have plenty to winter on and appear to be in good condition now. I take great pleasure in working with bees. I want to sell bees as well as honey if I make anything like a success of the business.

Cost \$4000; You Get It For 15 Cents.

The Money-Makers in the poultry business, whether owning a dozen hens or a thousand, are the people who watch what other successful poultry-keepers are doing and how they do it. It is to disseminate just such knowledge as this that **"How to Make Money with Poultry and Incubators"** was published. It is admittedly the handsomest book ever printed treating of the poultry question. It contains nearly 200 illustrations and numerous other features which brought its cost up to more than \$4,000. While it gives complete information regarding the **Cyphers Incubator** it is primarily a guide and manual for the person who is considering poultry from a purely business and money-making stand point. Its 192 pages (8x11 inches) are filled with practical articles, written expressly for this book by leading poultry experts. For example, Geo. H. Pollard, the well-known practical poultryman, contributes three chapters on "Profitable Broiler Raising," "Winter Chickens or Roasters," and "Best Breeds for the Market." Michael K. Boyer of national reputation, has an article on "Poultry for Profit on One Acre;" Myra V. Norys tells what energetic women have done in "Women's Work with Poultry;" A. F. Hunter, the well-known editor, discusses the "Demand for Fresh Eggs and How to Meet It;" Jas. Dryden, of the Utah Experiment station, writes of "Pulle's vs. Hens as a Profitable Layers." These are only a few of the many special articles. In addition there are many photographic illustrations and descriptions of the largest and most successful poultry farms in the world; also numerous copyrighted plans and specifications for laying and brooding houses, together with letters from over 250 successful poultry keepers reporting their experience with the **Cyphers Incubators.** Sent to any address for 15c. postage. Ask for Book No. 50. Address nearest office, The Cyphers Incubator Co., Chicago, Ill., Wayland, N. Y., Boston, Mass.

N. E. Ohio, N. W. Pa.—The Northeastern Ohio and N. W. Pennsylvania Bee-Keepers' Association will hold their 19th annual convention at Andover, Ohio, in Chapman's Hall, Jan. 17 and 18, 1900. Boarding rates of \$1.00 per day have been secured for those attending the convention. All bee-keepers invited. Send to the Secretary for programs.
Franklin, Pa. **ED JOLLEY, Sec.**

California.—The tenth annual convention of the California State Bee-Keepers' Association will be held in the Chamber of Commerce, at Los Angeles, Feb. 21 and 22, 1900. It will be called to order at 1:30 p.m., Feb. 21. At this time the railroads will sell round-trip tickets to Los Angeles and return for one and one-third fare, on account of the Industrial, Mining, and Citrus Exposition, which will be held in Los Angeles. Tickets good for 10 days. Let every bee-keeper bring some hive, tool or experience that he has found valuable, and we will have a good convention. **J. F. McINTYRE, Sec.**
Sespe, Calif.

Minnesota.—The Southern Minnesota Bee-Keepers' Association will meet in Winona, Jan. 23 and 24, 1900. **E. B. HUFFMAN, Pres.**
Homer, Minn.

Wisconsin.—There will be a joint convention of all Wisconsin bee-keepers' societies at the 16th annual meeting of the State Bee-Keepers' Association, Feb. 7 and 8, 1900, in the State Capitol, at Madison, Wis. Many prominent bee-keepers will be there and take part.

Excursion rates of a fare and one-third for the round-trip, for railroad tickets purchasable in the State, for over 50 cents each. Be sure to bring a certificate of each ticket purchasable so it can be signed Feb. 8, in Madison, and entitle the holder to a third fare return.

The State Horticultural and State Cheese-makers' Associations will meet on the same date in the Capitol.

Don't forget the date—Feb. 7 and 8. It will pay you to attend. **N. E. FRANCE, Sec.**
Platteville, Wis.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, Dec. 12.—We quote best white comb at 15c; an occasional small lot of fancy sells at 16c; off grades of white, 12@14c; ambers, 10@12c. Extracted, 8@9c for fancy white; 7@8c for amber; 6@7c for dark grades.

Receipts are larger and the demand is not as good as it has been; most of the retailers have laid in a supply to carry them over the Christmas time. **R. A. BURNETT & Co.**

CINCINNATI, Dec. 7.—There is a good demand for all kinds of extracted honey. White clover and basswood sell at 8@8½c; amber and Southern, 6@7c, according to quality and package. Fancy comb honey in no-drip shipping-cases sells at 15@16c; darker grades hard to sell at any price. Beeswax, 20c. **C. H. W. WEBER, Successor to Chas. F. Muth & Son and A. Muth**

KANSAS CITY, Dec. 9.—We quote No. 1 white comb, 13½@14c; No. 2, 13@13½c; No. 1 amber, 13@13½c; No. 2, 12@13c. Extracted, white, 7½@8c; amber, 7@7½c; dark, 5½@6c. Beeswax, 20@22c. **C. C. CLEMONS & Co.**

BUFFALO, Jan. 5.—Market bare of fancy white one-pound comb honey, and selling at 15@16c; fair to good, 12@14c; buckwheat, dark, poor, etc., 8@10c. Fancy pure beeswax, 28@30c. **BATTERSON & Co.**

NEW YORK, Dec. 10.—Demand is very good for all grades of comb honey. Receipts are somewhat light and not up to former years. We quote:

Fancy white, 15 cents; No. 1, white, 13@14c; amber, 11@12c; and buckwheat, 9@11c, as to quality. Extracted remains firm at following prices: California white, 8½c; light amber, 8c; white clover and basswood, 8c; amber, 7½c. Very little trade for extracted buckwheat as yet. Southern, fancy, 7½c per pound; other grades, as to quality, from 70c to 75c gallon. Beeswax quiet at 20@27c. **HILDRETH & SEGELKEN.**

SAN FRANCISCO, Dec. 20.—White comb, 11½@12½c; amber, 8@10c. Extracted, white, 7½@8c; light amber, 7@7½c; amber, 5@5½c; Beeswax, 26@27c.

There is no chance for extensive trading in this commodity at present, supplies having been reduced to small proportions. A sailing vessel clearing the past week for England carried 125 cases extracted. Prospects for coming season's yield are considered very good for this early date.

CLEVELAND, Dec. 1.—Fancy white, 16@17c; No. 1 white, 15@16c; No. 1 amber, 13@14c; No. 2 amber, 12@13c; buckwheat, 9@10c. White extracted, 8@9c. **A. B. WILLIAMS & Co.**

BOSTON, Dec. 8.—We quote as follows: Fancy white, 16c; A No. 1, 15c; No. 1, 13@14c; buckwheat will not sell in this city. Extracted, light amber, 7@8c.

There is very little now to report in the line of our honey market. The retail trade are loath to pay the higher prices and are buying in a very small way, still the demand is fully equal to the supply. **BLAKE, SCOTT & LEE.**

ALBANY, Dec. 10.—We quote: Fancy white comb, 15c; No. 1 white, 13@14c; mixt, 11@13c; buckwheat, 10@11c. Extracted, white, 8@9c; mixt, 6½@7c; dark, 6. Beeswax, 26@28c. **MACDOUGAL & Co.**

Successors to Chas. McCulloch & Co.

OMAHA, Jan. 4.—Prices remain unchanged. Fancy white is still moving slowly at 14@14½c. Extracted, white, 8½c. Now that holiday trade is over and dealers have taken their inventory, they soon will be thinking of replenishing their stock and more lively trade is anticipated in the near future, but no material advance is looked for during January. **PEYCKE BROS.**

DETROIT, Dec. 11.—Fancy white, 15@16c; No. 1, white, 14@15c; dark grades, 10@12c. Demand good and supply light. No extracted in market. White would sell for 8@8½c. Beeswax, 23@24c. **M. H. HUNT & Son.**

WANTED.—Extracted honey all kinds; mail sample and price expected delivered at Cincinnati. I pay spot cash on delivery. **C. H. W. WEBER.**

Successor to Chas. Muth & Son and A. Muth. 404½ 2146-48 Central Ave., Cincinnati, O.

We will buy it, no matter where you are. Address, giving description and price, 344½ THOS. C. STANLEY & SON, Fairfield Ill.

A LITERARY GEM

THE MOST

ENGAGING BOOK

EVER WRITTEN

BY IAN MACLAREN

REV. H. M. WHARTON, D.D.

J. WILLIAM BUEL, Ph.D.

"The Golden Morning"

N

EWS AND GOSSIP OF A NEW BOOK ON THE BIBLE have been current in book and Christian circles everywhere for some months. In its authorship was to be combined the superb talents and literary abilities of three of the greatest lights in the world of religious literature.

The book is about to appear and on its title page in collaboration as authors are found the names of that most popular of all writers, IAN MACLAREN (Rev. John Watson), together with H. M. WHARTON, B.D., the great Evangelist, and J. WILLIAM BUEL, Ph.D., one of the most prominent and popular writers on Biblical subjects. A MASTERPIECE INDEED must be the book which falls to its creation such a combination of unmatchable talents. IT IS A MASTERPIECE—and it is good news we bring our readers when we tell them that after the most persistent endeavor and the most industrious and earnest negotiations with the Publishers, this paper is one of a syndicate which has secured the entire first edition for distribution among their subscribers, not as a means of winning profits, but to encourage the people to become regular readers, because of the unusual privileges which are offered regular patrons.

The book is entitled "THE GOLDEN MORNING," and while it was intended to be a \$5.00 book, and has everything about it—authorship, illustrations, paper, printing and binding—to warrant that price, we have, after many objections and refusals, made terms whereby WE ARE IN POSITION TO OFFER IT TO OUR READERS AT A GREAT REDUCTION. It contains nearly 800 pages and over 500 superb illustrations. It is printed with clear type on coated paper, and is bound in beautifully illuminated covers, with gold and colored stamping.

IT IS IN REALITY THE BIBLE IN STORY FORM arranged so as to assure a perfect understanding of THE GREATEST OF ALL BOOKS even by little children. All ambiguous and obscure phrases and descriptions have been put into language which makes them clear as noon-day. The historic events have been arranged in their proper order, and the story is made continuous and of absorbing interest throughout. Poetical description so freely used in the Bible, and the many Parables, have all received analysis and now appear as plainly told tales which need no interpreter or explanation.

Hundreds of artistic and accurate pictures have been used to embellish its pages and fix in the mind of reader or student the scenes so graphically described. No book of a religious nature has ever been so sumptuously illustrated. This feature alone costing an enormous sum of money, as every drawing was made especially for this work.

It will be of highest value to the young, as from a few readings, they will get such an understanding of Bible truths and promises from this book, that it would require years for them to gather through Bible reading or study. Indeed, one of the chief claims of "THE GOLDEN MORNING" to universal popularity, is that the children will learn to reverence and love the Bible and to accept its teachings through reading this charmingly written story.

WE ARE READY TO DISTRIBUTE THIS GRAND BOOK AMONG OUR READERS who should order at once, as our portion of the introductory edition is limited. The prices are as follows, WITH POSTAGE PREPAID:

BOUND IN EXTRA FINE CLOTH, BEAUTIFUL GOLD AND COLORED STAMPING	\$2.75
SUPERB HALF MOROCCO, WITH BURNISHED RED EDGES	\$3.75

THE BOOK WILL NOT BE ON SALE IN BOOK STORES, AND SHOULD BE ORDERED FROM THE OFFICE OF THIS PUBLICATION. EACH ORDER WILL BE PLACED ON FILE ON ITS ARRIVAL AND FILLED IN THE ORDER RECEIVED. BECAUSE OF THE EXTREMELY NARROW MARGIN OF PROFIT, CASH WILL BE EXPECTED WITH EACH ORDER. SHOULD THE BOOK BE UNSATISFACTORY WHEN RECEIVED AND EXAMINED, IT MAY BE RETURNED AND THE MONEY WILL BE CHEERFULLY REFUNDED.

Glass Honey-Jars!

We have two sizes of clear flint-glass Jars,
No. 1 holding a scant pound of honey, with an
opal or white top held on with a screw metal
band under which is a rubber to prevent leak-
age. No. 2 is a rather tall flint-glass jar with
tin screw-cap, holding ¾ pound of honey. Both
are excellent for retail honey-packages, and
are put up in single gross lots. The prices are
per gross, f.o.b. Chicago, for the No. 1 jars, \$5.25;
for the No. 2, \$4.25.

We can fill orders promptly for these jars.
They give excellent satisfaction, we know, for
we have used the same jars for several years.

CONTRIBUTED ARTICLES

Success with the Nucleus Method of Increase.

BY FRANK L. REHN.

LAST spring I had six colonies of bees, all on movable frames, eight to the hive, and desiring to increase as rapidly as possible, and yet so as not to impoverish the parent colony, it became a question to me as to what method would be best to adopt.

This being my first year in handling bees, it became necessary in order to succeed to thoroly understand the manner of the natural increase of bees; after a close study of the bee, and a more close scrutiny of the bees on the frames at very near intervals, I determined to proceed; so, accordingly, on May 3 I set four colonies apart as those from which I would make my nuclei; the other two colonies I called into service later in a different way.

On May 3 I had but time to make two nuclei; on May 6

I made three more; May 13, 7; June 13, 6; Aug. 2, another; and Aug. 15, still another—making 20 nuclei from the four, and still leaving sufficient in each of the original four to re-cover, gather, and breed.

In making the nuclei I would have the new hives all prepared before I would open the parent colony, thus: I first nailed the body with two long nails just tight enough on the side to hold to the bottom-board temporarily; plug the entrance with fresh grass as tight as possible, and nail a strip of wood across so that not a bee could get out; and place a division-board and two frames with $\frac{1}{4}$ sheet of foundation in the hive. The hives being thus ready, and having the enamel-cloth and cover ready, I proceed.

Smoke the parent hive, and after a few minutes lift the cover, and remove the division-board; look for the queen, and remove the frame with her on it, and place it in an empty hive for the time being; then proceed to look for material for a nuclei.

I take a frame containing at least $\frac{1}{2}$ -frame of honey with adhering bees, and place it in the hive I wish the nucleus to occupy; then look at other frames until I find eggs that are under three days old—in other words, eggs that are standing straight up on end. This frame and clinging bees are put into the same hive alongside of the one with honey; then draw the two empty frames with foundation up to the bees, put on a cloth and cover, and locate it where I wish the hive to remain.

Summer View of the Apiary of Mr. Frank L. Rehn, of Delaware Co., Pennsylvania.

Winter View of the Apiary of Mr. Frank L. Rehn.

These operations must be done as rapidly as can be, so as to keep all bees that are possible on the frames before the effect of the smoke has worn off.

In this way I proceed until I secure all I want at that time. In some cases, where I found sufficient honey and eggs in one frame, and had sufficient clinging bees, I used that alone, or shook a few bees from another frame.

I replaced the frame with the queen in the old hive, and gave it several frames with foundation, replaced the cover, and let it alone for about a week or ten days, when I again went thru the same process.

There are three cardinal points to make this a success, I find, viz.: First, that the eggs must be under three days old; second, the bees must not be released until after nightfall of the fifth day after dividing, and then only allow an entrance of about one or two inches; and third, that the cover must not be removed, or frames disturbed, until the eighth day after dividing.

On the eighth day I draw the two side-nails so I can raise the body from the bottom-board, and clear out the dead bees and examine the frames to see the number of queen-cells the bees have started and capt while closed up. In every case I have found at least six, and have had them in numbers varying up to 30 on a single frame. When I found quite a few, I would cut out some, and make more nuclei, and insert a couple of cells between the frames, and these queens would hatch about the same time.

The queens I reared in this way I have found to be large and prolific, and have yet to find the first one that I can say is "no good."

Every week or ten days I would go to the nucleus hives, go over them, and give them a gentle smoking to inform them I would prefer they would load up; raise the hive from the bottom-board, brush off any dead bees, and watch closely for any indications of moth or refuse; replace the board, examine the frames, and as soon as I see the queen is mated and laying nicely, I close down and mark the hive.

Then I go to the other two hives that I had reserved at the beginning, and take from them all the frames that contain any quantity of sealed brood; brush all the bees off, put them in an empty hive temporarily, and put frames with foundation in their place, putting them in alternately, as far as possible. There being all the bees and queen left behind, they take hold of the foundation immediately, and in a few days they have a perfectly full frame of comb filled with eggs.

The frames of sealed brood I give to every nucleus that I think would be better by a little encouragement, and in a few days it has a great quantity of young bees, which is very stimulating to the health of each young colony.

This process I practiced several times during the season. Every time I gave a frame of sealed brood, if I thought the colony was growing well in population, I would give one or two frames of $\frac{1}{4}$ -sheet of foundation, but being careful in every case to see that I did not scatter the bees over too many combs, and always keeping the combs on the east side of the hive, to warm up as early in the day as possible.

From one of the four original colonies used I made 12 nuclei the past season; and later, at three different times during the summer, I took two frames of sealed brood (with-

out bees)—that is, six frames in all—and in September I also took six frames of honey and gave to nuclei. On Oct. 15, when I packed this hive, it had eight frames exceedingly full of honey, bees, and brood. This queen is a leather-colored one, very long, and pure in color clear to the tip, but is mated with a hybrid drone; her bees have five bands, very plainly marked, but are somewhat cross in disposition, tho' great gatherers and unexcelled breeders.

In every case each colony of bees gathered sufficient stores for winter, and when I packed them, the middle of October, all had a great deal of brood and bees, and all had eight frames.

Next year I shall change my method a little by rearing and using virgin queens, inserting each in a nucleus. I do not intend to limit myself in number, as I believe nobody knows until tried how great a number one can create from a single colony.

I herewith show a photograph I made of my apiary on the summer stands, and another of it in winter quarters, the latter showing all but two of the hives under one shelter. The back of the shelter is to the north.

Delaware Co., Pa., Nov. 27, 1890.

Qualifications of the Genuine Bee-Keeper.

BY G. M. DOOLITTLE.

AS the labors of the year 1899 have drawn to a close, and the long winter evenings of the first of the year 1900 are upon us, I thought that I might be excused if I were to say a few words on what I consider the duties of the apiarist along the line of spending these evenings in such a way that we may be gaining in knowledge regarding the pursuit we have chosen in life.

Having once chosen a pursuit in life, it becomes all to look after that pursuit with all diligence. In no business engagement is this more imperative than when the culture of the honey-bee is to be the occupation; and in no way can this be done to better advantage than in reading the bee-literature of the day. How often have I tried to get certain persons who were about to embark in bee-keeping by way of purchasing a few colonies of bees, to take a bee-paper, or to send for a good book on bees, only to be met with certain excuses which went to show that the person addressed would not make a success with bees.

A man or woman who is not willing to put a few dollars into the bee-reading of to-day shows by *that very thing* that he or she will not make a success of it; for had they the right kind of love for the little busy bee they would devour all the reading on the subject which came in their way as eagerly as a hungry man eats a good dinner. It is just this hungering and thirsting after knowledge regarding the practical part of bee-keeping that insures success; and unless a person does so hunger and thirst after knowledge along some special line of the many industries of the world, he or she will never make a success at anything, except, perhaps, it may be their working by the day or month, serving some one else. It is *only* the person who *loves* a calling in life who succeeds by and thru such calling.

One of the reasons why there are so many "calamity

howlers" in the world to-day is because there are so many who are more interested in loafing around and listening to idle gossip than they are in their chosen pursuit in life, and take more interest in a game of cards, chess or checkers, or hanging around the saloon or country store, than they do in studying on something which will lift them up morally and financially, or make them of real, practical use.

Besides the American Bee Journal take all the other bee-papers you possibly can; and, first, and before any of these, be sure to procure at least one good book on bees. Why I say procure the book, or books, *first*, is, that no man or woman is ready to understand the bee-papers until they are in a certain measure acquainted with the first or elementary principles of our pursuit. There is scarcely a week passes but what I receive lists of questions which I know would never have been asked had the writers a good book on bees, and had they read that book understandingly. From these books and papers the mind is stored with useful knowledge, which can be put in practical use as soon as the active bee-season of 1900 opens.

When I first thought of bee-keeping I procured the "Bee-Keepers' Text-Book," by King, and "Quinby's Mysteries of Bee-Keeping." As soon as I had read these I subscribed for the American Bee Journal and The Bee-Keepers' Journal, the two latter being all the papers there were devoted to bees at that time. All of this before I had a single colony of bees, and I was so interested in the books that I had them as familiar as a nursery rhyme. This, together with what I found in the bee-papers, placed me where I was ready to do something somewhat intelligently, and I procured my first two colonies in the spring of 1869.

That season was the poorest season I ever knew, but I recorded 12 pounds of honey and one swarm from the two old colonies, so I had three in the fall; but I had to feed some 40 pounds of sugar to give them stores enough for winter, which I did, as the books told me the way to do it. And that the readers may see where the price of honey once went, I will say I was offered 50 cents a pound for that 12 pounds of honey, right at my door.

I read and studied bees from all and everything I could find during all of my wakeful hours, and dreamed on them when asleep, and the reader will pardon me for saying that I am still doing the same thing, having greater zest in bee-keeping, and in raising it to a still higher standard, than in anything else.

When I read anything which I consider new and superior to what I am now using, I jot the name of the paper, number and page where it is to be found, on a piece of section, then I put it in the "pew" holding all such things which are appropriate to a certain month, having 12 of these "pews," and then when the month comes around I take out all there is in there, spread them out, and thus I have all of these valuable things before me.

Yea, more. When I am at work preparing hives, sections, queen-cages, etc., during the winter, or with the bees during the summer, my thoughts are always "running" on the subject of bee-keeping, and when something new strikes me, which thought seems of value, I "whip" out my piece of section and pencil, jot it down, and as soon as I arrive at the "row of pews," in it goes at the proper place, to spread out before me at the proper time.

Yes, further: Some of my dreams are jotted down; and allow me to say that one of the most useful things found in our queen-rearing of the present was "dreamed out," and put in practice as soon as I was awake, namely, the queen-cell protector. To be sure, it did not come in its perfection, as Mr. West now has it, but the thing in its crude form came in something seen in a dream by a bee-keeper having the bee-fever, and that fever has been raging now over 30 years.

In reading over the above, I see there is a good deal of Doolittle in it, and I beg the reader's pardon, but I really did not see how I could tell you just what I wanted to without giving some of my personal experience.

In conclusion, I wish to say in all kindness, if any person loves something else more than he does to study into bee-keeping, or does such study only as a sort of duty, let him be assured that he has mistaken his calling, and the sooner he leaves it and goes to that which at all times gives him pleasure the better off he will be in this world's goods, and the better it will be for the world.

If there are any who read this, who have no love for anything except to sit around all winter "whittling a stick," whirling the time away in that way, let me say to them that the world would have been better off without them, and that these lines were not intended for them, unless they can turn over a "new leaf." □

CONVENTION PROCEEDINGS

Report of the Illinois State Bee-Keepers' Convention.

The Illinois State Bee-Keepers' Association held its annual convention at the State House in Springfield, Dec. 26 and 27, 1899.

As some of the trains were late getting in, the forenoon of the first day was spent in getting acquainted with new members, and in a good, social time. At 1:30 p.m. the meeting was called to order by Pres. Smith, who addressed the meeting in a few well-chosen words. The secretary read the minutes of the last meeting, which were then approved. The treasurer's report showed that on account of our funds largely going to subscriptions for the American Bee Journal, our treasury did not become very flush.

The committee on legislation reported at length, reciting the ill-treatment they got before the House Appropriation Committee, when asking for a foul-brood law. Chairman Curtiss and Dr. Vincent, with only a few others, were our friends. Our Bill past the Senate without opposition.

FOUL BROOD.

The subject of foul brood was then discuss.

Mr. Black—If I had it among my bees it seems to me I would want to burn them, but I don't know how infectious it is.

Mr. Gastman—My bees had foul brood a number of years ago, and I would feel like burning them—hives and all—if they should get it again.

QUESTION—Can foul brood be brought thru the introducing of queens?

J. Q. Smith—In two cases that I know of it came in that way, but the queens came in 3-frame nuclei. I could not say as to their bringing it if they had come in cages thru the mail.

The following resolution was adopted:

Resolved, That it is the sense of this meeting that each member of the Association use his greatest influence with his candidates for the next legislature, to secure the passage of a foul-brood law.

A paper written by Dr. C. C. Miller was then read, on this subject:

Bee-Keeping as a Sole Business.

Now and again the questions come up, "How much profit is there in bees?" "Can one make a good thing of it with bees alone?" "Would you advise me to make a sole business of bee-keeping?" etc.

To meet such questions fairly and squarely is not always an easy matter. There are generally two sides to a question—sometimes more than two. Let us look at some of the sides of these questions.

John Smith got an average of 475 pounds of honey from each colony of bees in the year 1897. It is said one man can take care of 100 colonies without help. If he should get 475 pounds from each of a hundred colonies, and if it should be sold for 9 cents a pound, that would make \$4,275 a year, and in ten years that would amount to the snug little sum of \$42,750, the interest of which might support him for the rest of his life without work.

That looks very nice on paper, but it may be well to mention some modifying items. John didn't get that amount of honey every year. The two preceding years he got no surplus, and some years his bees not only gather no surplus, but have to be fed to keep them from starvation. Take one year with another, and he can get no 9 cents a pound for extracted honey. He has kept only a small number of colonies. With 100 colonies there would be a slump in his average yield. Few locations have such honey-yielding flora, and it is not likely that in his lifetime will John ever again meet with conditions so favorable as in the year mentioned.

It is not an uncommon thing to hear this or that man say that nothing on his farm has paid better for the amount invested than his bees. He will give plain figures for it to show that \$50 invested in 10 colonies of bees netted him more clean money than twice the amount invested in

cattle. That being the case you would expect him to give up to a large extent the keeping of cattle and invest heavily in bees. As a matter of fact, in nine cases out of ten you will find little or no increase in his bee-business, if indeed he has not gone out of the business altogether.

The man who holds the highest record for getting the most honey from one colony, of any man in the United States (1,000 pounds), has never been reported as having gone largely into the business, and it would be nothing so very surprising to hear that he now has very little to do with bees.

One who thinks of making a sole business of bee-keeping should understand that the element of uncertainty cuts a large figure in the case. Added to other items of uncertainty is the one that no bee-keeper can ever feel secure in the tenure of his pasturage. He may have a thousand head of cattle with sufficient acreage to support them, and feel perfectly secure that no one will trespass upon his pasturage. But he has not the least assurance that he can hold undisputed possession of the pasturage for his bees for a single year. There is no way by which he can prevent another man, or ten of them, from occupying the same territory that he does. Whether legislation could be secured that would make him as secure of pasturage for his bees as he is for his cattle is hardly a question just now to be considered. Even if legislators were favorable to it, bee-keepers would none of it. At least they would not when such a thing was talked about some years ago. It was admitted by all that when a man had prior possession of a certain locality for bee-keeping, no man had the moral right to intrude upon that ground if it was already fully stocked. But by some strange process of reasoning it was thought wrong to establish as a legal right that which was already a moral right. As if one should say no man had a moral right to steal, but there should be no legislation against stealing.

All things considered, the man who makes money his god will do well to steer clear of bee-keeping. But there are those who do not consider money the sole aim. To a man with a taste for the business, and a good location for it; who loves to get close to Nature, and have a life of enjoyment in the present; who loves health, and hard work in the open air, bee-keeping holds out inducements hard to be met with elsewhere. In any case, if no drop of honey should be secured, there should be enough bees in the land to assure proper fertilization for all the flowers that depend chiefly upon bees.

C. C. MILLER.

Mr. Gastman—Is there any place in Illinois where you can depend upon a crop of honey every year?

Mr. Hyde—On the Mississippi River I have had about one failure in 8 or 10 years.

Mr. Black—I fail oftener than that.

Mr. Becker—I do not believe there is a place in Illinois where you can depend upon a good crop every year.

QUESTION-BOX.

Miss Coulter—From what flowers do bees get the most of their honey?

Mr. Gastman—From sweet clover.

Mr. Becker—In different localities, from different flowers.

Miss Kennedy—I got 2,200 pounds of white clover honey the past season. Two years ago I got 3,000 sections filled.

Mr. Gastman—Do people generally like basswood honey?

Mr. Black—Not at first taste. If basswood honey is allowed to drain as it candies, it will get rid of its unpleasant taste.

Miss Coulter—How do you know if the bees have honey enough to carry them thru the winter?

Twenty to 25 pounds was answered.

Mr. Gastman—How can I keep my bees from swarming when I am away from home?

Several advised clipping the queens; others to divide the colonies.

Mr. Becker—Do bees gather honey from red clover?

Mr. Black—I saw bees this year working as strong on red clover as I ever saw them working on white clover.

The premium list committee for last year made a report, which was approved.

On motion of Mr. Black, the committee was continued for the next year—namely, the executive committee, composed of the president, secretary and treasurer.

The convention then adjourned till 9:30 a.m. the next day, with no night session, so that members could attend the meeting of the State Horticultural Society.

SECOND DAY.

At 9:30 a.m., Wednesday, Dec. 27, the meeting was called to order, with Pres. Smith in the chair.

A paper by Mr. S. N. Black was read, on

Wintering Bees.

Upon the subject of wintering bees I hope to learn rather than impart information. Tho I have had over 50 years' experience, there are some results that I can not account for.

The first requisite for successful wintering is sufficient well-ripened stores; and what may be enough for one winter may not suffice for the next.

The next, and of great importance, is ventilation, and I do not think it makes much difference how it is obtained, whether from bottom or top.

Dryness comes next in importance, and it would seem entirely essential were it not for the fact that some very wet winters, when the combs got very moldy, the bees came out very strong, and built up unusually soon.

Shall they be kept in the cellar or out-of-doors? Perhaps I have not had enough experience with in-door wintering to speak positively, having wintered bees in the cellar but four or five winters. My experience is in favor of out-door wintering. In the cellar the bees always consumed less honey than out-of-doors, but used much more after they were put upon their summer stands, and did not build up so rapidly in the spring as those wintered out-of-doors. However, had I a cellar or a room that I could keep just below the freezing-point, I would always use it, from the fact that I had one winter's trial of such temperature with a wonderful good result.

I had about 80 colonies in a pile, with carpet over the top, and the thermometer about 28 degrees for 90 days. The bees kept very quiet, and there were fewer dead bees than I ever saw, a smaller consumption of honey, and the bees built up very quickly, and very early. I do not know of any practical way that a temperature of 28 degrees can be maintained one season with another.

Then what kind of hives, or fixing, is the best? The chaff hive I have not used, and dislike to condemn that which I have not tried; but they are costly, bulky, and have many disadvantages; and the result does not seem to warrant their use. The experience of many years leads me to think them unnecessary.

With single-walled hives, with proper stores and ventilation, I have been so successful that for the present at least I shall winter bees on the summer stands, being careful to keep the entrance free, turning back one end of the painted cloth above the frames, covering the opening with burlap folded; or, better, with something woolen, leaning a broad board in front of the hive to keep the sun from the front on cold, sunny days. I prefer the hives to front south. I then leave the bees to their fate, with confidence that my loss will be small. So prepared, my loss has been small, not 5 percent. Three times since I have been keeping bees my loss has been heavy—one heavy loss I attributed to poor food, once to long, extreme cold, and once I could give no reason. Doubtless some other localities might require other treatment.

Were it not that long papers are not good for a convention, I would go into further details, such as, Can we use any absorbents to aid in keeping hives dry? etc.

S. N. BLACK.

Mr. Black—How can you keep moisture out of the hives?

Mr. Becker—I put a lot of large corn-cobs into the oven and dry them thoroly. Place two or three above the brood-frames and over them burlap. It seems to attract the bees to the space, and they get from frame to frame better than otherwise.

Geo. Poindexter—I have been in the habit of wintering bees in the cellar; I had them too closely confined, and came nearly losing them. Last winter I packed straw in the upper part of the hives above ducking, with good results. I have packed the same way this winter, leaving the ducking lapt back at the edges.

Mr. Becker—When we have an abundance of honey in the fall, and plenty of young bees, the loss will be small.

Pres. Smith—With hives not painted the bees winter better, because the sun dries the moisture out of the boards.

Mr. Black—I had a hive of bees knocked over on its side by a cow, one evening when the mercury was 30 degrees below zero; the bees lived and were all right the next day.

Mr. Hyde—Out of 125 colonies I lost five by cold weather. Some had 25 or 30 pounds of honey after they

were dead. I have known bees to live all winter in a hive lying on its side.

Mr. Black—I think Spanish-needle honey is as good as any for bees to winter on.

The committee on premium list reported a revised list, which was adopted.

The election of officers for the ensuing year resulted as follows:

President—J. Q. Smith; vice-presidents—1st, S. N. Black; 2nd, Geo. Poindexter; 3rd, W. H. Hyde; 4th, Miss Bird C. Coulter; 5th, Miss L. C. Kennedy; secretary—Jas. A. Stone, Bradfordton; treasurer, Chas. Becker.

A paper by Mr. G. M. Doolittle, of New York State, was read, on

Burr-Combs or No Burr-Combs on Top-Bars.

Your secretary has asked me for a paper to be read at your meeting. I don't believe in long, dry, exhaustive papers to be read at a bee-keepers' convention. Do you? Right here is a chance for a discussion among your members, and for them to let the bee-keeping world know what they think in the matter.

I believe that the paper to be read at a bee-convention is not the one that thinks for you, but the one that makes you think. Is my belief right? If you have any lazy, go-as-you-please members, here is a chance for them to show that Doolittle's belief is wrong.

But to bee-keeping more direct. We have been told of late that burr-combs on top of the brood-frames are a thing not to be tolerated, and thick top-bars for the frames are made and advocated to-day. Is this a move in the right direction? I hope you will not all stampede en masse in one direction, for if you do no light will be obtained. Perhaps Dr. Miller will suggest an "I don't know," if the rest of you are sure.

During the past poor season I had several colonies which did not have a single burr-comb on the top-bars of their frames—or "ladders," as I prefer to call such burr-combs—while the majority of the colonies had all the way from one to 15 ladders on top of the frames, when the surplus arrangement, filled with sections, was placed on the hives. I always leave these ladders on the tops of the frames to the amount above named (these ladders save using a Hill's device or sticks over the frames in winter), but remove all from the bottoms of the supers when they are taken from the hives. The result was that the colonies in hives having no ladders gave an average result of nearly 10 sections less than did those having them, and I have had experience very similar before. Did the ladders, by inducing the bees to enter the sections more quickly, cause the result? Here is a chance for some good, deep thinking and experimenting.

If the ladders were not the cause, are there any suggestions to be made as to the same? Suggestions in order.

If the ladders were the cause, then they were to my benefit of not far from \$1.20 per colony for those which had them, as the 10 sections averaged me 12 cents each. Now, which will pay the best, thick top-bars and no burr-combs or ladders, or \$1.20 per colony with the burr-comb "nuisance," as it is called?

Making my best bow, I retire. G. M. DOOLITTLE.

Mr. DeLong (of Nebraska)—If the space is made smaller, there will be but little bridging. They need the bridging to climb over the space; take away the space and the bridging will not occur.

Mr. Becker—I think they make the most bridging when they are gathering the most honey.

Mr. Black—I have seen them, when they were getting honey rapidly, wedge it in at the ends of the brood-frames, and in every place where the least space occurred.

The secretary asked the opinion of the convention as to what they thought of tacking thin strips of wood on the tops of the brood-frames to take up the space, the same as we suppose the thick top-bars do it. He had thought of trying it. But as none had tried it, there was no reply.

A resolution of thanks to those who so kindly furnished valuable papers was read and adopted.

Adjourned *sine die*. JAS. A. STONE, Sec.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Richards, Ohio.

DISPOSING OF INFERIOR HONEY AT HOME.

I wish to think out loud a little on one line of an editorial note found on page 777 (1899). "Sell inferior kinds at home, or give them away." 'Specks that depends upon which market one leans most upon, and cares most about. The home market is easier cultivated, and far easier to hold against all comers, than the city market. A really lively and first-class home trade can not be kept up permanently if much poor honey is sold—not even if you tell them it is poor, and only accept half price for it. No man having drunk ripe old wine straightway desireth the raw, new article. And no kids eating good syrup (such as mammy makes on the stove, and perfumes the house with when she boils it over, as she mostly does), no such happy kids straightway desire poor honey. Poor honey is a desperate problem. Doubtful if it has any legitimate field, except to be given back to the bees in warm spring weather. I have sometimes taken pains to give poor honey to families unlikely to buy; but something within me protested pretty loudly against it. Training up some of the best men and women, about to be, to consider honey rather poor stuff, and to be poor honey customers. Of course, all this does not apply to those samples of honey which are poor merely in looks.

SMALL TREES VS. BIG TREES IN THE APIARY.

The apiary of Mr. Page, which opens out No. 49 (1899), is a fair representative of a large class of nice-looking, well-kept, well-painted apiaries with small trees sprinkled about—makes those of us who are curst with lots of big trees feel inclined to quarrel with our "lot."

QUEENS CHEAPER NOW THAN SOME YEARS AGO.

Twenty-five dollars for a queen, and \$3.75 to the express company for bringing her! Surely, we have made a trifle of progress in cheapness since that day "some years ago" which Mr. Didwell tells of on page 770.

WHITE CLOVER HONEY BETTER FARTHER NORTH.

Pres. Whitcomb is evidently on the track of the truth in explaining that white clover honey is better the farther North we go (provided we keep down in well-settled latitudes, that is), while heartsease is rather inclined to be the other way. As a general rule, I think we may expect every plant to yield better, both in quality and quantity, where it flourishes best. And most of the leading honey-plants will grow, if a little pains is taken with them, where they will scarcely yield nectar enough to attract a bee at all. For instance, almost any reader of this journal can have a patch of alfalfa in his garden, if he wants to; but comparatively few of them would ever see it visited eagerly by bees. Page 771.

HANDY RULE TO DETECT QUEENLESSNESS.

Handy rule from Mr. Cogshall. If there are queen-cups in the super, and they are *polisht out*, the colony below is queenless. Page 771.

CURE FOR INKY DROPS FROM SMOKER.

The cure for inky drops has at last been hammered out pretty nearly to perfection. ("Iron sharpeneth iron; so a man sharpeneth the countenance of his friend.") But still I'll mix in once more, as one important fact in the matter has not been clearly mentioned, so far as I have noticed. Sound wood, altho it will let much of its moisture go without resistance, can not be made to part with all its moisture—not even nearly all—by any process which the apiarist is likely to use. I think (without having positive evidence at hand) that rotten wood of the soft and whitish fiber sort is readily dried to pretty nearly absolute dryness. Probably few or no kinds of rotten wood hold onto moisture with the desperate grip characteristic of sound wood. So the points are, stop most of the condensation by a warm nozzle, cut off the needless supply of watery vapor by using dry fuel, and

look a little out for those fuels which can not be dried except in part. Page 776.

LIKE A WOMAN'S LAST WORD—BUT SENSIBLE.

It may sound a little like a woman's last word, but all the same it's a sensible word, where the editor says, "Don't use barrels unless you know that *you* can use them without leaking." Page 776.

COLOR CARDS FOR GRADING HONEY.

I hardly know where I stand as to the proposed color cards to grade honey by (page 777). My practice has all along been to look thru honey to grade it; yet I am aware that strong objections can be made. Between a greasy-looking section with the cappings touching the honey—said honey being white—and a section with snow-white capping and deep air-space over quite dark honey, I strongly suspect a majority of customers would choose the latter, as more ornamental and just as good to the taste.

ASTER AS A HONEY-PLANT.

A botanist would be apt to smile audibly at Mr. Schmidt's fear that folks may think there are two kinds of aster, when really there is but one. The flora I use describes *forty-one* species, not counting those of the Gulf region and Pacific coast, either. The picture is very life-like, and the species it shows is the leading one here, at Ohio's north line, just as he finds it to be at the southern end of the State. Something I have read in the past makes me think it is still better in Tennessee—and a material addition to the honey-resources there—as here it is not. Bees are only occasionally seen on it here; and the amount of their gatherings from it never totals much, I think. And I am just illiberal enough to suggest that, even down in Hamilton County, that strong and peculiar smell he notices at the hives comes from some entirely different plant. Page 785.

RETARDING FOUL BROOD WITH NAPHTHALENE.

Comrade Dudley has a brilliant plan to *retard* foul brood by vapor of naphthalene until the apiarist can cure it at his leisure and convenience. Prof. Cook, as it seems on page 786, thinks the vapor would have to be strong enough to drive the bees out to do it. Apparently there is a bad misprint in that article. As 33 to 1,000 is not "one in 3,000," presumably the first figures should read 0.33.

THOSE QUEEN-EXCLUDERS.

Mr. H. H. Hyde seems to hate 'em bad—those queen-excluders—and so back into heathenish darkness he would have us all go. Page 786.

KEEPING MICE OUT OF STRAW MATS.

Mice kept out of a stack of straw mats in summer by plenty of ashes in each interval. Sir Mouse can't nibble in such a stack without getting his fur full of ashes, which would soon mean a sore skin—ergo he decamps directly. Quite an invention; altho the fuss of building the stack must be considerable. C. P. Dadant, page 787.

HIVING SWARMS WITH NUCLEI.

Dr. Miller "has the drop" on Mr. Doolittle as to four carefully observed cases of hiving swarms with nuclei without special precautions. All the same Mr. Doolittle's way is far the safest for the boys to follow, and the precautions are not burdensome. Page 788.

BOILING FOUL-BROODY HONEY.

Dr. Mason's saying, on page 789, that to *boil* foul broody honey is sufficient, regardless of the time, marks very decidedly one of the phases of opinion on an important point. I think a majority of authorities incline to favor the long boiling. Quite possibly this divergence arises partly from the difference between laboratory work and out-in-the-yard work. Spores which a laboratory man could coax back into life may be that far gone that they are not dangerous in the yard.

BEEES AS STRAWBERRY POLLENIZERS.

The pollenization of flowers by bees is all right. The importance of the thing both to the bee-man and to the general public is very great. We are doing just right to keep up considerable racket about it, lest folks forget somehow. Still, I must scold a little about that editorial quotation on page 793, where W. H. Jenkins thinks he lost several hundred dollars in strawberries for lack of bees—fruit mostly buttons instead of luscious berries. Now if Mr. Jenkins

sees bees habitually on the strawberry bloom where he lives, I'll take back what I'm saying as far as he is concerned; but the probability is that he does not. It is quite rare. Our bees are wonderful creatures, but they are not equal to the task of doubling the strawberry crop by looking on from a distance. My impression is, that the pollen of the strawberry is not adhesive, but circulates with the wind freely, and that the insects that help in strawberry pollenization are mostly minute insects, which escape general observation by being so small. Certainly magnificent berries in great quantities are often produced—nay, usually produced—without a bee touching the patch at all.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Stimulative Feeding in the Spring.

Next spring I would like to try stimulative feeding on two colonies of bees, and, when they are strong enough, divide them and buy a queen for the queenless half.

1. How early should I begin to feed?
2. How much feed should I give at a time?
3. What time of the day should I give the feed?
4. Should I use two stories for brood, or one?

I have "Langstroth on the Honey-Bee" to explain dividing. IOWA.

ANSWERS.—1. Begin after bees are flying freely about every day. If you begin when it is cold and chilly, the bees will be induced to fly out when it is too cold for them, and the number chilled and lost will not be made good by your feeding.

2. Give half a pint to a pint of thinned honey or sugar syrup daily.

3. In the evening. Less danger of robbing then, and the bees will not be so much excited to fly if the weather is a little cool; but you may better not feed when weather is too cool.

4. Use one story till it is full; then a second; altho there is no harm in having a second before it is needed.

5. Keep studying your "Langstroth" carefully, and you will not get very far astray.

Italianizing Black Colonies of Bees.

I have 26 colonies of black bees in dovetail and Langstroth hives; also one colony of Italians whose queen I got from Ohio last spring. I introduced her successfully, and she soon had a very strong colony of pure Italians. Next spring I wish to Italianize or hybridize my black colonies, as I find they are unable to protect themselves against the robbing Italians. I would like the best and simplest method of doing so, for one of limited experience. WIS.

ANSWER.—The first thing of importance is to study well some of the fundamental principles that you will find in your text-book, the mastery of which will be worth to you the cost of the book several times over; and then you can better tell just what plan will best suit you.

As you probably allow your bees to swarm, here is a plan that will work well with one having little experience:

See that your Italian colony, which we will call No. 1, has plenty of stores in spring so it will breed up strong, and give it brood from other colonies so as to get it to swarm first. When it swarms, put the swarm on the stand of No. 1, and set No. 1 in place of another strong colony, say No. 2, setting No. 2 in a new place. No. 1 will thus get the flying force of No. 2, and in two or three days will be nearly as strong as it was before. In a week or 10 days a young queen will emerge, and a swarm will issue from No. 1. Hive the swarm on the present stand of No. 1, and put No. 1 in place

of say No. 3, putting No. 3 in a new place. No. 1 will swarm again in a day or two, when No. 1 will be replaced by its swarm, and you will put No. 1 in place of No. 4. Next day or so another swarm will issue from No. 1, and you will proceed as before, so long as No. 1 sees fit to swarm. That will give you 5 or 10 swarms with young queens that are daughters of your best queen.

□ Now let us go back to the time of the first swarm. When No. 1 swarms, instead of letting the swarm be satisfied with an empty hive, fill up the hive with brood from other hives, and by strengthening it sufficiently it will be likely to swarm again in a short time, when the story can be repeated as before; and this can be kept up till you have as many as 27 colonies with improved queens. By following up the same thing each year, you will soon work out all the black blood; at least to such an extent that you will have no pure blacks.

Of course, there are other ways by which you can have all changed the first year, but this is intended as an easy and safe way for an inexperienced operator.

A Bunch of Beginners' Questions.

1. What is the "Golden method" for producing comb honey?
2. In artificial swarming, say I had 5 colonies and 5 empty hives, can I take out 4 frames (I have 8-frame hives) of brood, put them into hives containing 4 frames of full sheets of foundation, replacing the frames I took out with 4 frames of full sheets of foundation? Will the brood I put in the empty hives hatch out all right without any bees, nurses, etc.? Should I shake off the bees into the old hive before I put them into the empty hive? How about a queen for the new hive? Should there not be some queen-cells to hatch out also, in the four frames I transfer to the empty hives?
3. Can I easily know a queen-cell?
4. Are there queen-cells in every frame of brood-comb?
5. I intend to work for comb honey—swarming conditions being best for comb honey—would it weaken the worker-force by removing the four frames of brood, especially if I did not shake off all the bees into the old hive?
6. I don't quite understand about cutting out cells and putting in queen-cells, etc.
7. About the Heddon method of transferring—the box that is to be placed on top to drum the bees into—the top of the hive I suppose is taken off; is the box to be large enough to fit the whole top? If not, what is to prevent the bees from flying out around the sides of the small box? Is the bottom of the box all open, or just a hole for the bees to go into the box? How would it do to have a window in the top?

SOUTH CAROLINA.

ANSWERS.—1. You will find the "Golden method" fully described in this journal for 1899, pages 4, 33, 65, and 97.

2. No; to put frames of brood without any bees in a new hive will be only dead loss. Don't think of trying to make new colonies at all until you know more of first principles by studying a good text-book. If your friend, whose journal you read, has no text-book to lend you, it would be a very nice thing for you to get a book to lend him. You need both a bee-journal and a text-book; but you should have a book first if you *must* get along without one of the two.

3. You will have no trouble whatever in knowing a queen-cell the first time you see one. If you see on a comb something that looks like a peanut made of beeswax, that's a queen-cell.

4. There may be one or more queen-cells on one comb and none on the rest. There may be queen-cells on every comb in the hive. There may not be a queen-cell in the whole hive, and most of the time there is none present. Generally, however, rudimentary cells, or cell-cups are present. But a complete queen-cell will be found only when the bees are rearing a young queen.

5. Every cell of brood removed will weaken the future force, the time when such weakening comes depending upon the age of the brood removed.

6. You will probably have no difficulty in understanding all about it from your text-book. The object of this department is to supplement the text-book, and anything not clearly understood from your text-book will be most cheerfully answered here. You will easily understand that if all the things of the text-book are answered here, it would take up all the room, for beginners are coming into the family with every number, so the whole journal would be taken up with things that can be found in the books, and the journal

would be of no value to any one who has such a book in his possession. This is by no means meant to discourage questions; they are gladly welcomed; only let them come after reading the text-book.

7. When bees are to be drummed out of a box-hive, the box-hive will usually be found with no bottom nailed on; so the hive is turned upside down and the drumming-box placed over. If the box is not of the same size as the hive, then there must be some sort of adjustment by means of pieces of board or cloth, the particular adjustment depending upon the difference between the box and the hive. Latterly, however, it is not considered necessary to have a close fit; a little smoke will prevent the bees flying out, and the bees may be driven with a large open space unprotected. The more free the passage from the hive to the box the better. A window would hardly be worth the trouble, and is not necessary.

What Makes a Laying Worker?

What is a laying worker? Is it a worker fed a few days as a queen, or can any worker lay eggs? I have several times had colonies that became queenless when there was no brood in the hive, and such colonies never develop laying workers. This generally occurred in the fall, during a time when the queens were not laying. The bees would live until they were robbed out or died out in the spring, and never develop any laying workers.

I tried the experiment of putting a frame of brood, just ready to seal, in one hive, after which it produced laying workers. I also took from a strong colony its queen and all of its brood, and left it in that condition for 30 days, and no laying workers appeared. I then gave them some old brood, and in due time they develop laying workers.

I do not claim that the above experiments prove any thing, as bees do not always do things exactly the same, but I would like to know what some of the leaders think about it.

OREGON.

ANSWER.—Answering the spirit of your question, I must say I don't know what it is that makes a laying worker. It was formerly held by some that in some way, perhaps by being near a queen-cell, a young worker got enough royal jelly to enable it to lay eggs. Perhaps no one holds that opinion at the present day. It can hardly be that it is "a worker fed a few days as a queen," for the scientists tell us that for the first 3 days queens and workers are fed alike, the worker being weaned or fed on coarser food after the first 3 days, while the queen has the same diet continued during the remaining two days of her larval life. So you see if a worker were fed two days more than usual on royal jelly, she would be a queen complete.

Your own observations seem to show that workers may take up the business of egg-laying rather late in life.

It was formerly thought that a single laying worker did all the business. Then it was thought there might be several, and within a few years actual dissection has shown that a large number, if not the majority of workers in a colony, may be engaged in egg-laying.

The time of year and existing conditions may make quite a difference as to the matter of workers promptly taking up the egg-business. The kind of bees also has something to do with it. In some cases a colony may be queenless a long time with no laying workers. In other cases they may begin laying while a young queen is present but not yet laying.

All things considered, it seems not unreasonable to believe it is possible that any worker may get to laying, but just what conditions are necessary to make that possible I don't know.

York's Honey Calendar for 1900 is a 16-page pamphlet especially gotten up to create a demand for honey among should-be consumers. The forepart was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample free; 25 copies for 30 cents; 50 for 50 cents; 100 for 90 cents; 250 for \$2.00; 500 for \$3.50. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

VOL. 40. JANUARY 18, 1900. NO. 3

Note—The American Bee Journal adopts the Orthography of the following Note, recommended by the Joint Action of the American Philological Association and the Philological Society of England:—Change "ad" to "ad" final to "i" when so pronounced, except when the "s" affects a preceding sound. Also some other changes are used.

The National Pure-Food Congress will hold its annual meeting in Washington, D. C., March 7, next. We hope that Rev. Emerson T. Abbott will again be sent to represent the interests of bee-keepers. He has done so excellently in the past in that line, and knows exactly what is needed in pure food legislation, that he should be continued a member of the Congress so long as there is a necessity for its existence—and that will likely be for some time yet, judging from the slow way in which righteous laws have been enacted and enforced in the past.

A Black and Blue Bee Journal. Referring to the correspondent in the Canadian Bee Journal, who wants all reports of big crops excluded and failures honestly published, the American Bee Keeper says:

"We do not know of a bee-paper that does not honestly publish failures, but if the world be to have a journal that chronicles only failures, its pages, to be appropriate, should be a sombre blue, with a cover of black crepe, and its title 'Blasted Hopes.'"

Aptis Dormata has a faithful adherent in the American Bee Keeper. Referring to Dr. Mason's comments in the Bee Keepers' Review, it is not discouraged by the reports that come as to the failures to domesticate the big bee in other countries. It says: "What Australia, Holland or China may think or want in relation to this matter is of no

concern to America." In Australia the paramount question is, "not to secure more honey, but rather to develop a market for that already on hand and now coming in." So the American Bee Keeper can understand that Australians may not want to have more honey gathered.

After all, does not a bee-keeper in Australia think, "I'd like to have my crop increase as much as possible, but I don't care to have the entire output increase in proportion?" And will the American Bee Keeper name the bee-keeper in this country who doesn't think exactly the same thing?

Six Thousand Dollars Cleared on Bees.—Sometimes a man invests in bees and loses money by it. Sometimes a man makes money by it. Much depends upon the man as well as his opportunities. N. C. Alford, a Colorado bee-keeper, is one of the successful kind. He says in *Gleanings in Bee-Culture*:

"I commenced the business without knowing anything about bees, and was in the business eight years, and cleared \$6,000 in that time, after paying for the bees and all the supplies and labor hired. I liked the business, and it paid well; but I got to be 65 years old, and two years ago I sold my bees, as I had 1,000 acres of land in cultivation, and 500 head of cattle, and am a director in the Poudre Valley bank. I did not allow my bees to swarm. I took out the queens in June. I ran about 260 colonies most of the time."

The Automobile for Bee-Keepers. Rambler gives in *Gleanings in Bee-Culture* a glowing account of the way in which the automobile may be used by bee-keepers. It is no doubt sportively meant, but it would not be stranger than some other things that have come to pass if it should all come true. With an automobile one is entirely free from anxiety lest the motive power should run away or capsize the load because of a sting from a loose bee, and this applies not only when the bees are to be hauled, but when a horse is to be used in any way about an apiary. Migratory bee-keeping will be encouraged with better roads and greater speed that will come. The automobile can be jacked up so the wheels will not touch the ground, and can then run a saw or other machinery. It can also be used to run a washing machine, churn, sewing machine or honey-extractor! It might also be used to ramble the Rambler around.

Ice-Houses Instead of Cellars for Bees.—We received the following from Mr. C. N. Hoagland, one of our New York State subscribers:

Editor York: I elipt the following from a paper called *The Household*, published in Boston:

SHIPPING BEES IN ICE.

It is not generally known that a great many insects can live for weeks in a state of suspended animation under the influence of cold. Flies and bees can stand an intense degree of cold, and yet revive if slowly thawed out. This fact has been taken advantage of lately in the shipping of bees.

Different varieties of bees are often sent from England to her colonies, but cost heavily to send alive with plenty of food. Now they are frozen, packed quite freely in a very small box, and thawed out on their arrival.

A number of bumble bees have recently been shipped to New Zealand in this manner, where they are found most useful in fertilizing the red clover that has lately been introduced into that colony.

If the above be true, would it not be well for us bee-keepers to build ice-houses instead of cellars and caves for our bees? What a fun it will be to the apiarist, when the process for liquefying the air becomes cheap, and we can freeze the air in a hive of bees and thaw them out in the spring, without any loss of bees or honey!

My experience rather confirms the plan, for I winter my bees about 100 feet high in the open, on the roof of a building; and as cold as it was last winter, they came out in the spring all right.

I. N. HOAGLAND.

It is not so very strange that such things can go the rounds of respectable papers. Outsiders know very little about bees, even those that are smart enough in other things to make good editors. They think, "If other they

creatures can remain frozen all winter and come out all right in the spring, why not bees? Indeed, bees may be frozen for a short time and come out alive, but to be frozen long enough to be sent from England to some English colony is quite another matter.

The Weekly Budget

REV. EMERSON T. ANNOTT is again at the head of the editorial department of the Modern Farmer. It is now expected to make of it a good agricultural paper. We trust its publishers will be successful in their venture.

MR. E. T. FLANAGAN, of Mt. Clair Co., Ill., on Jan. 8, sent us a newspaper clipping telling of the 12 year old son of a farmer living near Mitchell, Ill., who was stung into insensibility by a colony of bees late Saturday night, Jan. 6. The boy's father had just bought the bees and put the hive in the yard between the house and the barn temporarily, the morning before the accident occurred. That night, the son, on going to the barn on an errand, ran against the hive and upset it. The weather being warm the bees just covered the boy and stung him almost to death before they could be smoked off.

Mr. Flanagan wrote: "The unusual case of one being stung nearly to death in the dead of winter, here where it is at that time so cold, is an event out of the ordinary." We should say it is an unusual occurrence, and a sad one, too.

Mr. Flanagan reported his own bees wintering well, having had a fine flight the day he wrote.

MR. J. H. MARTIN, of Los Angeles Co., Calif., when writing us Jan. 3, mentioned several things besides business, as follows:

FRIEND YORK: This is a happy day for California bee-keepers, for we are having another nice rain. The rains have arrived in regular order so far this winter, and we have every reason to believe that we will have a good honey crop. We must have the latter as well as the early rains to give vigor to the honey-flora, and the early rains have been so beautiful that we will certainly get the latter. Northern California has received a great amount, so much that it has interfered with the fall and winter plowing, and sowing of grain.

January 11 attended a parade that is characteristic of this part of the country, and which could be held in but few places in the United States. It was a "Tournament of Roses," and given in the city of Pasadena, nine miles from Los Angeles. It was a fine affair, and in the long parade the vehicles were lavishly trimmed with roses and other flowers. If you had dropped down here from Chicago you would have thought yourself in Fairyland. The skies were smiling, the breezes soft; there was no need of overcoats. There was an immense crowd of happy, smiling people, and any quantity of beautiful girls in vehicles covered with flowers that they looked like angels resting upon flower-clouds. I was extremely intoxicated with the odor of the roses. Some sons of Belial might say that the intoxication came from the rays from angelic eyes, sweet, laughing mouths, shapely heads, and saucy curls—but perish the thought!

When the cares of the "Old Reliable" are too much for you, and illness comes, seek these shores and we bee men and the climate will do all we can to mend you. Don't be afraid of earthquakes—ours are of the mild order, and only now and then rattle down a building in some remote mountain fastness.

J. H. MARTIN.

We are glad to know that California is getting the much-needed rain again.

Many thanks, Mr. Martin, for your kind suggestion for us to seek the fountain of perpetual youth where you are, when old age and general worn-outness come upon us. What with fragrant flowers, health-restoring climate, and, above all, luscious, intoxicating girls—my, my, Mr. Martin!

No wonder you stay in California. But as most people are human, we'll forgive you this time.

But we don't know about those "mountain fastnesses" that seem to be really *awful* only when a good shaker of an earthquake doesn't come along, and then they become well, "mountain lozenges," we presume. No, thank you, we prefer to stay on solid ground a while yet. Altho' it within a few years you should succeed in getting rid of the "shakers," and still have the climate and "angels," we'll promise to think seriously of accepting your generous invitation.

MR. I. B. WILKIN, of Nevada Co., Ohio, when renewing his subscription for 1900, wrote us thus encouragingly:

"Altho' the last two years have been failures in the production of honey, still I have hopes for the future, and will not do without the American Bee Journal. It stands by us and defends our cause in time of plenty, and we should still do our part when we have but little. Success to the ever 'Reliable.'"

AMERICAN FRUIT AND VEGETABLE JOURNAL. This is the name of a new monthly paper for fruit and vegetable growers, edited by Prof. T. H. Jones, associate editor of the Farm, Field and Household; but the new paper is in no way connected with the latter, which has this to say of Prof. Jones:

"Born in Ohio, Mr. Jones came with his father as a boy to a farm in Wayne Co., Ill. On the farm was an orchard of some 150 varieties or more of choice fruits planted by Samuel Halliday, father of Halliday Bros. This afforded an excellent object lesson in fruit culture. The young man saw that region greatly developed in the planting of orchards. After ups and downs, and a conflict with many pests in 1883, a wonderful crop of choice fruit was harvested, which was sold for some \$5,000. This proved that Wayne and neighboring counties were adapted to fruit. The Jones fruit farm became well known in the State.

"Prof. Jones was educated at McKendree College, Lebanon, Ill., graduating in 1890. He has ever since been more or less occupied with horticulture, first for ten years a teacher or superintendent of public schools, or a professor or president of a college. In 1896 he went to Kansas, and with a partner planted 175 acres in fruit, mostly in apples. He still retains a large interest in this orchard. In Kansas, also, Prof. Jones was connected with important educational institutions, and in 1896 returned to Illinois to take the presidency of the Orchard City College at Elora. As is well known, this is located in the midst of an apple growing region.

"During his educational work Prof. Jones has had experience as an editor, and as will be noted, has kept up a practical connection with fruit culture and with gardening in general. He is familiar with the orchards of Missouri, Kansas, Illinois, and other States, and has an extensive acquaintance with nurserymen and farmers interested in these branches of horticulture."

A sample copy of this new fruit and vegetable journal may be had by addressing Prof. T. H. Jones, 713 Masonic Temple, Chicago, Ill. We have made a very fortunate arrangement, so that we can offer our readers the American Fruit and Vegetable Journal with the American Bee Journal both for one year at the price of our journal \$1.00—to one who pays his subscription to the Bee Journal a year in advance. The price of the new paper is 50 cents a year. Or, we will give, as a premium, a year's subscription to the new paper to the one sending us one new subscriber to the Bee Journal for a year—with \$1.00. To any one interested in the growing of fruit and vegetables the new monthly will be extremely valuable. And as bee-keeping and fruit-growing go so well together, every bee-keeper ought to have both the American Bee Journal and the American Fruit and Vegetable Journal regularly.

"The Hum of the Bees in the Apple Tree Bloom" is the name of the new bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

Crystallization of Beeswax, according to a new theory advanced in the British Bee Journal, is to be credited with the hexagonal form of cells in honey-comb. Editor Cowan, however, gives pretty good reasons why it is not reasonable to put faith in the new theory.

Hunting Wild Bees in Winter.

—When a thaw comes, the bee-keeper may hunt for bee-trees, the best time being the day after the thaw, when there is a crust on the snow that will hold up a man. When a bee is found, the hunter circles around the bee till more are found, the bees being plentier on the side toward the tree. Under the tree they will be found in plenty, the largest number on the side opposite the wind.—Bee-Keepers' Review.

Bee-Keepers' Sins.—Ten of them are enumerated in Rheinische Bienenzeitung as the prevailing ones:

1. Wintering weak colonies.
2. Not allowing sufficient stores for winter.
3. Not packing colonies warm enough for winter.
4. Not uniting weaklings in spring.
5. Making untimely artificial swarms.
6. Extracting honey at the wrong time.
7. Using foundation too sparingly.
8. Selling honey at too low price.
9. Lazily attending conventions.
10. Being selfish about imparting information to others.

That last is not a common sin this side the water.

Watering Bees.—Morley Pettit gives in Gleanings in Bee-Culture a plan by which he thinks the bees are sure of getting water that is always clean in a convenient way. He says:

"What we have found to be the most complete watering-place is made from a wooden bucket, a piece of match flooring 10 or 12 feet long, and a few stakes. With an inch auger, bore a hole in the side of the bucket as near the bottom as possible. Take a piece of pine and trim the end until it just fits the hole water-tight. Then bore a hole in the end, half an inch across, and an inch deep. In the bottom of this hole make a gimlet-hole, also an inch deep. Now saw off this two-inch piece. This gives a round piece of pine, one inch in diameter and two inches long, having a hole thru it lengthwise half an inch at one end, and about the size of an ordinary nail at the other. Use this to plug up the hole in the bucket, putting the end with the large hole in first, and allowing the other end to project for a spout. A nail placed loosely in the gimlet hole will regulate the flow. Drive 3 stakes in the ground to form a stand. Set the bucket on these, and a shade-board will complete the fountain.

"The piece of flooring placed on edge with the groove up is the trough. Have one end slightly elevated to give a good fall, and allow the water from the fountain to drip into the higher end of the trough, and run along the channel. The whole should be high enough so that a pan or pail can be set to catch the water as it flows from the lower end. Allow the water to flow freely enough to make a good current along the channel. If the bucket and trough are thoroly washed every morning the current in the channel will provide the bees with clean water all day."

The Long-Ideal Hive is used by a comparatively small number of bee-keepers in this country, altho largely used in Germany. Instead of adding stories to give more room, the room is gained by spreading out laterally, 25 or more Lang-

Yellow Sweet Clover Seed

WE HAVE IT AT LAST!

We have finally succeeded in getting a SMALL quantity of the seed of the **YELLOW** variety of sweet clover. This kind blooms from two to four weeks earlier than the common or white variety of sweet clover. It also grows much shorter, only about two feet in height. It is as much visited by the bees as the white, and usually comes into bloom ahead of white clover and basswood. We offer the seed as a premium

A QUARTER POUND FOR SENDING ONE NEW SUBSCRIPTION.

So long as it lasts, we will mail a quarter pound of the seed to a regular paid-up subscriber who sends us ONE NEW subscriber for the American Bee Journal one year, with \$1.00.

We have been trying for years to secure this seed, and finally succeeded in getting it. It is new seed, gathered last season by an old personal friend of ours, so we know it is all right. But we have only a small supply. When nearly out we will mention it.

Root's Column

The ABC of Bee-Culture!

Revised in 1899

Three thousand sold in three months.....

67,000 copies published.....

Root's A B C—the 67th thousand! Who ever could have imagined it? But then, this is a book which requires to be known before the fact of its enormous circulation can be realized. And when once known it is a book to be prized beyond many others, for its complete, interesting and practical nature. "A cyclopaedia of everything pertaining to the care of the honey-bee" in very truth; a book of fine views and photographs, almost; illustrations of all the noble machinery used in one of the largest bee-supply factories in the world. Almost every thing a bee-man wants to know is given in precise alphabetical order, while its exceptionally clear type is brought out in the true American style of excellence. If there is any book on apiculture that may be thoroly recommended, it is this of The A. I. Root Co., Medina, Ohio.—BEE-CHAT, LONDON, ENG.

stroth frames being used in the one story. Perhaps the most prominent user of long-ideal hives in this country is the veteran O. O. Poppleton, who prefers this kind of hive for extracted honey, having used it extensively in Iowa, Cuba and Florida. In reply to an inquiry, he says in Gleanings in Bee-Culture:

"The dimensions of the long-ideal hive can be varied to suit any style of frame one wishes to use, keeping at least two points in view, viz., that the frames in use in them should beat least two or more inches deeper than is the standard Langstroth frame, and the hive should be long enough to hold as much comb in the aggregate as at least 25 Langstroth frames will hold. These are the essential differences between any simply made standard hive and the long-ideal.

"The hives I have in use are made of four boards 13 inches wide, front and back ones being 36 inches long, and the ends 15 inches. When nailed together the inside measure is 13 inches deep, 13 1/4 wide, and 36 long. Entrance to hive is 1 1/2 x 12 in the center of the lower edge of the front. The two sides have rabbets in the inside of the upper edge 1/2 x 1/2, for ends of top-bar of frames to rest in. I use a tight bottom-board projecting in front 1 1/2 to 3 inches. Tight bottom-boards are a necessity with me because I practice migratory bee-keeping, but are not essential. Like the Dadants, I prefer the old-style telescopic cover. I couldn't be induced to use any other kind; but these are not essential to this system. Any style of cover works the same on these hives as on any other.

"The frames I use are 12 inches square, inside measure; but for Mr. Emory, or any one else wishing to test this style of hive on a small scale, I would advise his using the extra-deep Langstroth or Hoffman frame now being made for use in the Draper barns. In case he should ever wish to do so they could be easily changed to the standard size by cutting off the bottoms of the end-bars. The dimensions of the hives in case those frames are used would be the same from front to rear as in the Simplicity hive—enough deeper to fit the deep frames, and not less than 30 inches long, inside measure."

GENERAL ITEMS

Results of the Season of 1899.

I commenced in the spring with about 80 colonies of bees, rather weak. They built up slowly, owing to bad weather, increased to 100, and got about 1,200 pounds of good honey, mostly all extracted. I united for winter down to about 80 again, as that is about the number that I care to keep, as I farm for a living. A. J. McBRIDE.
Watauga Co., N. C., Dec. 23, 1899.

Hoffman Frames—Introducing, Etc.

I think the Hoffman self-spacing frame is all right except the top-bar. The 3/4 is too clumsy and heavy, and occupies too much of the honey space; costs too much for freight, etc. The beaded frame has similar objection, and besides fastening the foundation to this bar with the roller is too much trouble and sometimes causes loss. The 3/8 bar is too light—liable to sag. What we want in all cases is the happy medium—1/2 inch, in my opinion would be right with sawkerf 1/4 inch deep to receive the foundation or wood guide, as might be preferred. This, to my mind, would be the ideal frame, and as this is the hive that our supply manufacturers are preparing for the coming year, I think they should give this a consideration. I shall order this frame for my own use, and to supply my trade the coming season.

The side queen-introducing cage workt all right for me when placed on old comb. The bees will eat in, but don't bother them

HAMMOND'S
Michigan Northern-Grown Onion Seed.
I sold 56,000 lbs. of this seed in 1899. My customers report yields of 450 to 1,250 bushels of onions per acre from this seed. Some of them intimate that this seed is worth \$5 to \$10 per lb. more than the California grown seed sold by anybody. I guarantee this seed to be new and freshly grown. We have seed of all the leading and standard varieties. We make special prices on large lots. Onion sets of all varieties. Buy direct from the grower. Catalogue—extended and illustrated—free.

Two Wagons at One Price.

It is a matter of great convenience and a saving of labor for a farmer to have a low, handy wagon. They save more than half the labor of loading in hauling manure, hay, grain, corn-fodder, wood, stones, etc. The man who already has a wagon may have one of these low handy wagons at the small additional cost for a set of wheels. These Electric Steel Wheels, with either direct or stagger spokes, with broad-faced tire, are made to fit any axle. You can convert your old wagon to a low, handy wagon in a few moments time. You thus virtually have two wagons at one price.

Write to the Electric wheel Co., Box 16, Quincy, Ill., for their catalog, which fully explains about these and their Electric Handy Wagons, Electric Feed Cookers, etc.

THE MOST LIVE CHICKS

Experience the Best Teacher.

But a wise man profits by the experience of others. Every farmer and dairyman needs a practical, helpful paper like

Dairy and Creamery

PUBLISHED AT CHICAGO, ILL.

filled with information gathered from the actual experience of practical and scientific breeders and feeders of cattle and pigs. He wants to know how other men get the best results; how to feed to the best profit; how best to utilize his skim milk; how to build up a first-class dairy from the resources he has; what crops to grow to keep up the flow of milk at all seasons.

Last year a patron of a Kansas creamery who read a dairy paper and kept good cows, made \$36.00 per cow more than the poorest patron of the same creamery who did not read a dairy paper. That means something; it shows the value of an up-to-date, reliable adviser like DAIRY AND CREAMERY. (Subscription 50 cts. per year.)

FREE!

We will send DAIRY AND CREAMERY, the best semi-monthly paper published for farmers and dairymen, absolutely FREE for one year to all new subscribers to this paper, and to all old subscribers paying their subscription one year in advance. Both papers for the price of one. Send your subscription to this office while this offer is open. Both Papers \$1.00.

AMERICAN BEE JOURNAL, CHICAGO, ILL.

A Further Offer:

We will give Dairy and Creamery for one year as a premium to any one of our readers who sends us one new subscriber to the American Bee Journal for one year at \$1.00. Unless these offers appear again after March 1, in these columns, they will be withdrawn at that date; so you would better take advantage of them at once. Address,

1D41 **GEORGE W. YORK & CO., 118 Mich. St., Chicago, Ill.**

Don't fail to mention the Bee Journal when writing advertisers.

till the 4th day, when with but few exceptions all will be well.

Burlap bagging is best for packing over frames with corncobs across the frames to give passage over them. Then fill up the super with carpet, old clothing, or chaff, as most convenient. We winter our bees on the summer stands here.

The past fall was an ideal one—plenty of rain and snow, and not cold. The bees had an outing the other day.

I began last spring with 12 colonies—one of these queenless—and increased to 32 good, strong colonies. I reared some queens, brought some, and used quite freely of foundation. I took 500 pounds of alfalfa comb honey. Considering the amount of alfalfa that we now have in this part of Kansas, and the great amount of moisture that we are having, the coming season promises to be a boomer. Comb honey is retailing at 18 cents.

The "Old Reliable" is up to date, and if you are fortunate enough to be a subscriber and will read it you need not fail to be thoroughly informed, nor fail to enjoy this goodly land of milk and honey.

STILAS HARTER.

McPherson Co., Kan., Dec. 26, 1899.

Bees Didn't Do Well.

I like the American Bee Journal very much, and I would not be without it; it is a great help. Bees did not do much good last season in this part of the country—hardly enough to keep them, and I had to feed. I had four colonies in the spring, and increased to six by the nucleus plan.

W. C. STORTZ.

Mason Co., W. Va., Dec. 22, 1899.

Putting Bees in Early.

I saw in the American Bee Journal that some one put a few colonies of bees into the cellar Nov. 7. He thinks that is pretty early to put in bees, so he tried only a few colonies to find out how it works. He promises to give the results in the spring. I assure him that the result will be good, if it works with him as it does with me. I put my bees into the cellar Oct. 30. We had quite a warm spell after that, but I left them in, and they are all right now. I also will give the results next spring.

In 1898 I put them early into the cellar, and took them out late in the spring, and they came out all right. I never before saw such strong colonies in the spring.

This year has been a very poor one for honey here. When we first put the bees out there was a slight flow from poplar and maple, which was stored in the brood apartment. Next came dandelion, and white oats. These filled the hives up pretty well, and the bees began to cast swarms. When the flow was over there came a long spell that there was hardly anything for them to work on, before white clover and basswood came into bloom. Basswood did not last long, and it was too dry for clover, but buckwheat helped us out; it started brood-rearing for the fall, and filled up the brood apartment, so the bees have at least buckwheat honey to winter on. Buckwheat is sometimes quite a source of comb honey here, also for extracted. JOS. BETHKE.

Sauk Co., Wis., Dec. 19, 1899.

Honey Season a Failure in 1899.

The American bottom in the vicinity of St. Louis seems to have been a failure the past season in the matter of honey. I lost 30 out of 65 colonies the winter of 1898-99. They had plenty of stores but it was too cold for bees on the summer stands. I obtained some more from a neighbor, started with 40, increased to 50, but got only about 50 pounds of comb honey. Bees got very strong on white clover—as strong as I ever saw—but after that there was nothing. Heartease and smartweed they did not work on, and of Spanish-needle I saw none. The fall asters, or whiteweed, were caught by frost as they were coming into bloom, and after that the bees did not visit them.

DOES THE WORK BETTER THAN HENS.

OUR INCUBATORS

are scientifically perfect, a 200 size hatching more chicks than 20 hens and at a time when sitters are hard to get. As money makers, no apparatus will equal a **Successful Hatcher.** We are the largest exclusive manufacturers of standard incubators and brooders. Send 6 cents for our 150-page Catalogue, printed in 5 languages. Address: **DES MOINES INCUBATOR CO., Box 78, DES MOINES, IOWA.**

Please mention Bee Journal when writing.

They went into winter quarters with plenty of honey to live on, principally from the white clover.

I think we are overstocked here with bees, but I will try one more season. White clover has come back again to us here; for 15 years we hardly saw any, while 25 to 30 years ago every place was white with it.

C. A. HAINES.

Laying Workers and a Remedy.

Where there is evidence of the existence of the pest, there are no nurse-bees, and the scant supply of field-bees is rapidly diminishing. By overcoming these two misfortunes the evidences of the existence of the troublesome insect will disappear.

REMEDY.—Give the colony a frame of hatching brood. In three or four days repeat the dose. After a like interval give it a frame of worker-eggs, and, if convenient, a queen-cell inserted in a West queen-cell protector. With me this remedy works satisfactorily. It may help our Indian Territory enquirer.

Still Dry—An Earthquake.

Everything points to another dry year here, yet there is plenty of time for an abundance of rain. Bee-keepers and dry ranchers have had a very hard time of it the past two years, but we still have great hopes for the future.

I enclose a clipping from my blackberry patch. This is a perfect morning, like your brightest day of June. But one thing happened to mar the beauty of the day. At 4:30 o'clock this morning, we experienced a severe earthquake, which destroyed two towns—San Jacinto, 23 miles from us, and Hemet, 20 miles away. No lives were lost, but buildings all torn down.

B. S. TAYLOR.

[The sprig of blackberry had fragrant blossoms on it. We are glad to hear that no lives were lost thru the earth's trembling—EDITOR.]

Plain Sections and Fences.

I will here give you the results of a test between the fence and plain section, and the old style bee-way section and the solid separator.

I fitted up two supers, put in one side fences and plain sections, and in the other side the bee-way section and solid separator—that is, I put 12 of each kind of sections and separated them in each of the two supers. From one hive I got over twice as much honey as usual, and from the other nearly three times as much—from the side that was fixt with the fence and plain sections. The honey was taken out of both sides as fast as filled. So I think I want the fence in my supers.

JOSEPH E. MORGAN.
Spartanburg Co., S. C., Dec. 25, 1899.

Had to Feed for Winter Stores.

The latter part of the summer (from the middle of August until the latter part of September) I was away from home, using the hot springs in South Dakota, to counteract the bad effects of la grippe, which had been fastening upon my system for the last 3 years, and I am happy to say that the water cure has had a most wonderful effect, inasmuch as I am greatly improved in my health.

But when I came home from the springs, expecting to extract at least 2,000 pounds of honey, I found to my astonishment that nearly all my bees were in a deplorable condition, yes, some even actually starving for the want of stores.

I went right to work, and fed in about a week's time 1,000 pounds of syrup, so that my bees are now in first-class condition. They had splendid flights Dec. 21 and 22, and also today.

Before going to the hot springs I took al-

most 1,000 pounds of extracted A No. 1 melilot (sweet clover) honey, and also some section honey. Having considerable dark honey on hand from last fall, I fed that, mixt with the best quality of sugar syrup, and thus I could sell all my melilot honey.

I now have the same number of colonies I had the commencement of the season—27 colonies in my standard hives with American frames, and 6 colonies in the new Heddon hives, with 12 queens of 1898 and 21 queens carefully reared in 1899.

WM. STOLLEY.

Hall Co., Neb., Dec. 23, 1899.

A Beginner's Experience.

I bought five colonies about two years ago, and have increased in the two years to 13. They are the first I ever owned, and I have had to learn by experience and the help of the American Bee Journal. My bees did but little good last season. I am not able to take the care of them that I would like to. I put the hives on a bench in winter, made about six inches high, set them as close together as I could, and put sacks on top and around them.

I sold my fall crop of honey at 15 cents a pound in the town of Asheville.

J. W. HAWKINS.

Buncombe Co., N. C., Dec. 27, 1899.

Cedar Hives—Moths.

I find in the American Bee Journal an enquiry as to red cedar for hives. I have used over 50 in my apiary for several years, and shall never use any other, no matter what the cost. There are several points of excellence in cedar hives—1st, they don't swell and shrink like those made of other lumber; 2nd, they keep drier; 3rd, they are lighter; and 4th, they don't warp as badly as pine. Give them a good coat of paint, and you will find them all right.

As to moths, keep good Italian bees, strong and healthy, and the moths won't bother.

R. G. HAUN.

Kittitas Co., Wash.

Bees Not Profitable for Him.

Bees have not been very profitable for em. I started with one colony three years ago, and have bought six colonies, all in box-hives, so I had to transfer to movable-frame hives. The first two years I didn't read any bee-literature, and I see now I made some grave mistakes. Every one who has only one colony of bees should read good literature on bees. A good newspaper is very instructive whether a man keeps bees or not. I have read several this year, and decided the American Bee Journal comes nearer to what I need than any I have seen.

J. R. SCOTT.

Lamar Co., Tex., Jan. 1.

A Dry Season—Wiser Marauders.

The past season was the driest that we have ever had—not one rain from the middle of April till the middle of September—not more than a five or ten minute dash. Corn, beans, potatoes and hay were about half an average crop; clover was conspicuously absent.

My 70 colonies stored about 60 pounds of surplus, and I gave them 600 pounds of granulated sugar for winter stores.

I have kept an out-apiary of 12 colonies at a Mr. Light's, who then ran a custom-mill. While he was grinding my feed I would look after the bees. He moved away last fall, and the family that expected to move into his house in a week or two failed to do so. About the middle of January, during zero weather, some young men and boys were cutting and drawing ice from the pond near the apiary, and some of them opened the hives, took out frames of honey and jammed others out of place, and left off some of the covers, so the bees were in bad shape when I found them, except two. I did not dare to leave them there, so I moved them home Jan. 20.

I did not make much fuss, but found out

who were at work there, and who were looking on. By the middle of April all but three colonies were nearly dead, but the boys had said enough so I found out some of them that had disturbed the bees. I saw a good lawyer, and told him to write each one and give them a week to come and settle with me. They sent a man, and found out what I would take, and after some quarreling among themselves, they raised the \$50 and paid me.

D. L. FILES.

Monroe Co., N. Y., Dec. 27, 1899.

Convention Notices.

Minnesota.—The Southern Minnesota Bee-Keepers' Association will meet in Winona, Jan. 23 and 24, 1900. E. B. HUFFMAN, Pres.

Homer, Minn.

California.—The tenth annual convention of the California State Bee-Keepers' Association will be held in the Chamber of Commerce, at Los Angeles, Feb. 21 and 22, 1900. It will be called to order at 1:30 p.m., Feb. 21. At this time the railroads will sell round-trip tickets to Los Angeles and return for one and one-third fare, on account of the Industrial, Mining, and Citrus Exposition, which will be held in Los Angeles. Tickets good for 10 days. Let every bee-keeper bring some hive, tool or experience that he has found valuable, and we will have a good convention. J. F. MCINTYRE, Sec.

Sespe, Calif.

Wisconsin.—There will be a joint convention of all Wisconsin bee-keepers' societies at the 16th annual meeting of the State Bee-Keepers' Association, Feb. 7 and 8, 1900, in the State Capitol, at Madison, Wis. Many prominent bee-keepers will be there and take part.

Excursion rates of a fare and one-third for the round-trip, for railroad tickets purchased in the State, for over 50 cents each. Be sure to bring a certificate of each ticket purchase so it can be signed Feb. 8, in Madison, and entitle the holder to a third fare return.

The State Horticultural and State Cheese-makers' Associations will meet on the same date in the Capitol.

Don't forget the date—Feb. 7 and 8. It will pay you to attend. N. E. FRANCE, Sec.

Platteville, Wis.

The Bee-Keeper's Guide

Or, Manual of the Apiary,

—BY—

PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipt, or his library complete, without THE BEE-KEEPERS' GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

A LITERARY GEM

THE MOST ENGAGING BOOK EVER WRITTEN

BY **IAN MACLAREN**

REV. **H. M. WHARTON, D.D.**

J. WILLIAM BUEL, Ph.D.

"The Golden Morning"

A BOOK FOR WHICH THE WORLD HAS WAITED

ITS PLACE IS IN EVERY CHRISTIAN HOME

IT WILL BIND THE BIBLE CLOSER TO THE PEOPLE

IT IS SURE TO EXERT A POWERFUL INFLUENCE FOR GOOD

NOTHING LIKE IT EVER BEFORE WRITTEN

NOT TO BE HAD - IN - BOOK STORES

NEW AND GOSSIP OF A NEW BOOK ON THE BIBLE have been current in book and Christian circles everywhere for some months. In its authorship was to be combined the superb talents and literary abilities of three of the greatest lights in the world of religious literature.

The book is about to appear and on its title page in collaboration as authors are found the names of that most popular of all writers, **IAN MACLAREN** (Rev. John Watson), together with **H. M. WHARTON, D.D.**, the great Evangelist, and **J. WILLIAM BUEL, Ph.D.**, one of the most prominent and popular writers on Biblical subjects. A MASTERPIECE INDEED must be the book which calls to its creation such a combination of unmatched talents. IT IS A MASTERPIECE—and it is good news we bring our readers when we tell them that after the most persistent endeavor and the most industrious and earnest negotiations with the Publishers, this paper is one of a syndicate which has secured the entire first edition for distribution among their subscribers, not as a means of winning profits, but to encourage the people to become regular readers, because of the unusual privileges which are offered regular patrons.

The book is entitled "**THE GOLDEN MORNING**," and while it was intended to be a \$5.00 book, and has everything about it—authorship, illustrations, paper, printing and binding—to warrant that price, we have, after many objections and refusals, made terms whereby **WE ARE IN POSITION TO OFFER IT TO OUR READERS AT A GREAT REDUCTION.** It contains nearly 800 pages and over 500 superb illustrations. It is printed with clear type on coated paper, and is bound in beautifully illuminated covers, with gold and colored stamping.

IT IS IN REALITY THE BIBLE IN STORY FORM arranged so as to assure a perfect understanding of THE GREATEST OF ALL BOOKS even by little children. All ambiguous and obscure phrases and descriptions have been put into language which makes them clear as noon-day. The historic events have been arranged in their proper order, and the story is made continuous and of absorbing interest throughout. Poetical description so freely used in the Bible, and the many Parables, have all received analysis and now appear as plainly told tales which need no interpreter or explanation.

Hundreds of artistic and accurate pictures have been used to embellish its pages and fix in the mind of reader or student the scenes so graphically described. No book of a religious nature has ever been so sumptuously illustrated. This feature alone costing an enormous sum of money, as every drawing was made especially for this work.

It will be of highest value to the young, as from a few readings, they will get such an understanding of Bible truths and promises from this book, that it would require years for them to gather through Bible reading or study. Indeed, one of the chief claims of "**THE GOLDEN MORNING**" to universal popularity, is that the children will learn to reverence and love the Bible and to accept its teachings through reading this charmingly written story.

WE ARE READY TO DISTRIBUTE THIS ORAND BOOK AMONG OUR READERS who should order at once, as our portion of the introductory edition is limited. The prices are as follows, **WITH POSTAGE PREPAID:**

BOUND IN EXTRA FINE CLOTH, BEAUTIFUL GOLD AND COLORED STAMPING \$2.75
SUPERB HALF MOROCCO, WITH BURNISHED RED EDGES \$3.75

THE BOOK WILL NOT BE ON SALE IN BOOK-STORES, AND SHOULD BE ORDERED FROM THE OFFICE OF THIS PUBLICATION. EACH ORDER WILL BE PLACED ON FILE ON ITS ARRIVAL AND FILLED IN THE ORDER RECEIVED. BECAUSE OF THE EXTREMELY NARROW MARGIN OF PROFIT, CASH WILL BE EXPECTED WITH EACH ORDER. SHOULD THE BOOK BE UNSATISFACTORY WHEN RECEIVED AND EXAMINED, IT MAY BE RETURNED AND THE MONEY WILL BE CHEERFULLY REFUNDED.

Address, **GEORGE W. YORK & CO.**

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Jan. 8.—We quote best white comb at 15c; an occasional small lot of fancy sells at 16c; off grades of white, 12@14c; ambers, 10@12c. Extracted, 8@9c for fancy white; 7@8c for amber; 6@7c for dark grades. Beeswax, 27c. Receipts are larger and the demand is not as good as it has been. **R. A. BURNETT & Co.**

CINCINNATI, Dec. 7.—There is a good demand for all kinds of extracted honey. White clover and basswood sell at 8@8½c; amber and Southern, 6@7c, according to quality and package. Fancy comb honey in no-drip shipping-cases sells at 15@16c; darker grades hard to sell at any price. Beeswax, 26c. **C. H. W. WEBER,** Successor to Chas. F. Muth & Son and A. Muth

LOS ANGELES, Jan. 4.—1-pound frames, 12½@15c; 2-pound cans, 2 dozen in case, per dozen, \$2.50; 2-pound glass pails, per dozen, \$2.50. Extracted, water white, 60-pound tins, per pound, 8½c; light amber, 7½@8c; dark amber, 7½c. Beeswax, 25@26c.

KANSAS CITY, Dec. 9.—We quote No. 1 white comb, 13½@14c; No. 2, 13@13½c; No. 1 amber, 13@13½c; No. 2, 12@13c. Extracted, white, 7½@8c; amber, 7@7½c; dark, 5½@6c. Beeswax, 20@22c. **C. C. CLEMONS & Co.**

BUFFALO, Jan. 5.—Market bare of fancy white one-pound comb honey, and selling at 15@16c; fair to good, 12@14c; buckwheat, dark, poor, etc., 8@10c. Fancy pure beeswax, 28@30c. **BATTERSON & Co.**

NEW YORK, Dec. 10.—Demand is very good for all grades of comb honey. Receipts are somewhat light and not up to former years. We quote:

Fancy white, 15 cents; No. 1, white, 13@14c; amber, 11@12c; and buckwheat, 9@11c., as to quality. Extracted remains firm at following prices: California white, 8½c; light amber, 8c; white clover and basswood, 8c; amber, 7½c. Very little trade for extracted buckwheat as yet. Southern, fancy, 7½c per pound; other grades, as to quality, from 70c to 75c gallon. Beeswax quiet at 26@27c. **HILDRETH & SEGELEKEN.**

SAN FRANCISCO, Jan. 3.—White comb, 11½@12½c; amber, 8@10c. Extracted, white, 7½@8c. Light amber, 7@7½c; amber, 5@5½c; Beeswax, 26@27c.

Market is very lightly stocked with extracted of desirable grade, and is firm at the quotations, with no likelihood of supplies increasing during the balance of the season. Comb honey is in fair supply, considering it has to depend mainly on local custom, but values for same remain steady.

CLEVELAND, Dec. 1.—Fancy white, 16@17c; No. 1 white, 15@16c; No. 1 amber, 13@14c; No. 2 amber, 12@13c; buckwheat, 9@10c. White extracted, 8@9c. **A. B. WILLIAMS & Co.**

BOSTON, Dec. 8.—We quote as follows: Fancy white, 16c; A No. 1, 15c; No. 1, 13@14c; buckwheat will not sell in this city. Extracted, light amber, 7@8c.

There is very little now to report in the line of our honey market. The retail trade are loath to pay the higher prices and are buying in a very small way, still the demand is fully equal to the supply. **BLAKE, SCOTT & LEE.**

ALBANY, Dec. 10.—We quote: Fancy white comb, 15c; No. 1 white, 13@14c; mixt, 11@13c; buckwheat, 10@11c. Extracted, white, 8@9c; mixt, 6½@7c; dark, 6. Beeswax, 26@28c. **MACDUGAL & Co.**

Successors to Chas. McCulloch & Co.

OMAHA, Jan. 4.—Prices remain unchanged. Fancy white is still moving slowly at 14@14½c. Extracted, white, 8½c. Now that holiday trade is over and dealers have taken their inventory, they soon will be thinking of replenishing their stock and more lively trade is anticipated in the near future, but no material advance is looked for during January. **PEYCKE BROS.**

DETROIT, Jan. 11.—Fancy white, 16@17c; No. 1, white, 14@15c; dark amber, 10@13c. Extracted, white, 8c; dark and amber, 6@7c. Beeswax, 24@25c. **M. H. HUNT & SON.**

WANTED.—Extracted honey, all kinds; mail sample and price expected delivered at Cincinnati. I pay spot cash on delivery.

CONTRIBUTED ARTICLES

Report of National Bee-Keepers' Union for 1899.

BY THOMAS G. NEWMAN.

IN making this, my fifteenth and last annual report to the members of the National Bee-Keepers' Union, I labor under peculiar disadvantages. My eyes refuse to serve me to see or read anything, and I am obliged to say that I shall be compelled to retire from the active management of the Union on account of this disability.

During the past 15 years, I have labored assiduously to maintain bee-keepers' rights and defend them when assailed by jealous and envious persons. In this work, the Union has been very fortunate. It has won victories over strong opposition, and judges, courts and jurors have affirmed the rights of bee-keepers who have been defended by the Union.

On account of the short crop of honey in nearly all parts of the United States, during the past year, there has been less manifestation than usual of the animosity of the enemies of the pursuit. When prosperity is not very apparent, envious neighbors do not usually trouble apiarists, or seek to abridge their rights and privileges. The National Bee-Keepers' Union has, as usual, in all instances maintained its record of triumph by either smoothing out the difficulties or crushing the opposition.

FRANK S. BUCHHEIM.—Hardly had the new year dawned, when I was called upon for further advice in the case of Frank S. Buchheim. In my last report I detailed the case of his arrest and imprisonment for keeping bees in the corporate limits of Santa Ana, Cal., of the trial and subsequent appeal to the Superior Court, and triumph therein.

In the meantime, his bees had been removed, and the question came up concerning their return to the spot from which they had been taken. I gave counsel to Mr. Buchheim in this matter, and all trouble seems to have been averted, fully ending the difficulty.

TROUBLESOME NEIGHBOR FOILED.—Last February I received a letter of complaint from Mr. R. L. Meade, of

Ontario, Canada, stating that he had received a threatening letter from a lawyer, who had been employed by his neighbor, who complained about bees alighting on his bushes in swarming-time. As manager of the National Bee-Keepers' Union, I wrote a letter to his neighbor, showing the rights and privileges of apiarists, quoting general law on pursuing and capturing swarms of bees, and advised him not to interfere with Mr. Meade in his business, or attempt to abridge his rights as a citizen. I sent him copies of the decision of the Supreme Court of Arkansas, concerning bees, advising him to read them personally, and also to present them to his lawyer. This was no doubt done, and produced the desired result, nothing further having been heard from that quarter.

POISONING BEES.—Last March, George W. Woodberry, of Los Angeles Co., Calif., complained that a fruit-drying establishment in the proximity of his apiary had exposed poisoned sweets to entice his bees and poison them. I reviewed the whole matter, considered all the circumstances and surroundings, and advised Mr. Woodberry as to the best course to pursue, promising to write to the fruit-drying establishment just before time for their operations for the season, and endeavor to amicably arrange matters so as to prevent the destruction of the bees, as well as to secure their employees from being annoyed by the bees. As the honey season was a failure, no further trouble occurred in that direction, but the foundation is laid for amicable arrangements during another season.

MAKING LAWS AGAINST BEES.—M. Hettel, of Madison Co., Ill., entered complaint last spring that certain persons in his neighborhood were endeavoring to excite the people on the subject of excluding bees from the city limits, by passing an ordinance to compel their removal, and sent a clipping from the local paper concerning the matter. I advised him to keep perfectly quiet, and let the people do just as they

chose, because they could not make an unconstitutional law constitutional by their foolishly voting it to be a law. I sent copies of the Supreme Court decision and other printed matter for distribution to those who would read them, instructing Mr. Hettel to secure the services of a good lawyer to look after the interests of the bees. This action quieted down the excitement and left Mr. Hettel in full possession of his rights and privileges as a bee-keeper.

BEES TROUBLE A NEIGHBOR.—Fred H. Fargo, of Genesee Co., N. Y., stated that bees had stung a neighbor and his horse, while working near his apiary; that he had endeavored to rent the land from his neighbor which was contiguous to his apiary, and thus prevent a recurrence of the

Thomas G. Newman.

annoyance. This, the neighbor refused to do, and consulted a lawyer for the purpose of compelling a removal of the bees.

I wrote several letters to Mr. Fargo to help him out of the difficulty, and furnish him with the Union's printed matter, and promise to aid him in every way possible to maintain his rights, at the same time advising him to try to obtain an amicable settlement of the difficulty, by following the course outlined by me. The matter was arranged without recourse to law, but plans had been made to defend him, had it been necessary.

THREATENING LAWSUIT.—In July, J. Youngblood, of Los Angeles Co., Calif., sent me a notice which had been served on him, demanding the immediate removal of his bees from proximity to fruit-drying premises, threatening him with trouble if he did not immediately comply. I gave the matter attention, wrote to Mr. Youngblood what course to pursue, sent him copies of the decision of the Supreme Court, and directed him to employ a good lawyer to defend the case. This he did, and further trouble was averted.

When the parties making the threat were informed that the National Bee-Keepers' Union were defending the case, they stopt to consider the matter, and calmly lookt the facts in the face, rather than let passion run riot.

In all these cases, it will be seen what a moral power there is in membership in a Union, which has such a magnificent record of victories, when defending the rights of bee-keepers. Its name and history compel respect, and prevents foolish men from running into trouble by pursuing an unwise course in their persecution of apiarists.

AMALGAMATION OF THE UNION AND ASSOCIATION.—Last summer, being invited to write an essay to be read at the national convention to be held at Philadelphia, Pa., on the subject of "Organization Among Bee-Keepers—If Desirable, Why? and How Best Accomplish?" I consented to do so, and a correspondence was the result, between Dr. A. B. Mason, secretary of the United States Bee-Keepers' Association, and myself, as secretary of the National Bee-Keepers' Union. It was mutually agreed that we should formulate a new Constitution suited to both organizations, and present it at the Philadelphia convention for discussion. After being amended by those present, Dr. Mason, secretary of that convention, duly notified me that it was approved by that body, and would be submitted by its members at the coming election, for adoption, and asking that it be also submitted to the members of the National Bee-Keepers' Union at the election taking place in January, 1900. It has already been submitted to the members of the United States Bee-Keepers' Association, and received almost unanimous approval.

I also submit it to the members of the National Bee-Keepers' Union, and request them to vote for its adoption in its entirety. This action and the election of the same officers will result in harmoniously uniting the two associations, as has been desired by a majority of both organizations for several years. It will present a united front to the world, and create a large and potent association to continue the work heretofore done by the two bodies.

[Then follows the new constitution (which we publish on page 707 in 1899) and financial report, which shows 108 members and \$126.00 in the treasury.—EDITOR.]

In submitting this, my fifteenth and last annual report, to the members of the Union, I desire to thank them for the courtesy and kindness shown me during that time, and shall ever remember such with pleasure.

Hoping that the future of the Union under its new name and management may continue to be a grand success, and that it may live long as a bulwark of safety for the apiarists of America, I remain,

Fraternally yours,

THOMAS G. NEWMAN, *General Manager.*
San Francisco, Calif., Dec. 31, 1899.

Mesquite as a Honey-Plant in Texas.

BY L. STACHELHAUSEN.

ON page 797, I find the following question: "Will some southwestern subscriber tell us thru the American Bee Journal all about the mesquite as a honey-plant, time of blooming, duration of flow, and amount of honey per colony an apiary will average from it in an ordinary season?"

Mesquite (*Prosopis Juliflora*) is a brush or tree which covers our Texas prairies in large quantities, and is one of

our most important honey-plants. It commences to bloom the end of March or the first days of April, and this first bloom lasts about four weeks. In a dry spring it blooms more, and gives more honey; this is a great advantage, because at such times all other plants fail to secrete honey. A rain will destroy the blossoms, and the honey-flow is suddenly closed for this time. It commences to bloom again in June, and keeps on till August, so we generally can see ripe beans and blossoms on the same tree. This second flow is generally not as good as the first one, at least in my locality.

It is hard to tell how much an apiary would average from this source. In 20 years' experience I do not remember that mesquite did not bring at least some surplus honey. The first bloom generally causes much swarming here. Last year I establish an out-apiary seven miles from my house, where mesquite covers many thousand acres of land. Around here nearly all is cropt out. This apiary averaged about 120 pounds per colony; while my home apiary did not quite average 50 pounds per colony. In both apiaries mesquite was nearly the only honey-source we had in this very bad year of 1899.

Mesquite honey is of fine flavor, and very light color. It is by far the best honey in this locality, and I estimate it as good as clover honey.

Bexar Co., Tex., Dec. 19, 1899.

No. 5.—The Bee-Smoker—How to Get the Most Out of It.

BY "OLD GRIMES."

THE first bellows smoker ever used in the Grimes apiary came from the first smoker inventor, Moses Quinby, and what a crude appearance it would present beside the elegant Bingham and the other smokers of the day!

As to construction, I do not believe the present smokers could be improved upon, and when the hereafter improvements come it will be in some radical change in the method employed to subdue the bees. In my day I have seen men eat tow and blow fire out of their mouth and nose, but the bee-keeper has never fathomed the secret—perhaps there is too much "hot blast" to it, but it is possible that some enterprising bee-keeper with an inventive turn of mind, will "catch on" to this idea some day, and all the bee-keeper will have to do will be to regulate his diet accordingly.

I have to deal, however, with the present smoker, and in the matter of either cold or hot-blast smokers the Grimes family have talkt the matter over autocratically at the breakfast table, and have come to the conclusion that all the bee needs to subdue her combative propensities is smoke, and the difference between hot and cold blast is not enough to make any material difference. We can make a cold-blast smoker hot-blast, or *vice versa*.

It depends much upon the fuel used, in order to make a lasting smoke. Some advise hardwood, maple, etc. Now, if you desire to make a hot-blast from a cold-blast smoker, just get a good wad of hardwood coals in the furnace, and the heat of the smoke will not be much more augmented if a hot-blast smoker is used. Now let us fill a hot-blast smoker with fine shavings, straw, or gunny-sacking, and after the smoke is well developed insert a compact wad moistened with water, and the smoke will be as cool as any one need desire.

I have seen many smokers since the days of Quinby, and have seen some immense, cumbersome fellows, with a sheet-iron fire-box as large as a stove-pipe. Such things need an extra man to carry them around, and to manipulate them, and life is too short to bother with them, any way.

The Grimes family use a medium-sized smoker. To start a smoker quickly we have used a little spring-bottom oil-can filled with kerosene. A few squirts with this upon the fuel before applying the match will insure a fire, every time. I have no doubt but Dr. Miller's saltpeter plasters would do as well. I take the Doctor's word for it, and he ought to know, for he is well up in the plaster business!

In our Grimes apiary we use gunny-sacking for fuel, as we have plenty of it, and we make a small square of it last half a day, and even longer. The sacking is prepared for business when the sun wax-extractor is in use. When the sun has done its work, and left quite a little hot slumgum, work the gunny-sack into it, and wipe out the tin bottom with it, and it will become saturated more or less with the residue of beeswax and bee-glue, and thus prepared it will burn a long time in the smoker.

But the boys and I are not arbitrary in our advice in

the matter of fuel for smokers; we use what suits us, and are willing that others should do the same.

If we were to try to improve the smoker we would make it quite small, and light weight; and then as to fuel, we believe there are cheap materials that can be combined whereby a large amount of smoke can be made from a small amount of fuel. For instance, a Chinese joss-stick not much larger than a knitting needle, and about as long, will smolder a whole day, and emit a wreath of smoke and a pleasant incense.

It is a good plan to temper the smoke to the colony. Some bee-keepers temper the smoke according to their fears of bee-stings, but the practical man has no fear of stings, and can exercise a little mercy upon the bee. The experienced bee-man soon knows how much smoke to use, just from the way the hive opens up. It is quite an orthodox rule to smoke the bees at the entrance of the hive when it is approacht, but the busy bee-man forgets this operation so often that it is after awhile wholly neglected. The first blast into the top of the hive after the cover is removed sends a thrill of alarm clear to the entrance, and the temper of the colony is soon learned.

It is perhaps not a very important matter as to where the smoker is kept when not in use, but an orderly bee-keeper will have a little closet near the honey-house large enough for two or three smokers, and lined with tin or asbestos, and having an exit for smoke. You can get more out of a smoker by using it well, and then if it is put in a safe place, and there is a little fire left in it, there will be no danger from the fire communicating with other things. Many bee-hives and buildings have been damaged from this lack of care.

And now when I have said all I care to say about the smoker, one of the boys at my elbow remarks that the fellow I refer to who ate tow and spit fire reminds him that some men use a filthy weed known as tobacco, as fuel for smoke, and a pipe, and the mouth for a furnace; and that reminds me of the old adage about the man with a cigar—"A little roll of tobacco leaves with a fire at one end and a big fool at the other." Don't be a fool; but if you are, get into the ranks of the wise people as soon as possible.

Report for the Season of 1899.

BY A. F. FOOTE.

IN the way of a report for the season of 1899, I have this to say: I lost 40 colonies last winter and saved 14, which increase to 30 by natural swarming, and I secured 600 pounds of comb honey, mostly from buckwheat and fall flowers, tho the bees did well on Alsike clover, but the supply was limited.

My bees were weak in the spring, but I fed them liberally till fruit-bloom, and after that till clover bloom, and again, after the supers were removed, during the warm days in the early part of November, and they are now in the cellar with very ample stores for winter. Their last flight was on Nov. 28, and I put them into the cellar Dec. 4.

Like many other localities, as reported in the American Bee Journal, the honey crop here was light compared with many years in the past—in fact, this is not an ideal country for bees at best. I have sold all my surplus, regardless of color, readily, at home for 15 cents per pound.

EXPERIENCE IN FEEDING BEES.

I can't resist the temptation to give a little of my experience in feeding, which was hardly "according to the books," neither were the consequences which followed the method. Let it be understood on the start that there were no "neighboring" bees to bother.

Every day, during the time I was feeding, when it was warm enough for the bees to fly freely, I put out (on boards, boxes, etc., several rods from the apiary) broken and unfinished sections of honey, and some old candied honey, diluted—all in shallow dishes of some kind—and let the bees help themselves. I regulated the supply so that it would all be cleaned up by the early part of the afternoon.

Well, did it teach them to rob? Not at all. Contrary to the theories advanced by the wiseacres at the Philadelphia bee-convention, there was not a single case of robbing or attempt to rob; when the day's supply of feed was cleaned up, they all returned to their homes and behaved themselves like the good little creatures that they are, and good-natured, too.

It seems to me my bees never showed so little disposi-

tion to sting as they did the past season, and they are mostly hybrids, too.

Now, a little further experience, and I am done: My first swarm, a large one, issued on May 27, just at a time when there seemed to be nothing for them in the fields, so I put a super containing several sections of uncapt honey on the hive to tide them over. A few hours afterward I went out, and it seemed as if half the bees in the apiary were hovering around that hive after the honey had been put into it, and I had quite a time dispersing them, but I succeeded at last, and saved the swarm.

I tried it again with a swarm that issued a few days later, with the same result. After that, as before, I did my feeding outside, and had no more trouble.

What are your experts going to do about it? Of course, the fact is perfectly clear that the stronger colonies secured more supplies than the weaker ones, and why should they not? There were more mouths to feed.

Mitchell Co., Iowa, Dec. 20, 1899.

Annual Report for 1899 of the Inspector of Apiaries for the Province of Ontario.

BY WM. M'EVROY.

DURING 1899 I visited bee-yards in the counties of Haldimand, Norfolk, Middlesex, Oxford, Brant, Wentworth, Lincoln, Wellington, Halton, Peel, York, Ontario and Simcoe. I inspected 126 apiaries, and found foul brood in 47 of them.

In places where I never had been before is where I found nine-tenths of the foul-broody apiaries the past season, and over three-fourths of the owners of these diseased apiaries did not know that their colonies had foul brood when I first visited them.

I took the greatest of pains to explain to the bee-keepers how to manage the business so as to have every colony a good, strong one, and in fine condition when they were cured of the disease.

In looking back over the nine years that I have inspected the apiaries in the Province of Ontario, I noticed that I had found foul brood very widely spread thru 30 counties, I succeeded in getting thousands of foul-broody colonies cured, the disease driven out by wholesale, and peaceful settlements made *in every case* where diseased colonies were sold thru mistakes of the parties selling, not knowing of their colonies being diseased at the time of sale.

Nine years ago very few among those that kept bees then were able to tell the disease from other kinds of dead brood, and not over half a dozen men in Ontario could cure an apiary of foul brood, and end the season with every colony in first-class order. The instructions that I gave while on my rounds thru the Province, and the driving out of the disease by wholesale, will make Ontario one of the safest places in the world in which to keep bees.

Mr. F. A. Gemmill is the man that deserves the credit for all the work that I have done, and the Government of our country that has paid for it. In 1890 Mr. Gemmill took hold and worked hard until he got the foul-brood Act past, which has proved to be a great benefit to hundreds of bee-keepers.

I am greatly pleased with the way the bee-keepers took hold in the past season, and cured their apiaries of foul brood. Where I found a few worthless colonies almost dead from the disease late in the fall (and near fine, sound apiaries) I burned them. The total number that I burned in the Province was 20 colonies, after the owners and I had reasoned out things nicely together.

And for the courteous and very generous way that I have been treated by the bee-keepers of every locality that I went into, I return to them my most heartfelt thanks.

Woodburn, Ont., Canada.

Selling Honey—Asking What It is Worth.

BY HARRY LATHROP.

I BELIEVE bee-keepers lose money by not having the grit to ask what their product is worth. It is the weak-kneed fellows that lower the price for the rest of the fraternity.

During the fall of 1898, the A. I. Root Co. sent out cards asking for prices on comb honey. I had some that I thought was fancy, and wrote them that they might have it at 13 cents on cars here. They replied that the price was too

high for them, but they were glad if bee-keepers were able to realize so much. I knew when I wrote them that they could not afford to pay what I askt, and smiled at my own presumption. But, as it turned out, I was justified in asking what I did, for that whole lot of honey, fancy and No. 1, netted me a fraction over 12½ cents. I loaded it into a box-car with hay under it, and no outer cases, and it went thru to its destination without being handled. This honey was sold by a commission house.

This year (1899) my honey was all light amber mixt. The commission men claim that amber honey does not sell well, consequently I sold my honey direct, realizing 12½ to 14 cents net for the amber comb honey. I sold it in lots direct to retail merchants, and not in a single instance has any one complained that the honey was not good. If I had listened to the Chicago commission men I would have concluded that it was a hard matter to sell such honey, and been willing to take any kind of price for it. I am glad to know that in New York State this mixt amber honey is appreciated. A market can be established for it here in the northwest if bee-keepers are firm in demanding what it is worth.

There is no sense in the idea that honey must be "white" in order to be good honey, no more than there is in the idea that honey in tall sections is better than it is in square sections.

My honey this year was produced from white clover, goldenrod, asters, and heartsease, all blended together, and many people prefer this honey to any other.

We should be shy of those persons who go to bee-keepers and offer a big price for "strictly white clover," or strictly something else, when they know he has none that is unmixt, and expect to buy his mixt grades for about half what they are worth.

Honey of good body and flavor need not go begging, even if it has been produced from a variety of flowers.

In conclusion, I would say to the producers, if you must sell your honey at a low price, it is better to let the jobber have it than to sell it to the retailer. The jobber knows what it is worth, and will not sell it at a price to demoralize the market as the retailer would be very apt to do.

The best sign of the times for bee-keepers is the fact that buyers were lately going about the country picking up honey in small or large lots. This indicates that soon there will be an established market value for honey, the same as there is for wool and other products of the farm.

Monroe Co., Wis.

CONVENTION PROCEEDINGS

Report of the Michigan Bee-Keepers' Convention

BY WM. G. VOORHEIS.

The Michigan State Bee-Keepers' Convention was held at Thompsonville, Mich., Jan. 1 and 2, 1900. The meeting was called to order by Pres. Geo. E. Hilton. Owing to the absence of Secretary Hutchinson, Wm. G. Voorheis was elected secretary *pro tem*. The secretary not being able to prepare a program, it was suggested that the members discuss any topic they may be interested in.

THE WINTERING OF BEES.

Mr. Chapman—I winter my bees in a very dry cellar under my house. I want my bees in good condition before I put them into the cellar. I put them in early—one time in September. Bees will consume more honey in six weeks in the fall when the weather is cool and frosty than they will in three months in the cellar. I use the single-walled hives, and keep the cellar dark—temperature about 45 degrees. I would not have chaff hives, as they are too much bother. Where I live it is very cold in winter, as the altitude is about the highest in the Lower Peninsula. I do not ventilate the cellar in cold weather or towards spring.

Mr. Van Amburg—I winter my bees in a cellar built in a sand-bank. I wintered them in a cellar for two years that was built in a clay-bank, and did not like it, as it was too damp. I do not think it wise to keep the bees out late in the fall when it is cold and frosty. I keep the cellar dark,

and temperature 45 degrees. I want good feed to winter bees on. Poor feed will not winter bees well.

Mr. Chapman—I winter my bees in hives with the bottoms nailed on. I leave the covers on, and use the Langstroth hive.

Mr. Van Amburg—I use the Heddon hive, and set it so it will tip forward. I shove the covers forward so as to leave a space of ½ inch at the back, and double up in the spring and fall. My bees get most of their honey from raspberry and white clover.

Mr. Coveyou—I have wintered my bees the last five years in a cellar, with a loss of about two percent. I use the 10-frame Langstroth hive, and do not like the bottoms nailed on. I use the single-walled hive, and get most of the honey from raspberry.

Mr. Kitson—I am a farmer bee-keeper, having 78 colonies. I wintered them in a cellar two winters, that was built in a bank close to a creek, and lost half of them each winter. Now I winter them in a cellar under a barn. I put in 32 colonies last winter, and did not lose any. I have used chaff hives, and lost 5 colonies out of 30 by spring dwindling. I do not see any difference in spring dwindling between single-walled hives and chaff hives. I could not see any difference in spring dwindling between bees wintered outdoors and those in a cellar.

Mr. Woodman—I winter bees in a cellar under the house, the chimney of the house going down to the bottom of the cellar. No trouble about wintering.

Mr. Hilton—The entrance of the hive must not be closed in the cellar or outdoors. If the bees find they are confined they will rebel, and then die.

Mr. Irwin—I winter bees outdoors, using Hilton chaff hives. I have no trouble with spring dwindling. I put four colonies in the cellar last winter, and lost all. I like the chaff hives best, as they are cool in summer and warm in winter. I use a cushion made of factory-cloth filled with chaff on top of the hive.

Mr. Hatch—I use the Hilton chaff hive, with a chaff cushion on top. Last winter my bees were all right up to March 1, but by the last of March I found that I had lost two-thirds of them. The bees had plenty of honey. The loss occurred in a period of from 15 to 20 days. The hive-entrances were closed, and about one-half of the combs mildewed.

Mr. Gifford—The closed entrance was the cause of the loss of the bees.

Mr. Kaufman—I winter my bees in a damp cellar. I first wintered with hive-covers on tight, and lost one-half of them. The hives came out damp and soggy. The next winter I left the entrances open 1½ inches wide, and lost them again. While it was dry near the entrance it was wet back from it. The next winter I put a piece of factory-cloth over them, and lost none. The next winter I did not leave anything over them, and lost one-half of them by dysentery. My bees ate too much honey. Now I set the hives on a 2x4 inch scantling, pile them four tiers high, diagonally, with a piece of factory-cloth over each of them. I have had no trouble since I used them.

Mrs. Morrow—I winter my bees outdoors in chaff hives, with chaff cushions four inches thick on top of the hives. I do not have any trouble.

Mr. Hilton—I want well-ripened honey to winter bees on. I do not extract from the brood-nest. You cannot expect comb honey where you use the extractor.

Mr. Calvert (of Ohio)—Nineteen years ago Mr. Root lost all his bees in winter by selling bees by the pound the summer before; but since that time he has not lost 5 percent. He uses chaff hives, and always winters his bees on sugar syrup. If bees get honey-dew you will lose them. Mr. Root uses chaff cushions on top of the hives, and feeds up in September and October.

Mr. Beecham—I do not believe in feeding sugar syrup to bees, as it gives the bee-keeper a bad name.

Mr. Calvert—I think it is safer to feed syrup than honey that one knows nothing about. Our bees will not take glucose.

A vote was taken on outdoor wintering and indoor wintering, resulting as follows: For outdoor wintering, 20; indoor, 11.

Mr. Collingwood—I use the chaff hive, and winter outdoors. I think that people living in the South should winter their bees in cellars. Bees will starve to death if kept too cold with plenty of honey in the hive.

Mr. Hilton—Towards spring, when a warm spell comes, the bees commence to breed, then if the weather should become cold the bees would starve before leaving their young to get honey. The bees cluster around their brood to keep

it warm, and do not like to leave it for fear the cold will kill it.

Mr. Collingwood—The cushion over the hive should be three inches thick, made of two thicknesses of burlap on each side.

Mr. Van Tassel—I have kept bees four years. I use chaff hives, and winter them outdoors. Bees will keep warm in the fall without trouble. The first winter I lost one colony out of eight. Last winter I lost 15. I throw snow around the hives when it is cold, and keep the entrances clear. Last winter a neighbor lost every colony he had in a building on top of the ground.

Mr. Van Amburg—A neighbor banks up his hives with snow. He uses chaff hives.

Mr. Hilton—I use chaff hives, and have wintered bees with snow around them. I do not dig them out until towards spring, and keep the snow away from the entrances.

Mr. Hatch—I like to shade the hives when the bees begin to fly.

Mr. Beecham—I have had bees 18 years, and wintered them outdoors in chaff hives until the last two winters, then I used single-walled hives in a cellar. I think the chaff hives are too much bother, the principal trouble being to spring them.

BEST METHOD TO PREVENT SWARMING.

Mr. Hilton—Bees swarm for two reasons—for increase and for lack of room. I can prevent swarming to a great extent by extracting and adding supers. I always put the empty super under the one that is partly filled. I have not had over one-third of my bees swarm by using the tiering-up process. Watch them closely, and see if they have plenty of room. If two supers should be one-half filled, place an empty super between them. In 1896 I bought bees from various persons, and several colonies had lost their queens. One queen swarmed out when two frames were filled with brood. There was no more space for brood, as the rest of the frames were filled with honey. They will not swarm so much if they have plenty of room. I do not use unfinished sections the following season, but use foundation, which I think is better than old comb; the latter I do not consider valuable to use in sections.

Mr. Calvert—I reduce the comb with a comb-leveler.

Mr. Gifford—I take imperfect sections that are nicely drawn out, extracted the honey from them, and use them again. These sections do not have any fish-bone in them.

QUESTION—Is there a non-swarming hive?

Mr. Hilton—I do not think that there are any non-swarming hives.

Mr. Coveyou—The trouble is, that the colonies do not receive the attention at the time that they should have it.

GETTING BEES TO WORK IN SUPERS.

Mr. Hilton—When the bees cap over the upper surface of the frames, they will not work in the supers. Bees that get their brood-nest clogged with honey will not use supers. Use the extractor when the frames get capped over; that will force the bees into the supers. You must uncap the brood-combs. You could use foundation in frames instead of combs.

Mr. Beecham—I have used the Heddon hive, and revert the hive to prevent swarming, but they swarmed 10 days after it was done.

Mr. Hilton—I do not use the queen-excluder in my hives, but a thick top-bar.

Mr. Chapman—I use the queen-excluder. My bees do not swarm, as I do not produce comb honey. My locality is not suited for it. I have young queens every year. My colonies are strong in the spring, and at the beginning of the basswood flow I kill all my queens. When I want increase I divide at the close of the season. Young queens will not swarm if given plenty of room. By keeping the swarming-fever down I keep the queen in the lower story. I take two frames from the lower story that are filled with brood, and place those over the brood-nest, and add frames from time to time as needed. I never use a queen more than one year. I get better queens in this way than I can buy. I have bought some queens—got them by mail; the trouble seems to be that they get injured in the mails.

Mr. Calvert—I think that queens that come by mail are not in as good condition as those reared at home.

Mr. Kauffman—I kill all my queens at the beginning of the basswood flow, and I get one-third more honey when I kill the queens.

Mr. Hilton—The plan of Mr. Chapman and Mr. Kauffman is to get honey instead of brood. As the young queen does not lay as soon the hive is not so full of brood for the

bees to take care of, so all the bees can gather honey. By letting the old queen live the family of brood eat the honey.

Mr. Chapman—I winter my bees in one-story hives; after the honey-flow the bees increase enough to make a good colony for winter.

[Concluded next week.]

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

The Clovers as Honey-Yielders.

What clovers and flowers are the best for the production of honey, in your opinion? Do they produce light or dark honey? I have noted somewhere that alfalfa and alsike clovers are good. Is that the case? If so, are there any others of the clovers? Sweet clover, I believe, is good, but it spreads so. Is there a law prohibiting the raising of this plant?

ILLINOIS.

ANSWER.—In your region, central Illinois, you will find any of the plants mentioned good, except alfalfa. Alfalfa is one of the very best honey-plants in some parts of the West, and it has been successfully raised as a forage-plant in Illinois, but for some reason it does not seem to be of any special value as a honey-plant as far east as Illinois. Alsike is an excellent honey-plant, and no doubt a valuable forage-plant where you live; the honey from it is light and of finest flavor. Sweet clover is one of the best honey-plants, the honey being light in color. Some say the flavor is objectionable; some say it is the very best. It is possible that the objectionable flavor only comes when the honey is poorly ripened. There is no law against sowing sweet clover, and altho it spreads along the roadside, in cultivated fields, it is no worse to spread than red clover.

Several Young Queens in a Hive.

Generally the books for beginners say that when there are two or more queens in a colony, to decide which shall rule the hive, the queens have a battle and the victorious one is the accepted mother.

Now, I have not had as much experience as some, and not any with a glass hive, but all my observance has been that the queen question is decided some way, then after it is settled, the doomed queen, or queens, are destroyed by the bees in about the same manner as drones, and the accepted one is going about her own affairs just as tho nothing was going on.

What I wish to know is this: Are my observations misleading me, or has there been a change of opinion since these books were first written, or are these statements in the books true generally? If I am going astray in this circumstance I may be going wrong from other observations which I might be accepting that I might believe true ones.

SUBSCRIBER.

ANSWER.—It is the general belief that the workers decide whether any of the young queens are to be slaughtered or not. If they decide that for the present all are to be spared—which is equivalent to deciding that there shall be one or more after-swarms—then the workers protect the young queens in their cells from the attacks of the young queens at large, and no others are allowed to emerge from their cells. When the workers decide that there shall be no more swarming, then none of the young queens in the cells are protected, and all are allowed to emerge from their cells that are sufficiently matured. When more than one is at large, there is a fight to the finish whenever two of them meet. Those in the cells too young to emerge have their cells torn open and their lives taken by their older sister,

the workers afterward concluding the work by carrying out the dead bodies and tearing down the cells.

If there are young queens in their cells when a young queen "is going about her own affairs," you will probably find, if you observe closely, that one of her important affairs is murdering her royal sisters in their cradles, or trying to do so if the workers keep her off. It will be an easy thing in many cases for you to see a royal battle, if you allow to come together two young queens. They do not make very slow work about it, either. One time I cut out of a frame a piece of comb on which were two mature queen-cells, neither of the queens having yet emerged. I laid down the two cells and closed the hive, then turned to take care of my two queen-cells. In that short time both queens had emerged and one of them was stung to death by the other.

Superseding Queens—Rearing Queens in Upper Stories.

1. When bees start queen-cells for the purpose of superseding their queen, are they apt to, or do they ever, let more than one cell mature, and then swarm?

2. When cells are placed in an upper story to be cared for, with an excluder between the upper and lower story, will the bees allow a cell to hatch and the queen to live in the upper story?
NEW YORK.

ANSWERS.—1. As a rule they do not. Most of the superseding is done near the close of the honey-harvest or after its close, and sometimes in the early part of the season before the honey harvest. In neither case will there be any swarming, and only one young queen will hold the field. But if superseding should occur during a full flow of honey, the chances are in favor of swarming.

2. A young queen will be reared in the second story, but will in some way disappear before she gets to laying. At least it has been so in a number of cases that I have tried. But the case is different if the young queen is reared in the third or fourth story. In more than one instance I have had a queen reared in the fourth story and continue laying there thruout the season, the old queen being in the first story with an excluder over it but no excluder between the other stories. There was an entrance to the fourth story.

Starting Foul Brood.

A friend of mine who has been keeping bees for a long time says his bees have foul brood, and doesn't have any idea how it started. He has run mostly for extracted honey. Now to the question:

1. If one should extract honey out of combs that contain brood, and kill considerable brood at the close of a honey-flow, and the bees allow the brood to remain in the combs until it becomes decayed, is it possible foul brood would start?

2. At this time of year is there any way to stamp it out, except by burning hives, bees, and everything that may be infected?

I am very much interested for fear the disease may spread, as it is only about 10 miles from me. I have 10 colonies in prime condition.
TEXAS.

ANSWERS.—1. If there is no foul brood anywhere in your region, I don't believe you can start it by any treatment of the brood. If it is in the neighborhood, bad treatment of the brood might favor its rapid development.

2. You will hardly be able to make a thoro cure of a genuine case of foul brood at this time of the year in any other way than by the utter destruction of the colony.

Domesticating Wild Bumble-Bees.

Has any one ever tried to domesticate the wild bumble-bee that builds its nest in the meadows? If so, what were the results? Did he get them domesticated? How did he try to domesticate them? Dr. Miller, this is a pretty hard question to answer, and I hope you will only do the best you can. I will try to domesticate them next summer, but if you know that they cannot be domesticated, and will please tell me, it will save me both time and labor.

My reasons for wanting them domesticated are these:

1. Because they are larger than honey-bees, and can therefore carry more honey at a single time. I suppose somebody will tell me they will also eat more than a honey-bee; but I explain it thus: If you have a large pig, and

bring it to market, you will get just as much for it as you would for two that were each only half as big; and the profit is, the large pig would not have eaten as much food as the two small ones. Altho pigs and bees differ greatly, in this respect they are the same.

2. They have a longer tongue, and can therefore gather honey from any kind of flowers.

3. They will gather more surplus than others.

4. Their honey tastes better than that of other bees.

5. They will take the place of *Apis dorsata*. IOWA.

ANSWER.—Yes, I tried it long before I knew a queen from a drone. No doubt a good many others have tried it. Bumble-bees can be domesticated as well as hive-bees; that is, they can be got to stay in a box, and only a small box is needed, but there can never be got honey enough to pay for the trouble. You never find any considerable amount of honey in a bumble-bee's nest. They don't get any serious surplus ahead like hive-bees. Bumble-bees' honey tasted to me, I think, as it did to you, the best of any honey I ever tasted. I suspect, however, that if some one had filled one of the pockets in a bumble-bee's nest with honey from a section, I would not have known the difference. A bare-footed small boy chasing thru the meadows till he had a ravenous appetite would be delighted with any sweet he might find, and the less of it the sweeter it would taste. It will cost very little, however, for you to try the experiment, and you can get some good honey; but there is no great danger that the market will ever be overstocked with honey gathered by bumble-bees.

Open-End or Closed-End Frames.

As I am a beginner in bee-keeping I want to start in with the best kind of hive for comb honey. The winters here (northern Maine) are severe, and I intend to winter my bees in a good, dry cellar. Which hive would you advise me to start with—one with hanging frames, or closed-end frames? It seems to me a hive with the latter style of frames in this climate might be better than the open-end frame.
MAINE.

ANSWER.—Your question is not so easy to answer. For the bees it is probably better to have close-end frames. That makes practically a double wall at each end. For the convenience of the bee-keeper it is better to have the frames spaced with staples or nails. I think the ideal spacer would be a nail with a head $\frac{1}{4}$ -inch thick, so that it would automatically be driven the exact depth; but you can't get such nails. For my own use, I have decided that the advantage of the closed-end frames to the bees would not be enough to overbalance the inconvenience of handling such frames. If there is no bee-glue where you are, and if you don't mind going slow enough to avoid killing bees between end-bars, then you might do well to have closed-end frames. So long as you winter bees in the cellar, northern Maine is no worse than northern Illinois. Indeed, even for out-door wintering it is possible you have the best of it, for you hardly have the savage winds that sweep over the prairies of Illinois. If I were to be set down on the next farm to you, I should prefer open-end frames; but all would not agree with me.

Why Comb Honey "Works."

If this is not too old a conundrum, please answer it in the American Bee Journal:

Quite a number of my sections of honey seem to "work" after being stored away. The combs look foamy and a good part of the honey runs out. Some were in a very warm place—others where it was cool—but all acted alike, i.e., all that worked at all. Do you know what caused this, and what will prevent it?
CHUCKLEHEAD.

ANSWER.—No conundrum is too old for this department. The only ones ruled out are those whose answers are plainly given in the text-books; so yours is in order.

The only reason for your honey working and foaming was because it—that is—well, it worked. "Why did it work?" Well, honey attracts moisture from the air, and when it becomes thin enough it may ferment. Now, that's enough to satisfy any reasonable person, but it will be just like you to say, "But what special reason was there why my section-honey should act so, more than other honey? All honey doesn't behave in that way." Well, since you insist, I must answer that I don't know. You may rely upon it, however, that unless there was some special characteristic about your

honey that made it different from other honey—which I very much doubt—the conditions were favorable for the absorption of moisture to a more than ordinary degree. Some sections were worse than others in the same lot, and that may have been because of difference in ripeness when taken from the hives, providing all had the same treatment after being taken from the hives. If one section is left on a hive longer than another, there may be a difference in ripeness.

Some of it was in a warm, and some in a cold, place. Other things being equal, the honey in the warm place had the advantage, but there may have been some reason why the warm place was unusually damp. If you keep honey in a warm room, and this opens into a warmer room in which steam is generated, your honey would attract moisture from the atmosphere.

The remedy is to keep the honey in a place where the constant tendency is toward drying. If thru the hot weather it be kept in a hot, dry, airy place, it will stand much more abuse when cold weather comes. Where salt keeps dry is a good place to keep honey.

Possibly no true guess has here been made to fit your case.

Feeding Bees in Box-Hives.

1. I am much interested in your answer to "New Jersey," on page 6, for I have lately purchased 3 colonies of bees in what are practically box-hives. One of them I will have to feed. I have no cellar, and want to pack them as I do the others on the summer stands. I can get the lids off, so how will it do to lay the candy on top of the brood-frames, and after putting a super on, pack above it as usual?

2. Can I put in enough candy so it will not be necessary to disturb them again until summer—I mean, would it be advisable to do so?

KANSAS.

ANSWERS.—1. Your plan will work all right, unless it should happen that the bees did not reach the candy, in which case they would starve with abundance over them. This might happen if you should operate in a very cold time when the bees were shrunk into a ball a little out of reach of the candy. Better make sure before covering up, that the bees actually reach the candy. If the weather is mild there will be no trouble; but if it should be cold it would be a good plan to drum on the hive enough to make them go up to the candy. This is on the supposition that they are so short of honey that they might starve before a day comes warm enough for them to reach the candy. If they have honey enough to last till the first warm spell, there need be little fear.

2. Yes, there will be no harm in putting in too much, and there might be much harm in putting in too little.

Transferring, Dividing and Italianizing.

I have two colonies of hybrids in Quinby hives, very populous, with about 40 pounds of honey in each hive for the winter. Next season I wish to divide, Italianize, and transfer them to Langstroth hives. Can I make one job of it in the following manner?

Smoke the bees at the entrance, lift the hive from the stand, take off the cover, and place the honey-board on top of the frames. Then set the new hive, No. 1 (fitted with Hoffman frames of empty combs or foundation, without bottom-board, and containing caged Italian queen) on top of the old hive, drum up the bees for 10 or 15 minutes, until about half of them have ascended, then set the new hive on the old stand.

Next set new hive, No. 2, on the new stand, fitted with frames as before, but without a queen; shake the frames with adhering bees and the old queen into the new hive, No. 2. Transfer the 10 combs of brood and honey from the old frames to Hoffman frames, and put five into each of the two new hives. Take away the old queen from hive No. 2 in two or three days, and introduce an Italian queen about two days afterwards.

When would be the best time to do this? Any change in the operation that you can suggest, will be gratefully accepted.

MASSACHUSETTS.

ANSWER.—Your plan might not work to your satisfaction. When you drive the bees into hive No. 1, you have no security that the queen will not go up with them. If you drive half the bees into No. 1, all the field-bees left in No. 2 will join No. 1 in a day or so, and you will have no bees left in No. 2 except half of the bees under 16 days old.

You may be better satisfied to transfer the colony into

Langstroth frames in time of fruit-bloom, reserving the extra combs for future use if you have more than you need for the Langstroth hive; then when the colony swarms, hive the swarm in hive No. 2. It will be just as easy to make a separate job of Italianizing, and will scarcely take any more attention than the plan you propose; for in one case your introducing the queen is a separate job, and in the other you will have to see to releasing her at the proper time. Before trying any original plans, always study thoroughly your text-book so as to have principles well in hand.

Bees Dying in Winter.

My bees seem all to be dying, and I don't know what can be the matter with them. They seem to be full and healthy looking, but some colonies are dying very fast, while others don't seem to be affected. Can you tell me anything about it? It can't be paralysis, for they don't have the greasy look that is described in "A B C of Bee-Culture." They have plenty of good sealed goldenrod honey.

Mo.

ANSWER.—With no other information than the bees are dying, and that they have a healthy look, it is hard to make any guess as to the cause, and possibly it would be no easier if one were on the spot. It is just possible that there may be nothing wrong. At this time of the year bees are constantly dying; more in some colonies than in others; and one with little experience might think the mortality excessive when only normal. It is nothing strange for a colony to lose half its bees or more in the course of the winter without anything being wrong. The simple fact that a pint or a quart of dead bees are found on the bottom-board is not a thing to awaken great anxiety.

Requeening—3 and 5-banded Bees—In-Breeding.

1. Does a queen begin to decline after her second season?

2. For profit, will it pay a bee-keeper best to requeen his colonies, or let them supersede their own queens?

3. Is there any difference in honey-gathering qualities between the 3 and 5-banded Italians?

4. I reared all of my queens from one queen. Do you think my future stock will be seriously affected by in-breeding, or would it be best to rear new blood for the swarms next season (of course, supposing I have any)?

CALIF.

ANSWERS.—1. That's a question that cannot be answered by a single word. Some queens may be on the decline before the close of the first year. Some queens may be as good as ever when 3 or 4 years old. If a queen is kept in a very strong colony, she will reach the limit of her usefulness sooner than if in a weak colony. Perhaps it may be said as a general rule that in an apiary where colonies are kept large and strong a queen is not as good in her third year, but with smaller hives there may be no decline till the close of the third season. It is by no means certain that this is correct, and whatever may be the general rule the exceptions are many.

2. Opinions are divided, the tendency being toward the belief that it is fully as profitable to leave the matter in the care of the bees. When a queen has gone beyond her prime, the bees will be pretty sure to supersede her, and their superseding will be done with less hindrance to the work of the colonies than if you take charge of the case.

3. Some 3-banders are very much better than some other 3-banders, and the same is true of the 5-banders; so the best 3-banders are better than the poorest 5-banders, and vice versa. If you could strike a fair average of both kinds you might find no difference.

4. There is danger of in-breeding where all or nearly all queens are from one mother, the danger being greater if only a small number of colonies are kept. I should say that they would be affected in your case to such a degree that it would pay well to get a new queen from which to breed.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the new bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

VOL. 40. JANUARY 25, 1900. NO. 4

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

The National Bee-Keepers' Union, in all probability, by Feb. 1, will be merged with the United States Bee-Keepers' Association, and the resulting society be known hereafter as the *National Bee-Keepers' Association*. There will then be but one general organization instead of two, as has been the case the past 15 years. It will have about 500 members to begin with, and ought to push on to 1,000 right away.

Mr. Newman presents in this number his 15th, and likely his last, annual report for the Union. He has done grand work in the position he has held and acceptably filled for so long a time. We clearly remember when the Union was organized for the purpose of defending its members in their rights. As Mr. Newman well says, it has been wonderfully successful in its efforts during the whole of its existence. If the amalgamated organization will always do as well, no fault can justly be found.

The Higginsville Hive-Cover is shown in the January Progressive Bee-Keeper by two very neat and distinct pictures, No. 1 showing the cover complete, and No. 2 "with one cleat removed to show how the joints are constructed." This latter picture shows the projecting shoulders to the main pieces, and the channeled ridge-pole to fit over them, so that no water can get thru without traveling uphill. This was given on page 760 of this journal for 1899, as an im-

provement by the A. I. Root Co., and to this the Progressive Bee-Keeper took exception. On page 824 (1899) it was explained that any error made was unintentional; and now that the illustration in the Progressive Bee-Keeper shows what the error was supposed to be, our worthy contemporary will see that we were merely quoting from *Gleanings in Bee-Culture*, and a second look on page 760 will show that a direct quotation was made from that journal, in which was distinctly claimed as an addition to the old Higginsville "that the two side or gable pieces have perpendicular shoulders, and the ridge piece is channeled so as to straddle over these two shoulders." So if there is any error in the case, it should be settled with *Gleanings in Bee-Culture*, and not with this journal.

Some Appliances for Moving Bees.—When Rambler holds himself down to bee-talk he is instructive and interesting. Ramble 179 in *Gleanings in Bee-Culture* is one of the right sort; that sort that doesn't ramble too far out of sight of a bee-hive. He takes a midnight ride with a friend on a load of bee-hives, and discourses as to some of the appliances used. A novel and exceedingly simple plan was taken to close the entrances, as follows:

"The entrances to these hives were of the orthodox order, and clear across the front. Into this long space was thrust a piece of wirecloth cut about 1½ inches wide, and bent V-shape the entire length. The spring of the V ordinarily holds the piece from working loose, but our boss took the precaution to drive in a few nails to hold it secure. Screen wirecloth was placed over the entire top of the hive, with only a bee-space between it and the frames."

That did well enough for moving at night, but for daylight in hot weather Rambler would have a special cover for ventilation. One way is to have a rim 3 inches deep covered with wirecloth, so that the bees could cluster in that 3 inches over the frames. If hives are to be piled one upon another, then the top must be of board, and holes in the sides covered with wirecloth for ventilation. In this case the cover is made about 6 inches deep. As an additional protection against the heat, a light frame-work supports a covering of cotton-cloth sufficiently elevated to allow a free circulation of air over the hives, and this is made more soothing to the bees by being occasionally sprinkled with water from a spray-pump.

In moving bees an important "appliance" is the driver, and Rambler thinks this should in all cases be a bee-keeper. Then if a bee gets out, or some other thing goes wrong, there will not be a ruinous panic.

Apiculture and the Government.—In the Annual Report of the Secretary of Apiculture for 1899, just to hand, we find the following:

WORK IN APICULTURE FOR 1899.

The work in apiculture has included further observations on honey-producing and continuation of the experiments of last year in the wintering of bees and tests of various methods of preventing swarming. The results thus far obtained appear in a revised edition of Bulletin No. 1, new series. Experiments in queen-rearing, which promise new results of practical value, are in progress. The acquisition of the Philippine Islands has greatly increased the interest which bee-keepers have long felt in the large honey-bee of the far East, the so-called giant East Indian bees, and very many requests for information concerning this species and applications for queens of these bees have been received. Private enterprise has tried to import these bees into the United States in the past, but all attempts have failed, and the Department has been repeatedly requested to undertake the work.

RECOMMENDATIONS FOR 1900.

I wish to repeat the recommendation of a year ago, that the sum of \$2,500 be added to the lump sum of \$20,000, provided for "Entomological investigations," the added

amount to be used for the purpose of experimental investigations in apiculture. The result of a recommendation of a similar nature a year ago was the introduction into the clause appropriating for entomological investigations of the words, "Provided, That two thousand dollars of this sum may be expended for the purpose of experimental investigations in apiculture." As a matter of fact, in previous years certain of the funds of this Division have been expended for experimental work in apiculture, since this subject comes properly under the scope of "Entomological investigations." There seems, however, to be a great demand among the bee-keepers of the country for more work of this kind than the entomologist feels justified in undertaking by means of the lump fund. In other words, there is so much work which must be done upon injurious insects that the entire sum is none too great to carry it on. If the demanded work in apiculture is done at all well, additional means must be provided for it.

Should this latter recommendation be approved, and should the appropriation be made, it might be the means of importing into this country successfully one or both of the giant Indian bees which inhabit the Philippines. Bee-keepers have long been anxious to have the merits of these large Indian bees investigated in the proper way, and this would create a favorable opportunity.

We presume that "the proper way" referred to in the last sentence above, means that the "large Indian bees" will be experimented with first in their native land. Then if they prove sufficiently home-loving as to be content to stay in hives, and not all desert for the limb of some tree, it will be time to consider the possibility of their importation and use as honey-gatherers in this country—likely in Florida, Louisiana and Texas, where they would perhaps do the best.

Bumble-Bees for Australia.—The San Francisco Weekly Bulletin reported that in January, 1899, the New South Wales department of agriculture had a short time before received a consignment of bumble-bees by steamer from New Zealand. They were liberated in the Botanic gardens and in the Linnean Society's grounds at Elizabeth.

Selling Granulated Extracted Honey.—In spite of the general opinion that the only plan to run successfully a retail trade in extracted honey is to sell it in the liquid form, and gather up for remelting that which granulates, there are some who insist that the public can be taught to do their own melting. There can be no question as to which way gives the seller the least trouble after a set of customers has been so taught, and the fact that the thing *has* been done is a very strong argument in favor of the belief that it can be done.

It is well known that the late C. F. Muth did a very large business in retailing extracted honey, and his clientele were so trained that they preferred the honey in the granulated form. He was saved all anxiety about this honey granulating too soon, all trouble of gathering up from groceries or private customers any that had begun to granulate—in fact, so far as Mr. Muth was concerned, it was the same as if he had honey that never candied.

Among those at the present day who advocate selling in the granulated state, there is probably no one more prominent than R. C. Aikin, and his advocacy is entirely consistent in view of his own experience. Those who have a permanent residence, and expect to have the same customers year after year, may well consider the advisability of following Mr. Aikin's example. He says in the Progressive Bee-Keeper:

"Do not tell me the people will not have it so—they will have it so, if we just put it up that way and keep it in the markets. The main trouble is introducing it where the idea is new; but that is easy, for it is so much better for the grocer that he becomes your voluntary agent in showing and explaining, and just get a customer to try a pail or two, and the thing is done.

"A little country town of probably less than 2,000 popu-

lation, a farming community with very few well-to-do farmers—such is my territory for trade, and honey in pails, and candied, *sells right along*. If my trade increases year by year as it has in the past five years, it will soon take carloads to supply it annually. Selling customers glass and other expensive packages with a *little* honey in them will soon disgust the masses with buying honey, when they can get a hundred pounds of sugar in a 5-cent sack. Study between the lines here and you will discover why honey does not become a staple—it *can* and *will*."

The Weekly Budget

BECAUSE THEY BE.

Yes, flies are flies, because they fly,
And fleas are fleas, because they flee;
And that is very clearly why
Bees are bees, because they BE.

—Modern Farmer.

"A. B. WILLIAMS & Co., of Cleveland, who some time ago furnished quotations of the Cleveland honey market for Gleanings in Bee-Culture, have made an assignment; and from all that we can learn their creditors will get very little. The liabilities appear to be from \$10,000 to \$12,000, and assets about \$1,500. We have not published their quotations the past season, because we were not fully satisfied with the way they treated their shippers. The principal complaint was their tardiness in answering letters. We did not have a sufficiently definite case against them to warrant our publishing a word of caution, yet we did not have sufficient confidence in them to continue publishing their quotations. They had 10 cases of our honey unsettled for when they failed. We know of several others who have likewise suffered loss. When I called on them about three weeks ago they had very little honey in the house, but I do not know how much they had sold, and had not yet settled for. I hope very few have lost at their hands."

We were surprised to find the above in Gleanings in Bee-Culture for Jan. 15. Nothing further need be said, we think.

MR. WM. H. EAGERTY, was born in Onondaga Co., New York, moved to Iowa later, where he engaged in the bee-business, and then about five years ago went to Republic Co., Kans., where he now lives and keeps bees. He has nearly 70 colonies, which he looks after both for pleasure and profit. He wrote thus of his work last September:

Wm. H. Eagerty.

"I have had four good years and only one failure. I try to do my part or share of the work. So many were going into the business in a shipshod way that we should have been swept away with the bee-disease known as foul brood. But now they will 'about ship,' and send for home quarters, I think. I never object to persons going into the bee-business if they will only pre-

pare themselves well for the work, and not just murder the bees thru ignorance."

Mr. Eagerty has written some for the bee-papers, and we have no doubt he understands the business all right. We do not know him personally, only that he has been one of our regular subscribers for years.

Queens Slow About Laying.—

The Australasian Bee-Keeper says: "We had one instance this season of a queen starting to lay on the 20th day after emerging, and many instances of their commencing on the 20th and 21st day. Usually queens lay on the 10th day. Cold spells and unsettled and wet weather, and no honey-flow, was the cause."

Leave Plenty of Stores for the Bees.—A statement made by Allen Sharp in the British Bee Journal, is worthy of occasional repetition:

"I have tried all ways of managing bees, and all methods of feeding them, and I say without any hesitation that the best plan is to leave sufficient natural stores in every hive to last until honey comes in again. Colonies so provided in autumn require no further attention until supering time arrives, and they are the ones which yield best results."

Locality.—Editor Hill says in the American Bee-Keeper:

"The noticeable inclination upon the part of some writers to ridicule the 'locality' idea is a clear evidence of limited experience. The young man who looks forward to apiculture as his life vocation would do well to receive his training in the country in which it is proposed to operate. Yet, our ability to choose wisely in the matter of a location is in proportion to the diversity of our observation and experience. Causes and effects in different localities are hardly less different in bee-keeping than are the varieties of vegetation and soil."

Glass Sample Cards for Grading.—Here is a suggestion by W. H. Pridgen, in the Progressive Bee-Keeper, that has at least a prepossessing appearance:

"While Dr. Miller and the Root Company are discussing the color-sample-card question, if there is sufficient demand to justify having such a thing, why not go ahead and have small panes of glass made varying in tints from clear to the shade of the darkest honey, viewed thru a flask 1/2 inch thick. By having one flask or flat bottle of a given thickness, and a set, say 12 different shades, beginning with white for number one, any one could grade his extracted honey by color and number."

Chaff vs. Single-Walled Hives.

—In the Progressive Bee-Keeper. R. C. Aikin expresses himself as in doubt as to which is best. He thinks there are times when a chaff hive may be about equal to a refrigerator for a weak colony. He says:

"I know that a colony in a single-walled hive will respond more quickly to the outside temperature in the matter of heat, and the same as to cold; but, still, that does not prove one or the other. The difficulty seems to be to protect against cold, and not against heat, too. Sunny, warm days will dry out a single-walled hive when it will not a chaff one, and in such case, unless a strong colony is inside, the chaff is a detriment."

"I say the chaff becomes a detriment to weak colonies. If there could always be a very strong colony for the time of year, then the packt hive is all right, for it retains the heat of the colony against outside cold; but colonies good, bad and indifferent as to strength, will show varied results about wintering, and more particularly about building up in early spring. With the opening of spring, and the first warm, pleasant days, colonies in single-walled hives rouse up and are the first to have queens to lay freely. Weak colonies suffer with cold nights, and general cold changes,

Cabbage Seed That Grows

There is no doubt or disappointment when you sow **Hammond's Improved Early Jersey Wakefield**. Undoubtedly the purest and earliest strain known. The result of years of careful selection, both for earliness and perfect heads. Especially valuable to market gardeners. 5c pkt.; 15c oz.; 60c 1/2 lb., and \$1.50 lb., all postpaid. **Hammond's Danish Ballhead.** A sure header of large, compact heads. My seed imported direct from R. Wobolts, Denmark. Guaranteed absolutely true to name. See catalogue for cash prices. Price same as above. **Catalogue free.**

Yellow Sweet Clover Seed

WE HAVE IT AT LAST!

We have finally succeeded in getting a SMALL quantity of the seed of the YELLOW variety of sweet clover. This kind blooms from two to four weeks earlier than the common or white variety of sweet clover. It also grows much shorter, only about two feet in height. It is as much visited by the bees as the white, and usually comes into bloom ahead of white clover and basswood. We offer the seed as a premium

A QUARTER POUND FOR SENDING ONE NEW SUBSCRIPTION.

So long as it lasts, we will mail a quarter pound of the seed to a regular paid-up subscriber who sends us ONE NEW subscriber for the American Bee Journal one year, with \$1.00.

We have been trying for years to secure this seed, and finally succeeded in getting it. It is new seed, gathered last season by an old personal friend of ours, so we know it is all right. But we have only a small supply. When nearly out we will mention it.

Root's Column

— THE —

ABC

— OF —

BEE = CULTURE

Revised in 1899—67,000 published.
3,000 Copies of Latest Edition Sold in 3 Months.

Read what F. Danzenbaker, the inventor of the Danz. Hive, says of this book. There are few bee-keepers who have spent so much of a study of the production of fancy comb honey as has Mr. Danzenbaker, and his opinion of the work should be read by all who contemplate purchasing such a work.

Mr. E. R. Root:—I have read former editions of the ABC of Bee-Culture, and I have carefully read all of the latest. It is so greatly improved, and brought down to date, brimful of the latest experiences of the most successful

F. Danzenbaker.

methods in all departments, that it might well be rechristened, "Bee-Keeping from A to Z." The hundreds of expensive and beautiful illustrations display to the eye what the text conveys to the mind, in a way to cover the entire field of apiculture, for beginners and veterans alike.

It is worth many times its cost to a beginner with but a single colony, and to those who have handled hundreds of colonies half a lifetime as well. It would have been worth thousands of dollars to me if I could have had such a book 40 years ago, and I would not take \$50 for the copy I have now if I could not get another.

If it could be placed in every school and library in our land, for the instruction of the masses, it would greatly increase the consumption as well as the production of honey, adding greatly to the health and wealth of the people.

F. DANZENBAKER.

Washington, D. C. Jan. 8, 1900.

The ABC of Bee-Culture is sold by all dealers in bee-keepers' supplies, or will be sent postpaid on receipt of \$1.20. When sent by freight or express with other goods, the price is \$1.00.

The A. I. Root Co., Medina, Ohio.

and if heavily packed, do not respond to outside warmth as more exposed colonies."

In reply, Mr. Doolittle seems to think that colonies in chaff hives will not come out weak in the spring, and says:

"With outdoor wintering not one colony in ten will come out strong when wintered in single-walled hives, in this locality, while with chaff hives, those having two or three inches of chaff packing, nine out of ten will be in good working order, and in two weeks' time will have double the amount of brood of that of the strong one, in the single-walled hive. Single-walled hives are only fit for cellar-wintering in this locality, and even then they are better off left in the cellar till settled warm weather comes. A trial of both side by side for the past 25 years, shows these things to be facts about here. And herein we have locality making all of the difference."

Points in Bees.—For the past few years the most important point to breed for has seemed to be color—at least in a great many cases. Queen-breeders tell us that purchasers have wanted more than anything else yellow bees. Now there seems to be a swing of the pendulum toward bees that have good qualities aside from color. Editor Root, in Gleanings in Bee-Culture, gives his idea of five points in the order of their importance, upon which a Stray Straw discourses as follows:

"Your classification of points for bees, Mr. Editor, is good: 1. Ability to get honey; 2. Good wintering ability; 3. Disinclination to swarm; 4. Good temper; 5. Good color. Possibly some other points ought to come in and shove color lower down, as whiteness of surplus combs. I rather think I'd want 2 and 3 to change places, making non-swarmer come next after honey-getting."

Some Pointers on Queen-Rearing are given by W. H. Pridgen in Gleanings in Bee-Culture. He favors having the upper story for queen-rearing separated by division-boards into three apartments, then if accidentally a virgin queen is present there will not be the loss of so many cells. Instead of transferring a larva, he prefers transferring the cocoon or bottom of the cell, larva and all. Select larvæ too small to transfer otherwise; transfer with the cocoon, give to bees taken from a hive with a laying queen, said bees having been shaken from the combs six hours previously, and 24 hours later give to the cell-builders. Or, take larvæ of the size usually transferred, transferring with cocoon, putting at once in upper story without first giving to queenless bees for 24 hours. Either of these two ways will save using up cells to furnish royal jelly. Instead of giving queen-cells to nuclei, give just-batched queens. It is quite possible that instead of having the combs for cells between combs with young brood, it may be better to have them between combs containing sealed brood.

Avoiding Obstruction of Queen-Cells, especially at swarming-time, has been a desideratum. F. L. Thompson tells in the Progressive Bee-Keeper how Geo. E. Dudley manages to have a queen caught in a trap when a colony swarms, and still allow free egress and ingress for the workers, as follows:

"He uses two entrances, to only one of which he applies the queen-trap (an ordinary trap, without any special modification). The queen always comes out thru this entrance, and is always caught in the trap; but the workers return from the fields thru the other entrance, the unobstructed one, tho they use both entrances indifferently when they leave the hive. This is accomplished by a modification of the bottom-board, so simple that I believe it would pay manufacturers to make all their bottom-boards on this principle. About two-thirds of the board, the rear end, is composed of a solid board, as usual; but the front third is composed of two 1/4-inch pieces, the top of the upper one being on a

THE LAND OF BREAD AND BUTTER

is the title of a new illustrated pamphlet just issued by the Chicago, Milwaukee & St. Paul Railway, relating more especially to the land along the new line it is now building thru Bon Homme and Charles Mix counties in South Dakota. It will be found very interesting reading. A copy will be mailed free on receipt of 2-cent stamp for postage. Address Geo. H. Heafford, General Passenger Agent, Chicago, Ill. 4A3

level with the top of the rear solid portion, and the bottom of the lower one on a level with the bottom of the rear portion. This leaves a space or hollow passage between them, 1/4 inch or more deep, and the width of the hive, and extending about 7 inches back of the ordinary entrance, which is provided for as usual by a bee-space on top of the bottom-board. The underground passage, as it might be called, is connected with the interior of the hive by two transverse slots, each about 2 1/2 inches long, where the solid portion is met. These slots are under the side frames, one slot at each side of the hive, and that is the secret of it. The side combs usually contain honey rather than brood, and the queen is usually not on those combs, but on the center ones, containing brood, and when a swarm issues she makes a straight shoot from the brood-combs to the only entrance that appears to be available—the ordinary entrance, where the trap is placed. The bees, as aforesaid, always return thru the lower entrance when bringing home honey or pollen, hence it does not matter how much the upper one is blocked up by the trap and by masses of bees hanging out. Mr. Dudley has tried this on a large scale two seasons without a single failure, and has made 200 such bottom-boards for future use."

Selling Extracted Honey, Etc.

My method is to extract all unfinished sections and put it into two-quart tin-pails holding 4 1/2 pounds of honey. Sell pail and honey for 50 cents. The pails cost \$5.75 per gross, so it gives me 10 cents a pound. I find no trouble to sell it the second time to the same customer. I warrant it strictly pure.

The past was the poorest season since I have kept bees. I had only about 60 pounds from 65 colonies. I had to feed up for winter. We are having a very mild winter so far. I hope to see the bees come out well in the spring, for I delight to see bees lively, and make the air hum with their activity.

The ground is covered here with snow now. I am afraid that a good many bees will starve thru this section.

I don't see how any bee-keeper can get along without some bee-paper. It seems to me as if they would be shut up from the outside, and would not know what their fellow bee-keepers are doing.

G. H. ADKINS.
Essex Co., N. Y., Jan. 16.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.10, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO., 118 Mich. St., Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

Selling Honey in Home Market.

My bees are in a locality where they surely do well in one respect—that is, they increase. Our winters are not cold enough to even thin them out good. To illustrate: I askt the principal merchant here if he could not handle some of my honey. His reply was, "No, no, every family in the town has bees!" That was a year ago. I bought, the past summer, two lots of bees, one in the town containing 50 colonies, 8 of which were in good hives, and the rest in boxes that took the regular size frame, or, rather, were built for them, but not used, as there were sticks instead. There were 36 supers and over two pounds of foundation, all for \$25. The other lot in the same vicinity (9 colonies) I got for 100 pounds of cheap honey that I retail to the Mexicans at 5 cents per pound, and the latter bees were hauled to my place.

In Las Cruces I askt a merchant to handle my honey, and he replied that honey was sold on the streets, and that the stores could not sell a pound per month. So it was with some misgivings that on June 10 I took some comb and extracted honey to Las Cruces. I had 23 sections, 3 half-depth frames, and 4 quart-jars. The sections

brought \$3.60, frames 90 cents, and the jars \$1.00. (I have since raised the quarts 5 cents.) I was agreeably surprised to find nearly every one to whom I showed honey wanted it. I could have sold more. The following Saturday (June 17) I sold all the comb honey I took, and some extracted, amounting to \$4.55; the 24th, \$5.05. July 1 I wrote for a friend, so that he could look after his peach crop. July 8 I sold \$5 25; July 22, in Mesilla Park and Las Cruces, \$4 15. I found sales rather slow, as fruit was very plentiful, and was taking the place.

I now go every other Saturday to Las Cruces with honey, as much to hold a few good customers as anything, altho I trade there. I find for one batching on a bee-ranch in the country, with only people of a foreign tongue for neighbors, the money received is not by any means the only source of profit.

I am starting in the chicken business in a small way, and want hens. I found one of my customers raising chickens for the table, and I exchanged roosters for pullets. Last but not least, we make pleasant acquaintances, see bright faces and happy homes, and the children run shouting to their mothers, "Here comes the honey-man!"

EDW. A. CHANDLER.

Dona Ana Co., New Mexico.

Pretty Poor Year for Honey.

One year ago I went into winter with seven colonies, and lost only one. I wintered them on the summer stands in chaff hives. The past year has been pretty poor for honey, considering the late swarming. They did not commence swarming till the last of May, and it lasted until the middle of June. I got about 30 pounds of surplus honey. All went into winter quarters with brood-chambers well filled with honey. I bought the wedge top-bar frames, and don't want any more of them. The old Hoffman is good enough for me.

ASA RICE.

Muskegon Co., Mich., Jan. 7.

Bees Wintering Splendidly.

My bees are wintering splendidly so far. We had a splendid flow of honey from Spanish-needle in September, so the bees are in fine condition for winter. I have 18 colonies, and got 50 pounds of comb honey and one swarm the last season.

GEO. H. WEED.

Carrol Co., Ill., Jan. 17.

Inky Drops and Smoker Fuel.

I have been making bee-smokers for 21 years, and using them in my own apiary 22 (excepting five years when I had no bees), and while producing comb honey every season (excepting as above) I do not remember having the inky spots referred to on a single section. For the last five years I have used tall sections exclusively, and I do not use bee escapes. During four years of that time I have used a 4-inch smoker, and know that not a single section or anything else has been injured by the drops mentioned.

The first thing that will be asked after reading the above, will be, What does Bingham use for fuel? And it is proper here to explain, that in the first place, convenience and cost decide that matter, as my smokers have always burnt anything put into them. The 4-inch is so large you can pour the smallest chips from a basket into it. So I scrape up a lot of dry chip-dirt in my woodshed, and drop it on a wire-cloth screen and shake out all the sand and real dirt; then pick off all the very large pieces of bark and use the balance for smoker-fuel.

In damp weather probably it would be better to dry the stuff I use, but it burns well enough, and so I don't take any pains to dry it. But if the sun is bright, I frequently set the fuel-box out where it will be handy and in the sun.

I should prefer to have the fuel hot from a stove-oven or the bright sun. A wax ex-

AMERICAN BEE JOURNAL, 118 Mich. St., Chicago, Ill

tractor would be a fine thing for the job, and handy.

I burn all the chips and make all the smoke I can when I handle bees, but I do not use a veil, and rarely get a sting.

The moral effect of smoke in an apiary can not be measured. If your smoker makes lots of smoke without puffing, you can handle your bees without smoking them much; but if you don't have a lot of smoke ready-made you will have to smoke them down, because, like the English in the Transvaal, you were not ready, and the bees got mad, and wouldn't let up till conquered.

T. F. BINGHAM,

Clare Co., Mich.

Something from Florida.

On the journey from Peoria, Ill., to Mobile, Ala., I watch for bee-hives, and only saw from the car windows a very few in Illinois. The market for honey in Mobile is undeveloped, as the demand for it has never been created.

Since my arrival here, I visited a resident who has a small apiary. I inquired how his bees had prospered during the past summer. He said:

"The February freeze last winter destroyed the fruit-bloom, and when it bloomed again in March the frost took it, and also the t-t-t. The February freeze also destroyed the bloom of the saw-palmetto, and there was no bloom at all. I fed my bees much sugar to keep them from starving, but I'll never do it again; if they can't make a living they may go. Three of my weak colonies were destroyed by moths."

At a store here extracted honey is drawn thru a gate from a barrel, and retailed at 20 cents per quart. It is good honey, and the dealer says weighs 12 pounds to the gallon. This honey was produced on the Choctohatchie, near Freeport, by an apiarist who owned 300 colonies. This honey was gathered last year.

Tho there was no surplus honey gathered in this locality the past season, on account of the previous winter's cold and summer's drouth, yet I am told there was some surplus at Wewahitchka. The land there is rich and damp, and tupelo trees yield much honey; also vines growing in the water, and are lifted into the sunshine by the tall, dead trees. Wewahitchka is an Indian word signifying "eye-glasses," as these two lakes are joined together like them. These lakes are 35 miles long, and from 2 to 17 miles wide. The land adjoining is very rich, like the delta of the Nile, made by the overflow of the river, which leaves a rich deposit.

Mrs. L. HARRISON.

Washington Co., Fla., Jan. 9.

Not a Good Year for Honey.

The past was not a very good year for the bees. Last winter's losses were quite heavy. I lost 16 out of 41, increased to 51, and took about 35 pounds per colony, spring count, of comb honey. All of my honey is sold in the home market at 12½ cents per pound.

F. E. HENRY.

Harrison Co., Iowa, Jan. 8.

Manufactured Comb Honey Again.

By request of Mr. M. E. Wolfe of this place, I write for information in regard to manufactured comb honey in one-pound sections, etc. It seems as if the majority of the people of this city, and about nine-tenths of the merchants, believe that the comb can be manufactured, filled with manufactured honey, and then capped and sealed over and put in the one-pound sections, just the same as is done by the bees. Mr. Wolfe wrote Rev. E. T. Abbott about the matter, and in answer to the letter Mr. Abbott said such an article as manufactured comb honey was not in existence, and that he would give \$500 for one pound of such honey, with the information as to where it was manufactured.

Mr. Wolfe also wrote Mr. A. H. Duff about the matter, and he also said that such a thing as comb honey being manu-

PREMIUM BEE-SUPPLY ARTICLES.

We will mail your choice of the following as a premium for sending NEW subscribers to the American Bee Journal for one year, at \$1.00 each:

Given for Sending ONE New Subscriber:

1. Two Porter Bee-Escapes.
2. One Porter Bee-Escape and one Queen-Clipping Device.

WANTED TO RUN AN APIARY for extracted honey, on shares or salary; 3 seasons' experience in large apiaries. Will go to any State where crops of honey are quite certain. Best of references. Address J. T. HAMMERSMARK, 618 N. Clark St., Chicago 4A1t Please mention the Bee Journal.

Convention Notices.

California.—The tenth annual convention of the California State Bee-Keepers' Association will be held in the Chamber of Commerce, at Los Angeles, Feb. 21 and 22, 1900. It will be called to order at 1:30 p.m., Feb. 21. At this time the railroads will sell round-trip tickets to Los Angeles and return for one and one-third fare, on account of the Industrial, Mining, and Citrus Exposition, which will be held in Los Angeles. Tickets good for 10 days. Let every bee-keeper bring some hive, tool or experience that he has found valuable, and we will have a good convention. J. F. McINTYRE, Sec. Sespe, Calif.

Wisconsin.—There will be a joint convention of all Wisconsin bee-keepers' societies at the 16th annual meeting of the State Bee-Keepers' Association, Feb. 7 and 8, 1900, in the State Capitol, at Madison, Wis. Many prominent bee-keepers will be there and take part.

Excursion rates of a fare and one-third for the round-trip, for railroad tickets purchased in the State, for over 50 cents each. Be sure to bring a certificate of each ticket purchased so it can be signed Feb. 8, in Madison, and entitle the holder to a third fare return.

The State Horticultural and State Cheese-makers' Associations will meet on the same date in the Capitol.

Don't forget the date—Feb. 7 and 8. It will pay you to attend. N. E. FRANCE, Sec. Platteville, Wis.

ROCKY MOUNTAIN

Bee-Plant Seed!

(*Cleome integrifolia*.)

...FREE AS A PREMIUM...

The A B C of Bee-Culture says of it: "This is a beautiful plant for the flower-garden, to say nothing of the honey it produces. It grows from two to three feet in height, and bears large clusters of bright pink flowers. It grows naturally on the Rocky Mountains, and in Colorado, where it is said to furnish large quantities of honey."

We have a few pounds of this *Cleome* seed, and offer to mail a ¼-pound package as a premium for sending us ONE NEW subscriber to the American Bee Journal, with \$1.00. Address,

GEORGE W. YORK & CO.,

118 Michigan Street, CHICAGO, ILL.

factured by machinery and put on the market in marketable shape, the same as the comb and honey made by the bees, was not in existence. Mr. Duff also stated that the "American Bee-Keepers' Association" has a standing offer of \$1,000 for one pound of manufactured honey, which has not been taken, altho standing for 15 years. Does Mr. Root still offer \$1,000 for one pound of manufactured comb honey? If he does, that would make \$2,500 for any one that will manufacture one pound of comb honey, the same as is done by the honey-bees.

As for Mr. Wolfe and myself, we take the stand that it is a mistaken idea, but for the benefit of others and the public in general we take this method of having it explained thoroughly and satisfactorily to all, thru the columns of your paper. It is surprising how large a percent of the public believes that comb honey is manufactured and placed on the market. This subject should be more thoroughly discussed, so as to correct such false ideas that so many people are laboring under. L. WAYMAN.

Labette Co., Kan.

[Mr. Wayman, you can assure Mr. Wolfe that there is no such thing as manufactured comb honey, and likely never will be any. The bee-keepers' association never has made the offer mentioned; Mr. Root did, and does yet, we believe. But we are certain it was not made with the idea that he wanted people to go ahead and manufacture comb honey so as to get the reward offered, but simply if any one heard that there was such an article being manufactured, he would give \$1,000 for a pound of it.]

We might say that a bee-paper is hardly the proper place to deny the existence of manufactured comb honey, but rather in the newspapers where it is kept going. Readers of bee-papers are hardly so foolish as to believe such a falsehood.—EDITOR.]

Honey Crop Generally Light.

As a rule the honey crop in this locality was light, altho a few apiarists report a good yield. I commenced last spring with three good colonies and one weakling. I took off a surplus of about 70 nicely-filled sections. I use the fence and plain sections, and like them very well. I increased to eight colonies, and had two swarms leave for the woods. I shall try dividing another year. I lost one colony this fall by the combs melting down.

IRA LUBBERS.

Sheboygan Co., Wis., Jan. 9.

Prickly-Ash Honey Bitter.

I can report 1,800 pounds of comb honey for 1899, and I sold it all for cash to a New York firm for 12 cents a pound. It was all bitter honey that I could not sell here. It was gathered from prickly-ash bloom.

I would not do without the American Bee Journal if it cost double the subscription price.

HENRY K. GRESH.

Elk Co., Pa., Jan. 12.

Best Season in Eight Years.

Another year has past, and it was the best I have had in eight years since I have been in the bee-business. I started last spring with 63 colonies, increased to 83, and extracted about 8,000 pounds of fine honey, which I sold long ago. I could sell that much more if I had it.

Our honey-flow commenced July 7, and continued until Sept. 12, when it turned cold, and we had a few hard frosts which froze everything that was in bloom. After that we had three weeks of fine weather—it got so warm that some white clover bloomed, and also some dandelion. Last winter was so cold that it froze almost all the clover in this vicinity, but the seed came up again, and the pastures are as thick as ever, which looks fine so far, and if clover does not freeze this winter the prospects will be good for another year.

The colony that I had on scales gained

327 pounds, but it did not swarm. I had another colony that filled five 10-frame Langstroth hive-bodies; the five were all on the hive at one time. That colony did not swarm, either. I had some colonies that swarmed three times, and then stored some honey in the fall. JACOB WIRTH, Henry Co., Ill.

Expects a Honey Crop this Year.

Bees in this section (north half of San Diego County) are generally in pretty good condition, bringing plenty of pollen and a little honey. We had a 4 1/2-inch downpour of rain a week ago, and feel reasonably sure of some honey next spring. All honey-plants look well. Days are bright, clear and warm—with the temperature about 65° from 10 a.m. to 3 p.m.

G. F. MERRIAM.

San Diego Co., Calif., Jan. 11.

Cayuga Co., N. Y., Convention.

The bee-keepers of Cayuga County, N. Y. met in Auburn, Dec. 21, 1899. At 10:30 a.m. the meeting was called to order by Pres. N. L. Stevens, after which he read a paper touching on different points of progress in bee-culture. Then the following officers were chosen for the ensuing year: President, N. L. Stevens; 1st Vice-President, Edwin Austin; 2nd Vice-President, J. S. Secomb; 3rd Vice-President, A. B. Comstock; Secretary, J. O. Pierson; Treasurer, T. Bridgon.

Each member was requested to give the number of colonies, spring count and fall count, number bought, and number of pounds of comb and extracted honey produced.

In the afternoon the question-box was taken in hand by Mr. Frank Benton, he reading each question and giving his opinion; then it was an open question for any member to discuss. After the question-box Mr. Benton gave a lecture, illustrated by drawings on a blackboard, of the fertilization of blossoms by the honey-bee, which lasted until the end of the session.

Cayuga Co., N. Y. F. E. WHITMAN.

Bees Cellar-Wintering Nicely.

My 80 colonies in the cellar seem to be getting along nicely. My loss last winter and spring was 123 colonies out of 166. It is to be hoped that we will not have such a winter again. W. C. NUTT.

Hardin Co., Iowa, Jan. 8.

Wintering Well in the Cellar.

Bees are wintering well in the cellar. I put in 126 colonies last fall. We have no snow. The temperature was 50° above zero the day before Christmas.

S. C. SWANSON.

Goodhue Co., Minn., Jan. 5.

Bees in Fine Condition.

Bees had a general flight the 7th, and have been flying more or less all the week since then. We are having a splendid January. Bees are in fine shape to date.

S. A. MATSON.

Nodaway Co., Mo., Jan. 13.

Prospects Good.

The weather is fine. Last Friday and today the bees had good flights, and appear to be in fine condition. The sky was clear and the thermometer at 48 degrees. The prospect is good so far. JOSEPH MASON.

Dekalb Co., Ill., Jan. 7.

Report for Last Year.

Last year I got just an even ton of fancy comb honey from 20 colonies, spring count, and increase to 44 colonies, to say nothing of 10 prime absconded swarms, and a novice attendant. E. WOODALL.

Lake Co., Mich., Jan. 13.

BEE = BOOKS

SENT POSTPAID BY

George W. York & Co. 118 Mich. St. Chicago.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopaedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers, \$1.00.

Bienen-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Bienenzucht und Honiggewinnung, nach der neuesten methode (German) by J. F. Eggers.—This book gives the latest and most approved methods of bee-keeping in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cts.

Bee-Keeping for Profit, by Dr. G. L. Tiuker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cts.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

Capons and Caponizing, by Dr. Sawyer, Fauny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fauny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 20 cents.

Poultry for Market and Poultry for Profit, by Fauny Field.—Tells everything about Poultry Business. 64 pages. Price, 20 cents.

DON'T TAKE CHANCES!

Buy no incubator and pay for it before giving it a trial. The firm who will not sell on trial have no faith in their machines. We sell the celebrated PREMIER INCUBATOR ON TRIAL. Also sole manufacturers of Simplot's, Catalogue and Poultry Helps, &c.

Columbia Incubator Co. 5 Adams St., Delaware City, Del.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Jan. 8.—We quote best white comb at 15c; an occasional small lot of fancy sells at 16c; off grades of white, 12@14c; ambers, 10@12c. Extracted, 8@9c for fancy white; 7@8c for amber; 6@7c for dark grades. Beeswax, 27c. Receipts are larger and the demand is not as good as it has been. R. A. BURNETT & Co.

CINCINNATI, Dec. 7.—There is a good demand for all kinds of extracted honey. White clover and basswood sell at 8@8 1/2c; amber and Southern, 6@7c, according to quality and package. Fancy comb honey in no-drip shipping-cases sells at 15@16c; darker grades hard to sell at any price. Beeswax, 26c. C. H. W. WEBER, Successor to Chas. F. Muth & Son and A. Muth

LOS ANGELES, Jan. 4.—1-pound frames, 12 1/2@15c; 2-pound cans, 2 dozen in case, per dozen, \$2.50; 2-pound glass pails, per dozen, \$2.50. Extracted, water white, 60-pound tins, per pound, 8 1/2c; light amber, 7 1/2@8c; dark amber, 7 1/2c. Beeswax, 25@26c.

KANSAS CITY, Jan. 19.—We quote No. 1 white comb, 13 1/2@14c; No. 2, 13@13 1/2c; No. 1 amber, 13@14c. Extracted, white, 7 1/2@8c; amber, 7@7 1/2c. Beeswax, 20@22c.

The supply and demand for comb honey is light. The demand for extracted since the first of the year not so good. C. C. CLEMONS & Co.

BUFFALO, Jan. 5.—Market bare of fancy white one-pound comb honey, and selling at 15@16c; fair to good, 12@14c; buckwheat, dark, poor, etc., 8@10c. Fancy pure beeswax, 28@30c. BATTERSON & Co.

NEW YORK Dec. 10.—Demand is very good for all grades of comb honey. Receipts are somewhat light and not up to former years. We quote:

Fancy white, 15 cents; No. 1, white, 13@14c; amber, 11@12c; and buckwheat, 9@11c., as to quality. Extracted remains firm at following prices: California white, 8 1/2c; light amber, 8c; white clover and basswood, 8c; amber, 7 1/2c. Very little trade for extracted buckwheat as yet. Southern, fancy, 7 1/2c per pound; other grades, as to quality, from 70c to 75c gallon. Beeswax quiet at 26@27c. HILDRETH & SEGELKEN.

SAN FRANCISCO, Jan. 10.—White comb, 11 1/2@12 1/2c; amber, 8@10c. Extracted, white, 7 1/2@8c. Light amber, 7@7 1/2c; amber, 5@5 1/2c; Beeswax, 26@27c.

Offerings and demand are both light, and this must continue to be the case until the end of the season. Business is necessarily of a retail character, but at generally firm figures, especially for choice extracted, which is in lighter supply than comb.

BOSTON, Jan. 12.—We quote as follows: Fancy white, 16c; A No. 1, 15c; No. 1, 13@14c; buckwheat will not sell in this city. Extracted, light amber, 7@8c. Demand is very light. BLAKE, SCOTT & LEE.

ALBANY, Dec. 10.—We quote: Fancy white comb, 15c; No. 1 white, 13@14c; mixt, 11@13c; buckwheat, 10@11c. Extracted, white, 8@9c; mixt, 6 1/2@7c; dark, 6. Beeswax, 26@28c. MACDOUGAL & Co.

Successors to Chas. McCulloch & Co.

OMAHA, Jan. 4.—Prices remain unchanged. Fancy white is still moving slowly at 14@14 1/2c. Extracted, white, 8 1/2c. Now that holiday trade is over and dealers have taken their inventory, they soon will be thinking of replenishing their stock and more lively trade is anticipated in the near future, but no material advance is looked for during January. PEYCKE BROS.

DETROIT, Jan. 11.—Fancy white, 16@17c; No. 1, white, 14@15c; dark amber, 10@13c. Extracted, white, 8c; dark and amber, 6@7c. Beeswax, 24@25c. M. H. HUNT & SON.

WANTED.—Extracted honey, all kinds; mail sample and price expected delivered at Cincinnati. I pay spot cash on delivery.

C. H. W. WEBER, Successor to Chas. Muth & Son and A. Muth. 40A St. 2146-48 Central Ave., Cincinnati, O.

Glass Honey-Jars!

We have two sizes of clear flint-glass Jars, No. 1 holding a scant pound of honey, with an opal or white top held on with a screw metal band under which is a rubber to prevent leakage. No. 2 is a rather tall flint-glass jar with tin screw-cap, holding 3/4 pound of honey. Both are excellent for retail honey-packages, and are put up in single gross lots. The prices are per gross, f.o.b. Chicago, for the No. 1 jars, \$5.25; for the No. 2, \$4.25.

We can fill orders promptly for these jars. They give excellent satisfaction, we know, for we have used the same jars for several years.

No. 5.

CONTRIBUTED ARTICLES

Apiary of Mr. Tofield Lehman.

BY THE EDITOR.

THE picture shown herewith is a part of the home apiary of 46 colonies, belonging to Tofield Lehman, of Fayette Co., Iowa. The crop of honey in 1899 from them was 2,000 pounds, which, he says, was a poor year.

In the picture Mr. Lehman is standing by the side of the honey-extractor, and the girl in front of the extracting-house is his 14-year-old sister.

The hives in the apiary are 6 feet apart in the rows, and the rows 16 feet apart.

He has kept bees for 7 years, and has been successful with them all that time.

One of his neighbors askt him how much honey a good colony of bees could store in one day during a good honey-flow. Mr. L. told him that some of his best colonies stored in one day 14 pounds each, during the basswood flow the past season. He could hardly believe it. Mr. L. weighed the colonies early in the morning before any of the bees left the hive, and then weighed them again in the evening when all had stopt flying. Some of the best colonies were then 14 pounds heavier than in the morning.

In 1896 Mr. Lehman sold \$22.50 worth of fine honey from a single colony. It produced 150 pounds which brought 15 cents per pound that year.

We have had some of the extracted honey produced by Mr. Lehman, and it was some of the finest we have ever seen—very thick in body, and of a rich flavor. If all who produce extracted honey would be as careful to put out as well-ripened an article, there would be less complaint against honey in the extracted form. Last fall we purchast fifteen or twenty barrels of honey from Wisconsin, and lately we have had to reliquefy it, and transfer to 60-pound cans, because of the honey fermenting and really bursting out the heads of the barrels. Undoubtedly this honey was extracted before the bees had ripened it. No one who has had the experience with extracted honey in barrels that we have had would ever favor using barrels for holding honey. Of course, Mr. Lehman uses cans, tho it is not so necessary in his case as in that of some others who are not careful to put out only well-ripened extracted honey. We hope the time will soon come when wooden barrels will be used no more for shipping honey.

Producing and Marketing Honey—Shall it be Comb or Extracted?—Analysis of the Subject.

BY R. C. AIKIN.

THE production of extracted honey will surely increase. Comb is consumed principally as a luxury, and so long as it sells at retail for 10 to 25 cents while other sweets, as sugar, sell at about half the average of the comb, it will not be other than a luxury. Other reasons why it is a luxury, is the greater skill required to produce it, making the cost greater, and the difficulty of keeping it indefinitely without greatly deteriorating. All these things help to increase the cost of comb honey over extracted, making it a luxury.

Should the production of honey continue to increase as it has in the past, it must of necessity become a product of no mean proportions, and largely produced it must be largely marketed. I can well remember in the New West, and in war times, when almost any kind of sugars were a luxury, sorghum molasses was the staple sweet. Granulated sugar is now as common as was sorghum in those days, and so will most likely be the change in regard to the use of honey.

Comparing the cost of production of comb and extracted

Apiary of Mr. Tofield Lehman, of Fayette Co., Iowa.

honey, much depends upon the location and environments of the producer. With the specialist the difference is not so very great, but with the man who has a few colonies (there are many such) in connection with other business, the choice between producing comb or extracted honey has to be made not so much on the ground of actual cost, but of ability to produce one or the other, and what can be gotten out of it. If I am so situated that I cannot give attention at proper times to get marketable comb honey, then my inability makes it expensive to me; but that matters not in the general production as a business. Honey-production as a business will not find the difference in cost so great as indicated by prevailing price.

□ To produce as a business, and to sell on the general markets, the choosing which we will produce is not a question of any great difference in the cost of producing, but of what it will bring after produced. I prefer to produce comb honey, it is much nicer and cleaner work; but laying aside my preferences, and looking at the matter in a business light, it depends upon circumstances, which I choose.

The first thing to do is to look the field over and see where and how the product is to be marketed, consider whether you can market by wagon or from the honey-house, or if freight must be paid and how much; whether your customers use honey as a luxury or as a common sweet, and never forget their ability to buy, whether luxuries or necessities only.

My home customers are not those who use many luxuries—they buy honey as a table sweet for general family use; do not want and will not buy much honey if it costs more than other good syrups. Comb honey sells in a limited way only, and at not to exceed 10 cents per section (pound) at retail. Were I producing comb honey for my local market, and to make a living out of it, it would be a slim living indeed that would come out of 10-cent honey. I can, however, make a living selling extracted at 6 to 7 cts.

I figure this way: If I produce for the home market it must be extracted, and that goes right along when the price is 6 cents for the bare honey (it is more this winter); thus the people can bring their own vessels and get it at about the same cost as sugar. If I sent the same honey to Chicago or Kansas City (my nearest general wholesale markets), the package, freights and drayage, etc., would cost me about 2 cents, and leave me about 4 cents for the honey—I would get about 6 cents there, usually.

If I am to ship out my honey instead of selling at home, I should produce comb. No. 1 comb would bring me somewhere about 10 cents in Chicago (remember I am talking about the general average one year with another, and not this year), the freight and package costing me about 3 cents. Thus, you see to ship my crop I would get something like 4 cents for extracted and 7 for comb, while to sell at home I would get about 6 for extracted, and sell enough to make a living out of it, whereas I would get about 10 cents for comb, and sell but little of it.

There are no doubt locations where one in well-to-do communities could sell quite a stock of comb honey; but there is this difficulty among the wealthy and such as buy luxuries, they buy a little nice comb, fruits and a great variety of things, so that because of the great variety the honey gets to be a trifling amount. If the customers are laborers or wage earners, and buy for every day use, one such customer is worth a dozen of the more wealthy who buy a little of everything.

We must, then, look at the matter squarely as a business proposition, not blindly but understandingly, then decide what we will produce. If your field is large, and the supply so limited that the demand will take all you can produce, go into comb honey. A wealthy community will take comb most likely rather than extracted, but you will need a greater number of families from which to get your customers. If the field is limited, and you must draw your trade from the middle and lower classes, then produce extracted, and make it supplant other sweets. Make customers out of your neighbors, supplying them a sweet as good and cheap as they have been buying elsewhere, then you have a trade that is worth much to any producer, a trade that is more to be depended upon than is the trade in luxuries.

Analyze intelligently the things to contend with, then go ahead, and once started on the right track keep right after it. The man who has been in a field for several years and carefully studied all the conditions, can discount some new competitor, in so far as knowledge goes. A competitor having a big advantage in the way of capital may discount one of limited means, but, other things being equal, the man who goes at a thing and stays right by it thru thick and thin, is the one who succeeds. Larimer Co., Colo.

The Home Market and Unfinish Sections.

BY JESSE M. DONALDSON.

AS I have received many valuable hints from articles written on this subject, I will give an experience that I had, from which I learned a lesson that may benefit others who, like myself, sell their honey around home.

My surplus is from white clover and raspberries. Buckwheat is not grown here, so my customers are not used to that kind of honey. Last year a man came thru this district selling buckwheat honey. It was a nice grade of comb honey, put up in cartons; he was selling it very cheap, and disposed of quite a large quantity. Some of my customers did not forget to call my attention to the difference in his price and mine. One of them told me he would ruin my trade.

I did not pay much attention to their remarks, as my crop was all sold, and I could not understand how he could hurt my trade, as he was selling buckwheat honey, and mine is from clover. But I soon learned my mistake, when I began selling my honey the past fall. One of the first houses I called at, I showed the lady a jar of extracted honey, telling her the price of the same. She said, "Our folks don't like strained honey. We always get ours in the comb."

Then I showed her a nice, well-filled section. After examining it, she said, "Well, that looks nice, and it is well filled, but we bought some last year that looked nice, and we could not eat it."

I knew it would be useless for me to have her try the extracted honey, then explain to her that it was the same quality, so I past on to the next house. One of my regular customers lived there, so I made a sale.

But I had gone down the street only a short distance, when I received almost the same story as I did at the first house. This set me thinking. How could I overcome these arguments? I thought if I could let them sample the comb honey, the same as I do with extracted, all would be well.

I was only three blocks away from home, so I went back and got some of my unfinished sections. I cut the honey out of one of them, placing it on a plate. I called at the same houses, and askt the ladies to sample my honey. The result was ready sales. I have used this plan since then, and I find it a great help, even when calling on my regular customers. When you give them a taste of honey (good honey) it seems to create a desire for more.

I suppose some will say that I could have used those sections for baits (just what I did do) to a much better advantage, so I will explain how I sort my comb honey.

I have my regular customers, and I believe in giving good measure, so I place in one pile all sections that are well filled and capt—they are for sale. Those that have nice, even combs, but are not well filled, I extract, and use for bait sections. Any section with uneven comb, or not built out full, I use on my own table. This is the kind I used to bait my prospective customers.

Speaking of bait sections, I see quite a number report trouble in getting them cleaned up. I had the same trouble until I hit on a plan that has always given me the desired results. Instead of leaving the sections in the super, I first uncap them, then I turn back one corner of the enamel cloth and place an empty hive-body on the hive. Then I fill the body with sections, placing them in any way so the bees can have access to all. It seems to me that the bees realize that sections placed on the hive this way are not accessible for winter stores. Worcester Co., Mass.

Migratory Bee-Keeping—Its Advantages and Disadvantages Pointed Out.

BY W. Z. HUTCHINSON.

MY father lives in an adjoining county, where there is an abundance of boneset and goldenrod. One year a younger brother, who had not left home, came to my place early in August and carried home with him 20 colonies of bees. An upper story filled with empty combs was placed over each colony, and the top covered with wirecloth. A hay-rack was covered with hay to the depth of two feet, the hives set on the hay, and held together in a bunch by passing a rope around them. The journey of 25 miles was made without mishap. Those 20 colonies furnished 400 pounds of surplus, and, besides, they needed no feeding for winter, while the bees kept at home stored no surplus, and each colony required feeding about 15 pounds on an aver-

age. I gave one-half the surplus to my brother as his share of the "spoils."

Had buckwheat yielded well, which, in this locality, happens once in about half a dozen years, nothing would have been gained by moving the bees. The inability to foretell the honey-flow in any given locality is the greatest obstacle in the way of successful migratory bee-keeping. In the Bee-Keepers' Review for August, 1889, Mr. R. L. Taylor said: "I might have made \$1,000 by moving 100 colonies there [to a certain locality] last year; but I might expend \$200 each year for the next five years in moving bees back and forth, and find at the end of that time that I could have obtained more honey if I had not moved them at all. This I admit is not likely, as the advantages of that locality for a full crop are so much greater than this, but it is possible."

Only 40 miles from here, on a direct line of railroad, is a locality where the main honey-flow comes in the fall; yet nothing is secured here at that time. All bee-keepers know that the distance of only a few miles often makes all the difference between no crop and a bountiful harvest, and the question is, Can't bee-keepers take advantage of this fact? If they can, why don't they do more than they do? Either the moving of bees to take advantage of transient, neighboring flows is unprofitable, on the whole, or else this part of bee-keeping has been neglected. Bee-yards, honey-houses, etc., are all gotten up with permanency of location in view. The bee-keeper gathers about him these conveniences and appliances, arranging his apiary, and if the honey comes to him, all right; if it doesn't, he does not think of *going to the honey*.

The expense of moving to and from a locality a few miles distant need not be so very great. From 30 to 40 colonies can be moved on a large hay-rack; or a special rack might be constructed, by means of which one team could haul 50 colonies. Small, light, readily-movable hives are a great advantage. One of the great advantages of fixed frames, about which there has been so much said of late, is that they need no fastening when an apiary is moved. An apiarist who is going to practice moving his bees to secure better pastures, must have hives, fixtures and other arrangements suitable for that purpose. It ought not to take more than two or three minutes to prepare a hive of bees for moving.

Some localities are blest with white clover, basswood and fall flowers—and, by the way, the man who is to make a specialty of bee-keeping ought to seek such a locality—but many who are already engaged in bee-keeping are permanently located, have friends and relatives living near, and prefer not to move away even if the profits would be increased thereby. Then, again, it is difficult to find a first-class locality of clover or basswood that is equally good for fall flowers. And the better the locality the greater the danger of its being overstocked by its very attractiveness, bringing together so many bee-keepers.

Years ago movable frames or combs were invented. In the last few years many of us have been learning to accomplish many things by handling hives instead of combs, and the expression, "readily-movable hive," has been coined. Now we are beginning to talk about readily-movable apiaries—those that, with a day's warning, can be picked up and set down 20 miles away where a "honey-shower" is passing.

I scarcely feel like advising a bee-keeper to move his apiary to some other locality, with the hope of securing a greater yield than it is possible to secure at home, when the yield at home may be a fair one; but when a bee-keeper has only one—white clover or basswood, or fall flowers—from which to secure surplus, yet lives only a few miles from one or both of the other sources, it does seem to me as tho he ought to consider the advisability of moving his bees to these other fields when the harvest is ready for the laborers. To me this seems like a more promising field for experiment than that of planting for honey. Instead of spending time and money for seeds, land and cultivation, let us move our bees to where Nature has already scattered the flowers with a lavish hand.

There is another form of migratory bee-keeping that has long been the dream of apiarists—that of starting with an apiary in the South at the opening of the honey season, and moving northward with the season, keeping pace with the advancing bloom, thus keeping the bees "in clover" during the whole summer. The difficulties to overcome are those of transportation. There is no single line of railroad running north and south for a sufficiently long distance to enable an apiary to be moved north for a long enough distance to make a success of migratory bee-keeping. When

shipping bees by freight on the migratory plan, the delays at junction points are sometimes not only vexatious, but disastrous. It is for this reason that longing eyes have been cast at the Mississippi River and her steamboats; and once C. O. Perrine tried moving several hundred colonies up the Mississippi on a barge towed by a tug.

The plan was to run up the river nights, and "tie up" during the day, to allow the bees to work. There were several reasons why the plan was a failure. The start was made too late in the season, and accidents to the machinery of the tugs caused delays. In order to overtake the bloom, it became necessary to confine the bees and run day and night. The confinement for so long was disastrous to the bees. Those who aided in the enterprise believe that, rightly managed, moving bees up the Mississippi, to keep pace with the bloom, might be made a success.

Mr. Byron Walker, who has had much experience in bringing bees from the South, greatly favors the Mississippi plan of practicing migratory bee-keeping. He would not put the bees on a barge and tow the barge with a tug, but would load the bees on a regular steamer running up the river, setting them off at some desirable point, and then shipping them by boat to another point farther up the river as the flow began to wane. In the fall he would take the bees back to the South for the winter.

Of course, bees moved in hot weather must have plenty of ventilation, but this alone will not save the brood. To save the brood, the bees must have plenty of water. As obstacle after obstacle has been removed in home bee-keeping, so the migratory plan may yet be robbed of its drawbacks.

Right here a hypothetical question comes to mind: Supposing that an apiary moving up the Mississippi secures six crops of honey—six times as much as a stationary apiary—would this be more profitable than six stationary apiaries? In other words, which is the more promising field for enterprise—following up the season or establishing out-apiaries? On this point there are many things to be considered, and varying circumstances would lead to different decisions. To establish six apiaries would require considerable capital, and the labor of caring for the honey crop would all come at one time, while there would be only a "chance" of securing a crop. With the migratory plan only one apiary would be needed, and the work of caring for the surplus would not all come at the same time. With the stationary apiaries, there would be no expense for transportation, which is a big thing.—Country Gentleman.

Genesee Co., Mich.

CONVENTION PROCEEDINGS

Report of the Michigan Bee-Keepers' Convention

BY WM. G. VOORHEIS.

[Continued from page 53.]

CLIPPING THE QUEEN'S WINGS.

Mr. Hilton—The trouble is where the queen's wings are clipped when the swarm comes out; if you are not on hand to catch her, you are liable to lose her.

Mr. Beecham—If you stay right at the hive and watch her it is all right. You must be there to see the queen drop, so as to catch her.

Mr. Bingham—I have tried clipping queens' wings a good deal. I do not do so now, as it is sometimes a great bother. The queen drops on the ground because she can not fly. The bees fly all over a 10-acre lot, trying to find her. Should other swarms come out, any one of them having a young queen, they will all cluster around the young queen. Then you will have a barrel of bees to separate. I have had as many as 7 or 8 swarms together.

Mr. Calvert—I think it is a good plan to clip the queen's wings where the swarm is liable to cluster on a high tree. Clipped queens are profitable in small apiaries where a farmer is out at work, and can not attend to them at the time. Where the apiary is large it is apt to mix up the bees all over the yard. It is more apt to make swarms go together.

DIVIDING FOR INCREASE.

Mr. Coveyou—It is not profitable to divide a colony in the spring, as you will not get much honey. Take two frames of brood and build up a colony from that.

Mr. Chapman—I make all my increase at the close of the season.

Mr. Kauffman—I divide by taking four frames of brood. I like natural swarming best.

Mr. Chapman—I use a queen-excluder to keep the queen in the lower story. Young queens will not swarm if you give them plenty of room. I use brood-chambers as I need them, and tier up as high as four stories.

FOUL BROOD.

Mr. Calvert—To stop the spread of foul brood shake the bees out of the old hive on a new hive with brood foundation, and burn the old combs. I have treated them in various ways, but like this way the best. The difficulty is that the bee-keepers do not know the disease when they see it. They should have a chance to examine bees affected with foul brood, so as to become familiar with it. The best illustration of it is in "A B C of Bee-Culture." The larvæ is tough, like India rubber; when you pull it out it springs back. It smells like old glue.

Mr. Rankin—Foul brood is one of the worst diseases. To get rid of it, shake the bees into a new hive on new foundation. Bees having foul brood seem very delicate, and should be taken out of the hive at the start. I can detect it as soon as I raise the cover.

Mr. Calvert—In Utah and Colorado they have an inspector in each county. The counties there are larger than in the East.

Mr. Rankin—One-half of the bees in the south and east part of the State are killed by foul brood.

Mr. Gifford—I move that the chairman appoint a committee to draft resolutions for the purpose of getting a State inspector appointed, and the foul brood law past at the next session of the legislature.

The chairman appointed Messrs. Rankin, Gifford, and Bingham.

Mr. Bingham—I think as the foul-brood combs are valuable, we can save them by using sulphur and washing-soda.

Mr. Hilton—I think they might be saved in the hands of an expert bee-keeper, but in the hands of a novice it would not succeed.

Mr. Rankin—I think that burning the combs is the best and only way. The danger of contamination is so great that it would not do to risk it. The starvation plan and putting the bees on new foundation are the only way.

Mr. Calvert—I do not think that Mr. Bingham's plan would work in out-apiaries.

Mr. Hilton—I would ask Mr. Rankin why the foul-brood law did not pass at the last session of the legislature?

Mr. Rankin—The reason is, the bee-keepers in this State did not stand by the Bill; they were so indifferent about advising their members of the legislature about it. It was pigeon-holed in the committee.

Mr. Hilton—If the bee-keepers of this State want the law past, they must write to their representative and State senator about it, then there will be something done. Write individual letters—that is what counts. One thing certain, unless it is done soon bee-keeping will soon be a thing of the past. The people of the State of New York are worse off, if anything, than we are. For my part, I would like to see the disease stampt out in this State. If the people in the State of New York continued as indifferent to the disease as they had been, we could soon sell honey to them.

Mr. Rankin—Vigorous measures must be adopted soon to quell this disease. The time has past for nipping the disease in the bud. It has spread over a greater extent in this State than people are aware of.

Mr. Bingham—I regard the honey-extractor a calamity. The trouble is where the foul brood exists in the apiary the use of the extractor will spread the disease all thru the apiary in a very short time. We must be very careful about using the extractor. Where one colony is affected with foul brood, we had better not use the extractor at all, as the germs left in the extractor will give it to the whole apiary.

OUT-APIARIES.

Do not put over 100 colonies in each out-apiary, as you are liable to overstock your locality.

Mr. Chapman—An out-apiary should be taken care of just the same as the home yard. The number of colonies would depend upon the locality.

Mr. Hilton—When I have an out-apiary I have a man to attend to it. I do not think it will pay in any other way. I would keep a man for six months of the year, and have from 100 to 150 colonies in each out-apiary. If you do not take good care of them, as you would any other farm stock, you will not succeed. Do not overstock your locality. The bee-keeper that follows the business must have out-apiaries.

Mr. Bingham—Bee-pasture can be overstocked. An out-apiary must be a large one or none at all. It is quite important to see one's bees every day. My bees gather as much honey from a poor pasture as some of my neighbors' bees gather from a good pasture.

CELLAR-WINTERING WHERE BEES ARE AFFECTED WITH FOUL BROOD.

Mr. Rankin—In cellar-wintering foul brood does contaminate the adjoining hives. We put a colony affected with foul brood into the cellar at the Experiment Station at Lansing, last winter. The hives were piled up alternately. Five colonies were affected from this one colony when we took them out in the spring.

PLACE OF NEXT MEETING—ELECTION OF OFFICERS.

A vote was taken for the next place of meeting, and Traverse City was selected.

The election of officers resulted as follows: President, George E. Hilton; Vice-President, H. K. Beecham; Secretary, Wm. G. Voorheis, of South Frankfort; and Treasurer, J. M. Rankin.

It was voted that the Executive Committee fix the dates for the next meeting.

PASTURAGE FOR BEES.

Mr. Hilton—Sweet clover on waste land is a great pasture for bees. It is a great honey-plant, and will grow on any soil from the poorest sand to the heaviest clay.

With several members this plant is a success.

Alfalfa was reported by several members to be a complete failure. One member sowed quite a large piece of ground, part of it grew and has done well, cutting hay from it three times last summer. He did not see the bees work on it.

Several members reported that catnip was a good honey-plant.

Crimson clover was reported to be a good honey-plant, but a dangerous feed for horses and cattle if allowed to get too ripe.

Alsike clover is a good honey-plant. It does best in moist or wet soil, and does not do well on dry, light soil.

Canada thistle and dandelion were named as good honey-plants.

GENERAL DISCUSSION.

As to the way to put foundation in sections, some kinds will be accepted no matter in which way put in. Other kinds must be put in so that the cells run diagonally from the top of the section.

Never use starters in brood-frames, as you will get too much drone-comb.

Mr. Gifford—I think plain sections are the best. I would use separators.

Mr. Hilton—I would not use light-weight sections. I prefer one-pound sections. I like tall sections best. At the same weight tall sections sell better than square ones.

Do bees always send out scouts before they swarm? From the discussion it seems at times that they would go direct from the hive to the tree in the woods. While bees usually cluster before they go off for good, they do not always do so.

Mr. Hilton—A neighbor of mine had a swarm come out; he hived it, but it would not stay. The swarm staid in the cluster all night, and in the morning I went over to help him hive it again. Just as I got there a number of bees flew into the cluster, seemingly from a distance. The swarm flew off as fast as they could go. We could not stop them. I think where the bees fly direct from the hive to the woods they must have come out the day before. I do not think that they send out scouts until after they cluster.

Mr. Calvert—I think that the plain section with the fence separator is the best, as there are less unfinished sections. The tall section will hold a full pound in a good flow of honey; in a light yield of honey we will have light sections.

Mr. Hilton—I think we should have sections holding a full pound. Sections will hold more where separators are not used, but I would use separators so as to have the sections more uniform. Light sections will hurt the trade, and in the end hurt the bee-keeper.

Which is best, starters or full foundation?

Mr. Rankin—I think full foundation is the best with sections, and the double starter. For the latter I would use a starter $\frac{1}{2}$ of an inch on the bottom of the section. Have the foundation from the top of the section come down to within $\frac{1}{4}$ of an inch of the bottom starter. It is important to leave this space of $\frac{1}{4}$ inch between the two starters to get the best results. I get better filled sections when I use this style of starter than in any other way. I use extra-thin foundation for sections. The new kind of foundation has the base of the foundation so very thin that when the bees draw it out they will not leave it so thick as to make fishbone.

Can we use thin foundation for brood-frames if we get out of brood foundation?

Mr. Hilton—No, it is not best to use thin foundation in brood-frames. When the bees commence to draw it out the weight of the bees and the warmth will get it out of place.

Mr. Calvert—The New York market wants a carton of pasteboard around each section. These cartons are becoming popular in other markets. They should have the name of the bee-keeper, but not his address; if the address is put on the merchant will erase it.

Is there any danger when the combs are infected with foul brood if afterwards it is made into foundation? No, the intense heat in melting the wax and making the foundation will destroy all spores of foul brood.

A vote was taken to see how many used 8 or 10 frame hives. From the result of this vote it was found that the 8-frame hive was used by a large majority, for both comb and extracted honey.

Mr. Woodman—The best way to render old comb is by the steam extractor. I also use a press with the same.

Mr. Calvert—For ordinary bee-keepers, or farmer bee-keepers, the solar wax-extractor will do just as well; but care should be taken to see that the glass on the extractor fits tight, so as to confine the heat.

Mr. Woodman—I use an uncapping-can with a screen in the middle to catch the bits of comb.

Mr. Beecham—I use an old extractor for an uncapping-can.

Mr. Hilton—I use a keg with a wire-cloth near the top. The meeting then adjourned. WM. G. VOORHEIS.

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Richards, Ohio.

BEGINNINGS OF FOUL BROOD.

Mr. Lovesy, on page 819 (1899), gives us what is possibly a very valuable observation about the first beginnings of foul brood in a hive. The nearly-grown larvæ are in distress and discomfort before any of them are enough affected to die. As one result of their writhings many young bees can be found with their heads toward the bottom of the cell—a position from which, of course, they can never get out. And this is the golden opportunity to go to work and cure the disease, before any filth has accumulated in the cells at all. I presume he would not claim that all attacks began thus gradually, or that all cases of reverts young bees indicate foul brood.

BEEES AND POULTRY ON A CITY LOT.

To carry on both the bee-business and the poultry business on a city lot 50x90—well, it shows that a fellow has quite a bit of that turn that "laughs at impossibilities and says, It shall be done." It so happens that both *Apis mellifera* and *Henibus eggifera* have special talents in the line of getting the neighbors after them, with sharp sticks in their hands, and the spirit of Judge Lynch in their hearts. If Mr. Heim can keep bees, and hens, and the public peace, all three, he must be a pretty good, and wise, and amiable man. The picture he shows us, page 801 (1899), I judge to be spring and fall arrangement. Or is he smart enough to manipulate in a two-decker shed during the honey season?

OLD GRIMES AND HIVE-NAILING.

Alarum! Enter "Old Grimes." We musically and

long ago thought he was dead—that good old man. If he isn't, of course we'll give him a reasonable chance to prove it up on us; but he mustn't expect this logical generation to believe it just by his saying so. I see he wants a nice-looking hive, and then to have it last a lifetime. And his method is the same as that whereby he preserved his old blue coat a lifetime; keep it every minute "all buttoned down before." His direction to "toe" the nails if they are required to hang on to wood lengthwise of the grain sounds decidedly like a live carpenter's dictum (just the thing bunglers like me would forget), and two nails close together, and toed in opposite directions, is our mechanical "pretty-est" in the nailing line. Page 801.

EXPERIMENTS ON QUEEN-REARING.

How much better it is to have our settled views on important points founded on careful experiment than on mere impressions! And how absurd it is to try to force our impressional views on the bee-keeping public at large! Thus I meditated on Dr. Miller's experiment, page 803. But reading that one just makes me the more hungry for another of the same sort. Dr. Miller would be one of the first to admit that a different strain of bees, in a different locality, and under different honey conditions, not only *might* show points of divergence, but would be pretty sure to show some. While on this matter we are not to lose sight of the fact that it is not somebody's victory over somebody else that we care for, but the practical work-a-day question: Is it safe to let a queenless colony rear its own queen? My *impressions* agree with Dr. Miller's experiment, that it is. But the bees in the experiment took older larvæ than I should have expected in advance—that is my chief surprise—and my chief delight is to see them keep on starting more for six days. I confess to feeling annoyed by what Mr. Hutchinson said about that. 'Specks he not only followed his impressions that time, but impressions wholly formed from colonies that couldn't well start more, because they were hard up to supply royal jelly to what princesses they had already on their hands.

OTHERS' EXPERIENCE MAY BE VALUABLE.

"Nothing is done for the looks of it, or because others do it that way." W. L. Cogshall on page 804. That's a sentence that can't be let loose without having a great deal of effect. Perhaps it ought to have a good deal of effect. But lest our young men who are forming their life maxims should throw themselves too completely into the arms of it, I'll jostle against it a little. I once knew a young man, and a very brainy, inventive young man, too, who started out in farming on just about that principle. He's not a farmer now—was an unusually conspicuous failure at farming. So far as farming goes it's clear that the joint experience and judgment of thousands and thousands of ordinary farmers has simmered down to an unwritten volume of practical wisdom; and that no man, no matter how good a head he has on him, can afford to throw it *all* away at once. Can we be sure that the throwing-away course in apiculture would always turn out well, even if Mr. C. does make things hum? But the convention essay in which the sentence occurred is so good that I don't believe even the Progressive Bee-Keeper would bark at it.

SWEET CLOVER HONEY ATTACKT.

Mr. Selser is a brave man; about the first to make a public attack on sweet clover from the apicultural side. Plenty of outside attacks and charges of being a general nuisance. We're up against the question now whether sweet clover honey is really fit to eat or not. Several facts will have to enter into the final decision. For one, most honeys are unfit to eat in the unripe state. Don't blame the 'tater for not being good, till it's done. For another fact, it is quite common for sweet clover to keep multitudes of bees busy for weeks when not a pound of surplus comes in. Likewise it is fearfully common for the bee-man not to know whence a small run of surplus does come—often credits it wrongly, oftener doesn't try to credit it at all. Now about how often do these unrecognized runs come in *at the same time*, when half the bees are playing around the sweet clover like moths around a candle? In other words, are not most alleged samples of sweet clover honey very largely mixt with something else? On the main question let us hear from Utah, which is supposed to harvest more sweet clover than any other region. Convention debate, page 805.

HOW MANY HOURS A DAY DO BEES WORK?

I wonder if Prof. Hodge realizes how big a job he is at

—to make the public and us believe that the busy bee is not a busy bee. I should presume the observations he mentions were taken when there was no honey-flow, and when (very naturally) the field-bees were merely prospecting a little once in awhile, and waiting for a change the rest of the time. A normal hive in the busy season has no such numbers of unoccupied cells as would be required to let each field-bee spend three-quarters of the time snoozing in one. Page 808.

POWER TO RESIST STINGS.

The power of the toad, and of some species of birds, to resist stings with little discomfort and no danger is simply one of the remarkable facts of Nature; but beyond the fact that it is a fact I fear we shall not be able to travel a great ways. Page 821.

PICTURE OF THE PHILADELPHIA CONVENTION—AND A BABY.

That's a nice picture of the bee-folks in front of the Franklin Institute, page 817. May I tell you that I enjoy looking at the human nature of such pictures about as much as I enjoy looking for my friends? For instance, that lady in the back row, the effort she is making that the baby may have a fair show—didn't mind so much that she herself is short and nearly hidden. Alas, the wicked camera! Did somewhere near justice by nearly every one else, and reported the baby's face as a simple white spot.

LOCALITY AND THE DURABILITY OF HIVES.

We had resigned ourselves to the freaks of "locality" in almost everything else, but to be told by Mr. Davenport, page 821, that one mile difference of locality may make a great difference in the durability of hives, that kind o' "strikes us sudden like"—comes like a new wave of la grippe when we thought the worst was over. And the worst of it is he seems to be correct. Our hives stand mostly within a few inches of the ground, and when one thinks of it we couldn't expect them to last as well in a damp hollow as on a dry, breezy knoll. The drifting dust of a road close by is an element few of us would have thought of; yet quite possibly that counts a little.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Supers on in Winter—Feeding, Etc.

1. I have 65 colonies on the summer stands. I put the supers on last fall, then covered them with quilts, then with store-boxes turned down over them; then I packed around them with forest leaves. The hive-entrances are to the south, and boarded up on the north. I wintered them that way last winter, without the loss of a colony. Is it a good idea to put the supers on in the fall?

2. What do you consider the best honey-plant?

3. Is there a feeder manufactured for feeding bees on the summer stands?

4. What do you think about feeding bees in the spring?

5. Is there a difference in variety of buckwheat in producing white or dark honey?

INDIANA.

ANSWERS.—1. I think a super on the hive with absorbent packing is a good thing; but it's worth twice as much to you to know what the bees think as to know what I think; and when a certain mode of wintering was entirely successful in so severe a winter as last, you may do well to tie to it.

2. There is no best honey-plant. What is best in one place is not best in another. For this locality, white clover is worth all the others put together; yet in some places alfalfa is worth a great deal more than white clover, while alfalfa seems to be worthless here. It is quite likely that in your part of Indiana white clover is the best honey-plant,

altho it may happen that linden may be worth more. Possibly some other plant.

3. Yes, a number of them; among them are the Miller feeder for feeding on top, and the Boardman feeder for feeding at the entrance.

4. Scarcely anything can be more important than to feed in spring if the bees are short of stores. Not only that, it is well to feed till they have enough to last for a considerable time, say a little more than enough to last till they can gather from outside sources. By some means, the bees seem to calculate ahead, and if they have only a very little honey they will not breed as freely as if abundance is in sight. If there is plenty of honey in the hive, there is still such a thing as stimulative feeding, but that sort of feeding is a two-edged sword, and those with little experience will do well to let it alone.

5. I think you may find a difference in the shade of different samples of buckwheat honey, but probably no difference made by the variety. The season and the soil have more to do with it.

Stores Bees Consume in Winter.

Here in southern Oregon the winter has been very mild, and no snow yet. My bees have a flight every few days, and sometimes every day for a week. Do they eat more honey when they can fly out than when it is so cold they can't fly?

OREGON.

ANSWER.—Yes, the consumption is considerably more when bees fly daily than when it is just cold enough to keep them in the hives. When the cold becomes very severe, then the bees must stir and consume more to keep up the heat, but the days of frequent flights are harder on the stores than the severe cold. But some of those in severe climates would be glad to swap places with you, even if it does cost more stores.

Banking Earth Around Hives.

My 84 colonies have just had their first flight in a month; loss of bees small, but dysentery commenced, which will no doubt disappear, as we have had a few fine days for bees to fly. Hives are badly spotted, and one hive-entrance is a perfect sight of the effects of dysentery. I have a neighbor one mile away who banks ground about the back end and sides of the hives; he has wintered very successfully for several seasons, and reports his bees as at present entirely free from any dysentery. Do you suppose this banking of dirt about hives has rendered his colonies free from it? It is the only reason I can assign for it. The temperature has been zero but a few mornings, and ranging most of the time of mornings from 15 to 25 degrees. My bees are in single-walled hives.

OHIO.

ANSWER.—Cold is one of the important factors in producing diarrhea, so banking up to make the bees warmer might make no small difference in the matter.

Candied Honey—"Hot" Honey—Extracting.

1. I wish to enquire about candied honey. I have been in the business four seasons—the first two seasons I didn't see a pound of candied honey. Altho some of the old honey was kept over till new honey began to come, it was clear and bright, but the third crop candied some the next winter and spring, and the early honey of the present season commenced candying in the fall. A gentleman living four or five miles away said he didn't know why his honey should candy and mine not.

Why was it? Was it because at the first my extracting-combs were all fresh and new—just produced from the comb foundation?

2. Will a dipper that has candied honey on it, if put into clear honey, cause the clear honey to candy?

3. What is honey produced from, that is sometimes so "hot," or causes such a smarting sensation in the throat, that it can hardly be eaten? It may otherwise be of excellent quality. What is a remedy for it?

4. I have noticed that my early honey was not of as good flavor as that produced in the latter part of the season; some of it had the flavor of syrup made from light brown sugar. A little was so objectionable that it was hardly marketable. In addition it gave considerable of the

smarting sensation that I spoke of. Would it do any good to leave it on the hive until fall?

5. By the way, that suggests another question: What is the best way to extract honey? To extract as fast as we can find combs pretty well filled and about half sealed, taking a few, perhaps two or three out at a time, or have plenty of super room, and when one is nearly filled put another filled with comb or comb foundation under it, and not extract but once, and that when the honey season is over?

6. Will it make any difference with the flavor of the honey, or with the working of the bees? I thought last summer that it seemed to discourage some of the swarms to take some of the frames away and supply their places with empty comb. When I have extracted, the weather has usually been dry and hot, and I have never had any trouble with unripe honey. KANSAS.

ANSWERS.—1. It may be impossible to tell for certain which one of several causes may have made the difference between your neighbor's honey and yours, if indeed it were possible to name all the causes that might operate. His bees may not have worked on the same flowers as yours, and there is a decided difference as to the granulating of different honey. The way in which honey is kept makes a difference in granulation, and his honey may not have been kept in the same way as yours. His new comb may have kept the honey longer from candying than your old comb in which some candied honey may have been present when the bees began to store in it.

2. It will have an effect in that direction.

3. I don't know. I never tasted any such honey but once, and I never care to taste it again. It think it was a sample that some one had at the convention at the World's Fair at Chicago. The effect was about the same as that of eating Indian turnips. At first you scarcely tasted anything wrong with the honey; but after you had tasted it, the biting, burning sensation kept increasing till it was quite painful. I supposed the honey was gathered from some special flower, and I know of no way of avoiding such honey unless it would be to destroy the objectionable plants. It is just possible that long keeping might modify its viciousness, for it is said that rank onion honey becomes quite good with age, but I should hardly expect this pungent article to give up its character. Can any one tell us from what plant it is gathered, and whether it improves with age?

4. Possibly it might not be so bad in the fall; but it would probably still be bad.

5. Some of our best bee-keepers practice the last plan mentioned, doing no extracting till the close of the season, and the tendency seems to be getting more and more away from the plan at first practiced by many, of extracting before the honey was sealed.

6. As a rule, the honey that is left long in the hive will be of better body and flavor. If taken too soon after being gathered, it is considered unfit to put on the market. So far as the bees are concerned, they are stimulated rather than discouraged by having an empty comb or combs given them.

Getting Bees Out from Under a House-Siding.

I enclose a drawing of a house in which is located a colony of bees between two studding and under the siding. They are, as you will see, about 16 feet above the ground, a little to the left and below a window in the second story. They have the space between the two studding, and about 8 feet in length, filled with honey, going in near the lower part thru a knot-hole. I would like to get the bees and honey out as early as possible in the spring and save the bees. Kindly tell me how you would do it.

ILLINOIS.

ANSWER.—If you are a novice in handling bees, it might be well for you to get the help of some one familiar with such things, and if at the same time he is a carpenter, so much the better. Erect a scaffold sufficiently high, and commence removing the siding above the bees. Apply smoke before and during the operation with sufficient frequency to keep the bees from being too intimate. As you get down to where the combs begin, thrust a knife down to sever the attachments of the comb to the siding before removing each piece of siding. When the combs are laid bare, cut them away carefully, still using smoke as much as necessary, and transfer the brood into the frames of a hive as directed in your text-book for transferring. By the time

you are thru with that part of the job, very likely a large part of the bees will be clustered on the place from which the combs were taken. Build some kind of a platform on your scaffold on which you can place your hive so that the entrance of the hive will be thrust into the bees. If they do not start to go in the hive of their own accord, brush a few into the entrance to give them a hint. If this is not a success, owing to the stubbornness of the bees or some other cause, hold a frame of the brood in the cluster till it is well covered with bees, then put it in the hive and use another frame, till the bees are all in the hive. Or, you may take something like a dipper and dip the bees up, and then gently pour them on the brood-frames. Persevere in one way or another till you get all the bees, for the queen might be in a small cluster remaining. If you happen to see the queen, you needn't be so particular about getting the last of the bees; but smoke heavily those left till they prefer some other quarter. Then set your hive where you want it to stay.

Moving Bees in March.

How should I pack my bees for a long-distance shipment? They are now packed in a box which is six inches larger each way than the hive. I filled in straw between. I am going to move to Minnesota in March. I got some nice honey last year, tho it was a poor one, about 45 pounds to the colony. The sweet clover was the main honey-plant. ILLINOIS.

ANSWER.—The main thing is to see that they have sufficient ventilation, and, if they have a long enough confinement, that they do not suffer for water. If you do not have fixt-distance frames, the frames must be secured against moving, and this may be done by driving a nail down thru each end of each top-bar, not driving the nail clear in, but leaving the head projecting enough so that you can easily draw it out with the claw of a hammer when the bees are again on the stands. Just what is the best way to give ventilation depends on the build of the hive. In March there is less air needed than when the weather is hot. If the entrance amounts to 12 square inches or more, all that is necessary is to cover the entrance with wire-cloth in any way that is convenient and secure. If the entrance is not large enough, you can make a rim the size of the hive and an inch or two deep, covered with wire-cloth, and let this take the place of the cover. Before fastening up the hive, there should be given a sponge filled with water, or a roll of wet cloth, which could be wet afresh on the journey if necessary, but perhaps it would not be necessary in March.

York's Honey Calendar for 1900 is a 16-page pamphlet especially gotten up to create a demand for honey among should-be consumers. The forepart was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample free; 25 copies for 30 cents; 50 for 50 cents; 100 for 90 cents; 250 for \$2.00; 500 for \$3.50. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the new bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it,

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY,
118 Michigan Street, Chicago, Ill.

[Entered at the Post-Office at Chicago as Second-Class Mail-Matter.]

EDITOR:

GEORGE W. YORK.

DEPARTMENT EDITORS:

DR. C. C. MILLER, "Questions and Answers." * * E. E. HASTY, "The Afterthought."

LEADING CONTRIBUTORS:

G. M. DOOLITTLE, F. A. SNELL, C. P. DADANT, R. C. AIKIN, PROF. A. J. COOK, "OLD GRIMES."

IMPORTANT NOTICES:

The Subscription Price of this journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec00" on your label shows that it is paid to the end of December, 1900.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

VOL. 40. FEBRUARY 1, 1900. NO. 5.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

The Colorado Convention Report is now in our hands, and its publication in these columns will be commenced next week. A good report is always assured from the Colorado Association, as they invariably have profitable annual meetings.

The Wisconsin Convention will be held at Madison, in the State Capitol, Wednesday and Thursday, Feb. 7 and 8—next week. The editor of the American Bee Journal expects to be present, and hopes to have the pleasure of meeting as many as possible of his good bee-keeping friends in that part of the country. Judging from the program, which was published in these columns recently, a good meeting is assured.

The Chicago Convention of the National Bee-Keepers' Association will be held next Aug. 28, 29 and 30—beginning Tuesday evening at 7:30 o'clock. The exact place in this city for holding the meeting is not yet definitely known. There are one or two places in view. The executive committee of the Chicago Bee-Keepers' Association having in charge the selection of a hall, think it would be well to hold their next local meeting in a certain place as a trial, then if all is satisfactory have the National convention meet in the same place. The next meeting of the Chicago Association will be held Thursday, April 5—about five months

before the National—so there will be ample time after that to announce the exact place of meeting in August.

In Gleanings in Bee-Culture for Jan. 15, Pres. E. R. Root has this to say in reference to the great annual bee-keepers' convention:

"The place of meeting is Chicago during the time of the Grand Army encampment, when low railroad rates will be in force all over the country. A program has been in process of preparation for some time back, and among some of the special features will be one, and possibly two, stereopticon lectures on two separate evenings. The question-box for the latter half of the day sessions will be another feature. The questions will be of a character to interest advanced bee-keepers as well as beginners. Every effort is being put forth to make this one of the best in point of discussion and attendance that has ever been held. Chicago is a central point, easily accessible from every direction, and there is no reason why there should not be a large meeting. Local associations, State and county, should see to it that delegates are appointed to attend this meeting."

The Ontario Convention for 1899 was held in Toronto, Dec. 5, 6 and 7. It reported a membership of 92, with a balance in the treasury of nearly \$117. Messrs. Wm. McEvoy and F. A. Gemmill were re-elected as inspector and assistant inspector, respectively. The next place of meeting will be Niagara Falls. A recommendation was approved which decided that the Association do not assume the publication of the Canadian Bee Journal. The new president, C. W. Post, was recommended as inspector of honey intended for the Paris Exposition.

The Article on Migratory Bee-Keeping, on another page, shows familiarity on the part of the writer with the subject. The question why more do not practice migrating is partly answered by Mr. Hutchinson when he says: "An apiarist who is going to practice moving his bees to secure better pastures, must have hives, fixtures and other arrangements suitable for that purpose." Every bee-keeper does not have these, especially the proper arrangement for hauling; and he does not know very well what he should have. Then he has a fear that bees may get out and make trouble *en route*—a fear not without foundation, for those who have had experience in hauling bees have generally had a pretty tough breaking-in, some of their experiences having been of a decidedly serious character. For some it would be a hard thing to find a spot to locate bees, even after having found the right pasturage; for there seems a general prejudice against having bees on the place, among those who have no bees of their own.

Altogether, there is no little to make a bee-keeper hesitate about making his first attempt at migratory bee-keeping.

California as a Honey-State.—That racy writer, Rambler, has been for a long time writing Rambles for Gleanings in Bee-Culture, in which, perhaps, too often there has been so little bee-talk that the busy bee-keeper hardly felt he could spare the time to read them; and yet did not dare to skip them for fear there might be a hidden nugget that he could not afford to lose. Latterly there has been an improvement in this respect, and his last Ramble, No. 181, is a perfect gem of its kind, and the kind is a good kind.

Rambler discusses California as a honey-producing State, and makes a masterly job of it. No attempt at quotation or condensation would do the article justice, and it is not worth while to attempt it. A little later on we expect to copy it. A remarkable accompaniment to the article, however, may be mentioned, in the shape of two maps. One is a map of California, showing the State divided into three portions, viz.: Northern California, largely undeveloped; central, with its alfalfa regions; and southern, undeveloped

at the north and south ends, between which are its orange belt and its sage regions.

The other map is a counterpart as to size and shape, the whole State apparently being turned into a sea of water in which are seen floating like great blocks of ice the States of Delaware, New York, New Jersey, Massachusetts, Vermont, Maine, New Hampshire, Connecticut, and Ohio. Contemplating this latter map, one is led to exclaim, "I certainly never realized before what a big State California is."

Mexican Extracted Honey.—About two weeks ago we received a sample of extracted honey produced in Mexico, from Mr. G. L. Kilmer, of the State of Jalisco. It is a thick amber honey, worth perhaps less in this market than ordinary buckwheat extracted honey, tho Mr. K. said he would ship us a carload of 30,000 pounds of it, in 60-pound tin cans, at 12 cents a pound delivered in Chicago. Here is what Mr. Kilmer said further in regard to the honey :

This honey is gathered by the natives working for the large ranchers here. The bees are driven out, the comb collected and put into boxes having wire sieves below ; the box is then covered with thin boards, and placed in the sun, the heat forcing the honey to run out thru the sieve. They have been getting out their honey this way since Cortez conquered Mexico.

Rice, corn, sugar-cane, wheat, oranges and lemons are the principal products of these parts. G. L. KILMER.

We see from the above that the Mexicans used a sun or solar extractor long before Mr. Doolittle and some others were born. Verily, there is nothing new under the sun.

But just to think of Mexican extracted honey at 12 cents a pound! And honey that is only fit for manufacturing purposes, at that. At that rate, we are not fearing its competition.

Alkali-Weed as a Honey-Plant receives high commendation from W. A. H. Gilstrap, of California, in Gleanings in Bee-Culture. Notwithstanding the great value of alfalfa, it is more or less a failure when it has too much or too little moisture, and sometimes it fails when there is no apparent reason for the failure. In many places alkali-weed comes in nicely. It is sometimes called "sticker-weed," on account of the small prickles with which it is covered. Here is what Mr. Gilstrap says concerning it :

"These weeds frequently grow as high as wheat before the latter is cut, and sometimes prevent its being harvested, as the weeds would decay in the stack. You need not expect much bloom before July or the first of August, except on strong alkali land where the weeds are stunted. Then the golden honey is produced until frost or early rain kills the plant. This year was an exception, as the honey failed about Sept. 23, and our first rain fell Oct. 10. Hardly enough frost yet for you to see. In seven years I have known two failures of this source, caused by drouth. The flavor of this honey is pleasant, not so sweet as alfalfa, clast as amber or light amber by different dealers. It is too yellow to excel as comb honey, and also granulates quicker than some other honey. These are reasons why it is no more sought after by apiarists."

The First Honey-Extractor put on the United States market was the Peabody. It was invented and manufactured by J. L. Peabody, and in beauty of finish has never been excelled by any of its successors. In effectiveness it is now out of the race, as the entire can revolved with the combs. Fresh interest in the matter has been awakened by the editor of Gleanings in Bee-Culture, who met Mr. Peabody at the late Colorado convention. He is brother to H. O. Peabody, the inventor of the Peabody rifle, to whom J. L. modestly gives all the credit for the neatness and mechanical excellence of his extractor, as H. O. was the mechanic who designed and built it. The machine did good work in its time. It was patented in 1869.

The Weekly Budget

MR. W. L. COGGSHALL, of Tompkins Co., N. Y., returned about a week ago from a trip to Cuba. He reports not much honey in the locality he visited, and whole apiaries destroyed by foul brood.

THE G. B. LEWIS CO., of Watertown, Wis., were the first bee-supply dealers to send us their catalog for 1900. Their advertisement is always found in the American Bee Journal—and their excellent goods everywhere.

MR. O. L. HERSHISER, of Erie Co., N. Y., we learned from announcement received at this office, Jan. 24, was married to Margaret J. McIntosh, at Toronto, Ont., Dec. 6, 1899. Even if a little late, our hearty congratulations are hereby extended to Mr. and Mrs. Hershiser.

DR. A. B. MASON, of Lucas Co., Ohio, writing us Jan. 20, said :

"Our bees in the cellar were never in better shape at this time of the year. It's a treat to have an occasional peep at the clusters hanging from the bottom of the frames, or rather, lying between the bottom of the frames and the quilt on the hive below."

DR. D. E. STRATTON, of Tuolumne Co., Calif., reports in Gleanings in Bee-Culture, that 1892 was his best year with bees. He says :

"From 54 colonies, spring count, I extracted 22,397 pounds, and increase to 72 colonies. Clear profit, besides the increase, \$786. My disastrous year was when I extracted 840 pounds, and had my apiary decrease from 145 good colonies to 54 poor ones."

THE HORSE "COGGSHALL."—Harry Howe tells in Gleanings in Bee-Culture of a visit he made to an apiary about 18 miles from Havana, Cuba, belonging to Senor Aguilera. Its 250 colonies all in new 10-frame dovetailed hives in all the colors of the rainbow, made a beautiful sight in their setting of banana trees, flowers and ornamental plants. "On the way back," says Mr. Howe, "I noticed that the horse seemed to have a rather queer name; and after I began to notice it, it seemed some way familiar, so I asked Senor A. about it. It turned out to be 'Coggshall,' with a Spanish pronunciation. It surprised me very much to find a horse with such a name, until Senor A. explained that the horse had grown into the habit of kicking the cover off from things, then all was clear."

PROF. E. N. EATON, who was recommended by the Chicago Bee-Keepers' Association as a suitable person to be assistant Pure-Food Commissioner and State analyst, received the appointment from Commissioner Jones, we are glad to say. Mr. Eaton, we believe, is thoroly qualified for the position, and will make an excellent assistant to Mr. Jones.

Here is what Editor Abbott has to say about Prof. Eaton, in the Modern Farmer :

"The bee-keepers of the country, and especially of Illinois, have cause to congratulate themselves on the appointment of Prof. Eaton. He is not only a fine chemist, and thoroly equipt for his position, but is a friend of the honey-producer. He has had a good deal to do with honey analysis, and will no doubt furnish valuable aid to the United States Bee-Keepers' Association in their attempt to drive the honey adulterators from their stronghold in Chicago. We congratulate the Commissioner on the appointment, and take this opportunity to assure him that he will have the hearty support of all honey-producers in his attempt to compel people to sell goods for what they are."

The Premiums offered on page 79 are well worth working for. Look at them.

Breeding for Tongues is thus mentioned in Gleanings in Bee-Culture:

"At the Michigan State Bee-Keepers' Convention, held in Thompsonville, Jan. 1 and 2, Mr. J. M. Rankin, who has charge of the apiarian department of the Michigan Experiment Station, reported some interesting experiments in the line of developing bees with long tongues. He found that the average length of the tongue of black bees is 4.5 millimeters; Italians, 5.1, while he had several colonies of a strain of bees at the Experiment Station apiary whose tongues measured 6.2 millimeters. He believed that, by a process of selection, and breeding with this trait in view, a race of bees might be developd which will secure more of the honey from clover-blossoms."

Foul Air and Cold in Cellars.—A Stray Straw in Gleanings in Bee-Culture says:

"Mr. Editor, you say that when bees quiet down in the cellar after a fire has been started, no one can state definitely how much of the trouble was due to cold and how much to foul air. Quite right. But I'll tell you one case in which you can tell definitely. Temperature in the cellar, 50°; same outdoors. Bees noisy. Fire started toward evening, running temperature to 60°. Next morning bees still, with thermometer 50° inside and out. Foul air had all to do with it in that case."

Editor Root follows with this footnote: "That is a clear case; and the fact being established in this case, it will be reasonable to assume that in the other cases foul air is equally the disturbing cause."

Making Honey-Vinegar Rapidly.—In the American Bee-Keeper, M. F. Reeve tells about a rapid plan used to make vinegar out of soured mead, of which several hundred gallons would have been otherwise wasted. The mead was made of Cuban honey and Demarara sugar spiced, but any solution of honey might be used. A whisky barrel set on end was the generator. Further details are as follows:

"It was bored full of half-inch auger-holes, sloping downwards, and was then filled with beech-shavings procured from a shoe factory. A false bottom was put in, on which the shavings rested, and a loose head was dropt on top. A spigot was inserted in the barrel, and the generator was ready for business. The already sour mead was poured into gallon stoneware jugs and heated over night on a shelf above the kitchen range; in the morning it was poured in at the top of the generator and allowed to percolate thru the shavings. The air admitted thru the sloping holes in the sides of the barrel did the business of supplying the required oxygen, and a few runnings thru the barrel, was all that was necessary to convert the fluid into the sharpest, clearest vinegar anybody ever tasted. There must be a generous body, say a pound of honey or sugar, or molasses, to the gallon; otherwise the maker will have a thin vinegar which will lack the prime requisite—acidity."

Wintering Bees in a House above ground has been pretty generally voted not an entire success, the bees being too often subjected for a long time to a very low temperature, without the advantage of a prompt flight on the occurrence of a warm day. F. L. Thompson reports 3 Utah bee-keepers who make an entire success of such wintering, the secret of the success appearing to lie in the fact that a sufficient number of bees are piled together to keep up the temperature. Practically, that makes it the same thing as cellar-win-

SEED DUE BILL FREE

To get new customers to test my Seeds, I will mail my 1900 Catalogue, filled with more bargains than ever and a 10c Due Bill good for 10c worth of Seeds for trial absolutely free. All the Best Seeds, Bulbs, Plants, Roses, Farm Seeds, Potatoes, etc., at lowest prices. Nine Great Novelties offered without names. I will pay \$50. FOR A NAME for each. Many other novelties offered, including Ginseng, the great money making plant. Over 20 varieties shown in colors. \$100 in cash premiums offered. Root's Column

— THE —

ABC

— OF —

BEE = CULTURE

Revised in 1899.

The only Encyclopedia on Bees.

Read what Dr. C. C. Miller says in the National Stockman :

"Not a bad index of the advancement of bee-culture in this country is the fact that besides two or three other good books on bee-keeping, the ABC of Bee-Culture has been so extensively used that it has reached its 67th thousand. The name is rather a misnomer, suggesting as it does a small primer for children. Instead of that IT IS THE MOST COMPREHENSIVE WORK IN THE ENGLISH LANGUAGE PERTAINING TO BEES, and a more appropriate name would be **The Encyclopedia of Bee-Culture**. It contains 437 pages measuring 9½x6½ inches each. It is profusely illustrated with fine pictures, many of them full page, and is printed on elegant paper in clear type that is a delight to the eye.

"It was first written by A. I. Root something more than 20 years ago, but bee-culture is not a science that is at a stand-still, so during all these years the book is kept standing in type, and with every advance in bee-culture there has been a change in type, so that the book, now double its original size, is just a little in the condition of a boy's jack-knife; he lost a blade and had a new blade put in, then the handle was broken and he got a new handle; but still it was 'the same old knife.' The work has been ably revised lately by E. R. Root, son of A. I. Root, also a skillful and experienced bee-keeper, and the whole is entirely up-to-date and practical. For one who has a single colony of bees, and who desires a work to which he can confidently turn for an answer to the thousand and one questions constantly coming up in practical bee-work, it would be hard to invest \$1.20 more profitably than to send for Root's ABC of Bee-Culture."

Sold by dealers in bee-keepers' supplies, or sent postpaid on receipt of \$1.20.

The A. I. Root Company
MEDINA, OHIO.

N. B.—Watch for our ad, next week,

tering, and the plan might well be considered by those who have a sufficient number of colonies in a region where ordinary outdoor wintering may not be advisable—where the winters are not too cold for the number of colonies kept. Of J. Bouck, Mr. Thompson says:

"Mr. Bouck, during the 7 or 8 years he has put his bees in the house, has not lost a single colony in the winter of those indoors. They are put in with settled cold weather, and taken out about the middle of March, being kept in darkness and not allowed to fly. The house is a mere lean-to against the east side of a granary, composed of inch boards, not battened, but the chinks are stopt in winter for the purpose of excluding the light. There is no floor. A cat-hole from under the granary lets the cats in to keep down the mice, and affords ventilation. The room is about 11x14, and the hives are piled all around the walls up to the roof, facing in, with a row thru the center. A tier is put in all about, then each cover raised at one end by putting a half-inch stick under, then another row set on, and the covers raised, and so on till completed. The heat from the 50 to 100 colonies keeps the apartment so warm that a bucket of water set in never freezes in the severest weather, and the hired man gets in the habit of dodging in there to get warm."

A Mass of Bees Warms the Cellar.—Says Dr. Miller in Gleanings in Bee-Culture:

"Formerly I kept my bees in two cellars, with the belief that the fewer bees the purer the air. I've changed my practice for the past few winters, and am shaky as to my former belief. I now cram all the bees into one room of my house-cellar—less trouble to watch, and so many bees keep it warm enough so fire is not often needed. The warmer cellar makes better ventilation.

Editor Root then adds this comment: "In a cold locality like that of Marengo, I am rather of the opinion that a large number of colonies in the cellar is more conducive to good results than a small number; but in the vicinity of Medina, where we have so much open winter (like spring today, Jan. 6), and the weather outside is even warmer than the atmosphere of the cellar, then a small number of colonies will give a better result."

Does the Queen Meet the Drone a Second Time?—The editor of Gleanings in Bee-Culture is asking his opinion as to the statement of Prof. C. F. Hodge in relation to the nuptial flight of a queen, "that within 15 minutes after the bees had removed the organs of the drone she flew again, and in 5 minutes returned with a second trophy of success."

To this Editor Root replies: "The language is susceptible of two or three interpretations. One is, that Prof. Hodge believes that queens may meet the drone more than once—before and after egg-laying; second, that they may be fertilized two or more times before actual egg-laying begins, but not after; or third, what is more probably true, the bees, on the return of the young queen, in their efforts to remove the outside appendages, took out all the organs of the drone, thus making the first flight of the queen fruitless, rendering a second one necessary. . . . A strong fact against the theory that the queen meets the drone a second time is that there has been no absolute proof to the effect that the progeny of any one queen changes from black to Italian or vice versa. The first bees hatched by the queen will be like all the rest reared from that mother, no matter whether she lives to be three months old or three years. It is true, there have been reports that the progeny of one queen changed all their markings, but so far as I can remember there have been too many chances for error on the part of the observer."

Sharples Cream Separators: Profitable Dairying

Extra Early Admiral Dewey

Or originated and introduced by
HARRY N. HAMMOND,
Seedman, Box 2, FIFIELD, MICH.
Largest grower of Seed Potatoes in America. The Dewey is the most wonderful New Potato. Its merits are fully described in Hammond's 1900 Catalogue. Free for the asking. Address as above. Write to-day. 20 other varieties of potatoes. Also Vegetable and Flower Seeds.

Two Wagons at One Price.

It is a matter of great convenience and a saving of labor for a farmer to have a low, handy wagon. They save more than half the labor of loading in hauling manure, hay, grain, corn-

fodder, wood, stones, etc. The man who already has a wagon may have one of these low handy wagons at the small additional cost for a set of wheels. These Electric Steel Wheels, with either direct or stagger spokes, with broad-faced tire, are made to fit any axle. You can convert your old wagon to a low, handy wagon in a few moments time. You thus virtually have two wagons at one price.

Write to the Electric wheel Co., Box 16, Quincy, Ill., for their catalog, which fully explains about these and their Electric Handy Wagons, Electric Feed Cookers, etc.

Dont Take Any Chances

on an inferior vehicle or harness. Your life and that of your family depends upon their quality and reliability. You can't tell very much about the quality of a vehicle by simply looking at it. The paint and varnish effectually hides the quality of material. Vehicles must be bought largely on faith—faith in the honesty of the manufacturer.

WE HAVE NO AGENTS

but have been selling vehicles and harness direct to consumers for twenty-seven years. In fact we are the largest manufacturers of vehicles and harness in the world selling to the consumer exclusively. These facts speak volumes for the quality of our goods and our method of doing business. You take no chances; we ship our vehicles and harness anywhere for examination.

No. 75—Single collar and harness, with nickel trimmings. Price, \$14. Good as usually sells for \$20.

24 cents Cash paid for Beeswax.

This is a good time to send in your Beeswax. We are paying 24 cents a pound—CASH—for best yellow, upon its receipt. Now, if you want the money PROMPTLY, send us your beeswax. Impure wax not taken at any price. Address as follows, very plainly,

IT HOLDS UP YOUR HAT

Don't you remember how your father used to test his grass and grain in this way? When it held up the hat it was always regarded as being a satisfactory and profitable "stand."

...THIS...

BROME GRASS

Surpasses Timothy in nutrition. Outyields Alfalfa. Yields four to five tons per acre. One sowing lasts 12 years. Grows well in light soil, or wet swampy land. Has no equal for arid regions. Drouth will not kill it. Animals enjoy it green or dry. Gives as much food in one month as Alfalfa does in three. Greatest boon ever offered as it thrives in any climate, under any conditions and makes productive what would otherwise be waste land. It is doubtful if the supply of seed this year will meet the demand, so great is the call already from States where hay is the essential crop. Price: Grade A—1 lb., 30c; 3 lbs., 85c, prepaid. 18 lbs. (enough for one acre) \$3.95; 100 lbs., \$18.00. Send for mammoth descriptive catalogue with treatise on cultivation and comparative food values of Brome Grass and Timothy. Address, **L. L. MAY & CO., Seed Growers, ST. PAUL, MINN.**

Warm January—Shipping-Cases.

The past season was a poor one for honey with me—not more than half an average crop. I think there are too many bees for the pasturage in this vicinity. I am somewhat fearful that this winter will be a hard one on my bees, on their summer stands, tho in chaff hives. They came thru the severe cold of a year ago finely; indeed, I have not in six successive winters lost a single colony by winter-killing. But I fear the effect of this warm and sloppy January. However, I must wait and hope for the best.

I notice that some one recommends nailing in the cross slats in no-drip honey-cases. I prefer to fasten them with bits of wax under them, well prest down; thus stayed, they will not slip. **ALBERT BAXTER.**
Muskegon Co., Mich., Jan. 19.

Wintering Bees in a Close Room.

It will be interesting, after so many years of pro and con ventilation, to know that in an atmosphere of 50° so charged with gas and so destitute of oxygen that a lamp would go out in a second, bees live for weeks, quiet and contented, with no greater death-rate than in an atmosphere in no respect differing from the one we breathe for the same length of time. **T. F. BINGHAM.**
Clare Co., Mich.

Fixing for a Big Crop.

Kansas is fixing for a big crop of honey this year. There is an abundance of moisture and but little cold. Bees have an outing every week or so. A number of people are buying bees and sowing alfalfa. I increased from 12 to 32 colonies in 1899, and secured 500 pounds of comb honey.

Mr. Doolittle's plan of superseding a black queen with a queen-cell above an excluder, as per his book, failed for me; but I think it was my fault.

Success to the Bee Journal.
SILAS HARTER.
McPherson Co., Kan., Jan. 17.

Two Dry Years in California.

It is raining to-day, and I feel good in anticipation of the future sweets, if this rain continues long enough (and the prospect is favorable), and if others follow. Of course, those who have kept informed are fully aware that Southern California has suffered two dry seasons in succession, and as a result an almost total failure of the honey crop. The loss of bees in 1898 was very heavy; I believe, judging from my own vicinity, that at least 60 percent of the bees died. I was one who had great faith in 1899, so purchased 125 colonies, which added to what I had before, gave me 173. The year 1899 proved about as bad as 1898, and all bee-keepers whom I met, of any prominence, said that our only hope of going thru successfully would be by requeening everything. With that object in view, I read and studied Doolittle's "Scientific Queen-Rearing," and began experimenting. I am glad to say I met with most satisfactory results, and reared young queens for all my colonies but six. **J. W. GEORGE.**
Los Angeles Co., Calif., Jan. 3.

A Beginner's Experience.

While on a visit to my brother in Maryland, last February, I found a large number of colonies housed in modern hives of different sizes, and it was thru his enthusiasm that I caught "the fever." On my return home I talked the matter over with a doctor (a friend of mine), and we bought four box-hives of bees, and a supply of 8-frame Langstroth hives. The "tug of war" came when

we proceeded to transfer the bees to the new hives, which we did on strictly beginner style, paying no regard to queens, thinking that of course they were all right, but found that we were disappointed.

Something must be done, so I began reading bee-lore, but being an old man I did not "catch on" very fast. We lost two colonies by the "French-leave" plan, and another was robbed out. We supplemented these with other purchases, and now have about the same number we started with, with reasonably well-filled frames, but they did not store a pound of honey more than will carry them thru the winter. The season was a poor one for bees.

Well, we made nothing except the big stock of experience in the business which we have stored by for the early spring. One large source of experience was gained in handling queens. June 25 we received a beautiful Italian from a well-known breeder, but the next morning after introducing her she was destroyed by halling. June 30 we received another beauty, and she was also carried out in the same manner in a few days. July 10 we received a three-frame nucleus from Kentucky, added five frames of comb, and on Sept. 25 they were full of brood and honey, which I think will enable me to rear my own queens for next season. J. M. HALL.

Davess Co., Ky., Jan. 15.

An "Off" Year for Bees.

It was an "off" year with bees with me just year. They got very little more than enough to winter on. I put 98 colonies into the cellar, and they are wintering nicely thus far. M. M. RICE.

Grant Co., Wis., Jan. 20.

No. 1.—Medical Animals.

Nature protects its own. Call it instinct or absolute knowledge, as you will. Their choice of remedies may not be extensive, but is evidently effective. The bee is frequently attacked by diarrheas, more or less violently, when it hastens to the wild-cherry, poplar, the red dogwood and hickory, to find the juices (sap) that cure.

Old Towser, when somewhat "off his feed," his stomach gone wrong, or liver out of fix, hies himself to the first bunch of couch-grass—the tall, strait kind with cutting edges that has often brought the blood to our fingers in our boyhood swimming-days. He makes no mistake in the variety, but bites off several big mouthfuls, and—soon doggie is well.

Gentle spring more often brings sorrows to cats; whether too bilarious living in winter be the cause is not explained, but true it is that Romeo, or his Juliet, frequently resorts to a patch of joint-grass growing handily in the front yard. They eat of it ravenously as if the tenderest "spinach-greens." No pharmacist could prepare a more effective "worm-mixture" than they have chosen. Worms are their natural enemies. But if in quest of a "love-potion"—a panacea to calm their perturbed nerves, to abate the excitement of a turbulent night—they deliberately trudge off to the barn-yard, and there, very near the corner of the old cow-stable—see?—where the ground is rich, is the luscious, big-headed "catnip" of childhood memory. There they roll and mew and eat of the succulent plant, with the zest of an epicure. Thereupon Tabby becomes exceedingly affectionate, and Tom, wise and complacent.

Dobbin, too—the dear old family steed, so gentle to the good, and patient to the thoughtless of the family—he also knows a thing or two about medicine! If he has "lampers"—the gums so swollen and painful that eating dry corn or even oats is a torture—he knows just where to find that nice, fat clump of plantain that grows so plentifully in the corner of the old rail-fence. Great, big, fleshy leaves, so cooling to hot, inflamed gums. Nice carrot-tops would do as well, if the children knew, and were thoughtful to give him.

As age advances, Dobbin gets short of breath—just as some old men are. If you

will turn him loose into the pasture, right there in that boggy swale, near the creek, you will soon notice he has found a big bunch of large leaves, of rather strong and evil odor, but what does he care for smells if the skunk-cabbage will improve his breathing! I guess almost any of us would devour a real skunk if it kept us from choking to death!

Cattle, as you know, get hurt accidentally, or cut by human brutes. A sore is formed perhaps on the neck, often around the ears or rump. If they can reach the sore to lick it, it not only keeps it clean, but the saliva tends to coat it over and prevent the flies from infecting the hurt. If out of reach, they have a way of telling their cow-friends of their misfortune, and behold!—another bossy comes up, and, after inspection, proceeds to lick the sore, day after day, until well.

Birds have a materia medica quite their own. If feeling indisposed, from any cause, they know exactly where to find that head of millet, so full of oil, the very thing they need for what ails them. If suffering sorely they'll hop off to a large plant of hemp or wild hops, whichever is convenient, and in their seeds find the sedative for the pain they suffer. Soon you see them comfortably perch, head under wing, and asleep. Mustard is the plant they consult if their stomachs don't properly digest. These strong seeds generally do the business, and no doctor's bills to pay!

I've got a rooster, and he is paralyzed—can't walk—and I want to tell the little bee-keepers of the American Bee Journal family how he got into this fix.

There! the editor, Mr. York, thinks I've said enough for one printing, but if he let's me I would like to tell you about Dick, because some of your chickens may weaken some time.

UNCLE FRANK.

[All right, Uncle Frank, next time you can trot out Dick, the rooster. Oh, but he can't even walk, did you say, much less trot? Well, may be by the next time we hear from you Dick will be "himself again."—EDITOR.]

Favorable Winter for Bees.

Bees made a better storage of honey here from the middle of September till freezing weather than they had done till that time. The winter has been favorable so far for bees on the summer stands—the only way they are wintered here.

M. GILMOR.

Jackson Co., Ohio, Jan. 15.

Plenty of Rain—Nice Weather.

We have been having a lot of rain since I wrote you last. To-day is the first fair day we have had since the latter part of last year—and 'tis true, every word of it. It began last Sunday, and continued without any intermission until some time last night. It just came down in torrents. But the rain has been keeping rather shy of the southern portion of the State. It is likely, tho, that before long they will get a much-needed soaking. I trust they may.

For about a week before it settled down to rain we had some cold weather, tho I have not seen any ice this year—for some months, I mean—except on or around the ice-wagons. There were some good frosts, but I notice that they were not hard enough to nip tender vegetation, to-wit: callas, heliotropes, geraniums, potato-vines, etc. Roses and callas are in bloom in profusion. While at Berkeley and Claremont Christmas day, I noticed that vegetation was never so tall at this time as it was then. From appearances the year is going to be a very propitious one.

Convention Notices.

Utah.—The Utah State Bee-Keepers' Association will hold its semi-annual convention in the City and County Building, Salt Lake City, Apr. 6, 1900, at 10 o'clock a.m. A full program in the interest of the industry will be presented, and all our bee-keepers can help themselves by aiding the Association, and in order to create a closer bond of union among our bee-keepers. As a further incentive to the success of the bee-industry, it is very desirable to have our bee-keepers, in all parts attend the spring convention.
J. B. FAGG, Sec.

California.—The tenth annual convention of the California State Bee-Keepers' Association will be held in the Chamber of Commerce, at Los Angeles, Feb. 21 and 22, 1900. It will be called to order at 1:30 p.m., Feb. 21. At this time the railroads will sell round-trip tickets to Los Angeles and return for one and one-third fare, on account of the Industrial, Mining, and Citrus Exposition, which will be held in Los Angeles. Tickets good for 10 days. Let every bee-keeper bring some hive, tool or experience that he has found valuable, and we will have a good convention.
J. F. MCINTYRE, Sec.
Sespe, Calif.

Wisconsin.—There will be a joint convention of all Wisconsin bee-keepers' societies at the 16th annual meeting of the State Bee-Keepers' Association, Feb. 7 and 8, 1900, in the State Capitol, at Madison, Wis. Many prominent bee-keepers will be there and take part.

Excursion rates of a fare and one-third for the round-trip, for railroad tickets purchasable in the State, for over 50 cents each. Be sure to bring a certificate of each ticket purchasable so it can be signed Feb. 8, in Madison, and entitle the holder to a third fare return.

The State Horticultural and State Cheese-makers' Associations will meet on the same date in the Capitol.

Don't forget the date—Feb. 7 and 8. It will pay you to attend.
N. E. FRANCE, Sec.
Plateville, Wis.

Everyone interested in poultry is also more or less interested in incubators. There are several good articles of this nature on the market, and one of the best is the New C. Von Culu. We are informed that it works to perfection and consequently never fails to give entire satisfaction when given proper attention.

The plant of The W. T. Falconer Manufacturing Co., of Jamestown, N. Y., who are the sole makers of the New C. Von Culu Incubators, is one of the most thoroly equip in the country, and also one of the largest, as can be seen by the above illustration. They manufacture, besides incubators, a first-class brooder and other articles used by poultrymen. Their advertisement appears elsewhere in our columns. Any of our readers who are contemplating the purchase of anything in their line should send for their catalog.

We can fully recommend the firm as being thoroly reliable and trustworthy. Please mention the American Bee Journal when writing to them.

A Prize for Incubator Users.—A prize of \$5.00 is offered by the Frank B. White Co., Chicago, for the best article, written by an incubator user on the subject, "Buying an Incubator." The company wants to ascertain how current incubator advertising strikes the average poultryman. What appeals to you most strongly in an incubator advertisement? What led you to purchase the incubator you now use? What claims have the most effect in influencing your decision? Each article must contain not less than 300 or more than 400 words, and must be sent to Frank B. White Co., Fisher Building, Chicago, before Feb. 25. We trust some of our readers will secure this prize.

IF YOU SEEK UNDOUBTED INCUBATOR VALUE

Experience the Best Teacher.

But a wise man profits by the experience of others. Every farmer and dairyman needs a practical, helpful paper like

Dairy and Creamery

PUBLISHED AT CHICAGO, ILL.

filled with information gathered from the actual experience of practical and scientific breeders and feeders of cattle and pigs. He wants to know how other men get the best results; how to feed to the best profit; how best to utilize his skim milk; how to build up a first-class dairy from the resources he has; what crops to grow to keep up the flow of milk at all seasons.

Last year a patron of a Kansas creamery who read a dairy paper and kept good cows, made \$36.00 per cow more than the poorest patron of the same creamery who did not read a dairy paper. That means something; it shows the value of an up-to-date, reliable adviser like **DAIRY AND CREAMERY**. (Subscription 50 cts. per year.)

FREE! We will send **DAIRY AND CREAMERY**, the best semi-monthly paper published for farmers and dairymen, absolutely **FREE** for one year to all new subscribers to this paper, and to all old subscribers paying their subscription one year in advance. Both papers for the price of one. Send your subscription to this office while this offer is open. Both Papers \$1.00.

AMERICAN BEE JOURNAL, CHICAGO, ILL.

A Further Offer: We will give Dairy and Creamery for one year as a premium to any one of our readers who sends us one new subscriber to the American Bee Journal for one year at \$1.00. Unless these offers appear again after March 1, in these columns, they will be withdrawn at that date; so you would better take advantage of them at once. Address,

HONEY AND BEESWAX MARKET QUOTATIONS.

CHICAGO, Jan. 23.—The trade is taking but little honey; the mild weather may be one cause, but the winter is two-thirds past, and therefore the season is short in which to dispose of what remains unsold; all of our customers speak of a light demand.
Prices remain as formerly quoted, but would be shaded to more round lots.
R. A. BURNETT & Co.

CINCINNATI, Dec. 27.—There is a good demand for all kinds of extracted honey. White clover and basswood sell at 8@8½c; amber and Southern, 6@7c, according to quality and package. Fancy comb honey in no-drip shipping-cases sells at 15@16c; darker grades hard to sell at any price. Beeswax, 26c. **C. H. W. WEBER, Successor to Chas. F. Muth & Son and A. Muth.**

LOS ANGELES, Jan. 4.—1-pound frames, 12½@15c; 2-pound cans, 2 dozen in case, per dozen, \$2.50; 2-pound glass pails, per dozen, \$2.50. Extracted, water white, 60-pound tins, per pound, 8½c; light amber, 7½@8c; dark amber, 7½c. Beeswax, 25@26c.

KANSAS CITY, Jan. 19.—We quote No. 1 white comb, 13½@14c; No. 2, 13@13½c; No. 1 amber, 13@14c. Extracted, white, 7½@8c; amber, 7@7½c. Beeswax, 20@22c.
The supply and demand for comb honey is light. The demand for extracted since the first of the year not so good. **C. C. CLEMONS & Co.**

BUFFALO, Jan. 5.—Market bare of fancy white one-pound comb honey, and selling at 15@16c; fair to good, 12@14c; buckwheat, dark, poor, etc., 8@10c. Fancy pure beeswax, 28@30c.
BATTERSON & Co.

NEW YORK, Jan. 10.—Demand is very good for all grades of comb honey. Receipts are somewhat light and not up to former years. We quote:
Fancy white, 15 cents; No. 1, white, 13@14c; amber, 11@12c; and buckwheat, 9@11c., as to quality. Extracted remains firm at following prices: California white, 8½c; light amber, 8c; white clover and basswood, 8c; amber, 7½c. Very little trade for extracted buckwheat as yet. Southern, fancy, 7½c per pound; other grades, as to quality, from 70c to 75c gallon. Beeswax quiet at 26@27c. **HILDRETH & SEGELKEN.**

SAN FRANCISCO, Jan. 10.—White comb, 11½@12½c; amber, 8@10c. Extracted, white, 7½@8c. Light amber, 7@7½c; amber, 5@5½c; Beeswax, 26@27c.
Offerings and demand are both light, and this must continue to be the case until the end of the season. Business is necessarily of a retail character, but at generally firm figures, especially for choice extracted, which is in lighter supply than comb.

BOSTON, Jan. 12.—We quote as follows: Fancy white, 16c; A No. 1, 15c; No. 1, 13@14c; buckwheat will not sell in this city. Extracted, light amber, 7@8c. Demand is very light.
BLAKE, SCOTT & LEE.

ALBANY, Jan. 10.—We quote: Fancy white comb, 15c; No. 1 white, 13@14c; mixt, 11@13c; buckwheat, 10@11c. Extracted, white, 8@9c; mixt, 6½@7c; dark, 6. Beeswax, 26@28c.
MACDOUGAL & Co.
Successors to Chas. McCulloch & Co.

OMAHA, Jan. 4.—Prices remain unchanged. Fancy white is still moving slowly at 14@14½c. Extracted, white, 8½c. Now that holiday trade is over and dealers have taken their inventory, they soon will be thinking of replenishing their stock and more lively trade is anticipated in the near future, but no material advance is looked for during January.
PEYCKE BROS.

DETROIT, Jan. 11.—Fancy white, 16@17c; No. 1, white, 14@15c; dark amber, 10@13c. Extracted, white, 8c; dark and amber, 6@7c. Beeswax, 24@25c.
M. H. HUNT & SON.

WANTED.—Extracted honey; all kinds; mail sample and price expected delivered at Cincinnati. 1 pay spot cash on delivery.

CONTRIBUTED ARTICLES

A Wisconsin Apiary and its Management.

BY E. D. OCHSNER.

FATHER and I are the only prominent bee-keepers around here, so we have everything our own way. We have five yards—four out-apiaries and one in the village—with, I think, nearly 400 colonies at present, mostly Italians, which are very quiet bees to work with, but not superior in honey-gathering over the blacks or the cross.

Now, in regard to our honey harvest: We have white clover in June, and basswood the last of June or the first week in July, which lasts about 15 or 20 days; and later on we have the usual fall bloom, which is not much except in two out-apiaries, the yard pictured here—Indian Mound apiary—being the best, I think, as it faces south to miles of bottom lands, east to marshes, and north and west to buckwheat. This yard has about 80 colonies in Langstroth hives, mostly 8-frame, which I consider the best all-round hive for size and convenience.

The bees in the apiary shown herewith are run for only comb honey. They are splendidly located on a sandy hill, with lots of shade around, and high enough so that we made a fine bee-cave in the north side of the yard, facing north, as such is the easiest to keep cool in spring. It is 28x8 and 8 feet high, has two entrances, and will hold 100 colonies without crowding, and winter well, mostly on account of the sandy soil where it is made, and because it is walled up with plank and so is never damp, as are most of the under-ground places.

Some bee-keepers want to make a bee-cave too fine, and so put up stone walls and cement floor instead of a tight floor of boards, so of course bad results may be expected.

There are two roofs over our bee-cave, the first one covered with a foot or so of dry sand, then about two feet of dry oak-leaves, and then the second roof, which you see above the ground, and is water-proof. This cellar has never been too cold for the little workers even in so cold a snap as we had last winter.

The shanty cost only \$10.00, and makes a work-shop and a place to sleep. It is under the shade of two large oaks.

The cave has two ventilators above, which I forgot to mention. Also, I am standing in front of the yard.

Two of the best yards are run for extracted honey, and we never put on an upper story without a queen-excluding honey-board. I think if more would use excluders there would be a finer grade of extracted honey put on the market, for we all know that dark extracting-frames make dark honey.

I tried one yard last summer on the no-swarmer plan, by cutting cells every 8 days in the honey-flow, and I am well pleased; but I think two things helped me—they were extracting-hives, and had clipped queens.

I like outside wintering above anything else, and have just made more chaff hives. Bees came thru in chaff hives strong last winter, but were poorly in the cellar. Nearly half of ours were wintered on the summer stands.

Foul brood we have never had, and honey-dew but once.
Sauk Co., Wis.

No. 6.—The Honey-House—How to Get the Most Out of It.

BY "OLD GRIMES."

WHEN the apiary grows to a condition of profit some sort of a special building is necessary for storing the honey and appliances, and for performing the various branches of work connected with the apiary.

If the bee-keeper looks forward to the expansion of his business into many apiaries, then so much more need of a

Indian Mound Apiary, of E. D. Ochsner, Sauk Co., Wis.

special central building, and it should be at least 30x40 feet. For an extensive business a two-story building could be used to advantage, but instead of putting the two stories above ground it is better to put only one above and one below, or, in other words, make it a two-story building with one story a basement.

As there will be quite an amount of honey stored in it during a good portion of the year, also many valuable appliances, it is well to make this building of concrete, and fire-proof. Wooden buildings are liable to burn, and when a season's labor goes up in a blaze, the owner is excusable for laboring under great depression of mind. Even when building and contents are insured, there is more or less loss, and the trouble of replacing building and tools.

A nice basement in our Northern climate makes an excellent place in which to store extracted honey, and in which to winter the bees; when it is made especially for the purpose, better success attends the wintering than can be attained in the ordinary house-cellar. In constructing a basement under a honey-house, or even under a barn or any out-building on the farm, a location should be selected where the exposed side shall face the sun; facing east or west will do, but facing south is better, but never under any circumstances face the basement to the north. Sunshine revives, but if the sunshine cannot enter, the basement is always damp and chilly, and subject to mildew.

A good way to construct a basement for the wintering of bees is to have plenty of windows in the exposed side, and ante-room. The windows should have closed shutters, then the ante-room can be darkened at will, or opened and warmed by the sun's rays. The inner room should be ventilated from the ante-room. In such a house honey must be heated, wax melted, and perhaps comb foundation made. A chimney should have its foundation in the ante-room, and a range or stove conveniently located. The chimney is not only a smoke conductor, but a ventilator for the basement.

Of course, our building will have a sort of a second story above ground in the attic. This should be easily accessible, for the attic is a great place for the odds and ends, and discarded utensils.

Whatever material is used in the construction of the house it should be made fire-proof, rat and mouse proof, as the latter vermin sometimes make sad havoc with empty combs and fixtures.

A room in this house should be set apart for storing comb honey and empty brood-combs, and in which they can be fumigated. Sulphur is the old stand-by, but lately bisulphide of carbon has been recommended. This cheap material sprinkled in a room will not only keep out the moth-miller, but also the ant, and the latter is not an unmixt blessing in some portions of the country.

When the apiary is worked for extracted honey, of course the extractor will be in the upper portion, and the tank or receptacle in the basement. And whatever style of building is used for extracting, there should be a drop of a few feet from the extractor to enable the honey to be drawn off with little labor in lifting.

At the out-apiaries the Grimes family have small portable buildings. An out-apiary is not considered permanent, and if the prospect for a honey crop is better in the early portion of the season in one location, and better later in another, it is better to have the out-apiary almost on wheels. A honey-house to be portable should be constructed in panels, and bolted together. When so constructed a few moments time with a wrench allows the owner to pack it upon a wagon. It is well to make such a house of planed boards and neatly paint it; but this of course depends upon the taste of the owner. Some bee-keepers can get along with any sort of a rude thing, while others will insist upon having a fancy structure.

If made of rough boards and not battened, a very good way to make it bee-tight, cheaply and quickly, is to line it up with cheese-cloth or gunny-sacking.

Any house that is built for bee-purposes should be provided with plenty of windows covered with wire screens, and fitted with the Porter house, bee-escapes. While we like plenty of ventilation for comfort during the heated term in the apiaries of the Grimes family, we prefer to have no windows near the doors, or doors with screens. A screen door is necessarily opened many times during a day, and it attracts hundreds of bees, and they are ready to skip in as soon as the door is opened. We, therefore, dispense with screens upon that side of our buildings.

The Premiums offered on page 79 are well worth working for. Look at them.

Rearing Improved Races of Bees, or Italianizing.

BY C. P. DADANT.

MR. DADANT:—In Langstroth Revised, when speaking of the rearing of improved races of bees, you advise placing, in the spring, two combs of drone-brood in the center of one of the best colonies of such race as you wish to breed, for the purpose of securing drones from that colony, while another colony or more, also of superior quality, will be selected for rearing queens. In another place you speak of more or less drone-comb being generally distributed thru all the hives. Will not this drone-comb defeat the end in view, which is to rear the drones exclusively from the best colonies?

Also would it not be right to manufacture drone foundation in order to be able to supply such foundation for the purpose above named?

When, in your opinion, is the best time to rear queens for improving the stock of bees in a small apiary?

ANSWER.—In natural conditions bees will build in their hives probably from one-fifth to one-tenth of drone-comb. To establish a rule on a matter of this kind would be simply to open the way for discussion in which there would probably be no result, as it is very certain that many circumstances have influence over the actions of the bees in comb-building. One thing, however, is positive; it is best to rear the greater quantity of drones from the colonies which are most desirable for increase. It is also best, as far as practicable, to rear the drones and the queens with which they are to mate from different colonies. It seems that Nature has taken pains to attend to this matter since she has provided that the espousals be not celebrated in the hive, but in the open air, on the wing, in full flight.

We know also—but perhaps this is not sufficiently impressed upon the minds of many beginners—that drones in an apiary are an expensive luxury; that when they exist in large numbers they may consume the greater portion of the surplus of the colony; and that man acts wisely in preventing their being produced in such great numbers that when a number of colonies are congregated within a radius of two or three miles, the drones of one or two hives, if numerous in those hives, will very probably be sufficient to cover the space traveled by the young queens, so the latter may not fail to meet one of them in their wedding-flight.

If we place drone-combs in the center of one or two of our most populous colonies, we will be much more likely to have early drones, and numerous drones, from such colonies than from any others. On the other hand, if we take pains to remove the drone-comb as far as practicable from all the other colonies, and replace it with worker-combs in full combs or in patches, as the case may be, we will still more increase our chances of producing good males. It is, however, a fact that work as we may there will be hundreds of drones hatcht in colonies where a superficial examination would have failed to reveal any perceptible quantity of drone-comb. It is only when the cells are full of brood—sealed brood—that the projecting cappings of the drone-brood show themselves with great display. At such times a very good way to dispose of them is to shave their heads off with an uncapping-knife. The exchange of drone-comb for worker-comb, however, should be done before the breeding-season has fairly begun. Two drones cost about as much to rear as three workers, and you can rear a very nice little swarm of worker-bees in the same space in which you would have reared a host of idlers.

If the thing is done properly, the drone-comb removed from hives whose reproduction is undesirable will be useful in the hives from which breeding is desired, and if the apiary is large only a very small portion of this drone-comb will be used. It is therefore entirely useless to think of producing foundation for this purpose; and this fact has been so well recognized by bee-keepers that not one out of five hundred ever asks for drone foundation.

The patching of frames out of which pieces of drone-comb have been cut is also easier with worker-comb than with foundation, and for such a purpose it is always well to save the combs of colonies that have died during the winter, or surplus combs from colonies that are too weak to cover all their combs in early spring. Such combs may be later on supplied with foundation or strips for guides and given to new swarms.

There is no doubt that even if we remove the drone-comb from our undesirable colonies there will still be a number of drones reared that are undesirable; but this should not deter us from pushing our work in the right direction. If a farmer should not cultivate a field at all after putting in his crop under the plea that some weeds would grow anyhow, and that he might as well let all grow that want to, he would surely be following a very poor policy.

If we do not try to prevent the undesirable drones, or to rear desirable ones, on the plea that there will always be

plenty of the former, we shall certainly not succeed, and if we follow the same argument in all our affairs, we will be sure to make a failure of everything.

Concerning the best time to rear improved races, or, to call it more plainly, to Italianize (for we do not know of any race that is desirable in our eyes outside of the Italians), we would prefer spring, as the job is shorter to Italianize a certain number of colonies than to wait and have to also Italianize the increase. Hancock Co., Ill.

Market Price of Honey.—Comb vs. Extracted.

BY DR. C. C. MILLER.

MR. EDITOR:—In the Farmers' Voice for Jan. 13, occurs in an editorial the following paragraph:

The market price of honey is from 10 to 15 cents in Chicago, and 12 to 14 cents in St. Louis—that is, in comb. Extracted and strained in barrels ranges from 6 to 6½ cents, while cans are one-half cent higher. The question naturally arises: Why this difference, and isn't there more honey in a pound of extracted than in the comb? Certainly, but beeswax, of which the comb is made, is worth 25 cents per pound, and, moreover, when the honey has been extracted and put in cans or barrels, about half of it is cheap syrup, and of course the price is cheaper. Honey in cans is not pure honey, and is not worth the money paid for the comb product, which it is impossible for the tricksters to adulterate. Buy or sell honey in the comb.

Wherever the Farmers' Voice is held in esteem, the effect of that paragraph will be to influence the market in favor of comb honey and against extracted honey. I produce comb honey exclusively, so it is to my personal interest to have a strong demand for comb, with little consumption of extracted. But as a matter of common fairness, I must enter protest against the erroneous statements of the Voice, which I believe it will be glad to correct when they are pointed out.

The reason that extracted honey is cheaper than comb honey is *not* because "when the honey has been extracted and put in cans or barrels about half of it is cheap syrup." When a bee-keeper puts extracted honey in cans or barrels, every drop of it is just as pure honey as that in the comb. Honey in cans *is* pure honey, altho when it gets into the hands of the Chicago adulterator it is only too true that it is debased by mixture with an inferior article. At the same time it is equally true that any one can buy in Chicago pure honey in the extracted or liquid form in any quantity, by the barrel, can, or jar. All that is necessary is to buy of reliable dealers, who are not hard to find.

The main reason for the lower price of honey in the liquid form is simply that it costs less. When honey is put in comb, every pound of the wax used in making the comb costs the bees several pounds of honey, besides the time and labor occupied in the manufacture of the comb. Quite different is the case of extracted honey. The completed combs are given to the bees to fill; when these are filled the honey is thrown out by centrifugal force, or, as it is called, *extracted*; then the combs are returned to the bees to be filled again, and this may be repeated again and again, the same set of combs lasting a lifetime. In other words, when extracted honey is sold, it is pure honey without any beeswax; when comb is sold, there goes with it a much more expensive article than the honey, altho the consumer has no benefit therefrom as an article of food. With these facts in mind, it is not necessary to explain the lower price of extracted honey by supposing it to be adulterated.

With improved laws against adulteration soon to go in force, and with the aid of the daily and agricultural press, it is to be hoped that a merciless warfare will be waged against adulteration, and that so delightful and wholesome an article of food as honey may be found as a staple article on the table of the rich and the poor.

McHenry Co., Ill.

Victory in the Chicago Honey-Lawsuit.

BY C. THEILMANN.

MOST of the readers will remember reading in the first number of the American Bee Journal for 1897, of the terrible stealing of produce from the shippers by a lot of Chicago commission men, something over three years ago, when many bee-keepers lost all of their honey of that season's crop by shipping it to them. Among them was the writer, who shipped 10,346 pounds of comb honey to H. C. Bartling & Co. It was sold to them for 1½ cents a pound, free on board the cars here, one-third to be cash on arrival of the honey at Chicago, and the rest in 60 and 90 days.

I waited about 10 days after shipping, and when no money came I went to Chicago, and found that my honey was sold (pretended, or partly hid). I demanded settlement, when a report was made out, which showed the honey all sold on commission. With the freight charges, cartage and commission deducted from the sales, it netted over \$200 less than the cash sale I had made with the firm before the honey was shipped. But I gladly accepted their statement, on which they paid me \$250, and promised to pay the rest later on.

I got their check certified to at their bank, and took further advice from my attorneys, Messrs. Masterson & Haft, then demanded the balance due on the statement, which they refused to pay.

Bartling was then arrested, but the justice of the peace dismissed the case.

Then Bartling arrested me for stealing the statement his partner gave me. The case was tried before Justice Hoffman, four or five miles out from the center of the city, which was also dismissed.

I then was re-arrested for libel, and sued for \$11,500, and would have had to go to jail if I had not had a rich

C. Theilmann.

friend at Chicago to go on my bond. At the same time Bartling was sued for the balance of his statement before the Circuit Court, which ended with a decision and a judgment for \$711.80 against Bartling. He asked for a new trial, which was granted, with the result that the judgment stood good.

Bartling then appealed to the Appellate Court, whose judges also held the judgment good. It took a long time in these courts on account of some mistakes, technicalities, and hair-splitting among the attorneys on both sides. But my attorneys forced Bartling to give bond for the judgment and costs before he could appeal.

Not satisfied with the decisions of the foregoing courts, Bartling appealed to the Supreme Court of the State of Illinois, and I was bound to follow him to the end of the courts. This court also decided the judgment in the former courts good. That ended Bartling's appeals—he was forced to make a settlement or go to jail. He preferred to settle, and paid up Jan. 16, 1900. The libel suit was dismissed some time before this, and, thank God, I again feel like a free man, and out of the teeth of one of the worst sharks in the shape of man that Chicago harbors, who did not hesitate to ruin his own father, but this Minnesota farmer and bee-keeper was too much for him. Bartling is *beaten*, and I trust he may see his mistake, and make his living honestly hereafter. To do this, he has natural gifts and abilities, if he would only make good use of them.

With all this experience and processes that I was forced to go thru in this unfortunate transaction, I feel it my duty to say to the shippers of produce and other goods: Never send anything to commission men, or any one else, before you have looked them up thoroly in every sense—their financial standing and their character first, then their abilities in their business management, etc. Forethought is better than afterthought, and will save much trouble and losses. But if you should be so unlucky as to fall into a covered-up pit, and need legal help, see Messrs. Masterson & Haft—they have proven their manly character and their ability in my case, even if I was discouraged now and then by outsiders who did not know them better than I did. They were also very reasonable in their charges.

The so-called complicated part (and not being the real issue in the 12th annual report of the National Bee-Keepers' Union), when I called for aid, was not complicated at all. The only question was: Would the cash sale of my honey stand good, after Bartling had sold it on commission, and he himself had so reported it? The courts held that the cash was not a sale under these circumstances, and Bartling made himself liable by selling my goods and converting it to his own use and benefit; while the cash sale would have been only a trust, and could not be collected unless Bartling had some property that was not exempt. I give this part of the history for the special benefit of the readers of the American Bee Journal, so they can look out. The outside matters did not make the main point any more complicated, and had no effect at all on it, in the main.

It seems the Union took but little interest in this case, and let me fight it all alone. The officers who answered my letters express themselves very sympathetically over the matter, and I have to say again, that that was all I got "financially," and I was a member from its start.

One of the Union officers (and he is one of our best and most practical writers and bee-keepers) got so far off the track, after his advice to drop the case, to write me these words: "If you have lots of money to spend in that way, so that this course comes in a sort of amusement for you, I have no objection to your doing it." Just think, readers, what a healing, soothing plaster that was to the sore wounds I had received from one of Chicago's honey-sharks! I will forgive the writer, for it can hardly be that he knew what he wrote, his mind probably being among his bees, inserting queen-cups, or studying out some other scheme. Smart men make big mistakes sometimes.

Where a man lives 400 miles from the place of trial, to fight a case of this kind comes very high, outside of attorney's fees, but it is worth something to constitute an example, but it should not be borne by one man alone, while many are benefited by it.

I herewith tender my hearty thanks to George W. York, editor of the American Bee Journal, for the kind assistance and helping hand he gave me in this my perplexing and long-standing trial. We have reason to patronize Mr. York, as he will do all he can for the bee-keepers. No one knows this better than I.

I also want to thank Mr. Secor for a number of encouraging letters he wrote to my attorneys. I think they had a good influence.

Wabasha Co., Minn.

CONVENTION PROCEEDINGS

Report of the Colorado State Convention.

The 20th annual session of the Colorado State Bee-Keepers' Association was held in Denver, Nov. 27, 28 and 29, 1899.

The meeting was opened at 10:30 a. m., Nov. 27, with the reading of the minutes of the previous session.

No set program was followed in this convention, except that on the second and third days some were appointed by a committee to introduce certain subjects.

BEST BROOD-FRAME FOR MANIPULATION.

□ Mr. J. B. Adams first asked the question, "What is the best brood-frame for manipulation and ease of access without considering its fitness for extracting purposes?"

Mr. Thompson—I have used the hanging frame $\frac{7}{8}$ inch all around, the Hoffman frame without a V edge, and the closed-end frame, both hanging and standing. I consider a self-spacing feature absolutely essential to ease of manipulation, providing it is attained by the frame itself, not by staples or nails, because the self-spacing feature enables one to shove a number of frames at once from one side of the hive to the other with the chisel or screw-driver. I prefer the closed-end frame. I think the hanging variety is a little easier manipulated.

Mr. Lansdowne—The most experienced bee-keeper in my neighborhood, Joseph Shatters, prefers long top-bars to end-spaced frames with short top-bars.

H. Rauchfuss—Neither will accomplish the purpose, unless there is a staple at the bottom as well as at the top. I think I already had a better frame five or six years ago—the closed-end standing frame, because it is always square in the hive, no matter how it is nailed.

Mr. Lyon—We are compelled to use a top end-staple with the length of top-bar now used. I prefer the long top-bar.

F. Rauchfuss—The long top-bar is to be preferred. These frames are not always used in dovetailed hives of this year's make, which are not of the same dimensions as in former years. The staple-spaced frame drops down, while the frame with a long top-bar does not.

J. B. Adams—Would you have objections to two staples, one at the top and one at the bottom?

F. Rauchfuss—Yes.

Pres. Aikin—My opinion of end-spaced frames is like my opinion of metal-cornered frames—I don't care to have them. I don't want a bottom-spacer. Better make the frame square at first, then when the comb is built they remain square.

H. Rauchfuss—I handled some new end-spaced frames lately with short top-bars. They slipped past each other. Even with staples the frames need to be accurate, because the hives will not remain uniform in length.

Pres. Aikin—I have had for years a leaning to closed-end frames. The old-fashioned $\frac{7}{8}$ -inch frame always has burr-combs on top and ends.

RETAIL PACKAGES FOR EXTRACTED HONEY.

H. Rauchfuss exhibited a self-sealing tin-pail as a possible honey-package, and said the workmanship showed it could be made cheaply.

Ch. Adams—It is more expensive. The cheap syrup manufacturers can afford to pay for a higher-priced package.

F. Rauchfuss—This is known as the self-sealing pail. It is expensive, tho I don't know why it should be so. A gallon pail costs 15 cents each in quantities. It is extensively used by Oliver Foster. It is all right for a honey-package. I filled one with new honey and dropt it a dozen times on a hard floor. The tin was dented, but not a drop of honey escaped.

Ch. Adams—It is a poor package to use again. It is hard to wash, and rusts on account of the rim, which prevents the moisture from draining.

Mr. Cornelius exhibited a stone preserving-jar, which he uses in his retail trade because it can be obtained cheaply. One costing $8\frac{1}{3}$ cents holds $5\frac{1}{2}$ pounds of honey.

Pres. Aikin exhibited fiber packages, the same that were referred to in last year's report. He had filled one with cold water and let it stand for ten days, without effect. Another in hot water of over 160 degrees had partially loosened in the seams. The package seemed to stand any amount of dry heat. It is furnished either with or without a parchment-paper lining. It is sealed either by passing a brush dipt in shellac around the lower edge of the cover, or by winding around a strip of cloth dipt in mucilage. He had bought 1,476 one-pound and four-pound sizes, an equal number of each, and paid the local freight, making the total cost a little less than three cents apiece, which includes an individual business-card printed on each one. The manufacturers said that if they were used in large quantities they could be furnished for considerable less. He considers them the coming package for the home trade. He now sells most of his honey in the candied form in lard-pails.

F. Rauchfuss—For that package to be satisfactory one must be sure honey can be liquefied in it.

H. Rauchfuss—How long does it take extracted honey to candy after the air has been expelled, so that it is perfectly clear?

A Member—About four weeks.

H. Rauchfuss—Honey that I extracted and heated in

August, to expel the air, is liquid yet. The air ought always to be expelled, because the foam that rises when candied honey is melted that had not been previously heated is an objection to the sale of the honey. But that previous heating which prevents the foam would also prevent the honey from candying soon, which would be an obstacle to depending upon the sale of candied honey in the way suggested.

Pres. Aikin—So long as the honey candies the fiber package is all right. I have never had any complaint of the foam.

J. B. Adams—My customers now prefer candied honey. They did not before.

A motion was made that each member be requested to state the number of his colonies and the approximate amount of honey for the year. After some discussion it was not carried.

THE HEALTH OF BEES IN COLORADO.

Introducing the subject, "Health of Bees," the secretary read portions of the inspectors' reports, showing that the first mention of foul brood was in 1886, and the first steps taken toward a law, in 1888; and that considerable foul brood yet existed. Every bee-keeper should inform his neighbors of the nature of the disease, and should hand them copies of the law, of which 1,000 have been printed, and should inform the inspector of the existence of bees affected. Very often the inspector does not know, and can not be blamed.

H. Rauchfuss—There is a disease far worse than foul brood. We have spared no time and money to find out about it. It seems to spread. It started with one colony in our apiaries eight years ago. Four years ago we lost 300 out of 400. It commenced April 27, and ended in June. Now the bees even die in the fall to some extent. We got some bees from a locality where they never knew the disease, and they would commence dying in a few days. Some wintered in the cellar did not have it, but as soon as they were taken out, became affected.

J. B. Adams—The statistics show a terrible state. As an inspector I can say that represents the worst, as only apiaries were inspected that were supposed to be diseased. But other apiaries not inspected are all right.

F. Rauchfuss—But it is well to let people know of the state of affairs here. I believe there is just as much foul brood in Arapahoe and Jefferson counties now as five or six years ago. Because an inspector can not find where the disease is does not show he is neglecting his duty. It was not intended as a criticism. Farmers with small apiaries often neglect their bees and let them die down without reporting. In some instances infected bees are moved from one county to another without permission.

J. B. Adams—I think there is not one case of foul brood in Boulder county where there used to be ten. But we have too much of it yet. The inspector is blamed for much that he should not be blamed for.

H. Rauchfuss—We must take into consideration that the percentage of foul-broody colonies is much larger than that shown by the reports. There is hardly any *bee-keeper* who does not burn up or cure his diseased colonies without reporting them. We treated 24 colonies without reporting them, and I know of another instance of 18 colonies so treated this year without being reported.

Mr. Brock—I think the secretary's statement is not exaggerated. There is not one yard out of ten that is clean in the southern part of Jefferson county. Around Littleton I have not heard of one that is. Last summer I bought 24 colonies, and found only one not foul. These were not reported.

Mr. Tracy—Last summer the inspector came around and asked if I had any foul brood, without asking how many colonies I had. So that apiary was not reported. But if an apiary has only one colony diseased, that is reported.

Mr. Lyon—I don't think the percentage is overestimated. If I find foul brood in my yard I treat it, and it is not reported. It is so every year. I know of one instance in which only two out of 12 colonies were not diseased, and another in which only one out of 10 was not. Those cases were not reported.

A letter from C. B. Elliott was read by the secretary, in which the following was requested by him to be placed before the Association: "Has an inspector any right to tell the condition he finds an apiary in after inspection, whether he finds foul brood or not?" Mr. Elliott further wrote he would put himself on record in this discussion as saying the inspector "has no right to tell any one whether

he finds foul brood or not. He is a public servant, and should not under any circumstances tell any one the private affairs of any one he is called to inspect their bees—understand me, I am not finding fault or censuring any one. The question was asked me, and the party asking wanted the matter brought up at this meeting."

Mr. Rhodes—According to law the inspector has no right to withhold the information whether foul brood exists in an apiary or not.

F. Rauchfuss—The inspector is paid by the county, and we are entitled to know. Mr. Elliott is the very person who was very anxious to find out if *his* neighbor had foul brood among his bees, and who went with the inspector for that purpose.

H. Rauchfuss—Health inspectors are compelled to put out notices on houses where certain diseases exist, such as scarlet fever. In fact, the law does say our inspectors have to tell.

The secretary here read Sec. 3 of the foul brood law, as follows: "Every bee-keeper or other person who shall be aware of the existence of foul brood, either in his own apiary or elsewhere, shall immediately notify the county inspector of bees, if there be one, and if not, the secretary of the Colorado State Bee-Keepers' Association, of the existence of such disease, and in default of so doing shall, on summary conviction before a justice of the peace, be liable to a fine of five dollars and costs." (See also Sec. 8.) Perhaps some inspector may have been indiscreet and said something out of school about other matters than foul brood. But he can be held to account for such things as well as any other man.

Mrs. Hord—The more public the cases of disease are made, the greater the incentive to keep our own bees clean. I can not understand the motive of the question.

Mr. Jouno—Does a high or low elevation, or shade or sunshine, determine the presence of foul brood?

Mr. Brock—It makes no difference at all. Foul brood is carried from one hive to another, whether either one is high or low.

A Member—I have had bees only a quarter of a mile from foul brood, and my bees did not take it.

F. Rauchfuss—The bee-keeper may do much to prevent his bees from taking it, by handling them so they will not get started to robbing, and if he notices they are robbing somewhere else, he should find out where, and take the proper measures to have it stopt.

Mr. Bates—I live on the Platte River bottom, and have 30 or 40 colonies. One man who lives above on high land has more foul brood than I have. I have reason to believe it is all carelessness. I think the inspectors don't do their duty as they should do. I brought bees nine years ago from Nebraska to West Denver. A few blocks away a few hives of bees were inspected by the inspector, who found six out of seven rotten with foul brood. The owner was away. I was with the inspector, and heard him tell the owner's wife to take care of them. I went four or five days later, but the owner did not want to kill the bees. The inspector should burn a colony right away. I inspect my own bees, and when I find a diseased colony I burn it up. Just as long as it is neglected we will never get rid of it.

Ch. Adams—The last apiary I visited had foul brood. According to law I had no right to burn the diseased colonies before five days' notice.

Mr. Bates—I don't know whether the inspector has the right or not, but he should have. I have had foul brood caused by the neglect of others, and know it. A neighbor of mine made a pile of his diseased hives and covered it with nothing but canvas.

Mr. Rhodes—Ch. Adams is correct—the inspector has no right to burn immediately. The law is lame in that respect, and also in that the inspector has no forfeit to pay if he does not do his duty.

H. Rauchfuss—Our law provides for that. Section 8 says there is a fine if any person exposes sources of infection—even *before* the five days' notice is up.

QUESTION—How long do you starve foul-broody bees after transferring, when there is no honey in the field?

Mr. Milleson—I put them in shape so they don't have anything to eat all winter—that is my invariable rule. It is cheapest, causes least anxiety, and doesn't cost very much to destroy them. It makes vinegar material, and material for the wood-shed, and saves so many chances.

J. B. Adams—I would burn out the hives with kerosene, and use them again.

[Continued next week.]

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Making Swarms Stay Hived.

After my bees swarm I have trouble in getting them to stay in the new hive. Can you give me any advice as to how this difficulty can be overcome?
PENNSYLVANIA.

ANSWER.—It's a tolerably safe guess to say that the hive is too hot and close for the swarm. Manage some way to have the hive cool and airy for at least two or three days. Raise up the hive, or leave the cover partly off, or both. Don't let the hive stand in the sun. Sprinkling well with water will help. If you give the swarm a comb of brood, they are not likely to leave it.

Getting All Worker-Comb from Starters.

How do you manage to have combs built on starters by any colony having a laying queen, and have worker-comb constructed?
ILLINOIS.

ANSWER.—The surest way to have all worker-comb is to have your "starters" fill the frame entirely, and many are of the opinion that this is the most economical way. Yet with proper management you can have all worker-combs and use only small starters. Only it may cost you more in the long run. The knowledge of a few basic principles will be serviceable in the case. Bees with a young queen are less inclined to build drone-comb than those with an old queen. The stronger the force of workers, other things being equal, the more the danger of drone-comb. A newly-hived swarm is not likely to build drone-comb the first few days after being hived. Applying these principles, you will give the preference as comb-builders to those colonies that have young queens. When a swarm is hived, instead of allowing it to start on 8 or 10 frames, finishing the combs to the bottom only after a number of days, confine the bees on 4 or 5 frames till these are entirely filled with combs, then give drawn-out combs or frames filled with foundation to fill the hive. If some combs are built with little patches of drone comb in them, cut out the drone-comb and give the frames to nuclei to complete.

What to Have Over the Sections.

What is the best thing to use on sections in the hives—enamelled quilts, tin sheets, or nothing?
ALABAMA.

ANSWER.—A very light covering only aggravates the case, for the bees will raise it up by thrusting bee-glue under, and then thrust in more glue to fill up the space thus made. If the covering be sufficiently heavy, there will be only a small distance into which the bees can thrust the glue, but they will make desperate efforts to fill that small space, so that many think it is better to leave a bee-space over the sections without any covering.

Has the Bee an Extra Sense?

I see by Dr. C. C. Miller's answer to my second question, on page 6, that he questions the truth of my statement. Now, if the Doctor will come to my place, when it is time to hunt wild bees next fall, I will convince him that bees will do just as I stated, or pay him \$100 for his trouble, and pay his traveling expenses both ways.
MASSACHUSETTS.

ANSWER.—I did not understand you to say you had positive testimony that bees would do as you said. If you have had positive proof, I'd rather take your word for it than to come and investigate. Still, I'd like to come and take a tramp with you after wild bees, unless you'd go too fast and lose me in the woods.

Hello, here comes another man to corroborate your statement, at least part of it:

FURTHER TESTIMONY ON THE SUBJECT.

On page 6, "Massachusetts" asked why a bee taken from a flower, we will say south of the hive or tree, and carried north and beyond its home, when liberated goes north and away from its home. In your reply you say you don't know, and before believing a bee will do this you should want reliable testimony. All that you will wish for testimony will be to try it. As a bee-keeper of more than 40 years, and a bee-hunter for nearly as many, I find it true, that when we are hunting bees and catch them when out

working on flowers, and carry them past their home, they invariably start and go out of sight the same direction they would have done from the flower when gathering honey.

As to the next time, as "Massachusetts" says, after filling its honey-sac it goes direct home, my experience is that not one bee in ten will ever come back to your bait again when carried to the opposite of its home when caught while out gathering honey. That bees can get "turned round," as we say, I feel sure of, as once when hunting them I caught a large number that were working on a basswood tree, the tree standing a little more than half way up a steep mountain, and on the east side of it. These I fed as usual, and every one went east toward the hive. Just to see what they would do, I filled my box and took a lot of bees from perhaps ten, and carried them just over the top of the mountain, and down part way on the west side, and to my surprise every one of them went west. They circled as if they were not sure where they were, but went down the mountain as before, only in just the opposite direction.

The bee-hunter that has not had much experience often "gets left," as we say, by carrying bees beyond the tree he lines in, as every one, if thus carried, will go in the same direction it would from the flower when caught unless carried over a mountain, as mentioned.

Hillsboro Co., N. H.

GEO. S. WHEELER.

Probably a Queenless Colony.

On Sept. 22, 1899, I introduced to colony No. 9, a select breeding queen purchased for \$2.00 from an Arkansas breeder. Of course, I had previously disposed of the hybrid mother. This Italian queen was accepted and commenced laying. There was no honey coming in, but I was feeding up the colony, as they were somewhat short of stores. Dec. 23 was a warm, pleasant day, and the bees were out for a flight in the afternoon. Dec. 25 I found a dead queen on the alighting-board of No. 9. Jan. 6 and 7 were warm days, and the bees were out in the afternoon. Jan. 19, 20 and 21 were also warm, and during the afternoon of the 20th I noticed that the bees in No. 9 were uneasy, and I strongly suspected from their actions that they were queenless. This afternoon (21st) I noticed that No. 9 was having quite a time with robbers, which appeared to be all coming from hive No. 3, about 25 feet away.

Now, I would like your opinion as to the queenless (or otherwise) condition of No. 9. Do you imagine that the queen I bought was old and nearly played out at the time I introduced her? What can I do, now, with No. 9 in order to save it? I think the bees have enough honey, tho' I have not opened the hive as they are well packed on all sides but the front, with straw; they are on the summer stands. I can put No. 9 above a strong colony with a queen. Can I unite in this way at this time of the year? I have no cellar where I could put this No. 9 colony until spring opens.
IOWA.

ANSWER.—The testimony points pretty strongly to queenlessness on the part of No. 9. The queen may have been at fault, and she may have been all right. Sometimes such things happen with a good queen.

The probability is that the colony is quite weak, and in that case the best thing may be to let things entirely alone, letting the bees rob out the honey that is in No. 9, for it will not be wasted; and if you go to making changes you may start robbing in some other direction. If, however, No. 9 is strong in bees, it might be worth while to try putting it on top of a strong colony. With not too free communication between the two, the chances are in favor of peaceable uniting; but if you leave the least chance for an entrance from the outside to the upper hive, look out for a bad case of robbing.

Top Hive-Ventilation—German Bee-Paper.

1. Last spring I bought a colony of bees which I divided, and both swarmed, one of which flew away, which left me 3 colonies. I bought 2 Italian queens, and after uniting 2 of the colonies, I Italianized them in September. In October I put them into a house, one hive on top of the other. In December I looked at them and found one hive wet inside. I then moved them around and left them. January 7 was a fine day, about 43° above zero. I took the bees out for a cleansing flight, and many froze to death. I then put the hives back again, and the next day looked at them and found water running out of one of the hives. I then ventilated the hives on top, and put a 2-inch piece of wood under one end. They appeared to be strong, with plenty of honey. Is the top-ventilation right?

2. I would like to know what honidug or thaa is. I had lots of bees in Denmark, but kept them out-doors the year around, and never lost a colony.

3. I am a German and don't understand much English. Is there any German bee-paper published in America?
ILL.

ANSWERS.—1. If your bees are set in a house, as seems to be the case, that is not considered good practice, that is, if they are entirely enclosed. If they are in a house as is practiced in Germany, the front of the hive being free, that is all right. The ventilation you have given may be all right, but it might be better to have cushions or cloths on top that would allow the air to pass slowly thru, and still keep the bees warm.

2. What you inquire about as "honidug or thaa" is probably honigthau, which is German for honey-dew, which some think to be in all cases the sweetish liquid thrown out by aphides or plant-lice, while others think it also is produced in some cases as a direct

exudation from plants. If your bees had much of that for their winter stores, they will not winter so well as upon flower honey. Sometimes, however, it seems to be all right.

3. No bee-paper is published in this country in any other than the English language. Some of our ablest bee-keepers in this country are German, but they are familiar also with the English language in nearly all cases, and a German bee-paper could hardly have a living support. Some, however, get bee-papers from Germany, where some able ones are published. We owe a deep debt of gratitude to Germans for their careful investigations, especially to Dr. Dzierzon for the Dzierzon theory.

Locating an Apiary.

Inclosed is a rough drawing of a section of country in Winnebago County, Wis. I would like to get your opinion in regard to which place you think would be the best to locate a bee-yard. You will see by the drawing where they were last season, and another place marked where I had some thought of placing them next season. This is a level country, no hills and no woods to fly over; the river is about 40 rods wide, and a good many bees drop in the water on days that are still and no wind, when they are loaded heavy with honey.

I have 114 colonies in the cellar, but they are not doing as well as you say yours were Jan. 5. WISCONSIN.

ANSWER.—Your question is exceedingly difficult to answer. As I understand the drawing, the question is between the location you had last year and one a mile farther south. Last year's location seems to be more fully in white clover, while the new location brings you nearer a patch of basswood (which, however, was not so very far from the old location,) and nearer a marsh of wild rice and fall flowers. On the whole, as there is a good allowance of white clover and a little better chance on the other things, it is altogether likely that the southern location may be the best. You can only be sure of the matter by trying a number in each location in the same year. Even then, it is possible that another year might not show exactly the same result.

Getting Honey and Increase.

In order to obtain the most honey and at the same time double the number of colonies, would it be a good plan to take, about the first of June, one frame with the queen and adhering bees to start a nucleus with, allowing the parent colony to rear a young queen? Would this plan be likely to stop swarming, or would the bees be likely to swarm with the first queen hatch? If you know of a better method that is not too laborious kindly let me know.

SUBSCRIBER.

ANSWER.—You can hardly take a surer plan to make your bees swarm than the one you propose. Instead of that, you might take from the old hive all but two or three of its combs, taking with each comb its adhering bees, putting these on a new stand, leaving on the old stand the two or three combs with the old queen, filling up with foundation.

Perhaps Pickled Brood.

We have had bees for about 15 years, and they had been very healthy until the spring of 1897, when I noticed dead brood in several hives. I at once supposed they had foul brood. I read up carefully on the subject and again examined them, and decided that they didn't have foul brood.

About 5 or 6 colonies are badly affected, and two swarmed out. I destroyed their combs. One colony got away, and the other one I lived on empty combs and they did real well.

While I was trying to devise some treatment, new honey and pollen began coming in, and the disease disappeared as if by magic. It did not appear again that year, or in 1898, that I noticed, except one or two colonies I thought were slightly affected, but last year (1899) it appeared again with a vengeance. I found evidences of the disease in about 90 percent of my colonies, and am inclined to believe that all were more or less affected.

SYMPTOMS.—I winter my bees in the cellar. Last winter they had the dysentery before removing them, and their combs were quite foul and moldy—the mold seemed to extend into the bee-bread as well. I fed sugar syrup and placed corn meal within easy reach of them to stimulate brood-rearing. Their first brood seemed all right, but within less than a month the brood began to die. In some colonies the bees would seem to shrink from the dead larvae and leave them in the cell, while in other colonies they would remove the dead and you would hardly notice the disease.

The dead larvae in the cells usually remained white for a day or so, then they would turn a light brown color and became watery and soft, but would not be "ropy," nor give off an offensive odor as in foul brood. The larvae were invariably attacked just before they were sealed, but some brood died after it was sealed.

The old bees seemed to be affected, too, as the bees disappeared from some colonies, and good young queens disappeared quite often also. I know that my bees were thoroly disheartened, and swarmed out very often.

The moths that never used to attack my Italian bees seemed to have perfect freedom to do as they pleased, and they worked great havoc.

I read an article on pickled brood, and I suppose that is what

ails my bees. I know that the bee-bread seemed to be moldy, and as the year was a poor one, the bees did not replace it with fresh.

What I would like to know is, what ails my bees and what I must do to get rid of it. What is pickled brood? Is pickled brood caused by mold in bee-bread? Would it remove the cause of pickled brood to cut out all bee-bread in the spring and feed flour, meal, etc., in its stead? Would medicated syrup help to effect a cure? How can I remove pickled brood? Is there any book on pickled brood?

IOWA.

ANSWER.—Answering your questions as a job lot, without taking them in exact order, this matter of bee-diseases seems to be getting more complicated all the time. At present they are having a time in New York, especially the eastern part of the State, with a disease that seems much like foul brood, but is now said with positiveness not to be that disease. Just what it is, and what is the cure for it, seems left for the future. Your disease may be pickled brood, but I don't know enough to say positively. There is no book on pickled brood, I think, the nearest to it being a leaflet published at the Bee Journal office. Page 577 of this journal for 1896, and page 530 for 1898, give a good deal of information as to pickled brood. Instead of becoming ropy and foul-smelling, the brood seems to sour and become watery without any smell. Moldy pollen favors the disease, and a plenty of fresh pollen favors its disappearance. From that it would appear that your suggestion to cut out all pollen and give a substitute ought to be a benefit, but I don't know for certain. There seems to be no testimony in favor of feeding medicated syrup.

A sample sent to Dr. Wm. R. Howard, 502 Main St., Ft. Worth, Texas, might decide at least what the disease is.

Increase by Swarming and Dividing.

I have 5 colonies of Italian bees and want them to swarm once. Would it do after they cast a swarm to divide the old colony into 4-frame nuclei, and introduce a queen in each?

In the A B C of Bee-Culture, page 204, it says there is one objection and that is, some of the bees will return to the parent colony. On the same page it says of Mr. Somerford's plan, that he leaves a queen-cell in each hive and stops the entrances with moss, and lets the bees gnaw out; by so doing they all stay.

I can't do this, as my neighbor keeps black bees. Would it answer the same purpose to close the entrance to the hive after introducing the queen?

ALEXANDRIA.

ANSWER.—Yes, from each colony that has swarmed you can make two nuclei having four frames each, and if the season is good enough they may make their way without any help, otherwise they will need help. You can use the closed-entrance plan all the same, whether you introduce queens or not. But in your case it will hardly be necessary to close the entrances, for dividing the mother colony in two will give you pretty strong nuclei. If you put the swarm on a new stand, and leave one of the nuclei on the old stand, you will certainly not need to close the entrance of the nucleus left on the old stand, for no bees will leave the old stand. The probability, however, is that you will put the swarm on the old stand; and if at the time you do that you divide the old colony into two parts, setting each part in a new place, enough bees will be left in each to make a good nucleus. A day or two after swarming, cut out all queen-cells in the nuclei, and they will be in good condition to receive a queen.

Making Nuclei—Stimulative Feeding.

1. I was much interested in Mr. F. L. Rehn's nucleus method on page 33, but I cannot understand how he keeps the bees in the nuclei from smothering after he "plugs the entrance with fresh grass as tight as possible and nails a strip of wood across," and leaves them so for 5 days.

2. Also, he mentions in two places that he gives frames with $\frac{1}{4}$ sheets of foundation; would it not be as good or better to give full sheets?

3. Will sugar syrup do for stimulative feeding? HOSPER.

ANSWER.—1. If you have ever tried closing tight a strong colony on a hot day, I don't wonder that you think it might be dangerous. But it is quite a different matter when you put only two or three combs with adhering bees in a full-sized hive, and you could hardly seal the entrance close enough to smother them.

2. I think the full sheets would be an improvement.

3. Yes, but it is not considered so good as honey. The Germans do a good deal in that line, and favor the use of honey and pollen masht up together.

If you are intending to follow the example given, it may not be out of place to remark that you will hardly get so good queens if cells are started in weak nuclei.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY,
118 Michigan Street, Chicago, Ill.

[Entered at the Post-Office at Chicago as Second-Class Mail-Matter.]

EDITOR:

GEORGE W. YORK.

DEPARTMENT EDITORS:

DR. C. C. MILLER, "Questionous and Answers." ** E. E. HASTY, "The Afterthought."

LEADING CONTRIBUTORS:

G. M. DOOLITTLE, F. A. SNELL, C. P. DADANT, R. C. AIKIN, PROF. A. J. COOK, "OLD GRIMES."

IMPORTANT NOTICES:

The Subscription Price of this journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec00" on your label shows that it is paid to the end of December, 1900.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

VOL. 40. FEBRUARY 8, 1900. NO. 6

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "i" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

Mr. Theilmann's Honey-Lawsuit.—We are pleased to be permitted to give a short history of this celebrated case. Mr. Theilmann deserves the hearty thanks of every honey shipper for his Boer-like tenacity and genuine fighting qualities shown in running down a Chicago commission shark. If only the others, who at that time (in 1896) could have had a similar dose, it would have been very beneficial to the legitimate commission business and a satisfaction to many honey-producers.

We desire personally to congratulate Mr. Theilmann upon the success which has finally crowned his efforts in this exceedingly trying case. While to push the case to a finish undoubtedly cost about all the over 10,000 pounds of honey was worth, it is money well invested. Mr. Theilmann has not only done a good thing for himself, but has placed every bee-keeper in the land in his debt. Hurrah for Mr. Theilmann and all who help him get deserved justice!

Some Articles on Honey-Production—a connected series—will be published in the Bee Journal before July 1, next, written by that very practical bee-keeper and fluent writer, Mr. R. C. Aikin, of Colorado, the hustling president of the Colorado State Bee-Keepers' Association. The series will begin with comb honey, giving the details of management which is the foundation of success. Before they are

closed there will be a treatise on extracted-honey production, following up the whole matter to the marketing of the product.

It will pay every one of our subscribers to read Mr. Aikin's articles carefully, and try to put his excellent ideas into practice. His articles alone will be worth more than the dollar subscription price of the Bee Journal, to say nothing of the many valuable articles written by Messrs. C. P. Dadant, G. M. Doolittle, Prof. Cook, and others. The bee-keeper who can not get back more than his little dollar investment in the American Bee Journal each year, must be a queer specimen of humanity. He certainly can't be very much interested in making a success with bees if he isn't wonderfully helped by what some of the leaders in bee-keeping write for these columns every year.

Educating Customers as to Candied Honey.—Whatever may be said for or against selling honey in the granulated form, there is no disputing the fact that whoever succeeds in getting a set of customers educated properly as to the matter will have an easier time of it ever after. There seems just now to be a mild tide setting in favor of the practice, and Dr. A. B. Mason is found in the ranks of those who have "good words" to say for it. He says in the Bee-Keepers' Review:

"Several months ago I was in a grocery in this city and saw several dozen jelly-tumblers of candied honey that had evidently been put aside as unsalable. I saw the producer's name (a Michigander) on the label, and knowing the producer well, I knew the honey was all right. I asked one of the salesmen if they had any good extracted honey for sale. He said, 'No; we have some adulterated stuff we bought for honey, but it's no good.' He showed me some of it, and I soon showed him that it was first-class honey, and how to put it in the same liquid condition it was in when they bought it; and I believe they now sell more candied honey than they do of the liquid."

Sub-Earth Ventilation for Cellars had a good many advocates a few years ago. The theory was that if the air could enter thru tile buried four or five feet deep, it would enter at a raised temperature, thus giving fresh air without cooling off the cellar. One after another of its advocates have apparently abandoned it, and now Dr. Miller, one of its most faithful adherents, confesses in Gleanings in Bee-Culture that his sub-ventilator has become clogged, and that he has not taken the pains to clean it out, because he is a little skeptical that the quality of the air thus introduced is not as good as that which finds its way thru the cracks in the walls of the cellar. But he insists as strongly as ever upon the advantage of a stove in the cellar when the temperature is too low, and even when not too low, but when the temperature outside and inside is so nearly alike that there is no change of air.

Eccentricities of Candied Honey.—The editor of Gleanings in Bee-Culture says that at the Colorado convention some of those present reported that their honey, after candying solid, would return partly to a liquid form. Indeed, in some cases it happened that one can would candy solid, while another, filled out of the same lot of honey at the same time, would remain liquid. Editor Root explains:

"As we learned later in the convention from Dr. Hedden, of the Colorado Agricultural College, there is only a certain portion of honey that really candies or assumes the granular form. Honey is made up of two elements besides water—levulose and dextrose. The latter candies, and the former remains a liquid. When one looks at a jar or pail of candied honey it seems almost impossible to believe that every particle of it has not candied. But the Professor explained that, if the mass were subjected to a heavy pressure the liquid portion (the levulose and water) would be squeezed out."

The Rich Honey-Fields of Colorado.—Editor Root, of *Gleanings in Bee-Culture*, was surprised to find how densely some portions of Colorado were occupied by bees, altho these areas are limited, for not a tenth of the State is likely ever to come under cultivation. There is supposed to be considerable overstocking in places, for the amount of the crop rises and falls to some extent with the number of colonies on the field, yet there seems to be no overstocking in some places where the density of occupation would prove ruinous in ordinary locations. J. E. Lyon has about 500 colonies in a location where there are 2,000 colonies within 5 miles of him; and there are locations where 300 colonies can be kept in a single apiary. This is possible where alfalfa and sweet clover both abound. Mr. Root adds:

"Now let me give a word of caution to the tenderfoot of the East who may look with longing eyes over toward Colorado. Take my advice. Keep out of it. The good bee-localities are already overstocked, and I did not learn of a single place where the Easterner or anybody else could locate and go into bee-keeping profitably, or, perhaps, I might say *honorably*, because the localities have been so thoroly taken up that it should be a matter of honor for others to keep out. I know of no way in which one can go into these fields without buying some one out."

Sweets for Children.—In a recent issue of the *Ladies' Home Journal*, Mrs. Rohrer wrote on "The Use of Sweets by Children," and among many excellent things we find this paragraph:

"We have in common use another sweet—honey. This is prepared by the bees from the nectar of various plants; it contains two kinds of sugar—one capable of crystallization, the other not. The former is similar to ordinary glucose. Honey may be taken in small quantities with bread and butter; it should be used from the comb, unstrained. It contains 78.74 percent fruit sugar, with only 2.69 percent of cane sugar."

But we don't quite understand why Mrs. Rohrer should advise the use of comb honey in preference to the extracted, or "strained," as she probably would call it.

Likely Mrs. Rohrer does not know that in all probability two-thirds of the annual honey crop is of the extracted kind, and doubtless the greater part of the honey used for table purposes is in the liquid or extracted form.

As that great honey specialist, Mr. W. A. Selser, lives near the office of the *Ladies' Home Journal*, perhaps he can call in some time and enlighten Mrs. Rohrer on the subject, or at least learn her reasons for recommending comb honey exclusively.

Eucalyptus for Honey and Health.—Dr. J. McLean, of Alameda Co., Calif., writing us Jan. 3, had this to say about eucalyptus and its honey, as well as something about the value of the tree as an impurity absorber for cities:

Dear Sir:—It has just occurred to me that it might be well for you to know—if yet unknown to you—that honey obtained from the flowers and leaves of the eucalyptus tree is worth 50 percent more than any other honey, however fine in quality it may be. I have for many years used it in Australia for many human ailments, with wonderful results every time—no human mixture can equal its curative properties, and were mankind made conscious of the marvellous benefits to be derived from the use of such honey, an extensive and ready sale would be sure to follow.

I am, however, conscious of the difficulty you would have in your peculiar climate to successfully cultivate eucalyptus plants of the eucalyptus globulus, or of the eucalyptus anygdalena species, yet there are others in the 150 different varieties quite hardy enough to thrive well with you, and would form splendid wind-breaks and hoar-frost-destroying fringes around your vineyards and orchards—planted 8 feet apart, and helpt properly to grow until one or two years old, no invasion of locusts or grasshoppers could approach the enclosure within 30 or 40 feet.

Bees love to work and rest amidst the evergreen euca-

lypti foliage, because of the agreeable warmth and sweet odor evolved all the year around from such.

Eight years ago I suggested in a treatise on the fever-destroying properties of the eucalypti, that fringes of choice eucalypti plants should be planted on the streets in Chicago by the corporation, placed in suitable guards so that six or more plants be placed in charge of every adjacent residence, and an annual reward be given for the best kept plot of plants—on an arbor day set apart for the special purpose of encouraging the growth and ornamental appearance of said plants.

If such a course were adopted, you might ere long transform the now unbearable, stewy summer heat, and perishing winter colds, into most agreeable and healthful temperatures during those seasons in and around your city.

For 20 years I was officially connected with forestry in Australia, and therefore know something of what I now suggest. I would be pleased in any way to aid the Chicago corporation should such an idea be favorably considered, even to the supervising of the planting operations.

Sincerely yours,

DR. McLEAN.

Certainly, it is very kind in Dr. McLean to offer to aid Chicago in an effort to become healthier by planting eucalypti. We wish the "city fathers" could be interested in the matter, but fear it would be a hopeless task.

Distance Bees Work.—Mr. Ira Barber gives some items in the *Bee-Keepers' Review*. In 1871 his bees worked on celandine or touch-me-not that covered a fire-slashing whose nearest point was four miles from him, and the farthest point nine miles. His bees were just as busy nine miles away as four miles, bringing in 5,000 pounds of celandine honey for which he got 25 cents a pound. His bees work on linden eight miles and more away. In 1897 they gathered 3,000 pounds of honey from lindens ten miles distant. He thinks bees prefer long distances. His bees have worked on alsike clover five miles away, when abundance of it was scarcely visited close by.

"Again," he says, "I have seen basswood blossoms fairly float with nectar right in my bee-yard, with colonies right under the branches, and remain there all day with scarcely a bee to be seen on them, while the entire force of the yard was going miles from home, in search of the same kind of honey."

MR. T. F. BINGHAM, of Clare Co., Mich., writing us under date of Jan. 30, said:

"My bees are doing well. We have no sleighing. The cellar is at 47 degrees, and not below 46 degrees so far, with bees quiet. It has usually been 50 degrees."

DR. MASON says this among his "good things" in the *Bee-Keepers' Review*: "I believe we as bee-keepers and honey-producers owe Bro. York a vote of thanks for inaugurating such a course"—talking bees and honey to school children. He thinks that parents of the children and others might be invited in, and that interest might be added by the use of large drawings of important parts of bees, also samples of honey.

MR. O. L. HERSHISER, we understand, did some good work in the Buffalo, N. Y., public schools the past year, in talking on bees to the scholars. We believe he was invited into nearly all the schools, and with bees, hive, and other things apiarian, enlightened the young minds a good deal concerning the little busy bee and its work. Mr. Hershiser was invited to do this by the superintendent of schools, we believe. It would be a fine thing if more of the kind could be done in every public school in the land.

Plain Sections do not sell so well in the west as the old style, according to F. L. Thompson, in the *Progressive Bee-Keeper*, for retailers must have it explained to them that plain sections hold as much as the others before they will take them. He says:

"Plain sections have as yet just two advantages, and no others, over all other sections; they are easily scraped, and there is less wood in proportion to the honey, because the comb comes closer to a straight edge laid across. In other respects, they are not perceptibly better filled than the old-style sections, and I'd like to know the color of his hair who is going to prove they are. They have no particular disadvantages; and when plain sections can be bought cheaper than any others, then they will have two more advantages. But at present they only have the two referred to."

The New York Disease Not Foul Brood.—Editor. Root attended the convention of New York bee-keepers at Geneva, and of course the new disease that is making such ravages in eastern portions of the State was a live topic. Editor Root says in *Gleanings in Bee-Culture*:

"From all the evidence presented, I feel sure in my own mind, at least, that it is not foul brood, because it differs in quite a number of important symptoms. Prof. Benton, from the Department of Agriculture, stated that so far the examinations with the microscope had *not* shown the *Bacillus alvei* in the diseased matter that had been sent to the Department from the affected districts. The preliminary examinations of Bacteriologist Howard, of Texas, seem to be to the same effect. It appears, however, whatever it is, that it is very contagious as well as destructive."

Home-Made Bicycle Foot-Power Buzz-Saw.—The time has come when bicycles that have been cast aside are by no means uncommon, and of one of these C. H. Pierce has rigged a power to run a buzz-saw. He says in *Gleanings in Bee-Culture*:

"It is the easiest-running foot-power saw I have ever tried. The saw revolves about 3,500 times per minute. I use it and the parallel gauges. In cutting off I have to pedal backward; but to a man used to the motion of a bicycle, that is nothing. In ripping I change my saw and pedal forward, drawing all my stuff toward me with a stick with a short sharp brad in it. The boards, being all short, are just as easy to handle, and all dust is thrown from the operator. The fly (or belt) wheel is the rear wheel to a bicycle, and in place of the tire it has about seven pounds of lead run into the hollow rim to give the wheel weight. Any one used to wheeling can sit in the saddle and work this machine with perfect ease."

Bees in a Schoolroom.—Prof. C. F. Hodge, of Clark University, tells in *Gleanings in Bee-Culture* how he awakened interest by the use of nature itself as a textbook. He says:

"For an entire season I had a honey-section hive in my study-window, and the whole time it was the most fascinating thing in the room. It was made from an ordinary pound section by driving brads into the corners, letting them stick out half an inch at the bottom for it to stand on, and $\frac{1}{4}$ inch from the sides and top to insure a bee-space all around. The glass case that fitted over it was made simply by cutting glass the proper size, gluing the corners together with narrow strips of cotton cloth, and carefully searing hot beeswax into the corners on the inside to prevent the moisture of the bees from softening the glue. To stock it I put in a handful of bees with an old queen which I wish to supersede. She laid the little hive full of eggs, and then decamped. The bees immediately set to work making queen-cells; and, happening to be cutting out a lot, I put in two large queen-cells—one of them, with malice aforethought, protected with screen wire.

"The queen from the unprotected cell emerged first, and then I had the whole story of 'piping' and 'quahking' where every movement could be easily observed. At noon

of the second day after piping began, the colony cast a swarm, which clustered about the size of a spool of thread, in the snowball bush in front of the window. I hived it back, removing the offending quahker, and the young queen staid, and laid, and kept up the colony until cold weather. I saw her take her nuptial flight. She was gone about 10 minutes, and returned with the organs of the drone. Within 15 minutes after the bees had removed these she flew again, and in 5 minutes returned with a second trophy of success.

Almost any day I could see a little bee emerge and make its first toilet—a most fascinating performance, and at all times I could observe the bringing-in and disposal of honey and pollen. I painted bees with different colors, and watcht them work from daylight to dark—that is, I watcht them from daylight to dark; but no single bee that I watcht ever workt more than $3\frac{1}{2}$ hours a day. Then there were all the different divisions of labor—the field-bees, the nurse-bees, the wax-producers, the police, the barbers, the drones, and the queen.

"I mention all these things to show how many interesting points in the natural history of the hive can be intelligently observed and studied in so small a device—an old honey-section, a handful of bees, a discarded queen-cell, and a few scraps of broken glass, all of which need not cost a penny. And I will guarantee that it will be worth more to a roomful of children than \$10 worth of books about natural history; but, of course, we need some books as well. And with all that has been written, not half the whole story of the hive has ever been told."

Burr-Combs.—Messrs. Aikin and Doolittle have their own times at having little family quarrels (?) in the *Progressive Bee-Keeper*. Mr. Aikin advocated divisible brood-chambers. Mr. Doolittle objected, amongst other things, to the burr-combs built between the parts. That was Mr. Aikin's chance, and he was prompt to recall that a certain man whose initials were G. M. D. had championed burr-combs, saying they "were fine things—made 'ladders' and steps for bees to 'climb to supers.'" But the big man with the small name was equal to the occasion, and smilingly replied that burr-combs are one thing between the parts of a divisible brood-chamber, and quite another thing between topbars and super—in the first case, "a disgusting, bee-killing, temper-losing, non-paying nuisance;" in the second case, a *paying* nuisance. In favor of this latter view he makes out a stronger case than ever before. A fresh argument in favor of burr-combs is that when an escape is put under a super, the bees fill up on the honey that is in the burr-combs instead of tearing open the sections. His heavy artillery, however, is a dollar and cent argument, after the following fashion, which also appears on page 37 of this journal:

"This past poor season I had several colonies which did not have a single ladder on top of the frames, while the majority did so have, from 1 to 10, perhaps 12 to 15, on some. Those colonies having *ladders* to the supers, gave an average of about 10 filled sections more to the colony than did those having no ladders. This honey averaged me 12 cents per pound net, or \$1.20 was given by those laddered hives or colonies over the no-laddered ones, as the pay I received for the nuisance of having to pry a little harder when taking off the supers, and having to clean off that part of them which adhered to the bottoms of the wide frames used in the supers."

It might be interesting to learn *why* these few colonies had no burr-combs on the top-bars. If because the colonies were not so strong and crowded, hence had not built burr-combs, the force of the argument might be weakened—but it is not well to be too inquisitive in a family quarrel!

York's Honey Calendar for 1900 is a 16-page pamphlet especially gotten up to create a demand for honey among should-be consumers. The forepart was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample free; 25 copies for 30 cents; 50 for 50 cents; 100 for 90 cents; 250 for \$2.00; 500 for \$3.50. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

GENERAL ITEMS

Selling Extracted Honey.

Look on this picture: There is no sense in the idea that honey to be good must be white in color, nor that honey in tall sections is better than in square ones. My honey this year was from white clover, goldenrod, asters and heartsease, all blended together, and many persons prefer this honey to any other. A market can be had in the northwest, or elsewhere, for such honey in case bee-keepers demand it, and are firm in asking the price it is worth. It is my belief that bee-keepers have lost, and are losing money, by not having the grit to ask the price their honey is worth. It is the weak-kneed fellows who lower or adulterate the price on honey for the rest of the fraternity. Thus writes Harry Lathrop, in substance, on page 51, and I happen to know that Harry's statements are not far from the truth.

Now look on this picture: My practice is to put my extracted honey into 2-quart tins, holding 4½ pounds each, net weight, and sell the whole package for 50 cents, which gives me 10 cents per pound for the honey, and covers the cost of the pail. Thus writes a correspondent on page 60, same number of the American Bee Journal.

Now this bee-keeper must be one of the "weak-kneed fellows" Harry refers to, or had in mind. But it may be possible that the price he asks, or gets for his honey, and from the consumer, is every cent it is worth. Or possibly his market for honey may have been glutted. The fact that he got, as he says, "60 pounds from 65 colonies" would somewhat indicate that there must have been a flood of something somewhere. M. M. BALDRIDGE.

U. S., Jan. 27.

Bees and Fruit—Requeening.

I have been a constant reader of the American Bee Journal for the past 4 years, and feel that I could not get along without it. It is indeed of great value to the bee-keeper, and should be found in the homes of all agriculturists, especially fruit-growers. Since I have been keeping bees I notice that our cherry crop is much larger than before, which, I believe, is caused by the bees fertilizing the imperfect blossoms.

We have 16 colonies of bees in fine condition, which we had requeened last fall with the golden Italian. Two colonies we requeened in August do not prove very satisfactory; both queens have been laying and rearing drones all fall (part drones and part workers.) Will they be all right when spring comes? We got them for tested queens, from a responsible queen-breeder, in Ohio.

We are having a very pleasant winter so far. The coldest weather we have had this winter was Dec. 16, when the mercury reached 14° above zero. At present the mercury stands at 60° above, and the bright yellow bees are flying in great numbers before the hives. They are gathering some pollen, and are flying about the water, which are indications of brood-rearing. GEORGE T. SMITH.

Whitman Co., Wash., Jan. 13.

Getting Unfinisht Sections Cleaned.

The following, on getting sections cleaned out by the bees, may perhaps be of value to some of the readers of the American Bee Journal:

"Those having but a limited number of unfinished sections, and who are surrounded by neighboring bee-keepers, will hardly care to pile them up outdoors or in the cellar for the bees to clean out, as by this course much of the honey will be taken by our neighbors' bees. If the sections are piled up on the hives (in supers) the bees

A Good Sign

for a good garden in 1901 is to plant Maule's Seeds. Maule's Seeds lead all, have done so for years and are as far ahead as ever in the race.

PLANT MAULE'S SEEDS

in 1900 and have the finest garden in your neighborhood. Our new catalogue, is the best seed book of the year. It contains hundreds of illustrations, four colored plates, up-to-date cultural directions and offers \$2,000 in cash prizes. It is free to all. Write for it to-day. Address,

WM. HENRY MAULE, PHILADELPHIA.

Please mention Bee Journal when writing.

For Sale at \$5.00 per colony

Shipment April and May, 1900. 50 colonies Bees on Golden's plan for production of Comb Honey, (2) two supers complete with each colony, 30 colonies bees in 8-frame dovetail hives, (2) two supers complete with each colony, and one W. T. Falconer Mfg. Co's winter-case. Reasonable discount on orders for two or more colonies. Correspondence solicited.

Farm Wagon Economy.

The economy of this proposition is not all found in the very reasonable price of the wagon itself, but in the great amount of labor it will save, and its great durability. The Electric

ELECTRIC

Wheel Co., who make this Electric Handy Wagon and the now famous Electric Wheels, have solved the problem of a successful and durable low-down wagon at a reasonable price.

This wagon is composed of the best material throughout—white hickory axles, steel wheels, steel hounds, etc.; guaranteed to carry 4,000 lbs. These Electric Steel Wheels are made to fit any wagon, and make practically a new wagon out of the old one. They can be had in any height desired, and any width of tire up to 8 inches. With an extra set of these wheels a farmer can interchange them with his regular wheels and have a high or low-down wagon at will. Write for catalog of the full "Electric Line" to Electric Wheel Co., Box 16, Quincy, Ill. Mention the Bee Journal.

will be very slow in removing the honey. All unfinished sections should have the cappings bruised by a knife; cells containing honey but not capt, should have the thick rim at the mouth of the cell bruised, then fill supers with them. Then go to several colonies having little honey or brood in the brood-chambers, remove the cover, put on an empty super, then on top of this put the supers of unfinished sections, as many as you please on each hive, and replace the cover. Having all cells bruised, and the sections removed several inches from the brood-chamber, the bees are very quick to remove all honey from them. In three or four days remove the supers, and the job is done. Always put on the supers of unfinished sections at night, then by morning the bees will defend themselves against robbers." **E. F. ATWATER.**
Yankton Co., S. Dak.

Poor Season Last Year.

Bees did poorly last year. I got scarcely any honey to sell. I have 52 colonies in good shape for next season, which I hope may be a fine one. Bees have had two good flights, and all is well so far as I can see. **HENRY LOHAUS.**
Platte Co., Nebr., Jan. 25.

Bees Outdoors in Winter.

Bees are wintering very nicely so far, where they had the proper attention in going into winter quarters. But should this warm weather continue long there will be reports of heavy loss by starvation. My experience has been that bees consume more food in an extremely warm winter than in a reasonably cold one. In a warm winter, when they can fly every day, they feed the queen, stimulating egg-producing food, with the result that she lays too many eggs; these eggs must be cared for, the larvae fed, and the "babies" reared, which consumes a large amount of food; and it frequently happens that just as they get the brood-chamber full of young bees there comes one of those cold waves, and—well, good-by, young bees. Spring result, a starved-out colony that under a more severe winter would have pulled thru all right.

In examining my bees I find much more brood than is usual at this time of year. Of course, I am speaking of bees wintered on the summer stands (and that is the way we all winter here).

GEO. W. WILLIAMS.
Polk Co., Mo., Jan. 24.

Moving Bees to Pasturage.

I had 32 colonies, spring count, in 1899, increased to 54, and got 3,150 pounds of extracted honey, and 150 pounds of comb honey. I always divide my bees about swarming-time, and aim to have a queen for all of the swarms, so they won't lose so much time in rearing them.

My honey-house, on the west of the beeyard, is 16 feet long, and then I have a board-fence 8 feet high running north 30 feet and east 50 feet, so I have a wind-break for the bees. I put the hives 6 feet apart each way. I have no shade for them except artificial, and I use it for shelter in the winter.

Every fall, about Aug. 1, I move the bees to the Illinois bottom for the Spanish-needle and heartsease, which is in abundance in a common season. It is about 12 miles there. I move them on a spring wagon, and can haul 10 on each load. I always take three loads, and leave the rest at home for the buckwheat crop.

I will give you an account of what I did in the fall of 1897. August 10 I moved the bees, and on the 24th we extracted two barrels of honey; on Sept. 4 we extracted two more barrels—that was just 10 days. This was done from 29 colonies; we moved 30, but one had no queen, so it did nothing.

I have a good trade in honey, selling out all I had three weeks ago, so I have no honey now for my customers. I sell my honey mostly in tin pails of three sizes, 4,

DR. MILLER'S
Honey Queens

One Untested Queen Free as a Premium for sending TWO New Subscribers to the American Bee Journal for one year.

We have been fortunate in making an arrangement with DR. C. C. MILLER—the well-known honey-specialist—to rear queens EXCLUSIVELY FOR US DURING THE

SEASON OF 1900. These Queens will be mailed in rotation, beginning about June 1, so "first come first served." We are ready to book orders now.

The Queens Dr. Miller will send out on our orders will be precisely the same as those he rears for his own use, so of course they will be from his best stock. His best colony in 1899 had a queen reared in 1898; May 5, 1899, it had brood in 4 frames, and he gave it at that time a frame of brood without bees. It had no other help, but May 25 a frame of brood with adhering bees was taken from it, and the same thing was repeated June 3, leaving it at that time 5 frames of brood. It stored 178 sections of honey, weighing 159 pounds (and that after July 20, in a poor season), being 2 3/4 times the average yield of all his colonies. A point of importance is the fact this colony did not swarm, and an inspection every week or 10 days showed that at no time during the entire season was there even so much as an egg in a queen-cell. Dr. Miller expects to rear queens from this one during the coming summer.

The demand nowadays is for BEES THAT GET THE HONEY when there is any to get, and Dr. Miller has such bees. You will want to have a queen from his best, we are sure.

Do not send any orders to Dr. Miller, as all orders MUST come thru us, according to our agreement.

Remember, send us \$2.00 for TWO NEW SUBSCRIBERS to the American Bee Journal for one year, and YOU will get ONE OF DR. MILLER'S UNTESTED HONEY-QUEENS FREE AS A PREMIUM. Orders for queens to be filled in rotation, beginning about June 1st.

Address all orders to **GEORGE W. YORK & CO.,**
118 Michigan Street, CHICAGO, ILL.

7 and 14 pounds. It is a good way to handle it.

I have my bees packed for winter in a way I never tried before. I set a row of the hives all around the board fence 6 inches apart, and 6 inches from the fence, and packed clover chaff in between and behind them; and then I set another row of hives right on top of them, and packed them with clover chaff, and covered the whole of them with boards, so they will keep dry.

I use the Simplicity hive, which is as good as any. I almost always buy my queens to increase with, so they will build up my stock with Italians, which are my choice.

The bee-business is like any other business, you can't make anything out of it unless you study hard and work hard, and stay with it.

JAMES GROVER.
Brown Co., Ill., Jan. 16.

A Beautiful Winter.

We are having a beautiful winter on the "Great American Desert." Our bees are wintering in good shape. We are hoping for a good harvest this year. Alfalfa is our main honey-plant.

J. C. ALLEN.
Finney Co., Kan., Jan. 27.

Wintering of Bees Assured.

Since I wrote before (Dec. 24, 1899) we have had most excellent weather. During this month my bees have had flights on 14 days; and the last day they were out was on the 23rd. Thus their wintering is pretty well assured. Since yesterday cold weather has set in once more, and it is very agreeable to know that my bees are well cared for, and ready to cope with any kind of bad weather that may come.

WM. STOLLEY.
Hall Co., Nebr., Jan. 26.

No Winter Yet, and Bees Fly.

We have had no snow or winter yet. Bees fly nearly every day, and are in fine condition.

T. J. GREEN.
Whitman Co., Wash., Jan. 24.

Foul Brood and Moth in Colorado.

We have foul brood in this vicinity, but are fighting hard to down it. I notice Mr. Root speaks of no bee-moth in Colorado. I could have shown him hundreds in old combs where the bees died of foul brood during last June. However, I do not notice that the moth damages good, healthy colonies that are strong.

Few bee-keepers manage their bees in a skillful manner, hence it is difficult to find honey suitable to ship. It retails here at 10 and 12 1/2 cents for No. 1 and 2; extracted sells for 7 to 10 cents. Bees winter with very little protection. They flew nicely today, when the sun shown. It freezes every night, but as there is no snow on the ground it is fine when the sun shines.

A. F. FOSTER.
Boulder Co., Colo., Jan. 22.

A General Report—Light Sections.

Bees are wintering well so far, having a good flight every two weeks. The last on Jan. 24.

The prospects are not very favorable for honey from clover next summer, as there has not been enough snow yet to cover the ground at any time, and the present cold and windy weather is very liable to kill out the clover, as happened last winter.

I lost 32 percent of my bees last winter, but nearly made up the loss by new swarms, which are strong with bees and heavy with honey. Bees built up wonderfully in the spring, but came nearly starving in June. Then came swarming in July and August, with a good crop of buckwheat, heartsease, etc., storing an average surplus of 45 pounds, which I sold at 12 to 15 cents a pound.

Basswood and Clover Honey In 60-Pound CANS.

We have a quantity of FINE WHITE EXTRACTED HONEY in 60-pound cans, gathered from basswood and clover—about one-quarter basswood, which gives it a fine flavor. We will liquefy this honey before shipping, and furnish it f.o.b. Chicago at these prices:

A sample by mail, 10 cents; two 60-pound cans in a box, at 9 1/2 cents a pound; four or more cans, at 9 cents a pound. Address,

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO.

bee-keeper producing comb honey to use a section holding about one pound. It would take less sections, separators, section-holders, foundation, etc., for a certain amount of honey. It would make quite an item in good years; and as a penny saved is a penny earned, it will apply as well to the above as in any other transaction. Also, the store-keeper always wants to buy your light weights by the pound, and retail them by the section. Many consumers are thus deceived, as they think they are getting a pound when they are not. It is also one of the causes of low prices. E. J. BABB. Stephenson Co., Ill., Jan. 29.

Bees Had Fine Fights.

Bees had a fine flight last Friday, and several good ones since, and seem to be in splendid condition. We have had several days of fine spring weather.

GEO. SPITLER.
Crawford Co., Pa., Jan. 24.

A Report for 1899.

Bees and honey in this locality the past year were almost a failure. I got a fair yield when other bee-keepers failed. From 40 colonies I had 1,100 pounds, mostly comb honey, which I sold at 15 cents for comb, and 10 cents for the extracted. Last winter was very severe on bees in this locality. A great many bee-keepers lost all their bees. What few bees were left were very weak. The trouble was honey-dew, which the bees gathered for winter stores. I lost 14 colonies—the first I have lost since I began bee-keeping, in 1893. Bees so far are wintering well. They went into winter quarters with plenty of good honey. They had three flights in December, and four flights to date this month.

The American Bee Journal has improved in all departments. Long may it live. J. W. PAYNE. Vermilion Co., Ill., Jan. 23.

The Prospects—Origin of Foul Brood

What does any one know about the Samoan Islands as a honey country? I hear it said that the climate is very fine, and summer all winter; and if I had any assurance of its being a good honey country I would go over and try my hand there awhile.

We feel very much encouraged here for the coming season. The rainfall has been quite good. We have had five or six inches already, and the eucalyptus, walnut, gooseberry, sycamore, buckhorn, redwood, and many other trees, are out in bloom. Horehound, filaree, mustard, and many weeds are also coming into bloom. Bees in good condition are bringing in heavy loads of pollen and storing a little honey. Everything seems promising for a good crop of honey this year.

I don't like the way many bee-keepers

4A3t

here handle their bees; but few take a bee-paper, or ever get a new queen. I think there are apiaries here that have not had a new queen for 20 years, and they would rather lose their bees than feed them.

I think the germ of foul brood comes from the egg of a parasite or small fly, deposited in the flower and carried by the bees in the pollen, being so small as to admit of being mixt with the food and fed to the larvæ; hatching out quickly after being moistened with the food, it devours the young bee, eats a hole thru the cap of the cell and disappears. Nor do I think it probable that the pollen from early bloom ever contains these eggs. I don't think for one moment that foul brood is contagious thru the use of honey, especially extracted honey. In case of a late flow, bees often store honey on top of pollen already in the cells, which pollen may contain these eggs that may not hatch until disturbed in the spring.

W. A. JOHNSON.

Los Angeles Co., Calif., Jan. 11.

The Page Woven Wire Fence Co., Adrian, Mich., have for nine years past issued a paper called The Coiled Spring Hustler. The name has been changed to Page Fence Age, but it is the same "Hustler" as ever, devoted to the interests of Page Woven Wire Fence, and full of information concerning it. It will be sent free to any farmer who asks for it. We can assure our readers that it is worth sending for. Ask also for their "Blue Folder," which gives complete descriptions of the different styles of Page Fence. When writing, please mention the American Bee Journal.

The Sure Hatch Incubator Co., of Clay Center, Nebr., received first premiums at the Kansas and the Nebraska State Poultry Shows. Maule's Seed Catalog for 1900.—As the years come and go the efforts of the leading seedsmen to publish catalogs which will keep pace with the improvement in the art of printing are never relax. Each succeeding year brings to our table more elaborate and handsome ones. This year the front cover page of "Maule's Seed Catalog for 1900" appeals to all lovers of the beautiful, the carnations being among the handsomest specimens of colored printing we have ever seen. The colored illustrations in the body of the book, of flowers and vegetables, as well as the partial view of the trial grounds of Mr. Maule on the back cover, are in keeping with the beauty of the front cover. Its hundred pages are crowded with illustrations and descriptions, as well as cultural directions of the large variety of farm, garden and flower seeds which Mr. Maule carries. A number of new things are listed, the most prominent of which is "Maule's 1900" Tomato, which promises to be the leader in the tomato field. He sends a packet of this new tomato seed free with every order for 50 cents worth of seeds, and offers \$600 in cash for 6 prizes in connection with this tomato, one of \$100 for the most appropriate name. He also offers \$1,900 in cash for specimens of vegetables and flowers grown from Maule's seeds and for the largest club orders sent in during 1900. The catalog will be mailed free to any of our readers who mention this paper, by writing to the publisher, Wm. Henry Maule, Philadelphia, Pa.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Jan. 23.—The trade is taking but little honey; the mild weather may be one cause, but the winter is two-thirds past, and therefore the season is short in which to dispose of what remains unsold; all of our customers speak of a light demand.

Prices remain as formerly quoted, but will be shaded to move round lots.

R. A. BURNETT & Co.

CINCINNATI, Dec. 27.—There is a good demand for all kinds of extracted honey. White clover and basswood sell at 8@8½c; amber and Southern, 6@7c, according to quality and package. Fancy comb honey in no-drip shipping-cases sells at 15@16c; darker grades hard to sell at any price. Beeswax, 26c. C. H. W. WEBER, Successor to Chas. F. Muth & Son and A. Muth.

LOS ANGELES, Jan. 4.—1-pound frames, 12½@15c; 2-pound cans, 2 dozen in case, per dozen, \$2.50; 2-pound glass pails, per dozen, \$2.50. Extracted, water white, 60-pound tins, per pound, 8½c; light amber, 7½@8c; dark amber, 7½c. Beeswax, 25@26c.

KANSAS CITY, Jan. 19.—We quote No. 1 white comb, 13½@14c; No. 2, 13@13½c; No. 1 amber, 13@14c. Extracted, white, 7½@8c; amber, 7@7½c. Beeswax, 20@22c.

The supply and demand for comb honey is light. The demand for extracted since the first of the year not so good. C. C. CLEMONS & Co.

BUFFALO, Jan. 5.—Market bare of fancy white one-pound comb honey, and selling at 15@16c; fair to good, 12@14c; buckwheat, dark, poor, etc., 8@10c. Fancy pure beeswax, 28@30c.
BATTERSON & Co.

NEW YORK, Jan. 10.—Demand is very good for all grades of comb honey. Receipts are somewhat light and not up to former years. We quote:

Fancy white, 15 cents; No. 1, white, 13@14c; amber, 11@12c; and buckwheat, 9@11c., as to quality. Extracted remains firm at following prices: California white, 8½c; light amber, 8c; white clover and basswood, 8c; amber, 7½c. Very little trade for extracted buckwheat as yet. Southern, fancy, 7½c per pound; other grades, as to quality, from 70c to 75c gallon. Beeswax quiet at 26@27c. HILDRETH & SEGELKEN.

SAN FRANCISCO, Jan. 10.—White comb, 11½@12½c; amber, 8@10c. Extracted, white, 7½@8c, light amber, 7@7½c; amber, 5@5½c; Beeswax, 26@27c.

Offerings and demand are both light, and this must continue to be the case until the end of the season. Business is necessarily of a retail character, but at generally firm figures, especially for choice extracted, which is in lighter supply than comb.

BOSTON, Jan. 12.—We quote as follows: Fancy white, 16c; A No. 1, 15c; No. 1, 13@14c; buckwheat will not sell in this city. Extracted, light amber, 7@8c. Demand is very light.

BLAKE, SCOTT & LEE.

ALBANY, Jan. 10.—We quote: Fancy white comb, 15c; No. 1 white, 13@14c; mixt, 11@13c; buckwheat, 10@11c. Extracted, white, 8@9c; mixt, 6½@7c; dark, 6. Beeswax, 26@28c.

MACDOUGAL & Co.

Successors to Chas. McCulloch & Co.

OMAHA, Jan. 4.—Prices remain unchanged. Fancy white is still moving slowly at 14@14½c. Extracted, white, 8½c. Now that holiday trade is over and dealers have taken their inventory, they soon will be thinking of replenishing their stock and more lively trade is anticipated in the near future, but no material advance is looked for during January.
PEYCKE BROS.

DETROIT, Jan. 11.—Fancy white, 16@17c; No. 1, white, 14@15c; dark amber, 10@13c. Extracted, white, 8c; dark and amber, 6@7c. Beeswax, 24@25c.
M. H. HUNT & SON.

WANTED.—Extracted honey, all kinds; mail sample and price expected delivered at Cincinnati. I pay spot cash on delivery.

NO. 2.—COMB HONEY PRODUCTION.

Getting Section Honey from Weak Colonies Can be Done, but Undesirable, and Why.

BY R. C. AIKIN.

THE production of comb honey is a very nice business; but to be successful year by year requires no little knowledge of the business, as well as experience. One may succeed in getting reasonable crops and in fair shape when the season is favorable, but let the season be poor, or the stock in bad condition, and success to even a reasonable degree may not be had. It is the good years—ones with abundant secretion of nectar and unusual crops—that give the amateur and others the bee-fever. They have perhaps one or more colonies that give them a good crop, then they straightway count that to multiply the number of colonies will equally increase the income, forgetting that with a larger apiary there must be some colonies that do not happen to be in prime condition when the others are, and so cut down the general average very much. They also forget that larger crops mean less price, and more effort to sell, etc. I suppose, however, we ought not to expect fever patients to be rational—they usually are flighty.

We will take it for granted that the reader has read my article preceding this, and has carefully studied his location, deciding whether he will produce comb honey, extracted, or both; where and how the product will be marketed, and all the details. Having done so, we will first consider the production of comb honey, and if any reader has determined on extracted honey, he would better read this, too, for it will surely help, tho you never produce a pound of comb honey.

The foundation in producing nice comb honey is to have strong colonies. I say, *have strong colonies* to put up your section honey for you. You can take even a very small colony, 3 to 5 Langstroth combs in size, and produce nice section honey. Yes, you may, in a good season, take nice section honey from a one or two frame nucleus—I have done so in years gone by. This is not contrary, however, to my statement in the second sentence of this paragraph in regard to the necessity of strong colonies to produce section honey—that statement is correct as a fundamental proposition.

Will you take section honey from a few bees? To do so the hive must be proportioned to the colony. I have an observatory hive that I used some years ago; it holds only three Langstroth combs when full. It is made with wooden ends and bottom permanent, and wood top and sides re-

movable. Grooves are cut on the inside of the ends from top to bottom, so that when one comb is hung in the center a pane of glass can be slipped down in the grooves either side of the comb. When more than one comb is needed, one glass side is pulled up and set out one groove farther, making a two-comb colony. If still more room is needed, pull out the glass from the other side and set it in the next groove, thus making room for the third comb. Thus the hive can be quickly changed and made a one, two or three frame colony by simply changing the glass from one groove to another. The wood sides are removable to allow observation, but always occupy the same place, the space between the wood and glass being more or less, as there are more or less combs used.

Having a colony that was getting too large for the three-comb hive, and a honey-flow on, I put some sections on top and spread a cloth over, and so had a number of sections filled. The principle is just this: If the colony is not strong you must fit the hive to the bees if you expect surplus comb honey. In this way one may, by having hives that can be easily contracted, squeeze the brood-chamber so that the bees must store above if they get more than the few empty cells in the brood-nest will hold, always *forcing* bees above or outdoors to find room.

While we can thus fit the hive to the size of the colony at the time the honey-flow comes on, and so get section honey from almost any colony, the plan is not altogether practicable. If the apiarist is one who has plenty of spare time to make the proper adjustments at the right time, can guard them to care for swarms, unite those that do not get strong enough for winter, feed those short of stores in the brood-chamber, and many other little things, such a plan will be fairly good. I say only *fairly* good, it cannot be *good*.

Some of the reasons why not good are these: Two or more weak colonies united are not so good after uniting as is one normal colony that has not been united. The normal colony has its stores in better shape (not always the best shape, but better), they have brood, pollen, honey and empty comb in the most nearly proper position and relation to each other. The united colonies must necessarily have the stores, brood and empty comb more mixed up and in disorder. Such colonies seldom winter as well as those that have been allowed to shape things to suit their own instincts.

Again, those little colonies that are not sufficiently strong for winter, if not united, must be fed, and this takes time and expense. I am confident that much disarrangement of the combs and stores damages the wintering prospects. Bees may be manipulated much without detriment, particularly in the spring; simply opening hives and removing one or more combs to look at any part of the colony usually does little or no harm if the combs are put back just as they were, but a general mixing up of combs that contain pollen, brood and empty cells is detrimental, more or less, save a judicious spreading of brood when the colony can stand it.

Having to feed either for stores, to get bees sufficient to winter, or both, or to have to unite for the same purposes, are expensive and unsatisfactory, yet become necessary by

the method of taking comb honey from small colonies that have to be squeezed or forced to the supers. More than this, it takes greater apiarian skill to handle such methods to obtain success, both in maintaining the stock in proper condition, and in getting a nice, salable product. Few indeed are the apiarists who do not desire increase of stock, and to those who do not want to risk a decrease in their apiary, and to all but the most skillful I must recommend getting surplus from strong colonies only.

My next article will continue this subject, entering more fully into the details of the work.

Larimer Co., Colo.

Price of Swarms and Queens in Germany— Honey in Switzerland.

BY L. STACHELHAUSEN.

ON page 730 (1899), it is said that in Germany the price of honey is very high, but for live bees the bee-keepers would seem to get very unsatisfactory prices, because heather swarms are advertised at 63 cents to \$1.00, and laying queens in the fall for 25 cents.

These low prices need an explanation. Generally the prices for swarms are much higher—75 cents to \$1.00 per pound; queens \$1.00 and more—about the same as in the United States. The bee-keepers in Lueneburg sell bees and queens very cheap only in the fall, and this has a proper reason. In this province prevail circumstances concerning the honey-flow which can hardly be found anywhere else. A management is adopted by the bee-keepers which has been taught in the craft for more than 100 years, from generation to generation, and is well fitted to the condition of the honey-resources.

The main honey-flow is late in the fall, buckwheat and heather, and the purpose of the spring and summer management is to get as many field-bees as possible for this honey-flow. The bees generally belong to the landlord, and he hires a man who has learned the craft during at least two years. This man is called an imker (bee-keeper), and 60 to 80 colonies in straw-skeps are given into his hands in the spring, and he has to manage them all the year around. To get his colonies strong he uses stimulative feeding. In April he migrates with the whole apiary to the river-bottoms, where good meadows will give him a honey-flow; or into the rape-fields, all for the purpose to develop his colonies as much as possible. If the weather is bad, or the honey-flow scarce, he feeds again in small quantities.

In May or June his hives are full of bees and brood, and the colonies can not get any stronger; he expects swarms now, and they do swarm, to be sure, every one of them. He catches them with a swarm-catcher similar to Taylor's, but much simpler and cheaper, and has done so for more than 100 years, without knowing anything of Taylor's invention.

But he wants strong swarms. The after-swarms are weak, so he unites so many that they fill at least one-third of his straw-skeps. These swarms build up to strong colonies by-and-by, if well cared for, and they always get good care.

In July he migrates again with 180 or 240 colonies to the buckwheat fields, from there to the heather, and at last home again. In the fall the prime-swarms are inclined to swarm again; he knows how to prevent this.

Now commences the honey crop. At first he selects carefully 60 or 80 colonies he wants to winter again; they must have a young queen and not too much honey, but plenty. All the other colonies are brimstoned, and the honey cut out. His honey is of the cheapest grade, nevertheless he clears a profit of about 2,000 marks a year for the landlord, and small wages for himself.

Very few bee-keepers with movable-frame hives in Germany do better, many not as well, and besides this they are good customers for the bees and queens the imker would kill anyhow.

Now instead of brimstoning he drums them out and sells them for anything, if he gets paid for the drumming, and he is an expert in this. If he can not sell all the colonies, he sells the queens at least.

The mobilist fills a hive with empty combs and honey-combs, hives the swarm in it, and feeds some sugar if necessary. If he winters the new colony all right, he will have increased his apiary with very little expense. This is the explanation why swarms and queens are sold as cheap by the heather bee-keepers in the fall; they do not cost him anything, and no queen-rearer can compete with him; but he has nothing to sell except in the fall.

Another correction is necessary. At the Philadelphia convention Prof. H. W. Wiley said that in Switzerland honey is adulterated, and that he didn't see a bee-hive while there. He said further: "If you have a variety of bees that can make honey out of snow, take them to Switzerland; they would find there an inexhaustible supply of the raw material."

It is true, and much is written about it in German bee-papers, that in the hotels of Switzerland glucose and other sweets are served to the foreign travelers as honey of the Alps; but the natives are smart enough not to eat that stuff. In so far I agree with Prof. Wiley, but the above statement seems to me to be one of the extravagant ones, which do "more harm than good." As Prof. Wiley puts it, the reader may think Switzerland is somewhere in the neighborhood of the Lady Franklin Bay. Quite the contrary is true; Switzerland is very suitable for bee-keeping, and this occupation is very advanced there, and is paying better than in some other countries of the continent.

In Switzerland is one of the best bee-papers in the world, the Revue Internationale d'Apiculture, published by Ed. Bertrand, and from there our American hives and methods are slowly but surely being propagated over the continent of Europe.

From the southern part of Switzerland the best Italian bees are exported, and in one point at least the bee-keepers of Switzerland are ahead of us—they have all over the country experiment stations in which simultaneously observations and experiments are made according to a well-considered plan.

Bezar Co., Tex.

Winter Passageways in the Brood-Combs.

BY G. M. DOOLITTLE.

A CORRESPONDENT writes me that he thinks much of the loss of bees during winter comes from the chilling of the bees, or the impression of cold on those bees occupying the outside of the cluster, or more properly the outer ranges of comb, when a sudden cold spell comes on with the cluster spread out all over the hive. He then goes on to say:

"Especially is this loss very considerable where comb-passages are deficient, as in such cases the detached clusters are unable readily to join the main cluster, and are not in sufficient numbers to maintain the requisite degree of heat, hence are lost. Thus, after each cold snap a loss occurs, and when there are a sufficient number of these cold snaps during the winter, the whole colony goes little by little till the remaining number are not equal to the occasion, when all perish. What is your opinion in this matter? Please tell us in the American Bee Journal."

In the above our correspondent brings up a subject which has been discussed at length at times during the past, and "winter passageways" thru the combs have been often recommended. The argument brought forth in favor of these passageways was that, on the first cold spell, the cluster of bees was obliged to contract in order to maintain the necessary heat; and in doing so those occupying the outer ranges of comb, being in a sluggish state from the influence of the cold, failed to pass up and around the comb quick enough to keep up with the receding cluster, hence were left away from the warmth of the main cluster to perish. To obviate this loss winter passageways were recommended thru the center of the combs, made by boring or cutting holes thru them, or by having a curled shaving suspended in each frame when the swarm was lived, so that the bees would of themselves leave such passageways, when they were building their combs.

By this means the outer bees had direct communication with the cluster or main body of bees in the center of the hive, so that, even though partially stiffened with the cold, they could easily recede so as to keep up the main cluster. As the bees would, as a rule, fill up these passageways each summer, it was found to be quite a job to make them each fall, when some one proposed boring a hole in the side of the hive at the proper place, when, with a square stick of suitable size, pointed at the end, which was to be slowly "wormed" (so as not to kill the bees) thru to the opposite side of the hive, and thus make a passage thru all the combs at once, thus making quite a saving of labor. Where such passageways are desired, probably there is no better way of securing them than this last.

However, it was soon found that the bees would remain and die within one-half inch of these holes, as I have seen them many and many a time, and as side holes were quite a

damage to the combs, the bees filling them with comb of the drone size of cell the next season, the practice of making such passageways has been generally discontinued, I believe. Where anything of the kind is used, several sticks of suitable length, and $\frac{1}{2}$ inch square, laid across the top of the frames, two inches or so apart above the center of the cluster, to hold up the covering over the bees that much, is now considered preferable to the holes, and is something which is used by many of our practical apiarists who winter their bees outdoor.

But from many careful watchings and experiments I found that bees would die within $\frac{1}{2}$ inch of any of these passageways, and that such death of bees rarely occurs except during the first heavy freeze each fall, and also that these bees die from lack of vitality, or what is commonly called "old age," rather than from the cause assigned. Usually we have cool, cloudy weather from two to four weeks before the first severe cold, so that the old bees do not leave the hive to any extent to die, as they do all thru the summer months, so that the number of dead bees dying from this cause would be considerable, providing some were chilled. But at this time of the year, instead of dying at once, these old bees seem to linger along for a chance to go out of the hive to die, and so gather in little clusters of three, six, ten, twenty, or more, in a place where they remain in a sluggish state till caught by extreme cold, or a chance is offered for a flight.

I find recorded in an old diary how one year, when a fine warm day occurred immediately preceding the first very cold weather, the bees all flew nicely, and at evening I was surprised to find sluggish bees clinging to the hives, fences, board walks, etc., all about the apiary, while a close examination showed them all about on the grass and ground. And this is something I have noticed several times since, and in some instances to a far greater extent than was noticed that year, varying as the bees cease breeding earlier or later in the season. And when seeing these dead and dormant bees scattered about and clinging to things in this way just after a late flight in the fall or early winter, I have always thought that I had discovered the real cause why bees are found dead in little clusters on the combs after the first cold spell of the season, where no flight has occurred for some time previous.

And to prove the correctness of this I will say that, upon a cold spell coming immediately after such flights, very few if any clusters of dead bees are found, and very straggling ones, with the whole colony clustered compactly for winter, whether there were any passageways or not. Then, again, I have often noticed that these little knots of bees were left to die only with the first contraction of the cluster, as later on no gain of dead bees clustered about in little knots seemed to be made among the combs with each expansion and contraction, even tho our correspondent would lead us to believe that it was a thing kept up after each warm spell.

There is only one way that I know of for each to arrive at the truth in these matters, and that is to set apart a few colonies for an experiment, trying them in each way, or in any way that the mind is led to think may prove a good thing. That which succeeds may then be tried on a larger scale, and if on this larger trial it still proves a success, then the whole apiary can be worked that way.

In the case now in question, set apart three or four colonies, making winter passageways thru the combs; then try an equal number with the sticks across the top of the frames, as alluded to above, while another like number is left without any preparation at all. In this way, after a series of winters, the truth of the matter can be found out by a careful comparison of the whole.

Onondaga Co., N. Y.

Experiences and Foul Brood in Cuba.

BY G. ROCKENBACK.

I AM upon the open veranda writing, wearing a light undershirt, crost or mosquito-bar pattern, with the thermometer registering 85 degrees in the shade. Tropical ferns wave around me, with the smell of pomegranates and bellflower blossoms in the air.

When I left the office of the American Bee Journal last fall, supplied with a good stock of bee-smokers and veils, I took a header direct for Havana, and then by rail to Caibarien, some 236 miles east of Havana. I changed cars three times, and bought three extra passes, because three different railroad companies operate between the two places, and they don't issue any thru tickets. Their charges

are only 10 cents a mile, baggage extra, which is a very stiff price for a ride in a stock-car, with hardwood benches, and lighted with candles.

After arriving in Caibarien I stopt one week with my friend, H. Gunz, postmaster of the place, having about 6,000 inhabitants. From there I went 36 miles east by sailboat, to Sta. Cataline, where the apiary of M. J. Carbo is situated, which consists of 75 colonies, all in the dovetailed hives with Hoffman self-spacing frames; also a 10-inch foundation mill, a 4-frame reversible Cowan extractor, Dadaut uncapping-can, three uncapping knives, four bee-smokers, 100 5-gallon cans, and a number of hogsheads; also "A B C of Bee-Culture," and other traps too numerous to mention. Mr. Carbo is the owner of a large sugar plantation, with a sugar-mill 20 rods from the apiary. He is also a practical apiarist, but not much acquainted with foul brood, with which his apiary is rotten, every colony being in bad condition. In some of them the bees swarmed out just before I came here; by raising the hive-cover the stench would almost knock a person down.

The first thing I was going to do was to cure that apiary of its disease by the McEvoy process, as the bees were in two yards, one of them containing 16, the other 60 colonies.

So, to begin, I made 100 pounds of foundation, lots of wax being on hand: also 125 hives and frames were boiled, as I had a large sugar-kettle, and all the steam I wanted, also two colored fellows to assist me. I tackled the small yard first, to see how the McEvoy plan would work. I hived the bees on full frames of foundation, and after four days I transferred them to a new set of hives and foundation, just as per the McEvoy treatment. Of course, little did I dream of not curing that yard. Two weeks later I examined them, and to my surprise all of the capt brood was black and rotten; in some of the combs not one bee would hatch. The foul brood was worse than ever. I had just read the "A B C of Bee-Culture," where it says no starving is required to cure it.

Not being satisfied with the McEvoy plan, I hived 20 colonies on foundation, and starved them four days in a dark cellar, and then I transferred them into new hives on new foundation. The result was just as before—one-half of the brood was dead and rotten two weeks after being hived the last time.

I have also tried three other ways with drugs, but with no success.

In the American Bee Journal for 1893 there are no less than 33 articles on foul brood, and not one of them will cure here. I believe M. M. Baldrige, in 1894, said he was going to give a foul brood cure which could be relied upon. As I have only a few copies of the different bee-papers to refer to, probably some new cure has been discovered within the last two years. I have not read any bee-papers since 1897.

A sample copy handed me when I was in the Bee Journal office last fall, contains a very interesting article by Fred Craycraft, read at the Philadelphia convention, which is very inviting for the American bee-keepers to go to Cuba, but it contradicts itself.

I have made 300 miles on horseback, in an unbroken country similar to the Rockies, with veil in pocket and smoker in hand ready for execution on any apiary that I came across. Half of the time I stood in the saddle. I have been as far south as Santus Spiritus; have also followed up the mountains which line the north coast from east to west some 30 miles; have examined about 50 different apiaries, some as large as 75 colonies, all in log gums, which were started last February with a few logs taken from the woods, and I have yet to find an apiary that is not rotten.

South of Yaguajay 15 miles is a native that was in New York State during the war, and he put in one season with a large bee-keeper in New York. He speaks English quite well, and has an apiary of 70 log hives rotten with foul brood. I have no doubt but the whole Island is rotten from end to end.

Would it be safe to import a number of colonies to begin with? I would like to hear from some of our foul-brood authorities on this subject.

I don't believe there is a single individual in the United States to-day who can cure foul brood here by drugs or starvation.

In the Progressive Bee-Keeper for February and December, 1895, "Rosehill Observer" says he came very near going with bag and baggage to Cuba. But don't envy Osborn and Craycraft. In short, let me say to "Observer," take \$500, as I did, go to Cuba, and inside of six months if you aren't back, much sadder and wiser, to all appearance, I am a—whatyoumaycallhim. Cuba, Jan. 21.

Is it the New York Bee-Disease?

BY ABEL GRESH.

HAVING learned about all I know about bees and honey production from the writings of the contributors of the American Bee Journal giving their experiences, I feel it incumbent on me to contribute an experience that I had out of the usual, or different from any other I ever met with.

In the autumn of 1897, having about 115 colonies of bees, which number, with slight variations, I had had for six or eight years previously, my assistant informed me he noticed brood in one hive that failed to hatch, and was a coffee-brown in color. I decided to be on the safe side of foul brood, so I sulphured the bees at once. In preparing the rest for wintering, my assistant again said he found several that showed signs of foul brood, but being late no further notice was taken of it. As was my custom, I put about 80 colonies into the cellar, where they had wintered well for about six or eight years, and the remainder I packed in large boxes with chaff on the summer stands, and I concluded I had a nice start in foul brood. My assistant had some previous experience with that dread bee-disease, and pronounced every symptom present, excepting ropiness in the dead larvæ and the glue-pot smell were lacking.

In the spring of 1898 bees generally came out alive, but some were quite weak; all were prepared to build up as usual, but many failed in hatching more than one-third to one-half of their brood, and in consequence remained weak, while others built up strong and healthy, and gathered honey freely. The brood that failed to hatch in some cases dried to a brown scale in the bottom of the cell; in others, where it was capped, the capping had a brown, sunken appearance, and usually had a small pin-hole in the center. At times we were convinced it was genuine foul brood, but at other times we still doubted, because, as I said before, genuine ropiness was lacking in the dead brood, as was the stench attributed to genuine foul brood.

In looking over the yard as a whole, I discovered that the disease largely predominated amongst the colonies that I wintered in the cellar, and a suspicion was at once aroused in my mind, that the cellar was responsible for the trouble. I then instructed my assistant in preparing colonies for winter, to double all weak afflicted colonies, see they had plenty of honey, and we would not put any into the cellar in the fall of 1898. I packed about 40 colonies in chaff, as usual—the best and least afflicted—and the balance, about 45, I left on the summer stands, with no protection except that I took off the enameled sheets, and covered the brood-frames with burlap sacking, placing on this a half-story rim, into which I put chaff or sawdust filled cushion, then the lid, and lastly shade-boards on the lid, projecting about 10 inches in the front and the rear.

In this condition they wintered fairly well, few failing to respond last spring, and, when building up, very slight traces of the malady was found here and there, perhaps from a few cells to a few square inches in extent, and I do not expect to find any trace of it next spring, as I have packed the same as last winter.

In 1898 I had about 1,600 pounds of comb honey, and the past year 1,200 pounds.

My cellar is inclined to dampness, and consequent molding. When I had about 80 colonies in it, the thermometer ordinarily registered 45 degrees, seldom fell as low as 40 degrees, and I frequently noticed when the honey season opened the bees would gnaw down some badly-molded combs and build new. I think high temperature enabled the bees to winter all right, and mold caused the larvæ to die in the combs.

My bees, as well as those within a radius of 20 miles or more, gathered considerable honey last fall that has a decidedly bitter taste. I am not sure of its source, but incline to the belief that it comes from the bloom of what is known as "devil's club," which was very largely visited by bees about the time blackberries were ripe. Elk Co., Pa.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the new bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

CONVENTION PROCEEDINGS

Report of the Colorado State Convention.

[Continued from page 85.]

THE HIVE QUESTION.

J. E. Lyon—I wouldn't give a snap of the finger for the kind of hives. The frames have more to do with it, and the bees more than the frames. It is true, they need shelter. But give me any old box, with movable frames, and I will produce as much honey as with the latest hive. There is no use in taking up the 8 and 10 frame question. But we do want frames every year. I have had to do a lot of work in cutting down frames. To produce honey in quantity we must handle frames. We can't handle hives, we must handle frames. I never produced a larger crop than last year. It was all by handling frames.

Mr. Martin—I am much like Mr. Lyon. The different lengths of the frames manufactured bother me more than anything else about the hives.

Mr. Tracy—There is a great deal in the frame, also a great deal in the hive. But if you get the dovetailed hive all the time, you get the same all the time.

J. B. Adams—I have dovetailed hives in my apiary that vary $\frac{3}{8}$ of an inch in length.

Mr. Bates—I like the Wisconsin hive the best—the frames always fit. I have mostly used the 8-frame Wisconsin, but have used others.

H. Rauchfuss—I have used almost every kind of hive, from the Heddon with a frame less than six inches deep, to those with frames 11 inches deep. I have some Wisconsin hives that I will sell cheap. I don't like the frame-rest. Sometimes every frame needs to be taken out, and the frame-rest projecting in the Wisconsin hive causes the honey in the brace-combs at the ends to scrape against it. Now they have improved the Wisconsin hive so it takes the Hoffman frame. But I don't like the Hoffman frame. My preference is a standing closed-end frame of $\frac{3}{8}$ -inch stuff all around, the top and bottom-bars $\frac{7}{8}$ inch wide, and the end-bars $1\frac{1}{2}$ inches wide. The top-bars are grooved on the underside for fastening foundation with melted wax, and the end-bars have a slight groove on the outside for the wires to rest in, so they will not get cut or dull the knife when the frames are scraped. For an extracting-frame this can't be beaten. All the help I have had always say when they come to the closed-end frames, "Now we can extract." The end-bars keep the fingers out of the honey, and the narrow top-bars favor uncapping, and do not cause the combs to break in the extractor. The Hoffman frame is the worst one to extract from. The top-bar projects beyond the thickness of the comb, causing the comb to break in extracting. The new Hoffman is not the frame for extracting. Moreover, a closed-end frame can be inverted, so that the comb may be built solid. The original idea of the wide top-bar was to do away with the honey-board. It works all right the first season. After that the bees will build brace-combs between the top-bars. Some of the top-bars warp. There is no brace-comb trouble with the honey-board.

Ch. Adams—Whenever I get a Wisconsin hive I get rid of it as soon as possible. I have had the same experience exactly in regard to the top-bars and honey-board.

Mr. Brock—The hive question would be easily settled if we could get all bee-keepers to use the same things. The most trouble comes when a bee-keeper buys other fixtures than what he started with.

E. R. Root—It is a pretty difficult matter to make one hive to please every one. We have sold frames with narrower top-bars for extracting, but we put up thick top-bars in extra supers to avoid having two styles of frames in the same hive. I suspect this is one of the questions which locality has something to do with. We shortened the top-bar in the new Hoffman frame to do away with the gluing to the ends of the hive. In regard to Mr. Lyon's remarks, Mr. Cogshall says locality comes first, next the man, and lastly the hive, and I have seen that demonstrated in his yards.

Mr. Tracy—The Danzenbaker cover furnisht with the new dovetailed hive warpt with me.

Mr. Root—We have had some complaints with the Danzenbaker cover in Colorado. Did you follow directions in nailing?

Mr. Tracy—Yes.

Mr. Root—If so, you nailed the wrong way. The directions we sent out were found to be wrong. That is changed now. I am afraid the time will come when a special kind of hive will have to be made for this locality.

H. Rauchfuss—I have always been in favor of a square-edged hive, but have come to the conclusion it is not the thing. For some seasons I have used a large number of supers, with some hives made to correspond, that were rabbeted in a peculiar way, and I find by actual practice on a large scale that this arrangement is superior to the square edge. The sides only, of the supers and hives, are rabbeted. The rabbet is made on the outside of the upper edge of the super sides, and on the inside of the lower edge. Hence, when a super is set on another, or on a hive rabbeted in like manner on the outside, the two rabbets fit together—that is, they fit together on the outside, thus making a close joint, and they would fit together on the inside if the rabbets above and below were cut to the same depth; but they are not, the outside rabbet at the top of the sides of one super being cut $\frac{1}{2}$ inch deep, and the inside rabbet at the bottom of the super above being cut $\frac{3}{4}$ inch deep, both rabbets extending in width half-way thru the thickness of the board. Hence, when the sides of two supers come together, there is a close joint outside, but inside there is a bee-space of $\frac{1}{4}$ inch. The ends of the supers are not rabbeted, but the same result is achieved here, too, in a different way, by making the ends only $4\frac{1}{4}$ inches deep, the sides, of course, being the regulation $4\frac{1}{2}$ inches. A thin strip projecting downwards about $\frac{1}{2}$ inch, nailed along the lower portion of the ends, makes the super tight outside here also. In this way there is virtually a bee-space of $\frac{1}{4}$ inch all around between the supers, or between a super and a hive, while at the same time all joints are tight. The result is that in actual practice, whenever a super is raised, however much the bees crowd over the edge where the bee-space is, they do not crowd over where the joints are tight, and the super may be slapt straight down again without killing one; furthermore, the supers are never propolized to each other or to the hive, and need no chisel to be pried apart; hence, supers may be inspected, lifted off and set on with the greatest ease. These two things may seem strange, and I do not know how to account for them exactly, but they are so, nevertheless. These supers and hives originally came from a Chicago supply firm which does not now exist. Then I think the square edge is not the thing, because we winter our bees outside, and the principal point is to keep them dry. The old covers were not wide enough; the new covers are better, but the water will run in and moisten the whole top of the hive, and the wind blows the rain and snow clear across under the cover. I think it would be better to have a rabbet outside, so the water could never get in, as in those Chicago hives.

Mr. Martin—Has any one any objection to the length of the Danzenbaker cover? I find it too short.

F. Rauchfuss—I have noticed that of late some covers have been furnished too short, so that it was necessary to plane the cleats at the ends of the cover, especially when burlap is used. As to the frames, the short Hoffman frames won't fit old hives. There is also a slight difference in hives of different years, as much as $\frac{1}{8}$ of an inch.

Mr. Root—Eight or nine years ago complaint was made of burr-combs at the ends of the hives, so we shortened the hive $\frac{1}{8}$ inch at each end. In regard to the covers, one of our men once made a mistake of $\frac{1}{4}$ inch, and those covers came to Colorado. We adopt the plan now of having hives nailed up to go with the hives we send out. If any one wants a long top-bar he can get it.

Mr. Sylvester—As to the covers, it is only necessary to plane off the underpart of the cleat. I should choose the new frame in preference to any of the others. When fixing up hives for winter, I put two or three thicknesses of newspaper over the frames, and water never comes thru, even with unpainted covers. I would like to sell some Wisconsin hives at half price.

Pres. Aikin—I have concluded the best thing is to have a thin inner cover, with any sort of a cover above and a ston on top of that.

Mr. Sylvester—The Wisconsin hive has an inner cover to rest on the frames. It is a great nuisance. Burlap is a nuisance, too—whenever it projects it draws the water.

H. Rauchfuss—The Wisconsin inner cover is a nuisance when put on the wrong way. When put on the frames the

cleats should be down, so as to leave a bee-space over the frames.

Mr. Porter—I have had much experience with the old Langstroth-Simplicity hive, with the ends of the top-bars in a notch stick. That arrangement is a great mistake. For a cover, the most practical for moving is just a plain flat one, one inch thick, as I found in moving half a car of bees recently. The moisture of the bees warpt the thin covers. Plain edges are much the best in tiering up hives and supers inside the house. For wintering, there is no objection to the dovetailed hive. The Wisconsin cover winters better. It would pay to make a substitute for wintering.

Pres. Aikin—I favor the square edge with the inner cover. If one does not have his hives in the shade, he is almost obliged to use a shade-board. I have often removed the covers from dovetailed hives and found the wax underneath white with heat—almost at the melting-point—and the bees driven from the supers.

A STANDARD SHIPPING-CASE FOR COLORADO.

The subject, "Shall we have a standard shipping-case for Colorado?" was introduced by Mr. Cornelius, who spoke briefly, saying he favored the double-tier case, and that last season he received some cases with the ends too narrow.

Mr. Porter—The intent of the question was to bring in uniformity of shipping-cases in loading cars. A difference of an eighth of an inch in thickness makes a great deal of difference. Any one who will load a few cars of honey will find this a real nuisance. Then as to the dripping-cleats, many did not know what to do with them—whether to use them inside or outside.

Mr. Root—We have been making the ends lighter to save freight.

F. Rauchfuss—Three-fourths of the bee-keepers threw the dripping-cleats aside, and many mistakes were made. In this country the material of cases in the flat should be weighted down when it is taken out of the crate, until it is nailed up. The double-tier case was adopted as the standard of this Association years ago. As to what other people think of it, Peycke Bros., in a letter last spring, said, "We would also advise to abolish the double-deck case. Thruout this part of the country, and in fact wherever our trade reaches, we find that it is objected to." But at our spring meeting the representative of Peycke Bros. admitted there was not much objection to the double-tier case. The double-tier case is a trade-mark of Colorado honey. It exposes more honey to view than the single-tier. Of course, it is more expensive, and the single-tier case ships better.

A Member—I think we ought to have a full eighth of an inch between the cover and the sections.

F. Rauchfuss—If you don't use the dripping-cleats you have that space anyhow.

Mr. Lyon—I think the sticks are a nuisance. There would be less height in the car if the sticks were done away with.

The secretary then read a letter from S. T. Fish & Co., date Nov. 16, 1899, as follows:

Mr. R. C. Aikin:—We intended giving you a letter on the subject of packages for Colorado honey, but on reflection think it best not to express *all* our views, but will be pleased to answer any inquiries.

Colorado should by all means adopt the single-tier case. We do not know of one advantage in favor of the double-deck, and there are many items against its use. It exposes to view too much honey. By this we mean it requires too much honey to make a proper facing. If the top tier leaks, it damages the bottom tier. It is not as convenient to handle, and not as convenient for freight men in shipping. It is more trouble in packing the honey, as you are compelled to get more facing. One thing that should be impressed upon the bee-keeper is that every man should have a rubber stamp and put his name on his honey-case.

Some cars contained cases in which the sections were interwoven, and the honey was only fit for the extractor. Some honey had moths in, or at least the web, and we can not trace these things, because the bee-keeper's name is not on the cases. It is no benefit to put the residence on, because some dealers are prejudiced against Colorado honey on account of having it granulate on their hands in past seasons, so that it is just as well that the residence be left off.

Another subject we should like your Association to take up, and that is to try to arrange to sell the honey by the pound and not by the case, simply because we can not educate the Eastern trade to buy by the case, as it is not customary, and your asking this is compelling a hardship upon

us to try to undo the custom in the East. Some cases weigh net 20 pounds, and we can not sell it when it weighs this net, by the pound, but must sell it by the package.

We much prefer the good-will of your Association, and therefore do not want to make any further comments today, but we are ready at any and all times to answer any inquiries, or answer any discussions.

Your system of grading is not correct, and should be remedied.

We could register further complaints, but it may not be judicious on our part at this time.

Respectfully, S. T. FISH & Co.

Pres. Aikin—Fish & Co. offered to write a paper for this convention on "Packing and Packages," and this is what they sent.

Mr. Root—Fish & Co. started us with the no-drip case. They had seen Hetherington's case, and urged us to adopt it. I have heard wishes express that the Colorado people would not use the double-tier case.

Pres. Aikin—I prefer the single-tier; not because there is less to face. I prefer the no-drip case, because sometimes a little honey drips from unsealed cases.

Mr. Porter—The double-tier case is used because our local market universally requires it. It always will be sold before the single-tier. I know of one dealer who sold out every double-tier case before he sold a single one of the others. I have changed sections from the single-tier to the double-tier in order to sell the honey.

Mr. Pease—We shipt out 22 carloads—if the Eastern market prefers the single-tier, why should we not adopt it?

F. Rauchfuss—As to Fish & Co.'s objection that the double-tier exposes to view too much honey, if anybody objects it should be the producer, not the dealer. In regard to selling by the case, we go by our grading rules, which guarantee a certain weight. As to the honey leaking, our Colorado honey does not leak so much. It is true the single-tier is more convenient for shipping. It is easier to tier it up to some height, especially now that we are compelled to put in 30,000 pounds to make a car. If they don't object to putting a producer's name on, why should they object to the address? I received a letter from a bee-keeper in Chicago who is also a honey-dealer, who also wanted a single-tier case used, and the stamp left off, for the very reason he didn't want it recognized as Colorado honey. Then, as to what they say of inferior honey, this season, on account of the scarcity, dealers bought a whole lot of inferior honey produced by farmers; but the honey that came thru our Association will bear comparison with any. If we guarantee a net weight of 22 pounds per case, that gives them a basis to figure on. Honey is quoted by the case in the Denver market. The sections here are almost uniform, all of the same width. As for the wax-moth, that is preposterous. We have no wax-moth in Colorado. As for granulating, here is a section of honey 15 months old, that has been exposed to the cold continuously, that does not show a sign of it. This year's product has not granulated. There might be a season in which it would granulate soon, but as a rule it compares favorably with honey produced in other localities.

Mr. Pease—If a single-tier case is preferred by commission men, why should we not have it?

H. Rauchfuss—One objection is that the cover and the bottom are wide and will shrink. Even double-tier cases sometimes have covers too narrow.

F. Rauchfuss—The single-tier covers and bottoms are usually in two pieces.

Mr. Root—One reason for preferring the single-tier is that these cases can be piled up high without toppling over. I remember seeing a pile of cases in a commission house that had tipped over with disastrous results. That is the main reason. It holds true in the car also.

In shipping carloads, paper on the top to keep out the dust is a good thing. Capt. Hetherington covers the whole carload.

F. Rauchfuss—We have done that three years, and for two years used a canvas over the whole, and the honey arrived in good shape.

Mr. Root—Personally, I prefer the Colorado honey. I keep a square can of it for use in my own home. I advise you to put labels all over your honey, and have it known as Colorado honey.

Mr. Brock—I prefer to have it labeled as Colorado honey, on account of the preference for it in the East.

Pres. Aikin—A house that handles a large amount of honey explicitly wanted me not to label mine. I consider that rascality.

H. Rauchfuss—They don't want the consumer or dealer to find out where the honey comes from. That is the main objection.

Mr. Lyon—There is more truth in that. Some of my honey found its way to Boston, and consequently a Boston man wrote to me direct.

Mr. Jones—I came from the far East, from Canada, and have been much interested in this convention. In Canada we use only the single-tier case, but produce nearly all extracted honey, as it is so cold. The honey here far excels ours for certain purposes. It takes very little white clover honey to satisfy one, but he can eat two or three times as much alfalfa honey.

Ch. Adams—One reason why objection is made to stamping the cases is that the buyers are afraid their customers will get used to Colorado honey, and won't get Eastern honey another year.

[Continued next week.]

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Giving Indoor Bees a Flight.

Would it be well to give bees a flight on a warm day in the winter, by taking them out of the root-house, if handy? Would it do them any harm if they appeared to smell all right, but a little uneasy? WISCONSIN.

ANSWER.—If "they appear to smell all right but a little uneasy," better let them alone till time to take them out for good. When bees are wintered outdoors, a warm day and a flight is a fine thing for them, but it doesn't seem to work just the same if they are in a cave or a cellar. Somehow they don't settle down quietly when returned.

Building up a Nucleus.

I have the queen received last fall in a small hive, that I made, about 10 inches to the edge inside. I could accommodate her in no other way, as it was too late and cold to introduce her, but I got a few bees and put in with her, and she commenced to lay. She laid about 100 eggs, only half of which hatched, and then stopt. There are only about 100 bees left now, as they have died off. I want to know some way to start her laying, as I think if she does not commence pretty soon they will all die out. I keep them in the kitchen, closing the entrance with a piece of wire-netting. She is a pure Italian, so I don't want to lose her. I carry them out every warm day. NEW YORK.

ANSWER.—Don't think of building up a colony from eggs laid by a queen with only a hundred workers. Remove the queen from one of your colonies and introduce the Italian queen, or else gradually add bees and brood to your little nucleus. You can take from one of your colonies a frame or two of bees (with brood if they have it), being sure not to take the queen, imprison these for a day or two, and then they can be given to your little nucleus.

Bee-Candy, Feeding, Etc.

1. I am located in central Ohio with my bees on the west bank of a pond of spring water, about 20 feet square, with a little hill and orchard on the west, the hives facing the southeast. We have white clover, goldenrod and linden blossoms in abundance, besides black and red raspberry, sweet clover, and a great many other wild flowers. Why is this not a good location, with the proper treatment and care?

2. I have the Falcon chaff hive. Is it as good as any other hive on the market, for out-door wintering? Should the chaff chambers be filled with chaff, or left as a dead-air space? I have two colonies in these hives, which were the increase of last year.

3. I bought a tested queen and introduced her in one of the hives, and I think their stores are rather short, and I would like to feed them. I have Hill's device and chaff cushion over the frames. Can I make bee-candy and feed them on the summer stand, or will I have to put them in the cellar?

4. Can I feed them while the weather is cold, or would I best wait until it is warm enough for them to fly?

5. If you have any special way of making bee-candy, please give it.

6. Does a cider-mill damage bees in any way?

7. What text-book would you recommend as the best—the A B C of Bee-Culture, or Langstroth on the Honey-Bee, or some other one?

SUBSCRIBER.

ANSWER.—1. From your description it would seem that you have a fine place for bees. If your bees are placed very close to the pond, it would be well to have them face away from it, for some bees are likely to drop in the water if the water is directly in front of the hives.

2. There is a difference of opinion as to whether chaff hives are best, but you cannot be far out of the way.

3. They can be fed where they are.

4. Unless you think there is danger of starvation, better wait for a warm day. If you think best to feed without waiting for a day warm enough for flight, see that the bees are stirred up enough to reach the cake of candy, and then cover up warm.

5. The common way of making hard sugar candy is good, but it is considered a little better to make the Scholz or Good candy. Heat good honey, but don't boil it. Stir in all the pulverized sugar it will take, then take it out of the dish and knead it with the hands like dough, adding what sugar it will take to make a thick dough. Make a cake about an inch thick and lay over the frames.

6. Yes, unless the mill is enclosed, many bees are drowned at times when there is a scarcity of pasturage, and the cider is bad for winter stores.

7. The books you name are both good; so is Prof. Cook's Bee-Keepers' Guide.

Moving Bees or Selling and then Buying Again.

I wish to move 24 colonies of bees about 53 miles by railroad, in a freight-car, and 6 miles on the wagon to the car, but the car has to be switched from one train to another. Could I try this moving, or would you advise me to sell the bees here for a low price, and start in the next place anew?

NEBRASKA.

ANSWER.—If the margin between the price you would get and what you would have to give is not too great, better sell and buy again. If you have had a little experience in moving bees and can be with them personally, better move them than pay too much on the exchange.

When to Begin Spring Stimulative Feeding.

I would like to know how long before a probable honey-flow one should practice stimulative feeding so as to have the largest number of workers when the flow comes. Our cherry, plum and prune trees generally bloom about the middle of March, then, too, alfalfaree and some other plants are in bloom at that time.

My bees have an abundant supply of honey, and yesterday (Jan. 21) there was a cluster on the outside of one of the hives. Every warm day the air is full of bees.

CALIFORNIA.

ANSWER.—A worker will begin storing about 37 days after the egg is laid. Beginning a little in advance of that would make the feeding begin about 6 weeks before the expected harvest.

Inside Coating for a Honey-Tank.

I made two honey-tanks of wood and painted them on the outside, but I would like to know what would be good and cheap for the inside. Perhaps you can tell me the name of the stuff alcohol-barrels are varnished with.

WASHINGTON.

ANSWER.—I do not know what varnish is used in alcohol-barrels, and did not suppose any was used. Paraffin is used by some for the inside of honey-barrels. Whether it could be easily and economically applied to tanks is a question. It is poured hot into the barrel, the barrel rapidly whirled so as to make the paraffin touch all parts and then quickly poured out. Possibly if the tank was in a hot place, or in the hot sun, the hot paraffin might be applied so the coating would not be unnecessarily heavy.

Transferring—Grape-Vine Shade—Ventilating Hives—Winter Stores.

1. I have 30 colonies of bees in square hives which I am going to transfer to Langstroth hives, into frames which are longer and a little shallower. Please tell briefly when and how best to transfer.

2. Tell how to train grape-vines for shade.

3. Why not ventilate hives by a register in the cover?

4. Will a colony, for which 25 pounds of honey would be ample to carry it thru the winter, consume any more if it had say 50 pounds given to it in the fall?

CALIFORNIA.

ANSWERS.—1. Follow the instructions of your bee-book, the only special point in your case being that the combs are to be transferred from one kind of frames to another of different size. When the first considerable flow of honey comes, so the bees are busy for a few days, cut the comb out of the old frame and then cut just enough from the top or bottom to make a comfortable fit in the new frame. That will fill the new frame, all but a vacancy

at one end, and it depends upon the size of the old frame as to how this vacancy shall be filled. If the piece cut away from the old comb is large enough, it can be used for that purpose, or an entire old comb can be cut up into pieces to fill some of these vacancies.

2. The most suitable training is on an overhead trellis, so the vines will form a sort of roof over the hives.

3. That has been practiced to some extent, formerly more than at present. One trouble is that the bees cover with glue the wire-cloth used to close the hole.

4. It would not.

Sweet Clover in Pennsylvania.

Will sweet clover blossom the first year? Do you think it would do well in Pennsylvania?

SUBSCRIBER.

ANSWER.—Sweet clover does well in Pennsylvania, growing the first year without blossoming, blossoming the second year, and in winter dying down root and branch.

Effect of Cold on Foul-Broody Hives, Etc.

During the fall of 1898 many of my bees died, leaving considerable honey in the hives. Since then the hives and frames have been empty, standing in a room almost as cold as outdoors. Now, if these bees died of foul brood, will it be safe to use these hives and frames as they are, or should they be put thru the usual process to avoid the return of the disease?

ILLINOIS.

ANSWER.—No amount of freezing would make them safe, if there's foul brood in the case. Don't trust them if you're at all suspicious.

Bees Getting Thru the Alley Trap.

Will queens get thru the Alley queen and drone trap when bees are swarming? What would be the effect on 10 strong colonies, of putting the queen-traps on about time for swarming to begin, and leaving them entirely alone with plenty of room for stores for 3 weeks? I am inclined to the belief that a large part of the queens will finally get out, and this one point is of the greatest importance in the scheme I have under consideration.

WISCONSIN.

ANSWER.—Queens are not supposed to get thru Alley queen-traps, and under ordinary circumstances do not. Answering what I suppose to be the heart of your question, I advise you not to try the experiment you propose on more than two or three colonies. One year I tried much the same thing on a number of colonies. When swarming began, each colony would swarm about every day. A number of swarms would settle together, then a clump as big as your body would all go to one hive, leaving the others too weak for work. Here and there a queen would get out, either thru a trap that was perfect or one that was faulty or thru some crevice, and among such queens there would be virgins, and one of those immense clusters would majestically sail out of sight. As the memory of those scenes comes up vividly before me, I feel like changing my advice and suggesting that a single colony will be enough for the experiment.

Management for Extracting with Little Attention.

When spring opens I will have about 20 colonies of bees in 10-frame hives. Circumstances are such that I cannot be with them oftener than one day a week, or one day in ten. I do not wish to dispose of my bees, and surplus extracted honey with as little increase as possible is my aim. I will give you my plan for handling them, and wish you to tell me where I am wrong:

The great-swarming fever here is during the alfalfa bloom, from May 20 to June 15, while our greatest surplus is in the fall. I thought of using two stories, the upper one to be filled with full sheets of comb foundation, and when I notice the colonies building up good and strong below (just before the swarming-fever comes,) remove 3 or 4 frames of brood from below and place them in the upper story, and place the full frames of foundation in their place.

I thought that by going thru the hives once a week and treating them thus, the queen would not be crowded for room, and if the hives were well shaded and with wide entrances there ought to be but few swarms, and a nice lot of alfalfa surplus honey to extract after the harvest.

I have queen-excluding zincs. Do you think it would be best to use them, or would it be better to give the queen the freedom of the 20 frames?

If you have a plan whereby I could get surplus with little increase, and only one day a week to look after bees, that you think beats my plan, please give it.

KANSAS.

ANSWER.—If you take only three or four frames, there would be swarming in some cases, most likely. Put the story of comb foundation below, either with one frame of brood or with nothing but foundation, and put the queen below with an excluder between. If this is done just before any notion of swarming is entertained, and if no crowding for room is allowed above, your chances will be a good deal better. With 3 stories and abundant entrance to each story, there is scarcely a chance for swarming. To avoid swarming in this case, it is safer to have no excluder at all; but an excluder over the second story would hardly make any difference, and they might stand one over the first story.

VOL. 40. FEBRUARY 15, 1900. NO. 7.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

The National Bee-Keepers' Association is the new name of the society resulting from the amalgamation of the two organizations, viz.: the United States Bee-Keepers' Association and the National Bee-Keepers' Union. We have received notices from the general manager of each former society—Messrs. Eugene Secor and Thomas G. Newman—informing us of the result of the balloting, which expired Feb. 1st, and the vote of each organization was practically unanimous in favor of amalgamation.

We wish to take this occasion to congratulate the whole membership, and all the bee-keepers in the land, upon the happy outcome of the last effort to unite the two national bee-keepers' organizations into one strong body. Now let all "bend to the oars," and roll up the membership to a thousand strong, by the time of the annual meeting here in Chicago next August 28, 29 and 30.

In the number following this we will have more to say regarding the result of the recent balloting on amalgamation, etc.

Oldest Honey-Comb in the World.—The British Bee Journal recently copied the following account of a "find" of what is supposed to be the oldest honey-comb on earth:

There is in the possession of Mr. W. Drake, of Broad street, Cambridge, a curiosity of great antiquity in the shape of a perfect honey-comb, in the center of what was

once an oak-tree, which, according to naturalists who have viewed it, is hundreds of years old; in fact, it is impossible to say what age the comb and tree may not be. The tree was raised on land in the occupation of Mr. Gale Cornell, of Brick-kiln Farm, Bottisham Lode. It had been known to be imbedded in the fen land for a long period, and when six feet of peat had been taken off the surface, it was decided that the tree, which is of the species known as bog-oak, should be raised. It was found to be no less than 100 feet long, and the men were in the act of splitting the tree into logs, when, in the center of it, they came upon a honey-comb, which, with the oak, had been imbedded in the peat. The comb was in a perfect state of preservation, and dotted about it and lying at the base of the aperture were bees.

The Wisconsin Convention, which met last week, was one of the best ever held by the State organization of bee-keepers. We were permitted to be there, and had a splendid time in the land of the fur overcoat and basswood honey. Next week we hope to have more to say about it.

The officers elected for the ensuing year are: President, N. E. France; vice-president, Jacob Huffman; secretary, Ada L. Pickard; and treasurer, Harry Lathrop.

"Phonetic Spelling" is the caption of an editorial in the Bee-Keepers' Review, in which Editor Hutchinson, after spending a page or so upon the difficulties of the case, ends with the following despairing paragraph:

"I sorrowfully admit that our spelling is something fearful to contemplate, and herculean to accomplish, and it will remain such so long as our alphabetical characters are so sadly lacking in numbers. This being true, it is better that we continue to spell as other folks do, rather than waste our energies in attempting to make changes which, even if accomplished, would bring us no nearer the goal—phonetic spelling."

Which seems to say, "The case is so desperately bad that we must just stand it with no effort to make it any better." Apparently Mr. Hutchinson has in mind the few reforms introduced in the columns of this journal and some others, from what he says; and he should understand that in these reforms the only thing attempted is to make a little improvement in a limited number of words, and not an entire system of phonetic spelling. The worst feature in the case is that so many, while admitting with Mr. Hutchinson "that our spelling is something fearful to contemplate," will at the same time insist that it must in no wise be marred by any change. It is awful, but it is venerable, and it would be sacrilege to rid it of any of its horridness. Possibly Mr. Hutchinson would join hands with those who say, "If you will give us a genuine phonetic system, I am with you." But such persons ought to know that men have worn out their lives trying to have accepted a truly phonetic system, have printed books and journals phonetically, but the public would none of it. The public will stand isolated and gradual changes much more readily, as may be seen by some of the changes in the Review as compared with the printed language a century ago, and admitting that every change makes a shock, as Mr. Hutchinson suggests, the more rapidly these shocks come the sooner will they be ready to accept what he seems to consider a desired goal.

Mr. Hutchinson emphasizes the fact that very few of our words are spelled phonetically, indeed, putting rather too much emphasis upon it, for he says that in a hundred consecutive words in the Review he found only *two* spelled phonetically, while of the first five words in the column in which this statement is made, five of them may be said to be spelled phonetically—"clip and fix over as." That is on the supposition that by "phonetically" we mean that each letter has its one sound, and each sound its one letter. Possibly Mr. Hutchinson has some other idea of what phonetic spelling is, for in a list of words that he says he looks upon as spelled phonetically occurs "pi," and if that is the

word he uses when some one has spilled a lot of type, then it is hardly phonetically spelled, for there are only two letters to express its three sounds.

Just how Mr. Hutchinson can believe that the changes adopted in this journal, "even if accomplished, would bring us no nearer the goal—phonetic spelling," it is somewhat difficult to understand. Much the same thought is expressed in another place, where he says, "It is true that the newly proposed changes shorten up the words, but they don't spell them phonetically. They simply compel us to unlearn one unphonetic way of spelling a word and learn another unphonetic method." Will Mr. Hutchinson point out a single word in which the spelling has been changed in this journal that was not a nearer approach to phonetic spelling? Will he point to a number of words in which the part changed was not phonetically spelled? On the contrary, it would not be difficult to make out quite a list of words that are changed from unphonetic to purely phonetic spelling, as *past* for *passed*, *mist* for *missed*, *rapt* for *rapped*, *scoft* for *scuffed*, *snuft* for *snuffed*, *stopt* for *stopped*, etc.

Mr. Hutchinson says: "If by making occasional changes, as proposed by the promoters of the so-called phonetic system, we could gradually change the spelling of words until they were all spelled really and truly phonetically, I should hold up both hands in favor of the plan; but with our limited number of letters this is simply an impossibility."

Now, Mr. Hutchinson, if you and others like you will stop trying to discourage, and give us the aid of your influence, the very thing that you would hold up both hands for can easily be accomplished. First, get all the silent letters thrown out, and come as near to phonetic spelling as can be done with our present number of characters, and that being once done, it will be a short job to import a sufficient number of additional characters to make the spelling phonetic. But *please* don't sullenly fall back on the breeching and say, "It's no use." Stop hindering, and delight us with your help.

Alfalfa and Bees.—In a very interesting paper read before the Kansas State Board of Agriculture, Prof. S. J. Hunter gave an account of a series of very thorough experiments and observations made tenting on the field. Referring to the fertilization of alfalfa, he says:

The alfalfa blossom is so constructed that it is impossible for it to fertilize itself, that is, the pollen can not fall upon the point of fertilization, but must be carried to that point by some agency. From the shape and size of the alfalfa blossom, it is not probable that cross-fertilization could be safely accomplished by means of currents of air.

So insects must do the work, bees being the chief operators, a bee while sipping its wee portion of nectar depositing a few grains of pollen brought from another flower. He says:

A hundred seed-pods were gathered from a field 25 miles away from any known colony of bees, and another hundred pods from a field less than one-half mile from a large apiary. The pods of these two groups were counted, and it was found that the pods taken near-by the bees averaged two-thirds greater number of seed, and showed seed larger, plumper, and more uniform in size. And while the bees were conducting this valuable seed-making work, they were likewise gathering a quality of honey which, submitted to all known tests, has proven itself the equal, if not the superior, of any other well-known variety of honey.

It has been my observation further that alfalfa will yield the greatest amount of honey under circumstances which tend to give the plant the most vigorous growth. If the plant is upon upland, dry weather will affect the secretion of nectar before it will in the valley, such as the Arkansas, where the roots of the plants extend to the water. During a dry period bees will fly over fields in bloom to a field which is irrigated, and is beginning to bloom.

The greatest activity in apiculture in this State is to be found in the alfalfa regions. In the alfalfa-growing por-

tions of the State the average yield per colony in 1898 exceeded 60 pounds, while in portions of the State where alfalfa was not a prominent factor in the honey-production, the bees did well to procure a livelihood for themselves without furnishing a surplus for their masters. Some colonies situated in the alfalfa region were able to yield that season a surplus of 200 pounds of comb honey.

The conclusions of the three years' study of the alfalfa regions of this State, then, briefly stated, are, that the highest returns from the alfalfa meadow are to be secured by an early spring cultivation of roots with the disk harrow, and a summer visitation of the blossoms by the honey-bee.

The Weekly Budget

REV. M. MAHIN, D. D., for nearly 30 years a reader of the American Bee Journal, is still interested in bee-keeping, tho he has preached 107 times since the last session of his conference—the North Indiana—last April. He has been doing the most of the work of a presiding elder who is an invalid.

MR. F. G. HERMAN, of Bergen Co., N. J., has lately had the picture of his nice apiary printed in his local newspaper, using the same engraving and sketch as we gave on the first page of the Bee Journal for Oct. 5, 1899. Mr. Herman's apiary is in an ideal spot, and its appearance in the newspaper referred to will doubtless help the sales of his honey. Others might follow this example and be the gainers thereby.

MR. L. A. HAMMOND, of Washington Co., Md., wrote us Feb. 2 about an effort being put forth in their State legislature, looking toward the enactment of a law against glucose adulteration. Hon. Chas. G. Briggs, who introduced the Bill into the State Assembly, reported to Mr. Hammond that the committee to which it was referred, reported unfavorably upon it, taking the "position that the adulteration of honey with glucose was not necessarily injurious, and said this should not make it a crime." Beautiful argument that, isn't it? If that is a fair sample of the great ability of Maryland legislators, it is high time that some honorable members are elected to make their laws. As adulterating milk with water would not necessarily be injurious, we presume that wonderful committee would say it would be all right!

We want to say that Mr. Briggs did all he could to have the Bill enacted, and regretted very much the unfavorable action of the committee.

What is first needed is a strong National law against food adulteration, and then uniform laws by all the States along the same line. That is a goal worth working for.

MRS. R. C. AIKIN, of Larimer Co., Colo., in Gleanings in Bee-Culture, referring to the spelling reform, says:

"Tho it will be like parting from an old and esteemed friend for me to adopt any other method of spelling phthisic, beaux, etc., yet I believe it will save much wear and tear on the coming generation to leave out some of the superfluous letters. By the way, I should like to ask if Dr. Miller, Mr. A. I. Root, Mr. York, or any of the other brethren, have ever eaten any ghouphthteightteaux. If not, I should like to have the pleasure of cooking some for them if they will make us a visit."

Thinking of phthisic and a few other words, one can easily puzzle out that "potatoes" may be the name of the article of diet referred to by Mrs. Aikin, and the spelling is legitimately copied from other words, all but the gh at the beginning; surely gh never has the sound of p in any English word! Hold hard; what about gh in hicough (pronounced hic-up)? Let us be very careful that no ruthless hand be laid upon our beautiful and symmetrical spelling!

But we have no doubt that if Mrs. Aikin has good queoughgheaei to go with her potatoes, etc., almost any bee-keeper would enjoy a meal at her table.

SEE ad. of Golden's Combination Hive in this issue.

Separators and Fences.—The idea that sections are better filled without separators than with them is a mere notion, says F. L. Thompson, in the *Progressive Bee-Keeper*. He quotes Heddon and Doolittle as agreeing with him in this. If entirely free communication is no better than separators, how can fences be better than separators? A number of times Mr. Thompson tried separators in half of a super with no separators in the other half of the same super, and the result was always the same—no difference to be seen.

Introducing Just-Hatcht Queens.—A *Stray Straw* in *Gleanings in Bee-Culture* says:

“W. H. Pridgen succeeds in giving a just-hatcht queen on the same day on which the old queen was removed. Friend Pridgen, if you take a queen just hatcht—one that has not been held in her cell—and put her in a hive where there is a laying queen, I think you will find that she is *always* kindly received without the removal of the old queen. The trouble comes when she attains a little age, perhaps a day or so old, when she begins to assert herself as a queen, at which time the two will no longer be tolerated under the same roof.” [Correct, according to my experience.—Ed.]

Why One is Disappointed in Purchasing Queens.—J. F. McIntyre says in *Gleanings in Bee-Culture* that he has bought queens from every breeder in this country who claims to have anything superior, and has generally been disappointed. As reasons for this disappointment, he gives the following: 1. The claims may be exaggerated. 2. The young queens are not as well bred as the mother, not reared under as good conditions. 3. The young queens may not be as well mated as the mother. 4. Queens are injured by long confinement in the mails, especially when shipped in full laying.

Candy for Shipping-Cages.—W. S. Pender writes in *Gleanings in Bee-Culture* that one of two queens sent from Medina to Australia came thru all right, and says:

“The cages were in splendid condition on arrival. They were very clean, free from any stains, and no loose grains of sugar. About two-thirds of the candy was consumed in each cage, and a part of the honey. You must have some secret process to prepare candy of coarse sugar, and yet be so soluble that the bees do not tear it out.”

To this the editor replies: “We have no secret process of candy-making. What we use is nothing more nor less than the Good (or Scholz) candy. We are careful to get pure cane sugar, powdered—not sugar and starch, in a combination known as confectioners’. This is what kills bees, but is just the thing for frosting on cakes. There is another important requisite—and that is, the art or knack of mixing the honey and the sugar—just as there is a knack in making bread.”

Superior Breeding-Queens.—The tide that has set in for bees of good performance rather than of good looks seems to suffer no diminution. J. F. McIntyre reports another fine queen in *Gleanings in Bee-Culture*. This is one of the cases in which it makes a difference how many colonies of bees a man keeps. If he keeps only two colonies, and one of them does twice as well as the other, it may not be a matter of much significance. But if, as in this case, he keeps 600 colonies, and a single colony makes a record away beyond the average, it is likely to be a matter of much significance. Mr. McIntyre says:

“Seven years ago I bought a queen from a man named Wallace. I reared about 20 queens from this one to test the stock. The next season was a dry one, and most bees had to be fed to keep them alive; but several colonies out of the 20 filled their supers with honey. Next season, 1895, I bred from the best of these; and in 1896, which was another dry year, this strain again filled their supers when others were starving. I have had many colonies of this strain which I considered ideal bees, and think that they have been improved by breeding from the very best each year. The present year was a very dry one, but I have one colony of

this strain that filled 2½ 10-frame Langstroth supers; and I wrote in my record-book, after the number of this hive, that such bees would make a man rich. They are beautiful, pure Italians, light 3-banded, queen large and yellow, and very prolific. I have reared about 200 young queens from her, and they are all like their mother. Her bees are gentle. She was one year old last July, and has never swarmed; and this strain does not swarm half as much as any other strain in my apiary. It is rare for me to become enthusiastic over a queen; but when a colony shows a marked superiority over 600 others in the same apiary, it is a rare thing.”

Winter Temperature of the Cluster.—In the *Bee-Keepers' Review*, Harry S. Howe gives a very interesting table made by H. C. McLallen, while in Cornell University. Five colonies were wintered outdoors, and two in cellar. In each hive a thermometer bulb was in the cluster, and in part of the outdoor hives a thermometer in the hive was out of the cluster also. Readings were taken twice daily, and in the table the average during a certain number of days is given. It will be noticed that the temperature in the cluster was higher in the outdoor colonies. But one will be puzzled to find any fixed rule as to variations. Sometimes the heat of the cluster went with that outside the hive, and sometimes it went in the opposite direction. The table is as follows:

	Jan. 4 to Jan. 23	Jan. 24 to Feb. 7	Feb. 8 to Feb. 14	Feb. 15 to Feb. 19	Feb. 20 to Mar. 4	Mar. 5 to Mar. 20	Mar. 21 to Apr. 10
Average temperature in the open air.....	33	19	40	24	31	48	43
Temperature in outdoor hives but not in cluster.....	45	41	51	42	45	64	64
Temperature of cluster in outdoor hive No. 1.....	71	74	75	72	72	81	83
Temperature of cluster in outdoor hive No. 2.....	66	65	68	64	65	76	77
Temperature of cluster in outdoor hive No. 3.....	68	68	71	63	67	80	86
Temperature of cluster in outdoor hive No. 4.....	73	73	79	74	74	80	80
Temperature of cluster in outdoor hive No. 5.....	71	75	80	79	77	83	84

Temperature of cluster in cellar hive No. 7.....	62	55	59	54	56	62	62

Refining Beeswax may be carried on to a considerable extent by simply allowing as large a body as possible to cool very slowly, a body of water being added if there is not enough wax, and when the whole is cooled the lower part of the cake can be scraped off and thrown away. There is, however, considerable wax left in this refuse, and those who handle wax on a large scale cleanse it with acid. Altho every one may not care to use this method, one may still be interested to know how it is done, and the following full description is given in *Gleanings in Bee-Culture*:

“We have no secret process of refining, for our wax-room is open to inspection to any bee-keeper. We simply have a large wooden tank capable of holding about 10 barrels. Into this is poured about a barrel and a half of water, acidulated with about 2 percent of raw commercial sulphuric acid. The hogshead—for that in reality is what it is—is then filled with commercial wax of all shades and colors, and the whole is then treated to a jet of steam. After it is thoroly melted the pipe is withdrawn, the tank is covered, and allowed to stand over night. The next morning the wax is ready to draw off thru faucets located at different heights on the tanks. During the night the acid and water, by reason of their greater specific gravity, settle down out of the wax, leaving it on top; during the same time the dirt now free from the wax settles into the water. The wax is then drawn off into deep cans, and usually has a bright yellow color, so totally unlike the product that went into the hogshead that one could hardly realize the two are one and the same.

“Of course, it is impracticable for the average bee-keeper to use so large a hogshead; but he can use practically the same methods with an ordinary barrel, reducing the quantity of acid and water, but, of course, keeping the relative amount of acid the same.

“The quantity of acid in any case will depend largely on the color of the wax before it goes into the refining vat. If the whole batch is almost black, then we would use about 5 percent of acid to water. If some of it is black, some yellow, some brown, then we would use about the percent first named.”

The Premiums offered on page 112 are well worth working for. Look at them.

Root's Column

DANZENBAKER HIVE.

The sale of this hive has nearly doubled each year since it was introduced 4 or 5 years ago, and our shipper reports a very decided gain so far this year. We send them all over the United States from Maine to California, besides a number of foreign countries. M. H. Mendleson, of Ventura, Calif., who is one of the largest producers in that State, uses this hive extensively and prefers it to all others for comb honey.

Do you want the names of some of the leading beekeepers who have tried this hive and have reported success with it from year to year? Do you want to know all about this hive and the advantages of this style frame and section? If so, write for **FACTS ABOUT BEES**. Please enclose a 2-cent stamp. It is a 64-page booklet, full of information. This hive, as well as **FACTS ABOUT BEES**, may be obtained of all our principal dealers, or may be ordered from the factory.

HONEY IN DANZ. SECTIONS.

FANCY COMB HONEY.

If you have a market for Fancy Comb Honey, you should not fail to try this hive. There are many reasons why it will pay you. In many of the leading markets honey in these sections will bring one to two cents a pound more than in the 4 1/4 beeway. If you produce comb honey for profit, you should certainly investigate the merits of this hive.

DANZ. BROOD-FRAME.

Watch this space next week....

THE A. I. ROOT CO., Medina, Ohio.

SEED **DUE BILL FREE**

To get new customers to test my Seeds, I will mail my 1900 Catalogue, filled with more bargains than ever and a 10c Due Bill good for 10c worth of Seeds for trial absolutely free. All the Best Seeds, Bulbs, Plants, Roses, Farm Seeds, Potatoes, etc., at lowest prices. Nine Great Novelties offered without names. I will pay \$50. FOR A NAME for each. Many other novelties offered, including Gladioli, the great money making plant. Over 30 varieties shown in colors. \$1100 in cash premiums offered. Don't give your order until you see this new catalogue. You'll be surprised at my bargain offers. Send your name on a postal for catalogue today. It is FREE to all. Tell your friends to send too. F. B. MILLS, Box 88 Rosehill. Onondaga Co., N. Y.

GENERAL ITEMS

Weather and Bees in Maryland.

We have been having a cold snap here since Jan. 28, but it seems this morning it will be warmer. The weather had been very warm thru January up to last Sunday evening—no snow with the exception of about one inch Dec. 31. The bees were doing well on the summer stands up to the cold snap. The coldest was yesterday morning, 6° above zero. L. A. HAMMOND, Washington Co., Md., Feb. 2.

All Publishers Not Swindlers.

I was very much surprised the other day to hear a farmer friend say that such and such a paper was published by a gang of swindlers. I at once hastened to correct his erroneous idea, but he stuck to it. When I pinned him down as to why he thought so, it developed that he had sent the paper a dollar for a year's subscription and had never heard anything from it. I asked him if he had ever written the paper about it, and he replied:

"No, what's the use? If they stole my dollar they wouldn't answer my letter."

Now, this is all wrong. Most men who are doing business try to do it "on the square." If they don't, the postoffice officials soon get after them. If you don't hear

BUY THE BEST.

If you want the best low-down wagon you should buy the Electric Handy Wagon. It is the best because it is made of the best material; the best broad-tired Electric Wheels; best seasoned white hickory axles; all other wood parts of the best seasoned white oak. The front and

ELECTRIC

rear, hounds are made from the best angle steel, which is neater, stronger and in every way better than wood. Well painted in red and varnished. Extra length of reach and extra long standards supplied without additional cost when requested. This wagon is guaranteed to carry 4,000 pounds anywhere. Write the Electric Wheel Co., Box 16, Quincy, Ill., for their new catalog, which fully describes this wagon, their famous Electric Wheels, and Electric Feed Cookers. Please mention the Bee Journal.

INCUBATOR FREE

on trial. The New C. Von Culin is most perfect in ventilation, moisture and heat.

HATCHES EVERY HATCHABLE EGG. Money made and saved. Catalog FREE. Poultryman's Plans, 10c. Address:

from the letter you send an advertiser or publisher, don't jump to the conclusion that they have your money and are trying to rob you. Your letter may have gone astray. Give the advertiser a chance to prove his innocence of wrong doing. Then, if he don't straighten out the matter, report it to the postoffice officials, and Uncle Sam will take the offender in hand.

The truth is that it is safer to do business by mail than over a counter.

JOE GRANGER.

Poor Season in 1899.

The past was the poorest season in 10 years. I started in the spring with 6 colonies, increased to 11, doubled back to 8, and got 50 pounds of surplus honey in all. I fed a part of them for winter, and will feed more in the spring. A number of bees thru this part of Iowa will starve this winter. Mine are doing nicely so far, having flights quite often. All are outdoors with but little protection for winter, but the weather has been fine—no snow to speak of.

WM. LYONS.

Sloux Co., Iowa, Jan. 30.

A Report for Last Season.

I started in the spring with 9 colonies, increased to 28, and got 700 pounds of comb honey and 300 pounds of extracted. Bees are wintering all right on the summer stands, packed with eight thicknesses of burlap over the frames. I look for a good crop for 1900, as there are a good many basswood trees in the range of the bee's flight, also lots of white clover.

G. B. DUFF.

Pike Co., Ill., Jan. 31.

Expresses His Thanks.

Allow me to express my thanks to Mr. Thos. G. Newman and also to the American Bee Journal, for the interesting report given on page 49. If all organizations would put before the public, as Mr. Newman did, the good work that they have done, can, and will do, there would be no trouble to increase the funds in the treasury. There would be quite a large number who would join as soon as they knew that their dollar would be a benefit to them, and also to others. I am very sorry that Mr. Newman is compelled to retire, for the world needs thousands of such willing and able men as he is.

Now let all the officers of the Association push forward in the wake of Mr. Newman, and we will increase our hundreds of members to thousands.

ROBT. J. CARY.
Fairfield Co., Conn.

Honey Eye-Wash.

Put into an ounce vial of pure honey a piece of alum as large as the end of the little finger, and then put the vial (cork of course) into a cornmeal dough, and cook it until the cornmeal is done. When cool, take out the vial and it is ready for use.

The above recipe was given to me a month ago. It cured a man here that the doctors said could not be cured; and the man who gave it to me got some for his little grandchild, and said if it cured her it would be worth \$500. He said the other day that she was getting better with the treatment. I gave him the honey for it.

N. M. HOLLISTER.
Greene Co., Mo., Feb. 3.

Heavy Loss in Bees Last Winter.

During the winter of 1898-99, while out deborning cattle, I made it a point to inquire about bees, and found something over 400 colonies in Tama and Marshall counties, and I think in February and March (as I was on the road) I found 87 of the 400 alive. I have learned since then that the 87 nearly half died before May. One man in Marshall county had 100 colonies, and lost every

are often reported by those who use a

SUCCESSFUL INCUBATOR

One reason for this record is absolute uniformity of temperature in egg chamber. Correct instructions for operating sent with every machine. Will hatch every egg that can be hatched. Send 6 cents for new 100-page catalogue. Filled with best information and plans of poultry and brooder houses.

DES MOINES INCUBATOR CO.
Box 78, Des Moines, Iowa.

one; another had 30, and got one colony thru. I had 52, and had 18 last spring, but nearly all in bad shape. I had 9 in chaff hives, and 7 of them died, and all had plenty of honey, but only a few bees. One colony had only one quart (prost lightly) of loose bees, that is, those that had not crawled into the combs; the strongest had about 2 1/2 quarts. The small amount of bees I think was due to the fact that there was no full honey, and therefore no full brood to rear young bees for winter.

Last season was almost a failure for honey here. I got about 300 pounds of comb honey, and also 200 pounds in brood-frames for the spring of 1900. I have 50 colonies now, 44 in the cellar and 6 in chaff hives on the summer stands.

THEO. S. HURLEY.

Tama Co., Iowa, Jan. 29.

Bees in Almost Air-Tight Places.

During the week since my discovery that bees could live for weeks in an atmosphere containing little or no oxygen, I have thought over the habits of ordinary insects, and how, under their usual surroundings, they do seem to exist in an air perhaps practically destitute of oxygen. Every bee-keeper knows how an old box or barrel containing old combs will heat up from the maturing larvae of the wax-moths it contains, which, while practically air-tight, does not hinder, but, on the contrary, assists their development.

Ants that live in families in the earth or old decayed logs, may find the air we breathe not essential to them. In Honduras I saw many ant-nests at the foot of trees larger than a bushel basket, practically a solid mass of living ants—so great were their numbers that they had roads and brought leaves from lemon trees to support their young. One would think fresh air would have been difficult of access in the center of such nests.

Perhaps an illustration may be found in the hatching of queens, which are sufficiently developed in an air-tight cell to be able to fly as soon as they can escape from it. In such cells it would be reasonable to presume the air might have become at least poor in her last 10 days' confinement.

Of course, it will be said that these references are of no value—Nature has her way of doing such things. That is all very well on general principles, but perhaps while the habits of insects have been studied carefully the chemical conditions of the air they breathe has escaped analysis.

Clare Co., Mich. T. F. BINGHAM.

Bees For Sale

I have 3 well equipt apiaries on least ground in the Kickapoo Valley, all well located in the white clover and basswood belt of Wisconsin, consisting of from 100 to 150 colonies, each in 8-frame Langstroth hives; extracting-cases, extractor, wintering-cellar, honey-house, etc., at each apiary, all in good condition, nearly new. I will sell one apiary or more, on easy terms, and at a bargain. Address,

A. G. WILSON, Readstown, Wis.

M. F. Hathaway, Palmer, Lake Co, Ind. Please mention Bee Journal when writing.

Convention Notices.

Utah.—The Utah State Bee-Keepers' Association will hold its semi-annual convention in the City and County Building, Salt Lake City, Apr. 6, 1900, at 10 o'clock a.m. A full program in the interest of the industry will be presented, and all our bee-keepers can help themselves by aiding the Association, and in order to create a closer bond of union among our bee-keepers. As a further incentive to the success of the bee-industry, it is very desirable to have our bee-keepers from all parts attend the spring convention. **J. B. FAGG, Sec.**

California.—The tenth annual convention of the California State Bee-Keepers' Association will be held in the Chamber of Commerce, at Los Angeles, Feb. 21 and 22, 1900. It will be called to order at 1:30 p.m., Feb. 21. At this time the railroads will sell round-trip tickets to Los Angeles and return for one and one-third fare, on account of the Industrial, Mining, and Citrus Exposition, which will be held in Los Angeles. Tickets good for 10 days. Let every bee-keeper bring some hive, tool or experience that he has found valuable, and we will have a good convention. **J. F. McINTYRE, Sec.** Sespe, Calif.

The Great "Liberty" Field Corn.—For 1900 **H. W. Buckbee, Rockford Seed Farms, Rockford, Ill.**, is offering his customers a new variety of seed-corn, which has already excited wide attention from corn-growers. It is Buckbee's Liberty Field Corn, which Mr. S. C. Clark, of Ohio, the largest grower of seed-corn in the world, has pronounced "the best corn of the century." The "Liberty" is the result of long years of selection, and Mr. Buckbee is proud of having produced a field-corn which combines more good points than are found in any other in cultivation. The test fields last year with only average cultivation, yielded upwards of 100 bushels per acre, with ears ranging from 8 to 12 inches, the cobs small and well filled with from 16 to 20 rows. The fodder stands 7 to 12 feet high and withstands storms perfectly. It matures in 90 days. While the corn is very pure in growth and habit, it is of a remarkable type and color, the grain being variegated, red, amber, golden-yellow, all on one cob. Every one who has seen this corn in the field is enthusiastic in praise of its abundant yield and its early maturity. A sample of this Great Liberty Corn will be sent free when requested, in combination with his 1900 seed catalog to any reader of the American Bee Journal. The catalog has on its cover a reproduction in natural colors of this remarkable variety of field-corn. Don't fail to see it. Address **H. W. Buckbee, Rockford, Ill.**, and please mention the American Bee Journal when writing him.

The Illinois Incubator.—No incubator made has done more to make converts than the famous "Illinois," made by **J. H. Jones, of Streator, Ill.** This is its 8th year on the market and every season has seen it grow in popularity. The explanation is that it is sold on the guarantee that it is a perfect hatcher. Write to Mr. Jones for the handsome free catalog, fully describing the machines and giving valuable hints as to the care of poultry. Please mention the American Bee Journal when writing.

Messrs. Flansburgh & Peirson, Leslie, Mich., appear as advertisers in these columns. This is a consolidation of two well known gentlemen of long experience in their several lines, and promises for its many patrons even more efficient service and better satisfaction than was possible when operating as individuals. Michigan grown stock is famous for its vigor and healthiness. Especially is this true of strawberries and potatoes, both of which are made a specialty by this firm. Their catalog shows a complete line. It is copiously illustrated with half-tones from photographs and hence true to life. Our readers will doubtless serve their own interests, and confer a favor on us, if they write Messrs. Flansburgh & Peirson for a catalog, and mention this paper.

THE PEN IS MIGHTIER than the sword, if the Pen is made of Page Fence. **PAGE WOVEN WIRE FENCE CO., ADRIAN, MICH.**

HAMMOND'S
 Michigan Northern-Grown Onion Seed.

I sold 66,000 lbs. of this seed in 1899. My customers report yields of 450 to 1,265 bushels of onions per acre from this seed. Some of them intimate that this seed is worth \$5 to \$10 per lb. more than the California grown seed sold by anybody. I guarantee this seed to be new and freshly grown. We have seed of all the leading and standard varieties. We make special prices on large lots. Onion sets of all varieties. Buy direct from the grower. Catalogue—extended and illustrated—free.

Harry N. Hammond, Seedsman,
 Box 2, FIFIELD, MICH.

HONEY AND BEESWAX
 MARKET QUOTATIONS.

CHICAGO, Feb. 7.—Trade is slow in comb honey, choice lots of white bring 15 cents, with that a little short of this grade, 13@14c; ambers range from 10@12c; dark, 8@10c; no fancy lots on the market.

Extracted, fancy white, 9c; amber to white, 7½@8½c; dark and buckwheat range about 7c. Beeswax is selling on arrival at 28 cents.

R. A. BURNETT & Co.

CINCINNATI, Dec. 27.—There is a good demand for all kinds of extracted honey. White clover and basswood sell at 8@8½c; amber and Southern, 6@7c, according to quality and package. Fancy comb honey in no-drip shipping-cases sells at 15@16c; darker grades hard to sell at any price. Beeswax, 2c. C. H. W. WEBER, Successor to Chas. F. Muth & Son and A. Muth.

LOS ANGELES, Jan. 4.—1-pound frames, 12½@15c; 2-pound cans, 2 dozen in case, per dozen \$2.50; 2-pound glass pails, per dozen, \$2.50. Extracted, water white, 60-pound tins, per pound, 8½c; light amber, 7½@8c; dark amber, 7½c. Beeswax, 25@26c.

KANSAS CITY, Jan. 19.—We quote No. 1 white comb, 13½@14c; No. 2, 13@13½c; No. 1 amber, 13@14c. Extracted, white, 7½@8c; amber, 7@7½c. Beeswax, 20@22c.

The supply and demand for comb honey is light. The demand for extracted since the first of the year not so good. C. C. CLEMONS & Co.

BUFFALO, Jan. 5.—Market bare of fancy white one-pound comb honey, and selling at 15@16c; fair to good, 12@14c; buckwheat, dark, poor, etc., 8@10c. Fancy pure beeswax, 28@30c.

BATTERSON & Co.

NEW YORK, Feb. 8.—During the past 30 days our market has been somewhat slow and easy in both comb and extracted honey. Stocks of comb honey, however, are almost exhausted, and there is a fair demand for all grades. Fancy white selling at 15c; No. 1 white at 13@14c; fancy amber, 11@12c, and buckwheat at 9@11c, according to quality, etc.

Our market is well supplied with extracted, the prices are firm and unchanged. Beeswax sells very well at from 26@28c, according to quality.

HILDRETH & SEGELKEN.

SAN FRANCISCO, Jan. 10.—White comb, 11½@12½c; amber, 8@10c. Extracted, white, 7½@8c; light amber, 7@7½c; amber, 5@5½c; Beeswax, 26@27c.

Offerings and demand are both light, and this must continue to be the case until the end of the season. Business is necessarily of a retail character, but at generally firm figures, especially for choice extracted, which is in lighter supply than comb.

BOSTON, Jan. 12.—We quote as follows: Fancy white, 16c; A No. 1, 15c; No. 1, 13@14c; buckwheat will not sell in this city. Extracted, light amber, 7@8c. Demand is very light.

BLAKE, SCOTT & LEE.

ALBANY, Jan. 10.—We quote: Fancy white comb, 15c; No. 1 white, 13@14c; mixt, 11@13c; buckwheat, 10@11c. Extracted, white, 8@9c; mixt, 6½@7c; dark, 6. Beeswax, 26@28c.

MACDOUGAL & Co.
 Successors to Chas. McCalloch & Co.

OMAHA, Jan. 4.—Prices remain unchanged. Fancy white is still moving slowly at 14@14½c. Extracted, white, 8½c. Now that holiday trade is over and dealers have taken their inventory, they soon will be thinking of replenishing their stock and more lively trade is anticipated in the near future, but no material advance is looked for during January.

PEYCKE BROS.

DETROIT, Feb. 10.—Fancy white comb, 15@16c; No. 1, white, 13@14c; fancy amber, 11@12c; dark and undesirable lots, 8@10c. Extracted, white, 7@7½c; amber and dark, 5@6c. Beeswax, 25@26c. Supply of honey fair with light demand.

M. H. HUNT & SON.

WANTED.—Extracted honey, all kinds; mail sample and price expected delivered at Cincinnati. I pay spot cash on delivery.

Farmer's Home Journal, Louisville, Ky.

A practical business paper for the farmer. It treats of farming and stock breeding from both practical and scientific standpoints. It is the oldest and best known agricultural weekly in the South. If you have anything to sell send us your advertisement. Every farmer who expects to mix "brains with muscle" in his business should read this paper. Subscription price, \$1.00 per year. Sample copy free. Address, **FARMER'S HOME JOURNAL, Louisville, Ky.**

\$100 to the Winners

These wintery evenings you have some time to spare, so here is a puzzle you can solve. If you have not the leisure to-night, put it aside until to-morrow night or, better still, call the attention of the members of your family who have a taste for puzzles, to it. Some of you can hardly fail to get it. It is purely a test of quick-witted observation without any element of chance. There is only one answer that can be obtained by properly finishing the letters and supplying the space to make words of the letters. We give below two lines of incomplete letter puzzles. By solving one of them you earn a prize, and by solving both correctly you come in on the \$100 prize to the winners.

Other Prizes To any contestant sending a correct answer to one of these puzzles, we will send their choice of a year's subscription to "The Gentlewoman," or "American Fruit and Vegetable Journal," or "American Poultry Advocate," or your choice of any one of the following books: "The New Hygiene," a book on up-to-date treatment to maintain health without medicine; the works in one volume of Charlotte M. Braeme; or the "Duchess"; or Miss Muloeh's; or Sylvanus Cobb, Jr., or Miss Braddon's; or Wilkie Collins; or Mary Cecil Hay. When sending in your answers name the prize you wish, should only one puzzle be answered correctly. The first puzzle is

This puzzle consists of a line of 13 incomplete letters, which if complete would spell three words. Only the lower two-fifths of each letter appears, the other three fifths have been cut off. What are these three words? They are all taken from this very advertisement. The words are not separated from each other, but the letters follow in correct order, all they need being the space. There is no transposition or trick of any kind. Taking one letter right after the other from the first to the thirteenth they spell three words. **EACH WORD IN BOTH PUZZLES APPEARS SOMEWHERE IN THIS ADVERTISEMENT.** There is no chance about it. If there were two correct answers to either one of these puzzles, the Farm, Field and Fireside would be refused the mail for running a lottery.

I A I L I L S I I A S I L

The second puzzle consists of 13 incomplete letters forming four words. The letters following consecutively as in the first:

I A I L I L S I I A S I L

In order to get all the words in this advertisement as promised we are compelled to tell the following little story: "Some animal was injuring our trees on the hill, so we placed a poisoned paste in a tart, which the animal ate, and I hate to say what the pest proved to be. Can you guess? We found that the poison had made it very ill, and we took it by the tail and drowned it in the pond."

The object of the puzzle is in part to secure a large number of new trial subscribers to the Farm, Field and Fireside, the greatest agricultural weekly in the west. Do you know of any farmer who might be interested in a good farm paper? We want him on our list for a short time, and as the contest is inaugurated for the purpose of introducing our paper into new homes we make the following the

Conditions: To be eligible to receive a prize every contestant must send with his or her answer the name of a person not now a subscriber, with 25 cents to pay for sending the paper to him on trial for three months.

Remember, if you get one line right you earn a prize, and if both are right you are in on the first prize. **THIS CONTEST WILL CLOSE MARCH 31.** ADDRESS PUZZLE DEPARTMENT FARM, FIELD AND FIRESIDE, 710 MASONIC TEMPLE, CHICAGO.

Experience the Best Teacher.
But a wise man profits by the experience of others. Every farmer and dairyman needs a practical, helpful paper like

Dairy and Creamery
PUBLISHED AT CHICAGO, ILL.

filled with information gathered from the actual experience of practical and scientific breeders and feeders of cattle and pigs. He wants to know how other men get the best results; how to feed to the best profit; how best to utilize his skim milk; how to build up a first-class dairy from the resources he has; what crops to grow to keep up the flow of milk at all seasons.

Last year a patron of a Kansas creamery who read a dairy paper and kept good cows, made \$36.00 per cow more than the poorest patron of the same creamery who did not read a dairy paper. That means something; it shows the value of an up-to-date, reliable adviser like DAIRY AND CREAMERY. (Subscription 50 cts. per year.)

FREE! We will send DAIRY AND CREAMERY, the best semi-monthly paper published for farmers and dairymen, absolutely FREE for one year to all new subscribers to this paper, and to all old subscribers paying their subscription one year in advance. Both papers for the price of one. Send your subscription to this office while this offer is open. Both Papers \$1.00.

AMERICAN BEE JOURNAL, CHICAGO, ILL.

A Further Offer: We will give Dairy and Creamery for one year as a premium to any one of our readers who sends us one new subscriber to the American Bee Journal for one year at \$1.00. Unless these offers appear again after March 1, in these columns, they will be withdrawn at that date; so you would better take advantage of them at once. Address,

BIOGRAPHICAL.

Mr. D. H. Coggshall, His Home and Apiary.

DAVID H. COGGSHALL was born Dec. 1, 1847, in Tompkins Co., N. Y., and was one of a family of 4 children. His early years were spent in the routine of farm life, where he early formed the habits of industry and self-reliance.

February 24, 1869, Mr. Coggshall was married to Clarinda F. Smith. Three children have been born to them, of whom two survive—a son and daughter.

In 1861 Mr. Coggshall's grandfather, Wm. Green, gave him a swarm of bees and he began a series of experiments in their management. He first tried wintering them in the house-cellar, but this was not successful. Up to 1866 his bees were kept in box-hives, when he bought the D. P. Kidder movable-frame hive and transferred his bees to them. Experience proved this to be a step in the right direction. The Kidder hive being double-walled he now began wintering bees outdoors, with fair success. During all this time he read all the books and papers on bee-culture which he could get, and among them was "Langstroth on the Honey-Bee."

In 1867 he made 13 Langstroth hives and put 13 new swarms into them. He now built a bee-house 12x16 feet, with a packing of sawdust in the wall one foot thick, and tried wintering bees in it, but with this he was disappointed, as the bees wintered no better than in the house cellar. The wintering problem was finally solved by use of the chaff

hive in which the bees are packed in dry sawdust and left outdoors.

In 1868 he made a honey-extractor with an apple-paring machine for gearing; this was a crude affair, and did not work to suit his ideas, so he built a heavier one, using clover-huller bevel-gears, geared one to three, which worked very satisfactorily, and is the one shown in the cut standing on hive No. 160 in the picture. This machine is non-reversible, taking 4 Langstroth frames, the frames hanging exactly as they do in the hive. Instead of being placed in the 4 sides of the basket, in the ordinary fashion, they are set down in the machine, two on a side. A strip of tin separates the two combs so that the honey from the inner one, instead of striking the outside comb, flies against the tin, draining down in the extractor. The cross arm and bearings are made of wood.

Mr. Coggshall says it is a great advantage to set the combs in the extractor in the same way they are taken from the hive, as they can be picked out of the hive and set down in this extractor more rapidly than the same number of combs could be picked out and inserted in a Cowan extractor, as in the case of the latter the frame is lifted out with one hand, and with the other turned at right angles so that it can be set down endwise in the machine.

Previous to 1866 Mr. C. practiced natural swarming, but after procuring the Kidder movable-frame hives he began increasing artificially, with alternate success and failure; but the artificial, or dividing, method appearing to have so many advantages was persisted in and perfected until

now, and for many years past it has been the only method used.

Soon after queen-excluders were put on the market he began using them with great success, and says that without them he could not manage all his out-apiaries. Since using them he has had no trouble in controlling the increase, and the end of the season finds the bees with plenty of honey in the lower story for winter use.

About 1870 Mr. Coggshall's brother, W. Lamar, entered

Home of Mr. D. H. Coggshall, Tompkins Co., N. Y.

into partnership with him in the bee-business, and they workt them together under the name of Coggs shall Bros., up to 1877, when the partnership was dissolved.

In 1881 his brother and himself shipt their first full carload of honey to New York City, since when the product has increased until the past season's shipments aggregated about five carloads.

Mr. Coggs shall now manages his home apiary and six outlying yards, numbering about 600 colonies, run almost entirely for extracted honey.

In the illustration is shown the style of beedress worn by Mr. C., which has a wire-screen in front of the face, fastened in the veil, which is attacht to a loose blouse gathered at the waist by a rubber cord, making it absolutely bee-proof.

There is also shown an 18-gallon honey-keg, 60 of which were filled in this yard in 1896 with well-ripened honey. Lying on the keg is a Crane smoker, the kind preferred. Near by is the wheelbarrow and queen-excluders. Near the center is the uncapping-can, while in front are some empty extracting-combs in frames, of which he has some that have been in constant use from the first.

The trees shown in the yard are Kieffer pears, which are well loaded, and only 10 years old.

The yard contains about 110 colonies, and is shown in September, after the extracting-stories were removed and stones put on the hives to hold the covers down. A part of the chaff hives in which the bees are wintered are also shown, and when put up in this way the bees in this yard have always wintered successfully.

After all these years of study, experiment, failure, and success, the subject of this sketch feels well repaid in the knowledge gained and the pleasure and satisfaction of achieving a well-earned success. Mr. Coggs shall has been a subscriber and constant reader of the American Bee Journal since it was published by Samuel Wagner at Washington, D.C., and now has complete files of the same.

No. 7.—How to Get the Most Out of the Honey-Extractor.

BY "OLD GRIMES."

WE have used quite a number of extractors in our work, and find that it pays to keep up with the times and use the latest improved styles, and now use the Cowan, and for general use the 4-frame extractor gives the best results. There is no doubt but a 2-frame extractor could be workt to advantage in a large apiary. It is certainly a fact that in a 2-frame extractor, where the combs are so near the spindle or center, the labor of turning the machine is trifling, and the honey is thrown out in less time than when the combs are a foot or more from the center. With the 4-frame extractor, if properly geared, and with a crank of not less than an 8-inch radius, the labor is not heavy.

In selecting an extractor the purchaser should buy one that is within the range of a boy's or a girl's strength to operate. There are some six or eight frame extractors; these are all well enough for power, but are a sort of a man-killer when run by hand, and would certainly be too much work to put on a boy or girl, or even the good wife.

Mr. D. H. Coggs shall and one of his Out-Apiaries, located in Tompkins County, New York.

A bee-keeper can get much more out of an extractor in this year of 1900 than he could 15 or 20 years ago. The machines are better made and less cumbersome in their work. The next 20 years will probably see as great improvements. It would perhaps be considered a backward movement to say that the future extractor will be improved along the lines of the 2-frame principle; still it must be remembered that many an old and rejected principle has been the best one all along. The future extractor will be entirely automatic as to reversal of frames and the motive power.

While operating an extractor the person should temper his strength to the strength of the extractor—a very strong and careless person will sometimes reverse this tempering, and the result is a broken machine.

In order to get the most out of an extractor it really seems as necessary for it to be of the reversing order, for many times while extracting new and fragile combs it is necessary to reverse before the honey is all thrown from one side; the weight of a comb against the wire-cloth of the basket will so indent into it that it will break the comb to pieces unless the reversals are made often and the motion is moderate.

In order to get the most out of an extractor some bee-keepers extract quite an amount of larvæ with the honey, but here is a case where the operator would better be content with a little less. Old Grimes learned a lesson many years ago that cured him of this trick. There was quite an amount of said larvæ in all stages of development in the strainer, and we all know that they never look very nice, and we prefer that our customers should not see them; but there came a city lady who was being shown the mysteries of the bee-business; everything was new and very interesting to her until she came to the strainer with the white larvæ in it, and the honey running over them. Then and there, from the remarks she made, she forgot all the rest she had seen, and only remembered "those worms," as she termed them, and thereafter she never would allow a drop of liquid honey to pass her lips—she knew just how it was extracted. Altho but a very little of our honey had been in contact with the larvæ, it made no difference, it was all alike to her.

If much larvæ is thrown out with the honey it will injure the flavor. A good way to overcome the larvæ trouble is to return to the hive all combs having unsealed brood. It may be a little trouble and a delay in the extracting of that comb, but it pays. Another way out of the woods is to use the queen-excluding honey-board; all honey stored above it is sure to be free from larvæ, and for that reason it is used quite extensively in our apiaries.

A honey-tank is almost a necessary adjunct to a honey-house and an extractor, because there are many localities where the honey is always of such consistency, and the bee-keeper so careful to extract nothing but ripe honey, that it can be safely run from the extractor to the barrel. Where barrels are used that hold from two to three hundred pounds, the tank can be very well dispensed with, but even then it is better to allow the honey to remain in some large vessel until the little specks of comb rise to the surface, then the honey will all be perfectly clear. When honey is put into smaller packages, holding from one pound to 60, the tank is a necessity, for the honey that is put up for table use should be free from all of those little specks. Nice, clean honey adds to the reputation of the bee-keeper.

Where a tank is used a very good size is a capacity for a ton of honey, or about four feet in diameter and two feet deep. We place this in our basement, but when used in the out-apiaries it is placed outside the building, and has a wire-cloth cover to it. The air has free access to the surface, and any thin portion that rises to the top is soon evaporated. A two-inch faucet should be used for drawing off the honey, and it is a very good idea to fix the gate so as to insert a padlock, and then there will be no danger that the gate will be elevated in our absence. Spilled honey makes the earth sweet, but it has the opposite effect upon the temper of the bee-keeper.

Hives, Queens, and Honey-Flow.

BY HENRY BIDWELL.

THE three greatest drawbacks to successful bee-culture in America are, small hives, forced swarms, and deficiencies in the flow of honey during the spring, summer and fall of each year.

A hive ought to be large enough for a queen to have brood-combs sufficient to enable her to lay all the eggs she

possibly can, so that her worker progeny will be numerous enough to gather all the honey possible during the yield of nectar.

The queen ought to be developed sufficiently so she can readily lay 4,000 to 5,000 eggs a day—the more the better—and the honey-flowers should follow in succession from early spring until late in the fall. A perfect knowledge of the flora within a mile of his apiary ought to be one of the first lessons to learn by a beginner in the bee-business.

We can all get one-hundred dollar queens by increasing the size and capacity of our hives, queens and flower fields, when the day of cheap queens will be in the past. One hive with a bushel of worker-bees capable of gathering 100 pounds of honey in a honey-flow is worth more than 10 colonies, each with a hat full of bees only gathering enough to feed the brood. I cannot remember a season in the past 50 years when there was not suitable weather for the bees to gather surplus from good honey-producing plants, with large hives and plenty of honey-gatherers. Providence is not to blame for our short-comings, because you can take a dollar queen to-day and in 10 years make it worth \$100, by careful and constant development; or you can reverse the process. But remember, it is easier and faster going down hill than up; and if you want to keep clear of foul brood, you would better let forced queens alone.

A queen capable of laying 1,000 to 2,000 eggs a day will find an ordinary 8-frame hive of sufficient capacity; but if she can do better than that, she needs a 10-frame hive; and if her capacity is 5,000 eggs a day, a double 10-frame hive is necessary for her to reproduce herself. You must expand the brood-nest if you wish to increase her capacity; and while she is doing her best is just the time to rear as good or better daughters if she is not already fully developed.

I think a queen lays a better egg in a natural cell when she wishes to reproduce herself than ordinary worker-eggs; and a good, strong, healthy queen is better in her prime than an old, weak and feeble one. I prefer to rear my young queens under the most favorable conditions for the full and perfect development of her greatest vitality and prolificness, and only allow the best and strongest colonies for that purpose. I also wait until they swarm out naturally, knowing it is one of their natural, God-given instincts to do so, and prosper better for it. I then hive the new swarm and place it on the old stand, and divide the old colony into as many parts as there are sealed queens, putting the combs into empty hives on one side, and placing each new part on the top of a strong colony, then give each a quart of the bees from the new swarm, leaving them until the young queens begin to lay, then substitute them with those underneath, removing them to a new place.

If you wish to grow flowers for honey alone, plant borage—one peck of seed to the acre, sowed broadcast early in the spring, if the land is clean, or drill it in and hoe or cultivate if the land is foul. It begins to bloom about the first of June, and increases as the season advances until frost. The honey is of good quality, amber in color, and as the flowers hang down the honey is not washed out by the rain or dew, but as the seed falls to the ground as fast as it ripens, and is quickly devoured by the birds and fowls, it requires great care to gather it.

The best farm crop for bee-pasturage here is alfalfa. Sow a peck to a half bushel of seed to the acre early in the spring, or just before the fall rains, on good, deep land where it can remain permanently. This begins to bloom about the middle of May, continuing about one month, but if a portion of the field is cut previously it comes on and blooms after the first, second, and third crops, continuing the bloom all summer and fall. Alfalfa is destined to be the principal honey-producing plant in the United States.

Sedgwick Co., Kan.

Shallow vs. Full-Story Supers for Extracted Honey.

BY C. P. DADANT.

I AM thinking of running my bees for extracted honey, to save time and to better control swarming. I use 10-frame Langstroth hives. Would you advise the use of half-story or full-story supers? You know what the "Draper barn" is. Would you use this hive with ordinary Langstroth hive-bodies for supers?

We have, at different times, in the columns of the American Bee Journal, stated our preference for half-story or shallow supers, and the reason for this preference. But it seems necessary, in a periodical publication, to come back to the same subject quite often, especially if it is of importance. The answer to questions like the above concerns

most especially beginners. Practical bee-keepers who have had years of experience do not look for advice on subjects of this kind, because they have either tried the methods recommended and adopted them, or have rejected them for reasons that are connected with their own practice; or because they have already traced for themselves a course to follow with which they are well satisfied, and do not care to try anything else. In bee-keeping, as in other pursuits, men succeed under different circumstances, following entirely different methods, and each man is prone to consider his method best if it has stood the test of experience in the circumstances in which he finds himself placed.

Let me state at the outset that I consider the "Draper barn" a better hive than the ordinary Langstroth. The Draper barn, called after Mr. A. N. Draper, of Madison Co., Ill., was originated to follow the methods recommended by us, and is substantially a Langstroth hive, the body of which is a little over two inches deeper than the ordinary style, giving the bees a greater breeding-space. This hive takes the same supers, sections, covers, etc., as the ordinary Langstroth hive.

We prefer a shallow super in extracting for several reasons, and before we give these reasons allow me to say that it was only after a practical trial on a large number of hives for several years of both a 10-inch super and 6 $\frac{3}{4}$ super that we gave our preference to the latter. Experiments on a large number of hives are quite expensive; but they are the only tests which may be called practical and conclusive. I would not accept as of any value a test made on one or two hives; as the experience thus gained might be distorted (if I may thus express it) by special conditions of the colonies which served for the test. There is so great a difference in the results obtained from colonies of different strength, or different degrees of prolificness, other circumstances and conditions notwithstanding, that it is well nigh impossible to assert anything, or lay down any rule from anything but a wholesale trial. In the latter case a fair average is usually struck, as you are likely to have on either side a test of colonies in all sorts of circumstances.

In the first place, we prefer the super with a 6-inch side-bar, what we call the "half-story super," because its frames are very much more easily handled for extracting than any other. The depth of the comb is just right for the honey-knife to reach across its face from top to bottom, and a comb is uncut at a single stroke. There is less weight, such a comb weighing from 3 to 5 pounds, and less danger of breaking down in handling or in extracting. The large combs we use in the body of the hive, weigh 8 to 10 pounds, and the combs of a "Draper barn" would come very near 8 pounds when full of honey. Those of a Langstroth frame weigh less, but are still quite heavy and unwieldy, and are readily damaged when handled in hot weather, if they are new and very full of fresh honey. This is, however, not the main reason for our preference for shallow extracting-frames.

Experience with the deep super full-size frame has shown us that with such supers the queen is much more readily induced to ascend into the upper story to lay than with a shallow super. I ascribe it to the fact that it takes quite awhile for the bees to occupy the entire super and place honey in every cell. In a shallow super the space is very much more quickly occupied, and tho' the cells are not filled at once, yet honey is put in most of them very soon after the super has been given. We have seen a number of cases when the queen deserted the lower apartment to occupy the one above, when the latter was a full story, but with the half-story super this has very rarely happened. Of course, in a very heavy honey crop such occurrences are rare even with the full-story super.

On the other hand, when a super is given to each colony at the opening of the crop it often happens that some of the colonies are unable to occupy the entire space, and a full-story super proves too much of an addition. If the nights are cool, the bees have more difficulty in keeping up the required temperature, and this causes more or less delay in breeding.

But after all we must not be exclusive. Success can certainly be attained even with full-story supers. We know of many practical bee-keepers who use nothing else for extracting. But for our own use we much prefer the super mentioned for the reasons above stated.

As for using a shallow super only 4 $\frac{1}{4}$ inches deep for extracting, that is out of the question. This is running to the other extreme, and such supers require altogether too much handling for the harvesting of a large crop of honey.

We have been called too conservative because we hold and practice methods which we inaugurated 25 years or

more ago. Our answer to this is that we believe in progress, but we have harvested large crops always with these methods; we see all the bee-keepers in our vicinity, or the most of them, imitating us because they see us succeed, and we can not help thinking that we are yet on the right track. All we want, all we seek, is practical results with the plainest methods that can be devised. Hamilton Co., Ill.

CONVENTION PROCEEDINGS

Report of the Colorado State Convention.

(Continued from page 102.)

TAXING BEES IN COLORADO.

QUESTION.—Would it not be a help to the inspector to have the county assessor keep a record of the bees in his county?

Mr. Gordon.—It is the county inspector's duty to inspect the apiaries of the small bee-keepers. How is he going to find them? If the assessor had a list, he would only need to consult it. I know of one case in which the inspector found out the existence of foul brood in this way.

Mr. Tracy.—Were those bees taxed? That was wrong. It is right to give them in.

J. B. Adams.—I understood that the assessor of Boulder County had 700 colonies on his list. There are over 18,000 colonies in Boulder County. The assessor doesn't get them on his record. They are not given in.

Pres. Aikin.—Bees are taxed in my county.

Mr. Rhodes.—I think bees are not subject to taxation. It is a fallacy to call them property. Bees have very different values in the spring and fall. I am opposed to taxing bees, because it is unjust.

Mr. Tracy.—Nearly three years ago Rauchfuss Bros. had 400 colonies. Two months after they had 100. Bees can not be taxed with justice to man and man. If I were a money-lender, and a man wanted to borrow \$50 with bees as security, I wouldn't give it. I gave just as much attention to my bees at the time I lost them as I did before.

F. Rauchfuss.—We expect protection, and can not expect it without taxation. We need to pay the inspectors. It is pretty hard to tax justly, but we should not shrink from a little taxation.

Mr. Bates.—Suppose I have \$100 worth of bees and \$100 worth of hens—am I asked to pay taxes on the poultry?

F. Rauchfuss.—Those that make an exclusive business of poultry are taxed.

Mr. Lyon.—If the government thinks our industry needs nurture, it is not for us to say nay.

Pres. Aikin.—Bees are property *in the hive*. When my house burns down after assessment I have to pay taxes just the same as in anything else.

A resolution by Mr. Rhodes was unanimously carried, as follows:

Resolved, That the Colorado State Bee-Keepers' Association recommend that all honey shipped out be marked with the address of the producer.

INCREASING THE LOCAL DEMAND FOR HONEY.

Pres. Aikin introduced the subject, "How can we increase the demand for honey in our local market and maintain the price?" as follows:

There are no wealthy merchants, and not many wealthy people, in the community where I live. Very few indulge in luxuries. Granulated sugar two or three years ago was 5 $\frac{1}{2}$ to 6 cents a pound. I reasoned this way: Here is honey at 10 cents a pound; then they can't stand it to buy honey. It was a question not of buying the thing wanted, but of supplying the table. I had to meet that question. Can I do better by shipping out? I looked at the quotations. The top notch was 7 cents. It would cost me 3 cents to get it to that place, leaving 4 cents for me. Then cans cost. Any way I could figure, I would be sure to have only 2 to 4 cents left if sold on commission. I concluded to put the price down to where it would compete with sugar. I could never make a sale of over 5 or 6 cents in Denver and at other places. I therefore said to the people, I will sell you

honey at 6 cents a pound. This is contrary to the general practice of business. But by so doing I get the custom of poor people. I sold them just the honey at that price and charged for the pail. I offered to sell honey thru the stores in my town at the same time. I wholesaled it to them, giving 3 cents to the dealers for four pounds sold. Our trade in extracted honey is doubling every year.

As to maintaining the price, this year a buyer offered me 5½ cents. I said to him, "You can't have it. I will sell it to you for 6 cents, which is cheaper than I am selling it to the people here." He bought it for 6 cents. I was at first afraid to raise the price in the home market for fear I would drive away my customers, but I am now selling it at home for 7 cents a pound.

I first run the honey from the extractor to a tank, then into pails and stack them up till the honey is candied. It does not cost me much more than to put it in cans. When I first started, 3-pound cans of corn-syrup were sold for 15 cents. I can not compete with that, but I have to compete with sugar. As to the fancy trade of honey, that is different. If I were at Denver, I would perhaps employ different tactics.

To-day the dealers in our town are demanding the 15-pound pails of honey instead of the small pails. That shows it is getting to be a staple with them. If we produced ten times as much as we do, and sold to compete with other sweets, it would be easier to sell. It would be like hogs and corn in Iowa—the buyers come and buy at the dooryard because there is a quantity to buy. When we produce in large quantities, and keep it before the people all the time, there is an inducement for the buyer to come around.

I should also say that I trade honey for nearly every last thing I can use. R. C. AIKIN.

Mr. Porter—Locality comes in again. We could not do much of that in Denver. However, there is something in not putting the price too high. I sold some jars to a grocer for 35 cents apiece, and after some time found he had not sold them. He had markt them 50 cents. Another dealer at the same time was selling them for 45 cents. It is not the wealthy people in Denver who buy honey. For example, I recently sold a 5-gallon can to a brickmaker for 8 cents a pound. The wealthy people want fancy packages, and a very little at a time.

H. Rauchfuss—I have had the same experience. To get some people to use honey I had to give them some. Then they bought small glasses. People should always be kept supplied with the kind of honey they are accustomed to. As long as we sell them alfalfa honey they eat it, but when they get clove or other honey they say they are tired of honey. I know the time when hardly any extracted honey was sold in Denver. Now it is sold in a great number of stores.

Mr. Porter—I sold the secretary of one of the lumber companies a can of sweet clover honey, after having sold him alfalfa honey. The next time I saw him he said he was getting tired of honey. If we get customers educated to alfalfa honey, we should never change. There is a trade that prefers the strong honey.

H. Rauchfuss—The Jews prefer the dark and strong honey.

Mr. Rhodes—I don't believe we ought to ship much honey out of Colorado. I produced four or five tons of honey in the early days of bee-keeping. One of the merchants had ordered two carloads of California honey to run us out. I followed that right up till I re-establish my trade. I never saw a vessel that exhibited honey better than a stone jar. Extracted honey poured into a stone jar has something very attractive about it. I sold only one day in the week, but could have sold all the time. Six cents a pound at home, without the package, is a good industry. A party in town selling extracted honey to the stores puts in a show-case with it, and guarantees it. Retailers would stand by us if we would get to them in that way.

Pres. Aikin—That party keeps the goods on hand all the time. That is a strong point. If your grocer runs out of sugar and coffee a few times, you are going to patronize some other grocer.

SELLING CANDIED HONEY.

Mr. Root—Bee-journals have not done their duty in recommending the sale of candied honey. It is suitable for men with whiskered mouths, and handier to give to children. I don't know any reason why store-keepers shouldn't sell candied honey if they could know it was good bee-honey.

Mr. Gordon—Will adulterated honey candy as pure honey will?

Mr. Porter—I have samples of that honey, that was referred to as sold in the stores, that show no signs of candying. One of them shows a few little cubical crystals near the top. If we could put up honey as Mr. Aikin does, we could down that kind of honey. The grocers are learning that pure honey will candy. Extracted clover honey will not candy as quickly as extracted alfalfa honey.

Mr. Root—I tried an experiment with adulterated honey. I put up one sample containing ½ glucose, one ⅓ glucose, one ¼ glucose, and one of pure honey, and have kept them four years. The pure sample candied solid. The mixtures clouded and made flakes. The glucose seemed to separate from the honey. The glucose and honey, therefore, will candy in time, but it candies in a peculiar way, so that it is readily distinguishable from the candying of pure honey. But sugar syrup will prevent candying longer than anything else.

Mr. Porter—This firm claims to have a process for delaying granulation. They would exchange the candied honey of others found in the stores for their own. This was about five years ago.

Mr. Rhodes—They must have something new, because their honey now is in better condition.

Mr. Root—The fact that the honey is *solid* is absolute evidence that it is pure. One of our workmen prefers candied honey to liquid honey.

Mr. Rhodes—Candied honey is good because the flavor is not driven off by heat.

H. Rauchfuss—I have a tank for liquefying by dry heat, which works better in that respect than by setting the cans in water. It holds six cans, and has a cover. It is double-walled, with water between the walls. The delicate flavor that alfalfa honey has is easily driven off. In selling to candy factories, I have learned they have a way of keeping the flavor, in making it into candy, but do not know what it is.

Pres. Aikin—I have some samples kept for several years. They remained candied solid for two years. One is now part liquid and part granules, and is much darker.

H. Rauchfuss—I have some samples kept a number of years. One of sunflower honey is solid yet. A sample of clove candied honey turned liquid, then granulated, then turned liquid again.

J. B. Adams—I had some packages at the World's Fair that I have yet. One is part liquid and part candied, and is darker. Another is now in layers of granulated and liquid honey. Another is of different colors.

Pres. Aikin—I have a sample of white clover honey 15 years old. It is entirely liquid now, and as black as sorghum, tho at first it was fair honey.

Mr. Porter—Some honey I had distributed to stores granulated and came back. I put it down cellar. I lookt at it some time ago, and found half of the jars as clear as crystal, and as nice as could be, while the others were candied solid.

H. Rauchfuss—I sold some honey in a can that was poured into jars. One jar remained liquid, and the rest is solid.

Mr. Rhodes—That shuts out the explanation that one colony would gather one kind of honey and another another. But I believe light has some effect.

Mr. Root—I have thought that moisture, or stirring, might have something to do with it.

J. B. Adams—Every one of my packages is glass-stoppered and sealed.

H. Rauchfuss—Some of my 60-pound cans of honey candied and some did not. They are sealed yet.

Mr. Gordon—Some honey sealed since 1889 with a rubber band did not candy.

Mr. Hackney—Have these packages been exposed to the heat? Some days in the summer are quite hot.

J. B. Adams—I doubt if any of my packages were influenced in that way. They were in a plastered northeast back room.

H. Rauchfuss—Mine were in just such a room, where they candied and liquefied.

Mr. Porter—Usually froth rises when candied honey is melted. This year I liquefied a great deal, and not a single can had any froth on, but they were as clear as could be. It was not alfalfa honey alone that acted so.

Mr. Brock—I observed no difference this year. The froth was there as usual.

H. Rauchfuss—I had the same experience as Mr. Porter. I had always thought it was the air-bulbs encased in extracted honey that caused the froth.

Mr. Porter—I restore the froth to honey, when I have it, by putting it in a separate can, setting this in water,

with a very little water sprinkled on the froth itself, heating and straining thru cheese-cloth. The water dissolves the air-bubbles, and the result is just as salable honey as any. The honey this year was no thicker than usual.

H. Rauchfuss—The late honey was thin this year.

(Continued next week.)

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Richards, Ohio.

MR. WHITNEY'S APIARY AND PLANS.

The year opens with a very pretty apiary picture; and we won't blame Comrade Whitney if he feels a trifle proud of it. Those slender and tall young elms to shade every hive part of the time, and no hive all the time, realize a definite plan of shading, whether the plan is entirely sound or not. The big hives and close spacing, and especially the diagonal placing, give the apiary a decided individuality. That's what we like (in pictures), notwithstanding the fact that the dead-earnest sort of bee-beginners might want to know which way is the best way, and then to have all the apiaries thus. And he gave his bees hand-sled rides in the summer time—my, my! I hardly expect that kink to prove very catching, altho quite likely he's right that on a smooth lawn the hand-sled is one of the gentlest of vehicles. Most of the brethren would prefer the made-a-purpose barrow, that both picks the live up and gently wheels it where it wants to go. And quite a good few of the brethren are blest, like myself, with hives that manifest a quiet and non-perambulating disposition.

KEEPING BEES ON THE ROOF.

Mr. Weber's apiary on the roof, page 17, shows one little invention which is important. Of course, such apiaries are crowded, and boards between adjacent hives to keep bees from mixing are a natural resource—here we see *two* boards for each narrow space, which very greatly increases the efficiency. If the keeper is careful and prompt enough to insure every parent colony a queen at swarming (even if he has to buy a queen), there is no other peremptory necessity for more space than can be had on the roof of a large building. Of course, there are many minor bothers, as well as some minor benefits, in such a position. For instance, bees are not attacking passers-by as they would be if down on the ground; and, per contra (out of sight out or mind), passers-by are not attacking the apiarist for keeping bees where he ought not.

MR. REHN'S APIARY AND MANAGEMENT.

Plenty of individualities to ask questions about in the apiary of Frank L. Rehn, page 33. He sets his hives high, and I wonder how the underneath blocks are managed to keep the whole edifice from being badly a-wabble. And why does he use such a promising growth of painted posts all scattered round? I *guess* he's got a whopping big sun-shade to mount on a post and shade the operator, and move to the next post when he moves; if so, I glory in his—lack of spunk. (He's a freshman and must be hazed a little. Hazing becometh not an editor; but it's not yet abolisht on the staff—is it Dr. Miller?) From 6 to 26 colonies is a good record for a beginner's first year. I feel specially interested in seeing his success in keeping nuclei shut up five days. He doesn't say anything about filling part of one comb with water, which I should think important in such long imprisonment.

SOME OF OLD GRIMES' IDEAS.

And so Old Grimes' old blue coat of a $4\frac{1}{4} \times 4\frac{1}{4}$ section is bound to be a new and taking fashion if he only wears it long enough. I think there are several of us that will spoil his game by walking right on in the procession ourselves. But as to the Grimes plan of booming for big and early swarms, and harvesting all the comb honey from them, and all the extracted from the consolidated remnants, I'll wait till the procession gets kind o' long, and then quietly drop in behind—half a dozen suspicions and counter prejudices in the way of joining right in now. Page 3.

TWO QUEENS IN SAME BROOD-CHAMBER.

That is an eccentric item which R. R. Stokesberry contributes on page 14. A queen being superseded in a *14-frame hive*, two young queens became fertile and began life on opposite sides of the unusually large chamber. A strain of bees that would always do this (and stay so) our English friends would pay a big price for—save them lots of hive "carpentearing."

FACING COLONIES TWO WAYS.

That Canadian item, page 10, is correct. A few colonies facing west in an apiary generally faced east will gain bees largely during winter flights at the expense of the east-looking colonies.

PERHAPS A "HASTY" CONCLUSION.

I e'enymost blush for my country that Mr. Secor should not be sharp enough to see thru that can of Hymettus honey, page 6. Not quite the identical thing as the horse-mint honey nicely canned for the mining regions, and labeled "California Sage Honey," but very like, I suspect.

THE APICULTURAL "TEN COMMANDMENTS."

Ten bee-keeping sins are held up to our view on page 42; and of course the apicultural ten commandments would be the "thou shalt nots" of these ten. This critic kicks—won't accept them short of opening the Ark and seeing them on the stone tables. Number 4 is not a sin; and 7, 8 and 9 are quite debatable. He moves the following substitute:

1. Thou shalt have no other craft *before* bees.
2. Thou shalt not bow down to other crafts, by calling thine own craft, "*Fussing* with bees."
3. Thou shalt not say naughty words when thy bees salute thee, neither when they cross thine expectations, neither when they clean out thy nuclei.
4. Remember and have a Sabbath corner in thy soul for *some* other things besides bees. Thou mayest have bees on the brain, but not on the whole of thy brain.
5. Honor the bee-book, which is as thy father, and the bee-paper, which is as thy mother. Whoso curseth father and mother let him die the death.
6. Thou shalt not kill—neither thyself by overmuch worryment, neither thy bees by overmuch neglect in the fall, neither thy Gentile neighbor by overmuch bee-talk.
7. Thou shalt not commit adulteration—neither at the glucose-barrel; neither shalt thou accomplish a similar thing by extracting thine honey too soon.
8. Thou shalt not steal thy neighbor's cash by selling him poor honey. Thy honey shall be pure, and clean, and ripe.
9. Thou shalt not bear false witness in favor of thine hobby—for the same is false witness against thy neighbor. Behold he will try to ride thine hobby, and fall bleeding by the wayside.
10. Thou shalt not covet for an out-apiary thy neighbor's range; neither shalt thine eye be evil toward thy Gentile neighbor's few hives; neither shalt thou covet the honey thy bees need for food. Thine heart shalt be large toward every creature; for, behold, the same God which made the insect and the angel, made thee.

DOOLITTLE'S BURR-COMBS.

As to the problem on page 37, I rather guess Mr. Doolittle did make his burr-combs count him in \$1.20 per colony; but I doubt whether different bees on a different occasion would always show the same result. It's "sartin sure" that the burr-combs didn't *gather* an ounce of the honey; and *sometimes* bees will "get there," and put there all the honey they have to spare, without any ladders to climb on.

DOOLITTLE'S DOZEN "LITTLE PEWS."

Twelve little pews, with 12 little Methodist "classes" of new ideas on section slips, to be called out for "love feast" one each month! That's the way Doolittle "doos" it. How many "doo" want to be Doolittles enough to "doo" that *much*? Page 35.

WINTERING BEES IN A LOW TEMPERATURE.

An interesting fact (but a dangerous one to run at large) is S. N. Black's success in wintering 80 colonies at 28 degrees, Fahr. If stores were always the very best, and bees always the very healthiest, it might perhaps be done right straight along. Page 36.

SHOOTING THE CANDIED-HONEY IDEA.

And so Mr. Aikin helps the public idea to shoot toward candied honey by not letting it have any chance to shoot

any other way. I see. It's true that people like new ideas, when informed that they are new; and saying, "This's a new plan; we let you melt your own honey, and buy it so much cheaper," is quite likely to go to the spot. Page 18.

HONEY THE THING FOR CHILDREN.

Prof. Eaton, on page 22, says a nobly forcible thing when he tells how almost all people try to repress children's appetite for sweets—right in the face of the fact that more than half the solid contents of mother's milk is sugar. Who will manage it to inform the Creator that he didn't know what children need?

WHAT ABOUT EXTRACTING-COMBS?

Page 26 is revolutionary enough to raise the whole big question, Why have extracting-combs cleaned up in the fall at all? Is it not better in almost every respect to let them stay sticky just as they are? What say about it, brethren? I have done that way to some extent, and the worst trouble I met was that they drip a good deal in certain turns of weather, and make a dauby mess on the floor, and waste some pounds of good honey that might have gone to the bees.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Wintering Bees in a Cave.

I put two colonies into a cave which I dug last fall. It has double doors, with a 6-inch pipe ventilator above, with two joints so as to keep snow out of the pipe. The bottom ventilator is 6x6 inches, and 40 feet long, with screen to keep the mice out. The roof is about two feet of dirt and manure mixt. The temperature is 38° to 40° above zero. I would like to know if this cave is all right to keep bees in. I have two colonies outdoors, with outside cases and chaff between.

NEW YORK.

ANSWER.—Very likely it is all right, but one cannot be certain without knowing just how the bees appear. A temperature of 38° to 40° seems rather low, but thermometers differ so much that it may be that your thermometer in the place in which you put it is all right.

Growing the Basswoods or Lindens.

In the book, "Bees and Honey," I have read that basswood is easily propagated from cuttings. Do you know of any one having succeeded in this way? If so, what time of year must it be done, and what kind of soil is best in which to put them? In digging up basswoods for transplanting, need one be pretty careful about cutting off the roots, else we kill the tree from this cause? My land is naturally adapted to basswood, and there is plenty of it all about here, but it is growing fast.

NEW YORK.

ANSWER.—I have no recollection of any reports from those who had done much in the way of raising basswoods from cuttings, the usual way being to dig up young seedlings that are growing wild. If you search in the region where basswood is plenty, you will probably find abundance of young trees. They may be raised from seed, but the seed seems to lie in the earth a year or two before coming up.

Young lindens or basswoods may be transplanted with less care than almost any other tree. Of course, the more roots the better, but a very small amount of roots will do.

Italianizing.

I started with one box-hive of bees 3 years ago. The next year I bought 5 dovetail hives, and in spring I had two nice swarms which I successfully hived. Last year I increased to 11, which are in good condition now. I lost one swarm in the blizzard—they froze, for they had honey left. It was over 20° below zero here, and I have now, and had, my bees on the summer stands without being packed. In June I put a select tested queen in one, and they went into winter as thorobred Italians. Next spring I would like to Italianize all. Your plan of doing so by self-swarm-

ing seems to be very simple, but I would like to try the dividing, and wanted to Italianize beforehand, and in this way:

I expected to take the brood-frames that have the queen-cells on them, and put them in the Italian hive; and after the bees have capt them over return them to their old hives, and kill the black queen. Will not that work? When, or before, the second queen batches I expect to divide the colonies and thus double the number.

VIRGINIA.

ANSWER.—If you take from any of your colonies a frame with queen-cells and eggs or larvae in the cells, giving these to the Italian bees would produce only black queens. If you take the Italian queen away, putting her in a nucleus, the queens reared by the queenless colony will be Italian.

Frozen Moisture in the Hive.

On looking at my bees, I see that in two of the hives, near the entrance, small icicles have formed from the bottom of the frames to the bottom-board. I suppose this is from the moisture of the bees condensing and freezing near the entrance. Will this hurt them? If so, how can I remedy it? They are packed in bay and leaves about 6 inches on each side.

NEW YORK.

ANSWER.—A small amount of frozen moisture is not likely to do any great harm. Perhaps nothing need be done now, but it may be well to consider whether a larger entrance another winter would not be desirable? This is not saying that it is desirable; only suggesting it in case the entrance is too contracted.

How Arrange the Extracting-Frames.

In arranging extracting-frames, is it best to have them placed above the brood-frames, so that the bee-space is continuous from the bottom to the top of the hive, or should they be placed so that the space between them comes over the brood-frames, similar to breaking joints? It can of course be easily regulated by the following.

UTAH.

ANSWER.—With proper spacing between frames, and proper distance between top-bars and bottom-bars (about 1/4-inch in each case) it probably makes no difference which way. If spaces are larger, and if top-bars are thin, there would be danger of some building up of combs if spaces above corresponded with those below, and if you are as neat about your work at the hive as you are about your penmanship, you wouldn't like that.

Bees Dying—When to Remove Honey.

1. I am a beginner with bees. I purchast 5 colonies last fall in box-bives, and they are dying from some cause or other. As they were not "robbed" last year, the hives are full of honey.

2. When is a good time to "rob" bees?

MISSOURI.

ANSWERS.—1. It is impossible to tell why bees die, with no other information than the fact that they die. Very often beginners are alarmed at bees dying in winter when everything is all right, for the general rule is that a great many bees die thruout the winter. If only a quart or two have died in a strong colony there is no cause for alarm, and several quarts may die in such a colony before warm weather comes.

2. It will be worth a great deal to you to get a good text-book on bees, for in that you will find the present question more fully and satisfactorily answered than can well be the case in this department. In general terms it may be said that there is no special time by the calendar when honey should be taken, but it should be taken as soon as all, or nearly all, is sealed in the super, if it is comb. If extracted, it may be taken whenever it is sufficiently ripe—that is, when it is sealed or nearly so, altho many think it best not to extract till the close of the season.

A New Size Honey-Section.

I desire your opinion of our new honey-section. We have a whole lot of section-cases for the 8-frame hive, also a whole lot of fences, slats, etc., for the Ideal sections, 3 3/4 x 5 x 1 1/2, but I don't think that section is just the thing, and never will be very popular. The 4 x 5 x 1 3/8 section is the very best section I ever have used or seen, but it cannot be used in the 8-frame hive section-case to good advantage, unless crosswise the case, and that doesn't seem to be just the thing, either; so we have gotten up and used with much pleasure a section that exactly fills the 8-frame case, both in length and width, they being of such size that 7 rows, 4 to the row, just fill the case. The sections are plain, and are supposed to be used with section-holders and fences, their size being 4 3/8 x 5 x 1 1/4. What do you say?

NEW YORK.

ANSWER.—This matter is one that depends so much upon circumstances that no hard and fast rule can be made for all. A question that you can best answer for yourself is, Do they suit your market? Trial must determine. Other things being equal, the section that you can use with the least inconvenience and with the least change of your present fixtures is the one for you. In this respect you have no doubt chosen wisely. A strong point in the eyes of many customers is the fact that a 4 3/8 x 5 x 1 1/4 section presents a large surface when laid on a plate. It looks much.

VOL. 40. FEBRUARY 22, 1900. NO. 8

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

"Are We Brethren?" is the inquiry of the American Bee-Keeper in reply to the request to name an American bee-keeper who does not with the Australian say: "I'd like to have my crop of honey increase as much as possible, but I don't care to have the entire output increase in proportion." Editor Hill hopes the younger generation now living may see the present annual production of honey in the United States increase five fold. No pessimist, he. He thinks such an increase is necessary to awaken an appreciation of the great possibilities of our industry, and says:

"America's most crying need is, more honey and united action in extending home consumption; and this united action can be secured only thru individual effort prompted by a fraternal, *unselfish* interest in the general welfare of our pursuit."

We Be Brethren.—In not many callings is there found a more brotherly spirit than among bee-keepers. It is pleasant to find that a wide expanse of ocean does not make any less this kindly feeling, and one warms toward British bee-keepers when reading the following appreciative words regarding one of our number, from W. Loveday, in the British Bee Journal:

"One whom we must place in the front rank of never-tiring helpers in our cause must be thank now if we would

ask him also to accept the compliments of the season with the next issue of the British Bee Journal when it reaches him. I refer to Mr. G. M. Doolittle, from whom we have learned so much thru his regular contributions to the bee-literature of his country, and which is handed on to us in the pages of the British Bee Journal. I am afraid that our American friend must burn not only a good deal of midnight oil, but exhaust a good deal of the sap of life, too, in his endeavors to assist others."

National Bee-Keepers' Union's Final Report.—We have received the final statement sent out by General Manager Newman, in which he gives the result of the vote by the Union on the question of amalgamation. It shows that 98 ballots were cast, of which 91 were in favor of the new Constitution recently adopted also by the United States Bee-Keepers' Association, which voted 143 to 4 in favor of it. Both societies having thus almost unanimously adopted the same Constitution, they are now *one*. If "in union there is strength," the amalgamated society ought to be very strong, and should do even better work than both could do singly.

The cash balance forwarded by Mr. Newman to General Manager Secor was \$173.95—a handsome addition to the fund already in the amalgamated society's treasury. There will now be a united membership of about 500. Why not double it this year?

As a result of the recent voting by both organizations, the officary of the resulting association is as follows:

PRESIDENT—Ernest R. Root.

VICE-PRESIDENT—G. M. Doolittle.

SECRETARY—Dr. A. B. Mason.

GENERAL MANAGER AND TREASURER.—Eugene Secor.

BOARD OF DIRECTORS—E. Whitcomb, W. Z. Hutchinson and A. I. Root, until 1901; J. M. Hambaugh, Dr. C. C. Miller and C. P. Dadant, until 1902; Thomas G. Newman, G. M. Doolittle and W. F. Marks, until 1903; and Ernest R. Root, P. H. Elwood and Rev. E. T. Abbott, until 1904.

Mr. Newman closed his final statement with these paragraphs, which show what a well-earned and glorious record the National Bee-Keepers' Union made for itself during its 15 years' existence:

I desire to thank my friends for their condolence in my affliction and present loss of eyesight, and, upon retiring from the management of the Union, would offer congratulations to all the members upon the efficient work done by the Union during its existence, and submit the following statistics for future reference:

Over 200 appeals have been made to the Union for protection from annoyance by envious and quarrelsome neighbors. About one-half of these cases have been settled or dropt as soon as it was known that the apiarists were members of the National Bee-Keepers' Union. Many of the remaining cases were settled as soon as the opposing attorneys had read the points of law furnished by the Union. Others were cases growing out of attempting to enforce ordinances past by cities to declare bee-keeping a nuisance, some of which were carried up to the Supreme Court; but invariably the result was a victory for the Union when cases were tried upon their merits. In some few cases bee-keepers have been put into prison on technicalities, only to be releast when defended by the attorneys for the Union, who demanded their rights guaranteed by the Constitution of the United States of America.

The Union has a proud record, and gives to the new amalgamated association a banner unsullied, with victory inscribed upon it, and I hope that it may wave in triumph over the new association for many generations to come.

THOMAS G. NEWMAN.

Wisconsin Convention Notes.—As intimated in our last number, we will endeavor this week to give a few comments on the convention of bee-keepers held in Madison, Feb. 7 and 8.

We arrived the evening of the 6th, and were met at the station by Secretary France, whom we had not seen for four years. It is wonderful what a preserving climate they have

in Wisconsin. Mr. France really looked younger than he did in 1896. The same may also be said of Pres. Wilcox, who seemed not a day older than when we used to see him so frequently in charge of Wisconsin's apiarian exhibit at the World's Fair here in Chicago in 1893—and that is nearly seven years ago. But, then, we really believe Mrs. Wilcox takes such excellent care of him that while he may live long he'll not likely grow old. Mrs. Wilcox was at the convention, and we decided, after seeing her and talking with her, that, like a good many of the rest of us, Mr. Wilcox is greatly indebted to a good wife. (Dr. Miller will surely say "amen" to this.)

For perhaps six or eight years we have had a desire to meet Mrs. W. J. Pickard—the lady bee-keeper of Wisconsin who has won the right to be called the "first lady" of the State, if not of the United States, when it comes to honey-production. We believe her crops have amounted to something like fifty or sixty thousand pounds of extracted honey in a single season. And the daughter, Miss Ada, who was also present, is following closely in her mother's footsteps, for in 1898 she alone, in an out-apiary of 100 colonies, harvested 16,000 pounds of extracted honey! How is that for a young lady bee-keeper?

Then there is Mr. Pickard—well, he gives all honor to his wife and daughter, as well he may. He says *they* are the bee-keepers—he only *sells* the honey after it is secured, and—we hardly think he pockets *all* the proceeds, for if two such charming and capable women should "get after him," he'd simply *have to* "shell out," as the boys would say.

There were other extensive bee-keepers present, among them Messrs. G. W. and A. G. Wilson, Jacob Huffman, C. A. Hatch, Mr. Ballou, B. T. Davenport, J. W. Van Allen—and many more whose names we might mention.

Mr. France, the newly-elected president, and one of the largest bee-keepers, as is well known, is the very efficient and popular inspector of apiaries for Wisconsin, and in his rounds thru the State has done wonders in the way of driving out the curse of foul brood. And in almost every instance the bee-keepers have done all they could to help him in his arduous work.

At least one very important thing was done by this convention. It was decided that *every* member should become a member of the National Bee-Keepers' Association. It was our privilege, upon invitation, to address the convention upon the history and work of the two national bee-keepers' organizations that just lately have been united, and we urged that the Wisconsin Association be the *first* local organization to become members of the amalgamated society.

So we were greatly pleased when the necessary action was taken to carry out the new provision in the recently adopted constitution of the National Bee-Keepers' Association, which says that when any local bee-keepers' society will join in a body, they shall be allowed to come in at 50 cents per member, providing the dues of the local organization are not less than \$1.00. In the case of the Wisconsin Association, it will add about 30 new members to the National, as perhaps 10 of them were already members of both the local and the national societies. In all probability but few of the 30 new ones would have joined the National at \$1.00 each, while by all going in at 50 cents each, there is a gain in money for the treasury, as well as a gain in membership—both very desirable objects, particularly the latter.

Suppose when Mr. Abbott attends the National Pure Food Congress in Washington, D. C., March 7, he could say he represents a national organization of bee-keepers one thousand or two thousand strong. Wouldn't that carry some extra weight with it?

And suppose when some jealous neighbor gets to fuss-

ing because a bee-keeper near him is making a little profit out of bees, and forthwith determines to try to compel said bee-keeper "to get a move on him" and his bees don't you think that when such bee-keeper lets Mr. Jealous Neighbor know that he is a member of an organization having a thousand or more able-bodied bee-keepers in it, and that all in said organization will aid in defending him in his rights to keep bees—don't you think that Mr. J. Neighbor will think several times before he tackles that strong "colony" of bee-keepers? We think he will. And these are some of the reasons why we believe there ought to be a *large* membership in the National Bee-Keepers' Association. Numbers mean much, whether in a hive during a honey-flow, or in any organization that means business.

Let's see, we're getting off our subject a trifle, aren't we? But, then, there were so many good things at that Wisconsin convention we can't mention them all now. The report, to be published later, will likely give the most important matters in a more or less concentrated form.

Mr. W. Z. Hutchinson was present beginning with the first evening session. He was unanimously elected an honorary member. We had been thus favored when attending the meeting four years before.

We might add that Mr. August Weiss had with him a splendid display of his excellent bee-keepers' supplies; also Mr. McCartney was there with his combined foundation-fastener and section-press. There were other things on exhibition, which we have forgotten, but likely the full report will mention them.

Reform Spelling Voted Down is the latest announcement in *Gleanings in Bee-Culture*. In making this announcement there is an apparent longing on the part of Editor Root to help in doing what he can not but see is really a good work, and as a closing word he well says this, albeit with a hint of sadness in his words:

"But in giving up for the present the proposed spellings, I have a feeling that, if all reforms were treated in a like manner, very little would be accomplished from century to century. We are still in favor of the shorter spelling, but do not wish to go against the expressed wishes of our subscribers."

Previously to this he says: "We have for several years used, without offense to any one, words such as *catalog* for *catalogue*; *program* for *programme*, etc. There are several other shorter forms, but they have been incorporated so slowly that no one has noticed them; and whatever change we make in the future will be made on the same plan."

Which goes to show that when it is a case of pure prejudice it is not well to call for votes. Had *Gleanings in Bee-Culture* called for votes as to the spelling of catalog, doubtless negatives would not have been wanting, since *clipt* for *clipped* is no more violent a change than *catalog* for *catalogue*, and if as quietly introduced would probably have been no more noticed.

Honey-Paste for the Hands.—Here is a recipe for an old-fashioned honey-paste for the hands, taken from a very old book on toilet recipes:

Take honey, 2½ ounces; the yolks of 2 eggs; almond oil, 3 ounces; powdered orris root, 1½ ounces; and a quarter of an ounce of any perfume preferred. Mix the yolks of the eggs and the honey together first, then add the oil very gradually, after having previously united the perfume to the oil; lastly, beat in the orris powder. First wash the hands thoroly, and dry them with a soft towel, then anoint them with the above paste, rubbing it well into the skin, and, lastly, cover the hands with loose doekin gloves, with the palms cut out for ventilation.

Breeding for Color has a word spoken in its defense by W. H. Pridgen, in the American Bee-Keeper. He rightfully holds that color can not be ignored, for whatever traits may be desirable to breed for, color will always be a distinguishing mark by which one can judge to some extent whether such desirable traits are present.

Dark Colors and Cross Bees.—According to W. H. Pridgen, in the Bee-Keeper's Review, dark objects do not irritate bees, but when they are irritated they are more likely to attack dark objects. He has seen bees in numbers attacking a dark handkerchief hanging out of the pocket of a man dressed in light clothes; but the bees were previously angered.

A Good Record.—I started in the spring with 60 colonies strong and 20 weak. I increased to 150, and have sold \$715 worth of extracted honey and 150 pounds of wax. My 70 colonies of bees at \$3.00 net brought \$210; 150 pounds of wax at 23 cents, \$34.50; extracted honey, \$715. Total, \$959.50. Have you a better report than this from 80 colonies?—THOS. M. SKELTON, of California, in Gleanings.

The Pickard Bee-Brush is thus described by Ada L. Pickard, in the Bee-Keeper's Review: Take a piece of broom-handle about 18 inches long and saw a slot in the end of the piece, lengthwise, about six inches long. Take some rope and cut it into pieces eight inches long, then unravel the pieces and draw the middle of the pieces down the slot in the handle until the slot is full, thus making a brush on each side. Fasten by nailing the handle ends together, or by wrapping wire around. This brush is very durable, soft, and pliable, and will not injure the bees. It may be washed when it becomes sticky with honey.

The New York Bee-Disease or Black Brood is what Dr. Howard has named the new disease that is making havoc among New York bees. The editor of Gleanings in Bee-Culture says:

"To relieve the suspense of some, I will simply say in advance that the Doctor finds this to be an entirely new disease."

But what relief, will our good friend tell us, is there in knowing that instead of foul brood about whose cure we are pretty well informed, we have to deal with black brood as to whose cure we are ignorant, when according to all reports so far it seems to be about as fatal as foul brood?

Bees in a City Drawing-Room.—In the elegant London home of Col. Baden-Powell a peculiarity in the drawing-room is the apiary. Two large straw bee-hives, with glass sides, stand on ornamental pedestals close to a large organ which occupies one wall of the large room which overlooks Hyde Park. The bees escape thru a wide pipe which leads out of the window. Wooden models of various objects, such as, for example, a bicycle, are placed by Miss Baden-Powell in the hives. Over these models the bees build their honey-comb, following the lines with delicate accuracy. The honey is drained from these beautiful specimens of waxen architecture, which are exhibited under glass cases.—Chicago Record.

Old Stagers and Cross Bees.—G. M. Doolittle, speaking of the difficulty some have in learning that quiet movements are important in getting along with bees, says in the American Bee-Keeper:

"Indeed, while visiting an apiary, as a body of bee-men, at the adjournment of a national bee-convention some few years ago, I saw nearly one-third of those bee-men (?) take off their hats and go to striking the air in a most desperate fashion, because some bees seemed to want a 'business association' with them. It was very ludicrous indeed to see ten or more 'old stagers' acting in that way."

So difficult is it to believe that one with a moderate amount of familiarity with bees should be found battling cross bees with his hat that one can not help wondering in what sense Mr. Doolittle uses the term "old stagers."

What to Do with Candied Comb Honey, the combs being old and dark, is thus answered by Editor Root in Gleanings in Bee-Culture:

"The best use you can make of these combs filled with honey candied solid is to put them into the solar wax-extractor next summer. The honey and wax will both be reduced to the liquid form—the former being separated off in a cake by itself. While the honey is not of as good quality as that which has been taken with the centrifugal extractor, yet it will do very well. If there is another and better way of treating such combs, I should be glad to be informed of it. Bees will sometimes take candied honey out of the combs and use it; but more often they will drop the granules on the bottom-board; and when warm weather sets in, these granules will be shoved out of the entrance. After the first rain these will be wet down, resulting in more or less robbing; so that I recommend that combs containing candied honey be treated as I have explained."

Stung to Death by Bees is the heading of an item in Gleanings in Bee-Culture, copying from a Cleveland daily paper the following, which we referred to some time ago in these columns:

"John Carson, a farmer, aged 65, of Newton Falls, was stung to death by bees. Carson desired to work in his apiary, and, to quiet the bees, burned sulphur. This only enraged the bees, however, and they swarmed over him, stinging him in hundreds of places. He made his way to the house, where he fell to the floor. Several hours later he died."

Editor Root comments that the man lost his life by not knowing enough to let bees alone when they ought not to be handled, and using the unheard-of method of trying to quiet them with sulphur. He might also have suggested that it is also within the range of possibilities that the stings alone were not the cause of death. Is it a sure thing that burning sulphur will always or ever enrage bees?

Sticks Instead of Wires in Foundation.—Some confusion seems to have occurred in the Australian Bee-Bulletin with regard to the splints used by Dr. Miller instead of wires (already described in this journal), as compared with what is used by the editor of the Bulletin. The latter is a middle bar running horizontally, of which Editor Tipper says:

"The sticks we use are the same width and thickness as the bottom-bar, length to fit between the two end-bars, placing it horizontal in the middle of the frame. A bit of wax fixes it, and the bees do the rest. From the experience of the past season we will not go back to wires again. There is far less trouble in placing them in, the combs are firm and strong, and no stretching of wire and comb breaking as under the old system, when extracting. We use Langstroth frames."

Starting an Out-Apiary.—Ada L. Pickard tells in the Bee-Keeper's Review how she manages it. A location is sought with a flowing stream and desirable pasturage, if possible placing the hives on an eastern slope with protection north and west from spring winds, and only rolling enough for pasturage. A written contract is made with the owner of the ground, stipulating the size of ground, price, and term of years. Then she encloses the ground with a good barb-wire fence of five wires, and builds a bee-tight honey-house about 12x16 feet. The bees are then brought and left permanently, being wintered in a partly underground cave. A bushel or two of unslacked lime is scattered over the floor and walls to make the air sweet.

A Caution to Purchasers of Bees is given by Editor Simmins, in Bee-Chat. From time to time he has reports from those who have bought not only bees, but foul brood as well. In some cases those who sold may have been ignorant that foul brood was present, but when a large number of partly diseased colonies are crowded together on a long journey, they generate the most fatal temperature for propagating the malady, and the development proceeds with alarming rapidity.

Honey Cough-Medicine.—The Farm Journal gives the following:

Boil an ounce of flaxseed in a pint of water, strain it, add an ounce of rock candy, some honey, and the juice of three lemons, and boil again. Result: A nice, old-fashioned cough medicine. Drink as hot as you can bear it just as you are getting in bed, and cover up warm.

Root's Column

So many of our customers who prefer the 8-frame dovetailed hive have wanted to use the 4x5x1 3/8 inch plain sections on these hives, that we have devised this style of super to meet this demand. We listed it for the first time in our catalog last year. This form of super has been used successfully by Lewis J. Whitney, of Mapleton, Utah. He has produced as large crops of fine 4x5 honey as one can find anywhere on the market, and anyone desiring to raise 4x5 honey on 8-frame hives cannot do better than to use this super; but, if you want to use the 4x5 sections on a regular 10-frame, dovetailed hive, you can order our regular Danz. super, such as is used on the Danz. hive, described on this page last week. The price of the L super is the same as all of our other regular 8-frame dovetailed supers.

The L Super.

For 4x5 plain sections, 8-frame size only.

Devised for those who want 4x5 sections on the 8-frame hive.

We are pioneers in the manufacture of modern fixtures for plain sections.

If you want to get them right, send to us or our branch offices and agencies.

What Others Say of Root's Plain Sections and Fences:

The plain section is far ahead of the old beeway section, and I would not return to the plain separator for any money. Every customer to whom I sell honey remarks, "How fine the honey in the plain section does look!" I have nothing but praise for my honey wherever I have offered it for sale this winter.
Cuba, Kan., Dec. 23, 1898. WM. H. EAGERTY.

We received four or five well-filled cases of basswood honey in the new sections; and to say that they were nice would be putting it lightly. It was a real pleasure to open those crates of honey and note the difference between them and the old-style section in regard to freedom from propolis, and consequent ease of cleaning.
Elsie, Mich., Jan. 7, 1899. I. A. WOOL.

I might say here that I gave the no-beeway sections, 4 1/4 x 4 1/4, a trial this season, and I am well pleased with them. I used about 1,200 of them alongside of the open-end or slotted section, 4 1/4 x 4 1/4 x 1 1/2, with plain separators. This winter I am changing all of my supers to no-beeway. I find that I can get half to one cent more for no-beeway in the Toronto and Kingston markets.
C. E. TAYLOR.
Harrowsmith, Ont., Dec. 28, 1898.

In regard to those fences bought of you last year for 100 hives, it is one of the best improvements since I began the bee-business, 50 years ago. Last year I had the best comb honey I ever raised. I think bees will commence on sections quicker, work the outsides of the crates just as well in the middle, and, best of all, bees do not travel-stain the combs. Make me enough for 50 hives more, about 400.
C. M. LINCOLN.
Rupert, Vt., Dec. 18, 1898.

THE A. I. ROOT COMPANY, MEDINA, OHIO.

EVERITT'S Earliest of All ..TOMATO..

DITTMER'S FOUNDATION

Wholesale and Retail

This foundation is made by an absolutely non-dipping process, thereby producing a perfectly clear and pliable foundation that retains the odor and color of beeswax, and is free from dirt.

Working wax into foundation for cash, a specialty. Write for samples and prices.

A full line of Supplies at the very lowest prices, and in any quantity. Best quality and prompt shipment. Send for large, illustrated catalog.

GUS. DITTMER, Augusta, Wis.
Beeswax Wanted.

Our Incubators
have all the latest improvements, are sold at very low prices and guaranteed to please every customer. Send 6 cents for our 150 page catalogue, which contains full descriptions of our extensive line and tells how to raise poultry successfully. Plans for poultry and brooder houses.
Des Moines Incubator Co., Box 78, Des Moines, Ia.

GENERAL ITEMS

Well Satisfied with Results.

I am well pleased with results of the past season. I started with 10 colonies in the spring, increased to 21 by natural swarming. I sold two swarms, and one took Greeley's advice and went West. I worked for comb honey exclusively, and my crop was 500 pounds, 400 of which was sold in my home market at 12 cents a pound. One old colony did not swarm nor store any surplus.
Marshall Co., Ind. J. W. MATHENY.

Report for 1899.

My report for 1899 is 10 colonies, spring count, and 20 fall count, with 600 pounds of comb honey from raspberry, white, alsike and sweet clovers.
E. N. JARVIS.
Tuscola Co., Mich., Feb. 10.

Mild Winter in Utah.

Here in Utah we have been having a mild, open winter, and as a rule the bees appear to be wintering fairly well. Some of our farmers and mountaineers tell us that there is only about one-tenth of the snow in the mountains now that there was at this time last year; but then, many of the tall pines were buried out of sight last year. The atmosphere was cold until June from the effects of those huge snowbanks, so that a warmer spring would be preferable, even if we do have less snow.

But we had a change, or rather a surprise, Feb. 6. It was a howler, a regular Kansas gale, 60 miles an hour, the first in seven years. It gave us a salt shower from the lake 15 miles off, and then a snow-storm

Cabbage Seed That Grows
There is no doubt or disappointment when you sow Hammond's Improved Early Jersey Wakefield. Undoubtedly the purest and earliest strain known. The result of years of careful selection, both for earliness and perfect heads. Especially valuable to market gardeners. 5c pkt.; 15c oz.; 60c 1/2-lb., and \$1.50 lb., all postpaid. Hammond's Danish Ballhead. A sure header of large, compact heads. My seed imported direct from E. Woboltz, Denmark. Guaranteed absolutely true to name. See catalogue for cash prices. Price same as above. Catalogue free.

from 3 to 6 inches. As a rule, we have very little wind; sometimes our bees can fly for weeks without enough wind to be called a breeze, but on Tuesday, when everything was as quiet as a lamb, real estate took a sudden flight upward, in such quantities that one could not see 50 feet away. Well, it will help out the water supply. As the old saying goes, "It's an ill-wind that blows no one any good." E. S. LOVESY, Utah Co., Utah, Feb. 8.

"Has the Bee an Extra Sense?"

Noticing the article on page 86, "Has the Bee an Extra Sense?" Michigan will corroborate Massachusetts. Every experienced bee-hunter knows that where bees are carried forward towards the tree, and by and beyond it, when liberated from the box they will continue on the same course, altho going straight away from the tree. The bee-hunter, however, is not misled, for if the bees do not return in about the same time, or sooner, than from the last place, he well knows he has past the tree. They will find the box after awhile, unless towards evening, in which case they seldom return. D. H. METCALF, Calhoun Co., Mich.

Poultry and Bees.

I want to tell what a friend of mine did with 300 hens in connection with bees for the year ending Jan. 1, 1900. This man is a bachelor, and I believe any good woman can do just as well, if not better, if she is a woman that will work, as it takes lots of work:

EGGS SOLD DURING 1899.

January, 155 dozen, @31c.....	\$48.05
February, 416 " @16c.....	66.56
March, 731 " @13c.....	95.03
April, 507 " @15c.....	76.05
May, 440 " @17c.....	74.80
June, 485 " @17c.....	82.45
July, 286 " @18c.....	51.48
August, 210 " @20c.....	42.00
Sept., 276 " @24c.....	66.24
October, 290 " @28c.....	81.20

Dec., 292 " @32c.....	93.44

Total for eggs.....\$844.26

Sold during the year 30 doz. broilers at \$3.00.....\$90.00
Sold during the year 20 doz. hens at \$5.25.....105.00

Grand total.....\$1,039.26

There was no account kept of the eggs or chickens consumed by the family during the year, and as he raises his own feed, no estimate was made of its cost.

Now, do you not think that the poultry business would pay for the women-folks to take hold of in connection with their husband's bee-business? G. T. JONES, Sutter Co., Calif.

Bees Still Working in Texas.

I have just come in from working with my bees, and find them still at work. They haven't lost more than one week so far this winter. They are bringing in pollen as in the spring of the year. I have 116 colonies all in good condition, with plenty of surplus.

If I had to cellar my bees I should go out of the business. Mine stay on the same stands summer and winter.

W. W. WILLIAMS, Goliad Co., Tex., Feb. 2.

No Wax-Moth.

On page 93, Mr. A. F. Foster claims to have seen hundreds of bee-moth in Boulder Co., Colo., during the past summer. While I don't know what Mr. Foster means by "bee-moth," I am fairly certain that there

Sharples Cream Separators; Profitable Dairying

\$100 to the Winners

until to-morrow night or, better still, call the attention of the members of your family who have a taste for puzzles, to it. Some of you can hardly fail to get it. It is purely a test of quick-witted observation without any element of chance. There is only one answer that can be obtained by properly finishing the letters and supplying the space to make words of the letters. We give below two lines of incomplete letter puzzles. By solving one of them you earn a prize, and by solving both correctly you come in on the \$100 prize to the winners.

Other Prizes

To any contestant sending a correct answer to one of these puzzles, we will send their choice of a year's subscription to "The Gentlewoman," or "American Fruit and Vegetable Journal," or "American Poultry Advocate," or your choice of any one of the following books: "The New Hygiene," a book on up-to-date treatment to maintain health without medicine; the works in one volume of Charlotte M. Braeme; or the "Duchess"; or Sylvanus Cobb, Jr., or Miss Braddon's; or Wilkie Collins; or Mary Cecil Hay. When sending in your answers name the prize you wish, should only one puzzle be answered correctly. The first puzzle is

These wintery evenings you have some time to spare, so here is a puzzle you can solve. If you have not the leisure to-night, put it aside

T A I L I S I T A S I L

This puzzle consists of a line of 13 incomplete letters, which if complete would spell three words. Only the lower two-fifths of each letter appears, the other three-fifths have been cut off. What are these three words? They are all taken from this very advertisement. The words are not separated from each other, but the letters follow in correct order, all they need being the space. There is no transposition or trick of any kind. Taking one letter right after the other from the first to the thirteenth they spell three words. EACH WORD IN BOTH PUZZLES APPEARS SOMEWHERE IN THIS ADVERTISEMENT. There is no chance about it. If there were two correct answers to either one of these puzzles, the Farm, Field and Fireside would be refused the mail for running a lottery.

T A I L I S I T A S I L

In order to get all the words in this advertisement as promised we are compelled to tell the following little story: "Some animal was injuring our trees on the hill, so we placed a poisoned paste in a tart, which the animal ate, and I hate to say what the pest proved to be. Can you guess? We found that the poison had made it very ill, and we took it by the tail and drowned it in the pond."

The object of the puzzle is in part to secure a large number of new trial subscribers to the Farm, Field and Fireside, the greatest agricultural weekly in the west. Do you know of any farmer who might be interested in a good farm paper? We want him on our list for a short time, and as the contest is inaugurated for the purpose of introducing our paper into new homes we make the following the

The second puzzle consists of 13 incomplete letters, forming four words, the letters following consecutively as in the first:

Conditions:

To be eligible to receive a prize every contestant must send with his or her answer the name of a person not now a subscriber, with 25 cents to pay us for sending the paper to him on trial for three months. Remember, if you get one line right you earn a prize, and if both are right you are in on the first prize. THIS CONTEST WILL CLOSE MARCH 31. ADDRESS PUZZLE DEPARTMENT FARM, FIELD AND FIRESIDE, 710 MASONIC TEMPLE, CHICAGO.

Don't fail to mention the Bee Journal when writing advertisers.

are no "wax-moth" (*Galleria mellonella*) existing in that locality. We have a small grain-moth, to which he evidently refers, the larvæ of which will feed on pollen, and therefore are found sometimes on brood-combs which are not protected by bees, but they are never found working in section honey. They resemble the larvæ of the codling-moth very much, in size as well as color. FRANK RAUCHFUSS.
Arapahoe Co., Colo.

Must Love Bee-Keeping.

I have been in the bee-business since a boy, I might say, and have made it almost a specialty for a number of years. I am satisfied that for one to be successful at it he must not only love it (*a la Doolittle*), but the bee-keeper who may consider himself pretty well informed will not only find that it will not only add to his pleasure, but will add to his income also in dollars and cents, to keep himself well informed and up with the times.

I have just been down in the cellar looking after my 80 colonies of bees, which seem to be in excellent condition.

Clover was in fine condition a short time ago, but the snow has thawed off, and we have had a few days of quite cold weather, which I fear is pretty hard on it.

W. C. NUTT.

Hardin Co., Iowa, Feb. 5.

Bees in Good Condition.

My 175 colonies of bees are in good condition at this date, in the cellar. The temperature is 45° to 48°. FRED. K. LOUCKS.
Lewis Co., N. Y., Feb. 6.

Bees All Right So Far.

I commenced last spring with 4 colonies, bought 5 in box-hives, and increased to only 12. They are all right this far. I winter them in chaff hives on the summer stands. I lost only one last spring. The past year was an off one with bees here. There were about 100 acres of buckwheat within two miles, but there was no honey to amount to anything. On examining with a magnifying glass, only a few blossoms had any honey. The drouth set in at the time it began to bloom, and when harvested it yielded no grain. Nearly two thirds of the bloom withered and died. But the bees filled the brood-chamber with honey. I got no surplus to speak of. ASA RICE.

Muskegon Co., Mich., Feb. 11.

Color of Honey—Extracting-Combs.

On page 29 is an item in regard to color of combs and color of honey. I have observed other causes than the one named for the discoloration of honey. Last summer was an unusually poor season for honey, and the fall flow did not commence until quite late; this left my bees pretty uneven in regard to strength and readiness to make use of the harvest when it came. We got some honey from buckwheat, but most of my bees were not ready to give any surplus from that source. Some colonies were ready for it, and carried it into the supers, but the remainder got just about enough to fill the brood-chamber. The result was, when at the close of the season I commenced to extract, the first-named had their comb filled with buckwheat honey, quite dark in color, and the remainder filled theirs with honey from other autumn flowers. There was quite a difference in the color and taste of the honey.

I have produced extracted honey for the last 25 years or more, but have never been able to see any difference in honey stored in old or new combs. Water, no doubt, would dissolve some of the coloring matter, but I doubt if honey would.

Years ago, when my children were small, they would frequently let pieces of bread covered with honey lie around, and when I would find them hours or days later, the bread was usually dry and hard—not soft like bread that is water-soak.

In regard to the care of extracting

The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

GEORGE W. YORK & CO.
118 Michigan Street, CHICAGO, ILL.

combs, I have practiced for years storing them in empty hives as taken from the extractor. I usually put 12 to 13 combs into a 10-frame hive, and store them in the barn until needed the following season. It is but seldom that I find a moth in any of them, and, besides, it seems to me that the bees have less trouble in cleaning them up, as when stored away dry.

If these observations do not correspond with those of others, let them make it known, for we all feel interested in the facts.
FRED BECHLY,
Poweshiek Co., Iowa.

No. 2.—Medical Animals.

Well, as I said before, our Dick—that's our Plym Rock rooster—is paralyzed. His legs won't work; can't get up, walk or scratch. Pretty bad, isn't it? Some say, "Kill him." No! He's a good two-year-old, and his family of a dozen biddies are much attached to him. So am I. But he's like some boys I could tell you about—he ate too much, and so got sick. You see, his stomach is affected, and in turn that gives him what doctors call "vertigo;" that, again, makes him dizzy, and he can't walk. That's all. I am giving him a small powder of nux, and later on I may tell you whether it has killed or cured him.

Now, chickens have lice. Of course, you have heard that before. But did you ever know that a certain quantity of lice—not too many, tho—is really a good thing for chickens? Eh-eh, that's so. The bugs eat off the old skin so that the chickens can peck it out to their great relief. Then when Mister Bugs have done their work Bidly looks around for a nice dry spot where the dirt is warm and loose, and by a vigorous series of back-handed kicks, it throws so much dust all over her that it smothers the creeping lice, or makes them let go and get away.

Now and then chickens get lonesome, even act crazy—the feathers come off, and they look like a fright. That's because they don't feel good. But just let them get at that pepper-grass out in your back yard, and you'll see what a change takes place in a short time. O, they know their medicine!

Then there is that old sow in the big pen. Of course she grunts, wouldn't you, if suffering awfully with the stomach-ache? Well, I guess! Only she has it worse than you ever did. Raise up that board so she can get out, and see her make tracks for the old pond. There she goes, wallowing right in the mud. Cool mud is exactly the kind of poultice her inflamed insides need.

No, just let her stay right there. She'll come home when well. A few loads of soft-coal screenings should always be kept in the pig-lot. They sometimes like it better than corn. It keeps the piggies well.

Rabbits? Yes, they are nice pets, but if you shut them up they soon get sick. They are great sufferers from tape-worm, and sometimes the worm is ten times longer than the Bunny. What do you think of that? Then is when they enjoy a big pumpkin—they will eat it, seeds and all.

Nannies, did you say? Yes, goats make nice pets, too; the trouble is, boys are so cruel to the little beasties. They hitch them to wagons and expect them to draw loads out of all reasonable proportions to their size. Under such harsh treatment they soon sicken, pine and die. But if gently cared for they become very affectionate. But the William goat, the whiskered Billie, won't do to depend upon! Better keep clear of him. I've had experience! They do best in hilly, rocky regions. They do not thrive on flat, wet prairie. They, too, are subject to big round worms, and if they can't have the moss and lichens off the rocks—which is their natural medicine—they grow thin and die.

Sheep are not quite so tender, but a hilly country is best for them, too. They have many diseases and bugs to trouble them, but if where they can nibble on willow they keep fairly well. Willow has much the properties of quinine, and maybe they need it, now and then, to keep off malaria. Who knows?

I had a Cossett once—that's a pet lamb grown up. I don't want another. To get a terrific thump in your back when you don't expect it, is a painful joke.

But I'll tell you what does make a queer pet—Mr. York yells, "Nuff sed."
UNCLE FRANK.

100 Cards and Card-Case —FREE—

We have arranged to mail a neat vest-pocket Aluminum Card-Case with 100 printed Business or Visiting Cards—all for sending us ONE NEW SUBSCRIBER to the American Bee Journal for a year at \$1.00. This is indeed a rare offer. You can have anything you wish printed on one side of the card. Your name

alone will be engraved on the Aluminum Case. It is something that everybody ought to have. Be sure to write very plainly what you want printed on the cards, and also the name for the case.

We will mail the cards and case for 50 cents, when wanted without sending a new subscriber, or will club them with the Bee Journal for one year—all for \$1.40.

Convention Notices.

Utah.—The Utah State Bee-Keepers' Association will hold its semi-annual convention in the City and County Building, Salt Lake City, Apr. 6, 1900, at 10 o'clock a.m. A full program in the interest of the industry will be presented, and all our bee-keepers can help themselves by aiding the Association, and in order to create a closer bond of union among our bee-keepers. As a further incentive to the success of the bee-industry, it is very desirable to have our bee-keepers from all parts attend the spring convention.
J. B. Fagg, Sec.

All interested in Fruit and ornamental trees, shrubs, roses, plants or seeds, will do well to write the Storrs & Harrison Co., Painesville, O., for their valuable free catalog. They are one of the most reliable as well as oldest in the business, and have a reputation behind them on which you can rely. When writing them please mention the American Bee Journal.

What is Bromus Inermis?—Our attention has been directed to this wonderful new grass by L. L. May & Co., St. Paul, Minn., whose advertisement appears elsewhere in this issue. Bromus Inermis or Brome Grass while referred to above as being new is not entirely unknown in this country, but it is in its native country of Russia that it is most highly appreciated. Its prime characteristics are its wonderful produc-

BROMUS INERMIS

tiveness and ability to grow, thrive and produce abundant crops of pasturage and hay in dry, semi-arid sections and localities where other grasses fail signally. It is hardly almost beyond comparison and is not affected by drouth, will not winter-kill and cannot be flooded out. It grows as well in low, swampy places as in the lighter dry upland where other grasses fail. This enables every farmer to make productive, portions of the farm that would otherwise be waste land. It has been found that the yield is greater than alfalfa; that it will produce heavy crops on the lightest of soils; that one seeding will last under ordinary conditions for 12 years; that it grows best when seeded alone and not in combination with other grains, and that the food value when converted into hay is superior to timothy of the same quality. There are many sections of the country where Brome Grass will prove of large value because of the excellent qualities enumerated above. In localities where there is only slight rainfall or where there is only a limited amount of water for irrigation purposes, it would seem especially wise to experiment with this grass. Write May & Co. for any special matter they may have on the subject. We feel personally that a new forage crop that offers such promise deserves the most careful consideration and investigation. Don't forget to mention the American Bee Journal when writing May & Co.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Feb. 7.—Trade is slow in comb honey, choice lots of white bring 15 cents, with that a little short of this grade, 13@14c; ambers range from 10@12c; dark, 8@10c; no fancy lots on the market.

Extracted, fancy white, 9c; amber to white, 7½@8½c; dark and buckwheat range about 7c. Beeswax is selling on arrival at 28 cents.

R. A. BURNETT & Co.

CINCINNATI, Dec. 27.—There is a good demand for all kinds of extracted honey. White clover and basswood sell at 8@8½c; amber and Southern, 6@7c, according to quality and package. Fancy comb honey in no-drip shipping-cases sells at 15@16c; darker grades hard to sell at any price. Beeswax, 26c. C. H. W. WEBER, Successor to Chas. F. Muth & Son and A. Muth.

LOS ANGELES, Jan. 4.—1-pound frames, 12½@15c; 2-pound cans, 2 dozen in case, per dozen, \$2.50; 2-pound glass pails, per dozen, \$2.50. Extracted, water white, 60-pound tins, per pound, 8½c; light amber, 7½@8c; dark amber, 7½c. Beeswax, 25@26c.

KANSAS CITY, Feb. 12.—We quote fancy white comb, 14@15c; No. 1, 13½@14c; No. 2, 12½@13c; fancy amber, 13@14c; No. 1, 12½@13c; No. 2, 12@12½c. Extracted, white, 7½@8c; amber, 7@7½c; dark, 6@6½c. Beeswax, 22@25c.

C. C. CLEMONS & Co.

BUFFALO, Jan. 5.—Market bare of fancy white one-pound comb honey, and selling at 15@16c; fair to good, 12@14c; buckwheat, dark, poor, etc., 8@10c. Fancy pure beeswax, 28@30c.

BATTERSON & Co.

NEW YORK, Feb. 8.—During the past 30 days our market has been somewhat slow and easy in both comb and extracted honey. Stocks of comb honey, however, are almost exhausted, and there is a fair demand for all grades. Fancy white selling at 15c; No. 1 white at 13@14c; fancy amber, 11@12c, and buckwheat at 9@11c, according to quality, etc.

Our market is well supplied with extracted, the prices are firm and unchanged. Beeswax sells very well at from 26@28c, according to quality.

HILDRETH & SEGELKEN.

SAN FRANCISCO, Jan. 10.—White comb, 11½@12½c; amber, 8@10c. Extracted, white, 7½@8c; light amber, 7@7½c; amber, 5@5½c; Beeswax, 26@27c.

Offerings and demand are both light, and this market continue to be the case until the end of the season. Business is necessarily of a retail character, but at generally firm figures, especially for choice extracted, which is in lighter supply than comb.

BOSTON, Jan. 12.—We quote as follows: Fancy white, 16c; A No. 1, 15c; No. 1, 13@14c; buckwheat will not sell in this city. Extracted, light amber, @8c. Demand is very light.

7

BLAKE, SCOTT & LEE.

ALBANY, Jan. 10.—We quote: Fancy white comb, 15c; No. 1 white, 13@14c; mixt, 11@13c; buckwheat, 10@11c. Extracted, white, 8@9c; mixt, 6½@7c; dark, 6. Beeswax, 26@28c.

MacDougal & Co.

Successors to Chas. McCulloch & Co.

OMAHA, Feb. 13.—Demand shows some improvement in January, having been much more active, but as anticipated there is no advance in prices. Market remains steady at 14@14½c for fancy white comb and 8½c for white extracted. The latter is pretty well cleaned up along the Missouri River, and it looks as if there would be some shortage before another crop comes in. From present appearances there is about enough comb honey to go around at the present prices, hence we look for no particular change in values.

PEYCKE BROS.

DETROIT, Feb. 10.—Fancy white comb, 15@16c; No. 1 white, 13@14c; fancy amber, 11@12c; dark and undesirable lots, 8@10c. Extracted, white, 7@7½c; amber and dark, 5@6c. Beeswax, 25@26c. Supply of honey fair with light demand.

IT HOLDS UP YOUR HAT

Don't you remember how your father used to test his grass and grain in this way? When it held up the hat it was always regarded as being a satisfactory and profitable "stand."

...THIS... BROME GRASS

Surpasses Timothy in nutrition. Outyields Alfalfa. Yields four to five tons per acre. One sowing lasts 12 years. Grows well in light soil, or wet swampy land. Has no equal for arid regions. Drouth will not kill it. Animals enjoy it green or dry. Gives as much food in one month as Alfalfa does in three. Greatest boon ever offered as it thrives in any climate, under any conditions and makes productive what would otherwise be waste land. It is doubtful if the supply of seed this year will meet the demand, so great is the call already from States where hay is the essential crop. Price: Grade A—1 lb., 30c; 3 lbs., 85c, prepaid. 13 lbs. (enough for one acre) \$3.50; 100 lbs., \$18.00. Send for mammoth descriptive catalogue with treatise on cultivation and comparative food values of Brome Grass and Timothy. Address, L. L. MAY & CO., Seed Growers, ST. PAUL, MINN.

CONTRIBUTED ARTICLES

Description of the Johansen Extension Hive.

BY H. JOHANSEN.

A PROPOS of questions which are continually agitating the bee-world, and with some casual reference to the small-large hive (or, more properly, colony) agitation which last summer was of apparently absorbing interest, the following remarks may shed interest and light upon some subjects.

Certain results, and observation of present methods in apiculture, led me to make some radical departures in the important matter of the hive. I was strongly impressed with the need and possibility of great improvement, and equipt an apiary of 25 colonies with a hive which includes the possibility of the best features of the standard hives (Langstroth, etc.), and makes possible the correction of some evils which bee-keepers experience.

If I had experimented with one colony I might not have been fully convinced of the correctness of my theories as represented in the hive, but having found the trial made on a large scale to have been eminently successful and convincing, I have seen my way clear to relegate the old furniture for the new; and I am convinced that however radical the ideas may seem, or how much opposed to commonly accepted practices, they are correct, and entirely follow along the lines of the natural habits and inclinations of the bee. That, of course, is the plan of procedure in successful apiculture. There is but small wisdom, for instance, in attempting to make the creature of instinct rise with its stores when entering the hive, if its instinct directs to do otherwise, however much it may be said that the bees deposit their stores all around the brood-comb, and accepting that as true. Now, I believe there is a good deal of such work attempted, and it cannot help being detrimental to a large extent to anything like success. I do not believe that present appurtenances are any more perfect than present methods of handling. Since the time of the great Langstroth there have been some improvements in hives, it is true, yet the main features remain the same.

It seems barely possible none of the predecessors thought of *all* the requirements, and it is even possible that errors have been made which altho perhaps slight, or mere perversions, are still detrimental to a degree.

In contemplating a change I had the following ideas in mind, and they are all of sufficient importance to warrant the attention and careful consideration of bee-keepers:

1st. I recognized the importance of preventing the bees from wasting time during the season when one is anxious they shall rise to the super (if such is considered), or, in other words, force them thru natural impulse to fill the sections without the delay so often experienced.

2nd. Preventing the detriment of swarming when it becomes such—and it usually does become detrimental when running for honey.

3rd. Facilities when desirable to run several queens in one hive because of its economy in honey-production, as I shall explain later.

4th. The necessity of better means than present ones for keeping the sections clean, and handling when removing them.

5th. The desirability from my standpoint of a chaff hive with the features mentioned.

I may describe the hive which I built, briefly as follows: It is made to accommodate standard Hoffman brood-frames, of which it will hold eight or 20, according to the manner in which it is run. Across the back of the hive is a space designed to hold two section-frames of eight sections each. On each side of the brood-frame I hang two section-frames similar to those at the back, with eight sections in each frame. This honey or section frame is simply a frame with lock and hinges which incloses eight sections in such a manner as to expose only the edges for the bees to stick over with glue, and can be hung in the hive in the same manner as, and alongside of, the brood-frames, or elsewhere.

When the hive is run for extracted honey ordinary frames, such as are used for the brood, take the place of the section-frames, being separated from the brood only by excluders; or the brood-chamber can be run thru to the sides and back, as the case and the intentions may require. Next

Mr. Johansen and His Extension Hive.

to the sides and back, and between them and the honey section-frames, are hung division-boards, either in the form of a frame with glass, or a light wire screen; in either case intended to make it possible to see the sections, and being equally serviceable and desirable.

If a very large colony is produced either by a very fine queen or by uniting swarms, as I mention later, one sec-

tion-frame on each side of the brood-frames can be removed; or both, thus making brood-chamber of the entire front of the hive; or the section-frames can be removed from the sides and back, giving still more room for brood-chamber. In the first case we have eight brood-frames and six section-frames; in the second case we have 12 brood-frames and four section-frames; in the third case we have 16 brood-frames, and two section-frames in the back of the hive; in the fourth case we have 20 brood-frames, and a colony with such a brood-chamber being naturally very strong, there will be no trouble in getting the bees to rise into a super constructed of section-frames, similar to those already mentioned, except that they may contain four or eight sections, according to the demand. Such a super would contain 50 or 100 sections. Both side and back walls are removable for convenience in taking off the surplus (whether in sections or in honey-frames for extracting).

After the removal of the section-frames or honey-frames at the close of the season, the space so left in the back and sides is filled with straw. The front of the hive is of two pieces, with tar or oiled paper between to keep the heat in. The hive usually facing the south, it is not necessary to take quite the precaution in chaffing that side, and I am confident the double wall will be sufficiently warm for the front. The floor of the hive is well chaffed, as is also the roof or cover, which is besides fitted with a cluster space and means of ventilation thru the chaffing.

It is not designed to run a super except when more than one queen is run, or when the hive proves too small for the accommodation of the brood and surplus of a colony with a very strong queen. When running several queens they will be excluded from each other and the surplus by queen-excluders, but all the bees being from the same colony will intermingle. The front of the hive will have two entrances to be used as explained later.

The advocates of the 8-frame hive could run this hive without changing their theories in regard to the brood-chamber; and those who advocate large brood-chambers would be equally well suited, as the hive has elastic qualities in which an expert will delight.

I start the hive with eight frames of brood and two section-frames on each side, and two at the back, for instance. I then find that my queen can fill more commodious quarters, and take out two section-frames, which still leaves four section-frames containing 32 sections, and increases the brood-chamber to 12 frames. If I begin expanding the brood-chamber before hanging the section-frames, I of course simply move out the division-board as the requirements direct, and this I can do to 20 frames in the brood, in which case the strength of the colony, with perhaps two or even three queens, will easily send the bees up to the super

as before mentioned, for it will, of course, then be necessary to have a super.

Normally, we will consider that the hive has six of the section-frames holding 48 sections, on the sides and back, and that this is the only reasonable and economical way of running a moderately strong colony, or even a strong colony under the usual conditions.

It is well known that the lower part of the hive has to be filled before the rise to the super takes place; but how often the bees loaf around and sometimes miss a crop, even when there is no apparent reason, the common cry alone can tell. We occasionally read in the bee-papers of some one's plan of *forcing* the bees into the sections. Now it is simply impossible to force bees to do anything, and one can reverse the order of things as much as one likes, and in the end the result will be the same. Towards fall, for instance, when there are a large number of empty cells in the brood-combs, the bees will carry honey down from the super, if there is no honey-flow, etc.

I have concluded that the bees apparently do not rise into the super with stores as readily as they will deposit their stores in the lower part of the hive; at least not until there is a superabundance of bees in the hive. Herein lies the difference, and I believe also from observation, that bees prefer to spread to the sides rather than spread upward. From the experiment I find that the bees will build to the sides indefinitely, and enter the sections without any hesitancy or delay whatever, never failing in this respect if there is honey flowing. Now, this is a valuable consideration, and in connection with the clean sections, and straight, full combs obtainable with the system, would be worth any inconvenience, if indeed there were any. As the bees enter the sections from the side, and only the edges are exposed, there is no possible chance for any gluing or dirtying of the sections, and one can remove section after section with scarcely a speck of bee-glue to be seen, and it is consequently not necessary to scrape them either by hand or machinery.

Another reason which makes this honey section-frame desirable is its easy removal. To be considered quite distinctly are the following:

1st. That when one desires to know how the sections are filling it can be discovered in a moment, and without disturbing the bees, by simply removing the side or back, thus exposing the sections from the side, which in itself is much superior to peering down between the cracks thru a colony of bees rising towards one's face.

2nd. When removing the sections one does not straight-way invite every bee which feels it has had its roof-tree and stores stolen, to rise to a friendly caress; to say nothing of the disturbing nature of the proceeding, which is undoubtedly felt in the work of the entire colony.

3rd. Full section-frames removed are at once replaced with new section-frames ready at hand; and the vexation of removing a super with sections in all stages of completeness and incompleteness is minimized, as it is of course only possible to remove about eight sections at a time, and, as they are pretty well localized in the same part of the hive, are apt to be in about the same condition.

It might be added that the storing of honey is not en-

tirely interrupted when removing sections during a honey-flow, as working on one side only there are still two sides in which the storing goes on uninterruptedly.

One of the main features of the hive is what I will call its elasticity. An 8-frame hive is the thing to have if the rearing facilities are only sufficient to produce brood enough

to cover that number of frames, but if more bees than eight frames will accommodate be produced it will be necessary to induce swarming thereby, or accommodate them in the brood-chamber, and no one will have any objection to a large colony, no matter how large, because the more bees it has the more honey can be produced—providing it does not become crowded so as to induce swarming. It will not do

to be arbitrary in the selection of either a large or a small hive, for all colonies do not work alike, and what would suit one colony exactly might not suit another, like a large shoe on a small foot. What is necessary, then, is a hive to meet every exigency, and to accommodate a large or small colony equally well. Personally, I believe in having plenty of bees in the hive, and by that I mean all I can get, either by means of good queens or by a plan which I intend hereafter to pursue for this reason, and incidentally to solve the swarming question, or rather, control swarming in the interest of honey-production. Both of these highly desirable things I can accomplish with the new hive in the following manner: I start with eight brood-frames. If I find a necessity for 10 I expand the brood-chamber and this I can do indefinitely in the manner and as previously described.

A still more sure plan is that at which I have already hinted, viz.: two or more queens to a hive. This, as I have before said, was an afterthought too late to put into practice during the last season, and while I have not tried it, yet unquestionable authority not differing in essentials, confirms my belief in it. Running more than one queen in a hive is not an entirely new proposition, and such a plan, if practicable, would have, to any one, its own obvious reasons unnecessary to dwell upon.

I quote as authority Mr. G. M. Doolittle, and while my references are found in his book on "Scientific Queen-Rearing," the circumstances alluded to by Mr. Doolittle are not different in an ordinary working hive. Any one can convince himself of the possibility by reading from the middle of page 93 to page 96 carefully. One or two other references, perhaps not so applicable, can also be found. It may be noticed that mention is made by Mr. Doolittle of these things having occurred in an upper and lower hive, while I use only a lower hive. This, however, can in no way affect the proposition. A double-queen system in a working hive would hardly be possible, except in one having the features which I describe, and outside of this possibility its advantages are so numerous as to render it very valuable. The following, then, would be the method of procedure:

If the bees show a tendency to cast a swarm I am perfectly willing to let them do so; rather gaining than losing thereby, as by the management I will still have the united force of all the bees I had before, and in addition an increase producing facility as hereinafter explained.

As soon as a swarm is cast, having first placed the new swarm in the hive from which it issued, I expand the brood-chamber. I do this, if I have already hung the surplus frames, by sacrificing one on each side, or all, as the case may seem to require. Before returning the new swarm to the old hive, I push the old swarm and brood-frames to one side of the hive, and isolate the queen by means of an excluder, leaving half of the brood-chamber to the domain of each queen. Having given the new swarm the necessary brood-frames with starters, I close the hive, and the operation is practically complete. In order to be sure that the

young queen shall return to the right side of the hive when she returns from her flight, if she should not happen to have been fertilized before the swarm was cast, I have two entrances in the front of the hive which I use as follows:

Having prepared one side as I explained, I close the entrance which opens into the space for the new swarm, leaving the entrance which opens into the space for the mother colony for a passageway for all the bees; if the new queen has not been fertilized, it will of course leave and enter by this entrance. This insures separation of the queens.

After a few days, when I am sure the new queen has been fertilized, I remove the obstruction from the closed entrance and run them as necessary. If still another swarm is cast, I handle it in very much the same manner by placing the new swarm in the rear compartment and giving it four brood-frames. The queen-excluder already in place serves to exclude the queen from the rest of the hive.

Having hived the swarm I examine both sides of the original brood-chamber to ascertain, if I have not seen the swarm issue, which side cast it. This is necessary in order to arrange the entrance on account of the possibility of an unfertilized queen, as before explained. Having cleaned out the remaining queen-cells, if any, while investigating the two sides, I can close down the cover on a single hive with the rearing power of two or three colonies, and feel quite secure about further swarming or dwindling on account of it.

If the second swarm issues after about June 1st, it is of course a question for the bee-keeper to decide whether he will install it as colony number three of the hive, reinstate the bees, or handle the swarm in some other manner, but the facility is ready for the emergency if required. No moving around or handling of the hive is necessary. Such a thing would at least be very singular and rare, so the objection which might occur to some is not of weight. The size of the hive is about 22x26 inches.

In the fall, in preparing for chaffing, the hive is reduced to one colony (if more than one queen is successfully used) occupying about eight frames; leaving chaffing spaces of three to five inches on the sides and back; or preferably two colonies are left, the brood-chamber being reduced to about 10 frames, which is sufficient, considering considerable room in the cluster-space; there will then be about a five-inch chaffing space in the back and about 3½ inches on each side. The side spaces can be advantageously used for feeding, either in the fall before chaffing, or in the spring by removing the chaff from the warm side and placing the food there.

In the event of reducing the brood-chamber to one colony, there will be a considerable increase of colonies either

SECTION FRAME —
SHOWING SECTIONS
IN PLACE. —

for next year's apiary or for sale. The same will be true also if some of the hives have three colonies, and it is decided to winter with two. Other advantages of the system might be mentioned, and further explanation and details given, but space would not permit. Cook Co., Ill.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it.

NO. 2.—COMB HONEY PRODUCTION.

Some Preliminaries to the Harvest—Wintering, Breeding, Etc.

BY R. C. AIKIN.

TO obtain strong colonies by the time of the honey-flow is one of the great problems. The time of the flow must be known, and all must be planned for that time. There are localities where the crop-yielding nectar comes in the late summer or fall, and in such case it is easy to get the colony ready to do good work; but for an early summer flow from such source as white clover we usually can not get ready too soon.

One great difficulty in harvesting good crops of honey is to keep the colony from wasting strength in swarming. If we could surely control swarming so as to have it come when we wish, and not till then, we would make a great step forward. The colony that swarms becomes too weak to do much in storing surplus, and the swarm, too, must be hived in a contracted hive to be in shape for good section-work, and even when in a contracted brood-chamber the flow must be fair to very good if we get satisfactory work.

White clover being the most common source of nectar, we will study principally from a clover standpoint, and choose the latitude of southern Iowa and figure on dates that correspond to that, so those living farther north or south, or if for any other reason the season in the reader's location should be earlier or later, just make the proper allowance. As the clover will advance just about the same in a given time when once started in spring, so you make your estimates.

In southern Iowa spring may be expected to begin about March 1, and white clover to mature and be ready to yield nectar about June 15. In southern Missouri the dates would probably be two weeks earlier, and northern Iowa say two weeks later. Seasons vary from year to year, and crops mature fast or slow as the weather conditions may favor or not, yet each one can approximate very closely by a little observation and thought.

Having reached the opening of spring the object is to get the colonies to breeding well so as to build up to good strength as soon as possible. If wintered in the cellar there should be hatching bees near March 1, and the same when wintered outdoors if the winter has been an open and warm one. Usually southern Iowa finds a little brood started in the center of the cluster by Jan. 10th or 15th in strong colonies, and by the middle of February in all fairly strong ones. Weak colonies that can not get up enough heat must wait till the weather is in their favor.

Thus it comes about that some colonies are away ahead of others in breeding up in the spring. Much depends upon how the colony goes into winter, whether weak in bees, or with plenty of strong, young bees, or old and feeble, etc. Two colonies may go into winter with an equal number of bees, while if one has many old and but few young, while the other has the reverse, the young colony will outlive the old, and care for more brood in the late winter and early spring.

Then, too, one colony may have sufficient ventilation to carry off surplus moisture, and the next one be poorly ventilated and become wet, weak and diseased. But whatever the cause that makes the colonies unequal when they start breeding in late winter or early spring, if they do not get an equal start they can not give equal results. Perhaps three things are in the main to blame for the unequal start, viz.: Going into winter in varied conditions as to age and numbers of bees; variations in ventilation, allowing accumulation of moisture, thus affecting the health and life of the bees; and, third, the disposition and proportion of honey, pollen and empty comb.

It is desirable and important to have the colony even and in normal condition in the fall and winter, if possible, and if so we may expect much the same in the spring. Should the colony come out at the opening of spring with but a handful of bees, or so few in numbers that they can not get and hold heat to hatch eggs and mature brood, all they can do is simply to wait for warm weather, and when waiting they often pass to the "long wait." I want a colony to have hatching bees by the time they begin to forage in early spring, for those young bees remain close to the hive and brood nearly all of the time, and very much help on the breeding work; but should there not be hatching bees when spring foraging begins, then the death-rate soon leaves the colony in that weak, waiting condition, and, no difference how good the queen, they can not increase.

BREEDING CONDITIONS.

As before stated, it is natural for the colony, with sufficient strength or number of bees, to begin breeding in January, at least early in February. Bees should be hatching by March 1. Spring opening about March 1, and young bees then emerging, the colony is practically safely wintered. Up to this time honey should be close to the cluster, and in very easy reach of the bees so they can have unsealed honey in the cluster at all times. After the weather is warm enough so they can almost daily get out from the cluster to uncap and carry in honey, it is not so important that the stores be in so close proximity to the cluster.

I take it that most locations have early pollen, such as maple and willow, also a little honey, too. That was the condition in the part of south Iowa in which I used to practice, and in such breeding goes on about as well if the colony be let alone, probably better, than if meddled with. They need the encouragement of warmth and a little fresh pollen, and, if dry and warm, breeding can not be much helped by anything more we can do.

Should the location not have early pollen, and little or none is in the hive, then artificial pollen, such as flour mixt with bran, or chopt oats, should be placed in easy reach of the bees in the yard, or may be put right into a comb close to the brood. The thing that will encourage rapid breeding, if there is sufficient heat, is pollen and unsealed honey, and with these plenty of comb that the queen can freely use.

As the season advances and the colony begins to have so many hatching bees that the birth-rate is freely gaining on the death-rate, then is the time that one may spread brood if it is done carefully. The first act in that direction is to turn the combs rear end foremost, at least the ones containing brood. The brood-nest is almost invariably started next the entrance. If the combs containing brood be turned front end to the back, keeping them in the same position to each other in other respects, the brood now to the back and the honey to the front—thus arranged the honey will be removed from between the brood and the entrance, and placed unsealed close around and above the brood, and the comb from which the honey has been emptied will soon be occupied by brood.

This manner of spreading brood is quite safe—it is really causing the colony to do the spreading, and for stimulating breeding it is almost equal to a honey-flow. It also has this merit, that combs will be filled from end to end with brood instead of nearly every comb having the front end with brood and the back with honey.

Read this again, and think awhile over it—it is a valuable "kink." Larimer Co., Colo.

California and Its Vast Honey-Resources.

BY RAMBLER.

WITH the rains that have fallen so bountifully upon our charming western country there is a mark revival of the hopes of our bee-keepers; and this hopeful influence must be exerting an influence upon the fraternity in the far East; for letters are dropping down upon us making all sorts of inquiries about this country, and just as tho we had never had a drouth.

It was naturally supposable that Cuba and the other islands that have been thrown open to the enterprise of our people would be the magnet to draw bee-keepers into new and untried fields; but it seems that, in spite of new domains and our dry seasons, California still has a magnetic influence; and as the aspects in the honey-business are rapidly changing in this State, it is no more than fair that we devote a little time and space to it.

I believe the boast has been made that California produces the largest honey crop of any State in the Union. I believe I have made some such remarks in the past myself.

We can estimate quite closely, perhaps better than almost any other State, as to the annual product. Our honey is shipt over a few transportation lines, and all we have to do is to look into the books of said lines; and when the grand total figures up to 300 carloads, and in addition to this a large home consumption, perhaps we are justified in our boast for largest production, and may be further pardoned if we sail our hats a little when we reflect upon the long trains of honey that are leaving our State. But this exuberance is all the result of a good season, and we have to use this qualifying term, for we have our poor as well as good seasons.

During the nine years I have been in Southern California, four of them have been total failures in honey-produce-

tion, while two others have been a partial success, leaving three good years in nine. Therefore, taking the average production during these nine years, I have come to the conclusion that in a series of years California will make no better showing than some of the Eastern States. There is not much comfort in that for those who wish to come here to embark in the bee-business; but let us look at the map of California, and make a few comparisons, review a little of the past, look at the present, and deal a little in futures.

For nearly 800 miles the western side of California is white with the spray of the Pacific Ocean. Measure off 800 miles on the Atlantic side of the continent, and it would include all the coast from Maine to Georgia. In area it equals the ten far Eastern States, as shown in the accompanying cut. Thus far the honey-production in this vast area has been confined to a few favored localities, and there are wide stretches of country where a bee could not live; but the prospects are bright for these desert places becoming our most reliable honey-districts.

The history of the bee-industry in California is decidedly interesting, and shows many mark changes in the area of production; and those changes so favorably begun will go along with rapid strides. That the seeker for a good honey-location in this State may know just where to look, refer again to the maps. I have divided the State into three parts—Northern, Central and Southern.

The production of honey in California commenced in the Sacramento Valley, in the northern portion of the State.

As the resources of the State became more generally known it was found that the southern end was far the best for honey, both in quality and quantity, and in that portion the industry has reached its greatest development, and the honey produced in the seven southernmost counties will ever hold the reputation gained for quality; for in no portion of the State is there the amount of various sages that are found here; and while the valleys have been put under cultivation, and the sages destroyed, the canyons and mountain sides are still its home, and there will always be very good pasturage, for the land can be used for no other purpose.

It is in this portion of the State where those phenomenally large yields have been produced; but we can refer to them only as phenomenal, for they seldom occur twice in the same locality. These phenomenal yields have always been within the sage-belt, and from that source; and it is safe to say that, in the production of quantities of pure sage honey, California has seen its best days—but not its best days in the production of honey, mind you.

Referring to the little map of comparisons, we find that California has a population of a little over a million, while the Eastern States of the same area have 16,000,000. It is a foregone conclusion that the waste-places in California will rapidly fill up with people, bringing changes in the products of the soil, and more of a diversity in the honey-resources and in the quality of the honey.

That the honey-resources of California are changing, and will increase to greater proportions than ever, can be easily demonstrated in Central California. In this portion of the State, where a few years ago the land was so barren

that, upon hundreds of square miles, a bee could not live, there are now thriving farms and thousands of acres of alfalfa. Irrigation has made this great change. This area of alfalfa is now confined in a great measure to locations not at a great distance from the railroads. Outside of this area are thousands of square miles yet to be populated and brought under cultivation, and it is safe to say that alfalfa will be one of the principal crops.

We never hear of phenomenally large yields of honey in Central California, but they are blest with something better—no total failures. The honey-yield fluctuates more or less, as it does in all locations; but there is a reasonably sure income from the apiary every year; and the carloads of honey from Central California, which are already numerous, will steadily increase. In the eastern portion of the middle of the State we find Owens River Valley, not of great size. It is hemmed in by immense mountains, and here the bee-keeper produces alfalfa honey of the finest quality. Owing to location, or some other cause, the honey is of lighter shade than honey from the same source in other portions of the State.

The development of the honey-resources in Northern California has not kept up with the development in the south. It is a mountainous country; and in those portions where honey can be produced, the cost of transportation to market eats too much into the profits to make it a paying business at the present prices of honey. It is safe to say that there is an area in Northern California equal to the area of New York State, where there is not a carload of honey shipped; and where it is produced it is sold in the limited home market. It costs as much to ship honey from the Oregon line to San Francisco (a little over 300 miles) as it does from San Francisco to New York. There is a future, however, for Northern California honey-production. With more and competing lines of transportation, more settlement of waste-places, and more alfalfa, carloads will begin to move out. Many of our prominent bee-keepers, even in Southern California, see in alfalfa the great and permanent honey-plant of the future.

This great forage-plant is in direct accord with the interests of every agricultural community. Alfalfa first, cattle next, then the flowing of milk and honey, typical of the highest prosperity of a State.

California is justly noted for its immense fruit-industry, and much has been said about this source of honey. However, it cuts but a small figure. The time of bloom is of short duration, and the secretion of honey not abundant. The orange-bloom, where the trees are abundant, gives a fair surplus; but it would not pay for the bee-keeper to depend wholly upon that source alone for his living.

At present the best locations for success in honey-production in California are found all the way from the Sacramento Valley to San Diego; and the bee-keeper who intends to move to this State should write to the Chamber of Commerce in San Francisco and Los Angeles for literature giving much information about the respective ends of the State. In fact, it would be a good plan for almost anybody who would like to know more of the resources of this great State to send for this literature.

Then it would be a good plan for the emigrant, when he arrives, to take time to look the ground over. Ride by rail and wheel thru the central portion of the State. The largest alfalfa districts are between Fresno and Bakersfield. Two weeks' time could be profitably spent in looking this field over, and a longer time could be spent in Southern California; for you can see, by referring to the map, that the great State of Ohio covers only about half of this end of California.

When a location is selected it is of the utmost importance that the occupant of it make up his mind to like his new home, and laud it to the skies upon any and all occasions. That is always the first duty of all true Californians.

I am sorry to know that some people are always cursing their lot and their surroundings. Well, we want no such people here. Their somber souls would be sadly out of place in this God-given land of health and sunshine; and wherever a number of such people congregate, there you will find a dead town and a well-filled graveyard.

In thinking over the matter of a change of residence, do not hesitate on account of health or old age, for this is a healthful climate, and, as Dr. Gallup has it, "It is the old man's paradise."

Taking it all in all, the bee-keeping industry of California has a brilliant future; and all the present members of the fraternity have to do is to stick to the business and hasten the day of great prosperity.—Gleanings in Bee-Culture. Los Angeles Co., Calif. □

CONVENTION PROCEEDINGS

Report of the Colorado State Convention.

[Continued from page 118.]

PACKAGES FOR EXTRACTED HONEY.

Mr. Pease—Tin packages can be used again. The fiber package can not. Mr. Doolittle advises wooden boxes.

Pres. Aikin—I don't know anything about them from experience.

Mr. Root—I think a lithograph label is so much more attractive than the printing on the fiber package that it would pay the difference in price.

Mr. Porter—There has been some talk of a uniform package for extracted honey. If enough would use them, it might pay to have a stamping machine of a certain size.

[The secretary has looked up this matter, and found that the dies and other machinery for making 10-pound tin honey-packages would cost about \$300, and for making 5-pound packages about \$200.]

H. Rauchfuss—One man should put up the honey to get it uniform. A uniform package of honey would drive corn syrup out of the market; 35 cars of corn syrup a year are used here.

SECOND DAY.

Mr. Lyon thus introduced this subject :

OVERSTOCKING OF LOCALITIES :

There is no question that there is great danger of overstocking a field. Locality and the man have everything to do with it. A man capable of caring for bees as he would care for other things will not feel the overstocking as another would. Wintering has a good deal to do with this question. Our winters here are hard, and we have sunny days that encourage the bees to fly to their detriment. It would pay to close up the hives if it could be done at all. Fifty percent of an apiary was lost at Longmont last winter. The cover was sealed down, and the moisture could not escape. A few years ago a man moved his bees to a quarter of a mile from mine, and got no crop of consequence. It is the same as with cattle; there is such a thing as overdoing. I have not hitherto kept over 125 colonies in one place, but next season I will try 150 or 200. It will save the expense of one man. But we can not be too careful of overstocking. There is no question there is room for all. If one sees his neighbor getting a good crop, it is folly to move in close to him. The man that gets his bees in shape to gather the nectar will get the honey.

Mr. Moon—There were two apiaries, one a mile and one a mile and a quarter from mine, and the crop is better since they moved off. I have 330 colonies in one apiary, and there are 100 more within a quarter of a mile. But there are immense quantities of alfalfa and sweet clover near by. My crop this year was 865 cases, the largest crop I have had, from about 275 colonies, spring count.

F. Rauchfuss—Mr. Moon keeps more bees in one place than any other person in Colorado.

Mr. Lyon—Wouldn't Mr. Moon get more if he kept his bees in different places? I received one-third more by dividing up.

Mr. Thompson—Within a radius of a mile or so, or a circle of something like two miles in diameter, perhaps 2½, there are some 700 or 800 colonies at the town of Montrose. Wm. Willis has 60 or 70 colonies right in the midst of them, and gets a bigger average than any of the others. George Hone has about 270 colonies in his home apiary, and about 240 colonies in his out-apiary, about a mile and a quarter distant, and there are a number of colonies in the neighborhood. He thinks his region is somewhat overstocked, but he gets fair crops. He is considered a good bee-keeper. Mr. J. R. Penniston evidently thinks his locality is overstocked, for he is thinking of selling 40 of his 60 colonies and getting as much honey from the remainder of 20 as from the 60. There are about 100 acres of alfalfa accessible, and a total of 100 colonies in the neighborhood, including his own.

H. Rauchfuss—In this locality it is hard to keep up the number of colonies in an apiary when it exceeds 75 or 100. Before they reach that number, they increase; afterwards,

they do not. I believe an alfalfa locality is easily overstocked. Sweet clover is better. Last year we had hardly any honey from the first crop of alfalfa at a time when beekeepers close to the foothills were getting a fair flow. One year the flow commenced June 25 and stopt July 9. If sweet clover had been in the locality it would have continued. It was not because the alfalfa was all cut; 80 acres remained uncut after that, but there was no gain.

J. B. Adams—I believe the reason a large apiary does not increase here is that the yield from apple-blossoms is very light.

Mr. Lyon—Believing my locality was overstocked, I moved to Longmont. That shows my faith in the possibility of overstocking. We are just on the point of overstocking at Longmont.

H. Rauchfuss—Along Bear Creek there are 2,000 colonies within seven miles, including several large apiaries. The cultivated portion is not seven miles wide, and there is much barren country included. But it is an exceptionally good locality. There is much sweet clover, and the foothills, which furnish spring flowers, are close.

F. Rauchfuss—I think Mr. Adams is right—we can not breed up our bees in the spring in the average alfalfa locality here. That is seen by comparing the apiaries east of Denver with the bees at the foothills. In regard to overstocking, the bee-papers have been making various allusions to the large unoccupied fields of Colorado. All the good fields within easy reach are occupied. Only about one-twentieth of the area of the land is in alfalfa, and only in 14 counties, principally in the valleys of the Platte, Arkansas, Grand, Gunnison and Uncompahgre. The biggest portion of Colorado is unfit for bee-culture, owing to a wide area of high mountains and desert lands, fit only for grazing.

Mr. Porter—At Lakewood there are at least 800 colonies within an area of 2½ miles square. The yield is not so good there as five or six years ago, altho sweet clover has increased.

H. Rauchfuss—In former years it seemed as if alfalfa yielded more than it does now.

Ch. Adams—One reason is that hay is cut earlier than then.

One year there was a great deal of bloom, and I could not see more than a dozen bees on it. My average was 17 pounds.

Mr. Lyon—Another very important reason has not been taken into consideration. There are ten bees now on the flowers where there used to be one. That depends upon the strength of the colonies—that is the man part of it. It is true that alfalfa does not yield some years as it does others.

Mr. Porter—The dairy interests affect the alfalfa around Denver, and in the northern part lamb-feeding, which has assumed great proportions, requires tender alfalfa, cut early. The main point is the grasshopper. Take away the grasshopper and you will double the yield. It prefers the bloom.

A Member—The grasshoppers eat the alfalfa which is left along the ditches, and the sweet clover also.

Pres. Aikin—I never cared to have more than 100 colonies in one place, partly because the robbing is much worse in a large apiary, and also the annoyance in working among the bees. I prefer a small apiary. I think Mr. Lyon put it mildly. There are probably 20 bees now where there was one formerly. The farmers cut later this year in my locality, and my crop was better. The first year I had the best flow, and the bloom was continuous. I can almost time the flow to a certainty by the amount of hay cut. I seldom get any from the second bloom. At present, the farmers aim to cut it just as it is in bloom. Last year there was an abundance of moisture in my locality when it was dry here, and the result was, the farmers got behind in their work, and there never was such a good flow as this year, because the alfalfa never had such a chance to bloom. Three or four years ago there was lots of bloom, but little honey. There were black spots on the leaves. One season there was a large amount of web-worms, and if the grasshoppers commence the flow is no good. Overstocking, therefore, is not all. Mr. Farr told me he kept a large number of colonies in one place in Utah, and could not see that the yield was reduced enough to pay to divide. For some reason in Iowa the flows dropt off. The bees decrease so there are not nearly so many, but to-day they don't get the yield they used to.

Mr. Lansdowne—I agree about the grasshoppers. One year I sowed alfalfa with wheat, and the grasshoppers ate it all off.

Prof. Gillette—I think the damage from grasshoppers

is overestimated. When they are not very abundant they eat about the borders of a field, and make quite a show of damage. There is no better method of destroying them than to use the hopper-dozers or pans, or the plow, or cultivate in spring; altho a bran-mash of one pound of arsenic to six pounds of bran, with water, around the borders of a field, is good.

H. Rauchfuss—That is just where we don't want them to eat. That is where the alfalfa and sweet clover is not cut by the mower; there, and along the ditches. But last year we had hardly any grasshoppers, and still the flow was not good until the latter part of the season.

Prof. Gillette—I think they injure the sweet clover as much as the alfalfa.

Ch. Adams—That bran-mash is pretty strong. Around Greeley I used a small handful of arsenic to half a bushel of bran, with a very little water; otherwise they would not eat it.

Prof. Gillette—The proportion I mentioned always seemed to me very strong. It was used originally with white arsenic, which is tasteless.

J. B. Adams—I used one to two pounds of bran, with black molasses. It did the business. They ate it all up.

USE OF SEPARATORS.

Mr. Tracy—I use one or two separators in a super, and believe in using as few as we can. We want our sections to weigh as nearly a pound as possible. You will not find many combs built crosswise where there is a separator to every three rows.

H. Rauchfuss—I want a separator between each two rows. Bees don't seem to enter a super as readily when separators are used, but they work just as readily after they are started. Separators make the number of unfinished sections less; and when full sheets of foundation are used, and one drops, only one section in a row is spoiled, when separators are between each two rows. Then no combs project, and much time and annoyance is saved in getting the honey into the shipping-case. If the colonies are strong enough to enter a super all at once, they will build straight combs without separators, but if they enter on only one side, they will not.

Mr. Tracy—I don't care if my honey is not all capt. I am surprised at such a bee-keeper as Mr. Rauchfuss taking the stand he does.

H. Rauchfuss—I wouldn't care to do any extracting from unfinished sections; and old combs don't make first-class comb honey the next year. Last spring I didn't use more than 50 old sections.

Mr. Allen—I have used separators, and found many combs fastened to the separators. I have concluded not to use them. I found, too, that the combs were thinner, and scant in weight. Then separators take up more work and time to put them in.

F. Rauchfuss—Have you ever observed at what stage of comb-building the attachments were made to the separators?

Mr. Allen—No.

F. Rauchfuss—In the majority of cases those connections are made after the comb is finished and sealed, showing that if the honey had been removed when it should have been, there would have been no such trouble. In one instance last season a bee-keeper had such connections made to his separated honey, but the braces were attached to the capt comb, showing they were built after the honey was sealed. The same man had another lot of supers without separators, but the honey in them was unsalable. He used only one super on a hive at one time. That explains it.

H. Rauchfuss—More depends upon the management than upon the bees, in this respect. If only a small starter is used, many sections will be spoiled when no separators are used. Out of 350 cases of comb honey that I produced last season with separators and full sheets of foundation, not one section was "tied" to the separator. In one lot of 25 supers only two sections were spoiled, and that was because the foundation had dropt.

Mr. Lyon—I would not use one separator. I can produce better honey without.

F. Rauchfuss—Why?

Mr. Lyon—Because with separators honey can not be produced heavy enough to suit the Eastern market.

F. Rauchfuss—Here is a quotation from a letter from Peycke Bros., who last year handled over 20 cars of honey: "We notice that you demand average weight on No. 1 comb honey should be 22 pounds net. Our experience has been that where separators are used (and we advise that the use of these be made one of the most stringent rules of the association) it is not an easy matter to reach the 22-pound

average weight; but with our extensive trade, which reaches all thru the Eastern States, we have never found any objection to light weight. We had several cars out of Utah last year which averaged from 20¼ pounds to 21 pounds per case, but the honey was so perfect and so pretty that it took the preference over everything else that we had. We consider it of much more importance that each section is perfectly filled than that the comb should be thick. By this, of course, we do not mean to say that we favor a reduction in the size of the present section."

Mr. Lyon—I have had as large a correspondence with the East as any one except the secretary, and can say that my experience is different.

Ch. Adams—I got a letter from Kansas City which gives the same advice as given by Peycke Bros.—"Be sure to produce honey with separators." Bees will gather as much honey with separators as without.

F. Rauchfuss—Another dealer corresponding with reference to one or two cars requested *only* separated honey. Another firm, in Pennsylvania, also preferred separated honey, and was rather partial to the lighter weight.

Mr. Lyon—As a rule, the average bee-keeper produces better honey with separators.

Mr. Whipple—I have had the best satisfaction with separators, tho this year I had more combs than usual fastened to them. The standard sections will be light, it is true. I ordered some 1 15/16 sections, and found that every time a case would average 24 pounds net. But the honest weight doesn't cut any figure. I use separators all the time, and have adopted the standard 1½ section, and get the same price. I'm no worse than anybody else.

Mr. Tracy—The first 24 cases of mine weighed only three pounds less than enough to make an average of 24 pounds each.

Mr. Whipple—I weighed 15 cases of mine this year, and they overran 22 pounds net. The buyer said that's good enough.

I am pleased with the Golden method. From three colonies I took five supers of 28 sections each.

Pres. Aikin—When I first came to Colorado the flow was the best, and I averaged 150 pounds. I used two separators to every 10-frame super. For that rapid, heavy flow, two separators were enough. But in general, not half the bee-keepers can pull out sections where no separators have been used without damaging them; and if this is so, only a small percentage of *dealers* can. I handled this year a carload of comb honey besides my own. The buyer said, "Produce with separators all the time." He went out to see one man's honey produced without separators, and tho he wanted all the honey he could get, he told him to sort out only the best, and he would give him \$2.15 a case for it. It is not a question of weight. The reason we use separators is to have the honey within the wood. Another reason is, the retailer must handle something which preserves the average weight in each section. True, a little more room is needed, but that cuts no figure when you get 25 or 50 cents a case. In a good honey-flow the honey is uniform, and *then* almost every fool can produce a good article. In a slow, light flow the case is different. The buyer told me I could have all I could make over 5 cents in handling one lot produced by weak colonies without separators. Somebody said some colonies produce burr-combs and others do not; but when any colony is crowded in the flow, that non-burr-comb strain is going to build burr-combs. If an honest section is wanted, make a larger section. When the separator does not come within ⅜ of an inch of the bottom or top of the section, and the colony is crowded, or the flow slow, the bees will extend that part of the comb above and below the separator. Separators are all right when one knows how to use them, and they make the proportion of finished sections larger.

J. B. Adams—Do you prefer wood or metal separators?

Pres. Aikin—There is not much difference.

Mr. Whipple—I sell my honey more readily by using separators than I can without. The parties that buy to retail prefer the straight combs.

Mr. Porter—In the sales this year the buyer did get all the non-separated honey, but that was because of the scarcity of honey.

Mr. Whipple—I got \$2.40 a case for an average net weight of 22 pounds, in the early part of September.

[Continued next week.]

The Premiums offered on page 142 are well worth working for. Look at them.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY,
118 Michigan Street, Chicago, Ill.

[Entered at the Post-Office at Chicago as Second-Class Mail-Matter.]

EDITOR:

GEORGE W. YORK.

DEPARTMENT EDITORS:

DR. C. C. MILLER, "Questions and Answers." * * E. E. HASTY, "The Afterthought."

LEADING CONTRIBUTORS:

G. M. DOOLITTLE, C. P. DADANT, PROF. A. J. COOK, F. A. SNELL, R. C. AIKIN, "OLD GRIMES."

IMPORTANT NOTICES:

The Subscription Price of this journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec00" on your label shows that it is paid to the end of December, 1900.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

VOL. 40.

MARCH 1, 1900.

NO. 9.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England;—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

A World's Congress of bee-keepers will be held in Paris, France, Sept. 10, 11 and 12, 1900, during the Exposition. Our National Bee-Keepers' Association should be represented. The delegate might be selected at the Chicago convention, next August. We nominate Mr. C. P. Dadant. He, no doubt, would be willing to bear a good deal of the necessary expense in order to have the privilege of visiting his native land. And he would be an excellent representative of the bee-keepers of the United States.

The Bee-Column in an Agricultural Paper is sometimes a good thing, and sometimes it works mischief. Depends upon who takes care of it. An agricultural paper of good standing to hand has for spring the unqualified advice, "The hives should be lookt over and the weak colonies fed." Saying nothing about looking over "hives"—colonies no doubt being met—suppose the owner of bees tries to follow the advice, and finds a colony that plainly has hardly half as many bees as the other colonies. He says to himself, "That's a weak colony, and it must be fed." So he feeds it, regardless of the fact that it already has more food than it can possibly use, doing more harm than good by its disturbance.

"A well arranged apiary that is simple and convenient is thus described by an Illinois subscriber;" and then fol-

lows a description so complicated that this deponent can not make it out.

Five reasons are given for keeping bees, the first being that bees "work for nothing and board themselves, only requiring a house to live in," with no hint that they require any care or labor on the part of the bee-keeper. The third reason for keeping bees, "Because honey is the only product on the farm which will not only spoil if not hurried to market." Must be that writer thinks grain is raised only in elevators!

Horseradish for Bee-Stings is spoken of in high terms in several of the foreign bee-journals. Bruise the leaves and apply the juice to the wound. It is even said that if the hands be well rubbed with horseradish juice it will prevent their being stung.

The National Bee-Keepers' Association is the organized body of bee-keepers that now stands to defend bee-keepers and bee-keeping against adulteration and wrongs of other kinds; the amalgamation of the two old societies being now an accomplished fact. The present Association is stronger by 63 names than either of the old ones was, and its future is bright with promise; there being now no divided interest, it becomes every bee-keeper to throw in his influence and his dollar. Whether you are a member or not you will undoubtedly be benefited by the work of the Association, but the benefit will be vastly greater if each bee-keeper joins. Send your annual membership fee (\$1.00) to the Bee Journal office, if more convenient, or to General Manager Eugene Secor, Forest City, Iowa.

Early Orders for Bee-Supplies usually receive the most prompt attention by the dealer. Many bee-keepers wait until the last minute, then order by return freight, and if they don't get the goods at once, feel greatly disappointed. Now, one who stops a minute to think, would see that no dealer can fill every order the same day it is received.

The best way is to order early, so as to avoid any possible rush later on that might cause vexation and loss to the bee-keeper.

In many instances, of course, one cannot know exactly what will be needed very far in advance of the season; in such case we would suggest that at least some of the goods be ordered early, and, if it is found that more are needed, then order again.

Many bee-keepers will also find that if they have their supplies on hand early, they can put in some time at odd hours in getting them all ready for use, so that when the time comes to use them they won't have to stop other important work to get things in shape.

Suppressing Hives.—In one of the bee-papers a query appears about a certain hive which has not been pushed to the front as have some others. It is insinuated that certain other hives were pressed upon the bee-keeping public to the exclusion of the one in question. Now, that was really too bad, wasn't it? Just to think that any one would try to get every bee-keeper to use a certain kind of hive in preference to a certain other kind!

One might as well ask why any one of the numberless dead bee-papers weren't pushed on to success by those already established. We are not of the kind that expect that our bee-paper competitors are going to work very hard to make the American Bee Journal a success. That is what we are here for. Neither should any one expect that every manufacturer is going to turn in and push some other hive than his own. The manufacturers are not in business simply for their health, any more than bee-keepers produce honey just for fun.

The *Western Bee-Keeper* was the name of a new bee-paper started in the West a year or so ago. We learn that it has recently turned its subscription list (?) over to the *Progressive Bee-Keeper*. We did not announce its advent, as we failed to see wherein it had sufficient merit. It certainly was no credit to the printer's art, and we failed to see where it could be of much advantage to anybody—not even to its publisher. This latter opinion has now been verified, by its giving up the effort.

There is generally an amusing feature connected with the starting of new bee-papers. They usually want to exchange advertising space with the old and established papers, instead of paying cash for it as do others. Of course, the *Western Bee-Keeper* followed that rule, and when the application was received here, we simply quoted regular advertising rates, and that was the last heard from that quarter. They had practically nothing to give in return on an exchange basis, and certainly could not afford to pay cash for advertising a new paper of so little merit.

While it really is none of our affair, we can't help feeling sorry for the poor, misguided people who think there is money to be made in publishing new bee-papers. In about forty-nine cases out of fifty they have proven to be a delusion and a snare. But we presume we shall see new bee-papers in the future as in the past—with about the usual result.

Reformed Spelling seems to stir up some people to a paroxysm of foaming and frothing that is fairly amusing. A friend sends a clipping from the *Daily Telegraph* of Philadelphia for Feb. 5, and among the pet names applied to the reform are, "craze—delusion—ridiculous—deformed—absurdity—silly impertinences." The *Telegraph* says: "Some journals which otherwise are beyond reproach are found to be so injured by it as to have their usefulness seriously impaired." Doubtless the usefulness of the *American Bee Journal* is so seriously impaired by an occasional word changed in its spelling that its readers will not be able to secure as much honey as they otherwise would!! The way to be certain to succeed with bees is to take a paper that puts *ugh* on *lho*, and *uc* on *catalog*. The flowers will yield nectar then!

The Weekly Budget

MR. O. O. POPPLETON, writing us from Dade Co., Fla., Feb. 13, said:

"This has been a very hard winter on bees in Florida, so far as I can hear. One of my apiaries is doing first-class, one very good, and two very poorly."

MR. A. H. COWAN, eldest son of Editor Thos. Wm. Cowan, of the *British Bee Journal*, was married Jan. 9. Mr. Cowan has a fruit-farm in Placer Co., Calif., where he lives. The *American Bee Journal* wishes the happy couple a long and blissful life.

PROF. A. J. COOK, of Los Angeles Co., Calif., under date of Feb. 14, wrote as follows:

"The outlook for the season in Southern California is not at all encouraging to the bee-keeper, or even to the general farmer. While we have had almost as much rain as we had during the entire season of a year ago, we yet need a great deal more for a successful year. Northern California has had fine rains. The southern part of the State is in sore need of many and copious showers which must come within two or three months. Usually there are huge banks of snow on the tops of the mountains, while now there are

almost none. We are all hopeful that we shall yet have the rains so much needed to bring the usual success to this end of the State."

THE WISCONSIN CONVENTION PHOTOGRAPH, taken by W. Z. Hutchinson, is ready for delivery to all who desire it. It is 8x10 inches in size, mounted on a 10x12 heavy cardboard, and will be sent postpaid for 75 cents. It is one of the best and clearest convention pictures we ever saw. If you wish a copy of it, send the above amount to W. Z. Hutchinson, Flint, Mich.

THE ELKHART CARRIAGE AND HARNESS MFG. CO., of Elkhart, Ind., have issued one of the best catalogs for 1900 that have come to our desk. It contains 144 pages and cover. Practically every page is illustrated, showing their excellent vehicles and harness. This is their 27th year. Better send your name and address for their catalog, not forgetting to say you saw their advertisement in the *American Bee Journal*.

DR. E. GALLUP, of Orange Co., Calif., we notice by a markt newspaper item received last week, has just lost his wife and infant child. The death of the mother was a peculiarly sad one, tho no possible means were neglected to avert the sad ending, three skilled physicians being in attendance. Our sympathy, as well as that of bee-keepers everywhere, will go out to Dr. Gallup in his deep sorrow.

MR. JOHN F. CROWDER, of Fresno Co., Calif., says the *Tulare Advance*, is perhaps the most extensive bee-keeper in Central California. He has about 3,000 colonies of bees in all. These he has divided into apiaries of about 300 each. His 10 apiaries are located usually about three or four miles apart, and are within a radius of from 10 to 15 miles of his home. Mr. Crowder started about six years ago with 25 colonies. By careful work and much study he has been able to build up what is perhaps the largest bee-business controlled by one man in the United States. He employs quite a number of men in his apiaries, and keeps them up in just the right shape. He produces principally extracted-honey.

HON. EUGENE SECOR is the president of the Winnebago Co., Iowa, Farmers' Institute. He has mailed us a copy of the program of their fourth annual meeting, which was held Feb. 13 and 14. On the last page of that program we find the following, which is well worth your reading and heeding, tho it is not exactly on bee-keeping:

"Agriculture is the oldest employment of man, but it does not follow that there is nothing to be learned in farming. It is not one of the exact sciences, for climate and other ever-varying conditions require varying methods and practices. What is best in one locality may not be in another. The annual rainfall, extremes in heat and cold, distance from market, kind of soil, etc.—all have an influence in determining what our farming practices should be if we would obtain the best results. There are many problems of agriculture not yet solved. If we are satisfied with ourselves, and believe that the practices of our forefathers can not be improved upon—that there are no better ways, no better implements, no better crops than they knew, then there is no reason to read, study or watch what our wide-awake neighbors are doing. But if we think there is room for improvement in our county we ought to use every means to that end. The highest farming requires as much brains and study as any other calling. The farmer should not regard his work as beneath that of any other station on earth. And he should pursue it so intelligently and skillfully as to command the respect due to him. He should be a student. He should avail himself of every help. The county institute was created by law to increase your interest and efficiency in agriculture. Whatever does that should also increase your wealth and happiness. Attend the Farmers' Institute. It is planned for your benefit."

After all, what is good advice for the farmer is pretty good for the bee-keeper also.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song,

QUESTIONS AND ANSWERS.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Buying Bees or Rearing Them.

Which would be the cheaper to stock an apiary, buy the bees or buy sugar and rear them? I have been reading bee-papers and books a year, and have an idea I could rear them cheaper, but I would like to know what you think.

TENNESSEE.

ANSWER.—You can probably buy sugar and rear bees for less than you can buy them, altho of course that depends upon what you have to pay for the bees; but a still cheaper way would be to rear the bees on natural stores without buying sugar.

Uneasy About Bees in the Cellar.

Please give me some advice in regard to my bees that are in the cellar. This is the first that I ever wintered them in the cellar, and I don't know whether they are doing well or not. My cellar is under the dwelling-house, and is in clay soil, and I think is rather damp. I have to build a fire in it in cold weather to keep the temperature up to 45 degrees, and I have kept the dead bees swept up clean. The bees seem to be doing very well with the exception of one colony which has dysentery, but not very bad. I have 50 colonies in the cellar and eight on the summer stands.

INDIANA.

ANSWER.—From what you say, you are probably managing all right. See that the air of the cellar is kept pure, opening the door or window any night that is warm enough. It is not long now till bees in Indiana can be put on the summer stands, and a flight will cure the diarrhea promptly.

Honey Taffy—Clover for Lawns.

1. How can I make honey taffy or candy? I tried several times to make honey taffy, and every time it gets dark and tastes as if it was burned, but it can't be burned as I am very careful that it doesn't boil fast.

2. I sowed grass seed on my lawn and most of it turned out to be weeds. I was told then by a friend bee-keeper that if I would sow clover seed on the lawn it would kill all the weeds and make a fine lawn. I want to know whether this is true, and what kind of clover seed would be the best.

NEW JERSEY.

ANSWERS.—1. If you will pardon the statement, the probable truth is that you did burn it after all. Honey is very easily burned, and doesn't need to boil very fast to be burned. The whole secret is to cook it very slowly. Don't put it on too hot a place on the stove.

2. It's asking a good deal of clover to kill out weeds. Still, it may do so, especially if the weeds are mowed down occasionally as short as the clover. White clover is the best clover for a lawn.

Bees Killing Off Each Other—Shavings to Absorb Moisture.

1. My bees have been fighting for the last week or ten days. They have killed off a good many. There will be a bunch of bees in two or three places on the alighting-board, and as soon as they kill one they jump on another. They have plenty of honey. My neighbor's bees are doing the same thing, and when the weather is so bad they can't fly, they are fighting just the same at the entrance.

2. My hives are on the summer stands in winter, and in spring, when I open them, I find them very damp inside. Would it do to fill a super with dry pine shavings, and put it on to take up moisture?

OREGON.

ANSWERS.—1. With no further information, it is hard to tell what is the trouble. It may be a few robbers are trying to obtain unearned treasures, and are taking their punishment therefor, and if the number is not great it doesn't signify. It may be that bee-paralysis is present, and the well bees are getting rid of the sick ones. If the persecuted bees are robbers, they are very alert, trying to escape, and generally succeeding in escaping, from their tormentors. If the worried bees are sick, they appear sluggish, making little attempt to escape, perhaps swollen, shiny, with a

trembling motion. As far north as Oregon paralysis ought hardly to be a very serious matter. In either case, if the colonies are strong, you will probably find matters mended as soon as good weather for flying comes.

2. Yes, planer shavings are the kind to use, as ordinary bench shavings made by a carpenter with a hand plane do not pack close. Some practice putting hot bricks on top to dry out when a warm day comes, and opening up a little at such a time helps to dry out.

Unslackt Lime for Dampness.

I have about 50 colonies of bees in the cellar under the house and it is rather wet. Would it do any harm, or injure the bees, if I put chloride of lime in the cellar?

WISCONSIN.

ANSWER.—Common unslackt lime will cost less and will be better.

Swarming and Producing Comb Honey—Italianizing.

1. I have two colonies of Italian bees, and I wish to run them for comb honey, and still get one or two swarms from each. I also have three colonies of blacks in box-hives, and I wish to put them in movable-frame hives, and let them swarm. How many times should I let them swarm in order to get the best results. My desire is to run for comb honey exclusively.

2. Would you Italianize the blacks, or let them be till in the fall?

CALIFORNIA.

ANSWERS.—1. Certainly don't let them swarm more than once if you can help it. Put the swarm on the old stand with the mother colony close beside it, moving the mother colony to a new stand a week later. Perhaps you will do as well to leave the blacks in the box-hives till they swarm; then treat them as mentioned.

2. It will probably be as well to wait till near the close of the harvest.

Fence Separators—Cause of Bees Perishing.

1. Are fence separators intended to be used with plain sections only, or will they do with any style of section?

2. I am wintering my bees outside, packed with sawdust and chaff cushions on top, and I notice that the bees in one or two of my colonies persist in flying out, and of course perish in the snow, while the rest are quiet. What is the probable cause, as they have all first-class stores?

ONTARIO.

ANSWERS.—1. Fence separators may be used with any kind of sections, but separators suitable for the plain sections will not do for sections with insets. For the latter, fence separators must be differently constructed.

2. Hard to tell. The difference may be in the bees themselves. Some bees seem more uneasy than others under like circumstances. It is possible the sun shines more freely into some hives than into others. It is not a bad plan to put a board in front of the entrance at a time when bees fly out to their detriment.

Italianizing—Distinguishing Queens.

1. I have 18 colonies of bees, partly Italians and partly blacks. Would it be possible for me to kill the old black queens when they swarm and put in a laying Italian queen instead, when I have them, with any degree of certainty? Or, would it be better to take the nucleus that the Italian queen was reared in, and give the swarm with it?

2. And what would be the best to introduce in the parent hive (the hive the swarm issued from), a laying queen, a virgin queen, or a ripe queen-cell, after cutting all the cells out of the hive and being sure there are no virgin queens present in the hive?

3. Is there any way of telling a three-banded queen from a five-banded one, before they have any bees hatched from their eggs, supposing, of course, they are purely mated? I don't think there is, but my opinion doesn't amount to much.

ILLINOIS.

ANSWERS.—1. It would be safer to let the swarm run in with the nucleus, of course first killing the old queen.

2. It would be largely a matter of your own convenience, either one being all right.

3. Your opinion is all right in this case, at any rate.

“The Hum of the Bees in the Apple-Tree Bloom” is the name of the new bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a “hummer.” We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

MAN-WEIGHT TOOLS

FOR FARM AND GARDEN.

Your weight does the work. One of the greatest labor-saving inventions of the age. The easiest running tool ever made. Drag bars are hinged so that hose work in and out close to plants.

NO AFTER-HOING REQUIRED.

All sorts of man-weight garden tools, plows, harrows, hoes, drills, cultivators, or all combined, at astonishing low prices. Send for illustrated Catalogue and throw away you back-breaking hoes.

GENERAL ITEMS

Bee-Keeping in Oklahoma.

I am trying to interest people here in bees and honey, but I find conditions, climatic and otherwise, somewhat against me. I have had bees here five years, and I know they will do well if handled properly. They require to be fed and strengthened up very early in order to store any surplus. Bees must be in condition to store honey here, by May 1. One colony last season stored 48 finish sections, while no others completed a super full. I find bees will empty unfinished sections if they are scraped with a knife.

Bees are now in good shape; and have flown every week this winter. I hope for a good season this year. F. VAN DE MARK, Payne Co., Okla. Ter.

Fears a Dread Bee-Disease.

I notice on page 100 an article by Abel Gresh, stating that he has amongst his bees a disease which seems to be similar to the New York bee-disease. I was quite alarmed to note this fact and desire to investigate the matter thoroly if I can possibly do so.

I have noticed a peculiar odor about my bees ever since they were placed in the cellar, and did not know what to attribute it to, and in fact do not yet know whether it is a real or an imaginary odor. Will some of the readers of the "Old Reliable" please inform us as to its peculiarities?

Do bees affected with this disease give off a different odor when placed in the cellar? Is cellar-wintering favorable to its spread?

Come, let's rouse up and find out what this disease amounts to, and to what extent it has already spread. I fear that it has gone to far greater proportions than any one thinks.

I would like to be prepared to fight this disease when it first makes its appearance, if it comes here, and so would a host of other bee-keepers in New York and Pennsylvania.

I am getting somewhat alarmed over the matter, and do I not have good reason for it? Most certainly. Are not my future prospects at stake? If the disease should ravage my bees would it not deprive me of my only source of income? Are these not good reasons for being alarmed? I think I have good reasons for sounding a note of warning.

There has never, since I have kept bees here, been any disease to bother me, and I fairly tremble at the thought of having to encounter this new malady. There is but one way out of it, and that is to stay at my post and be prepared to defend myself against its ravages. G. F. TUBBS.

McKean Co., Pa., Feb. 15.

Hunting Wild Bees.

I want to add my experience in hunting wild bees, to that of Massachusetts as given on page 86. I hunted bees a good deal in my younger days, having found many a bee-tree, and have caught bees from the wild flowers late in the summer and in early autumn, and set them at work from the stand. I have smudged or burned honey-comb after the frosts had killed all the flowers; have lined them and cross-lined them; have moved them several times where they went long distances; have moved them beyond the tree, and of course have watcht them; I never had any trouble about their coming back; only these two things I have noticed:

In the first place, it takes longer when you go beyond the tree to get them started, than it does while tracing the line: in the second place, my observation has been, after leaving the stand on which the bait

\$100 to the Winners

until to-morrow night or, better still, call the attention of the members of your family who have a taste for puzzles, to it. Some of you can hardly fail to get it. It is purely a test of quick-witted observation without any element of chance. There is only one answer that can be obtained by properly finishing the letters and supplying the space to make words of the letters. We give below two lines of incomplete letter puzzles. By solving one of them you earn a prize, and by solving both correctly you come in on the \$100 prize to the winners.

Other Prizes

To any contestant sending a correct answer to one of these puzzles, we will send their choice of a year's subscription to "The Gentlewoman," or "American Fruit and Vegetable Journal," or "American Poultry Advocate," or your choice of any one of the following books: "The New Hygiene," a book on up-to-date treatment to maintain health without medicine; the works in one volume of Charlotte M. Braeme; or the "Duchess"; or Miss Muloch's; or Sylvanus Cobb, Jr., or Miss Braddon's; or Wilkie Collins; or Mary Cecil Hay. When sending in your answers name the prize you wish, should only one puzzle be answered correctly. The first puzzle is

This puzzle consists of a line of 13 incomplete letters, which if complete would spell three words. Only the lower two-fifths of each letter appears, the other three-fifths have been cut off. What are these three words? They are all taken from this very advertisement. The words are not separated from each other, but the letters follow in correct order, all they need being the space. There is no transposition or trick of any kind. Taking one letter right after the other from the first to the thirteenth they spell three words. EACH WORD IN BOTH PUZZLES APPEARS SOMEWHERE IN THIS ADVERTISEMENT. There is no chance about it. If there were two correct answers to either one of these puzzles, the Farm, Field and Fireside would be refused the mail for running a lottery.

T A I L I E S I T A S I L

I I A I I A N T I L L

In order to get all the words in this advertisement as promised we are compelled to tell the following little story: "Some animal was injuring our trees on the hill, so we placed a poisoned paste in a tart, which the animal ate, and I hate to say what the pest proved to be. Can you guess? We found that the poison had made it very ill, and we took it by the tail and drowned it in the pond."

The object of the puzzle is in part to secure a large number of new trial subscribers to the Farm, Field and Fireside, the greatest agricultural weekly in the west. Do you know of any farmer who might be interested in a good farm paper? We want him on our list for a short time, and as the contest is inaugurated for the purpose of introducing our paper into new homes we make the following the

Conditions:

To be eligible to receive a prize every contestant must send with his or her answer the name of a person not now a subscriber, with 25 cents to pay us for sending the paper to him on trial for three months. Remember, if you get one line right you earn a prize, and it both are right you are in on the first prize. THIS CONTEST WILL CLOSE MARCH 31. ADDRESS PUZZLE DEPARTMENT FARM, FIELD AND FIRESIDE, 710 MASONIC TEMPLE, CHICAGO.

These wintery evenings you have some time to spare, so here is a puzzle you can solve. If you have not the leisure to-night, put it aside for some other time. The words of your family who have a taste for puzzles, to it. Some of you can hardly fail to get it. It is purely a test of quick-witted observation without any element of chance. There is only one answer that can be obtained by properly finishing the letters and supplying the space to make words of the letters. We give below two lines of incomplete letter puzzles. By solving one of them you earn a prize, and by solving both correctly you come in on the \$100 prize to the winners.

The second puzzle consists of 13 incomplete letters, forming four words, the letters following consecutively as in the first:

rests, as they rise to go to the tree they begin to circle and rise higher and higher, and as they ascend the circle enlarges, and if one is very observing he will notice that each time the circle is made there will be a pull or a bend in a certain direction. Experience and observation has taught me that is the direction in which you may expect to look for the tree, and will find, when they settle down to business, that will be the way or direction they will go.

It is difficult, sometimes, to get bees to come back to the bait, if there is an abundance of bloom. My opinion is you cannot rely on a bee's steadiness in going and coming in the midst of flower-bloom. There is a fickleness about their movements that indicate this on their return to bait. I have seen them come direct from the bloom to the bait, and vice versa. I never had any trouble about bees coming back to the baits after going beyond them; they are generally a little slower about getting to work. Clark Co., Wis. L. ALLEN.

Wintering Very Well.

Bees are wintering very well here. My 80 colonies in the cellar are wintering better than I ever knew them to do before—no dead bees to amount to much. They have good honey. Macon Co., Ill., Feb. 16. FRANK BAKER.

Expects a Fine Year for Bees.

We are having fine weather here now. The bees have been flying for a week or more, rearing some brood and bringing in loads of pollen. I think we are sure to have a fine year in this locality. H. HEWITT. San Joaquin Co., Calif., Feb. 3.

Cold Hard on Clover.

Bees are wintering well so far; but the continued cold, hard, freezing weather, with no snow to protect the clover-roots, is anything but cheering to the man who looks to his bees for his principal means of support. Let us be hopeful. J. W. WILCOX. Jo Daviess Co., Ill., Feb. 16.

Sweet Clover—Candied Honey, Etc.

We have been sowing sweet clover here on the farm in a small way for several years, and a year ago last summer we cut about a half acre of the same mixt with red clover, and put in the bottom of the mow where most of it had been until this winter, when we finish feeding it out. The horse did not seem to like it very well, but to know just what cattle would do with it I

took some sweet clover hay out in cow yard, where there were three head, and threw the hay down to the cattle. Two head ate the hay just the same as if it had been red clover, while one cow I had bought in October would not even taste it or try to eat it.

Sweet clover mown down and fed to cattle when about two feet tall, grown on good soil, was eaten readily last summer here at our place.

Now a pointer to anyone short of pasture: Teach cattle to eat sweet clover, then go on the highway or elsewhere and cut a lot of it, load on the wagon, and drive into a pasture field and scatter it rather thinly over the ground, and let the cattle help themselves.

Two or three years ago we began putting up our honey in raised-cover tin pails, and let most of it candy, then put it on the market to be mostly sold on commission, and what was sold for cash was sold with the understanding that if the groceryman could not dispose of it for a fair profit I was to take it out of the store and return the cash, which I did.

But since Dadant's sell all their honey when granulated, I was determined our ripe, rich honey should go the same way, and the consequence is we now have a good trade built up on honey in the granulated form. Outside of what we put up in one-pound bottles, it is not liquefied to satisfy any one's whims.

Last fall we put up 600 pounds of honey in common quart fruit-cans, with a large, suitable label, which for cheapness are just the thing, for they sell well.

Fourteen years ago in the spring we began bee-keeping in a small way (according to the books), and to this date we have taken off 16,303 pounds of honey, about 2/3 being extracted, and find, by keeping a careful record, we have taken off an average of 27 pounds per colony for the 14 years. We have a poor locality for bees, haven't we? **C. A. BUNCH.**

Marshall Co., Ind.

Bees Wintering Well.

My 125 colonies of bees in the cellar are keeping the best I ever had them. There is not a gallon of dead bees on the floor.

A. L. KILDOW.

Bureau Co., Ill., Feb. 19.

Report for the Season of 1899.

Last summer was a hard one for me. I had a hard spell of sickness so the bees had things a good deal their own way. They come out of winter quarters in good condition, losing 5 out of 111; I sold 26 and doubled down to 73. There was great loss of bees here, a number of bee-keepers losing all. One man 3 miles from my place lost all he had—100 colonies. Mine did fairly well last season, as I got 2,000 pounds of comb honey and 500 pounds of extracted. The fall flow of honey was the best we have had for years. I increased from 73 to 125 colonies, sold some, and doubled down to 93, all in good condition, with plenty of stores for winter. **JOHN TURNBULL.**

Houston Co., Minn., Feb. 15.

Extractors, Large and Small.

EDITOR YORK:—On page 114 is a picture of D. H. Coggsball's apiary with that extractor looking very familiar, for I think I had a hand in making that machine. On the same page "Old Grimes" gives some points on extractors as positive facts, which do not accord with my philosophy or experience. Isn't it the centrifugal force that throws out the honey? And isn't that force proportioned according to the square of the diameter? A comb 4 inches from the center spindle will feel only one-fourth as much centrifugal energy as a comb 8 inches from the center spindle.

I admit it is easier to make one revolution with a two-frame toy machine, but deny that it is easier to make 6 revolutions with it to do the same work that Morton's favorite 8-frame extractor would do in

much less time. With large machines it is the inertia to be overcome in starting and stopping that takes muscle. Starting is usually done by a push on the basket-reel with the left hand, anyway, and the brake does the stopping with ease; and I have found it necessary to slow down when using the big extractor, to avoid injury to combs after getting used to rapid turning with a smaller one.

"It isn't the distance travelled, but 'tis the pace that kills"—holds true in extractors.

Tompkins Co., N. Y.

Extracting-House on Wheels.

Can any reader of the American Bee Journal furnish information as to how best to build an extracting-house on wheels, so it can be easily transported and operated from place to place, very near to the hives, with two horses? If so, let him kindly arise and explain. I want to build one.

La Salle Co., Ill. A. MOTTAZ.

Building Up Weak Colonies.

Many colonies of bees are lost during April and May that might have been profitable to their owners if judicious care had been given them. During my first years of bee-keeping I used to let them go it alone, live or die, and they generally came out the latter way.

My practice with weak colonies during my last years of bee-keeping was to give them young bees from strong colonies as soon as they were hatched. The bees should be shaken into a dish in order to return the queen if she should happen to be shaken off with the bees. When running them into the colony use a little smoke.

A few bees from five or six strong colonies will build up a weak one and enable them to care for a frame of brood. If there are not enough strong colonies to spare the necessary amount of bees at one time, wait a few days and repeat the operation before giving them brood.

J. H. ANDRE.

YOUR MONEY'S WORTH.

No. 209—Farm Harness. Complete sets for \$8 to \$10 more than our price. Price, \$21.50

You have a right to expect that, because you are entitled to it. To meet this condition is our aim and has been so for all the 27 years we have been in this business. To do this we sell all goods direct from our factory to the consumer at wholesale prices. The advantages of this plan are many and obvious. This plan has built us up until we are now the largest manufacturers in the world selling vehicles and harness to consumer exclusively. We make 173 styles of vehicles and 65 styles of harness. The buyer takes no risk on our plan as we ship our goods anywhere for examination and guaranteed safe arrival. Send at once for a copy of our large illustrated catalogue—FREE.

Elkhart Carriage & Harness Manfg. Co., Elkhart, Indiana.

AMERICAN BEE JOURNAL, 118 Mich. St., Chicago, Ill.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.10, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO., 118 Mich. St., Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

Convention Notices.

Utah.—The Utah State Bee-Keepers' Association will hold its semi-annual convention in the City and County Building, Salt Lake City, Apr. 6, 1900, at 10 o'clock a.m. A full program in the interest of the industry will be presented, and all our bee-keepers can help themselves by aiding the Association, and in order to create a closer bond of union among our bee-keepers. As a further incentive to the success of the bee-industry, it is very desirable to have our bee-keepers from all parts attend the spring convention.

THE WAR IN SOUTH AFRICA

has demonstrated the great foresight of the Boers, in availing themselves of all the opportunities in times of peace to prepare for war. Similar foresight should lead you to improve the opportunity of securing better farms than theirs in this country. They are on line of the Chicago, Milwaukee & St. Paul railway in Marinette county, Wisconsin, where the crops are of the best, work plenty, fine markets, excellent climate, pure, soft water; land sold cheap and on long time. Why rent a farm when you can buy one for less than you pay for rent? Address C. E. ROLLINS, Land Agent, 161 La Salle St., Chicago, Ill.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Feb. 19.—A little trade in honey in a peddling way by the case, no demand for lots, neither has there been for the past 3 months. Comb honey of the choice grade is selling at steady prices, and there is not too much of it; off grades are slow. Extracted is steady with no change in prices. Beeswax sells at 2c cents if yellow and clean. R. A. BURNETT & Co.

CINCINNATI, Dec. 27.—There is a good demand for all kinds of extracted honey. White clover and basswood sell at 8@8½c; amber and Southern, 6@7c, according to quality and package. Fancy comb honey in no-drip shipping-cases sells at 15@16c; darker grades hard to sell at any price. Beeswax, 26c. C. H. W. WEBER, Successor to Chas. F. Muth & Son and A. Muth

LOS ANGELES, Feb. 15.—1-pound frames, 12½@15c; 2-pound cans, 2 dozen in case, per dozen, \$2.50; 2-pound glass pails, per dozen, \$2.50. Extracted, water white, 60-pound tins, per pound, 8½c; light amber, 7½@8c; dark amber, 7½c. Beeswax, 25@26c.

Stocks of honey in all parts of the United States are lower than they have been for 10 years. It is most desirable that rain should come as prices are likely to be high.

KANSAS CITY, Feb. 12.—We quote fancy white comb, 14@15c; No. 1, 13½@14c; No. 2, 12½@13c; fancy amber, 13@14c; No. 1, 12½@13c; No. 2, 12@12½c. Extracted, white, 7½@8c; amber, 7@7½c; dark, 6@6½c. Beeswax, 22@25c. C. C. CLEMONS & Co.

BUFFALO, Jan. 5.—Market bare of fancy white one-pound comb honey, and selling at 15@16c; fair to good, 12@14c; buckwheat, dark, poor, etc., 8@10c. Fancy pure beeswax, 28@30c. BATTERSON & Co.

NEW YORK, Feb. 8.—During the past 30 days our market has been somewhat slow and easy in both comb and extracted honey. Stocks of comb honey, however, are almost exhausted, and there is a fair demand for all grades. Fancy white selling at 15c; No. 1 white at 13@14c; fancy amber, 11@12c, and buckwheat at 9@11c, according to quality, etc.

Our market is well supplied with extracted, the prices are firm and unchanged. Beeswax sells very well at from 26@28c, according to quality. HILDRETH & SEGELKEN.

SAN FRANCISCO, Feb. 14.—White comb, 11½@12½c; amber, 8@10c. Extracted, white, 7½@8c. light amber, 7@7½c; amber, 5@5½c; Beeswax, 26@27c.

Beyond the filling of small orders by jobbers, there is practically nothing doing in honey. Offerings are light, and are mainly comb. Quotations are unchanged, but at present represent little more than jobbing rates. A shipment of beeswax was made the past week of 3,200 pounds by steamer to Germany. Stocks are small and prices steady.

BOSTON, Jan. 12.—We quote as follows: Fancy white, 16c; A No. 1, 15c; No. 1, 13@14c; buckwheat will not sell in this city. Extracted, light amber, @8c. Demand is very light. BLAKE, SCOTT & LEE.

ALBANY, Jan. 10.—We quote: Fancy white comb, 15c; No. 1 white, 13@14c; mixt, 11@13c; buckwheat, 10@11c. Extracted, white, 8@9c; mixt, 6½@7c; dark, 6. Beeswax, 26@28c. MACDOUGAL & Co.

Successors to Chas. McCulloch & Co.

OMAHA, Feb. 13.—Demand shows some improvement in January, having been much more active, but as anticipated there is no advance in prices. Market remains steady at 14@14½c for fancy white comb and 8½c for white extracted. The latter is pretty well cleaned up along the Missouri River, and it looks as if there would be some shortage before another crop comes in. From present appearances there is about enough comb honey to go around at the present prices, hence we look for no particular change in values. PEYCKE BROS.

DETROIT, Feb. 10.—Fancy white comb, 15@16c; No. 1, white, 13@14c; fancy amber, 11@12c; dark and undesirable lots, 8@10c. Extracted, white, 7@7½c; amber and dark, 5@6c. Beeswax, 25@26c. Supply of honey fair with light demand. M. H. HUNT & SON.

CONTRIBUTED ARTICLES

Bee-Keeping in Almost a Perpetual Summerland

BY W. O. VICTOR.

WELL might I say that this is a land of perpetual summer, if I am to judge from present indications, for to-day, (Jan. 5), I have near my window a peach-tree almost in full bloom, and a little further on I see the water-elm and cottonwood looking as if to-morrow I might hear the busy hum of the bees among their branches. In the apiary I see a box-elder with beautiful green foliage and large bunches of fresh-looking white flowers.

There has not been a week this winter that the bees have not gathered more or less pollen; this, however, I do not consider an advantage in every respect, as it causes brood-rearing at a season when the bees should be quiet. Altho ice has been almost an unknown thing with us this winter, we sometimes have sudden changes, with low temperature, which confines the bees to the hives for several weeks at a time; and we lose heavily by their not being in a condition for this long confinement.

At this time my bees have considerable brood, and should the weather continue pleasant I will soon have hives overflowing with bees, and, I might say, consuming tons of honey, when they should be just beginning to rear brood for the spring harvest. However, I do not expect a continuance of springlike weather, tho we may expect enough of it to carry the elm and cottonwood to full bloom in February.

Speaking of perpetual summer brings to my mind Mr. C. Theilmann, of Minnesota, whom we all know to be worthy of a warm place in our hearts, and a remark he made at a meeting of the South Texas Bee-Keepers' Association, Dec. 27, 1894, when the temperature dropt from summer to

a few degrees above zero, mention of which he has made. He said he had read a great deal of the perpetual summer of the Sunny South, and he had come down to see if he could not see some of the other side of the question, and thought he had come at just the right time!

As I do not want to go on record as saying we have perpetual summer in the "Beautiful Sunny South," I will see if I cannot show a genuine winter scene.

I send you a photograph of the "River Ranch" (as the boys call it) four miles below town, on the bank of the Colorado river. The snow shown in the picture began falling Feb. 13, 1895, and continued thru the 14th, the average depth being 18 inches. The photograph was taken Feb. 16, when the snow had melted to a considerable extent. The "stump" in the foreground, with "moss" on each side toward the top, is your humble servant. "Tom" and "Rose" in the background have seen many years with the bees; on this occasion they drew a rudely constructed sled, carrying the photographer and myself.

A Snowbound Out-Apiary in Texas.

On the 17th I went down with a load of lumber to build a honey-house. I had been using a tent previous to this. On arriving at the apiary I discovered that depredations that had been going on all winter had been repeated. I followed the tracks to the hive that had been robbed; by it in the snow I could see the print of a bucket. Having secured his booty, the thief took himself off in an opposite direction from which he came. I determined to make good the opportunity the snow afforded, and followed the tracks; they soon bore to the left and came around to the side whence they came, following the same trail

for quite a while, and, to my great surprise, I came to two sets of tracks. I luckily decided to follow the right hand set first; they soon circled back, and the thief for a short time doubled on his tracks, evidently to throw me off, should I happen to visit the apiary before the snow was gone. I continued my search, and ere long the trail brought me to a Mexican woodchoppers' camp.

The following morning I returned with an officer and necessary papers, and we found in their tent the bucket of honey with comb foundation (fishbone) in it, said to have come from a tree.

We took five Mexicans to jail, and after detaining them

some 30 days, they were tried, and released, as I could not prove which one went to the hive on this particular day; but the detention had the desired effect, however, and I have had but little trouble along this line since, save when Mr. Bruin struck me pretty heavy on several occasions.

By Feb. 25 the snow was all gone, and we had genuine spring weather. Wharton Co., Tex.

Temperature of Cellars in Wintering Bees.

BY C. P. DADANT.

SOME time ago an article from me was published in the American Bee Journal, in which I mentioned the proper temperature, in my estimation, for the safe wintering of bees in cellars, and placed it at 40 to 45 degrees. I also stated that I had, years ago, met a bee-keeper who held that bees could be wintered successfully at a temperature as high as 90 degrees, but that I had ascertained at the time that he was only guessing at the temperature, and did not use a thermometer.

This article of mine was reproduced in the Bee-Keepers' Review for November, and at the same time an article was published from Ira Barber, of New York, who says that he has done this very thing, and that he did use a thermometer. I quote a passage from his article:

"The highest temperature that was found when a thermometer was used was 90 degrees, and all the colonies were clustered on the outside of the hives, but not in one mass all together. In the seven winters that I had bees in this particular cellar, tests were made two or three times each winter until the last winter, when I did not go there until March. Then I was sent for to see what ailed the bees. Upon going there I found the bees, 225 colonies, ALL IN A SOLID MASS ON THE HIVES, there was no part of a hive to be seen, yet all the bees were as quiet as tho clustered upon the outside of their hives on a damp, muggy morning in August."

Mr. Barber goes on to report that these bees wintered with the loss of only one queen, and in the best condition of any lot that he ever wintered. He ascribes the success to the damp condition of the cellar. I do not wish to find fault with this statement, altho I can not help thinking that in an Illinois cellar it would have been very difficult for the bees, which were clustered in one mass, to find their respective hives again. Neither would I want to leave bees from the beginning of the season until March without making an occasional examination of the conditions in which they were placed.

But what I wish to do here is to warn the inexperienced apiarist against experimenting with high temperatures in the cellar. Aside from the fact that it would be very difficult to obtain such a temperature—which is almost to the point of blood heat, and higher than that of any summer night in our latitude—the statement that the bees in such temperature have to lie outside of their hives shows clearly that these were uncomfortable, which any one would surely expect. When bees are uncomfortable and clustering in this way, they will seize any opportunity that offers to change their condition, and the least ray of light, the least jar, is bound to be noticed by them, and to cause them to fly about. The exceptional instance mentioned above serves only to emphasize the need of a low and equal temperature which will keep them as quiet and as closely confined as possible with the least expenditure of food, and this is to be found without a doubt at the degree mentioned in my previous article. This has been tested over and over in different cellars, by different apiarists.

A test may easily be made by any one who winters bees in a cellar, and will settle this matter to the satisfaction of the person himself. Let each cellar be provided with a thermometer, then examine your instrument often, at each time taking note of whether the bees are quiet or noisy. If the temperature is right they will make such low hum that nothing will be perceptible above a faint murmur in a cellar containing even a hundred colonies. If it is too low or too high the hum will be more perceptible. At too high a temperature they will become restless, they will slowly emerge from the hive-entrance, and will cluster on the front board. They are then ready to take flight at the least disturbance by light or jar.

It is very difficult to write on a subject requiring as much exactness and accuracy as bee-culture and its details without meeting some one who is ready to contradict one's assertions. But we must console ourselves with the thought that not bee-culture alone is open to contradictory views, and that he who would teach what he thinks he knows well must be ready not only to discuss his views and his reasons, but must be prepared for an occasional open contradiction.

In another article I spoke of the common error of fruit-growers who think they know that bees can and do injure sound grapes, and incidentally I remarked that there were many who thought that cheat could grow from wheat. No one has seen fit to oppose me on the first proposition, probably because they have felt that I was too sure of my subject; but I have had half a dozen encounters with well-informed farmers who positively know that wheat does turn to cheat under certain circumstances. Gentlemen, I peremptorily decline to furnish proofs of my own on *this subject*, and will respectfully retire behind Gray's Botany, our best text-book, in which wheat is described as "*Triticum vulgare*," while cheat is listed as "*Bromus secalinus*," two entirely different tribes of the graminæ, and which cannot even mix in their bloom and form a mongrel, as between the melon and the cucumber. If some one positively knows better, and can adduce proofs, it is time that our text-books were corrected to agree with the facts. But superficial observations will not do either in botany or in bee-culture.

Hancock Co., Ill.

"The Best Hive for Northern Illinois."

BY EDWIN BEVINS.

I NOTICE on page 5 that at the Chicago Bee-Keepers' Convention a paper was read by W. C. Lyman, on "The Best Hive for Northern Illinois." Mr. Lyman said some good things on the subject, but not all that might have been said, and I feel like protesting against the removal of the viands before the appetites of the guests are half satisfied.

He says that the hive for Northern Illinois should have a brood-chamber large enough to contain honey to carry the bees thru the winter and spring without having to feed, and thinks one of 10-Langstroth-frame capacity will fill the bill, but would like a hive of that capacity taking only 8 frames.

I have proven by long experience that for safe wintering of bees vertical expansion of the brood-chamber is better than lateral, and I agree with Mr. Lyman that the supers of an 8-frame Langstroth hive are large enough for best results in comb honey production when the hives are deep or deeper than the Langstroth are used. When wider and shallower brood-chambers are used a wider super to correspond may give as good results—I do not know, having never tried them.

While Mr. Lyman thinks he would like these deep 8-frame hives for wintering bees, he at the same time seems to think he would not like them to have swarms in when working for white comb honey. The swarms that issue from these deep hives he would have in brood-chambers of about half the depth of those from which they issued. This practice, it seems to me, would be attended with a good many difficulties and no adequate compensating advantages.

My experience with the deep 8-frame hives has not been so unsatisfactory in comb-honey results as to lead me to the use of a shallower hive for swarms while using the deeper hives for colonies.

Anybody who has read what I have written in the American Bee Journal knows that I have no great reverence for the standard, but adherence to the standard would be preferable to the use of hives of different depths in the same apiary, unless the hives of similar length and depth were worked as a small apiary by themselves. If I thought it imperative to have shallow brood-chambers to have swarms in, I would use the sectional brood-chamber hive—using one section until the end of the white honey harvest, and then putting on another section for extracted honey or winter stores. In fact, I am using some with brood-chambers $7\frac{3}{4}$ inches deep, that take supers of the 8-frame Langstroth hive. With queen-excluders these do reasonably well, but somehow I have a preference for brood-chambers that are not divisible. The hives in sections are just as good for wintering bees as the deep 8 and 10 frame hives, and it may probably be conceded that somewhat more white comb honey can be secured from bees working in brood-chambers having as much again capacity. But, as to general results, I am compelled to say with Dr. Miller, "I don't know."

There may be seasons in which there will not be much honey gathered after the white honey harvest, and then one might wish that some, or all, of the white honey surplus was in the brood-chamber, and that the brood-chamber was a little large. To be sure, one could resort to feeding, but feeding is something Mr. Lyman would avoid.

I think that Mr. Doolittle reported at one time unfavorably on the use of sectional brood-chamber hives, but that report may have been due to "locality." There is one thing to be said in favor of the sectional hive—an apiary can be requeened by its use very cheaply, if properly managed.

Of one thing I am tolerably well convinced, and that is, that the wintering of bees without the necessity of feeding, and the securing of a large amount of surplus, are things which can not be with any certainty combined. The time may come when these results may be approximated, but it will be after more attention has been given to the rearing of our queens.

I will remark here that there is one other advantage in the use of the sectional brood-chamber hive besides the one above mentioned. Full sheets of foundation in the brood-frames may safely be dispensed with.

If I lived in Northern Illinois, and were keeping bees with a view to comb-honey production, and wish to reduce the labor and expense of feeding to insignificant proportions, I would use the deep 8-frame hives, fill the frames full of wired foundation, and be content with the amount of surplus that Providence and the bees permitted me to have. It is unsafe to hive swarms, or to build up nuclei, in the deep hives or frames having only starters of foundation. The man who tries many different sizes of hives will sooner or later find that the departures from the standard should not be made without mature consideration.

Decatur Co., Iowa.

Bees Stinging Farm Stock—What to Do.

BY PROF. A. J. COOK.

THE readers of the bee-papers will remember Mr. Clark, of San Bernardino Co., Calif., who has had for a good many years a large and very profitable apiary. Mrs. Clark has full charge of the bees, and in certain seasons has done all the work of this large apiary, and has secured very large yields and corresponding profits. I had the pleasure of spending the night with Mr. and Mrs. Clark not long since, and learned of an occurrence which was very interesting to me, and I think will be to most of the readers of the American Bee Journal.

Mr. Clark has a spring situated some distance to the west of his apiary in the canyon. He had a fine Jersey cow which he used to picket out to feed. The forage was especially good between the apiary and this spring. Mr. Clark observed that the bees were flying toward the spring for water in great numbers, yet the good feed tempted him to picket the cow on this line, as the apiary was some distance from the place, and he apprehended little or no danger. Yet the fact that there were so many bees did raise a question in his mind, but not knowing that cattle were unlike horses, he picketed the cow slightly, so she could get away in case of an attack.

At night, when Mrs. Clark went to get the cow, she was cold in death, and a great many bees were dead around her.

There are several facts in this account that I think are of special interest, and should be noted by all bee-keepers. The first, that the instincts of the cow when she is stung will not lead her to run away as would be the case with the horse, and she stands by until stung to death. Mrs. Clark told me the cow was very close to where she was picketed. She had pulled the stake up so she could have run away if she had been so disposed.

Again, the fact that the attack was so general that most of the colonies in the apiary were very much depleted in numbers.

Every apiarist has observed that when one bee stings, others, maddened by the odor of the poison, join in the attack. But I should not have expected that all the bees of the apiary would thus become so demoralized as seems to have been the case in this experience of Mr. Clark's. I do not think I should have hesitated to have picketed the cow at this place, but I can see now that it would be dangerous. I should have expected the cow to have run away, and should not have looked for such a general attack. The fact that the bees were going *en masse* to and from the spring would, of course, tend to make any attack a general one, and that seems to have been the case at the Clark's. The loss was heavy, for not only was the cow killed, but the apiary was seriously injured by the loss of a great number of bees.

This is the first time that I have ever known of a cow being attacked in this way. I have known several cases of

horses. Some years ago Dr. Southard, of Michigan, had an accident of this kind. His team ran away and went dashing into the apiary, which was situated in a grove. Of course, the horses struck the trees and were thrown down, and as the bee-hives were turned bottom side up the horses were terribly attacked. Dr. Southard, being an experienced bee-keeper and also a physician, knew just what to do. He at once liberated the team and led them to the barn, and covered them with blankets which were kept wet with cold water. Altho the horses were terribly stung both of them recovered.

Here, then, we have another point that is worth remembering. Of course, the inflammation and congestion consequent upon so many stings would be terrible, and anything that would lessen it should be done. The blankets constantly wet in cold water would be one of the best agents to accomplish this. If Mr. Clark had discovered his cow at the beginning of the attack, and had led her into an enclosure, the bees of course would have at once left and would have ceased the attack. If this had been followed by the use of the wet blankets very likely the cow's life could have been saved, even tho she might, at the time, have received thousands of stings.

I was once stung quite seriously myself. Over 80 stings were taken from my face, but by taking means as above to counteract the congestion, I suffered no serious harm, tho I hardly need say I was not exactly comfortable for two or three days. Los Angeles Co., Calif.

CONVENTION PROCEEDINGS

Report of the Colorado State Convention.

[Continued from page 135.]

ANALYSIS OF HONEY.

Dr. Headden, professor of chemistry at the State Agricultural College at Fort Collins, then gave a lecture on the analysis of honey, illustrated by performing actual experiments with chemicals, together with an explanation of the polariscope illustrated by one he had with him. It was found impossible to report this lecture, owing partly to the technical nature of the subject, which required complete instead of fragmentary notes to be taken, and partly owing to the constant reference to objects such as solutions, test-tubes, etc., used in the experiments. It was, however, to those who were present to see and hear, a complete and lucid explanation of the theory and practice of both the chemical and dialytical methods of analysis, illustrated by the performance of the actual chemical process, except that the quantities of the ingredients were not measured, as they would be in an analysis. Specimens of dextrose and levulose, the two sugars of honey, were exhibited.

Among other things, Dr. Headden said that the presence of not more than 10 percent of cane-sugar did not show adulteration, and that he had analyzed sugar syrup fed to bees, and found it wholly inverted.

[The following digest of Dr. Headden's lecture appeared in Gleanings in Bee-Culture for Feb. 15:—EDITOR.]

Whatever sugars may be present in the nectar of flowers matters not in answering the question as to what sugars may be present in honey; for it has been proven by direct experiment that the bee, in imbibing and disgorging the sugar, will invert as good as all of it, even tho it be a pure cane-sugar syrup which is fed. Honey is essentially the solution of invert sugar, composed of approximately equal parts of dextrose, levulose and water. The name applied to such a mixture of sugar when it has been derived by action of a hydrolitic agent upon cane sugar is "invert" sugar, and when occurring as a natural sugar it is called fruit sugar. Usually there is but little cane sugar present in honey, especially in that deposited by the ordinary honey-bee.

Honey candies upon standing, because of the ability of the dextrose to assume a crystalline form much more readily than the levulose; therefore, if the candied honey be subjected to sufficient pressure the greater portion of the levu-

lose can be obtained, containing only a comparatively small portion of dextrose; or a more convenient method is to place a portion of the candied honey on a sieve floated on a weak alcohol containing about 20 percent of water, whereupon the levulose will readily pass into solution in the alcohol, leaving a mass of crystals upon the sieve, which are crystals of dextrose.

If we take some of these crystals, dissolve them in water, and examine the solution by the aid of an instrument called a polariscope; we shall find that it turns the plane of polarization to the right. If we take the alcoholic solution and examine it by the aid of the same instrument, observing proper precautions, we shall find that this solution turns the plane strongly to the left. This is the reason that we have designated the sugars as right-handed sugar and left-handed sugar.

While the left-handed sugar, or levulose, can be obtained crystallized, it is with much more difficulty than in the case of the dextrose. If into a solution of dextrose there be introduced some crystals of this sugar the crystallization can be facilitated very materially; and in our climate, where evaporation takes place rapidly, it is possible that we can bring about the candying of extracted honey by adding to it a small portion of already candied honey or crystalline dextrose.

W. P. HEADDEN.

Mr. Root—Is there the same amount of dextrose in all honey?

Dr. Headden—Yes.

Mr. Root—What becomes of the levulose when the honey is candied solid, since it is only the dextrose that candies?

Dr. Headden—It can be taken out if the honey is prest, or placed in a centrifugal machine.

Pres. Aikin—What is the reason why one lot should candy and another not?

Dr. Headden—We are completely in the dark as to the cause of granulation.

Mr. Root—What is the process of candying—crystallization?

Dr. Headden—In ripe honey it is altogether crystallization, and is a purely automatic process. Some crystallizable solutions are strongly affected by stirring, but I doubt whether honey is. It is too viscid.

J. U. Harris—I understand that Section 8, of the clause of the horticultural law that relates to spraying fruit-trees in bloom, has been repealed. I move a committee be appointed to investigate.

Carried, and Messrs. Harris, Whipple and Brock were appointed as the committee.

Prof. C. P. Gillette, professor of entomology of the State Agricultural College at Fort Collins, then read a paper on the principles necessary to the understanding of foul brood, explaining germ diseases, and showing that it is one of them. He had with him a large microscope with a slide on which some stained foul brood bacilli were clearly visible, magnified 1,000 diameters. His paper is as follows:

Foul Brood—Germ Diseases.

Foul brood has long been known as a true contagious disease. Such diseases do their most destructive work when they attack individuals that are crowded together in densely populated communities. The fact that the honey-bee lives in such communities, and the further fact that both the bees and their products are shipt freely from place to place, have made this a very serious and widespread malady. If it once enters an apiary, and nothing is done to eradicate it, it is almost certain that it will, in time, destroy every colony in its immediate neighborhood. Colorado's pure air and abundant sunshine seem to offer no impediment to the rapid development and spread of this disease, which is widely disseminated in the State. It is important, therefore, that all who keep bees should know the cause of this disease, its symptoms, its methods of dissemination, and also the preventives and remedies that may be used to lessen its destructive work. I presume most of you are better acquainted with the symptoms and remedies of foul brood than with its real cause and methods of dissemination, so I have chosen to dwell principally upon these latter topics.

The researches of the past 35 years, and chiefly of the past 15 years, have shown that most, if not all, contagious diseases are the result of the attack of microscopic parasites upon some part of the diseased plant or animal.

Every one understands how it is that parasites, such as ticks, lice, and mites that produce itch, scab and mange, are conveyed from one host to another, and also how it is that the particular complaint accompanying each of these

parasites could not occur in the absence of the particular parasite. Cholera, small-pox, diphtheria, and typhoid fever are also parasitic infections, but the organisms producing these diseases are so small that they can not be seen by the unaided eye.

On account of the minuteness of these organisms, requiring the aid of a compound microscope to enable man to see them, there are many people who think that the "bacilli" and "microbes" of which the scientist speaks exist only in his own fertile imagination.

What are these minute organisms? How do they increase in numbers? What do they look like under the microscope? and how do we know that they are the cause of contagious diseases? These are questions that I shall attempt in some degree to answer.

In the first place, it is conceded that these organisms belong to the vegetable kingdom in spite of the fact that they are able to move freely about in the moist media that they inhabit. They are closely related to such vegetable growths as rusts, smuts, mildews and molds, with which all are more or less familiar.

Altho micro-organisms are the cause of nearly all contagious diseases of plants and animals, these organisms are not all detrimental to man's welfare. Some are of the utmost importance. Without them there would be no decomposition of dead animal or vegetable matter, and the soil would lose its fertility. There would be no fermentation, no souring of vinegar or milk, no ripening of cream or cheese.

These organisms vary greatly in shape. Some are merely oval bodies, being nearly as broad as long; others are cylindrical or rod-shaped; of the latter, some are very short and others are long compared with their diameters. Others are variously curved, some taking the form of a spiral. All have the power of movement, and when seen alive under the microscope they are usually moving very rapidly about, often in countless thousands.

The germs of foul brood have been named *Bacillus alvei*. They are very large compared with most bacilli, and are in the shape of short rods of varying lengths. The longer ones have about the proportions of the half of an ordinary lead-pencil. Altho these germs are very large it would require 5,400 of them placed end to end to reach one inch. Of the spores formed from the rods it would require 12,000 to span one inch. Some micro-organisms are so small that it would require more than 50,000 to span one inch when placed end to end. Perhaps it would be more intelligible to say that 1,800,000 of these spores could rest side by side on the head of a common pin. This will, at least, made it evident that there would be no use to look for these organisms with the naked eye, or with any of the hand magnifiers. Nothing but a powerful compound microscope can reveal them to the human eye.

In 1850, Davaine, of France, discovered great numbers of minute rod-like organisms in the blood of animals dying of splenic fever, or anthrax. He considered these objects as one of the symptoms accompanying the disease, but did not think of such a thing as their being the cause.

A few years later Pasteur, also of France, began a series of experiments to determine the cause of fermentation of beer and wine. He succeeded in proving beyond question that the real cause was the presence and growth of micro-organisms, and that without these organisms no fermentation could be produced. These announcements of Pasteur in 1863 led Davaine to suspect that the rods that he found in the blood of animals having splenic fever might be the cause of that disease. To test the matter he inoculated healthy animals with blood of diseased animals containing the germs, and found that he could produce the disease with great certainty. So it was about 37 years ago that it was first proven that micro-organisms might be the cause of a contagious disease.

When Davaine's announcement was made there were very few, even among scientists, who would believe it. In consequence of this the experiments were carried thru again with the utmost care by Dr. Koch, of Germany, in 1876, and by Pasteur, of France, in 1877. The results were so conclusive in proving that the bacilli were the real cause of the disease, that Davaine's theory was generally accepted.

In the meantime, in 1865, Pasteur announced the results of his investigation of a terrible silkworm disease known as *Pebrine*, which threatened to destroy the silk industry of France, showing that this disease was also caused by a specific microbe.

These discoveries struck the key-note to the real cause of all similar diseases, whether in man, the lower animals, or in plants. It is one of the epoch-making discoveries of

modern times. I will tell you briefly the process by which it is proven that a special microbe is the cause of a particular disease.

In the first place, it must be determined that the organism does not occur in the tissues of the healthy animal. Secondly, the microbes must always be found in the tissues of the animal having the particular disease in question. Thirdly, the organism must be taken from the tissues of a diseased animal, separated from the other organisms and grown thru several generations. Then the organisms from the last culture must be inoculated into the tissues of a healthy animal, and cause the particular disease. Lastly, the tissues of this diseased animal must be found to contain the characteristic germ with which the experiment started. Such proof must certainly be conclusive. It is in this way that Cheshire proved foul brood to be caused by the organism that he named *Bacillus alvei*.

Now let us consider how these organisms can increase so rapidly as they must to cause the death of a large animal in a few days after they attack it, which is not an uncommon thing.

A single spore or rod of *Bacillus alvei* is sufficient to start foul brood in a colony if it is eaten by a larval bee, and a few weeks later the germs will be present in countless millions, and nearly all the brood will be diseased or dead. Cheshire estimated that a single bee-larvæ might contain a thousand millions of these germs. An illustration or two may help us to understand the enormity of this number. If each of the thousand million germs could be represented by a block an inch on a side, these blocks would be sufficient to build a wall an inch thick, 10 feet high, and more than 130 miles long. Again, if each of these microbes was a foot long, and they were all placed end to end, they would reach more than seven times around the earth.

The method of increase in these organisms is by division. One of the rods attains a certain length, and then divides into two rods. The two soon attain adult size and divide, forming four. These four and all succeeding ones grow and divide in like manner, which gives an increase in geometrical ratio. A few minutes' figuring will prove to you that, if one of these germs and its progeny divide every four hours, they will amount to a billion in less than five days. So, altho the number is enormous, the manner of increase makes it possible to attain such numbers in a little time.

Appreciating to some extent the extreme minuteness of these organisms, and remembering that they are hundreds of times smaller than the smallest mote that we can see floating in a sunbeam, we are prepared to understand how they can float about with great readiness in currents of air. Micro-organisms are always about us, in the food we eat, the water we drink, and the air we breathe, but they are more abundant about cities and thickly populated communities than in more thinly populated places. Water exposed to the air always contains them. Experiments by Miquel, of France, showed that rainwater contains 64,000 germs to the quart. Most of these germs are perfectly harmless; but when pathogenic (disease-producing) germs do occur in any place, it is easy to understand how readily they may be carried about upon one's hands or clothing, in milk or water, in letters thru the mails, by insects such as flies and mosquitoes, and in similar ways.

There is a difference of opinion as to how the foul-brood germs are introduced into the bees. The popular belief is that they are taken into the alimentary canal along with the honey that the larval bee eats. This being the case, there should be large numbers of the germs in the alimentary canal in the early stages of the disease. Cheshire says that the germ almost never makes its attack in the alimentary canal. He thinks the germs come in contact with the surface of the body, begin to develop there, and then penetrate to the interior.

Foul brood was so named because of the offensive odor which usually accompanies it, and the supposition that it attacks the larval bee only; but Cheshire found that mature bees often succumb to the disease. He also states that queens of badly diseased colonies frequently have the disease, and that the eggs laid by them contain bacilli. Pasteur, in 1865, found that the eggs of the diseased female silkworm moths always contained germs of the silkworm disease, and that worms hatching from these eggs always died prematurely. If queen-bees can become diseased, it seems probable, then, that the eggs they lay would contain germs of the disease which would develop and destroy the future larvæ.

While there can be little doubt that the foul-brood germs are usually communicated to the young bees in

honey given them as food, it may also be carried from colony to colony upon the hands, upon knives used to trim burr-combs, or upon boards or cloths or sections, or other furniture used in the hive of an infested colony. If a diseased colony becomes weak, it may be robbed by other colonies, all of which would probably contract the disease.

The symptoms of foul brood are quite characteristic. The larvæ lose their pearly whiteness, gradually changing to a coffee color, finally turning black, and drying down to a mere scale at the bottom of the cell. The coffee-colored mass that the larva changes to is entirely shapeless, showing none of the structure of the grub; and if a sliver or pin be used to remove it from the cell it will stretch out for some little distance, and then snap back. If the larva is nearly grown before the disease attacks it, it may cap its cell, and then, after it dies, the capping usually sinks, and often has a hole at the center. When mature bees are attacked they weaken and die, but retain their form.

You are familiar with the methods of treating this disease as given in the State law, in bee-journals, and by county inspectors, so I shall not take time to treat this phase of the subject, except to warn all, especially beginners, against any attempts to cure the disease. You will do better to bury or burn the entire colony as soon as found to be diseased.

C. P. GILLETTE.

Mr. Whipple—I have noticed some pickled brood, dead brood with a watery substance around it.

Mr. Root—A great many samples of dead brood have been sent to us. Those from New York were not pickled brood which retains its shape, while this other kind does not, and is of the same color as foul brood. It is not cured by the starvation plan.

Mr. Bates—I found two colonies affected with dead brood. It was dry, and had none of that watery appearance. I sprayed with brine and carbolic acid, and closed the hives. That was the end of it. I took three supers of honey from one, and two from the other.

Mr. Harris—The bee-inspector in Mesa County found a great deal of brood dead, in some cases one-half. It was not pickled brood.

Mr. Thompson—In Montrose County some of us noticed a good deal of dead brood thru the summer, in cells scattered everywhere among the healthy cells. It was of a brown color, but neither foul brood nor pickled brood. In Utah I heard of a good deal of what is there called pickled brood, but I think not correctly.

The report of the legislative committee was then heard.

Mr. Harris—Your committee waited on the assistant of the attorney-general. He said an attempt was made to repeal the spraying clause, and in his opinion there was a question whether the clause had not been repealed.

Prof. Gillette—Near Fort Collins last June there was a case of prosecution under that law, and the fine was paid. Hence the law was in force.

(The report of the committee was received and the committee continued.)

Mr. Milleson—There need be no fears about any law being amended or repealed if due diligence is exercised by the committee. There is no member of the Horticultural Board, with one exception, but is in sympathy with us. The opinion is almost unanimous all over Arapahoe County that bee-keepers should be protected.

Mr. Harris—I refer to the Repealing Act of 1899, page 299. The horticulturists in Mesa County say the law is repealed, and they will spray all they please.

Pres. Aikin—We were assured last year there was no repeal.

Prof. Gillette—I know that Mr. Harris is correct in his assertion that prominent Mesa County horticulturists are against the law. There is no need of spraying in bloom, and I have always told horticulturists so. I wish to know whether the bee-keepers would like experiments performed to ascertain the degree of heat necessary to destroy foul brood.

J. B. Adams—I would like the Professor to take up the killing temperature of foul brood. Some think boiling a short time is enough, and others that it should be boiled a long time.

Mr. Whipple—I have found that when the honey is diluted half and half with water, and brought to a sharp boil, it is safe.

H. Rauchfuss—I would like the Professor to take up the question of queens carrying the disease.

Mr. Whipple—I introduced a queen from a diseased colony to a healthy one without infecting it.

Mr. Porter—Is the odor of foul brood injurious?

Prof. Gillette—The odor is caused by the gas set free by the chemical action of the germs. The germs are the cause, and the disease the effect.

J. B. Adams—I move that we request Prof. Gillette to take up foul brood experiments, and that we help him all we can. [Carried.]

[Continued next week.]

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Richards, Ohio.

THE MESQUITE AND ITS HONEY.

Mesquite honey far the best of its locality (southwest Texas), and at least sometimes the only surplus in a very bad season. So says very competent authority—L. Stachelhausen. We can mentally "stick a pin there;" and if we had pins enough we'd know something about the different honeys of this great country of ours. All our Northern trees grow mainly above ground, with only a minor fraction of the plant under ground. Mesquite reverses this, and grows mainly under ground. This is probably the reason why it stands the terrible drouths of its locality so well. Page 50.

SMOKER MAY BE TOO LARGE—BURNING SLUMGUM.

Probably Bro. Grimes is right, that a smoker may be too large. And when we begin to feel as tho we needed an extra man to carry it we've got to Tubig station ourselves. I incline to put in a mild protest against burning slumgum in a smoker. Robbers will get after you worse. The ability to do some work at morn and eve, and the apiary at large not find out what's going on, is precious. If we use a smoke directly calculated to put mischief in their minds, we will have to wait longer at night, and stop sooner in the morning—at least I'll say so till some brother says he's tried it out and out, and the slumgum doesn't make a "dit o' bifference." Page 50.

FEEDING SWARMS IN ROBBING-TIMES.

Mr. A. F. Foote should learn that a swarm in robbing-times should not have honey given them till evening. But don't omit to give it then, else the danger of their taking "French leave" of you one or two days later is much increased. Brethren have got "locality" nicely rubbed into them, and now we must rub in "the diurnal conditions." Half of us are still somewhat oblivious on this—don't realize that a swarm in famine times *must* have honey, while a swarm in times of plenty doesn't care a fig for it. A swarm won't stay and starve on the roost—who can blame them? Page 51.

BUMBLE-BEE HONEY.

Dr. Miller's remarks, page 54, suggest quite an interesting problem which I have often pondered over. Is bumble-bee honey *really* better than ordinary honey (as it seems to be), or is its special deliciousness wholly owing to the stimulated relish with which it is usually eaten, and the smallness of the quantity which we are limited to? I once plundered an unusual nest which gave me honey, not all I wanted, but somewhere in that direction, and I failed to notice that the last sip was less delicious than the first. I guess bumble-bee honey is *some* better—gathered from a different set of flowers as a general thing. Also the bumble-bee (like the native Brazilian bees) adds a flavor of its own to the honey. Probably the hive-bee does something in that line likewise, but not in nearly so great a degree. If *Bombus* had a hundred pounds to flavor up, his elixir would run out, too, I reckon.

CAUSE OF SOME HONEY FERMENTING.

The Doctor does not fully meet Chucklehead's conundrum on the same page. A *small patch* of honey sometimes bursts off its cappings and runs out, leaving the rest sound in the same section. Bees gathered a small amount of extra-poor honey just because they couldn't bear to be idle, I think. Don't believe there is any remedy—except to keep

such lazy bees as will not work except when the conditions are perfectly "apple-pie."

DRIVER IMPORTANT IN HAULING BEES.

Rambler is right, that an important "appliance" in moving bees is the driver. We don't want him to think the foundations of the world are breaking up, and take to the tall timber, just because he has got two or three stings, and a few dozen bees are loose; so the non-bee-keeping driver is mostly ruled out. Page 56.

AN UNDERGROUND HIVE-ENTRANCE.

I hope Mr. G. E. Dudley's "underground" entrance will prove an excellent thing, and eventually be added to all hives where entrance traps are used. Apparently little danger of a queen's ever getting out; but perhaps a little wider trial is needed, especially to assure us that drones would never find the way. Page 59.

A PRETTY, SPREAD-OUT APIARY.

And now comes Mr. Lehman with a pretty apiary in the widest kind of wide spacing—6x16 feet. Apparently he clips his queens and make them crawl back into the hive themselves, when they have found that the "bull pen" surrounding their domicile can not be surmounted, however much they may want to abandon it. Comparatively few of our craft would favor taking so much pains to wall in individual hives—but "many men of many minds." His hives-stands and shade-boards are admirable ones. Page 65.

THE RICH VS. THE "WORKS" AS TO HONEY-BUYING.

The complicated conditions of modern life make success something like walking a tight rope. We want every element well in hand. R. C. Aikin, page 66, forcibly sets out one of the elements. The honey custom of a working man's family may be made worth more than the custom of many rich families. So many delicacies are to be had, and the rich want to buy a little of each, that so it comes about that their purchases of honey aggregate but very little. But they would buy the same little at high prices; and with high prices the workman's family wouldn't buy any.

THE ANTI CLIPPERS ON TOP FOR ONCE.

On the question of clipping queens I was pleased to see that in the Michigan convention the anti-clippers for once seemed to have the upper hand. Don't enjoy seeing my sort of fellows playing the role of "under dog" all the time. Mr. Calvert is doubtless right that clipping, and so compelling swarms to return, works more satisfactorily in small apiaries than in large ones. Page 67.

FOUL BROOD CONVEYED IN THE CELLAR.

That was an important and rather gruesome fact contributed by Mr. Rankin, page 68, that a foul-broody colony infected five of its neighbors while in the cellar. I should hardly have expected this.

MEASURING BEE-TONGUES.

With due respect to Mr. Rankin (page 74) I nevertheless venture to hint that perhaps there is "something rotten" about his measurements of bees' tongues. The difference looks too great—especially as the samples for measurement seem to have been taken in an extempore sort of way. We may use his figures as ratios merely, and say as 4.5 is to 5.1 and 6.2; and if we accept them at face value, he already has bees with tongues nearly 38 percent longer than those of average German bees.

WINTERING AND VENTILATION.

Yes, plenty of air and a big stack of strong colonies, say 80 to 120, would very likely make an aboveground wintering-house succeed by the sheer power of internal heat. The trouble is that these winter-house fellows mostly all get cleaned out by a cold winter before they reach the 80 strong colonies. And the idea which Dr. Miller contributes—that internal warmth *makes* ventilation—is a very valuable one. Page 75.

PERHAPS A SORT OF CRISSCROSS.

If queens frequently meet more than one drone the same day there must then be frequent cases when one of the drones was an Italian and the other not. And "what would the harvest be?" In good sooth it would be a state of mixedness which we would a little rather not contemplate. Yet we mustn't shut our eyes to assured facts, if Prof. Hodge, or anybody else, can bring them. Page 75.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Questions on the Dickel Theory.

An esteemed correspondent sends some questions about the Dickel theory which, if answered in full, would lead to a discussion of the same. It is very doubtful that it would be wise to take up room in this department for such purpose, and I have intentionally refrained from taking up such room by saying anything either for or against the Dickel theory. Page upon page has been occupied with it in the German bee-journals, and to go over all the same ground here would not be well, since we can afford to wait and see how our able friends in the Fatherland will settle the question, thus allowing the room in our journals to be occupied with other things. Whether the theory be right or wrong, so far as I can see, will make no practical difference whatever in our management of bees.

It may possibly be objected by some that the American Bee Journal is unfair in allowing only one side, for an article in favor of the theory has been published on the other side. That may not be observing strict neutrality, but it is better to err on the side of too much rather than too little politeness to a stranger.

C. C. MILLER.

Moving Bees from Nebraska to Indiana.

I will have 40 or 50 colonies of bees to move in 1901, from Saunders Co., Nebr., to Starke Co., Ind. What is the best method of doing it? How should they be packed for shipment? When is the best season of the year for moving them? NEBRASKA.

ANSWER.—It will be better to move them early in the season when the temperature is somewhere from 35 to 60 degrees. How they shall be packed depends upon the kind of hives, and whether one hive is to be piled on another. The points to be looked after are to see that no bee can possibly get out of a hive, to have the frames run parallel with the railroad track, the frames so fastened they can not move in the hive, and especially to have plenty of ventilation. If your hives are so constructed as to have an entrance of 20 square inches or more, covering the entrance with wire-cloth will give all the ventilation necessary, unless the thermometer is up to 70 degrees or more. Still better ventilation can be given by making a frame or box without bottom or top to fit on the top of the hive, with wire-cloth nailed over it. But this will not do if something is to be piled on top. In such a case the cover should be so constructed that openings at the sides and ends of the cover shall be covered with wire-cloth. Make sure that the hives are in some way fastened in the car so they cannot move about, and especially that there is no chance of a hive tumbling down.

Getting Bees to Fertilize Red Clover.

We commenced growing red clover last year in considerable quantity, saving the second crop for seed. The season was propitious, and a fine second growth came on, but on threshing there was but about half the amount of seed looked for. A foreigner working on the place claimed there were not sufficient bumble-bees in the country to pollinize the flowers properly. Will you kindly give your views as follows?

1. Would the lack of bees account for scarcity of seed?
2. If so, can the bees be imported, and how must they be started?
3. Where can they be obtained, and where should they be turned loose? Any information you may be able to give, or cite me to, will be greatly appreciated. OREGON.

ANSWERS.—1. Yes, the lack of bumble-bees is sufficient to account for the lack of bees. Bumble-bees do not, like hive-bees, start with a full colony in the spring. A single bee begins the nest, so that when red clover is in bloom the first time, bumble-bees are very scarce, and no one ever counts on saving seed till the second crop. Probably the only reason that the second crop is so much better for seed than the first is that by the time of the second crop the number of bumble-bees has increased many fold.

2 and 3. I don't know where to refer you as to the desired information. From some experience I had when a boy with a colony of bumble-bees that I captured and tried to domesticate, I should advise as follows:

In the first place, determine whether there are no bumble-bees

in your region. It is possible that altho they may not be in sufficient numbers there are yet a few nests in the neighborhood, and, if so, they will probably increase without further importation. If there are none present, by all means get at least one colony. Get some friend in a region where clover seed is raised, or in any region where bumble-bees are plenty (in all the older States they are plenty) to send you by mail or express a colony of the bees, nest and all, as found by the boys in the meadow. Something like a cigar-box will hold them, with holes for air. Along in June will be a convenient time, probably. Put the nest in a sheltered place, perhaps in the side of a barn or other out-building, with a hole thru the wall for the free passage of the bees, and pack some old cloths about the nest. An advertisement in this paper would probably bring plenty of responses from those who would send you the bees, possibly some one close by.

Propolis on Unfinished Section-Combs.

1. Last fall I took off some sections that were half or two-thirds drawn, which I thought would be quite a help for the coming season. Now, in making up my supers, I find these sections have a slight rim of propolis on the cells, which in my hurry last fall I did not notice. Is this what is called "travel-stained"? They look as if the bees had put it there purposely.

2. If I use these sections will the bees clean them all right for honey, or will it be better to make a cake of wax of them and have all new?

I had some fine honey last year and do not care to spoil my reputation by giving my customers bee-glue to chew. The combs look very nice, with the exception of this extra finish the bees gave them. Of course, there is some bee-glue on the sections, but when I sell my honey I am not particular to scrape them free of this. If left on, people know it is genuine honey that they buy, and they do not complain. MASS.

ANSWERS.—1. That's probably a little more propolis than would usually be called travel-stain, altho it lies somewhat in the same line. The bees undoubtedly put it there purposely, because you left the sections on after honey stopped coming in, and as they didn't know what else to do with them they thought you wanted bee-glue on them. Next time, take the sections off when the honey-flow stops, even if you have to put them back again afterward.

2. No, don't think of using these sections as they are, nor with the least bit of honey in them. The bees will not remove a particle of the glue. Better melt them up, or, still better, remove the propolis with a Taylor Handy comb-leveler.

Methods of Introducing Queens.

Having seen in your paper two plans for introducing queens (pages 433, 547 and 644, 1899) and having tried the one with the wire cage stuck into the comb, with indifferent success, and considering the other very cumbersome, I have planned and made a cage as described below, which I think is an improvement on any other I have seen, tho I have not given it a practical test as yet:

Take a frame and rip it carefully in half lengthwise; cut away from the top of the inside edge of each end-bar, enough to allow for the spacing projections on the frame; tack a narrow strip of separator to the outside of all the half end-bars, then, with short pieces of separator nailed to the end-bars, connect the two half-frames at such a distance apart as will allow a frame to slip down between them. Now tack a piece of wire-cloth, as wide as the frames are long, from the top on one side around to the top on the other. Two cuts about an inch long and an inch apart, can be made from the top of the wire on one side, so as to make a door by which to introduce the queen. You have then a cage, which, when the frame is split in, is quite bee-tight. When you wish to use it, take a frame of brood with some honey, that has bees just emerging, place it in the cage, then open the little wire door and allow the queen to run in on the comb, close the door with a couple of tacks in the top-bar, place the cage in the hive, and after 48 hours, or longer if thought necessary, the door may be opened, or the frame removed from the cage and placed in the hive. BRITISH COLUMBIA.

ANSWER.—If it were ever safe to say a thing is all right before it has actually been put to the test with the bees, I should say unhesitatingly that your plan is all right, and enough better than the wire-cloth cage plan to pay for all the extra trouble. I had already planned to try something in the same line, only my frames have top-bar, end-bar and bottom-bar all the same width, so instead of having a cage in which to slip a frame, I can tack a wire-cloth cover on each side of the frame. Of course you will have no unsealed brood in the comb used, and the more mature the sealed brood is, the better.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY,
118 Michigan Street, Chicago, Ill.

[Entered at the Post-Office at Chicago as Second-Class Mail-Matter.]

EDITOR:

GEORGE W. YORK.

DEPARTMENT EDITORS:

DR. C. C. MILLER, "Questions and Answers." * * E. E. HASTY, "The Afterthought."

LEADING CONTRIBUTORS:

G. M. DOOLITTLE, C. P. DADANT, PROF. A. J. COOK,
F. A. SNELL, R. C. AIKIN, "OLD GRIMES."

IMPORTANT NOTICES:

The Subscription Price of this journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec00" on your label shows that it is paid to the end of December, 1900.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

VOL. 40. MARCH 8, 1900. NO. 10.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

Gathering Grapes When Bees are on the Bunches.

—The Critic of the Bee-Keepers' Review refers to Mr. Hasty (American Bee Journal, page 711), "gently apologizing for the grape-man," and thinks there is danger of granting too much as to the trouble of bees in vineyards. Away from home bees do not volunteer to sting, and Mr. Hasty is granting too much when he speaks of the man in the vineyard with "one eye closed, and hands swollen too stiff for service." Mr. Taylor says:

"I, at least, am glad of the help of the bees in gathering up the juices so that it may not aid in hastening the bursting of the sound grapes adjacent, and only regret that they can not gather it more quickly."

Isn't that a new theory, that moisture on the outside of a grape will hasten its bursting? If confirmed it will certainly not be objected to by bee-keepers.

Newspaper Rot About Bees and Honey.—Why is it that books and papers reliable in other respects will be so utterly unreliable in matters pertaining to bees? It is doubtful that there is a better, brighter, cleaner, and more reliable daily paper in the world than the Chicago Record, and yet its issue for Feb. 17 shows that it has been imposed upon to the extent of a column and a half of stuff whose chief distinction is its improbability. It is headed "Cave

of Wild Honey," and a few extracts will show that it is much after the usual manner of yarns about big caves filled with honey:

"Bees work the year round"—"they never have to stop working on account of lack of material or bad weather"—"tons of it; in clefts in the rocks; in hollow trees, in caves, and in the famous 'Devil's Punch Bowl,' " "out of which bees swarm always in clouds so thick that at a distance of two or three miles it has the appearance of a great signal smoke."

How's that? These best honey-districts, it is said, are about 125 miles from Del Rio, Texas, and when the honey is strained and brought on burros to Del Rio it brings 15 cents a pound! A man could make a lot of money by buying up extracted honey in Chicago and shipping it to Del Rio.

Sticking Labels on Tin.—The Australian Bee-Bulletin says that for sticking labels on tin, flour and water well blended and boiled, with perhaps a little alum to preserve it, is as good as any.

Improving Our Stock.—Except by buying new queens there probably never was a time when so much attention was given to improvement in breeding as at the present. But that "so much" is comparatively little, and Editor Hutchinson, of the Bee-Keepers' Review, helps to send the ball rolling after the following fashion:

"Our hives and methods of management are probably not perfection, but they are pretty fair, at least; our methods of putting up honey and marketing it may possibly be considerably improved; but at present the most promising field in which to turn our energies loose is in that of improving our stock. Too many of us look upon bees as *bees*, in something the same way as a country merchant buys butter—it's all butter. The man who has kept bees many years, trying different strains, and keeping his eyes open, well knows that there is a difference in bees. The most of us know this. The trouble is, that we do not put our knowledge into practice."

Addressing Packages of Honey.—There has been quite a little said lately about the honey-producer putting his name and address on the packages holding his crop of honey when shipping it to market. We want to give a few words of caution on this subject. We have had a little experience in handling honey produced by others, and believe we express the desire of the great majority of honey-dealers when we say *we* don't want the producer's name and address on the packages of honey we purchase.

Does the farmer put his name and address on the bags of wheat, corn and potatoes he sells? Does he brand the cattle, hogs, horses and poultry that he raises for market? Does he put his name and address on the eggs, butter, etc., that he produces for others to eat? Of course not. Then why put it on honey?

For example, we have spent a good deal of money and time in advertising and working up a demand in Chicago for "York's Honey"—is any one fool enough to think that we would put honey on the market here with somebody else's name and address on it? Suppose we should furnish some grocer with a case of nice comb honey having on it, "Produced by Walker Wheelering, Honeytown, Wis." What is there to hinder that grocer ordering his whole supply next year from Mr. Wheelering? Then, of course, he would sell to the grocer at two or three cents under the market price, as some unbusinesslike bee-keepers do here every year. What is the result? Our salesman calls on Mr. Grocer, and is met with, "Oh, I'm supplied. I bought this fine lot of comb honey in Wisconsin, at 13 cents a pound, while your price is 16 cents."

Or, the grocer may go down on South Water Street and tell some honey-dealer there that he bought "just as good

comb honey as that for 13 cents," when the dealer is trying to hold the price up to 15 cents.

If some bee-keepers should decide to address their honey-packages, we would not be surprised if some dealers would refuse to handle it. *We* certainly should. We can't afford to spend hundreds of dollars in creating a demand for honey, and then permit our honey customers to get their supply direct from the producers. It not only is unjust to us, but demoralizes prices all around.

Again, the producer, of course, would want to label only his best grades, and likely try to shove off on the dealer the poorer grades, and perhaps generously "kicking," besides, if a good price were not realized on the inferior honey.

There are always two sides to a question like this. Bee-keepers should co-operate with the wholesale dealers instead of each trying to go it alone, except in their home market.

It is all right for the bee-keeper to put his full name and address on all the honey he retails himself, but not on that which he ships to another to sell, unless he first has permission to do so from the one to whom he ships the honey.

The Illinois State Food Commission has located in the Manhattan Building, on Dearborn St., between Van Buren and Harrison Sts., Chicago, Ill. Hon. Alfred H. Jones, the new commissioner, has just issued a pamphlet giving the "laws of Illinois relating to the office and duties of the State Food Commission and the adulteration of butter, cheese, milk and other foods, with rulings thereon." It also contains the rules adopted by the State Food Commission, which are to govern in determining as to adulterated articles. Here is the rule applying to honey:

"Honey adulterated with glucose or any other substance not deleterious to health may be sold when labeled 'ADULTERATED HONEY.'"

It seems to us that when so labeled, there won't be much of that stuff sold, and the pure article of honey will have a fair chance.

We presume that copies of the pamphlet referred to may be had by those interested, by writing to Commissioner Jones, as directed above.

Illinois Apiarian Statistics for 1899.—In the Statistical Report of the Illinois State Board of Agriculture for Dec. 1, 1899, we find the following under the heading, "Bees and Honey:—"

The year 1899 was a very poor one for bees and honey, a smaller amount of honey being produced than ever before, but 398,025 pounds being reported. Of this amount Northern Illinois produced 193,377 pounds, Central Illinois 103,718 pounds, and the Southern division of the State, 100,930 pounds.

The average price obtained for honey was 13 cents per pound, thus returning to the bee-keepers of the State \$53,369.

The number of colonies of bees in the Northern division of the State was 20,035; in the Central division 16,565, and in Southern Illinois 18,583, a total of 55,183.

We notice in the above nothing is said as to whether or not the report covers both comb and extracted honey. The price per pound of course refers to comb honey. After all, such statistics are not very reliable, and yet we presume there ought to be some commendation offered for at least attempting to get them.

Bees and Honey in Europe.—The British Bee Journal some time ago published these paragraphs:

"Germany, which has 1,910,000 colonies of bees, producing 45,000,000 pounds of honey every year; Spain has 1,690,000 colonies, producing 42,000,000 pounds of honey;

Austria, 1,555,000, producing 40,000,000 pounds of honey; France, 950,000, producing 22,000,000 pounds; Holland, 240,000, producing 6,000,000 pounds; Russia, 110,000, producing 2,000,000 pounds; Denmark, 90,000, producing the same; Belgium, 200,000, producing 5,000,000 pounds; Greece, 30,000, producing 3,000,000 pounds.

The annual production of honey in Europe is calculated to reach 40,000 tons, valued at £2,200,000, and of wax 15,000 tons, of the value of £1,350,000. A colony of bees produces from 20 to 50 pounds of honey yearly, according to its size, and multiplies tenfold in five years."

But we shouldn't wonder at it if apiarian statistics in Europe are about as definite as are those to be found on this continent. It is well nigh impossible to secure figures at all accurate. We notice that Great Britain is not mentioned in the list.

Organization Among Bee-Keepers has some earnest words said in its favor by R. C. Aikin in the Bee-Keepers' Review. Band together, select a few of your best business men to do the work for the rest, and pay them for it. These managers can keep informed about supply and demand, and hold up prices somewhere near the right point. Mr. Aikin very pertinently says:

"Why should buyers go about among producers and offer five cents for honey that is worth much more, and because they can buy from my neighbor at that, use it for a lever to pull me to the same price? Just such things are done, and will continue to be done until we organize and post ourselves."

The Weekly Budget

MR. GUS DITTMER has sent us a copy of his catalog for 1900, describing the bee-supplies he has for sale. He makes a specialty of comb foundation. See his advertisement in every number of this journal.

MRS. DAVID EVANS, of Placer Co., Calif., kindly sent us, two or three weeks ago, blossoms of the fragrant manzanita, which she says is the earliest honey-plant of the foot-hills of Placer County, growing in great luxuriance over the hills, and blooming from January to March or April.

MR. M. H. MENDELSON, of Ventura Co., Calif., writing us Feb. 26, said:

"We had an interesting and instructive convention at Los Angeles, Feb. 21 and 22. Messrs. Oliver Foster, of Colorado, and Frank McNay, of Wisconsin, with other noted bee-men, were present. We will have another bad honey year for Southern California. No rain for nearly two months, and the country drying up again."

VERMONT ON THE RIGHT TRACK.—The premium list of the Vermont State Fair contains this paragraph, which ought to find a place in the lists gotten out by every fair in our whole country, and then be thoroly enforced:

"Now, then, three-card monte and shell-game men, snides, gamblers, fakes and bums of every sort, kind and description, take notice! That gambling of every sort and form, and the sale of beer, ale, wine, or other intoxicating liquors will be excluded from and about the grounds. If, as you say, we can not run without you and your goods, we will close our gates. We neither want nor will we tolerate you; and by this we serve notice upon you that, if you come, prison-doors yawn for you."

The Premiums offered on page 158 are well worth working for. Look at them.

An Old Colony.—A. Tobias has a colony that has been in the same hive continuously without intermeddling for 50 years.—Leipzig. Bztg.

Milk-Feeding in Spring is the best to stimulate brood-rearing, where pollen is lacking, says Dr. Dzierzon in Leipzig. Bztg. Fresh milk is boiled and made very sweet, especially at the beginning, and fed in old combs in the open air.

Winter Bee-Flights seem not desired in Germany. Lebrecht Wolf says in Deutsche Illustrierte Bztg. that formerly it was thought to be a good thing if the weather allowed a flight in January; but now it is generally considered a disadvantage to have a flight in December, January, or the first half of February, and every effort is made to prevent it.

The Need of Air for Bees increases with the temperature. A bee was sealed in a little glass tube, which was placed in water, and by means of ice and hot water kept at a fixed temperature. For lack of air the bee became stupefied, and revived on being allowed fresh air. At 100° it was suffocated in 11 minutes; at 85° in 22 minutes; and at 60° in 109 minutes.—Pfaelz. Bzcht.

No Wax-Moth in Colorado is the statement of R. C. Aikin in the Bee-Keepers' Review. He says: "At our conventions many have asked about the moth, and it is a fact that I have never found moths here, nor any apiarist that even knows the moth, unless having made its acquaintance elsewhere. Combs can stand anywhere here for years, and never a wax-moth."

Frank Rauchfuss says: "The claim of Colorado honey being infested with moths is amusing, as there are no wax-moths in existence in this State."

Introducing Queens.—R. Benne says in the Australian Bee-Bulletin:

"For introducing queens from my own nuclei I simply take the queen from the nucleus with the comb and bees she is on, and exchange for a comb with brood, bees and queen (if there is one), from the hive she is to be introduced to. For a queen received by mail I take one frame of bees and brood from each of four or five colonies, about noon (taking care to leave the queens behind), and put them into a hive with contracted entrance on a new stand, and put the new queen amongst them, at dusk.

□ **A Good California Report.**—F. E. Brown, secretary of the Central California Bee-Keeping Association, gives the Hanford Sentinel an interesting account of the bee-keepers' experiences for the year in his section—the San Joaquin Valley:

PHASES OF THE YEAR.—The season of 1899 was a very successful one for the bee-keeper of this (Kings) county, as it was the best season for the production of honey that we have had in the past 10 years. The honey-flow commenced early in June and flowed steadily until late in September, and was quite general over the county. However, there were some localities that did not fare quite so well as others. The most favored parts of the county the past season were the eastern and southern, while the western did better than the northern. However, this is not usually the case, as the northwestern portion of the county has a good record for quality, which, as a rule, is darker than that produced in the part south of Hanford.

□ Along with the good work that the bees have been doing the past season, the Central California Bee-Keepers' Association has also accomplished a good work, and as a result the man who has a good start in the bee-business can look the world square in the face this winter, and is not afraid that he will be called upon to pay a bill that he cannot meet.

□ **CO-OPERATIVE MARKETING.**—The Bee-Keepers' Association has this season marketed its own honey and bought its cans and cases by the carload, thus keeping within its

ranks a great saving, which has heretofore helped to flush the comforts of the buyers, as we can market our honey a great deal cheaper than the buyer would want for his part. We have demonstrated beyond doubt the fact that we can save \$10 on every ton which we have to market, which means a net gain to the association for the past season of \$1600. Is it any wonder that there are so many buyers in the field wanting our honey to speculate upon?

We can save at least 5 to 10 percent by handling our own cans and cases. Then, by being associated together, we are better prepared to grade our honey, which gives it a better appearance. Heretofore we have bought our cases anywhere and everywhere, no two cases being the same or of the same weight, and there was always difficulty in adjusting the tare.

THE CROP.—Kings County, for the season of 1899, produced and handled thru the association, 13 cars of extracted honey, or 162 tons, which netted the producers something over \$19,000. The association shipped in and used 5 carloads of cans and cases, the honey being mostly sold f.o.b. Hanford and Guernsey, and shipped to Chicago, Boston, New York, Kansas City, Philadelphia and San Francisco.

The coming season promises to be another good one for the honey-man, and there is a good swarming season expected.

Oil in Beeswax.—A Stray Straw in Gleanings in Bee-Culture is as follows: "The Leipziger Bienenzeitung reports that some foundation made of pure wax 10 years old was very brittle. A few drops of linseed oil were mixed with the melted wax, and then the foundation was all right. [I am not surprised that foundation 10 years old should be brittle—at least if it were of the old process, which it undoubtedly was; but if the foundation under consideration was melted up again, and then worked up again into foundation, it would be soft and pliable whether linseed oil were melted up with the wax or not. I am of the opinion that linseed oil had nothing to do with it. Anything of an oily nature should be left out of the wax, otherwise the bee-keeper will have a mess on his hands some day when the weather is pretty warm.—ED.]

Dr. Mason Invading Critic Taylor's Preserve.—If Dr. Mason doesn't keep a sharp lookout, he will stray over the fence into Critic Taylor's foraging ground. In the last number of the Bee-Keepers' Review, he quotes the assertion that bees do not and cannot move and redeposit eggs, only to give his own assertion in positive contradiction, saying, "Several years ago one colony of our bees *did* move and redeposit several eggs, and they hatched, and from one of the redeposited eggs they reared a good queen." In another place he takes a whack at Doolittle because Doolittle pokes fun at his use of "locality." For this latter one can not blame him, for however much we may joke about the laying everything to locality, there is no disputing the fact that the one who reads bee-literature without ever taking locality into account, is likely to get into a quagmire.

The Busy Bee well deserves its name. A. Astor fed a market bee which worked from 6 a.m. till 5 p.m., making 110 trips a day, and kept it up for 12 days. But it aged terribly in that time.—Revue Int. On the other hand Prof. Hodge's bees worked only 3½ hours a day. [Now, if we had a national experiment station, or experiment station of any kind, in this country, making bee-keeping a specialty, here would be a nice field for investigation; and there would be something practical to be learned from it, too. For instance, what strain of bees make the greatest number of trips in a day? and does the amount of honey depend upon the number of trips? Perhaps some bees have larger honey-sacs as well as longer tongues.—ED.]—Stray Straw in Gleanings in Bee-Culture.

A Refutation of the Miller-Experiment as to larvae chosen for queens occupies the whole of Critic Taylor's space in the January number of the Bee-Keepers' Review. Perhaps "refutation" is hardly the word. "Review" is what Mr. Taylor calls it, unless the heading be written by the editor. At any rate, Mr. Taylor follows up different points to show that instead of Dr. Miller having proven what he supposed was proven, the exact opposite was proven, and closes by saying: "The Doctor's experiment is very valuable; but principally because it establishes the fact that this method of queen-rearing is neither desirable nor safe."

Root's Column

OUR 8-FRAME DOVETAILED HIVE WITH IDEAL SUPER HOLDING 30 3 3/4x5x1 1/2 INCH PLAIN SECTIONS.

Some of our customers want a super very plain, no fixings. To meet the demand for a very simple hive, yet embodying the valuable features of the deep plain sections, we devised this super. It already has a large sale. It is specially adapted for those who want a super for

EITHER COMB OR EXTRACTED HONEY.

YOU WILL DO WELL TO INVESTIGATE THIS SUPER.

What Others Say of Root's Plain Sections and Fences:

I had your plain sections in use with fences, and I must say that I am pleased with them, particularly the 13 3/4x5x1 1/2 sections. They were very nice, better filled than the old style, and made a great deal better show, so much so that they brought me a better price, and they sell much quicker. I am so well pleased that I will use none but plain sections this season, and have sent my order for such.

P. I. HUFFMAN, Albion, Va.

The A. I. Root Co., Medina, Ohio.

DEAR SIR:—After three years' experience with the Danz. hives I can say that I like them very much, especially the closed-end frame feature, also the super and plain 4x5 section and fence. I have no trouble at all in keeping the fence separators clean, and that, too, in a locality where propolis is very abundant, as my apiary is in the central part of this State where pitch and other resinous substances ooze out of the pine and other trees and stumps in unimaginable quantities. Here, too, I find the closed-end frame very easy to manipulate, for the reason that they are wedged up together, and offer no space nor cracks to be stuff full of the horrid stuff.

131 W. Bridge St., Beloit, Wis., Feb. 9, 1900.

FRED G. BERNER.

We are pioneers in the manufacture of PLAIN SECTIONS AND FENCES. If you want to get them right, send to us or our branch houses or agencies.

THE A. I. ROOT COMPANY, Medina, Ohio.

A Dozen Different Blossoms From a Single Seed.

This is possible only with our wonderful novelty, the new **Chameleon Nasturtium**

In richness and variety of coloring it surpasses all others. Mammoth size, perfect flowers of crimson yellow, blotted and mottled in perfect shades. Value alone 10c. For 1 lb we will send you a pkt. of chameleon seed and one pkt. each of these

Five Most Popular Flowers.

- 1 pkt. Sweet Peas, 25 kinds
- 1 pkt. Giant Pansy, 12 kinds
- 1 pkt. Mignonette Giant
- 1 pkt. Morning Glory, Giant
- 1 pkt. Cosmos, New Early

Total six pkts. retail value \$30c, for only 14c, together with our annual "Gardening Illustrated" for 1900, describing the best flower seeds in America. It tells the whole story for the Garden, Lawn and Home.

GENERAL ITEMS

Report for the Season of 1899.

Last season was a poor one for honey. I secured 2,000 pounds of honey, and increase from 42 to 64 colonies. I have not lost any bees that I know of so far this winter.

A. T. SCOTT.

Shelby Co., Iowa, Feb. 27.

An Experience with Bees.

In the fall of 1897 I got a copy of "A B C of Bee-Culture" and began reading it. The result was that I had, in a very short time, a bad case of bee-fever (so called). In March, 1898, I persuaded my brother to embark with me in my new venture. Accordingly I started for North Carolina, a distance of about 100 miles, where my uncle lived, who was a bee-keeper, for the purpose of buying bees—all I could pay for. But after getting his advice I took only five colonies; hired a man with a team, loaded them into the wagon, and rolled out over the roughest road, considering the distance, I have ever seen.

After driving four days we arrived home with the bees in fairly good condition. We gained three colonies during the season, making eight in all, which, when fall came on, we divided equally. My four came thru the winter pretty well excepting one, which remained weak till later in the season of 1899. I got two nice swarms in April, and increase to 15 colonies by natural swarming, excepting two nuclei which I made. One swarm took Greeley's advice, or I would have had 16. I also sold \$14.80 worth

them. I don't need to get little pails to put it in as they take it from the extractor in gallon lots. If I only had lots of bees I could make more out of them than in farming.

I saw an article some time ago where a writer claimed that eggs were left where the queen laid them. I don't think so. I tried one colony. It had six old combs, so I fixt up four more frames with full sheets of foundation, and put two on each side of the old ones. The bees went right to work and drew them out. When out about half way I lookt at them, and they were full of eggs, some cells having two and three in them, but the old combs had none at all. I lookt the next day, and there was not an egg to be seen in the new comb; they moved them to the old combs to hatch.

The prospect is good for this year. I use 10-frame hives, as I think they are the best. It looks reasonable that the more room the bees have the more bees you will have to

Farm Wagon Economy.

The economy of this proposition is not all found in the very reasonable price of the wagon itself, but in the great amount of labor it will save, and its great durability. The Electric Wheel Co., who make this Electric Handy Wagon and the now famous Electric Wheels, have solved the problem of a successful and durable low-down wagon at a reasonable price.

This wagon is composed of the best material thruout—white hickory axles, steel wheels, steel bonnds, etc.; guaranteed to carry 4,000 lbs. These Electric Steel Wheels are made to fit any wagon, and make practically a new wagon out of the old one. They can be had in any height desired, and any width of tire up to 8 inches. With an extra set of these wheels a farmer can interchange them with his regular wheels and have a high or low-down wagon at will. Write for catalog of the full "Electric Line" to Electric Wheel Co., Box 16, Quincy, Ill. Mention the Bee Journal.

New Aids to Truck Farming.—The number of firms in business to-day that have an unbroken record of half a century is comparatively small, but the Ames Plow Co., of Boston, Mass., is one of the few. However, their new catalog now before us shows that pride in their past does not monopolize their attention. We do not remember to have seen a more modern line of hand-cultivating tools anywhere. Prof. I. P. Roberts, author of "The Fertility of Land," forcibly says: "The one fundamental labor of agriculture is the stirring and mixing of the soil." Truck farming more than any other requires the benefit of all the cultivation it is possible to give, and in these days of close competition, the judicious selection of implements is productive of inereast returns in the way of larger and better yield at reduced cost. Truck farmers and gardeners generally understand the sterling qualities of the genuine Mathews Seeder, which they have known for so many years, and those prime favorites, the Mathews New Universal, as the latest improvements are called, are popular everywhere. The whole line of separate drills and wheel hoes is the most complete ever offered. Send for free book illustrating and describing this means of success in the Market Garden, to Ames Plow Co., Boston, Mass., and mention the American Bee Journal.

gather the honey. It is just like having a lot of men to do a lot of work—more men, more work is done. Besides, I don't believe they will swarm so badly.

VIRGIL ROGERS.

Buffalo Co., Neb., Feb. 24.

Bees in Good Condition.

Bees are wintering well so far in this locality. Some of my neighbors are wintering theirs on the summer stands, and they seem to be all right. But this has been a mild winter up to a week ago when it turned cold and snowed, which is still on the ground, and it is a good thing that there is snow, as it will protect clover and other plants. So far clover looks all right, and I don't think it will freeze any more, for it is getting along toward the first of March. The mercury has been 7° and 8° below zero, but it is getting warmer again.

My bees are wintering nicely in the cellar that I built last fall. It is made of river stone, which I dug myself, and did the mason-work myself. I work at the mason trade when I can get away from my bees. I am going to run a small nursery with my bees, as I think every bee-keeper ought to raise some fruit, so that his neighbors, who do not keep bees, and claim that his bees injure fruit, can be convinced that they do not, but that they help to fertilize all kind of fruits and some farm crops, such as clovers. I think that alsike is one of the best of clovers for hay and pastura, and it will stand a damp and cold soil better than the common red. Another advantage alsike has over the other kinds is that the bees can and do work on it more readily. It is this work done by the bees that causes it to bear seed the first crop, and in this part of Illinois it gets ripe a little before timothy, so that when the hay is made lots of the seed falls on the ground to come up the next spring and take the place of the old clover.

Last fall I went out thru what little timber there is left in this vicinity in search of bees, and I found three trees one afternoon that had bees, but it was too late to do anything with them last fall, so I thought I would wait until spring, and if they are then alive I will transfer them. While two men were cutting cordwood in this timber this winter, they happened to fell one of these trees that contained a colony of bees that I found. This was Jan. 23, and they came and told me about it. I did not like to see the bees starve and freeze to death, so I fixt up a small hive with some nice combs of honey, and started for the tree. It was nice and warm, so it was not a hard job to get them into the hive, and I brought them home and put them into the cellar. They are doing nicely so far. I think they will come thru all right.

JACOB WIRTH.

Henry Co., Ill., Feb. 19.

Nuclei, Spring Dwindling, Etc.

In the fall of 1898 I had 63 colonies and three 3-frame nuclei, all nicely arranged in chaff hives for outdoor wintering. I did not expect the nuclei to live thru, but thought to try the experiment.

After the well-remembered extremely cold snap (26° to 25° below zero here) was over, there came some nice warm days late in February. On looking the bees over I was surprised to find all alive and apparently in fine condition. The surprise was that the nuclei should endure such extreme cold. In most colonies there was young brood. From that time till April 9 the weather was cold, cloudy or blustery, so the bees could not fly. On April 9 I lookt them over again, and found the three nuclei and 16 colonies dead, and many others very weak. In all the dead colonies there was dead brood. I think my loss was chargeable to early breeding and bad spring weather, rather than the extreme cold.

In the summer I had a colony that I thought was queenless, but in looking them over I was surprised to find a capt queen-cell! I was determined to see what was in it, and on cutting it open found a drone

**DR. MILLER'S
Honey Queens**

One Untested Queen Free as a Premium for sending ONE New Subscriber to the American Bee Journal for one year.

We have been fortunate in making an arrangement with DR. C. C. MILLER—the well-known honey-specialist—to rear queens EXCLUSIVELY FOR US DURING THE

SEASON OF 1900. These Queens will be mailed in rotation, beginning about June 1, so "first come first served." We are ready to book orders now.

The Queens, Dr. Miller will send out on our orders will be precisely the same as those he rears for his own use, so of course they will be from his best stock. His best colony in 1899 had a queen reared in 1898; May 5, 1899, it had brood in 4 frames, and he gave it at that time a frame of brood without bees. It had no other help, but May 25 a frame of brood with adhering bees was taken from it, and the same thing was repeated June 3, leaving it at that time 5 frames of brood. It stored 178 sections of honey, weighing 159 pounds (and that after July 20, in a poor season), being 2 2/3 times the average yield of all his colonies. A point of importance is the fact this colony did not swarm, and an inspection every week or 10 days showed that at no time during the entire season was there even so much as an egg in a queen-cell. Dr. Miller expects to rear queens from this one during the coming summer.

The demand nowadays is for BEES THAT GET THE HONEY when there is any to get, and Dr. Miller has such bees. You will want to have a queen from his best, we are sure.

Do not send any orders to Dr. Miller, as all orders MUST come thru us, according to our agreement.

Remember, send us \$1.00 for ONE NEW SUBSCRIBER to the American Bee Journal for one year, and YOU will get ONE OF DR. MILLER'S UNTESTED HONEY-QUEENS FREE AS A PREMIUM. Or, send us \$1.50 and we will mail you the American Bee Journal one year and a queen. Or, the queen alone for \$1.00. Orders for queens to be filled in rotation, beginning about June 1st.

Address all orders to **GEORGE W. YORK & CO.,**
118 Michigan Street, CHICAGO, ILL.

THE WAR IN SOUTH AFRICA

has demonstrated the great foresight of the Boers, in availing themselves of all the opportunities in times of peace to prepare for war. Similar foresight should lead you to improve the opportunity of securing better farms than theirs in this country. They are on line of the Chicago, Milwaukee & St. Paul railway in Marinette county, Wisconsin, where the crops are of the best, work plenty, fine markets, excellent climate, pure, soft water; land sold cheap and on long time. Why rent a farm when you can buy one for less than you pay for rent? Address C. E. ROLLINS, Land Agent, 161 La Salle St., Chicago, Ill.

"None Better" Incubators.

One of the very latest and most up-to-date hatching machines on the market is the "None Better," made by the Hawkeye Incubator Co., of Newton, Iowa. A good incubator, made on a correct principle, of the very best material by expert workmen, is what the manufacturers claim for it, and they guarantee perfect satisfaction. Their catalog is full of straight, manly talk on the incubator question, which every poultry-raiser will find profitable to read. Their machine is one of the simplest made. Send for catalog and please mention the American Bee Journal.

almost ready to emerge. I suppose it would have been proper to have called "it" a "king."

The summer season was a failure, no honey in the white clover, but on Aug. 25 the flow began on heartsease, and for two weeks was very rich, with quality good.

September 1 a swarm emerged. I looked for queen-cells and found only one had been started. It had an egg in it. September 3 two swarms came out. I searched them carefully for queen-cells, and found none had yet been started in either hive. That was all the fall swarms I had.

I have now 67 colonies in chaff hives. They have had frequent flights, are out today (Feb. 12), and seem in fine condition.

I had quite a pile of "slumgum" last fall. Some from a steam extractor and some from a solar extractor. I had gotten out all the wax I could by those presses, but felt sure there was still more good wax in it; so I took two oak boards 2 inches thick, 12 inches wide, and 6 feet long, and hinged them one inch apart at one end with a pair of very heavy strap hinges. I then filled a big iron kettle two-thirds full of water and filled up with slumgum. I gave it a good boiling, and then dipped a quantity out into a grain-sack and gave it a squeeze. The beautiful yellow wax gusht out in great shape. I worked up all my slumgum and got 9 1/2 pounds of nice yellow wax, entirely unstained or injured by the iron kettle. I got big pay for the amount of work it took. C. W. McKOWN.

Knox Co., Ill.

Evergreen Trees by the Million.—One hundred million trees growing on one farm! It hardly seems possible, yet that is what a correspondent recently saw at the nurseries of D. Hill, the well-known evergreen specialist, at Dundee, Ill., the largest grower of evergreens in the world. Mr. Hill has built up his enormous business by living up to every promise made in his advertisements, and in his catalog. He believes that a satisfied customer is the best advertisement, and he has lots of them. It is a well-known fact that there is no more valuable, serviceable and ornamental tree for the farm than a good evergreen; it will resist any drouth or exposure and forms a valuable wind-break and protection for orchards and stock. The Minnesota State Horticultural Lecturer says that many farms in the northwest have been increased \$1,000 in value by well-arranged, generous plantings of evergreens. Mr. Hill issues a good catalog showing different varieties and describing how best to make them grow. Send for it, not forgetting to mention the American Bee Journal.

The Sang Digger.—One of the most picturesque figures in America is the "Sang Digger" who roves over the mountains of the Eastern States, hunting for the root of the ginseng plant. It is readily converted into goods or money, as the demand for this plant far exceeds the supply. Dealers pay \$5.00 and \$6.00 per pound for the dried roots. The "Sang Digger" has so depleted the native forests of the ginseng plant that it is becoming scarcer every year. This fact has led to its cultivation with very profitable results. F. B. Mills, the well-known seedsman of Rose Hill, N. Y., is making a special offer on ginseng seed and plants. His advertisement, which appears in another column, offers special inducements which our readers would do well to investigate. Send for his regular seed catalog, which is sent free, and kindly mention the American Bee Journal.

Langstroth on... The Honey-Bee

Revised by Dadant—1899 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the Ameri-

can Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helpt on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.,
118 Michigan St., - CHICAGO, ILL.

Convention Notices.

Utah.—The Utah State Bee-Keepers' Association will hold its semi-annual convention in the City and County Building, Salt Lake City, Apr. 6, 1900, at 10 o'clock a.m. A full program in the interest of the industry will be presented, and all our bee-keepers can help themselves by aiding the Association, and in order to create a closer bond of union among our bee-keepers. As a further incentive to the success of the bee-industry, it is very desirable to have our bee-keepers from all parts attend the spring convention. J. B. Fagg, Sec.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Feb. 19.—A little trade in honey in a peddling way by the case, no demand for lots, neither has there been for the past 3 months. Comb honey of the choice grade is selling at steady prices, and there is not too much of it; off grades are slow. Extracted is steady with no change in prices. Beeswax sells at 28 cents if yellow and clean. R. A. BURNETT & Co.

CINCINNATI, March 3.—There is some demand for extracted honey from manufacturers at 7@7 1/2c for amber and Southern; clover, 8@8 1/2c. Comb honey is selling firm at 14@14 1/2c in a small way. Beeswax, 25@27c.

C. H. W. WEBER,
Successor to Chas. F. Muth & Son and A. Muth.

LOS ANGELES, Feb. 15.—1-pound frames, 12 1/2@15c; 2-pound cans, 2 dozen in case, per dozen, \$2.50; 2-pound glass pails, per dozen, \$2.50. Extracted, water white, 60-pound tins, per pound, 8 1/2c; light amber, 7 1/2@8c; dark amber, 7 1/2c. Beeswax, 25@26c.

Stocks of honey in all parts of the United States are lower than they have been for 10 years. It is most desirable that rain should come as prices are likely to be high.

KANSAS CITY, Feb. 12.—We quote fancy white comb, 14@15c; No. 1, 13 1/2@14c; No. 2, 12 1/2@13c; fancy amber, 13@14c; No. 1, 12 1/2@13c; No. 2, 12@12 1/2c. Extracted, white, 7 1/2@8c; amber, 7@7 1/2c; dark, 6@6 1/2c. Beeswax, 22@25c. C. C. CLEMONS & Co.

BUFFALO, March 3.—Market nearly bare of all grades of honey. Probably no more from any source to market, but if so, fancy white comb is firm at 15@16c. Other grades from 14c downward, with the poorest at 8@9c. Fancy pure beeswax continues at 28@30c. BATTERSON & Co.

NEW YORK, Feb. 8.—During the past 30 days our market has been somewhat slow and easy in both comb and extracted honey. Stocks of comb honey, however, are almost exhausted, and there is a fair demand for all grades. Fancy white selling at 15c; No. 1 white at 13@14c; fancy amber, 11@12c, and buckwheat at 9@11c, according to quality, etc.

Our market is well supplied with extracted, the prices are firm and unchanged. Beeswax sells very well at from 26@28c, according to quality. HILDRETH & SEGELEN.

SAN FRANCISCO, Feb. 14.—White comb, 11 1/2@12 1/2c; amber, 8@10c. Extracted, white, 7 1/2@8c. light amber, 7@7 1/2c; amber, 5@5 1/2c; Beeswax, 26@27c.

Beyond the filling of small orders by jobbers, there is practically nothing doing in honey. Offerings are light, and are mainly comb. Quotations are unchanged, but at present represent little more than jobbing rates. A shipment of beeswax was made the past week of 3,200 pounds by steamer to Germany. Stocks are small and prices steady.

ALBANY, Jan. 10.—We quote: Fancy white comb, 15c; No. 1 white, 13@14c; mixt, 11@13c; buckwheat, 10@11c. Extracted, white, 8@9c; mixt, 6 1/2@7c; dark, 6. Beeswax, 26@28c. MACDOUGAL & Co.

Successors to Chas. McCulloch & Co.

OMAHA, Feb. 13.—Demand shows some improvement in January, having been much more active, but as anticipated there is no advance in prices. Market remains steady at 14@14 1/2c for fancy white comb and 8 1/2c for white extracted. The latter is pretty well cleaned up along the Missouri River, and it looks as if there would be some shortage before another crop comes in. From present appearances there is about enough comb honey to go around at the present prices, hence we look for no particular change in values. PEYCKE BROS.

DETROIT, Feb. 10.—Fancy white comb, 15@16c; No. 1, white, 13@14c; fancy amber, 11@12c; dark and undesirable lots, 8@10c. Extracted, white, 7@7 1/2c; amber and dark, 5@6c. Beeswax, 25@26c. Supply of honey fair with light demand. M. H. HUNT & SON.

Value of Bees in Fruit-Oorchards.

BY J. E. CRANE.

IT is not my object in this paper to thrash over old straw, but rather to gather some golden grains of truth from a harvest of facts that has ripened since the memorable discussion of this subject a few years ago, and gathered into a most interesting symposium.

Perhaps nothing in that symposium was more noticeable than the difference of honest opinion held by many intelligent observers, and for good reasons as the sequel will show. It is an interesting fact that the new light on this subject has come thru the efforts of the fruit-growers rather than the bee-keeper, and that the solution of the problem is a most complete proof of the value of bees to the fruit-grower.

Before giving the new facts that have come to light on this subject, I must tell how it came about.

Many years ago, down in Virginia, a farmer planted out a large pear-orchard. As he was a bright man he thought he would make a very profitable investment, and not plant any unproductive trees. As Bartlett pear-trees are almost universally known as the most productive as well as profitable, he planted his entire orchard of this variety. He cultivated his orchard with great care, fertilizers were applied, and when he lookt for fruit he found "nothing but leaves." But he kept on until his means were exhausted and his place went under a mort-

The Effect of Cross-Fertilization in Enlarging Fruit as well as Seeds.

gage. The new owner thought he had a bonanza in that pear-orchard, and he, too, cared for it until his ability to do so failed, when it past into the hands of another person; but still it failed to yield a crop of fruit. I take it that the last owner had some faith in "book-farming," for he sent to the Department of Agriculture at Washington for a solution of the problem of an unproductive orchard of Bartlett pears. Mr. M. B. Waite, of the Department, was sent down to study the subject on the ground. He guesst the trouble to be the lack of cross-pollination with other varieties, and, fortunately, he guesst right. More or less of the orchard was grafted with other varieties; but before it came into profitable bearing it was struck with "blight" and ruined. But it had served a useful purpose. A new interest was taken in the subject of the effects of self and cross pollination of fruit-blossoms, and the scientific study of the subject began. This was carried out by taking pear and apple blossoms just before they open, and removing a part of the blossom and then applying either pollen of the same variety or some other variety, and covering at once to prevent insects from interfering. In this way it could be told whether a given variety would prove fertile with its own pollen or not, and just the effects of crossing with other varieties.

As a result of these studies Mr. Waite says: "Many of the common varieties of pears require cross-pollination, being partially or wholly incapable of setting fruit when limited to their own pollen. Some varieties are capable of self-fertilization. Self-pollination takes place, no matter whether foreign pollen is present or not. The failure to fruit with self-pollination is due to sterility of the pollen, and not to mechanical causes, the impotency being due to lack of affinity between the pollen and ova of the same variety."

"Varieties that are absolutely self-sterile may be perfectly cross-fertile. The normal typical fruits, and in most cases the largest and finest specimens from both the so-called 'self-sterile' and 'self-fertile' varieties, are crosses."

"Self-fecundated pears are deficient in seed, and the seeds produced are usually abortive. The crosses are well supplied with sound seeds."

He gathered most of the cross and self-pollinated fruits resulting from most of his experiments for study and comparison, and found, as a rule, a decidedly better development of the blossom-end of the fruits of those cross-pollinated than those self-pollinated. He found, also, a disposition or tendency in self-pollinated late varieties of pears to wither before ripening, while those resulting from crosses ripened perfectly. My son has offered to copy several of Mr. Waite's illustrations.

Fig. 1 shows a Bartlett pear cross with pollen of Easter pear.

No. 2 shows a self-pollinated Bartlett pear.

No. 3 shows seeds under *a* from cross-pollinated Bartlett pears; under *b*, seeds from self-pollinated pears.

About three-fifths of the varieties of pears experimented upon appear to have been wholly self-sterile, or were greatly benefitted by cross-pollination.

Even with those varieties capable of self-fecundation, the pollen of another variety is prepotent (more powerful); and unless the entrance of foreign pollen is prevented, the greater number of fruits will be effected with it.

As apples blossom soon after pears, a large amount of work was done with them to ascertain the effects of self and cross fertilization. He says:

"In a general way the results were similar to those obtained in the experiments with pears. The division of the varieties into self-sterile and self-fertile sorts was not nearly so well marked.

"Crossing gave decidedly better results in all cases than self-pollination. The Baldwin, which was experimented upon freely, may be cited as a variety that comes as near being self-fertile as any, and yet even this is far from being entirely so; for in the best trees the percentage of fruit resulting from self-pollination was not more than a fourth of that which resulted from crossing. Some of the Baldwin trees, in fact, seemed to be self-sterile, and all the varieties occasionally set self-pollinated fruit."

He does not seem inclined to place much confidence in a strict classification, even of pears, as a variety may be quite self-sterile in one section, as in the North, and yet be quite self-fertile in the South or in some other season.

Among the sorts of pears he found more or less completely self-sterile are the Bartlett, Anjou, Boussock, Clairgeau, Clapp's Favorite, Sheldon, Louisa Bonne de Jersey, and other common varieties. Still less would it be possible to classify apples. A variety may be self-fertile this year and quite the reverse next year, or in one section of country

and not in another. The weather at blooming-time is important. He says:

"The weather during the blooming period exerts both a direct and indirect influence on the setting of fruit. Even when not injured by frosts, the blossoms are often chilled by the cold to such an extent as to interfere with fecundation. Moderate cold renders the self-fertile trees self-sterile, and severe cold renders them sterile to cross-pollination as well. Warm and sunny weather at this time indirectly aids the fertilization by favoring insects in their work of cross-pollination."

The results of self-pollination in apples are very interesting. Again I quote from his paper: "The apples resulting from some of the experiments were collected and studied, and the results were found to be parallel with those obtained in the experiments with pears, the crosses being larger, more highly colored, and better supplied with seed. For example, *the hand-croft Baldwin apples were highly colored, well matured, and contained abundant seeds*, while the self-fertilized were only slightly colored, were but one-fourth to two-thirds the regular size, and seedless. The crosses were, in other words, like the better specimens of apples not bagged from the same tree, and the self-fertilized fruits corresponded with the undersized, poorly-colored specimens from the same trees." The italics are my own, for I wish to call attention to the inferior quality of apples produced by self-pollination, rendering them of little value except for cider or swine.

Fig. 4 of my illustrations shows a Baldwin apple cross by pollen of the yellow Bellflower, while No. 5 shows a large specimen of Baldwin self-cross, and No. 6 a small specimen of the same. The effects of cross-fertilization in increasing the size of fruits is an exceedingly interesting fact.

Prof. Munson, of the Maine Experiment Station, has found that the size of tomatoes may be quite dependent upon the amount of pollen they receive while in bloom. One receiving a large amount may be four times as large as one receiving only a small quantity. We have, doubtless, all observed that a pea-pod that has set only one or two peas is greatly dwarfed in size. What the pod is to the pea, the skin and pulp are to the apple-seeds. Facts prove, beyond the shadow of a doubt, that the cross-pollination of apples does affect not only the seed but the fruit also.

Prof. Waite gave considerable attention to the quince, but did not find so great a difference, and the fruits were as perfect and as abundant where self-fertilized as when cross. This is not as we should have expected, but we should be satisfied with the truth.

Prof. F. A. Waugh, of the Vermont Agricultural College, has been at work along this same line in a careful study of the numerous varieties of native and Japanese plums, and has found them, almost without exception, self-sterile here in the North.

In concluding his paper Mr. Waite says: "The number of insect visitors in any orchard determines to a great extent the amount of cross-pollination carried on. The pollen of the pear and apple is not produced in sufficient quantity, nor is it of the right consistency, to be carried by the wind; and the pollination of these trees is, therefore, dependent upon the activity of insects. . . . If there is no apiary in the neighborhood, therefore, each large orchardist should keep a number of colonies of bees. Honey-bees and other members of the bee-family are the best workers in cross-pollination."

His advice to fruit-growers is to plant not more than three or four rows of any one variety together, unless the variety is known to be perfectly self-fertile, and be sure there are enough bees in the neighborhood, or within two or three miles, to visit properly the blossoms, and, when possible, to favor the bees by planting in a sheltered situation, or by planting windbreaks.

I must confess a keen enjoyment in again taking up the study of this subject under the light that recent scientific investigation by careful, painstaking, and unprejudiced observers has thrown upon it. We can now see why there was such a variety of opinion on this subject in the symposium referred to. We find that, while some varieties of both apples and pears are, under favorable conditions, capable of self-fertilization, yet a majority of the various varieties of apples and pears are either wholly dependent upon insect visits, or greatly benefitted by them, in setting and maturing their fruits.

Should any wish to study this subject further, I would refer them to a paper by M. B. Waite, Assistant Pathologist, Division of Vegetable Physiology and Pathology, in the Yearbook of the Department of Agriculture for 1898, which I wish might be placed in the hands of every fruit-

grower of the land. Prof. L. R. Jones, of the Vermont Agricultural College, informs me that Mr. Waite is quite conservative, and does not overestimate the value of bees in this connection.—Gleanings in Bee-Culture. Addison Co., Vt.

Something About Honey-Extractors and Their Use.

BY C. P. DADANT.

AS I intend to buy an extractor this year, I should like to get some information in relation to it from a user's standpoint, and not from the manufacturer.

Would a machine for a 12-inch depth frame take (if a two-frame extractor) four of the six-inch extracting-frames? I may wish, at times, to extract from the brood-frames, which are standard length, and 11½ inches deep.—J. P. COBURN.

ANSWER.—Any extractor made for large frames, with a basket 13 to 13¾ by 20, will take one of the large frames in question, or two of the shallow extracting-frames. So a two-frame extractor will take four shallow frames with side-bar 6 inches deep, such as we use.

We have always used a four-frame extractor, and those that were made for us years ago were of the Excelsior pattern, then manufactured by Mr. Newman, in Chicago. These extractors took four large Quinby frames, or eight small ones, and are still in use by us. We have five of them, and altho some of them have been very much battered by rough usage and transporting in wagons with honey-barrels from one apiary to another, they are still fit to be used, tho some of them have been repaired a number of times.

They were made without any center rod, so the frames can be turned over without lifting them out, and we find that such extractors are about as convenient as the reversible, which are necessarily much more cumbersome since the frame baskets in them have to swing around in the can. The task of turning the frames over when they do not have to be lifted out, makes but little additional work, and one is able to put twice as many frames in the same space. The four-frame reversible extractors are quite expensive and cumbersome.

Economy in extractors is a mistaken saving. A farmer might as well economize in buying a plow, or a carpenter in buying a saw, or a gardener in buying a spade. The original cost of these implements is nothing compared to the amount of work they do, and an apiarist with but two colonies of bees can easily pay for his extractor in one or two years by using it judiciously.

So, in buying extractors, I would urge always to buy the very best regardless of cost. If a lubricant is needed when using it, use honey only, but be sure and wash it off in hot water as soon as the work is over. Tin will remain bright under a coat of honey, but wherever the tin is worn the iron under it will color the honey and will rust if allowed to stand any length of time. So we always wash our extractors with hot water as soon as the crop has been taken off, and dry them thoroly at once.

The extractors that are now made are of much better quality than those made previously, strength being now more considered. The apiarist may save much strain to his machine by using combs of fairly even weight in the opposite baskets of the machine. This is the principal requirement, as the overbalancing caused by a greater weight on one side will be likely to warp the baskets or the frame.

There is no need of fast turning, especially in warm weather. Ascertain the speed necessary to throw out the nectar, and regulate the motion in accordance with this. A great speed only serves to break out the comb, or to crush it against the screen.

Hancock Co., Ill.

Cellar-Wintering of Bees—Something About It.

BY G. M. DOOLITTLE.

ACORRESPONDENT writes that he is wintering his bees in the cellar for the first time this winter, and that upon going into the cellar lately he found one of the colonies roaring to quite an extent. He wishes to know what caused the roaring, and also wishes me to tell thru the columns of the American Bee Journal how a person can know when bees are wintering well in a cellar.

Answering the above as best I may, I will say that it is not an uncommon thing to find a single colony somewhat noisy upon going into the cellar, but when one is so found it is well to mark it in some way, that it may be watcht or

lookt after the next time you go in. Very probably the next time the cellar is visited he will find this colony as quiet as any, for without more light on the subject, I should expect that this colony was in the act of taking honey into the cluster.

Where bees are wintered out-of-doors they generally "break cluster" with every warm spell that comes, and go over to the outside combs of sealed honey, uncap the same, and carry quite a store of it over into the center combs surrounding the cluster, so that they may have plenty of unsealed honey near at hand to carry them over to another warm spell. This, in a measure, insures their safety from starvation should the cold hold out longer than the sealed stores immediately above them last, as they have this much in addition. In thus carrying honey the whole colony is aroused, and a merry hum is given off, the same as with colonies when being fed at any time, or when procuring nectar from the field, for, so far as I have observed, bees never move nectar from flowers, or feed on honey from feeders or the combs, but that this hum of happiness is heard.

Now and then a colony will carry honey into the cluster as above while in the cellar, doing this as often as the unsealed honey is consumed surrounding them, which would account for the roaring spoken of by the correspondent; but the majority of colonies wintered in the cellar do not usually thus carry honey. If this particular colony keeps up this roaring I should try (if it were possible to do it without disturbing other colonies) giving such colony more or less ventilation to its own hive, until I struck the right amount, when it would remain as quiet as the others.

As to the part about bees wintering well, it would be a hard matter to tell exactly about it; but that I may do the best I can, I have just been into my cellar and will tell the reader as near as I can what I did and how I found things, and I think the bees are wintering fairly well this winter.

My bee-cellar is *perfectly* dark, in fact, so dark that I have many times taken a piece of perfectly white paper in with me, a foot or more square, and after having staid so long that my eyes have become accustomed to the darkness, all they would were I to remain there 24 hours, I have taken this piece of paper and past it backward and forward before my eyes without being able to discern the least sign or shadow of it.

There are four doors leading to the cellar, all of which are shut behind me in entering one after the other, so that no disturbing ray of light or breath of cold air shall disturb the bees from their quiet slumbers, special pains being always taken that all of my movements shall be of the most quiet kind, so that no jar or loud noise shall ever greet them. Being in total darkness I stand still and listen, for in this listening we can tell more about how the bees are wintering than by any other one thing after we have struck a light. The sound I hear is like a low, faint murmur of a slight breeze in some far off tree-tops, the rumble of some train of cars miles away, or the lashing of the waves on some distant shore, which is very nearly indescribable. Occasionally this semi-stillness is broken by a bee flying out on the cellar-bottom, or some single bee giving off a "zeep, zeep," as we often hear while holding the ear close to a hive in midsummer, but the same being very much fainter and more suppress.

I have about 75 colonies in this cellar, and the above describes as well as I can all that could be heard for a time sufficient to count slowly 500, I standing perfectly still all of this time before striking any light. Should there be any mice or rats present in the cellar, their presence is more quickly detected in this way than with a light, for they are very apt to make a noise by running about among the hives, which is easily heard in the deep darkness and stillness which reigns.

If the correspondent has only a few colonies of bees in the cellar, he may be obliged to place his ear near the hives to hear their low hum, and stay half an hour or so to hear a bee fly out; while if there are 200 to 300 colonies in the cellar the hum will be louder, and bees be flying nearly all the while, if near spring, which it will be before this is published.

If the bees are in the house-cellar it will be necessary to get up before the family in the morning, so that all may be still, in order to test this part of the matter.

After listening till satisfied, I strike a match and light a paraffin or spermaceti candle, thus, not annoying the bees to nearly so great an extent as a lamp or lantern, while with it I can secure a much more satisfactory result. These candles can be procured at almost any country store, and I always advise their use in bee-cellars.

Having the light I carefully proceed along the rows of hives, looking closely for any traces of mice, for so far I have not succeeded in fully keeping mice from any beecellar. The presence of mice is detected by finding heads and abdomens of bees with the thorax gone, the same having been eaten, and by fragments of comb under the hives. If these are found buy a common choker trap, if you do not have any, and for bait use squash or pumpkin seeds, as these have an attraction for the mice beyond anything else ever used in or on a trap.

Having the mouse question settled, I next look at the bees at the bottom of the combs. Where wintering well only rows of abdomens appear, the points all standing outward, and nearly or quite motionless, unless you have been awkward in your movements so as to arouse them needlessly. Be careful not to hold the light too near, or breathe on the bees, as they are easily aroused by either of these. I sometimes raise the covers to a few hives and look in at the top of the frames, but as this can rarely be done without disturbing the bees, it is better not to do it unless some positive need requires it.

As I am about taking my departure I look at the temperature, which to-day (Feb. 28) was 46 degrees, which is as near right as any unless such should be 45 degrees. But should it go down to 42 degrees, or rise to 50 degrees, the bees would show but little difference, except that the murmur heard would be somewhat louder.

At the near approach of the time for putting bees out, the hum will become louder, they will not remain so quiet under the light from the candle, and more will go to the cellar-bottom, even when wintering in good shape.

Onondaga Co., N. Y.

Color Cards for Grading Honey, Etc.

BY WM. MUTH-RASMUSSEN.

MR. E. E. HASTY (page 38) does not seem to "catch on" to the object of color cards for classifying honey. Comb honey is clast as white, light amber, amber and dark. By these designations it is quoted in the various markets. The classification applies only to the color of the honey, and has nothing to do with the whiteness, greasiness, evenness, fullness, or any other external feature of the comb.

When I am grading and packing my honey, it is of importance to me that my grade marks shall be correct and acceptable in any market where the honey may go. If part of my honey is called light amber in one market, and amber in another; and another part of it is called amber and dark in different markets, I never know how I stand, or what I may expect to get for my honey crop. Hence, the necessity of having a definite standard to go by.

If we could always be sure of the source of the honey, we might designate it as White Clover, Basswood, Alfalfa, Sage, Buckwheat, etc.; but this is not always practicable, particularly with the colored honeys. The classification should be uniform for the whole country, so that a case markt "Amber" by me will be accepted and paid for as amber, whether it is sold in San Francisco, Chicago, or New York, and not knocked down as "Dark" after it leaves my hands and control. If customers prefer dark honey in a white comb, the correct grading and classification is just what will enable them to get what they want with the least trouble.

WHAT MAKES A LAYING WORKER?

To this question (page 39) Dr. Miller gives his usual answer. Allow me to advance a theory in this regard. The nurse-bees are governed in their activity partly by the temperature and partly by the amount of nectar and pollen brought in by the field-workers. It has been said that the queen is furnished with a special, prepared food, which stimulates her reproductive organs and causes her to lay. According as this food is furnished in greater or lesser quantities, the egg-laying is increased or diminished. When this queen-food is entirely withheld, the egg-laying ceases for the time being.

I believe that all worker-bees are capable of laying at some time of their existence, if not thru the whole of their adult life. Under normal conditions the queen-food is never offered to worker-bees, but when a colony is queenless and anxious for brood, may not the nurse-bees select such workers as in their judgment are most capable of egg-laying and furnish them with queen-food? and may not this queen-food have the same stimulative effect on the dormant

and defective organs of these workers as it has on the queen? "I don't know," but I think so.

REMINISCENCES—HONEY-EXTRACTORS.

In Gleanings in Bee-Culture is a description of the Peabody honey-extractor—the first extractor made and sold in this country—together with illustrations of the machine and its inventor. How this brings up memories of olden times, when Wagner, Langstroth, Quinby, Grimm, Novice, Baldrige, Heddon, Argo, and many others, more or less unknown to the present generation, used to write for the American Bee Journal.

In the spring of 1871 I bought my first extractor of Mr. Peabody, and, when sending it, he wrote: "I have just received an order for another extractor from California." As far as I am aware, I was the first bee-keeper on the Pacific Coast to own and operate a honey-extractor. If any one preceded me, let him arise and claim the priority.

Previous to that time all liquid honey was here produced by the sun-extractor, or, as we called it, the "sun-strainer." The first sun-strainer I worked with had a capacity of a ton on a hot day. That was in Southern California.

Inyo Co., Calif.

NO. 3.—COMB HONEY PRODUCTION.

Spreading Brood—Encouraging Breeding—Strengthening Weak Colonies.

BY R. C. AIKIN.

THE preceding article closed with my method of spreading brood by putting the combs back end foremost, *i. e.*, putting the end of the comb having brood in it to the back of the hive, and the honey end to the front. The same thing may be practiced by simply turning the entire brood-chamber half around, but of course this can only be done with hives having loose bottoms and the entrance in the bottom-board.

To thus change the position of the brood is a splendid way to get the combs full of brood from end to end. It is the nature of the bees to cluster near the entrance, *generally* right at the entrance, and this results in the brood-nest being close to the front of the hive. This rule will be more nearly universal in sunny climes, and where the hives face the sun. To face them north would cause very many colonies to start breeding at the back, but simply because there they find the most heat and the driest part of the hive. Also to face east or west will cause many to start at the side, but in this case the brood will usually be nearest the entrance end.

After the starting of the brood-nest at the very beginning, the way it is spread thereafter depends upon the location of the entrance, in the early spring spreading both toward the entrance and toward the warm side; but once the colony becomes fairly strong, then mainly toward the entrance. If the first breeding of the season has been about the center of the front end, they will spread crosswise of the combs, and have brood in almost, if not quite, every comb, while there is a lot of the back ends free of brood.

Following these ideas I reverse the order when a colony has fairly started, so as to have the equivalent of 1½ to 3 combs of brood, even with less than that if the weather is warm and the bees seem able to guard the entrance so far from the breeding cluster. This plan gets the combs filled with brood from end to end, and while we get no less brood—probably more—it is in *fewer combs*. It surely encourages breeding, for the bees will stretch the cluster to the front to guard the exit, thus taking all that can be spared from the brood, and the queen, finding bees all over the combs, and the honey being cleared from the part of the comb near to the front, occupies with eggs. It is nice when I want to contract a brood-nest by putting in a dummy, to find 6 or 8 combs of brood *in 6 or 8* and not in 10 combs.

I also make use of the same idea to stimulate breeding—I reverse combs having the back ends full of honey and the fronts empty, when the bees uncap and move the honey back. If a colony is made to handle honey, and have much in their sacs, they feed the queen and brood well, and we gain much the same effect on breeding as if they gathered from the fields.

The effect of these manipulations will be by far more noticeable if there be no gathering from the fields. If nectar is being brought in of course we lose the effect of the

bees handling their old stores, but shifting the brood has its effect under either condition, and is well worth the trouble to accomplish it. I got this idea several years ago, and have largely practiced it ever since. If a colony had the fronts of all their combs filled with brood, and the backs of all, or nearly all, empty, when the honey-flow starts the first stored goes right to those back ends; but just turn the hive at that time and get the brood to the back, and they will store in sections rather than put honey so close to the entrance, and between it and the brood.

To have empty comb next the entrance, and the brood back of it helps quite materially to lessen swarming. I know from experience that *dry comb* placed below and forward of the brood *just at the beginning* of the flow, will very largely control swarming when running for extracted honey. I have practiced it. Of course, this is not practical in producing comb honey, but in a comb-honey colony, if there must be empty comb in the brood-chamber when the honey-flow starts, have it as much as possible between the brood and the entrance. Thus arranged, much of the honey that would have been put in this comb had it been back, will be put above in sections.

Referring again to those colonies that failed to get a good start in early spring, and so are not able to get to proper strength when the flow begins, it is well to help such just as soon as others are strong enough to spare help for them. Remember that the weak colony is not in need of brood, it is *bees* they want. Give them bees and the queen will very soon get the brood. The queen has simply been held back because she had not workers enough to care for the brood, and when she has the bees, is ready to supply the eggs. I suspect that many a good queen has been condemned (blindly) because she did not have a good, strong colony when she was not at fault at all.

I say give the weak colony *bees*. My method of giving the bees varies according to circumstances. Usually I find and give a comb, from some strong colony, that has a goodly patch of brood from which the bees are *just emerging*. There should be bees enough emerge in a short time after the comb is given to care for the rest of the brood in that very comb and keep it from chilling, for the trouble with the colony is that it has not bees enough to care for what the queen can already supply. In two or three days the larger part of this ripe brood is hatched, and the queen is supplying the vacated cells with eggs.

Another way is to bring bees from an out-yard, if such you have, bringing them in a wire cage and hiving them in just at dark or nearly so. They should be sprinkled with sweetened water, or in some way made to fill their sacs so that *all go in loaded*. If the weather is cool, hive them in both full of honey and so nearly chilled that they are glad to get in out of the cold, thus the danger of having the queen killed is reduced to the minimum. In putting strange bees into a colony always have both those added and those in the hive being added to, full of honey. Also try as much as possible to add young bees; old ones will be far more likely to kill the queen.

In localities where there is little or no honey brought in before the main harvest begins, it is a good plan to try to have each colony almost out of stores just the last few days—say a week to 10 days—before the flow begins. This keeps down the disposition to get the swarming-fever, and it is a great gain to have all come right up to the flow without thought of swarming.

If, however, there is a light flow for some days or weeks just prior to the main flow, then it is almost out of the question to have that "semi-starvation" condition, and so much harder to keep the swarming under control. The next best thing to the short-stores plan is to have adjustable brood-chambers so that they can have plenty of comb and ventilation, the surplus comb to be removed at once when honey is coming in freely. The difficulty with the extra-comb supply is to keep the queen from spreading her brood too much; not getting too much of it, but getting it *scattered* into too many combs. Larimer Co., Colo.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription *a full year in advance*, we will mail you a Wood Binder free—if you will mention it.

The Wild Aster in North Carolina.

BY W. H. PRIDGEN.

IN reading Mr. Schmidt's excellent description of wild aster, on page 785 (1899), I was struck with what I suppose is another peculiarity. Judging from the date of blooming in Ohio compared with that of this place, it begins North as soon as the right atmospheric conditions prevail, and keeps pace with those conditions southward, altho the young shoots for next year's growth are now forming around the old stems at the ground, and the further South the longer the season for development.

Here it begins to bloom in September and lasts until late in November, varying with the seasons. Last year our bees commenced storing rapidly Oct. 5, and continued a month before there was any evidence of a hold up, except from an occasional rainy day, the peculiar odor referred to being very pronounced.

When the flow from it is light, the honey sometimes has a strong or bitter flavor; at other times it is good, and especially if extracted and allowed to candy, which it does quickly.

It flourishes best on moderately dry alluvial soils, or good uplands that are cultivated every third year. The first year after the land is cultivated, it is thinly set, but the bunches present seem to attain their full growth, while the second year nearly everything else is crowded out, and while in bloom it presents a field of whiteness.

Where the conditions are the same, some plants bloom much earlier than others, and the time of blooming is hastened or delayed by the different conditions or kinds of soils, and the surroundings also, which supplies a prolonged, continuous flow from this source.

The cultivation of only a small plot of land two years in succession, altho it may be surrounded by or in a lot, treated as above described, throws matters out of joint, and the spot can be detected for several years, even if so treated only once, and afterwards remains unbroken for two years. This is true, altho one year's cultivation apparently destroys it root and branch.

It furnishes excellent early grazing for cattle or sheep, and is seldom seen on pasture lands. On roadsides and in fence-corners, waste-places, etc., where the land is neither broken nor continuous grazing allowed, it thrives for years, possibly from the same roots, but finally yields to the laws of nature, and gives place to something else.

Years ago I regretted to see frost during the time of its bloom, but I have learned that light frosts do not injure it in the least, and that heavy dews and cool nights are conducive to the best yields, while hot, dry or windy weather has the reverse effect.

Like other plants, it sometimes fails to yield nectar at all, but can usually be counted on for at least a little help. I think many of my colonies stored at least 50 pounds each from it the past season.

Warren Co. N. C.

York's Honey Calendar for 1900 is a 16-page pamphlet especially gotten up to create a demand for honey among should-be consumers. The forepart was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample free; 25 copies for 30 cents; 50 for 50 cents; 100 for 90 cents; 250 for \$2.00; 500 for \$3.50. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

"**The Hum of the Bees in the Apple-Tree Bloom**" is the name of the new bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us *one new* yearly subscription to the American Bee Journal at \$1.00.

CONVENTION PROCEEDINGS

Report of the Colorado State Convention.

(Continued from page 150.)

Prof. Gillette then exhibited some sections. One contained a starter of foundation colored by lampblack, removed from the bees when they were just beginning to draw it out. It showed pellets of wax added by the bees. Another sample, containing lampblack foundation extending half-way down, showed that the bees transferred wax from the upper to the lower portion. Another sample containing a full sheet of black foundation showed that the bees had transferred wax from it to the corners of the wood. Samples of wax molded in test-tubes were also shown, showing the amount of wax in pound sections of honey under different conditions. (The exact weights were not obtained for these notes.)

SPRING MANAGEMENT OF BEES FOR COMB HONEY.

Mr. Lyon—Wintering comes first. I can carry them thru the spring better than thru the winter. They get weak in the spring. Shall we double weak colonies or not? I have done it only in one way, by taking one hive to another, and uniting. With me, it has been a terrible failure. In two or three weeks they don't seem to be stronger than before. There are other questions. Shall we change brood from the strong to the weak? Should we spread brood in Colorado, or turn the combs end for end? Should the hive-entrance be left open in winter as in summer?

Mr. Pease—I have sometimes tried spreading brood, and thought it beneficial, but can not say certainly.

H. Rauchfuss—I used to spread brood to double up, and to draw from the strong to give to the weak, but do so no more. It gets the brood-nest out of the proper shape. The bees make the colony, not the queen. You can give the queen of a weak colony three pounds of bees, and you will be surprised at the amount of brood you will get.

Mr. Martin—Instead of reversing one frame at a time, have you tried reversing the whole hive end for end?

H. Rauchfuss—I have thought of it, but never tried it.

Mr. Martin—I tried reversing in this way, as the bees consume the honey in the front end first. I think it was a success. It causes them to consume more honey and to convert the honey into brood.

Mr. Moon—I generally leave them alone. They increase faster than they can cover the brood. I give them plenty to eat, and consider that the most I can do to stimulate them. They work more after being fed; they seem to "rustle" for pollen better. The cold nights here make it unadvisable to spread brood.

J. B. Adams—I don't spread brood. I would reverse the whole hive, or all the frames. If part is reversed, the bees can't follow toward the front fast enough to cover it.

F. Rauchfuss—When do you feed, Mr. Moon?

Mr. Moon—I have an excellent location for early spring, but there is nothing between the early sources and alfalfa. I feed in that interval. That is right after fruit-bloom, about the middle of May to the 20th. I feed bran early so as to prevent the bees from becoming attached to places where they will bother the neighbors.

J. B. Adams—Does it pay to feed a colony already well stocked?

Mr. Moon—Yes, I believe it pays to feed all I can get for stimulation.

Mr. Lyon—I believe in feeding. I wouldn't run a yard without feeding. Some try too early and make a failure. Unless these things are done at the right time, they should be left alone. Above all, use plenty of salt and carbolic acid. I never open a hive without an atomizer. My plan may not be a success with you, and yours not a perfect success with me. You are all against spreading brood. I take the other stand. If you spread brood with a handful of bees, you do more harm than good. I go to a strong colony, take a frame of brood with as many bees as possible, and make the weak colony strong, and after a certain time take another. It does not do harm if done judiciously at the right time. If the weather is cold, I avoid it; if right, then I commence spreading.

Mr. Harris—I took a comb from a strong to a weak colony last spring; and think otherwise I would have lost it. It made a booming colony. I think it well to equalize.

Mr. Lyon—Don't some of you try this and blame me. Be sure the strong colony is in the right condition. These things are very misleading when not given in a prepared essay.

H. Rauchfuss—I want the bees. I don't want the brood so much. The bees go back to the old stand. I think just changing the positions of the weak and the strong colony will accomplish this without spreading.

Mr. Martin—I think Mr. Lyon refers to brood very nearly ready to hatch, with very little unsealed, and in that case I know the plan is very successful.

Mr. Brock—I think the bees know more about the brood-nest than I do. When the weather is warm I assist the weak colonies with combs and brood.

Mr. Pease—Our hives are *not* in the natural shape.

Mr. Rhodes—I began early one season to feed the bees. I had no honey, but fed sugar. The result was I had them very strong at the flow. From seven or eight colonies I had a surplus of 1,000 pounds, while my neighbor with 100 colonies didn't have enough to spread over a buckwheat cake. I think it better to feed 21 days or a month before the flow, as the flow comes June 15.

DRUG TREATMENT OF FOUL BROOD.

J. B. Adams—Mr. Tracy did not have a case of foul brood when a foul-broody apiary within a quarter of a mile was robbed out entirely. He said he read in *Gleanings in Bee-Culture* about carbolic acid and salt. He would fill the cells along the top-bars by means of an oil-can, and headed off many a case of foul brood. Don't attempt to cure with this. I want to emphasize this. The proportion is one part of carbolic acid to 300 parts of water, with a heaping tablespoonful of salt to every pint of the mixture. Shake well before using. It is best to buy a 5-pound can of the acid.

Mr. Brock—I have used the mixture a number of years. I add 1½ teaspoonfuls of the acid to a gallon of water, with a handful of salt, and apply with a whisk-broom.

Mr. Martin—Was this treatment used the year the bees died off so?

H. Rauchfuss—Yes. I have tried it a good many different ways the last four years, tho not for foul brood.

F. Rauchfuss—The instance Mr. Adams quotes can also be paralleled when nothing of the kind was done. I kept bees a number of years near foul brood, but my bees did not get it.

Mr. Root—I tried carbolic acid in the proportion of 1 to 500 in pure cultures, without killing the germs. I tried a 1 to 300 solution, but that did not kill them. A 1 to 200 solution did. I sprayed all the hives without doing much good. Cheshire recommends feeding carbolic acid in syrup. Mr. Cowan recommends the same, in the proportion of 1 to 300. He thinks naphthol beta a better disinfectant. I have not tried it.

FENCE SEPARATORS AND TALL SECTIONS.

H. Rauchfuss exhibited a Danzenbaker super, with fences, in the condition in which it was after the sections of honey were removed, showing a number of brace-comb attachments to the fences. This super was the second one put on a hive. The first one that came off was filled with ordinary sections and separators, and had no brace-combs attach to the separators. The brace-combs in the Danzenbaker super were not due to crowding. The outside sections were not finished when it was removed, and another empty super was on top of it while it was being finished, so the bees had plenty of room. I used 10 of the latest Danzenbaker supers last season, and aimed to put them on the best colonies I had. All had more or less attachment to the fences. The spaces between the slats would be filled up in spots and then attach to the combs. Many of the combs themselves were built out on the cleats, beyond the edges of the sections. It is claimed that this system results in better filling of the sections. I produced 350 cases altogether, and could see no difference in filling between the plain and the ordinary kind.

Mr. Harris—I tried the fences in five or six 10-frame supers, and did not find a brace-comb on them, tho I did on others.

Pres. Aikin—I didn't get to use any this season.

Mr. Porter—I have been too busy to make experiments.

Mr. Harris—The spaces between the slats were not wide enough at first.

F. Rauchfuss—I have had no actual experience myself,

but expected to get reports in handling supplies. Owing to the shortness of the regular stock, some $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{2}$ sections were used by a few. Mrs. Booth likes them, but doesn't think of adopting them. Carl Moon thinks the same. The others have not express themselves. The main objection is they are too expensive. Even admitted that they would be cheaper, honey is sold by weight, and we have to take a correspondingly greater number of sections to make it out. There is more comb surface, therefore more foundation required. Perhaps honey would really cost a trifle more to produce in plain sections. One reason why they were not tried more here is that many have supplies left over from the previous season.

Mr. Root—It is hardly fair to compare the tall plain sections with the $4\frac{1}{4} \times 1\frac{1}{8}$. Under like conditions, if the separators are exactly the same as those used with the $4\frac{1}{4} \times 1\frac{1}{8}$ sections, that is, if plain sections are used with cleated plain separators, they will not be filled any better, because it makes no difference whether room is taken by a cleat on the separator or by the same amount of wood in the section. If $4\frac{1}{4}$ full bee-way sections, with the corners cut down, are used for comparison instead of the scallopt sections, then the conditions are exactly the same. Some think more honey is produced without separators. I don't know. But the fences are the next thing to having no separators. As to the attachment of the combs to the fences, we have had only one other such report. Attachment to plain separators also happens, but is thought rare. If any bees are inclined to attach to plain separators, those same bees might be inclined to attach to the fences. I have seen thousands of pounds of honey in plain sections in New York, and saw no burr-combs attach. But the 4×5 sections can hardly be compared with the $4\frac{1}{4}$ square section. A plain section equally as well filled as an old-style section will appear to be better filled. I recently secured the statement of four leading commission-houses in regard to plain sections. They all preferred the plain sections because they appeared fuller.

F. Rauchfuss—In Mesa County 700 of these plain-section supers were sold last year.

J. B. Adams—I tried one super of the 4×5 sections. They were not fastened to the fences.

Mr. Root—A good many have the impression that the comb is even with the wood in plain sections, but it is not so. The wood does project a little. A super with fences on a weak colony is not filled so soon as one with tight separators. Where the colonies are strong we have had a good many reports that the sections are entered sooner. Other reports have been just the reverse. In regard to the fastening of the combs to the cleats, the comb is more apt to be fastened to a narrow cleat.

Pres. Aikin—My opinion was once asked about the thickness of the cleats. I said $2/12$ of an inch was too thick. This is the confirmation. Bees sometimes work out to the cleats, and then round the comb out. For years I have been dissatisfied with the scallopt section. I have used sections with bee-ways clear across. The combs were always nicely finished. I would prefer the plain section scallopt out a little. I do feel favorably toward the fences. I was experimenting with fences before Mr. Root took hold of them. When he took hold then I quit. I thought I would let others do the experimenting.

Mr. Root—The New York bee-keepers claim that the corners of a comb are better filled out in a notched section. In a scallopt section the combs are rounding at the corners.

Mr. Martin—Would it justify the extra amount of labor to use the fences?

□ Mr. Root—I have seen fences that had been in use nine years at Mr. Morton's. All they need is a little scraping across the cleats and along the slats.

□ F. Rauchfuss—Mr. Root, have you any reports of the Hyde-Scholl separator?

Mr. Root—We have had one report. If made of wood it is not durable. Even if it is of tin it is a flimsy affair.

(Continued next week.)

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses, when writing us on other matters.

The Premiums offered on page 173 are well worth working for. Look at them.

The Amount of comb occupied with brood just before the flow commences is the right number of frames to have in the brood-chamber during the flow.—DOOLITTLE, in Gleanings in Bee-Culture.

Get Colonies Strong for the Main Harvest is the rule with L. Stachelhaus. His experience, as well as that of many others, is that while a colony of 20,000 bees may store no surplus, one of 30,000 may store 20 pounds, and one of 60,000 may store not only 40 pounds, but 120 or more. But he wants as few bees as possible at a time when bees are consumers only.—Bee-Keepers' Review.

Introduction of Queens.—M. Giraud-Pabou reports in L'Apiculteur that he introduces queens by rolling the queen in honey, then placing her between two combs well covered with bees. The colony must be queenless from one to nine days. Of 80 laying queens thus introduced, only three were refused. Virgins are introduced in the same way, only the colony must be queenless at least two days. Of 68 virgins thus introduced, 55 were accepted. This method of introduction was much in vogue years ago, but was not always considered successful.

Cold With and Without Wind.—In Gleanings in Bee-Culture the point is emphasized that 10 degrees above zero may be worse than 20 degrees below without wind. Dr. Miller thinks Marengo, with its all-day-long prairie winds, is a worse place for wintering than many places away North. Editor Root says:

"If this is true, it behooves us to put up windbreaks in the shape of high board fences or evergreen trees. It will be remembered that the winter losses out-doors at Medina have been very low—scarcely ever exceeding 5 percent, and usually about 2 percent. Our apiary is shielded on the north and west sides by a solid phalanx of evergreen trees from 20 to 30 feet high; and on the east and south by brick buildings and lumber-piles. The result is, that on the days of our highest winds there is comparative quiet in the apiary. True it is, there is a great roar of the wind from without, but there are only slight air currents within. A wind-break of evergreens does not cost much, and is perpetual after it is once put down. One consisting of a barn and out-buildings, with an occasional stretch of a board fence on the north and west sides, would be equally effective; and I am satisfied that the slight expense of maintaining the fence or trees would be made up in a few years' time, ten times over, in the saving of many colonies of bees, and preventing others from getting so weak that they are practically useless for honey-production."

Cameras for Taking Half-Tone Pictures.—At first blush, that hardly seems to be a subject germane to bee-keeping, but really it has come to be decidedly so. Pictures add no little to the pleasure of reading bee-papers, and sometimes a glance at an illustration gives one a better idea of some implement than a whole column of reading-matter. A late number of the Bee-Keepers' Review gave rather a discouraging view to those who had kodaks, which are so common, saying their pictures are passably sharp, but that is all, and to get really fine work one must have an adjustable focus. The following from Editor Root, of Gleanings in Bee-Culture, is reassuring to the kodak fiend:

"Bro. Hutchinson seems to have gotten a wrong impression of a kodak. Only a few of the cameras bearing that name are of the fixt focus type; but their pictures are very sharp—much better than 'passably sharp.' But those of the adjustable-focus type of the same grade, and with the same stop, give no better results. There are high-grade kodaks of both kinds, and either gives the same sharpness of detail. Why, the smallest pocket size of fixt focus with a picture $1\frac{1}{2} \times 2$ will make a picture so sharp that it can be enlarged to 10×12 inches. The sharpness of detail is dependent, not upon the fixt or adjustable focus, but upon the price paid. All instruments bearing the name 'Kodak' are of the highest grade."

VOL. 40.

MARCH 15, 1900.

NO. 11.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

Improvement in Bees is discussed in the Bee-Keepers' Review by L. A. Aspinwall, in a way that shows familiarity with the subject. For six years he has been laboring for improvement, and hardly realized what improvement he had made until an absconding swarm of Italians came to him and gave him a chance for comparison. He supersedes the queens of all vindictive colonies; of those that build much brace-comb; also queens that are unprolific. Selections are made from the best honey-gathering colonies; and size, not only of workers, but also of drones and queens is by no means neglected. In working for size, the drones, rather than the workers, are considered; and from one queen which produces extra-large drones he has taken daughters to re-queen nearly a fourth of his apiary. This gives a better chance for the fertilization of young queens.

Sweet Clover for Forage and Honey.—Prof. Thos. Shaw, one of the leading writers and experts on agricultural topics, both in Canada and the United States, has recently written a new book on "Forage Crops Other than Grass," in which he has this to say about sweet clover:

Sweet clover (*Melilotus alba*) is so named, doubtless, from the fragrance of the odor which characterizes it. It is also frequently called Bokhara clover. The two species, *Melilotus alba* and yellow sweet clover (*Melilotus officinalis*)

are closely allied, but the blossom of the former is light-colored, while that of the latter is yellow.

Sweet clover is a strong, vigorous-growing biennial. It is branchy and upright in its habit of growth. It is one of the most hardy plants of the clover family. When once firmly rooted it has great power to withstand drouth and heat, and it can also endure low temperature. Being a ravenous feeder it is able to maintain itself in soils too poor to sustain other species of the clover family. The writer has succeeded in growing sweet clover on a vacant lot in St. Paul, from which several feet of the surface soil has been removed, inasmuch that only sand and gravel remained. Moreover, it is a legume, and one which has much power to renovate soils. A plant, therefore, which is possess of such powers should not be looked upon as worthless. That it is so is the popular idea. It has even been looked upon as a weed, and some countries and States have included sweet clover in the list of proscribed noxious weeds.

But sweet clover has been grown to some extent to provide hay for live stock in the cured form, and also to provide pasture. And it has been grown to furnish food for bees when it is in bloom. It has been grown for all these uses in the South, more particularly in the States of the lower Mississippi basin. For providing hay it is not very suitable, for the reasons, first, that it is woody and coarse in character; second, that it is difficult to cure; and, third, that it is not much relished by live stock. They do not care to eat it when they can get a sufficiency of other food, as corn, sorghum, or other clovers. As a food for bees it is excellent; and if a part of the plot or field is cut before coming into bloom, the season of bloom will be much prolonged. It is also sown along the sloping embankments and the sides of railway cuttings. The object sought is to prevent these from washing, and it has proved highly serviceable for the purpose.

Sweet clover has not been much grown for pasture, but for such a use it may yet prove to be of value. When sheep have access to a variety of grasses they will probably pass sweet clover by, even when it is young and tender. But if confined to such a pasture when it first begins to grow, they would soon begin to crop it down. To force animals thus to eat food under constraint is not good for them; but thus it is that in some instances sheep have to be confined on rape, and forced to eat it thru sheer hunger. In a short time they become very fond of the rape. So likewise they may be taught to eat sweet clover. Of course, where other and better kinds of clover will grow, it would not be wise to trouble with sweet clover. But in the semi-arid belt east of the Rocky Mountains, and in the poor sandy soils of the South, it may yet be found that an important mission awaits this plant; first, in growing a crop that will renovate the soil when plowed under, and increase its power to hold moisture; second, in furnishing food for bees; and, third, in providing pasture. Hay should be sought from it the first year rather than the second.

Sweet clover can be sown only in the spring or summer in very cold latitudes; but in those that are mild it can be sown in the autumn or spring, preferably the former. Usually not less than 15 pounds of the seed is sown to the acre. In the South it is frequently sown on the surface of stubble land after the crop has been harvested; and when thus sown it is simply covered by the harrow. If sweet clover is kept from blossoming the land will soon be freed from it when it is so desired.

We are glad to be able to present the foregoing concerning the varied values of sweet clover from so high an authority as Prof. Shaw. It will pay to show it to those who are foolishly against sweet clover.

Fool Stories About Bees and Honey.—Some time ago one of our subscribers sent us the following clipping from the Minneapolis Journal, desiring our opinion concerning it:

CORRUPTING THE BEES—TAUGHT TO SWINDLE.
ONCE HAVING MADE GLUCOSE HONEY, THEY ARE TOO LAZY TO HUNT FLOWERS.

According to information which has reached State Dairy and Food Commissioner Bowler, the dear little busy bees, belonging to some of the bee-sharps of the country, have been made the unwitting means of perpetrating a horrible fraud upon honey-lovers. Of late years it appears that economical bee-keepers have discovered a way to keep the bees from taking their annual winter vacation. The bees are provided with warm rooms in which maple syrup, and

cane-sugar are spread out over unleavened corn-bread. The innocent bees feed upon this saccharine combination and proceed to produce glucose honey, tho put up in regular combs. The deception is complete, but the honey is about as unlike the real article made from flowers as a wholly artificial imitation. Honey produced in this way is very cheap as to cost of production, when it is considered that the bees would otherwise be idle. The price of honey is also higher in the winter than at other times.

Major Bowler said yesterday that he had decided that such honey was adulterated honey. He says, however, that he will not prosecute the bees, considering them as innocent accomplices in a fraud which must be charged to their owners.

There will not be any difficulty in making prosecutions so far as the law is concerned, for it defines pure honey to be made by bees from plants.

The bees consider this manner of making honey such a snap that once they have been thoroly initiated they are of no more use for honest toil in the fields. Their extractors lose their cunning, and, remembering the luxurious affluence of winter, they refuse to buzz over the countryside and take infinite pains to get a drop of honey.

The above is a fair sample of what may be evolved out of the brain of a wild-eyed reporter who is hard up for something to fill space. And there will be plenty of people to believe that a colony of bees can be got to spend the whole winter making glucose honey out of maple and cane sugar, and that fortunes can be made thereby. What next will be started, and to what extent a strain may be put upon the gullibility of the public, it is hard to conjecture. Perhaps something like the following imaginative tale may be expected to go the rounds:

A NOVEL INDUSTRY.

THE BEES' OCCUPATION AT AN END—A NEW FORCE IN NATURE.

In the parish of Alfalita, on the boundary line between Georgia and Mississippi, just north of the lovely lake of Atchaminoka, is an exquisite little valley, so hemmed in on all sides by gently sloping hills that no hint of its existence is seen till one comes suddenly upon it. In the center of this beautiful valley rises an imposing structure, or rather a series of imposing structures, with a grand central tower. What transpires within these walls has been for generations a profound mystery.

From time to time great hogsheads have been brought in the dead of night on the little spur of railroad that shoots out from the Great Southern and Inland railroad system, and from time to time also such hogsheads have been seen loading up on the cars run alongside one of the outside walls, but well-armed guards have carefully prevented too close scrutiny of the incoming or outgoing vessels. The employees, whatever may have been their occupation, were never seen outside the walls. At intervals some negro was known to go inside, but what became of him afterwards, whether buried inside at the end of his days, or spirited to some other region, was never known.

Ambitious reporters had tried, but tried in vain, to obtain entrance. At length one of our most skillful investigators, thanks to features not altogether unlike those of an African, and to a proper application of burnt cork, made successful application for employment. How he safely escaped, if safely it could be called, and how he managed to get entire information as to all points, does not come within the scope of the chronicles. The facts, in as few words as possible, are sufficient.

The contents of the hogsheads that make their nocturnal entry are nothing more nor less than the crude sap of sugar-cane gathered from thousands of acres of growing cane. Pneumatic pumps at various points in the outer circuit of buildings send a constant stream of the raw sap toward the central building. In the very midst of this, to which none but a select few of the most trusted employees are admitted, stands a creation unlike anything to be seen elsewhere in the whole wide world. And yet it is very like what may be seen in any bee-hive, for it is simply an immense bee, apparently endowed with every attribute of life. Its wings are constantly in motion with a gentle fanning action; at intervals one after another of its six feet are lifted and set down again, and the head sways alternately from one side to another, as if investigating its surroundings. In color, form, proportion, there is really nothing to distinguish it from one of a thousand of the busy denizens

of the hive, the only point of difference being its size. One of its dimensions being given, it is easy for one familiar with the form of a bee to estimate the others. From the extreme limit of its antennae to the tip of its tail is 117 feet!

Not less remarkable, indeed much more remarkable, is the inner construction. All that is found inside a honey-bee is here found, only on a colossal scale. The various streams of the cane sap converge into one huge stream which enters the mouth of the bee, or rather enters a large aperture in its tongue, and out of another aperture nearer the base of the tongue emerges the stream after having ramified thru all the minute vessels of the great body. The difference is that what made its entrance as crude sap makes its exit as an excellent quality of the finest liquid honey. One would naturally suppose that some cunningly devised chemicals had produced the remarkable change. Nothing of the kind. The entire establishment is innocent of drugs of all kinds.

A force in Nature is at work that has elsewhere escaped observation. It is well known to scientists that a chemical change may take place in some cases because of the presence of another material, this latter material remaining itself unchanged. In the present case there seems to be a change made not in any chemical way, but by some occult power by which the *form* of the huge bee so affects the lifeless liquid that the entering sap emerges as nectar fit for the gods.

In vain may scientists say no such force is impossible; there is the crude sap, there is the verisimilitude of a gigantic bee, and there is the honey. Facts are stubborn things.

In the light of what is here divulged, it need no longer be a matter of wonder why liquid honey, or that which in trade circles is called the extract of honey, is always sold at a lower price than the genuine article made by the bees and stored in honeycombs.

And so we might go on "spinning yarns" about something that doesn't exist, similar to those ground out by the average newspaper reporter. No doubt if the foregoing piece of apiarian fiction appeared in the Chicago Record the majority of its readers would not only half believe it, but would soon tell it as a fact, and it would be a difficult matter to convince many of them that it was all a rattle-brain story.

But such are newspaper life and stories, and all bee-keepers can do is to keep on trying to spread and uphold the truth regardless of what others do or say.

Tin and Wood Packages for Honey were discussed in a lively manner at the Wisconsin convention, the discussion following our paper on "Honey—From the Hive to the Table," which will appear in these columns later. The points in the discussion are well summed up by W. Z. Hutchinson, in the Country Gentleman, as follows:

"For retailing honey, selling it to grocers, the jacketed tin cans, two in a case, each can holding 60 pounds, possess decided advantages. They seldom leak, unless carelessly punctured by a nail when nailing on the jacket. If a can does leak, or meet with an accident, the loss is slight compared to what occurs when a barrel 'loses its head.' There is no loss from 'soakage,' as is sometimes the case with wooden packages. Honey in a can is easily liquefied. The greatest objection to tin cans is their cost. A barrel holding 350 pounds of honey can be bought for 80 cents. The same amount of honey put in tin cans would call for an expenditure of about \$2.25 for packages. In shipping a large crop, this is a big item.

"Barrels are more easily handled, as they can be rolled, while cans must be lifted and carried, or else shoved. Manufacturers, and others using honey in large quantities, usually prefer it in barrels, as they have arrangements for handling it to advantage in such packages, and they wish to avoid the expense of tin packages. Care is needed in securing the right kind of barrels—that they are made by a man who understands his business. When it was proposed to wax the barrels, the reply was: 'Wax your cooper instead of the barrels.' However, the waxing of barrels, or rather the coating of them on the inside with paraffin, is worthy of consideration, if, as some asserted, a barrel will absorb from five to ten pounds of honey, which must be lost by the producer. A barrel can be coated on the inside with paraffin at a cost of 10 cents—much less if there is any way of heating the barrel."

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Wiring Brood-Frames—Sweet Clover.

I have just bought the dovetailed hive with foundation starters one inch wide in the brood-frames, the frames being pierced ready for wire, but no wire in them.

1. Will it be necessary for me to wire these frames before putting bees in the hives?
2. What is the color of the bloom, and what is the shape of the stalk of the sweet clover?
3. Does the sweet clover grow and produce honey on the east slope of the Blue Ridge mountains? VA.

ANSWERS.—1. If you use full sheets of foundation, unless the foundation be unnecessarily heavy it will be likely to stretch and sag if you have no wires.

2. There are two kinds, one with white and the other with yellow blossoms. The stalk is round.

3. I have no positive knowledge as to that particular spot; but I doubt that there's a place in the State of Virginia where sweet clover will fail to grow and yield honey.

Wooden Sticks Instead of Wiring Foundation.

The more I manipulate frames, the more I realize the importance of having the comb come to the bottom of the frame.

1. Do you put all of the five foundation-sticks on one side of the sheet of foundation, or alternate them on both sides?

2. What detrimental results may I expect if sticks 1-12 or 1-10 inch square are used, in place of 1-16 inch, as you say yours are? MICHIGAN.

ANSWERS.—1. All on one side. Much easier done, and just as good.

2. It would probably make no great difference. The only thing would be just so much unnecessary wood, and a little more perceptible ridge over the sticks when brood was sealed. It would probably be easier to make the larger sticks if you make them by hand. Manufacturers who have slicing machines with which they slice separators can slice the sticks quite cheaply.

Prevention of Swarming.

The bee-fever again demonstrated its supremacy over environments, when in my case, June 10, 1899, I bought a strong colony of Italian bees and placed them in an attic room of a house in the middle of a busy city, with electric cars passing every 15 minutes during the day.

I placed the hive beneath a sky-light partly open. The room is plastered and that with ventilation from a small end window prevents undue heat.

This colony was ruined in moving—smothered, queen lost, and all but about a pint of bees which I carefully nursed and furnished with a new queen.

During this time I consulted my A B C of Bee-Culture with great assiduity, and thereby saved the colony from being robbed out by another, which I bought meanwhile.

Colony No. 2, by the way, must have contracted the swarming-fever prior to my taking them, for no sooner had I gotten them home than they swarmed (June 24) in my absence. Of course, this swarming of bees in a city is very embarrassing to the owner, to say the least, not to mention the opinions of neighbors; so, since then, my main object in the study of bee-literature has been with the view to dis-

covering some means of checking swarming, and to the getting of the most honey (increase not desired.)

I subscribed for the American Bee Journal thru whose guidance I have so far safely wintered the two colonies, altho I had to feed sugar last fall.

At present the bees are quiet and healthy in the attic room, from which light is excluded by curtains.

I should have stated before that the hives are the 8-frame Langstroth. After conning the Bee Journal diligently, I had about decided to try the Danzenbaker 10-frame hive, putting two bodies together and extract the honey; give plenty of ventilation below, with the entrances at each hive-body, and kill the old queen before time for swarming, according to the discussion on that point as given in the Bee Journal of Jan. 25. This was seemingly contradicted in the edition of Feb. 8, which says, "Probably no surer plan for causing swarming could be adopted."

If I use two hive-bodies and two entrances, do I need a separator or excluder between? and what plan better than the one contemplated would you advise for the coming season? MASSACHUSETTS.

ANSWER.—If you kill the old queen just before swarming season, you may be pretty sure of swarming, no matter how much room or ventilation, unless you kill all queen-cells but one nine days after swarming, in which case you would not be likely to have swarming. Or, listen for piping each evening after the eighth day, and when you hear piping destroy all cells.

Whether you use excluder between stories depends. (It may be mentioned in passing that in any case a large entrance to each story will do no little to keep down swarming.) You may allow the queen full range of the two stories, better still three stories if the colony is strong, and there will likely be no swarming. You may confine the queen to the lower story with an excluder, doing this just before the swarming season, leaving all the brood in the two upper stories and empty combs with the queen below, and you are pretty safe from swarming.

Treatment of a Laying-Worker Colony and a Colony with Drone-Laying Queen.

I think I know what you would do with a colony of bees having a laying worker, but if you had one colony with a laying worker and another with a drone-laying queen, I would like to know whether there would be any difference in your treatment of the two colonies. This is a point never touched upon in any bee-literature that I remember reading, hence the question. IOWA.

ANSWER.—Your evident belief that there is a difference as to treatment is correct. If the colony with the drone-laying queen has been in that condition a long time and is weak, then there should be no difference; break up. A colony with laying workers is generally rather weak, if not very weak, and what bees there are have past their prime; whereas the presence of a drone-laying queen may be discovered while the colony is still strong with a fair quota of young bees. In such case, kill the drone-layer and give another queen. Such a colony, you no doubt know, will accept a queen more readily than a colony with laying workers.

Sulphuring Mothy Brood-Frames.

How much sulphur should I burn in a house 6 feet square and the same height, to kill moths in brood-frames? What is the proper way to burn it to get the best results? NEW JERSEY.

ANSWER.—To kill worms in comb honey, when as yet they are tiny things, is quite a different matter from killing worms of full size in brood-combs. My experience has been that the latter is a very difficult matter, and I don't know how much sulphur would make it a success. I would try about two pounds as a starter, closing up everything as tight as possible, and leaving it closed for 24 hours after starting the fire. If that should not prove successful, you might try a stiffer dose. Take a dish of almost any kind, and put ashes in it. In this set another dish to contain the sulphur, and lay a hot iron or live coals on it. Unless the number of combs is considerable, it may be well to go over them by hand and pick out the biggest worms. But I wouldn't fool with sulphur in cold weather; put the combs where they'll freeze, and that will end the worms.

Root's Column

Many bee-keepers now using the 4¼x4¼ inch bee-way sections in the dovetailed hives want to try Root's plain sections and fences, but do not like to have any other size than the 4¼x4¼. For such we recommend the hive shown below :

Root's AE64P/8 Hive.

These hives are fully described in our catalog and shown in Fig. 303. We have sold more of these hives than any other style the past season.

These hives may be ordered of any of the following dealers :

- The A. I. Root Co., 1024 Mississippi Street, St. Paul, Minn.
- The A. I. Root Co., Mechanic Falls, Maine.
- The A. I. Root Co., 10 Vine Street, Philadelphia, Pa.
- The A. I. Root Co., Syracuse, N. Y.
- George W. York & Co., 118 Michigan St., Chicago, Ill.
- Vickery Bros., Evansville, Ill.
- Walter S. Pouder, 512 Mass. Avenue, Indianapolis, Ind.
- Jos. Nysewander, Des Moines, Iowa.
- W. W. Cary, Lyonsville, Mass.
- M. H. Hunt & Son, Bell Branch, Wayne Co., Mich.
- Geo. E. Hilton, Fremont, Mich.
- John Nebel & Son, High Hill, Mo.
- C. H. W. Weber, 2146 Central Avenue, Cincinnati, Ohio.
- A. F. McAdams, Columbus Grove, O.
- Buell Lamberson, Front St. (180) Portland, Oregon.
- Prothero & Arnold, Du Bois, Pa.
- John H. Back, 235 W. 3rd North St., Salt Lake City, Utah, or

The A. I. Root Co.,
MEDINA, OHIO.

GENERAL ITEMS

Wintering Well—Good Prospects.

Bees are wintering well, and the prospects are good for a honey-year.
H. W. MCCOMBS.
Washington Co., Iowa, March 7.

Management Important.

My bees seem to have wintered all right. I have 250 colonies; have been in the business 22 years, and have never yet had a complete failure. I believe that is doing pretty well in a locality where one has to depend entirely upon white clover, Spanish-needle and smartweed for a crop. Another disadvantage is that the land, as a rule, is all well cultivated, kept rather clean of weeds, and the wet places tiled. My experience is, however, that success depends a great deal upon management.
EMIL J. BAXTER.
Hancock Co., Ill., March 7.

Bees Gathering Pollen.

We are having fine spring weather, and bees are busy bringing pollen, but I think hardly any honey. Wintering bees is no problem here, but how to make them fill their surplus apartment is sometimes a puzzle that's hard to solve. Last year they wouldn't work in the surplus arrangement at all, and we couldn't make them, as the white clover from which we get our surplus was a total failure—something that doesn't happen every day. The first thing bees find in spring is pollen from cedar, then follow in order as named: Willow, dandelion, maple, fruit-bloom, huckleberries, blackberries, salalberries, greasewood, white clover, nightshade, fireweed, etc. I seeded a patch to sweet clover last summer, and it came out about 3 feet; this year it ought to grow much taller, but, will it have honey, is the question.

AND. OLSON.

Jefferson Co., Wash., Feb. 26.

Eucalyptus for Honey.

On page 89, Dr. J. McLean speaks of the eucalyptus tree as being very good for honey, and as they do well here I would like the names of the best varieties for honey. I also would like to know about the time of blooming.

Geo. B. MACLEOD.

Ventura Co., Calif., Feb. 20.

[We referred the foregoing to Dr. McLean, who has kindly replied as follows:—EDITOR.]

I would say that the best varieties of eucalyptus to plant in California for Mr. Macleod's purpose, are those known as Eucalyptus Globulous and Eucalyptus Amygdalina; both thrive amazingly in that State when properly planted and cared for during the first three years of their growth. The globulous has much more rapid growth, and if planted within a reasonable distance from the sea coast (the nearer the better) will grow at the rate of eight or ten feet per annum.

In order to form a nice little grove they should be planted in clumps of

SEED
7D4t Please mention the Bee Journal.

The State of Michigan which in years past has contributed so much material towards the building and furnishing of our homes, is coming to the front very rapidly as the choicest and surest seed supply of the country. Fruit, celery and potatoes have been their staples, but one enterprising man, Harry N. Hammond, of Field, is making a great reputation by the most excellent quality of his field, garden and flower seeds. Mr. Hammond will be remembered by the stir he created last year with his Admiral Dewey Potato. Its success was so instant that it is probably the most popular potato to-day with those who always get a "little better" than market prices for their produce because it grades above the average. This season Mr. Hammond is scoring another success with his Thorobred White Dent Corn. His new Czar of Russia Oats also is destined to be generally popular. Write Mr. Hammond to-day for a copy of his free catalog which is profusely illustrated, and describes the above and hundreds of other equally notable bargains and prize offers. say, about four, placed about three feet apart from each other in semi-circular form, each clump being about 18 feet apart. The planting must be determined by the nature of the soil; if hard and stony, holes must be dug for each plant, or for the clump, to a depth of say 18 inches; the plants carefully let down to the first leaf-shoots, and then tenderly filled around with mellow soil, leaving a basin around each about six inches deep for the first year, to receive the early rainwater. The second year gently rake in the loose soil and leaves, etc. If the soil be soft and free for the plow, a subsoil plow may be run the full length of intended grove or fringe, making two close furrows, into which plant and fill around with mellow soil as in the dug holes.

Much hardier plants than the two named must be used in and around Chicago, which I will be pleased to name for the guidance of any *bona-fide* enquirer. **DR. J. McLEAN.**

LATER.—It has just occurred to me that I omitted to state in my letter in reply to Mr. Macleod, regarding the time that the eucalyptus named by me blooms. They commence to bloom about the middle of February, and continue for about three months. Sun-flowers may be planted between the clumps in a grove, for the bees to work on at any time, said flowers therein planted become changed to somewhat resemble the eucalypti odor and medicinal quality. **J. M.**

Bees Getting Along Nicely.

My bees are getting along nicely in the cellar, by what I can read. I bought two fine colonies last spring, and put five in the cellar. Last year was not a very good one for the bee-keeper, but this year may be pretty good. There is nothing like keeping up one's courage. You know an Irishman always "tries again."

WESLEY HUNTER.
Ontario, Canada, March 5.

Fine Rain, but Too Late.

We have just had a fine rain amounting to an inch, which will materially help growing grain, but the bee-interests seem to be almost beyond help so far as getting much profit out of the business this year. The warm, dry weather of January and February brought the sage forward prematurely, and I think destroyed the hope of getting much nectar from those splendid honey-producing plants. With our average amount of rainfall this month, and some in April, most bees will probably pull thru in fair condition, but as for there being much honey to spare from this part of the State this year, I for one do not believe it.

ALBERT ROZELL.
Los Angeles Co., Calif., March 6.

No. 3.—Medical Animals.

Dick's dead. Yes, gone to Roosterland! His large family cackled his praises, sung of his prowess and brave deeds on various barnyard battle-fields; of how he overcame the Shanghai Philistine, and of his many other virtues; but for all that he was mortal, and made room for a younger and red-

Sharples Cream Separators: Profitable Dairying

der chanticleer. He rests in piece-ess. You would naturally suppose that donkey's could have nothing to trouble them but brutal men and thoughtless boys, but they really get sick every now and then, generally as the result of bad treatment and starvation; and finally die like other living beasts. Their greatest trouble is an inflammation of the stomach, which bloats and swells until death comes to their relief. But whenever they can find a patch of big bull-thistles there is their panacea. They'll eat and eat of its prickly leaves, and lie down in the hot sun, and shortly they are well.

But what a miserable life is theirs! A 250-pound brute straddles the poor little burro, armed with a big club to beat it, and expects to climb the side of a steep hill with him! As well expect a child to carry a big sack of corn! Such inhumanity has made my blood boil more than once, and I have often wisht that patient Jennie would spill its burly tormentor down the precipice, irrespective of consequences.

The patient ox, too, is not proof against sickness. Men have trouble enough with one stomach, but old Jerry has three of them—no wonder he feels out of sorts at times. But he knows just how to cure himself if turned loose to find his medicine. He waddles along with his nose nearly to the ground, hollow-eyed and heated horns, now and then so weak he braces his legs so he can stand up. He makes a bee-line for the clump of poke-berries yonder in the pasture-lot—he's had it in mind a long time, and he is no

The Best Paying Crop

For home trade or shipping in Fancy Muskmelons.

VAUGHAN'S MUSK MELON SEEDS have been carefully saved by growers who know the business. They produce big crops which sell while the "PAUL ROSE" others rot on the dump. DR. MILLER'S Honey Queens

One Untested Queen Free as a Premium for sending ONE New Subscriber to the American Bee Journal for one year.

We have been fortunate in making an arrangement with DR. C. C. MILLER—the well-known honey-specialist—to rear queens EXCLUSIVELY FOR US DURING THE

SEASON OF 1900. These Queens will be mailed in rotation, beginning about June 1, so "first come first served." We are ready to book orders now.

The Queens Dr. Miller will send out on our orders will be precisely the same as those he rears for his own use, so of course they will be from his best stock. His best colony in 1899 had a queen reared in 1898; May 5, 1899, it had brood in 4 frames, and he gave it at that time a frame of brood without bees. It had no other help, but May 25 a frame of brood with adhering bees was taken from it, and the same thing was repeated June 3, leaving it at that time 5 frames of brood. It stored 178 sections of honey, weighing 159 pounds (and that after July 20, in a poor season), being 2 2/3 times the average yield of all his colonies. A point of importance is the fact this colony did not swarm, and an inspection every week or 10 days showed that at no time during the entire season was there even so much as an egg in a queen-cell. Dr. Miller expects to rear queens from this one during the coming summer.

The demand nowadays is for BEES THAT GET THE HONEY when there is any to get, and Dr. Miller has such bees. You will want to have a queen from his best, we are sure.

Do not send any orders to Dr. Miller, as all orders MUST come thru us, according to our agreement.

Remember, send us \$1.00 for ONE NEW SUBSCRIBER to the American Bee Journal for one year, and YOU will get ONE OF DR. MILLER'S UNTESTED HONEY-QUEENS FREE AS A PREMIUM. Or, send us \$1.50 and we will mail you the American Bee Journal one year and a queen. Or, the queen alone for \$1.00. Orders for queens to be filled in rotation, beginning about June 1st.

Address all orders to **GEORGE W. YORK & CO.,**
118 Michigan Street, CHICAGO, ILL.

HAMMOND'S
Michigan Northern-Grown Onion Seed.
I sold 56,000 lbs. of this seed in 1899. My customers report yields of 400 to 1,265 bushels of onions per acre from this seed. Some of them intimate that this seed is worth \$5 to \$10 per lb. more than the California grown seed sold by anybody. I guarantee this seed to be new and freshly grown. We have seed of all the leading and standard varieties. We make special prices on large lots. Onion sets of all varieties. Buy direct from the grower. Catalogue—extended and illustrated—free.

100 Cards and Card-Case FREE

We have arranged to mail a neat vest-pocket Aluminum Card-Case with 100 printed Business or Visiting Cards—all for sending us ONE NEW SUBSCRIBER to the American Bee Journal for a year at \$1.00. This is indeed a rare offer. You can have anything you wish printed on one side of the card. Your name

alone will be engraved on the Aluminum Case. It is something that everybody ought to have. Be sure to write very plainly what you want printed on the cards, and also the name for the case.

We will mail the cards and case for 50 cents, when wanted without sending a new subscriber, or will club them with the Bee Journal for one year—all for \$1.40.

GEORGE W. YORK & CO.,
118 Michigan Street, CHICAGO, ILL.

Great Poultry Operations.—H. S. Karsendick, New Orleans, purposes having one of the largest poultry farms in the world. Altho now well stocked, he will install 55 new Prairie State incubators, capable of adding to his big flocks about 15,000 chicks every third week. In Georgia, State Senator White, at Smyrna, has bought 10 of these incubators, and G. M. Clark & Co., at Kensington, 10 of the same capacity. These will be among the largest poultry operations in this country. All their apparatus, incubators, brooders, etc., were made by the Prairie State Incubator Co., Homer City, Pa. Our readers interested in chickens should write for their 128-page catalog, not forgetting to mention the American Bee Journal.

Strong, Healthy Chicks

are hatched by our incubators, and more of them than hens can hatch. Why? Because our regulator never fails to keep the heat just right. Catalogue printed in 5 languages gives full descriptions, illustrations and prices, and much information for poultry raisers. Sent for 6 cents.

sooner up to them than he begins to munch on its leaves; then lies down to rest. After awhile he tries it again, and the first thing you know he's all right, and ready for all the tender grass he can get.

But of all the "cute" animals familiar to us is the festive mule. He knows a great deal more than the drivers who generally have supervision over him. When treated kindly Mr. Mule is very tractable and industrious, but if abused he tries to "even up" scores by a vigorous kick when the chance offers. I admire his pluck!

From one cause or another he, too, gets shy on his feed, hangs his head down, with ears nearly to the ground, just able to wabble to the sunny side of the barn. Poor Mule looks very disconsolate—not even a handful of oats will prove an allurements. But he smells his medicine from afar! Open the gate and you'll see him make a straight shoot for a bunch of jimson-weed growing in such luxuriance just below the pig-pen, down there. What a breath that mule must have after his feast! But it won't be three days before he will be kicking up his heels like a trained "foot-baller."

Because of bad harness, muley often has a sore back which he proceeds to cure as follows: He hunts up the thickest patch of smartweed in the slough—near the creek, you know—and he'll roll and roll over those weeds until he has rubbed on plenty of its juice, and the mud that also sticks to him acts as a piece of court-plaster to protect the sore while it is healing. Isn't that good mule-sense?

The most pathetic, because the meanest, use that mules and horses are finally put to, in some European countries—France and Austria in particular—is being driven into leech-lakes, where the leeches may thrive and fatten for market on the poor old horses and mules that have so long

and faithfully served their heartless masters. It is a pitiful sight to see the poor beasts literally covered with the leeches that are sucking the last remaining drops of blood, finally to drop exhausted, food for wolves and ravens.
UNCLE FRANK.

Bees Didn't Do Well.

Bees have not done well here the last two years. Last year was too dry for white clover, also for fall bloom, which found the bees short of stores for winter. I have 70 colonies on the summer stands apparently in good shape. They will probably require a little feeding later on.

G. C. ALLINGER,
 Marion Co., Ohio, March 5.

Convention Notices.

Chicago.—The Chicago Bee-Keepers' Association will hold its regular semi-annual meeting in Wellington Hall, 70 N. Clark St., Chicago, Ill., April 6, 1900, afternoon and evening. The meeting will be called to order at 1 p.m. Dr. C. C. Miller is expected to be present if his health will permit. Mr. E. R. Root has been invited, also Mr. N. E. France, and others. A good time may be expected by all. Let every one come, especially the ladies.
 Park Ridge, Ill. HERMAN F. MOORE, Sec.

Utah.—The Utah State Bee-Keepers' Association will hold its semi-annual convention in the City and County Building, Salt Lake City, Apr. 6, 1900, at 10 o'clock a.m. A full program in the interest of the industry will be presented, and all our bee-keepers can help themselves by aiding the Association, and in order to create a closer bond of union among our bee-keepers. As a further incentive to the success of the bee-keeping industry, it is very desirable to have our bee-keepers from all parts attend the spring convention.
 J. B. FAGG, Sec.

We Wish to Call Your Attention to the advertisement of the Kalamazoo Carriage and Harness Company, which appears in this issue of our paper. These people are large manufacturers of vehicles and harness, and have just recently adopted the plan of selling their goods direct to the consumer. As will be noticed from the advertisement, they make the new and entirely novel offer to sell vehicles or a harness at less than wholesale prices. Considering their large and completely equipt factories we should say that they were entirely justified in this claim, for they certainly have the means at hand to make the public this unparalleled offer. Our readers will observe by reading their advertisement that these people make a most fair business proposition. All goods are shipped subject to the approval of the customer, and if not found entirely satisfactory and exactly as represented, may be returned at company's expense. It will certainly pay our readers to write these people for catalog before buying goods of this class. Address them at Kalamazoo, Mich., box 53, not forgetting to say you saw their advertisement in the American Bee Journal.

Here we are to the front for 1900 with the NEW CHAMPION CHAFF - HIVE,

a comfortable home for the bees in summer and winter. We also carry a complete line of other SUPPLIES. Catalog free. R. H. SCHMIDT & CO. Sheboygan, Wisconsin.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, March 8.—There is a small trade in choice to fancy white comb honey at 15c per pound, but aside from this there is little doing in any other grade, with an uncertain range of prices, for those who have it want to sell and buyers can get reductions from prices asked. Off grades of white, 10@13c; ambers, 8@10c; dark, 7@9c. White extracted weak at 8c; ambers, 7@7½c; dark, 6½@7c. Beeswax steady at 28c.
 R. A. BURNETT & Co.

CINCINNATI, March 3.—There is some demand for extracted honey from manufacturers at 7@7½c for amber and Southern; clover, 8@8½c. Comb honey is selling firm at 14@16½c in a small way. Beeswax, 25@27c.

C. H. W. WEBER,
 Successor to Chas. F. Muth & Son and A. Muth.

LOS ANGELES, March 1.—1-pound frames, 12½@15c; 2-pound cans, 2 dozen in case, per dozen, \$2.50; 2-pound glass pails, per dozen, \$2.50. Extracted, water white, 60-pound tins, per pound, 8½c; light amber, 7½@8c; dark amber, 7½c. Beeswax, 25@26c.

The prospect for a crop is very had. Small lots in the hands of wholesale houses are firmly held.

BOSTON, March 9.—Our honey market is showing some signs of lower prices, altho the stock on hand is not large. At the same time prices are so much higher than previous years that the trade have taken it very slowly and the results are that the holders are willing to range prices quite a little in order to move stock on hand. Prices range: Fancy white, 17@18c; No. 1, 15@16c; amber, 10@12c; huckwheat almost unsalable. Extracted, best white California, 8½c. BLAKE, SCOTT & LEE.

KANSAS CITY, Mar. 10.—We quote fancy white comb, 15c; No. 1, 14c; No. 1 amber, 13½c; No. 2 amber, 13c. Extracted, white, 8c; amber, 7c; dark, 6c. Beeswax, 22@25c.

The supply of comb is very light, demand good; supply of extracted light, especially white, demand fair. C. C. CLEMONS & Co.

BUFFALO, March 3.—Market nearly bare of all grades of honey. Probably no more from any source to market, but if so, fancy white comb is firm at 15@16c. Other grades from 14c downward, with the poorest at 8@9c. Fancy pure beeswax continues at 28@30c.
 BATTERSON & Co.

NEW YORK, Feb. 8.—During the past 30 days our market has been somewhat slow and easy in both comb and extracted honey. Stocks of comb honey, however, are almost exhausted, and there is a fair demand for all grades. Fancy white selling at 15c; No. 1 white at 13@14c; fancy amber, 11@12c, and buckwheat at 9@11c, according to quality, etc.

Our market is well supplied with extracted, the prices are firm and unchanged. Beeswax sells very well at from 26@28c, according to quality. HILDRETH & SEGELKEN.

SAN FRANCISCO, Feb. 28.—White comb, 11½@12½c; amber, 8@10c. Extracted, white, 7½@8c. light amber, 7@7½c; amber, 5@5½c; Beeswax, 26@27c.

Supplies and demand are both at present limited, which is to be expected at the close of a light crop year. Business doing is mostly of a small jobbing character, and at practically the same figures as have been current for some time past.

OMAHA, Feb. 13.—Demand shows some improvement in January, having been much more active, but as anticipated there is no advance in prices. Market remains steady at 14@14½c for fancy white comb and 8½c for white extracted. The latter is pretty well cleaned up along the Missouri River, and it looks as if there would be some shortage before another crop comes in. From present appearances there is about enough comb honey to go around at the present prices, hence we look for no particular change in values.

CONTRIBUTED ARTICLES

A Michigan Bee-Keeper and His Apiary.

BY CARSON VAN BLARICUM.

THE illustration shown herewith is my apiary, taken some five years ago, when I concluded to engage in bee-keeping. I began to know a honey-bee as early as 1884, from that time until 1894 I had from one to eight colonies which were manipulated on the "know-nothing" plan, and of course without any profit except what little honey we had for table use.

My first colony was purchased of a neighbor for \$4.00. My father did the "riot act" all that summer with cotton cloth around a stick in place of a smoker, which I manipulated to his dictation. This same summer (as noted above) my father was badly stung and of course has held aloft from the bee-fever ever since.

I remember one day when we had finisht taking honey—to "take" was to cut the honey from the brood-frames, replacing the same to be filled again.) About one hour afterward, we noticed a smoke issuing from the hive we had examined, and coming near we beheld the cover on fire. It took but a moment to remove it; the quilt was on fire and the brood-frame top-bars were blazing, the bees were in the air and on the ground in a state of complete rout. We extinguishd the blaze and shortly after they cast a swarm which made two colonies. They died the following winter.

My next venture was the coming June, when another neighbor placed a swarm in the hive for 50 cents, which was the nucleus of my present apiary of 32 colonies. These bees were large brown ones with gray bands instead of yellow ones.

My bees at present are nearly all Adels, which I think are superior, having tested different strains. I have been successful in controlling the swarming-impulse.

My plan of wintering has been an entire success for eight years. The winter of 1898-99 I prepared on the summer stands for winter 30 colonies, and lost two. I then increast them to 32. My intention is to double this number the coming season.

I produce comb honey exclusively, but I have a great call for extracted, of which I shall produce enough to supply the demand.

In 1898 my crop was 2,400 pounds, of which I sold 2,020 pounds. The past season I had only 1,800 pounds, and have sold to date 1,600 pounds.

My apiary is located as shown in the picture, each hive having its mate, or in pairs. The hives face east, and the two apple-trees on the north were blown out by the wind, so I plant sun-flowers for shade.

That person—a six-footer—with his thumb down the smoker-nozzle, is myself. The view was taken in the month of May, and in a rainstorm.

Calhonn Co., Mich., Feb. 25.

ORGANIZATION AMONG BEE-KEEPERS.

Enlarge the Membership of the National Bee-Keepers' Association and Establish Others.

BY F. GREINER.

AS a child is looking forward to the Christmas-time with great anticipations, so some of us bee-keepers look forward to the time when we will convene again at our annual gathering. Altho Mr. Hutchinson is of the opinion that the bee-papers have largely taken the mission of disseminating knowledge among the bee-keepers away from the bee-keepers' conventions, and that after returning home

Mr. C. Van Blaricum and His Apiary.

from one of our gatherings the most of us in answer to our dear wife's question, "What have you learned at the convention?" could only scratch our heads, yet I believe very few, if any, will ever go away from a bee-keepers' convention without having received some benefit, having learned something.

I would not have the reader infer that Mr. Hutchinson discourages, or in any way opposes, bee-keepers' meetings. He does not. He doesn't underrate the value of becoming acquainted with those who are engaged in the same pursuit with us, for the social intercourse affords us not only pleasures never to be forgotten, but we see and hear what others are doing, get their ideas, form an opinion of them—we become broader-minded and better.

I want to mention another great advantage which accrues from these simple meetings. Even the casual observer can not fail to see that organization brings with it benefits which are entirely out of reach for the single individual. Just see how people in other lines of business organize, and what they accomplish. Notice the coal combines, iron trusts, sugar, oil, and other trusts. These people don't spend their time and money in organizing for fun, but for the money that is in it. If we had a mind to we might get some money out of our organizations, and plenty of fun besides.

"In union there is strength," is an old adage. And still the majority of us bee-keepers are plodding along singly, each trying to cut his own path thru the bushes and briars, but few succeeding as they might. It seems hard to understand that two with their united efforts can overcome an obstacle much easier than either one alone. Instead of our National Bee-Keepers' Association counting its members by many thousands, it has in reality but a few hundred. And, after all is it not wonderful what this handful of men have accomplished? They are like the 300 Spartans at Thermopylae, holding the Fort against the Million. I can somewhat imagine what we might accomplish if we all would unite our efforts. But should I pen my imaginations, it might appear to many that my pen had run away with my reason, so I defer.

I am a member of a small county organization, and I am proud of what we, under the leadership of an energetic and progressive president, have accomplished. As an illustration only, I will speak of some of these achievements in the hope to inspire others to do likewise or better: In numbers few, comparatively, we succeeded in having an anti-spraying bill passed. We stirred up the State organization into activity, in consequence of which the adulteration bill is being pushed on. We succeeded in interesting State and Federal government in bee-culture so that appropriations have been conceded. In the State of New York any local organization may now have the aid from the Bureau of Farmers' Institutes.

We have also shown our influence with the managers of local, county, and State fairs. Very much more liberal premiums have been offered of late years for apianian exhibits than formerly, which, of course, benefits the bee-keeper. His business is in consequence recognized much more as an important branch of agriculture with the general class of people than it was heretofore.

When the National Bee-Keepers' Association first started, I joined its ranks; but I became discouraged and (I may as well say it) disgusted, because the bee-keepers did not support it. I thought then that I had reason to leave the organization, and did so. A better spirit, however, prompted me to again enter the ranks a few years after, and to-day I am proud of the achievements of that body of good men.

Xerxes with his million warriors tried in vain to subdue the 300 Spartans—he could not do it by fair means. The adulterators of food and honey with their millions of dollars, and the fraudulent commission men—they quake in their shoes before the handful of energetic men in the National Bee-Keepers' Association. It is only by foul means that they occasionally gain a slim victory. It does not often require a lawsuit to bring transgressors to terms. Many a bad debt has easily been collected, the sale of adulterated honeys has been discontinued in instances when the offenders were aware that an organization was after them.

Is it necessary for me to enter into all the details? It seems to me that even the skeptic might be convinced of the advantages to be gained by uniting our efforts in the furthering of our interests and the protection of our pursuit.

By the way, I hold that it is about as essential to support the local bee-keepers' association as it is to give your support to the National. I am afraid there are a great many bee-keepers who stand idly by waiting to see some

one else, more determined, more progressive, haul the chestnuts out of the fire with their own paws, as it were; and as soon as they find the danger of burning their paws is over, they will flock around the fire and try to get their fill free of cost.

Friends, is that strictly honorable, or even fair?

Let us stand by another by thousands, not merely a few hundred. Germany's bee-keepers are setting us a good example; one we might well follow. A petition regarding adulteration of honey has lately been sent to the Reichstag in Berlin with 34,623 signatures!

Brethren, are we asleep? If so, let us bestir ourselves. It costs but one dollar per annum to be a member of the National Bee-Keepers' Association, and perhaps 50 cents a year membership fee in your county association. Give these associations your support. If you can not for some reason attend the annual meetings, send in your dues, anyhow. It requires some money to conduct the business of the association properly and decently, and very often the larger part of the expenses has to be borne by the officers.

The new constitution of the National Bee-Keepers' Association provides that all members of any local bee-keepers' association may become members of the National on application of their secretary and his paying 50 cents per annum for each local member. If the membership of a local association will act in unison, every member may for \$1.00 be a member of both organizations. It seems to me that is "dirt cheap." No bee-keeper in our land ought to miss this opportunity; no bee-keeper can afford to get along without the benefits accruing from belonging to these associations, and the protection and insurance guaranteed by them. Let us all join! Ontario Co., N. Y.

No. 8.—The Honey-Knife—How to Get the Most Out of It.

BY "OLD GRIMES."

A SIMPLE tool is a honey-knife. All there is of it is the handle, the shank, and the blade. We can all remember when the latter was a long, thin, flexible blade, and the best in that line was the Novice honey-knife. But since the introduction of the heavier Bingham and Hetherington knife but few of these light knives are used. The Bingham and the Cowan now take the lead, with the Bingham the greater favorite, which seems to be just the right weight to avoid clumsiness.

In selecting a knife for rapid work there should be a proper balance between handle and blade, and the bent shank should be very rigid. A good share of the shanks are made too light, and give too much, and not infrequently break. When said broken shank is mended, and made so heavy that there is no give to it, there is much more comfort in working with it.

A honey-knife is immerst more or less in cold or hot water, and this has a tendency to loosen the shank in the handle, and when this occurs while busy extracting it is no small vexation. Manufacturers should be sure to make a hold-tight connection.

It may be entirely superfluous to say that to get the most out of a honey-knife it should be kept sharp; still we have known men to haggle away with a dull knife to the detriment of the comb and the temper of the operator. While we have seen knives sharpened on grind-stones, emery wheels, scythe-stones and files, I consider the grind-stone the right tool to keep the proper bevel on the blade, and an oil-stone to finish up with. Always have the oil-stone handy, and keep a razor-edge on the knife.

To get the most out of a honey-knife have plenty of light. We have seen many dingy honey-houses and the uncapping-can in the most dingy corner. The full light of a large window should fall upon the work.

We have our knife in hand and are ready to uncap. We will suppose that we are working our bees in a Langstroth hive, and have before us a Langstroth frame nicely filled and capped. The value of a comb for rapid work depends upon its age and the uniformity of surface. If we have used foundation and carefully spaced the frames we will have combs of full value. Now, before we make a cut on the surface of that beautiful comb, we must decide whether we shall use a hot or a cold knife. In any event we must have two honey-knives, and a shallow pan in which to place them. A long bake-tin about three inches deep will do, but where there is much extracting to be done a dish that will hold a gallon of water is better.

Ordinarily we can use this water cold, but if the honey

is very thick, the combs new and the weather cool, heated water is necessary, and an oil-lamp accomplishes the purpose. Some bee-keepers prefer to use hot water upon all occasions, and a water-heater is fitted to a common lamp. In fact, it is a jacketed tin chimney, and the knives are inserted from the top. A hot knife will certainly slip under the cappings beautifully for a few times, but it soon cools, and must be changed for a hot knife. With this continuous changing the water in the little heater soon becomes thick with honey carried into it by the knives, and we soon have boiling syrup instead of water to contend with. Ordinarily in hot weather the uncapping can be done with less bother to the operator by using lukewarm water, or water warmed by the temperature of the hot weather.

One would think that the shaving of the cappings from a comb would be done in quite the same way by different individuals, but there are about as many ways as there are men to do it. Here is a man that has never uncapped much honey, and he lays the comb flat upon a bench, and is dipping the cappings off with the point of the knife. Another will hold the comb upright and uncapped with that portion of the knife that extends from the point to the curve. There are others who hold the comb in such a way that the cappings when they slide over the knife immediately attach themselves to the comb again, and have to be removed the second time.

The proper way to hold a comb is to grasp the upper corner firmly between the thumb and fingers, allowing the lower corner furthest from you to rest upon the support. And this support is worth considering. A sharp-pointed wire-nail makes a good support. The frame will not slip from it, and can be readily whirled around when necessary. If the comb is capt only half way down, one cut up will do the job for that side; and be sure to hold the comb over at such an angle that the capping, as it leaves the knife, will drop into the uncapping-can.

If the comb is completely capt it will take two strokes or shaves to a side. Many prefer to make both of these an upward cut. A very neat way practiced by some is to make one cut up on the far side, then keep the knife right along under the cappings across the top in a curve until the point of the knife is toward you, and then down, making a continuous cut from start to finish. It requires considerable practice to get on to this movement, but the wrist and the fingers can soon be trained to the accomplishment. Another method is to shave up one side and down the other. The downward shave here requires a firm wrist and a quick eye.

Some operators allow the knife to dig into the comb and to take off quite an amount of honey with the cappings. It is better to take a thin capping unless dealing with an uneven comb. Where there are prominences and hollows the operator should heroically shave down to an even thickness, and at the next extracting you will have a good crop to work with.

To get the most out of a honey-knife the extracting-frames should be free from projecting nails or projecting metal of any kind, and all so-called metal self-spacing devices should be avoided. When a nicely sharpened knife runs against one with a drawing motion, it causes a shock to the operator as well as to the knife.

When the extracting season closes, clean the knives and lay them away until needed for extracting again. An uncapping-knife is for uncapping, and will not work well as a butcher-knife, or for scraping bottom-boards or covers. Use the proper tools for these purposes, and in that way you will get the most out of your tools.

A Few Notes and Comments.

BY S. T. PETTIT.

HONEY TAFFY.—On page 138, Dr. Miller, in answering "New Jersey" on how to make honey-taffy and not burn it, says: "The whole secret is to cook it very slowly. Don't put it on too hot a place on the stove." Good so far, but there is another secret that is very helpful, viz.: Frequent, or better still, constant stirring until it boils. Even on a very slow fire there is danger of burning if the latter precaution be not observed.

SUPPRESSING HIVES.—Again, on page 136, I note what you say under the heading, "Suppressing Hives." You don't seem to think it the duty or business of manufacturers to boom some one else's hives to their own injury. Nor do you believe it your business to help those who would start another bee-paper. Now, if you will carry that thought

right down the lane until you come in contact with poor, struggling bee-keepers who are being crowded out by new comers and beginners; and then if you will show up those intruders as you have your own would-be opponents, I believe the majority of our best apiarists would appreciate your summing up of the matter. You know, not long ago, you thought every farmer ought to keep some bees, and that every bee-keeper ought to teach them just how to do it. I am glad most bee-keepers have failed to agree with you in that matter. I trust you will give me a hearing.

EARLY BREEDING.—On page 132, R. C. Aikin gives us a readable article on comb-honey production, but does he not err in advocating so early breeding? I have attained to my idea of perfect wintering when my bees remain quiet until suitable weather and the time for putting them out arrives—so quiet that when carried from the cellar they seem nearly dead; and with but little loss of stores, and the less the better I am pleased. Such colonies have practically all the energy, vitality, vim and push of which they were possess when they went into the cellar. Their numerical strength is much the same, and the queen is fresh and ready for heavy duty. In all my experience these are the bees that give a good account of themselves.

It may be necessary later to remove some of their stores to make room for the queen; if so, you will find a call for it in those colonies that were breeding so early, whose old bees are disappearing so rapidly, and may be a little weak when the harvest comes, while the others will be boiling over with bees right from the start.

Mr. Aikin and I are a good way apart in this one particular. I believe nurse-bees that are confined to the hive until young bees are emerging, are played out.

The time is upon us for making observations, and I hope those who hold with Mr. Aikin will give this matter careful examination. Bees are wintering pretty badly indeed if a few colonies in the cellar can not be found very quiet with but very little brood, if any, and whose stores are not much reduced.

NEW HIVES.—On page 129, Mr. Johansen's apiary and those pretty trees make a lovely picture. In my early bee-keeping days a hive on exactly the same plan was exhibited by a man whose name I have forgotten, at the Western Fair, London, Ont. He was a good talker, and I came near investing in it. I have never heard from it since. He had great faith in his hive. West Ontario, Canada.

Shallow Divisible-Brood-Chamber Box-Hives.

BY C. DAVENPORT.

THERE are some who consider shallow divisible-brood-chamber hives superior in some respects to any kind or style of single-brood-story hives, but they cost more, and if one makes his own hives, aside from the cover and bottom-board, it is double the work to make them, in fact more, if closed-end frames are used, for with this style of frame the workmanship needs to be much more exact. It is, I believe, owing principally to these reasons that shallow divisible hives are not more largely used.

For the last seven or eight years I have been using a number of shallow divisible-brood-chamber box-hives with most excellent results, and, all things considered, I prefer them to this style of hive with frames, and with my management or method of using them I can obtain as much honey, either comb or extracted, and with less work than I could if they contained frames; and this is no experiment or hastily arrived at conclusion with me, for, as I said, I commenced using them a number of years ago, and have been gradually increasing their number, so that I have at present about 40 in use. Colonies in these hives can be de-queened, requeened, or divided as quickly, and usually more easily than in the most modern frame hives.

But the great advantage of these hives is that they cost no more, and are about as easily made as the old-fashioned box-hives; and as there has been such a sharp advance in the price of frame hives lately, and a poor crop in general last season, it may be of interest to some who will need more hives the coming season, for me to describe how these hives are made, and explain the method or methods to be followed in using them, for as probably all who will read this know that one, if not the principal, advantage claimed for divisible-brood-chamber hives is that nearly all the necessary manipulations are performed by handling the sections of the hive instead of the frames individually. This necessarily entails a different management from that

followed with single brood-chambers, and unless this was understood and taken advantage of it would be folly to use divisional hives, for it would require more work to obtain the same results as could be obtained with single brood-chambers.

The main objection I found, aside from their cost, to divisible hives containing frames, was that with thick top-bars the queen would not usually pass readily from one story to the other, and with thin top-bars there would be more or less sagging, and burr-combs between the sections; but with these box-hives this is to a great extent overcome. The queen passes readily from one story to the other, and in actual use there is much less burr-comb between the stories than I expected, or than one would think from reading the description of how they are made and used.

But now I wish to be frank about the matter, and mention one fault about them, and this is in regard to drone-comb. As no foundation is used in these hives, it is a more difficult matter to replace drone-comb that may be built in them with worker-comb than it is with frame hives, but it can be done, and I have many of them that are filled with solid worker-comb.

There are other minor faults about them which I will not take space to explain, for all I claim for them is that they will answer an excellent purpose for those who have not the money to spare to buy all frame hives, unless one has as many colonies in frame hives as he wishes, and desires no further increase. In such case, if running for comb honey and any method is practiced by which swarms, either natural or artificial, are hived on empty frames, or on frames containing only starters, then I consider these hives superior to any frame hive, for I believe fully as much honey with less work can be obtained from them.

Last year the season was, with one exception, the poorest ever known in my locality, but I took off 97 finished sections of white honey from one of these box-hives. This was considerably more than any other colony in the yard produced, and there were about 75 colonies in frame hives in the same yard, some of which did not fill a dozen sections. But to be frank again, some in box-hives did no better. The one that outstript all the others was exceptionally strong at the commencement of the white honey-flow, and made no effort to swarm, but seemed to devote its entire energy to filling sections.

I have this kind of hive of various depths, but the most of them are about 7 inches. They are made from common 8-inch boards, but here the so-called 8-inch boards actually measure only about 7½ inches, and if the edges are drest or planed, it leaves them about 7 inches wide, which, for the use I make of them, is about the depth I prefer to have these hives; but whatever the depth, they are all otherwise the exact size of the 8-frame dovetailed hive.

The top-bars are made from common lath nailed a bee-space apart, and from the top edges of the hive. No bottom-bars are used. The bottom-boards and covers are just the same as those of the dovetailed hive. On account of there being no bottom-bars I expected, when two or more sections were used together, that there would be trouble on account of the combs in the upper story being built down and attached to the top-bars of the lower story; but altho I have used them tiered up two and three stories high by themselves, and also tiered up in combination with frame hives, the combs in the upper stories have never been fastened enough to the top-bars below to loosen the combs in the upper stories when separating them, or to make any practical difficulty, and on this account, with all being so simply constructed, these hives possess in common with hives made on the same principle as the dovetailed, the great advantage of the tiering-up feature, and this tiering feature I consider to be by far the most practical improvement that has been or can be made in hives, since the frame hive was invented. No one who has not used large numbers of hives that did not possess it, and then large numbers that did, can fully appreciate the great advantages that the tiering-up feature has or admits of.

In my next I will describe my methods of using these hives, unless anything in favor of box-hives in the present advanced state of our pursuit is considered so much out of place that this is thrown into the waste-basket.

Southern Minnesota.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

CONVENTION PROCEEDINGS

Report of the Colorado State Convention.

[Continued from page 167.]

WINTERING BEES.

Mr. Porter—There is a universal complaint here about bees wintering in dovetailed hives with flat covers. I have here a frame made of pieces two inches deep to fit on the hive, the lower side covered with wire-cloth, and the upper side with burlap, and filled with planer-shavings. With an ordinary flat cover I have used cleats under each end of the cover, so as to carry off the moisture. This arrangement could be used in winter for that purpose, and in summer left on over a piece of cotton-cloth. The idea of the wire-cloth is to be able to use the frame in moving bees. One lot of my bees was half in the Wisconsin and half in the dovetailed hives. Those in Wisconsin hives came out in much better condition.

H. Rauchfuss—I have used a super of chaff. It does very well. But I believe it is even better to have a heavy burlap and a high cover. A flat cover is a great detriment.

F. Rauchfuss—Mr. Porter forgot to mention why he has holes bored in the sides of the frame, and covered with wire-cloth. With the ordinary rim of wire-cloth, the first thing the bees do is to rush up and obstruct it by clustering upon it, and it is possible a strong colony might be smothered in the heat of the day; but the holes at the sides of this frame would allow a current of air under the cluster.

H. Rauchfuss—I don't think a wire-screen is so good for moving bees as burlap. The bees crowd against the screen when they will not against burlap, and so it gives more ventilation.

Mr. Harris—Last spring I lost 30 percent. My bees were weak in the spring, owing to the hard winter. This is an important question.

Mr. Lyon—Four years ago I was using a common super. My loss didn't amount to anything as long as I used that, and I am going back to it. We don't always need it, but last winter we needed something of the kind. We want no sealed covers here. One yard at Longmont lost 50 percent on account of sealed covers.

Mr. Brock—For 23 years I have wintered my bees without losing over 10 percent; some years not over 2 percent. I use the old Langstroth hive with top 8 or 10 inches deep, large enough to rest on cleats below the top of the live-body. I put on two thicknesses of gunny-sacking, and the cover over the sacking.

Mr. Porter—I have a number of Langstroth hives built the same way. They winter all right, but I could not be persuaded to make any more, for other reasons. I could use supers, but I want my supers in the house during the winter to fill with sections. I would rather go to the expense of having a substitute on the hives during the winter. These rims can be piled up when they are not wanted, and the wire will prevent the mice from entering them.

J. B. Adams—Last winter an apiary lost 50 percent one mile from mine. I lost only four colonies, of which two were queenless. When I first came here I put the hives in a board box and packed all around. About the first of May the rain and snow drifted in, and two or three days later the bees were swarming out, and I had to pull everything to pieces. Last winter I used oil-cloth sealed down, and put four to seven gunny-sacks on top of the oil-cloth. The bees came thru in good shape, and gave a good crop.

F. Rauchfuss—When did you examine your bees the last time that fall?

J. B. Adams—In October and November.

F. Rauchfuss—Then the covers were not sealed very tightly after you got thru.

J. B. Adams—You are right.

F. Rauchfuss—That saved your bees. They couldn't seal up the covers again that late.

J. B. Adams—The entrances were left wide open.

F. Rauchfuss—A full entrance with little cracks above gives sufficient ventilation to carry off all the moisture.

THIRD DAY.

Annual Report of the Secretary.

As this is the 20th annual meeting of our Association, I consider it appropriate to give a short retrospect of the history of our society, and some of the work accomplished during that period.

Owing to the loss of all records previous to 1884, a new constitution and by-laws had to be framed that year. W. L. Porter was president, and Robert James secretary. The Association had then about 25 members. In 1885 Mr. Shiff was secretary, who, as far as can be found out, made the first attempt at gathering statistics of our industry in the State. He reported that there were about 500 bee-keepers, having about 6,000 colonies of bees. Two bee-keepers had 150 colonies each, and reported a crop of five tons of honey for that season.

It was estimated that more than 30 tons of honey, which went into the channels of trade, were produced in Colorado during 1887.

In 1888 J. M. Clark reported that from 10 to 12 tons of honey had been marketed in Denver.

Foul brood was not noticed among the bees in the State until 1886, and in 1888 it had spread along the Platte River, from Littleton near to Brighton, and from Morrison near to Smith's Lake.

In 1889, while J. M. Clark was secretary, statistics of the bees owned by members were taken with the following result: Colonies, spring count, 2,247; increase, 931—total, 3,178. Yield of comb honey, 130,000 pounds.

The Association was then composed of 38 members. In 1889 the foul brood law was past by the legislature.

In 1890 30 pounds of comb honey per colony was reported as the average for the State that season.

In 1891 a meeting was held in Arvada.

In 1892 one meeting was held in Golden and one in Loveland. A premium list to be used at fairs was adopted.

In 1893 a set of rules for grading comb honey was adopted. Members of the Association contributed honey for an exhibit at the World's Fair in Chicago.

In 1894 the number of colonies of bees in the State was estimated at 60,000. An exhibition of apiarian products was held at the Gettysburg Building.

In 1895 the membership fee was reduced from \$1.00 to 50 cents.

In 1896 reduced rates on bee-supplies were secured for the members of the Association, and a committee on organization was appointed. A great loss of bees was reported in the spring of 1896.

In 1897 the committee on legislation reported that there was a law on adulteration in existence in the State.

A law was past to have the proceedings of the State Bee-Keepers' Association incorporated with the Horticultural Report. A law preventing the spraying of fruit-trees while in bloom was past. Samples of honey were bought to be analyzed.

Statistics on bee-culture were gathered with the following results: 14 counties reported 35,306 colonies (which is not more than half the total number in the State). The average value is \$3.36, and the average percent of increase 20. The average yield per colony was 26 pounds; the average price 10 cents a pound. Foul brood existed in eight counties. Six local societies were in existence.

In 1898 the constitution and by-laws were amended; 43 members reported 5,648 colonies, and had produced 147,478 pounds of comb honey and 105,878 pounds of extracted. A new set of grading rules was adopted.

In 1899 some more amendments to the constitution and by-laws were made. Circulars were sent out to over 200 bee-keepers, soliciting for membership; 500 copies of the constitution and by-laws, and 1,000 copies of the foul-brood law, were ordered printed, and part of them distributed among the bee-keepers. At the present time there are 217 names of bee-keepers enrolled on the books of the Association, 165 of which are in good standing.

All members were supplied by the Association with the numbers of the American Bee Journal containing the last convention report, as well as with the copy of the Bee-Keepers' Review containing a half-tone of sections illustrating our grading rules.

The honey crop of Colorado for the past season is estimated at 1,000,000 pounds of comb honey and 200,000 pounds of extracted. There were 22 carloads of 30,000 pounds each shipped out of the State. Prices ranged between 10 and 11 cents per pound for comb honey, and 6 and 7 cents for extracted.

FRANK RAUCHFUSS, Sec.

The report was adopted and placed on the records of the Association.

Mr. Harris—I think a committee should be appointed to insist that the report of our proceedings should be published together with the report of the Board of Horticulture.

Mr. Rhodes—I don't know how our report can be published as long as one has the power to cut it down.

At this juncture some members of the Board of Horticulture came in, and David Brothers, President of the Board of Horticulture, spoke at some length, in substance as follows:

"I think our interests are identical. The main body thinks so. We come bearing the olive branch. Anything the Board can do for you, we will do—nine out of ten of us, anyhow. It is not right for your report to be cut all to pieces. I think the report should be printed just as it leaves your hands."

A committee consisting of Messrs. Rhodes, Harris and H. Rauchfuss was appointed to confer with a committee from the Board of Horticulture on an arrangement for holding the next meetings of the Board and the Association jointly to such an extent as would be satisfactory to both.

Pres. Aikin had not prepared an annual address, but spoke in substance as follows:

A Statement by the President.

To think we have had an organization for 20 years, increasing in interest, efficiency, and membership (now 217), is certainly very encouraging. That this was accomplished without work is not true. Those on committees know this requires work, foresight, studying of human nature, and intense thought. I have spent practically days and days in thinking, planning, and writing. I did it with pure motives. I spent of my money and time; tho perhaps they could be called selfish motives, for I wanted to see the organization stand high, and the upbuilding of the organization is an honor to the executive board.

Then, we are not only generally but individually benefited. Largely because of my position, and also because of my writing in the bee-papers, I have become known all over the country as a producer, and so it has been a help to me in my private business. And yet, your prosperity is my prosperity. Whenever we undertake to break down the business of a neighbor we break down our own. As a community we are trying to get people here. Who is so selfish as not to want people in our business? Each one has just as good a right as I have. It would look unfair to come right beside me and reap the benefits of my preliminary work, but you have a right to come into my territory. We should ask ourselves what we would do if we were in that man's place.

As to the position of the Association, 217 is not half what it ought to be. Any one who buys honey knows that there are those all around who don't know the first principles of honey-production. A lady observed me fixing up supers and separators and taking the honey off, and said the ideas gained paid her well. I bought her honey, and it was largely improved by separators, but the grading was very unsatisfactory, and it cost me something. The Association with a large membership and a small fee would enable the executive to reach those bee-keepers who overstock, and who damage the reputation of goods, and could publish the proceedings, and put them in the hands of every member.

We don't expect members to be here. The money for membership comes back in many ways. The effect of the work of our marketing organization has put money in the pockets of our bee-keepers all over the State, causing them to get 15 to 20 percent more than they otherwise would have gotten. We know this to be a fact.

I want to see the Association prosper, but I have other burdens, in lines that most of you know nothing about, and I want to see the executive go into other hands.

R. C. AIKIN.

Mr. Harris offered a resolution thanking the officers for the efforts put forth for the Association for the past two years, which was carried.

A motion that Dr. Headden, Prof. Gillette and E. R. Root be made honorary members was carried unanimously by a standing vote.

QUEENS—BREEDING, ETC.

Mr. Harris—We are not careful enough in breeding to see where our stock comes from. The pedigree is not stated, and it should be. The matter of good, prolific queens is of the greatest importance. Proper stock comes first, then proper condition and handling, and then we are

ready to produce comb or other honey. Stock-raisers of all sorts, if they are up in their business, when buying, investigate the pedigree. I think the time will come when we will investigate more closely.

H. Rauchfuss—It is not all in prolificness. There is more in longevity of the bees. I have noticed many colonies with a scarcity of brood and an abundance of bees, and others the reverse. We have bred from the former with excellent success. Another item is that they should not be inclined to swarm. I had one colony so weak that the most brood they had could have been put in five frames. That colony was on scales, and outstrip any colony in the yard. It has done so for six years. Once it gathered 18 pounds of honey in one day and stored it in extracting-combs. Then, I have found a weak colony in the spring and thought I would kill the queen, but instead have given her to a queenless strong colony, and it was astonishing how much brood they would have. Still, if I had left that queen there, next spring her colony would have been weak again, as the fault was in the wintering of her bees. I have reared queens from that queen, which did not winter well, and then selected again with reference to wintering, with good success. I don't care whether queens are hybrids or not. I have had big-priced queens that didn't winter well, tho they had lots of brood.

Mr. Harris—Supposing we have prolific queens of that long-lived stock—are we not on the right track?

Mr. Root—We had what we called a red-clover queen. Her colony gave two or three times as much honey as the others. As robbers they excelled all, and were hardy. We kept her four years. Her daughters almost duplicated her, but we haven't found her equal. Mr. Doolittle got one of her queens that he thinks remarkable. Very recently we had an order for a \$25 queen, and we had to explain that we did not have such a queen in stock. Then the man wanted a \$10 queen, but we had none. I have offered \$100 for a queen, and the result of that offer has been that a good many have discovered good points in their queens. We succeeded in getting a queen from Mr. Alley, which he said was remarkable, and in the summer he wanted her again, and we let her go. We found out afterward by her progeny that she was remarkable. The tendency has been to produce five-banded bees, and it is very easy to do so by selecting with reference to color. I think now the tendency is toward business qualities. I don't know that bee-keepers would care much for hybrid queens. One difficulty about a \$100 queen is that she will be old before she can be found out, and it is hard to get daughters that will turn out in the same way. A good practice is to give drone-comb to a drone-laying queen whose record has been good. We think we have a little fortune when we have such a queen. A great many queens are not good after journeying thru the mails. That is one trouble with imported queens. I would urge bee-keepers to rear their own queens.

F. Rauchfuss—Is it your experience that the majority of queen-breeders are also honey-producers?

Mr. Root—Generally honey is a side-issue with queen-breeders, and often not even a side-issue.

F. Rauchfuss—I think we should place our orders with those who pay some attention to the honey-producing qualities of their bees.

H. Rauchfuss—I would send a queen to a queen-breeder to breed from.

Mr. Root—Why not requeen your own apiary with queens of your own rearing?

H. Rauchfuss—I can make more money producing honey than in rearing queens, as the springs are late, and we need all the bees to build up.

Mr. Porter—Perhaps the queens reared elsewhere are not used to handling large crops, and it might be better in the long run to rear our own queens partly!

Mr. Cornelius—I wish to ask Mr. Root if he rears queens by the Doolittle method?

Mr. Root—Yes. We take advantage of the swarming-impulse.

H. Rauchfuss—That is just why we can't rear our own queens in any quantity. The swarms come too late.

Mr. Root—Feed.

H. Rauchfuss—We can't feed to bring on the swarming-impulse here. We often have snow in May, and I have seen frost in June.

Mr. Root—Locality again. What do you consider the best time to requeen?

H. Rauchfuss—I like the queen to begin laying at the beginning of the flow. I have reared some queens myself, and find that the best time.

Mr. Martin—Has any one brought out different qualities of capping the combs?

H. Rauchfuss—When I raise up the oil-cloth and see wax instead of propolis, I mark that colony a wax-producer. I have a number so markt. That is all the guide I need. Those that produce plenty of wax gather the honey. They need plenty of honey to produce the wax. As a rule, they also produce whiter comb, because they don't gather much propolis.

Mr. Cornelius—I think Mr. Martin refers to the fault of bringing the cappings close to the honey.

H. Rauchfuss—I have one such colony. But usually in rearing queens from such wax-producing colonies, that problem solves itself, as they do not cap their combs that way.

Pres. Aikin—In the 70's I was located where I got only fall honey, coming the last half of August and in September. I had all summer to get the colonies bred up. I almost felt like saying I had a non-swarmer strain of bees. But white clover had been increasing, with a little basswood, and then I had lots of trouble with swarming. Swarming depends so upon the conditions, that I have always taken accounts of non-swarmer bees with a grain of salt. And so it is with other characteristics. One may have a good queen, and she may have weak progeny. One may have a good queen, but her hive was subjected to different conditions, and consequently her bees did not winter well. She may be the best queen. Many of the best queens are sacrificed because of peculiar conditions. I am not combating the ideas advanced. But there is a tendency to drop into a particular line. Select a vigorous queen, and then don't discard a good queen because conditions don't favor her. Ordinarily I prefer to rear my own queens. It is not all in the queen, and not all in the conditions. Don't run wild over the idea you can just get a good queen and then get everything.

Mr. Martin—I have noticed a few colonies year after year that were not satisfactory for comb honey.

Pres. Aikin—Suppose one queen has laid freely at a time when she will have bees hatch at the right time to take advantage of the flow, and the colony of another queen has just as many bees at that time, but younger; which queen is better? Twenty years ago I had a colony whose queen failed in the spring. I introduced a queen-cell and gave brood, but it was hard to get them requeened, and I lost two or three queens before I succeeded. That colony, when the flow was on, was queenless, and had few bees. But it was never hopelessly queenless, and the bees were old. They had nothing to do but to gather honey, and they did well.

Mr. Root—I realize that a queen should be judged by the performance of her daughters under various conditions. Then we get a stock that is ahead.

H. Rauchfuss—I requeened all of one row of hives with the progeny of one queen. They all wintered well, and not one of them gave less than four supers of honey. Other rows did not do so well. It was because all that row were daughters of a good queen.

(Concluded next week.)

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Richards, Ohio.

TWO BAD YEARS TOGETHER SPOIL QUEENS.

J. W. George, page 76, may be right, that two bad, idle years, with no surplus and no swarming, spoils all the queens, but somehow I doubt it a little. If the queens were kept sufficiently idle, and sufficiently comfortable, they'd last seven years, I believe—and be serviceable to some extent the sixth year. (Don't you risk any money on it.)

UNCLE FRANK AND HIS "FAITH CURE."

Uncle Frank, it's a new sort of faith cure that you are treating us to, page 77—and a real nice kind. You have all the faith, and all the "animiles" get well. Please, Uncle, enlarge your business a little; and next time I get to peel-

ing and eating young raspberry shoots have it cure me of my troublesome oblivious and forgetful spells—that's a good Uncle.

IMPORTANCE OF DRONE PARENTAGE.

I shall have to keep on barking, I plainly see, about the important matter of drone parentage. C. P. Dadant, in his otherwise excellent article, page 82, leaves out the few words for lack of which the beginner following directions will be somewhat likely to get more of his queens mated with undesired drones than he would if he let the whole matter run itself. Drone parentage is not a matter of numbers, but of *readiness*. A dozen drones ready count immensely more than five hundred that need a few minutes to get ready. By preventing drone-rearing in a hive we *greatly increase the readiness* of the few they rear in spite of us. By securing the rearing of many hundreds of drones in a favored colony, we *decrease their readiness*. The few words I would have Mr. Dadant add are: Select drones should be secured homes a few in a place, if they are to have a fair chance in the struggle for parentage.

BEE-CAVES AND THEIR ROOFS.

I think E. D. Ochsner has given us a valuable hint about roofing bee-caves. One foot of sand and two feet of leaves better than three or four feet of sand—which will sooner or later cave the whole thing in by its own weight. Presumably chaff would do just as well as leaves where it is handier—ah, no, not quite as well; for chaff will entice and breed mice much the worse. I take it that the great besetting sin of bee-caves, take them as they run (they do run, gentle reader, into the hill) is leaky roof. Any old rattle-top of warped and split boards seems good enough for a bee-cave, when it really deserves as good a roof as the owner's kitchen. The apiary in front of which he stands so respectfully businesslike seems to be the much maligned rank and file, with medium spacing. What signs has he got posted on that shanty? No admittance? Beware of the dog? Don't spit on the floor? or all three? Page 81.

APIARY BASEMENTS, ETC.—SOME OF OLD GRIMES' IDEAS.

How doctors do disagree! Our O. G. says never on any account face an apiary basement to the north; while the last man, only the page before, recommends the north facing of his bee-cave. Heat doesn't get in so bad in the spring—certainly a very comprehensible advantage. But the Grimes arrangement *in full* keeps the spring sun off all right; so there is no real conflict. But I'm not going to subscribe to the Grimes honey-tank down in a basement. Better have it where there will only be a light roof between the surface of the honey and the sun. Separate structures on a side-hill; else a lean-to next the Grimes building. This matter is rather important; and the mere sentiment of having everything snug as a bug in a rug in one big cubical building should yield, I think. The Grimes shanty, made in sections to take down with a wrench, is tip-top for perambulating out-apiaries. Page 82.

SELF-SEALING HONEY-PAILS.

Self-sealing honey-pails bad because we can't wash 'em and drain the water out properly. Rusting ensues, and damage to the next lot of honey put within. Chance for an inventor. Page 84.

TREATMENT OF EXTRACTED HONEY.

I don't know how much there may be in it, but perhaps a whole bushel—for which we must thank H. Rauffuss, of the Colorados. The idea is to heat all honey immediately upon being extracted. Retards granulation somewhat, and prevents foaming when the honey is reliquefied, to the customer's peace and confidence of mind. If it will prevent foaming I think it will also retard deterioration with age, which is a great matter with the poorer grades of honey. The best honey goes thru the next summer with but little damage; while poorer grades, quite tolerable at first, are apt to be nearly spoilt before the next winter. Perhaps a light is dawning as to how to obviate this difficulty. Page 85.

A LITTLE DOUBTFUL ABOUT EUCALYPTI.

We are prepared to believe that the eucalypti are healthy trees to have about, and that eucalyptus honey has curative properties; but nevertheless we must hesitate a bit about accepting all that Dr. McLean in his enthusiasm tells us on page 89. That a Light Brigade of 600 (million) grasshoppers would be halted in their charge 40 feet away—well, our faith in that respect isn't exactly like an anchor to the soul. If all he means is that resident grasshoppers

edge away out of the smell of eucalyptus, may be we can go that; but may be even that is a little like the power of ash leaves over rattlesnakes.

BEEES WORKING AT LONG DISTANCES.

I think Ira Barber's contribution to our knowledge about bees working at long distances somewhat valuable. That it largely contradicts prevalent impressions makes it more so. Page 89.

"BEE-ING IT" ELSEWHERE—FOUL-BROOD SCHEME.

And so Mr. Johnson would like to go to our newest island possession, Tutuila, and "bee it." Typical American. Feel that way myself. But his scheme of foul brood as a "varmint" that eats the holes so characteristically seen in the cappings, escapes thru the holes, and disappears; hope he'll take that scheme with him when he goes, and drop it in the mid-Pacific. Page 95.

CUBA AND ITS FOUL-BROOD SCOURGE.

Rockenback's painting of Cuba, rotten from end to end with foul brood, and not a man in it capable of curing a colony by any method whatever, is rather unpleasant and Dante-esque. Cuba not likely to demoralize our honey markets much just now, if that's correct. Were the painting entirely true, without any exaggeration, both disease and bees would soon die together, and Cuba would soon be safe virgin territory in which to begin apiculture. This is not likely to happen, more's the pity; so the truth is probably *worse* than the picture. Page 99.

WARFARE AGAINST FENCES AND PLAIN SECTIONS.

Mr. F. L. Thompson seems to be getting into something like a warfare against fences and new styles of sections; both his practice and his theory finding nothing of special value in them. If it's well to be "zealously affected in a good thing" I guess it's also well to be zealously affected in a fight against novelties that are humbugs. Page 106.

QUEENS THAT EXCEL GREATLY.

McIntyre will make us all want one of his queens if he doesn't let up. He thinks that when a queen greatly excels among 600 others it means a deal more than pre-eminence in a small apiary. And sure enough it may, *sometimes*. But the bigger the apiary the wider the scope for that quiet, silent, sneak-thieving which seems to be the real cause of the seeming excellence in many cases. You see, I'm sore-headed on this point, as I have been trying for a superior strain for many years, with scant results to show for it. The strain which I have favored for several years swarms a little worse than the others, which is "pizen." Sometimes, I think, a queen gets an undeserved reputation because her bees are *hospitable*, and will receive kindly lost bees (mainly young and valuable) from all the colonies round about; her hive being so located as to be the most prominent and eligible one. Marvellous wintering strains are almost always of this sort, I take it. Page 106.

THAT COMMISSION-SHARK CASE.

Mr. Theilmann fought a noble fight; and doubtless he thought that the Union might wisely have contributed some cash toward showing the *possibility* of bringing one Chicago commission-shark up on justice's deck. And doubtless the Union officers thought that a Supreme Court decision whether one particular sale was a sale outright or a sale on commission would not be of sufficiently general application to justify putting their scanty funds into it. Let each party charitably try to believe the others did the very best they knew. Page 83.

INTRODUCING YOUNG QUEENS.

That a *really* young queen, soft and not yet fully colored, is always received kindly everywhere, and does not awaken antagonism until beginning to "put on the airs" (or at least the smells) of queenhood—well, I guess it's a fact; but it was not in my mind as it ought to have been, and as I hope it will be now, thanks to page 106.

THE AIR IN A QUEEN-CELL.

I think Mr. Bingham, page 109, is entirely wrong in supposing a queen is developopt in bad air. Reliable experiments show that the amount of air that will in time pass thru a brick or a stone is quite surprising. And the wall of a queen-cell (made purposely of porous texture in its basal half) is not going to have air much poorer on one side than on the other.

VOL. 40.

MARCH 22, 1900.

NO. 12.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

The Brosius Pure-Food Bill.—Rev. E. T. Abbott, the representative of bee-keepers' interests at the recent Pure-Food Congress, in Washington, wrote us March 16, that the revised Brosius Bill will be before both houses of congress in a short time. He says:

"Urge your readers to write at once to their congressman, pressing upon him the importance of supporting the Brosius Bill as revised by the last Pure-Food Congress. Also urge them to be on their guard against any attempt to side-track this bill in the interest of one which is backed by only a few individuals. 'Pass the revised Brosius Bill,' is now our watchword."

We trust our readers will quickly act on Mr. Abbott's suggestion. The Brosius Bill should be past during this session of congress, and will be if every lover of pure food will do his full duty.

New York Spraying Law in Danger.—Mr. Frank I. Clark, of Cayuga Co., N. Y., has sent us a copy of a bill introduced into the legislature of that State, amending the spraying law which allows experiments at experiment stations and by private persons. Mr. Clark urges us to request that every bee-keeper in New York State write at once to their representatives in the senate and assembly to vote against the passage of the bill. As the legislature

will adjourn about April 1, it will likely be past or defeated before that time. Better write *at once*.

Editor Root, referring to this subject in Gleanings in Bee-Culture, says:

While the bill is innocent enough on its face, yet the measure was framed by the opposers of the spraying law, who, having been unsuccessful in having this same law repealed at the last session of the legislature, are now taking this apparently innocent but nevertheless effective method of taking the very teeth out of the law. Mr. Marks says that the experiment stations, or the experimenters, have none of them asked for such an amendment; and he desires all the bee-keepers of New York to write to their senators and representatives at once to protest vigorously against the passage of the amendment under consideration.

When I was in Colorado I understood that a similar attempt was made to practically kill the spraying law in Colorado; and it behoves the bee-keepers of the different States having such laws to be on the watch, because there is a lot of ignorant fruit-men who are up to just such tactics as this.

Organization Among Bee-Keepers.—On another page in this issue Mr. F. Greiner—one of the leading bee-keepers and writers on both bee-culture and general agricultural topics in the State of New York—presents a ringing article that we hope every one of our subscribers will read very carefully. Not only that each shall read it, but the next thing he does after reading it, send his dollar for membership dues to Hon. Eugene Secor, Forest City, Iowa, and become a member of the National Bee-Keepers' Association right away, if not already a member.

Every bee-keeper in the United States ought to become a member of the National organization, at least. Everything and everybody are now working harmoniously along the apicultural line. This is just as it should be. It is a splendid time to unite in a strong organization, such as this or any other country has never seen. Mr. Greiner has made a grand plea for this very thing, and we wish simply to "second his motion."

Shall there not be "falling into line" among bee-keepers all over our broad land, until our National organization may be all that Mr. Greiner has so graphically outlined?

If it is more convenient for our our readers to send their membership dues to us, we will forward them to Mr. Secor, who will then promptly mail a receipt to each. Now for a host of volunteers for the Grand Army of Bee-Keepers!

Adulteration of Honey is bad enough at the best, and any of it is too much, but many times it happens that the matter is greatly exaggerated. It is not an uncommon thing to see in the foreign papers a railing accusation against all honey sent across the ocean from America, and even well-informed Americans are under the impression that when honey from this country lands in Germany or some other European country, only a small part of it ever saw the inside of a bee-hive. A foreign letter in the Country Gentleman has the following sentence:

"I regret to see that complaints are rife as to the importation of adulterated honey, and need hardly say where the complaint chiefly lies."

It requires no great stretch to interpret that as meaning: "It is too bad, and I wish it were not so, but adulterated honey in these foreign countries comes chiefly from America."

Pertinent to the subject is the testimony of H. Guehler, of Berlin. He is an expert honey-dealer, carrying on an immense business with 1,600 places of sale in Berlin and elsewhere, handling perhaps more honey than any other man living. He says much of the American honey is prepared without intelligence and without care, and on that account is considered adulterated. But he says in the Deutsche Ill.

Bztg., that he has analyzed a great number of samples of domestic and foreign honey, and the amount of adulterated honey that is found in bulk is very small indeed. In reality he never found but three specimens adulterated in all that he ever analyzed, one was German, one was Hungarian, and one American.

The probability is that those who adulterate honey could hardly afford to adulterate it and export it at the low prices. They can make more money to put it up in fancy packages of small size and sell it at a high price.

Number of Dead Bees on a Cellar-Bottom.—"Figures can not lie," it is said, but somehow they do not always tell the same story when manipulated by two different persons. Editor Root, in *Gleanings in Bee-Culture*, said, "75 or 100 colonies in a cellar 10x10 may furnish dead bees before spring sufficient to cover the floor an inch or two in depth." With that as a basis, Mr. Taylor figured in the *Bee-Keepers' Review* that "colonies of bees in a cellar may lose anywhere from 2½ to 5 quarts of superannuated bees from a colony during the winter."

Then Editor Root fell to figuring, and made out that instead of 2½ to 5, the highest loss could only be 1 3/5 quarts per colony, or less than one-third as many as Mr. Taylor had figured! The principal difference seems to come from the different ways in which the two men had the bees packed in the cellar. Mr. Taylor seems to have had his colonies in some way suspended from above, leaving the entire floor to be covered with bees, while Mr. Root placed his upon stands, the 25 stands occupying the greater part of the cellar-bottom, leaving the balance to be covered with bees.

Incidentally, Mr. Root makes an interesting contribution to apicultural lore by giving the number of dead bees in a quart as 2,664. This is much less than the number of living bees in a quart, which is 3,200, according to the book "A B C of Bee-Culture."

Bees and Fruit-Growing.—At the Leland Stanford University, in California, they have what they call a lecture course for agriculturists. Among the lecturers and lectures Feb. 21, was Prof. O. P. Jenkins, on "Bees and Fruit-Growing." Mr. A. B. Shearer, one of our subscribers located there, sent us a copy of the *San Jose Daily Mercury*, which speaks as follows of Prof. Jenkins' lecture to the students:

Prof. O. P. Jenkins is not a stranger to the orchardists of this county, and his lecture yesterday, on "Bees and Fruit-Growing," was the renewing of an acquaintance that was as mutually agreeable as it has been pleasant in the past. The practical application of his lecture was made plainly apparent.

In opening, Prof. Jenkins told of some of the rudimentary principles regarding the pollenization of plants. "The more," said he, "we can find out about the limits and laws that control the life of the plant the better fitted we are to raise the plant."

In explaining the pollenization of the flower he showed a map displaying the parts of the flower and picturing the pistils and the ovaries at their root. It is found of absolute necessity that the ovule of one plant be brought into contact with the ovule of another plant. On the top of the pistil is a stigmatic surface where the pollen lodges. It sprouts and pushes down to the ovule below a filament, sometimes three or four inches long, and thus is the fertilization accomplished. Some flowers have both pistils and stamens, while in others one plant bears a staminate flower and another a pistillate flower.

"How is the pollen carried from the staminate to the pistillate flower? By three ways chiefly—the wind, insects, and birds. Those carried by the wind have to be adapted to the wind's way. Flowers that fertilize in this manner produce and scatter a large amount of pollen, tho one grain only is needed to fertilize the flower."

He described the formation of flowers in which the bees operate as pollen-carriers, and showed how bees become

useful agents in the work of fertilization, and how thus the plants make use of the bees.

"The type of most fruit flowers," said he, "is the same; they have both stamen and petals in the same flower. Below is a disc which contains sweet fluid that the bees desire. Contrary to general belief, the wind can not fertilize these flowers. It has been known for some time that some varieties of trees do better if they are planted in with other varieties, so that cross-fertilization can take place. It is this way with the almond."

He explained the valuable experiments that were conducted by Prof. Waite, of the Department of Agriculture, in the cross-pollenization of the pear. By these experiments he ascertained that some varieties were produced by cross-pollenization and others by self-pollenization. In all cases, however, it was ascertained that cross-pollenization always produced the best fruit.

In his judgment, the reason why many orchards do not bear is because the flowers are not properly fertilized.

Of the many insects that visit flowers some are more adapted for pollen-carriers than others, and the bee is found to be one of the best. With the pear more than the apple, the bee is found to be the main fertilizer. From experiments tried it has been found where there are large numbers of fruit-trees the bees are insufficient in number many times to do the pollenizing.

"I would think it advisable," said he, "in this valley, where there are so many fruit-trees, for bees to be kept not for their profit, but the more completely to do the work of fertilizing our fruit-flowers."

We move a vote of thanks to Prof. Jenkins for his clear putting of the truth. Mr. Shearer rather forcefully, tho truly, put it when he said in a note accompanying the clipping:

"See, we are beginning to get it hammered into them by these learned men—men they must recognize. Yet they will set out the poison."

MR. GEO. C. HAMBURGH, of Pierce Co., Wash., has sent us a sample of his 5½-inch alighting-board which he attaches to the hive by a piece of tin tacked on top at each end of the board. It is easy to put on and off, requiring only two tacks. When on it slants downward a trifle.

MR. W. A. PRYAL, of Alameda Co., Calif., writes us March 8:

"We have been having some good old-fashioned rains lately. I am pleased to know that the south end of the State is getting a wetting at last. We have been having all we require in this portion. I never saw the grass and other vegetation looking better than it now is. Many kinds of fruit-trees are in bloom. Garden flowers are out in profusion."

MR. HARRY HOWE, Secretary of the Cuban Bee-Keepers' Association, wrote us as follows, March 12:

FRIEND YORK:—I wish to correct one point in the article on D. H. Coggs shall in a recent issue of your paper, in regard to the 4-frame extractor. The one built by D. H. Coggs shall took the frames in the usual four-sided form, with the upright shaft in the center of the can. I made the first drawing of the other kind with the frames in pairs, and W. L. Coggs shall had two made by the late Miles Morton. These were used in the apiaries of W. L. Coggs shall for two years before D. H. Coggs shall had his first one made. This was made from the pattern which he borrowed of W. L. Coggs shall.

Bees are swarming here now. Foul brood is really much worse than has been described in the papers. Nearly every apiary in Cuba has it. I have gone into partnership with a Cuban who owns about 7,000 acres of fine honey-country to put in bee-ranches to the tune of 2,000 colonies. This gives me entire control of my bee-range.

HARRY HOWE.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Hives in the Shade or Sun.

Which do you think is the better, to set hives under trees, or out in the hot sun? NEBRASKA.

ANSWER.—I would very much rather have my bees in the shade of trees, both for the comfort of the bees and for the comfort of the bee-keeper; and I suppose the same rule will hold in your State.

Queen-Breeders' Terms—Veil Injuring Eyes, Etc.

1. Looking over queen-breeders' advertisements, I notice such terms as "golden Italian," "dark Italian," "3-band Italian," and "5-band Italian." Now, which one is pure Italian?

2. I believe wearing a bee-veil is injuring my eyes. The veil is black tulle. How wide should the hat brim be so as not to injure the eyes?

3. What do you think of the Johansen extension hive, described on page 129? MISSOURI.

ANSWERS.—1. They may all be pure. Dark Italian and 3-banded are terms applied to those that come direct from Italy; golden Italian and 5-banded after they have been changed in this country. I believe G. M. Doolittle thinks none of them are pure because not of fixt characteristics.

2. You can probably have nothing better than black tulle. If the veil is attached to the edge of the brim, it makes little difference how wide the brim is, the difference being in favor of the narrower brim, for you can see a little better with the veil close to your eyes than when farther away. But the better way is to have a wide brim, say 8 inches, and then have the veil sewed on as close to the face as possible without having the veil touch the face. Then the outer part of the brim shades the veil; for the sun shining on the veil makes it hard on the eyes. Of course the tulle should be the genuine article, of fine silk.

3. It seems to suit the inventor well: whether others will see advantages enough in it to make them adopt it, remains to be seen.

Some Actions of Bees—Alfalfa as Stock Forage.

DR. MILLER:—I think I can help you to answer "Massachusetts's" questions, on page 6. I will first state what I have seen, and then draw conclusions.

Some years ago I set some combs out at the west of the apiary for the bees to clean, and after they had gotten well to work I concluded to move the hives of combs to a more sheltered place, and so carried them to the north of the apiary. The bees were continually leaving these hives while I was carrying them, and after I had set them in the new place, and it amused me to see them all start directly east, as they should have done from the old stand. Some of them would fly 10 steps and others nearly as far as I could see them, then they would circle a little and turn towards home.

Again, last summer, I carelessly left a hive of combs just extracted, near the door, just east of the apiary, and they were soon covered with bees. I carried the hive away from the house to the southwest of the apiary, and the bees all started west on leaving the hive. The wind was pretty strong from the west so they could make but little headway against it, but they would struggle a short distance and then turn to the northeast for home.

If you "want more reliable testimony," I hope you will try it yourself in the spring.

The bees evidently did not realize that they had been

carried since alighting on the combs, and so started in the directions in which they supposed home was, till they saw a familiar object. Their ability to recognize objects is doubtless very acute.

I notice you did not entirely endorse the story of a cat's finding its way home. I am glad of it, for it is all bosh. A few years ago a certain bee-keeper, in trying to prove that mankind only had reason, wrote some wonderful stories about cats, but bees and cats have no more a sixth sense than we have. To be sure, one will sometimes, by chance, start in the right direction, and so find home, and these cases are exaggerated and reported.

Regarding "New York's" question on the same page, I will say that alfalfa does frequently kill cattle, and that, too, when they are accustomed to eating it, especially when it is young and tender, or when wet with rain or dew, or by drinking immediately after eating. My son lost two on this place last summer, and several others bloated badly, but were discovered in time to save them. I have had no experience with sheep, but am told that they are more subject to bloat than cattle. It is not usually pastured except the old stubble in the fall. It does not produce honey in this locality, but where I was in Colorado it furnishes nearly all the surplus. I. W. BECKWITH.

Fremont Co., Wyo., Jan. 10.

ANSWER.—This is interesting, and shows it is not well to be too skeptical when so many close observers are on hand with "reliable testimony." The point emphasized is that when bees are freed after being carried a distance, they fly in the same direction they would have done if no moving had taken place.

Who Should Pay the Freight?—Wax-Worms.

1. Do you think it is right for the producer to pay transportation charges on what he has to sell, and also what he has to buy? To illustrate: Suppose I have some honey and wax to sell. I send it to some supply dealer to exchange for his goods. I have to pay freight both ways—on his goods and also on mine. Now be candid, and give an unprejudiced answer.

2. I also send a clipping from a country paper. Please give your opinion on the kind of bee-worms the writer had reference to. The clipping reads as follows:

WEAK COLONY OF BEES.—When a colony of bees is found at the close of the season light in weight, it is generally better policy to destroy it than to try to keep it thru the winter. The weak colony is probably already infested with bee-worms, and the sooner the propagation of these is arrested the better, as their increase makes greater danger for all the colonies next year. If the weak colony is destitute of a queen its bees may be transferred to a larger and stronger colony with advantage to both, tho in some cases more food must be provided for the strong colony after this addition, to enable it to winter without loss. ILL.

ANSWERS.—1. Whether it be that the editor prefers to have the question as to who shall pay freights answered by one who is not prejudiced in favor of the supply dealer, or whether it be that with a wicked chuckle he sends the question to me as a poser—in any case he has turned it over to me, and I can hardly say the answer is difficult. It is simply a matter of fairness, agreement, and convenience.

Suppose I sell honey to a dealer. He says to me, "I can get all the honey I want of the same grade as yours, delivered here for 15 cents a pound." I say to him, "But I don't want to pay the freight, and I don't think I ought to." "All right," he replies, "I'm willing to pay the freight, but as it will cost half a cent a pound to get it here, I can afford only 14½ cents a pound if I pay the freight." Then suppose I want to buy a thousand sections. He asks for them \$3.50. But I tell him I want him to pay the freight. "Certainly. But the freight to your place will be 25 cents, so if I pay the freight I shall have to charge \$3.75 for the sections." Certainly there can be nothing that I see wrong in that. So I make both trades, selling honey at 14½, and buying sections at \$3.75, and he pays freight both ways. Or I may sell honey at 15, buy sections at \$3.50, and pay freight on both.

I think you will find the dealer willing to pay freight one or both ways, but certainly you cannot expect the price to be the same whether he or you should pay freight.

2. The item is not nearly so wide of the mark as many an item written by those who know little or nothing about bees. The "bee-worms" mentioned are no doubt the common wax-worms. In these days of Italians, one smiles at the great danger from the propagation of "bee-worms" to "all the colonies next year."

Root's Column

FIRST RUN OHIO MAPLE SUGAR —AND— SYRUP.

CROP OF 1900.

DO YOU KNOW that Ohio produces the finest Maple Sugar and Syrup to be had anywhere?

DO YOU KNOW that, according to the pure-food laws of this State, every gallon of syrup put up here must have the name of the producer on the label, and there is a heavy fine for adulteration?

THE RESULT is that Ohio Maple can be depended on every time. Do you want something fine, something that will please all of your family? then order some of our Maple Syrup at once. In one-gallon cans, \$1.00; same in lots of 10 one-gallon cans at 90 cents per gallon; 25 one-gallon cans at 85 cents per gallon.

SUGAR

New Maple Sugar, No. 1, at 10 cents per pound; No. 2, at 9 cts. per pound; 50 pound lots at 1/2 cent per pound less; barrel lots of about 200 pounds at one cent per pound less.

ORDER AT ONCE and get the first run, which is something fine.

IF YOU EXPECT to send an order later for bee-supplies and want some sugar or syrup reserved for you, send along your order and make this request.

The A. I. Root Co.,

MEDINA, OHIO.

GENERAL ITEMS

Bees Wintered All Right.

The bees have come thru the winter all right; 90 colonies, and no loss so far. They are having a nice time after the stormy weather. They have no dysentery—have not spotted the hives any. I wintered them out-doors altogether. I pack with forest leaves on top and between the outside shell and hive proper. I use the Gallup frame, run for comb honey, and do all my own work. I am 73 years old. The American Bee Journal is all right.

D. C. MCLEOD,
Cheshire Co., Ill., March 11.

Clipping Queens—Euphorbia.

I am one that does not like to see a queen's wings clipped, but I practice clipping as a dire necessity, for reasons that have often been given. I make the clipping serve to show me how old the queen is whenever I see her again, as well as to prevent her flight, thus:

Of those reared one year I clip the left wing straight across; of those reared the next year, a slanting cut on the same wing; the next year a slanting cut on the right wing; and the fourth year, a cut straight across the right wing. As a queen seldom lives over 4 years, I can go over the same rotation in succeeding years.

On page 767 (1899) I tried to describe a plant that I thought might prove of value to bee-keepers, and later I was asked for a further description of it, which I was not able to give until recently. My neighbor who raises it says the name that the florists give it in their catalogs is Euphorbia Hetophilla, or Mexican fire-plant. The plant exudes a milk wherever broken or cut, like the milkweed. When the whole plant is cut off the bees will work on the stubble for some days. Branches cut off and stuck in water will keep fresh for months, and when the sun shines on it the little nectar-cups will fill, and new flowers continue to form. I intend to plant some soon to see if it can be raised easily enough to justify its cultivation for honey or forage, or both. T. W. LIVINGSTON,
Sumter Co., Ga., March 9.

Domesticating the Bumble-Bee.

Doubtless there is no other subject that interests the bee-keepers more at present than that of establishing a strain of bees for business.

When I was a boy I found a bumble-bees' nest in a hollow stump, some 50 yards from my father's house. The stump was somewhat decayed and not more than 2 feet high. The entrance was in the top of the stump and ranged downward.

Oh, how eager I was to transfer these bumble-bees into a frame hive so I could handle their combs, rear queens, etc.

So I made a small hive with frames in it; secured the help of my younger brother, and got a glass fruit-jar that would hold a quart or more. Mother

remonstrated, but we promist to take good care of her jar.

So with hive, smoker and jar, we started for the stump to domesticate the bumble-bees.

The family dog, Pug, offered his assistance. After some consideration it was decided to let him go along.

Now when Pug was a mere pup some cruel person had cut his ears off, and bobbed his tail, so what tail he had left wasn't more than an inch long.

On arriving at the stump we placed the mouth of the jar over the hole to catch and hold the bees so that we could work to a better advantage in transferring.

Now the work began in real earnest. With club and stick we drummed on the stump, and to our happy surprise quite a goodly number of enraged bumble-bees came into the jar. The drumming and loud buzzing of the bees in the jar excited Pug's curiosity, so he began to render his assistance by exercising his vocal organs to their fullest extent. But by accident we overturned the jar. Falling to the ground it was broken in pieces. Of course this releast the enraged bees. Without hesitation brother and I fled for safety. Pug seeing our retreat quickly took in the situation. Unfortunate for him, one of the enraged bees fastened itself on the stump of his tail. With a howl he set off for the house. In at the door he went, turning over one or more chairs, upsetting the center table and throwing the Bible to the floor, and scattering other literature promiscuously. In a few minutes father came to the door, and said, "Boys, come over to the house a few minutes, please."

After explaining the matter from start to finish, and receiving some good advice, I was convinced that to domesticate the bumble-bee, so as to make it profitable, might take considerable time and ability.

But there is a sense in which the bumble-bee, when provoked to anger, is real business, and Pug ever afterwards remembered it.

H. B. LAMBERT.

Simpson Co., Ky., Feb. 28.

On pages 54 and 55 Dr. C. C. Miller answered questions concerning the domestication of the bumble-bee. Now, if of sufficient interest yet, I will relate what I know about it.

When a boy I tried my hand at it, and I was quite successful in hiving the bumble-bees, as also in removing them from their original location to a small shed purposely prepared for them. I have had as many as 20 colonies in one season, and nearly all of them of different markings, size and temper. I made hives of clay, sufficiently large to provide room for their nest. At night, I took their nest, with the surrounding bedding of dry grass and moss, and placed it on a board, and then I put over it my clay hive, and left it on the original location for a few days. The bumble-bees were not slow in adopting their new surroundings, and, after removal, they carried on their business all right.

The variety of the bumble-bees in northern Germany is very great, as well respecting their color and markings, as the size of the different species. They also vary perceptibly in the quantity of honey they gather.

GEORGE W. YORK & CO. 118 Michigan Street, CHICAGO, ILL.

But, of course, the whole business did not amount to anything, except that it was very interesting to me.

With the approach of winter, all my bumble-bees disappeared, and none of them wintered in their little clay hives, so that only the pleasant remembrance of my boyhood undertakings remained with me, and they ever will.

Hall Co., Nebr. WM. STOLLEY.

[The above experiences will probably suffice on this subject for the present. Altho it is interesting reading, it is not specially helpful to very many of our readers.—EDITOR.]

Hunting Bees.

It appears my question to Dr. Miller, signed "Massachusetts," has brought out some good points in regard to hunting bees. As several bee-hunters have come forward to substantiate my statements, I will venture to give one or two more of my observations along the "line."

I have noticed when working up on the "line," and the bees are working strong on the bait, one can tell when he gets pretty near the tree, by the number of bees that will be seen hunting and flying about in the grass and around the trees. I suppose they are bees that have not found the bait, but know there is a big boom in honey somewhere not far off.

I also find when timing bees from the bait to the tree, it makes quite a difference whether it is a young bee or an old one with ragged wings. It takes the old one much longer to go and come.

A. E. WILLCUTT.
Hampshire Co., Mass.

Ordering Bee-Supplies Early.

I have never made a kick, I think, on anything contained in the American Bee Journal. I will have taken it 8 years next June, if I mistake not. It is my favorite bee-paper, but the editorial on page 136, on "Early Orders for Bee-Supplies," is a case of "last straw that breaks the camel's back."

Of course, I know the dealers' advertising amounts to a good deal more than my paltry \$1.00 on subscription; nevertheless, I know most, if not all, papers are conducted ostensibly in the interest of the subscribers.

Now this old warning about ordering supplies early is, or has been, printed in bee-papers and supply catalogs almost times without number. I think it is high time we hear something about dealers shipping goods in a reasonable time after getting our cash, or else informing us why they can not. I know of no other business that makes a regular thing of taking your cash order and not sending goods for months afterwards. (It makes me hot all over.)

Now I want to tell some of my experience. I may not have dates exact for 4 or 5 years ago, but the last deal or two is fresh in memory, I can assure you.

I bought supplies first of a large Wisconsin firm. The first order was filled within a few days, but they got slower and slower. The last order, given in December or January, was received about March 10. I think I did order 5 hives yet after this, and got them the

Supplies from Lewis! Thousands of Bee-Hives! Millions of Sections

DR. MILLER'S Honey Queens

One Untested Queen Free as a Premium for sending ONE New Subscriber to the American Bee Journal for one year.

We have been fortunate in making an arrangement with DR. C. C. MILLER—the well-known honey-specialist—to rear queens EXCLUSIVELY FOR US DURING THE

SEASON OF 1900. These Queens will be mailed in rotation, beginning about June 1, so "first come first served." We are ready to book orders now.

The Queens Dr. Miller will send out on our orders will be precisely the same as those he rears for his own use, so of course they will be from his best stock. His best colony in 1899 had a queen reared in 1898; May 5, 1899, it had brood in 4 frames, and he gave it at that time a frame of brood without bees. It had no other help, but May 25 a frame of brood with adhering bees was taken from it, and the same thing was repeated June 3, leaving it at that time 5 frames of brood. It stored 178 sections of honey, weighing 159 pounds (and that after July 20, in a poor season), being 2 2/3 times the average yield of all his colonies. A point of importance is the fact this colony did not swarm, and an inspection every week or 10 days showed that at no time during the entire season was there even so much as an egg in a queen-cell. Dr. Miller expects to rear queens from this one during the coming summer.

The demand nowadays is for BEES THAT GET THE HONEY when there is any to get, and Dr. Miller has such bees. You will want to have a queen from his best, we are sure.

Do not send any orders to Dr. Miller, as all orders MUST come thru us, according to our agreement.

Remember, send us \$1.00 for ONE NEW SUBSCRIBER to the American Bee Journal for one year, and YOU will get ONE OF DR. MILLER'S UNTESTED HONEY-QUEENS FREE AS A PREMIUM. This offer is made only to our present regular subscribers. Orders for queens to be filled in rotation, beginning about June 1st.

Address all orders to GEORGE W. YORK & CO., 118 Michigan Street, CHICAGO, ILL.

Please mention the Bee Journal when writing Advertisers.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The holsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a long time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.10, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00). We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO., 118 Mich. St., Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

Don't fail to mention the Bee Journal when writing advertisers.

latter part of the summer, after swarming was over. I quit them.

Next I tried an Iowa dealer. He was about as slow on the first order, so I gave him up as hopeless. Oh, yes; I got some queens of him. I got a good queen, the last one, but it was a month or six weeks in coming.

I gave another large Wisconsin firm a few orders which were filled reasonably quick, so I have no kick on them.

But the worst deal of all is the one now on hand. About 5 years ago next spring I began to deal some with a third Wisconsin firm. The first order for comb foundation was filled the next day after its receipt, and as his foundation is fine, I thought I had found it at last. He was pretty prompt for a year or two, but gradually got slower. But I was so well pleased otherwise that I thought I would try him again. Now, understand, I have always ordered my hives, sections, etc., early, generally in January or before, except of course, some years I might require more than calculated on, and so be compelled to send for a small supplemental order later on.

So last September I wrote for quotations on 30 pounds of foundation and 2,000 sections. I was quoted a satisfactory price, and I sent the order a little after, or about the middle of October, with the request to ship the foundation immediately, as I was afraid of breakage in cold weather. Hearing nothing for a couple of weeks, and not knowing whether the order had been received, I wrote, asking about it, and again urging to ship the foundation before cold weather should set in. So the foundation was shipped Nov. 9, and I was told the sections would follow later on.

Wanting to fix up the supers, I wrote again Jan. 26, asking for the sections. The reply came that they would be sent in a week or 10 days. About Feb-15 I sent an order for \$3.50 worth of nails, wire, smoker, bee-escapes, etc., and again urged sending on the sections, and now, at this date (March 5) I have heard no more of the order.

Do you wonder that I can't read that advice to "order early" with patience any more? Surely all winter is more time than justice requires to fill orders for stuff that should always be in stock? They do a cash business, they wouldn't trust me for a dollar; then why shouldn't they send goods promptly? Let them keep more help if the business is rushing—surely the laborer is worthy of his hire.

I suppose nothing can be done, but I thought I would write about it any way. Perhaps we will be spared on the subject of ordering early hereafter, even if the editor can't see his way to touching up the dealers on filing orders the same winter they are received.

The bees seem to be wintering well so far. We have had a pretty fair winter to date.

E. S. MILES.
Crawford Co., Iowa.

[We trust every one of our bee-supply advertisers will read the foregoing, and particularly those referred to as evidently having been born slow. The trouble with Mr. Miles was, he didn't happen to send his orders to the right dealers to get prompt service. We could tell him of several places where

we feel quite certain he could get his orders filled at least the same season, if not sooner! But he mustn't find fault with our advice to "order early." for the advice is all right—it was the dealers he chose to patronize that happened not to be of the get-there-quick kind. Next time try—try—well, we'll leave the selecting to you, Mr. Miles.—
EDITOR.]

Bees Wintered Well.

My bees have wintered well. I took off 5,100 pounds of honey last year from 70 colonies, and increased to 120. I am making my arrangements to be at the convention of the National Bee-keepers' Association next August, in Chicago.

J. T. HAIRSTON.
Cherokee Nation, Ind. Ter., Mar. 10.

Report for the Season of 1899.

Our 50 colonies of bees, spring count, last season, gave us \$129 worth of honey, above expenses, and we put into the cellar 105 colonies. The crop was light.

O. E. CLARK.
Calumet Co., Wis., March 10.

Bees Having a Picnic.

My bees had a general flight March 8—the first since Jan. 25. The weather is fine to-day, the mercury being 72° in the shade. The bees are having a picnic working on the water and carrying meal for pollen. I am minus only two colonies out of 46, and all appear to be in fine condition.

S. A. MATSON.
Nodaway Co., Mo., March 11.

Bees Are Hustling.

Almond, apricot, plum, peach, nectarines and many wild flowers are in bloom, and the bees are not able to gather all the food, but they are so busy that it does me good to see them. My bees wintered all right even to the weakest colonies. We are troubled with foul brood, but my bees are free from it yet. The weather is lovely, and very springlike.

L. NEHF.
Merced Co., Calif., March 4.

Sore Throat and Lung Remedies.

I send you two new honey remedies that are good, and will produce good results.

No. 1.—Dissolve one teaspoonful of boracic acid with ½ pint of boiling water; add one tablespoonful of extracted honey, and use as a gargle for sore throat.

No. 2.—To two tablespoonfuls of extracted honey, add one teaspoonful of powdered alum. Give a small quantity on the end of a spoon every hour for an expectorant, and in case of croup give larger doses—½ teaspoonful every ½ hour—till relief is obtained.

This last is a fine thing, and is indorsed by my physician.

My bees have wintered fine; have started brood, and I don't think there will be any loss to report out of the 35 colonies.

L. C. SALSBURY.
Bradford Co., Pa., March 6.

Convention Notices.

Chicago.—The Chicago Bee-keepers' Association will hold its regular semi-annual meeting in Wellington Hall, 70 N. Clark St., Chicago, Ill., April 6, 1900, afternoon and evening. The meeting will be called to order at 1 p.m. Dr. C. C. Miller is expected to be present if his health will permit. Mr. E. R. Root has been invited, also Mr. N. E. France, and others. A good time may be expected by all. Let every one come, especially the ladies.
Park Ridge, Ill. HERMAN F. MOORE, Sec.

Utah.—The Utah State Bee-keepers' Association will hold its semi-annual convention in the City and County Building, Salt Lake City, Apr. 6, 1900, at 10 o'clock a.m. A full program in the interest of the industry will be presented, and all our bee-keepers can help themselves by aiding the Association, and in order to create a closer bond of union among our bee-keepers. As a further incentive to the success of the bee-industry, it is very desirable to have our bee-keepers from all parts attend the spring convention.

The Bee-Keeper's Guide

Or, Manual of the Apiary,
—BY—
PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without **THE BEE-KEEPER'S GUIDE.**

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.
118 Michigan St., CHICAGO, ILL.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, March 8.—There is a small trade in choice to fancy white comb honey, at 15c per pound, but aside from this there is little doing in any other grade, with an uncertain range of prices, for those who have it want to sell and buyers can get reductions from prices asked. Off grades of white, 10@13c; ambers, 8@10c; dark, 7@9c. White extracted weak at 8c; ambers, 7@7½c; dark, 6½@7c. Beeswax burnt at 28c.
R. A. BURNETT & Co.

CINCINNATI, March 3.—There is some demand for extracted honey from manufacturers at 7@7½c for amber and Southern; clover, 8@8½c. Comb honey is selling firm at 14@16½c in a small way. Beeswax, 25@27c.
C. H. W. WEBER,
Successor to Chas. F. Muth & Son and A. Muth.

LOS ANGELES, March 1.—1-pound frames, 12½@15c; 2-pound cans, 2 dozen in case, per dozen, \$2.50; 2-pound glass pails, per dozen, \$2.50. Extracted, water white, 60-pound tins, per pound, 8½c; light amber, 7½@8c; dark amber, 7½c. Beeswax, 25@26c.

The prospect for a crop is very bad. Small lots in the hands of wholesale houses are firmly held.

BOSTON, March 9.—Our honey market is showing some signs of lower prices, altho the stock on hand is not large. At the same time prices are so much higher than previous years that the trade have taken it very slowly and the results are that the holders are willing to range prices quite a little in order to move stock on hand. Prices range: Fancy white, 17@18c; No. 1, 15@16c; amber, 10@12c; buckwheat almost unsalable. Extracted, best white California, 8½c.
BLAKE, SCOTT & LEE.

KANSAS CITY, Mar. 10.—We quote fancy white comb, 15c; No. 1, 14c; No. 1 amber, 13½c; No. 2 amber, 13c. Extracted, white, 8c; amber, 7c; dark, 6c. Beeswax, 22@25c.

The supply of comb is very light, demand good; supply of extracted light, especially white, demand fair.
C. C. CLEMONS & Co.

BUFFALO, March 3.—Market nearly bare of all grades of honey. Probably no more from any source to market, but if so, fancy white comb is firm at 15@16c. Other grades from 14c downward, with the poorest at 8@9c. Fancy pure beeswax continues at 28@30c.
BATTERSON & Co.

NEW YORK, Feb. 8.—During the past 30 days our market has been somewhat slow and easy in both comb and extracted honey. Stocks of comb honey, however, are almost exhausted, and there is a fair demand for all grades. Fancy white selling at 15c; No. 1 white at 13@14c; fancy amber, 11@12c, and buckwheat at 9@11c, according to quality, etc.

Our market is well supplied with extracted, the prices are firm and unchanged. Beeswax sells very well at from 26@28c, according to quality.
HILDRETH & SEGELKEN.

SAN FRANCISCO, Feb. 23.—White comb, 11½@12½c; amber, 8@10c. Extracted, white, 7½@8c. Light amber, 7@7½c; amber, 5@5½c; Beeswax, 26@27c.

Supplies and demand are both at present limited, which is to be expected at the close of a light crop year. Business doing is mostly of a small jobbing character, and at practically the same figures as have been current for some time past.

OMAHA, Feb. 13.—Demand shows some improvement in January, having been much more active, but as anticipated there is no advance in prices. Market remains steady at 14@14½c for fancy white comb and 8½c for white extracted. The latter is pretty well cleaned up along the Missouri River, and it looks as if there would be some shortage before another crop comes in. From present appearances there is about enough comb honey to go around at the present prices, hence we look for no particular change in values.

CONTRIBUTED ARTICLES

A New Bee-Cellar—How to Construct a First-Class Winter Repository.

BY T. F. BINGHAM.

THE view of the roof covering my practically air-tight bee-cellar is well illustrated by the cut. It is 20 feet wide and 20 feet long, and, as shown in sectional view, very steep, affording a large room for work above the cellar. But, what is of more value to the bees, the room is dark. It is into this room that the cellar is ventilated, or from it the bees receive the air they use without taking it from the unwarmed air outside. [See sectional view on next page.—ED.]

The sectional view shows the ventilator as passing up thru the roof in the middle of the floor. This is correct, all but in that the ventilating-tube, which is a three-inch tin conductor reaching from the bottom of the cellar two feet above the floor over the bees, does not directly reach the outside.

The value of this modifying room will be better understood by the fact that it is in reality a part of the cellar, and not merely a roof. The cellar is in all respects a cistern. It is 16x16 feet on the level of the ground, and 12x12 feet at the bottom. The sills are 2x12 inches, and 18 feet long, and lie flat in the cement of which the sides and bottom of the cellar are composed. The roof, as you will note, extends below the level of the ground, and discharges its water into board conductors leading to lower ground.

The floor above the cellar is 2 inches thick, composed of dry inch boards. Three inches of dry pine sawdust covers this floor. Every corner and crack thru which air could circulate is closed with Portland cement. Three trap-doors are of the same thickness as the floor, and an easy stairway leads to the cellar. The hives are in rows on all sides, three high, directly over each other, leaving an open square in the middle of the room.

The square hives stand on their regular bottom-boards, and have a back and front entrance 11 inches by 7/8, with no possible upward ventilation or communication. The roof is made of tamarack (larch-tree) boards, one foot wide, and battened with the same kind of lumber 6 inches wide, and covered with coal tar.

The cost every one will want to know. It was from \$50 to \$55. It now holds 90 colonies and would hold 90 more if necessary.

The ventilating-tube reaching to the bottom of the cellar proved to be a failure. While

it supplied cold air, and kept the temperature all right, it failed to dilute the carbonic gas, and has been taken out. Only the three-inch hole in the upper floor has been used for the last month, and seems all right. The extreme variation in the cellar has been 4 degrees, being below 50 all the time, but no time as low as 45 degrees.

Feb. 14.—Bees O. K., 47 degrees. Out-doors, about 6 degrees. Death-rate about 2 pounds of dead per month, for the 90 colonies. The last sweeping gave an increase of 1/2 pound. They are swept out every twelfth day of the month, and the dead weighed. They were put in the cellar Nov. 12. Clare Co., Mich.

[As I have said elsewhere in this issue, I believe it is to be one of the cheapest and best repositories ever devised. The scheme of having a gable roof and a good, thick frost-proof floor over the cellar, the latter below ground-level, is most excellent. The objection to the cellars of ordinary dwellings is, that about two feet of the cellar is above ground; and in the two feet of wall there is liable to be one or more windows thru which cold and light enter. By the Bingham plan, the whole, or practically the whole, of the repository is under ground. This thick frost-proof ceiling or floor overhead, further protected by a gable roof, makes almost an ideal protection.

Incidentally it is interesting to note how little ventilation, if the temperature is right, is required. I hardly need say that Mr. Bingham, the inventor of the smoker, honey-knife, and hive bearing his name, is a man of no ordinary ability. He is a fine mechanic himself, and a practical bee-keeper; and whatever he says is good, is good in my estimation.—EDITOR.]—Gleanings in Bee-Culture.

The New Bee-Cellar of Mr. T. F. Bingham, Clare Co., Mich.

Some Questions Answered—Ripening Honey, Etc.

BY G. M. DOOLITTLE.

QUESTION.—What is the best plan of ripening honey where we can not afford to wait until it ripens in the hive? If an extra building or anything of the kind is required, I wish to prepare for it this winter, or in early spring.

ANSWER.—If you must ripen honey out of the hive, I know of no better way of doing it than to place it in tin cans holding from 200 to 300 pounds each, allowing these cans to remain in a temperature which can be maintained at from 90 to 100 degrees of heat for a month to six weeks, leaving the top of the can open, and tying cloth over it to keep out the dust and insects. If you have the means, and are in a hurry to have the honey ripened, it can be done by slowly running the honey over a zigzag evaporator, which is kept at the proper temperature by heated water, steam, or

Sectional View of Bingham Bee-Cellar—See previous page.

lamps, so that it will be ripened fast, and yet not scorch or change the flavor of the honey. But let me advise you to let the bees take care of this ripening part.

I am not sure that there could be any locality or circumstances where "we cannot afford to wait" for the bees to ripen the honey in the hives. We used to think we could not afford the combs to use in tiering-up hives that were necessary to wait till the end of the honey season, but I think this was a mistake. Not affording the combs, the bees had to remain partially idle while the honey was being sealed, which was a loss in time, so the honey was extracted every three or four days, when it was thin and unfit for use; but in these days of comb foundation, much the better way is to tier up the hives, adding foundation as needed, letting the bees seal the honey as far as possible, when it is to be brought into a warm room, if so cool in the fall to be necessary, and, when thoroly warmed, it will be little more work to extract it than it would be were it taken from the hive when two-thirds sealed, as was considered the proper thing years ago. Honey obtained by this tiering-up plan is superior to that secured in any other way, increasing the demand for extracted honey in the markets, instead of decreasing the same as did the honey of 15 to 20 years ago.

INCREASING THE NUMBER OF COLONIES.

QUESTION.—I wish to increase my bees to 50 colonies next season. I have 17 colonies now to do it from. I should like to know the best way to do it and still get some surplus honey.

ANSWER.—A large increase of bees, and "some surplus honey" at the same time, is something which is not very likely to occur, especially with a novice at the business. Still, there are ways in which it is sometimes accomplished. One of these ways would be to let the bees swarm naturally, hiving the first and second swarms, returning all those which come out after the second. Put sections on the first swarms, hiving them in contracted brood-chambers; and if the swarms came early enough in the season, put sections on all of the old colonies as soon as the young queens commence to lay.

A still better way would be to keep the colonies from swarming as much as possible, hiving the few swarms which did come in contracted brood-chambers as above, and six days after the swarm issued divide the old colony into nuclei, with a queen-cell for each. Occasionally, as needed, to keep those not having swarmed from taking the swarming-fever, take frames of brood from them and give to the nuclei, thus building them up into strong colonies. Replace the frames of brood taken with frames filled with comb foundation, thus preventing the building of drone-

comb. If successful as you should be, seven of the colonies swarming would give all of the increase needed to make the 50, thus leaving 10 to roll up all the surplus honey they possibly could, were the same 10 worked for no increase, provided you do not draw brood from them more than to keep down the swarming-impulse.

WHICH WAY SHOULD HIVES FACE?

QUESTION.—Which way should hives front, all things considered, in order to obtain the most profit from the bees? East, west, north or south, where they are wintered on the summer stands? and which way when they are wintered in the cellar?

ANSWER.—Some seem to think that it makes no difference which way the hives face when they are on the summer stands, but I think otherwise, especially in the winter. I have had hives facing almost all points of the compass, and those doing the poorest faced the north, while those facing south to southeast invariably did the best. I have lost colonies in winter facing the north, when those facing south and southeast would have good cleansing flights, and be in good shape for another long cold spell, the others not flying at all on account of the sun not shining on the entrance, hence they died with diarrhea, as it is called, by not having a chance to void their excrement.

Again, in summer bees in hives facing the sun will generally work longer each day than will those whose entrances the sun never shines upon.

Once more, the prevailing winds are from the southwest to north in this locality, and where hives face the west or north, more stores are consumed in keeping up the heat of the cluster where the prevailing winds blow directly in at the entrance, carrying off the heat generated by the bees.

Then, again, in all windy days the bees can reach the entrance readily when the hives have their backs toward the wind, while if faced toward the wind they are blown from their doorway, time and time again, before they can strike just right to partly fly and run in. This last part was what caused me to say that I would never face any hive, even during summer, in any other direction than south by east.

But to the other part of the question. If I am to understand by the latter part of the question that the inquirer thinks that it makes a difference which way the hives face while in the cellar, I can only think he is making a mistake, for I can not see how it can make any possible difference in a cellar of even temperature and total darkness. If there is a window in the cellar which admits light, it is better to darken the window; yet at my out-apiary cellar the people don't want the cellar dark, so I face the hives toward the wall and away from the light, when they winter very nearly as well as they do here in my perfectly dark cellar. Yet, if I am right, it is conceded by all that a perfectly dark cellar tends more toward a successful wintering of bees than does a light one.

Experiences of a City Honey-Salesman.

BY S. A. NIVER.

WHAT strange game one sees when he has no gun." That wise saw is forcibly brought to my mind as I meet the many strange notions people will persist in advancing as good argument when I am showing honey with the hope of selling a big (or little) order. Your average dealer hardly "knows a honey-bee from a mudwasp," but is well posted on just how artificial comb honey is produced, and what large quantities are sold of "the stuff" every year!

Only last evening I overheard a clerk telling a lady customer that you could easily tell when comb honey was genuine—"by noticing the number of layers in the comb." (I just held my breath to catch the rest of it.) "But whether it is one or two layers that show it to be genuine honey, I have forgotten." Simply another case of, "Good indigo will either sink or swim, and I don't know which."

The good old way of sitting down to a long visit to inform your customer thoroly is costly, and many times impossible on account of the rush of business; besides, these city grocers only like to sell just what is called for, seldom calling a customer's attention to something new and especially desirable.

Another woefully ignorant and intensely annoying individual is that near-by bee-keeper, who doesn't take the bee-papers, but just loads in his honey, and goes towards the city selling his honey four or five cents per pound

cheaper than quotations. One chap of this class lost enough this year in that way to pay for a bee-journal for 75 years.

Say, Mr. Editor, can't you think of some way to get people who frequent saloons to take honey in place of "booze?" Great Scott! what a market that would open up. One man said that if I would bring around honey in a jug or beer-keg, "so as to look kinder nateral," I might sell lots of it. He did not label his remark "sarkasm," as Josh Billings did, but it sounded that way a bit.

"Why is honey so seldom seen on restaurant tables?" I askt of the cashier where I took lunch. He was a roly-poly Dutchman, and smiled at me in stupid tolerance. Showing him a sample of as fine extracted honey as one could ask for, and getting him to taste it, I actually imagined I had created a favorable impression. He took a liberal taste, then smiled in his broad, stupid way, and muttered, "Glooco—all glooco. Dot real honey is in leedle comb-cells—never coom loose like dot. Dey don't got him out onct yet." I went away from there. Life is so short to post up *all* these poor human critters who never heard of an extractor.

That makes me think, Mr. Editor, that your lecturing before the schools has been followed up by Mr. Hershiser, of Buffalo, who was engaged by the school board to give a series of lectures before different schools in that city. Why can't you persuade that exceedingly modest lawyer bee-keeper to write up that experience for the benefit of *all* bee-keepers? He said: "Oh, I am not given to tooting my own horn," when I askt him to tell us his methods, conclusions and impressions of that way of educating the coming citizen to eat honey.

In a small grocery an old lady was the only occupant that I saw, so I askt her if she kept honey in stock for sale. She replied, "We do;" while a loud voice from behind a pile of flour, in unmistakable Kilkenny accents, says, "I do." He had plenty of honey on hand—that nice clear "honey" in tumblers, with a piece of comb in it, which never granulates, and sells cheap—and he knew it was pure honey, for he went to his wholesaler and saw him take the honey right out of the combs, and if I would go I could see them do it every day in the year! How does that strike you, Mr. Editor? Extracting honey in a wholesale grocery house in February, thermometer down to zero! But I accepted the gentleman's statement, and moved on, searching after more advertisers in the same line.

The pure-food law may help out some if a determined effort is made by somebody to enforce it; but who is that somebody? And is it likely to prove a boomerang, by frightening grocers into refusing to sell *anybody's* honey, under any circumstances?

The problem of getting honey to the consumer at a price which will make it a competitor of sugar and syrup, has so many factors to it that a solution seems far in the future, if it is ever accomplisht at all.

NO. 4.—COMB HONEY PRODUCTION.

Putting on Supers—Clipping Queens—Age Limit—Controlling Swarming—Crowding the Brood-Nest.

BY R. C. AKIN.

WE have considered methods of encouraging breeding, and of getting the brood in the best shape and position in the hive. Following the lines indicated will have each queen produce almost as many bees as she could well do, tho there will almost always be a few colonies that become so weak in winter as to be unable to build up to good ones. If care has not been taken to supersede aged and weak queens, such will cause a few additional weak colonies.

As the flow is just ready to begin, or has begun, the colonies that are to store the surplus must be prepared and supers put on. We have come to a time when we do not care for very free laying by the queen, *unless* there be a second flow. If the crop is to come from one flow, and that only, no attention need be given to increasing brood when once the flow has arrived, but instead turn all effort to getting the most honey possible.

Every colony that works in sections must be strong. I would select those that are already strong enough to work in supers, and give them their supers first. Those that are *almost* strong enough I would help up by adding bees from

a weaker one, taking from the weak one both brood and bees, leaving only enough bees to care for brood as the queen will lay. In selecting the brood to take, pick out much ripe brood, or that which will give to the colony to which it is to be added the greatest number of workers in the shortest time. In this way unite and build up to super strength as many as possible, the weak ones being left to build up again to full colonies.

I favor the practice of clipping the queens—I clip and recommend it. That is a job best done in the spring, or early enough to have done with it before the colonies become very strong. Clipping serves us in several ways: It gives the apiarist somewhat more liberty, for he can feel that if he must be absent, awhile, and a swarm issues, it is not lost (the loss of a queen at this time is unimportant; it occurs when there are hundreds of good young queens going to waste; it is practically no loss unless brood is wanted for a later flow). As soon as a swarm issues provision is made to let them hive themselves as the apiarist may wish, and they will return and enter a hive much quicker, and with much less labor, than if hived by taking from a tree or other clustering-place; and also there is much advantage in keeping track of the age of queens.

It is almost impossible to know how old a queen is unless clipt. The practice of clipping gives the apiarist an insight into the age limit and supersedure methods of the bees, that he would scarcely get in any other way. Of course, a record is a part of the system—should be of any system.

In the years gone by much has been written at times about clipping queens and how it damaged them, of how they were more apt to be superseded, etc. Now I have handled hundreds upon hundreds, yes thousands, both clipt and unclipt, practicing methods that required much close inspection of the internal working of the colony, and surely if clipping caused damage to queens and undue superseding, I ought to have found it out. I have found out much about conditions that favor superseding, but those clipt do service just as unclipt, and so long as they are *good*.

Well-bred queens are good for two full years' work, and the great majority for the third year. A queen hatch in the early part of the season, so that the year of her hatching she does much breeding, is aged and very uncertain her third summer. Hatch in mid or late summer she will complete that year, all the next, and make a good colony for the next honey season after that, when she ought to be superseded. Don't expect a queen to do more than two hard summers' service. Many will be good for longer, but enough will not to make it unprofitable to risk keeping longer.

Having reacht the active season when supers are on the strong, and those that have been helpt to proper strength, the next great care is to keep the honey-gathering going, and not too much swarming. Here comes the place that of all the season requires skill, prompt and intelligent work. If you have failed in getting the colony to proper strength, you can partially remedy the matter by uniting, but if you fail in handling the work properly in the storing of the surplus, you have a poor product that can never be remedied. To fail in getting strong colonies is to lessen the quantity of the crop, and to fail in management when the harvest is on is to damage the quality and lessen the price.

As already taught in these articles, some things help to keep down the swarming-fever, and having practiced these, and natural conditions favor you besides, you should be able to run for 10 days to 2 weeks of a flow with very few swarms; but if general conditions have been favorable to swarming, you may expect wholesale swarming almost simultaneous with the coming of the flow unless you have striven against it. I am so successful now in the preventive measures taught hereinbefore, that I can usually depend upon a week to 10 days of a flow with a very few if any swarms *any season*.

I have never been in the basswood regions, nor experienced more than a very limited flow from this source, but I gather from reading that a basswood flow lasts only from one to two weeks. Any honey-flow that is harvested in two weeks' time ought to be, and *can be*, manage with very little swarming. Flows lasting longer than two weeks are more difficult to handle successfully. Remember this, *previous management of the colony has much to do with controlling swarming*, and to control swarming means much in both quantity and finish of the honey.

Never allow a colony to become crowded in the brood-chamber. This may result from various causes. A colony that has just enough bees to nicely handle the brood-chamber and send out a reasonable field-force, will crowd the

brood-chamber *regardless* of sections and room above. A flow that comes rapidly, giving the bees all they can do—a flow that just keeps every bee to all it can do, and for two weeks or more, will get super-work from many a colony that in a slower flow would not touch the sections.

When all the conditions of weather and nectar-secretion are favorable, almost any colony will do fair work; but as these conditions are wanting, the greater is the demand for other helps, such as strength of colony, bait-combs, and all the little encouragements we can give. To have all these helps, and then come the favorable weather and flow, and the apiarist has what is known as a paying crop—one of the record breakers that astonish the tenderfoot, and even the apiarist himself—to look after the details pays first, last and all the time.

A weak colony will crowd the brood-chamber in a good flow, a medium colony will do the same thing in a medium flow, and a strong colony will *just do the same thing* in a very light flow, or one that is very long-drawn-out, coming in *very slowly* for a long period. These are facts that we must consider, for just as we ignore them we detract from our success. The results we may rest assured will be according as these factors stand in relation to each other, and it is the science of apiculture applied, to bring the greatest number of favorable factors to bear at one time.

Larimer Co., Colo.

Safe Introduction of Queens—Building Up.

BY C. T. BONNEY.

THIS is one of the most important manipulations in apiculture. Upon it depends the improvement of stock (which is all important); upon it depends the queen-breeder's business almost entirely. If a plan of introduction could be found that would always guarantee safe introduction of queens, it would perhaps help as much as anything else to make the apiarist master of his trade.

A number of plans of introducing queens have been given to the public in the past, all, or nearly all, of which have been successful in a measure, but it seems that no plan yet introduced is always successful. I have used every plan that I have ever seen recommended, and have had good success with some, yet I have sometimes failed with all, but the plan which I now use has never failed, no matter what the conditions of the bees were. I got the idea from Mr. Doolittle's "Scientific Queen-Rearing," only I carried it a little farther. The plan is as follows:

Go to the hive to which you wish to introduce a queen, take out the present queen, smoke gently and jar the hive until the bees have filled themselves with honey, then shake about half the bees into a box 15 inches square, with wire-cloth sides; set the box away in some cool place until the bees mourn for a queen, which can be told by the bees hurrying around the box in every direction, as if greatly excited. Then introduce the queen by dropping her in at the top; the bees will at once accept her, and form a cluster.

Let them remain so for some time, then shake them in front of the hive whence they came, and let the queen and bees run in, smoking the hive gently.

I have introduced queens by this method at a time when there was no honey-flow, and queens not laying, and have never yet had a failure. Queens coming a distance, when treated thus, will lay sooner than by the caging plan, and are not so liable to be superseded.

I treat laying workers in the same way, only the bees used are taken from some strong colony, care being taken to get as many young bees as possible, and a queen that is laying. Smoke the hive containing the laying workers thoroly, and run in the bees and queen, and the work is done. Bees treated thus will stay anywhere.

It might be well to add that the best time to take the bees out is in the morning, and run them in in the evening.

This is also the best plan I have ever tried to build up weak colonies: Take one or two quarts of bees from some hive that can spare them, cage them for eight or nine hours, then run them into the weak colony, giving a frame or two of brood at the same time, and the effect will be magical. A weak colony will be turned into a strong one almost at once. I believe it a wrong idea to overburden a weak colony with brood, as it does not give them a good chance to defend themselves. They should have bees as well as brood. If there is any quarreling (which there will not be once in a hundred times) give tobacco-smoke until you quell the riot.

Marion Co., Oreg.

CONVENTION PROCEEDINGS

Report of the Colorado State Convention.

[Continued from page 182.]

THE USE OF COMB FOUNDATION IN SECTIONS.

Mr. Pease introduced this subject by saying there was no danger of using too much. He uses a wide strip at the top, and a narrow strip at the bottom.

Mr. Thompson—I experimented a little last season on the width of the sheets. In one super I had alternate rows of full sheets coming as close to the wood on each side as could be got in conveniently, and full sheets cut rather narrow so as to be $\frac{1}{4}$ inch away from the side. The sections containing the wide full sheets were much better filled than those containing the narrow full sheets. It made more difference in the filling of the combs than anything I have ever tried.

Mr. Martin—I would recommend using full sheets, tho I always use foundation in proportion to circumstances. I always fasten both the top and bottom of the sheet.

Mr. Thompson—Don't the combs bulge?

Mr. Martin—No.

Mr. Thompson—Do you use separators?

Mr. Martin—Yes.

Mr. Thompson—I tried virtually the same thing for pinching together a full sheet with a bottom starter, and those sections all bulged more or less. But they were not used with separators.

Mr. Martin—It is something of a trick to fasten foundation in my way, and I would not advise any one to do so unless he does it right.

F. Rauchfuss—Does it pay you to use full sheets?

Mr. Martin—I would use as much as I could. I mean I wouldn't run in debt for foundation. One reason I fasten both the top and the bottom is, it makes the combs better for hauling. I can put in one full sheet quicker than a full sheet and a bottom starter. I fasten it by pressure.

Pres Aikin then called for a rising vote on full sheets vs. starters. Five were in favor of full sheets.

Mr. Pease—I believe in using full sheets, but don't do it.

Mr. Porter—It is the same with me.

Mrs. Hood—The results are better, but they cost.

Ch. Adams—The advantage in using a bottom strip is greater than that of using a full sheet.

Pres. Aikin—All in favor of using full sheets rise. (18, and none opposed.)

Mr. Porter—One thing we must always look out for in fastening is a sufficient amount of heat.

Mr. Lyon—It should be enough so that the foundation is seen to be melted where it touches the wood, so it squashes out a little. To get an abundance of heat I substituted a student-lamp for the little lamp that comes with the Rauchfuss machine, and lower the flame when the wick is too great.

Mr. Adams—The hot plate should be manipulated so as to get the wood warm.

Ch. Adams—That is just what I want to avoid.

H. Rauchfuss—Keep the wood cool and the wax hot. If the wood is hot, the foundation will pull down when the section is turned over.

J. B. Adams—The boy that works my machine works slowly and needs less heat. He does not turn the section over until the foundation is cool.

H. Rauchfuss—Last summer I had a 14-year-old boy fold, fasten in foundation, and put in the supers 1,000 sections in half a day. He was not so quick as I have had them. I have had 1,500 sections put up in that time. With my machine, one has to work fast to do satisfactory work.

Mr. Lyon—There should be lots of heat, and I think a larger burner should be used, which can be turned down if it gets too hot. The section must not get too warm.

F. Rauchfuss—The foundation should be as cool as possible. A bucket of cold water is handy to keep the can of foundation in, covered up.

Mr. Lyon—That is a very important point. The foundation should be cut early in the day. I keep mine in a can until it is wanted.

Mr. Porter—I use a refrigerator.

Pres. Aikin—My machine works on the same principle as the Rauchfuss. I have found the section and the foundation can both get too warm. The foundation should be kept from wiggling while it is cooling.

HONEY-PLANTS FOR COLORADO.

Mr. Harris urged the importance of considering new honey-plants which might be adapted to Colorado conditions, and suggested yellow sweet clover, which blooms a month earlier than white, and fireweed.

F. Rauchfuss—We have yellow sweet clover here already.

H. Rauchfuss—It blooms before alfalfa. A field of it near me was cut, and died in the forepart of July. It doesn't live as long as the white.

Mr. Porter—In regard to fireweed, it grows only where a fire has cleared the brush. Since the land has cleared, it has disappeared. To grow that here would be like introducing cleome to Michigan.

OFFICERS AND COMMITTEES.

Officers for the ensuing year were then elected, as follows: R. C. Aikin, President; Ch. Adams, vice-president; F. Rauchfuss, Box 378, Denver, secretary; Mrs. R. H. Rhodes, treasurer; W. L. Porter, member executive committee.

Messrs. Cornelius, Crawford and Junno were appointed a committee on exhibits, and Messrs. Pease, Harris and J. B. Adams a committee on supplies.

The committee appointed to confer with a committee from the Horticultural Board on the next program reported that the committees had jointly decided that both the horticultural and the bee-keepers' meeting should be held on the same days, and that at 2 o'clock of the first day the bee-keepers should adjourn to meet with the horticulturists to listen to a lecture of interest to both, secured by the horticulturists, and that at 2 o'clock of the second day the horticulturists should adjourn to meet with the bee-keepers to hear a similar lecture arranged for by the latter. This report was adopted, and the committee retained.

H. Rauchfuss—Prof. S. J. Hunter delivered a lecture to the horticulturists to-day on the relation of insects to the fertilization of blossoms, that did us more good than anything I have ever heard. Every bee-keeper should get a copy of the horticultural report, for the sake of that lecture.

HIVE-COVERS, BOTTOM-BOARDS AND SUPERS.

Mr. Root, by request, then exhibited two hive-covers and a bottom-board he had with him. The bottom-board was a combined stand and bottom-board, with a sloping front serving for an alighting-board, and the part of the bottom-board coming under the hive had a gentle slope from rear to front, so as to make a large entrance. One of the covers had fine grooves on its top near its edges, so as to prevent rain-water from flowing over the edge and into the hive. The other was of two pieces, with a third piece above over the joint of the others, the three being so grooved to correspond with each other, that the shrinkage of the upper piece would draw the two lower pieces together, and keep the joint tight. The springs in the new supers were also exhibited.

Mr. Gill—I think a great deal of the springs for this dry climate. I have used them in 800 supers.

TIERING-UP SUPERS.

Mr. Gill—A great deal of honey is lost by improper tiering. A colony that needs a super needs it badly. A great many bees could be employed in a second super that would otherwise be idle. They should be watched closely. I always put the additional super under the first one. It is necessary to know the condition of each individual colony at least once a week.

Mr. Thompson—For the last three years R. D. Willis has come to rely more and more on tiering-up by adding the additional super above the first one. I found, when in Utah, that Mr. Geo. Hone does so. He is one of the best bee-keepers in Utah. I still felt incredulous about it, as the other Utah bee-keepers think Mr. Hone gets good crops because he is a good bee-keeper anyway, and that he would get one-fifth more by following the orthodox plan. Since returning here I have learned that H. Rauchfuss is dropping into it also, and I begin to think there is something in it. I would like to call on Mr. Rauchfuss to give the reasons for his doing so.

H. Rauchfuss—A great many times unfinished sections

are obtained by the practice of adding the super below. But judgment is needed in applying the other method. I would not recommend it in all cases. When the super is three-quarters full, and there are good prospects for more, I would put the added super under the first one. If there was any doubt of the flow continuing, such as would be caused by hail or drouth, I would put it on top. If you use only starters, without bottom starters, and the bees are slow, put it on top. But if full sheets with bottom starters are used, and the bees boil up when the quilt is thrown back, or work up on the bottom starters of the new super an hour or two after it is put on, then the super should be placed above. But I do not leave it in that position. When the first super is almost finished, then I alternate them. The honey is not stained with propolis nearly so badly when this method of adding the new super above is followed.

Mr. Martin—My experience is about the same as that of Mr. Rauchfuss. I have previously used the ordinary method, but during the last year or so I find it doesn't always pay. I want to take off the honey as soon as it is capt. By this method the bees are kept at work building comb, and at the same time the sections are finished quicker.

Mr. Brewer—I have a glass hive with glass supers, and have seen the bees working in all three when the supers were added on top. If only one or two supers had been given them, they would not have had room.

Mr. Martin—The ordinary method is very good to get the bees in the new super, but the other brings down the number of unfinished sections to as small a number as possible.

Mr. Brewer—I have stacked the supers six high that way.

H. Rauchfuss—I have had six supers on a colony at once by the ordinary method, but the outside sections were not finished. One season I ran a colony with not more than two supers on at once. That colony gave 252 pounds of comb honey.

Mr. Moon—I hardly ever tier up more than two. I don't believe the hanging out of bees in front does any harm. They are curing their honey. I don't think it a good idea to give them more room than they will employ.

Mr. Martin—One objection to raising the super to put a new one under is that the work of capping in the upper super is hindered while the bees are building comb in the lower one, so that both are finally capt at once, and the work is retarded. I like to have the honey capt quickly with nice, clean wax. When the bees are capping and drawing out at the same time, the capping is not done so readily as when the super they are capping is below. Those bees that lie around are the ones that build the combs. Bees build comb on the outside of the hive sometimes.

Mr. Harris—How many practice baiting the bees up into the super when the first super is put on? (Mr. Brewer and Mr. Cornelius responded they did.)

Mr. Cornelius—The first new super that is occupied I break up and distribute among the other supers, bees and all. It seems to start them.

H. Rauchfuss—If the colony is not in the right condition they will hang out even if they have nothing else but combs. It happens frequently that some of the best colonies are comparatively idle in the best of the flow. I remember one instance when they hung out after I had added supers, I don't know why. I have had colonies alongside not half as strong that finished two supers. In that case, bait sections would do no good. The condition of the colony counts far more than the bait, tho I use bait sections.

Mr. Harris—Often a bait section with a little honey draws them up.

H. Rauchfuss—That shows the colony is in the right condition.

Mr. Martin—Sometimes I have stubborn cases of lying out, and the bees will not cap the corners of the sections, and make thin combs. Such a colony should be requeened. I usually give it extracting-supers. If stubborn, I give the super underneath a few days, and then put it on top.

Mr. Brewer—Have you ever tried withdrawing one comb and putting in a blank?

Mr. Martin—Yes, but I thought it not successful.

The committee on resolutions offered resolutions of thanks to the press and to the Board of Capitol Managers, and then the convention adjourned subject to the call of the executive committee. FRANK RAUCHFUSS, Sec.

The Premiums offered on page 173 are well worth working for. Look at them.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Feeding Sugar Syrup in Spring.

What would be the result to feed with syrup before the spring honey-flow commenced, so that the brood-chamber would become filled and the bees would be forced to carry all new honey into the upper chamber? Would it produce an inferior quality of bees being fed on anything but honey while maturing?
MASSACHUSETTS.

ANSWERS.—Some have claimed that bees reared on sugar syrup would lack stamina, but the fact is not established with entire certainty, and many have had bees reared on syrup without mentioning any difference in the quality of the bees. Caution is needed, however, in feeding syrup largely in early spring. If the weather is objectionable, the feeding may induce bees to fly out and be lost, making more loss than gain. If there is too much syrup in the brood-chamber, there is some danger that some of it may be carried into supers after they are put on.

Plan for Avoiding Swarming.

I have 25 colonies of bees in good condition. I expect to be away this summer and would like to avoid their swarming, and would like to know if this plan will work:

I have 15 hives, each holding 17 frames with a division-board in the center, and a queen and two bees on each side of the division-board, but isolated thoroly. Now suppose I go to the hives filled as above, and between fruit-bloom and white clover, or about the first of June, and pull out the division-board and put on the supers at the same time, and close the hive. Will they swarm with two queens present, or will one queen be killed, if they would swarm?

I expect to give this a trial, and then about the first of August take off honey, and put in the division-board as before, and give a good ripe queen-cell to the side having no queen. By this way I could have a new queen in the hive this year, that is, if the old one was always killed. I have never read of a plan of this kind, and have thought it out myself.
PENNSYLVANIA.

ANSWER.—One of the queens would most likely be killed, but the entire plan may not give as much satisfaction as you expect, and it will be well to try it on part only.

Late Feeding—Italianizing.

Last winter I kept my 5 colonies in our cellar which has brick walls, cement floor bottom, with lath and plaster ceiling, and did not lose a colony, and the winter was the severest we have seen for many years. Last fall I had 14 colonies, and the fall and early winter being so nice, I left them on the summer stands until to-day (March 3), when on examining I found only 4 alive. Thinking they would need some feeding soon, I put them into the cellar, and gave two colonies sugar candy made from a recipe taken from the "A B C of Bee-Culture." The other two colonies are in box-hives, but judging from the weight of them they are better fixt for stores; they were my first ones, or the first hives I had; for the others I used the 8-frame Langstroth.

Most of those that I lost were rather small colonies, and nearly all had plenty, or some, honey. I am under the impression that they froze out, as the temperature got 14 degrees below zero about Feb. 15 to the 20th. I had them in an orchard on a southwest slope with a good north and west windbreak.

As last season was a poor one here in northwest Nebraska, the late swarms did not store enough to winter on, so I fed them until it got too cold. I have the Champion or Miller and the tin feeders.

1. Do you think feeding until it got too cold would be injurious to them? I used a syrup made of granulated sugar.

2. One of my surviving colonies are blacks or hybrids, that I captured from a cottonwood tree near by. Which will be best to give them, the first queen-cell from one of my Italians, or give them a queen? There are not any bees within 15 miles of me, and as I like to work with them I would like to do better than I have this winter.

There are not much of any clovers or buckwheat raised here, and no basswood, but lots of heartsease and wild flowers. I have 5 or 6 acres of alfalfa, and have sown and got a good start of white clover. About June 1, 1898, I had a swarm issue (while at dinner), and go into a box-hive with the brood-chamber nearly filled with old, empty comb. They filled the brood-chamber and stored 54 pounds of surplus honey, which I thought was doing pretty well. The alfalfa was about all they worked on.
W. H. R.

ANSWER.—1. Feeding too late might certainly help toward destruction. Better get feeding done in August and September. Too much swarming was probably a chief trouble. If your five had increased to 10 instead of 14, you would probably have had more this spring.

2. So far as Italianizing is concerned, it will make little difference whether you give a queen-cell or a queen, providing you get them to use the queen-cell. But of course they will be farther on with a queen. A good way would be this: When an Italian colony swarms, set the old hive in place of the black colony, setting the blacks in a new place. Then the Italians will swarm again, giving you a strong swarm with a good queen.

A Beginner's Questions.

1. When is the earliest in the morning bees will swarm out?

2. I have heard bee-men say they could tell the night before they swarmed. How could they?

3. How can I prevent a swarm from going away?

4. If you go to a hive in the morning how can you tell whether it will swarm before night?

5. Will a swarm that runs away ever come back if it can find no place to suit it?

6. When a swarm is going to alight on a high branch, how can you prevent it, and make it alight on a low one?

7. Do bees ever come out of a hive after you have them?

8. How can I prevent them?

9. Will bees swarm on a cloudy or windy day?

ONTARIO.

ANSWERS.—1. Generally you need not look for swarms before 9 o'clock, but in rare instances they may swarm as early as 6.

2. They probably referred to afterswarms, not prime swarms. About 8 days after the prime swarm, if you go to the hive at night, put your ear against it and listen, you may hear the queen piping, saying in long, drawn-out and rather shrill tones, "peep, peep, peep." If you hear that, you may look out for a swarm the next day. If there is no piping you need expect no swarm the next day.

3. Let the hive be well shaded and well ventilated, having it raised up from the bottom, and for the first day or two it may be well to have the cover raised half an inch or so. Some practice giving to a swarm a frame of brood to hold them.

4. You can't. If other colonies are working hard, and a strong colony seems idly hanging out, you may suspect an intention to swarm, but you cannot be certain. If you find sealed queen-cells in the hive at the usual season of swarming, a swarm may issue within 24 hours, but not positively.

5. No. It will fly around in the air some yards or rods from the hive, and finally settle on a tree or some other object. After being thus settled, if it starts to sail away, you may take your last, long, lingering look at it—you'll never see it again. Better hive it before it starts off; but you needn't fear its going for some little time; generally it will wait your motion a quarter or half an hour.

6. Pretty hard job, after it has fairly made up its mind to settle on any given spot. If you "shin up" the tree lively with a well-loaded smoker, and smoke heavily and continuously on the spot selected, they may change their minds about settling there. Some induce them to settle on an accessible limb by hanging on it a lot of dead bees strung like beads on a string.

7. Alas, yes. Set the hive out in the blazing sun, hav-

ing; it closed up with only a small entrance, and they will be pretty sure to come out. Put them in, and they will probably stay till it gets hot the next day, and then out they'll come again.

— 8. See answer to question 3.

— 9. A prime swarm is not likely to come out in bad weather, but will hardly mind a little cloud or wind, and an after-swarm may come out in almost any kind of weather.

Cover for Over Brood-Frames—Slow Breeding.

1. What would you use besides the thin board cover in your hives, over the brood-frames, to keep the bees warm in the spring? The dovetail hives that I have do not fit so tight but some cold air gets thru in the spring.

2. What would you do with a colony of bees that do not seem to breed fast enough in the spring to expect them to gather any honey, such a colony having honey enough so as not to need feeding? WISCONSIN.

ANSWERS.—1. Most of my hives have the plain board cover, which is not very thin, $\frac{7}{8}$ inch, and that is the only thing over the top-bars. Something warmer would be better, and I have in use (expect to have more) 50 covers that are made with a dead-air space in them. The worst thing about the ordinary plain board cover is that in time it will warp and twist so it will not lie close on the hive. However, you ought not to have much trouble in spring, for the bees will fill with glue all openings in the fall, and they should at that time be so well stored with honey that they will not need to be opened early in spring.

2. If they have all the brood the bees can cover, that's all you can expect. If they could cover more brood than they have, you may hurry up matters in more than one way. The frames that have brood very likely have a border of sealed honey above the brood; uncap or bruise this, so the bees will empty the honey and allow the queen to replace it with eggs. If there is no honey over the brood, put next to the outside frame of brood a comb of honey with the cappings broken. Another way is to lift out the middle frame of brood, and turn it end for end. Or reverse one or both of the outside frames of brood. But remember, remember, that you may do a lot more harm than good by meddling with the brood-nest in cool spring weather, or at a time when a cold snap may come after your meddling.

The National Pure Food and Drug Congress.

BY REV. E. T. ABBOTT.

THE third annual meeting of this congress, which was held in Washington, D. C., March 7, 8 and 9, was in many respects the most interesting and profitable meeting that has ever been convened for the discussion of the subject of pure food.

The writer, who went to represent the interests of the National Bee-Keepers' Association, made the trip over the lines of the Missouri Pacific and the Pennsylvania railroads. As both of these lines are thoroly equipt for the handling of passengers, and have a national reputation for speed and comfort, it is not necessary for us to say that the ride was as pleasant and enjoyable as any railroad ride can be.

As we reach Washington at 1:30, and the congress was called to order at noon, we did not hear the addresses of Secretary of Agriculture Wilson and his assistant, Secretary Brigham, but we heard both of the addresses spoken of in the highest terms. A number of excellent addresses were delivered, and among the many speakers was Senator Mason, of Illinois, and a number of congressmen from various parts of the United States. Several valuable additions were made to the ranks of pure-food advocates, and among them were two congressmen from our own State—Champ Clark and C. F. Cochran. We think we are safe in saying that the friends of pure food can depend upon Mr. Cochran's splendid ability being thrown on the right side when the final battle comes on the floor of the house. He made a ringing speech before the Food Congress.

One of Mr. Clark's sallies was as follows: "I regard this pure-food congress of vaster importance than even a national political convention called for naming a president, for we can live in this country under almost any kind of a president, as has been demonstrated within my recollection. But we can't live without food. There is no doubt but that a man's eating has a lot to do with his top piece."

Altho this is only his second term in the house, there is probably no man on the floor who can command a more respectful and attentive hearing than Mr. Cochran. He has the reputation among his fellow members of being thoroly posted on all public questions, and of never talking simply for the sake of being heard, so that when he does speak his hearers always expect him to throw some new light on the subject under discussion, and they are seldom disappointed. Mr. Cochran is a man who attends very closely to the business he has in hand, so that he is always found in his seat during the sessions of the house, looking closely after the interests of his constituents, and the "common people" in every part of the United States. Just now there is a heated campaign going on in his own district, and most men in his situation would be at home looking after their "political fences," but he prefers to stay in Washington and attend to the business of the people who sent him there.

The thing of most importance to our readers is to know what the Food Congress did. First, they raised nearly \$600 on the floor of the congress to wipe out a debt which had accumulated on the hands of the executive committee during the year for necessary and unavoidable expenses.

Second, they made some slight changes in the Brosius Bill, as it was drafted by the congress of two years ago. These changes were thought necessary after mature deliberation, to strengthen the bill and render it more effective if it ever becomes a law.

Third, we fought to a finish one of the most exciting and closely contested fights that the writer has ever witnessed in a deliberative body. There was an attempt made by some parties who had never before attended a meeting of the congress, to sidetrack the Brosius Bill and substitute one of their own making, known as the "Babcock Bill," in its place. They came prepared for "war," and they got it from start to finish. We are glad to say that when the finish came the Babcock Bill was hung up high and dry, and the Brosius Bill was pushed to the front stronger than ever.

The main secret of the enthusiasm for the Babcock Bill was that it hangs out several political plums for the enthusiastic henchmen, while the Brosius Bill does not offer anything of the kind, but leaves the execution of the law in the hands of the secretary of agriculture, where it should be.

One quotation from the Babcock Bill will show clearly that it proposes to place dangerous power in the hands of one man, who is to be known as "food commissioner," at a salary of \$5,000. It reads as follows: "The food commissioner is here authorized to cause all compound, mixt or blended products, not only to be properly branded, and prescribe how this shall be done, but he may designate the color or colors and shape of packages, labels, printing, and wrappers containing the same." When we think of putting such dangerous power in the hands of any man, and then of the temper of the man who was slated, according to the program of these would-be reformers, for this position, we feel like saying, "Praise God that the Babcock Bill was not a go."

We now call upon all bee-keepers, and all who believe in fair play, and all who believe that the secretary of agriculture is competent to fill the position to which he has been appointed, to write to their congressman at once and urge upon him the importance of supporting the revised Brosius Bill as indorst by the National Pure Food and Drug Congress to the exclusion of all others; for there will no doubt be an attempt to get the infamous Babcock Bill substituted for the Brosius Bill in the house and senate. Simply say, "Pass the revised Brosius Bill," and sign your name. Every congressman will know what that means when he gets it on a postal card from one of his constituents.

We thought we would tell more about the congress this time, but we have said enough for the present. The time for talking has gone by, and the time for action has come. The time for the people to act. DO IT NOW.

We might say in conclusion that the house committee on interstate and foreign commerce invited the food congress to a hearing before them, and we appeared there over one hundred strong. A number of speeches were made by different members of the food congress. The writer had the pleasure of presenting the subject of pure food in behalf of the bee-keepers of the United States. We were greatly pleased by the thoughtful attention which the committee gave to all the speakers, and the deep interest which they manifested in the subject of pure-food legislation. This hearing can not fail to be productive of much good to the country.—Modern Farmer.

IMPORTANT NOTICES:

The Subscription Price of this journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec00" on your label shows that it is paid to the end of December, 1900.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

VOL. 40. MARCH 29, 1900. NO. 13

Note—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

The Hive Question—A Correction.—An editorial in a former number of this journal, referring to the views of L. Stachelhausen as given in Gleanings in Bee-Culture, says he was led to the conclusion "that for extracted honey a large hive is best, and for comb honey a small one." Referring to this in Gleanings, Mr. Stachelhausen says:

"Certainly I did not mean to say this. For the welfare of the bees and their proper development it makes no difference whether the bee-keeper extracts the surplus honey or takes it off in the form of filled sections. If a small hive is ill-fitted in this respect for extracted honey, it can not become better for comb honey. By the present management we can not use the advantages of large hives in producing comb honey, so we can form only one conclusion, and that is, *the present management is incorrect.*

"The problem is to find out a management by which all advantages of large hives can be utilized, and at the beginning of the honey-flow to get the colony in such a condition that the work in supers is started at once, and all the honey stored there—that is, to get the brood-chamber in the best possible condition."

Alsike Clover.—The Warren (Ind.) Republican contains an address by Dr. I. A. Smith, in which he discusses alsike clover in a somewhat exhaustive manner. He makes a bushel of seed sow about 8 or 10 acres, and says:

"As I sow chiefly with oats as a nurse crop, my rule is to wait until March 25 before sowing my oats. After this time I begin sowing as soon as the soil is in suitable condi-

tion, using shallow cultivation, never plowing immediately before as some do, but usually by disking, dragging and harrowing, so as to get the surface fine and mellow, the finer the better, and sowing the clover behind the finishing harrow, being sure, wind or no wind, to sow before any rain falls upon the freshly harrowed soil; this is very important. If the land is in suitable condition, as in case of having been fall or winter plowed, I prefer to use a good, sharp drill for putting in the oats, and sow the clover immediately behind the drill; I have had the best success in this way."

Alsike stands drouth and close grazing better than red clover, and heaves less with freezing. When firmly established it may be freely pastured till early September. Many fields have kept in thrifty condition for three years, one field for five. A persistent stand is favored by cutting the first and pasturing the second. It should be cut in full bloom, but later cutting is not so objectionable as with red clover. He considers it a better fertilizer than red clover

Rietsche's Foundation Press has obtained a popularity that is surprising to an American, there being now 16,000 such presses in use. In this country comparatively few bee-keepers make their own foundation, the number of such being perhaps less now than a few years ago. Germans are probably more saving of outlay, but another item makes a difference that would not generally be suspected. It is that a bee-keeper in Germany who does not make his own foundation may buy that which is adulterated. Such a thing is never suspected in this country, the manufacturers of foundation being entirely reliable. Adulteration is not all confined to America.

"No Wax-Moth in Colorado."—Prof. C. P. Gillette, of the State Agricultural College at Ft. Collins, Colo., sends us the following about the moth that infests comb honey there:

On page 154, I notice that Mr. Aikin and Mr. Rauchfuss state that the wax-moth does not occur in Colorado, and Mr. Rauchfuss can not understand why people should claim that Colorado honey is sometimes infested with these insects.

It seems to me that two insects are probably being confused. So far as I know, the old-fashioned wax-moth does not occur in Colorado, but there is a smaller moth that is generally distributed over the country, commonly known as the Mediterranean flour-moth, which I have repeatedly seen infesting honeycomb. The larvæ of this insect do not seem to care for wax or honey, but feed upon pollen, and perhaps propolis as well. The larvæ are sometimes quite troublesome on stored frames of old comb, and I have seen them in crated sections of comb honey.

Both the larvæ and the moths of this species are considerably smaller than the old wax-moth.

C. P. GILLETTE.

Uncapping Honey in the Spring was recommended in a paper by D. W. Heise at the Toronto convention, and reported in the Canadian Bee Journal. When there are yet only two to four frames of brood in a colony, he raises each of these frames sufficiently high so the honey along the top-bars and in the corners can be uncapped. This helps the bees to the honey, and allows the queen to fill the comb with brood to the top-bar. If there is no honey between the brood and the top-bar, he places a comb of honey next the brood on each side, first uncapping it. In the discussion following, Mr. McEvoy said:

"I have followed the uncapping system off and on for 17 or 18 years, and I have made it pay after I got right into it and understood pretty near how to do it, but I have had it go the other way at times. I have always made it pay between fruit-bloom and clover. There is a gap at that time in most localities, and it pays to uncap some. I have uncapped sometimes too much, and have made a mistake, but just to uncap two or three combs in an evening in the bare time in order to supply them with unsealed stores and to feed the larvæ, in this way I get the honey used up rapidly,

and I increase in bees. A little later on I uncap more. Old bees will not uncap the old sealed honey fast enough, when they are caught suddenly, to keep pace with the amount of larvæ on hand; then it pays to look after uncapping or bruising.

"This year (1899) I went thru the colonies three times between fruit-bloom and clover, and with 95 colonies I had it so arranged that almost every frame was filled with brood clear up to the top-bar, and from end to end to the outside wall. Did it pay? Yes; I never did anything in my life that paid so well. I would not advise every one to do it; some might go on a morning of a spring day when there was not much required and uncap too much. You must use judgment."

Selling Candied Honey is nowadays advocated by a number, the idea in general being that the consumer shall be educated to liquefy it. J. H. Martin, in *Gleanings in Bee-Culture*, brings out a point that may be worth considering. There are some who prefer honey in the candied state (possibly their number might be found greater if honey were always sold in that condition), and those who eat candied honey by preference eat more of it than they would of the liquid.

The Age at Which Young Bees Become Field-Workers is generally called 16 days, but there is by no means unanimity of opinion on the subject. L. Stachelhausen discusses it in *Gleanings in Bee-Culture*. He thinks it depends upon the condition of the colony. Prof. Menzel found bees commencing to gather pollen when 18 days old; Berlepsch found in three experiments the first gathering on the 16th day, and a few years later he observed them on the 19th day. Doenhoff found the 19th day. Others the 12th and 14th. A. I. Root said about two weeks, but if necessary when only 5 or 6 days old. Neither is there agreement as to the average length of life of workers in the busy season. It is given all the way from 30 to 45 days. The age at which larvæ are sealed is another disputed point. Menzel, Cowan and Vogel give it at 5 days. Greiner, 5½; Langstroth, 6; Root, between the 6th and 7th day.

The Weekly Budget

HON. EUGENE SECOR, General Manager of the National Bee-Keepers' Association, has been appointed judge of the apianian exhibits at the Minnesota State Fair next fall. "Judge" Secor will give entire satisfaction to the Minnesota bee-keepers. He always does.

MR. J. H. MARTIN says in *Gleanings in Bee-Culture* that Belgian-hare growing has grown to be a business of importance, the head center of the business being at Los Angeles, Calif. A number of bee-keepers have given up bees for hares, and Mr. Martin thinks the two industries might well be combined.

MESSRS. R. MCKNIGHT AND J. B. HALL.—The Canadian Bee Journal for February contains this paragraph from the pen of Mr. D. W. Heise, which refers to an incident at the last Ontario convention:

"Whatever justification there may have been for the unpleasant things that were said about Mr. McKnight's opposition to certain convention proceedings in the past, he truly endeared himself to every bee-keeper's heart when he brought his 'appropriate and inspiring' motion that J. B. Hall has been the 'life and soul' of its conventions. And what J. B. Hall has been to the conventions, R. McKnight has been to the Association; and no one can recognize that fact more forcibly than the members who were associated

with the earlier history of the Association. And I feel sure that the present members are not so forgetful, or so void of appreciation of valuable services rendered, but what they will in the near future, in some way reward him for his services."

STENOG APPROVES THE "OLD RELIABLE."—He says:

"Mr. York deserves great praise for the excellence of the mechanical part of his journal. Its freedom from typographical mistakes is quite in keeping with the high moral tone of the journal."

Coming from the man who is mainly responsible for the fine mechanical appearance of *Gleanings in Bee-Culture*, such endorsement pays for a good bit of effort.

MR. T. F. BINGHAM—the bee-smoker man—has sent us his new smoker made of brass instead of tin, and with the nozzle hinged on. It is a beauty, tho we believe we would prefer it made of tin in the usual way. We think the brass is not so stiff as the tin, but it will likely not burn out so soon, and will not rust. But if a Bingham smoker made of tin lasts 15 years, what more does anybody want? Surely, any bee-keeper would want a *new* smoker at least two or three times during his life.

MR. FRANK MCNAV, now in Los Angeles Co., Calif., wrote us March 18, as follows:

FRIEND YORK:—There has been only one light rain (about one inch) here since Jan. 3, and bee-keepers have given up hopes of a honey crop from sage, and are moving to the irrigated alfalfa sections, as that is about the only prospect for a honey crop in Southern California this season.

I expect to return to my Wisconsin apiaries about May 1.

THE CHICAGO BEE-KEEPERS' ASSOCIATION, as announced on another page, will meet in Wellington Hall, 70 North Clark St., Chicago, Friday afternoon and evening, April 6, beginning at 1 p.m. (April 6 is the correct date, as the hall was engaged for the day before). Dr. C. C. Miller expects to be here; Editor E. R. Root writes that he will make an extra effort, and, if nothing interferes, "will be on hand." F. A. Snell says: "I shall aim to be present, if I can do so." J. A. Green wrote: "It is quite possible that I may attend the meeting." F. Wilcox, of Wisconsin, says: "I may be able to get away to your convention." Dr. Mason and Mr. Secor both wrote that they would try to write and send a paper on "What can local bee-keepers' associations do to help the National?"

It is expected that there will be a large attendance, particularly from this (Cook) and adjoining counties. No special individual notices will be sent out by Secretary Moore, as it is thought best to let the announcements in these columns suffice for this time. Let all come who possibly can do so, and help make it the best meeting ever held by the Chicago Bee-Keepers' Association.

EDITOR LEAHY, of the Progressive Bee-Keeper, has more experience than he had six or eight years ago, along the line of publishing bee-papers. We recently announced the "passing away" of the Western Bee-Keeper, and expressed our regret that there should be any one so bereft of reason as to think of starting a new bee-paper these days. As a comment on this, Editor Leahy wrote thus in the last number of his paper:

"Don't do it, friends. It will only use up your surplus money, and you will be glad to get some one to help you let go. The Progressive was run at a loss three years before we assumed control. We ran it at a loss for two or more years; then two or three years more it barely paid expenses; and now, after ample experience, we are satisfied that the same money and time invested in almost any other legitimate business, would pay much better."

Mr. Leahy, in the same editorial, rather disapproved of our "jumping onto something that is dead"—referring to the Western Bee-Keeper. Wouldn't it hurt anything worse to "jump on it" when it is alive, or nearly dead, than to wait until it is past feeling? Of course, it is often a mercy to help hasten the death of some things, and yet if we had done that, some people would have unjustly accused us of being jealous of the poor little Western Bee-Keeper.

Honey-Poultices.—For boils, carbuncles, abscesses, etc., and for injured bones, mix the honey with flour, and spread on a piece of linen rag. If the abscess is coming to a head, cut a hole in the center of the rag to allow of free discharge of matter. Honey added to an ordinary bread-poultice will answer the same purpose, or it may be used in conjunction with linseed-meal poultices; it will render them more emollient.—British Bee Journal.

Weak Colonies in Spring.—J. B. Hall says in the Canadian Bee Journal:

"My experience of over 20 years is that if you take weak colonies and put them into three you will still have three weak colonies; if you shut them down and don't meddle with them at all there will sure to be some of them that will come up and be good colonies, and the others that are no good will die out, and if you put them together one of the poor queens may be saved. We don't open them except they are hungry; we don't open a colony of bees in our yards until the fruit blossoms. We let weak colonies die if they choose."

More Hopeful of Cuba.—Editor Hill refers to the report of G. Rockenback in this journal as the bluest yet given, and says:

"Reliable information in regard to the apicultural outlook in Cuba is now of interest to bee-keepers everywhere, and it is gratifying to note that resident producers of honey take a much more cheerful view of the situation than the Journal's correspondent, whose article clearly shows that he would not be clast in the language of the hour, as an 'up-to-date bee-keeper.'"

If Mr. Rockenback's testimony is thought hardly reliable, what will Mr. Hill do with Harry Howe's, which was given on page 185, last week? Mr. Howe's simply corroborates Mr. Rockenback's, or is even stronger.

Reform Spelling in Gleanings in Bee-Culture is given up for the present, and a Stray Straw says:

"Now that immediate danger of violence to English spelling in Gleanings is no more, and that Mr. Wanser, who wants spelling progress to emanate from our public schools and colleges, may not be too severe if he should happen to see 'honor' for 'honour,' or 'clipt' for 'clipped,' it may be well to say that the changes he opposes with so much earnestness have not emanated from a few cranky ignor-amuses, but *have* emanated from colleges. The changes were recommended by some of the most eminent scholars of America and England, among them professors in Yale, Harvard, University of Pennsylvania, St. Johns, Columbia, etc., in this country, and, in England, in Oxford and Cambridge."

Fertilization of Fruit by Bees was discust by Frank Benton at the Ontario Co. (N. Y.) Bee-Keepers' Convention, as reported in Gleanings in Bee-Culture. In part, he said:

"An apple-blossom has many stamens, and the pollen is produced at the extreme end of each one, forming there an enlargement called 'anther.' A single anther contains one million or more grains of pollen, of which but five are needed for the fertilization of one blossom. A raspberry blossom is built differently from the forenamed one. The raspberry (fruit) is composed of some 200 separate little sections, each containing a seed, and so the blossom is constructed in a like manner. What will later be the fruit is already present in an embryo state, 200 little sections in miniature, and from each of them protrudes the pistil, like a fine short hair. A grain of pollen must be conducted thru every little hair—really a tube, the end of which is receptive thru the organ called 'stigma.' A bee, after alighting on a blossom of this kind in search of honey, which is to be found at the base of the blossoms, rubs over the anthers with its body, which is covered, especially on the under side, with many hairs of a compound feather-like nature, and becomes covered with the pollen-dust. Whirling around, first one way then another, in order to reach fully all the nectar-secreting glands, it brushes again and again over the 200 protruding pistils. One bee after another vis-

its the same blossom at short intervals as long as the secretion lasts; and in time every one of the stigmas receives its grain of pollen, and a perfect fruit results.

"During the earlier part of the season, when pear and apple trees bloom, the weather is often unfavorable for pollination—the pollen remains too moist and sticky. In such a case, not much fruit can set. Should the sun come out for but an hour, the pollen becomes dry. The bees turn in; and the more numerous the bees are, the more fruit will set. There may be seasons when fruit would set abundantly without the help of the honey-bees. In an unfavorable season, however, they are an absolute necessity. Cross-fertilization is strictly necessary for raspberry, gooseberry, and huckleberry. When the bee visits a blossom of the last-named kind, and pushes its body into the bell-shaped flower, it seems that the stamens are so arranged that the white pollen is dusted upon the head and thorax of the bee. The bee is unable to remove the dust from these places; and when the next blossom is entered, the head and thorax of the bee come in contact with the stigma first, and before the anthers are toucht, and in this manner cross-fertilization is assured.

"It would take too much space to go thru the long list of flowers benefited by bees. However, bees are not the only agents to perform this work. There are other insects and the wind. In the early springtime bees are most numerous, and therefore indispensable."

Cure for Bee-Paralysis.—After many trials with different drugs I found ultimate success with a mixture of sulphurous acid and tincture of podophyllin in the proportion of one of the former to four of the latter. I wanted a purge and an antiseptic for after effects, or in other words, something that would expel the excrement and leave the intestine in a condition afterwards not conducive to the growth of bacilli.

To $\frac{1}{2}$ ounce of this mixture I added one pound of extracted honey heated to 90° Fahr., and then with a mouth-spray I daily sprayed combs, bees, brood, etc., as I took frame after frame out of a diseased hive. I applied the remedy in this way, as I found it the easiest to get the bees to take the medicated honey, each cleaned up her neighbor and combs, and thus unintentionally imbibed the dose required. Result: In from 3 to 5 days a clean, healthy hive.—The Australasian Bee-Keeper.

Artificial Increase.—When an increase of not more than 50 percent is desired, with a chance for a goodly store of surplus, the following excellent plan is given in Gleanings in Bee-Culture, by G. M. Doolittle:

"About 8 to 10 days before your expected honey-flow, go to a populous colony, which for convenience we will call No. 1, and shake all the bees and queen from their combs into a hive filled with empty comb or frames filled with foundation, placed where the old one stood, placing the surplus arrangement from the old hive on the colony thus made. In this way you have a strong colony containing all the bees and queen from one of your very strongest colonies, a hive full of comb or foundation, and the partly filled sections from No. 1, all being in readiness to take advantage of the harvest as soon as it comes. Now take the combs of brood taken from No. 1 to No. 2, and set them on No. 2's stand, having previously moved No. 2 to a new stand a rod or two away. Just before setting the combs on the stand of No. 2, go to one of your nuclei and get the comb the queen is on and take it, bees and all; and as soon as the combs are on the stand of No. 2, shake the bees and queen from it in front of the hive on No. 2 stand, and let them run in with the bees from No. 2, now hovering about trying to find their old home. Put sections on this hive, and the work is done. Thus you have a colony composed of a full hive of combs and brood, a good young queen, and workers to protect her, and all the field or working force from No. 2, which make a big, strong colony ready for business as soon as the honey harvest arrives. No. 2 has a hive of combs and brood, their old queen and sections partly filled, but they have lost their working force. In from 8 to 10 days they are quite well stockt with workers again, when they are also in fine shape for the harvest which is now on.

"I have told you this plan at length as you wisht it made plain, and because I consider it the best plan of artificial increase in existence. If you wish a greater increase, go thru the same operation again just after the harvest, less the sections, and see that No. 1 is fed in some way, or supplied with combs of honey."

Root's Column

GLEANINGS IN BEE-CULTURE.

THERE are some things every bee-keeper must have, and we believe no one can expect to succeed as a bee-keeper without reading one or more good papers devoted to this industry. Gleanings in Bee-Culture will not only keep you posted on all important topics but is always on the alert to bring to its readers' notice new methods proposed by able writers, new implements for labor saving, and everything by which a larger and better crop of honey can be secured. We believe it pays to use a superior quality of goods, and there is no doubt but what improvement can be made in the appearance of honey by use of the BEST methods. Gleanings tells you of all these and tells you where to market your honey after you get it, by our HONEY COLUMN. Our market reports are ALWAYS UP-to-date, and can be DEPENDENT upon. We know of many bee-keepers losing a good crop of honey by sending it to some irresponsible party. Avoid this by subscribing to Gleanings and getting the best MARKET REPORTS.

Some bee-keepers like to take a bee-journal during the honey season only; some want to try it a few months before subscribing for a longer time. To accommodate such we offer Gleanings in Bee-Culture SIX months beginning April 1st for ONLY 25 CENTS. There will be many important things brought out in its columns during the coming six months. Do not fail to send an order at once for this time.

If you wish to subscribe for a whole year, we shall be glad to have you avail yourselves of any of the following:

Special Offers for New Subscribers.

Offer No. 25.—For \$1.00 we will send GLEANINGS one year and a Clark Smoker, postage 20 cents extra. Or, for \$1.25 we will send the Cornell Smoker, postage 25 cents extra.

THE A. I. ROOT CO., Medina, Ohio.

GENERAL ITEMS

Wintering Well—No Snow.

Bees are wintering finely. We have no snow, and have had but little this winter. When the west had the blizzard, and were buried up in snow, we had a warm rainstorm.

HENRY ALLEY.

Essex Co., Mass., March 15.

Changeable Weather.

It looks very much as if we are just now getting our winter in this part of the State. We had had but very little snow thus far this winter until to-day we have 7 inches and the merry sleigh-bells can be heard far and near, with the thermometer hovering around zero. Bees are not wintering very well, as the weather has been very changeable, with the thermometer up in the 60's one day and the bees flying as in early spring, with a sudden change to a cold wave in 24 hours of from 30 to 40 degrees. My loss of bees will be greater than last winter, but I hope that we will soon have nice weather.

W. H. HEIM.

Lycoming Co., Pa., March 16.

Bees Doing Well.

Last spring, I had two colonies of bees; I increased them to four, and got some honey, tho a poor season. Bees seem to be doing well, and flying freely on fine days. We are having a regular blizzard now; it has snowed all day, and is still at it—12:45 a.m.

WM. A. SHUFF.

Philadelphia Co., Pa., March 16.

Prospects Not Flattering.

I got 6,000 pounds of extracted honey last summer from 100 colonies, spring count, which sold readily at 7 cents a pound. I started in the winter with 110 colonies, and have lost 3 during the winter, so I now have 107 apparently in good condition. The prospect for a crop of honey this year is not very flattering, as I am afraid the white clover, which got such a nice start last summer, is all killed out this winter.

F. B. FARRINGTON.

Clayton Co., Iowa, March 20.

Bees Appear All Right—Bee-Proof.

My bees appear to be all right as yet. They were very lively about a week ago. I have 20 colonies outdoors. I think they are better off outdoors if they are properly cared for. I always take the cover off in the fall, and pack them in leaves, and never lost any that way. I had 17 colonies last spring, and got about 1,200 pounds of honey, comb and extracted. I extract only in the fall, then I kill all the surplus colonies that are not strong for the winter. I am going to feed as soon as they have another flight. I feed outdoors and let them go for it as they please. I have a very fine lot of Italians; if any get crost with black drones I kill them in the fall. It is no use to keep more than

Sharples Cream Separators: Profitable Dairying

Admiral Buggy—Fancy painted; fancy trimmed with shafts. Price, \$50. Dealers would charge \$75.

We Sell Vehicles and Harness at Less Than Wholesale Prices.

On the above buggy the saving to the purchasers in the neighborhood of \$25. The quality is all right in every particular. one needs. I sometimes let them swarm and sometimes divide.

I have been used to bees about 70 years. I had a dose of their sharp ends last summer. A swarm settled on a post entangled with grape-vines. I could not brush them off, so I set the hive and sheet at the bottom of post and gave it a kick, and down went the bees, then up and at me. I stepped back; my hat and veil caught on a plum bush, and I should think half the swarm on my head, face, and all over me. I ran and dropt my head in a tub of water, went into the house and got Mrs. White to pull out the stings—about 500 or more on my face, hands, and all over. But I went and hived them afterwards, and it never swelled nor hurt me one bit. The milkman came for milk, and the bees chased him and his horses away; so you see I must be bee-proof.
HENRY WHITE,
 Humboldt Co., Iowa, March 21.

A New York Report—Black Brood.

The bees are sleeping and the weather is very cold. If I recollect I promise to report the season of 1899, and will now try to do so.
 In the spring of 1899 the season opened with all prospects for a good year, but ended just the reverse.

In February (1899) I came to this State, with all hopes and expectations of seeing the largest honey crop in the country, and took up my quarters with Mr. Frank Boomhower, of Schoharie County—a noted bee-keeper who has produced honey by the tons for years. I expected to engage in the bee-business as fast as means would permit, but lo, my hopes were like some of those of Rambler's—they were blasted.

After arriving at Mr. Boomhower's we began making hives and all necessary fixtures to handle a large crop of honey. Over 200 colonies of bees were bought up thru the country from farmers, and out-yards established, until at least 450 colonies had been gathered to our fold. Most of these were in box-hives and on odd-sized frames of every description. After these bees were moved to our yards a picnic began in transferring, which was playwork for us. N. E. Boomhower, the oldest son of F. Boomhower, and myself, transferred as high as 72 colonies a day from these old traps, to an up-to-date hive. No combs were transferred, but the bees were put on full sheets of foundation. All this was done and waiting for the harvest to come. We continued to manufacture extracting-supers, etc., but alas, dry weather set in and buckwheat was a small crop, and the honey crop was also small, only about 18,000 pounds being secured.

We were in the heart of that dreadful disease known as New York bee-disease, or black brood. Many called it foul brood, but some have decided not to call it foul brood, and Dr. Howard has named it black brood. Call it what you will, it is undoubtedly a very destructive disease, and has wiped out most of the bees in this neighborhood. I never saw foul brood, but from the description this so-called black brood resembles foul brood very much; it makes its appearance mostly in the unsealed larvæ, and at first it appears to show in the center of the white grub a small, yellowish dot on the larva, and finally this larva becomes yellow, some

more so than others, and then it turns darker and darker, and at last is almost black, after which it dries down to an almost invisible object. It spreads as if by magic, and seems to be very contagious. As a rule it makes its appearance first among black and hybrid bees, the Italians almost always being the last to be affected. Sometimes in our yard a colony of Italians would be free from it, and in a flourishing condition, when surrounded by colonies rotten with the disease. Our bees were mostly destroyed to prevent its spread, and even water that we washed our hands in while working with the bees or honey, was not allowed to be thrown where the bees could get it. In spite of all this, over 200 colonies have been destroyed, and many hives and fixtures have been burned.

I hope and trust that the disease will die this winter, and not make its appearance again in the spring. It has caused many a man to surrender and lose practically all he had in this world to make an honest living. When and where it will stop I can't say, but I trust it has run its time, and will not appear again.

In killing the bees we used brimstone, and I wish to call the attention of Editor Root (a friend of mine) to page 122, where he enquires whether sulphur ever enrages bees. It does. We found by experience that in killing bees with sulphur, now and then a few that escape seem to attack a person very readily; also after having used brimstone in the smoker, and then filling it with fuel, it still has a decided brimstone odor, and bees hate it and show fight at once.

Our outyards were from 9 to 12 and 16 miles from home. The crop was mostly extracted honey.

With all the disappointments of last season, I shall try the bees again this year, with a view of securing a good crop of honey. P. W. STAHLMAN.
Albany Co., N. Y., Feb. 26.

Bees Breeding in the Cellar.

I hope a good many will make careful observations about breeding and not breeding in the cellar. I feel so sure that accurate work in this line will show that breeding in the cellar causes mischief, and that not to breed

DR. MILLER'S
Honey Queens

-One Untested Queen Free as a Premium for sending ONE New Subscriber to the American Bee Journal for one year.

We have been fortunate in making an arrangement with DR. C. C. MILLER—the well-known honey-specialist—to rear queens EXCLUSIVELY FOR US DURING THE

SEASON OF 1900. These Queens will be mailed in rotation, beginning about June 1, so "first come first served." We are ready to book orders now.

The Queens Dr. Miller will send out on our orders will be precisely the same as those he rears for his own use, so of course they will be from his best stock. His best colony in 1899 had a queen reared in 1898; May 5, 1899, it had brood in 4 frames, and he gave it at that time a frame of brood without bees. It had no other help, but May 25 a frame of brood with adhering bees was taken from it, and the same thing was repeated June 3, leaving it at that time 5 frames of brood. It stored 178 sections of honey, weighing 159 pounds (and that after July 20, in a poor season), being 2 3/4 times the average yield of all his colonies. A point of importance is the fact this colony did not swarm, and an inspection every week or 10 days showed that at no time during the entire season was there even so much as an egg in a queen-cell. Dr. Miller expects to rear queens from this one during the coming summer.

The demand nowadays is for BEES THAT GET THE HONEY when there is any to get, and Dr. Miller has such bees. You will want to have a queen from his best, we are sure.

Do not send any orders to Dr. Miller, as all orders MUST come thru us, according to our agreement.

Remember, send us \$1.00 for ONE NEW SUBSCRIBER to the American Bee Journal for one year, and YOU will get ONE OF DR. MILLER'S UNTESTED HONEY-QUEENS FREE AS A PREMIUM. This offer is made only to our present regular subscribers. Orders for queens to be filled in rotation, beginning about June 1st.

Address all orders to **GEORGE W. YORK & CO.,**
118 Michigan Street, CHICAGO, ILL.

Langstroth on... The Honey-Bee

Revised by Dadant—1899 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the Ameri-

can Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

Report for Last Season.

My bees have wintered in fine shape, and are working nicely. Last year I lost one-half of my bees on the summer stands without any protection. I had 16 left, and they averaged 66½ pounds of comb honey, and increased to 20, so I now have 36, and everything looks encouraging. I made by hand 150 hives with supers complete. I think that pretty good for a man 62 years old. **W. T. WRIGHT.**

Nez Perces Co., Idaho, March 17.

Bees Wintered Well.

Bees have wintered well here. We had a good crop of honey in 1899. I increased from 6 colonies to 15, and got 380 pounds of comb honey. I have lost two colonies this winter.

W. P. BRANSON.

Decatur Co., Kan., March 16.

A Beginner's Report.

I came thru the winter of 1898 with 1 colony out of 4; in the harvest of 1899 I took off 70 one-pound sections of honey, and had no increase. I have now 3 colonies, having bought 2 at \$2.50 each. **H. C. SPRINGER.**

Story Co., Iowa, March 21.

Mild Winter—Beautiful Weather.

We have had a mild winter, and the weather is beautiful at present. The bees are flying strong, and are bringing in pollen; they also appear to be getting a little honey. I have had

The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

GEORGE W. YORK & CO.
118 Michigan Street, CHICAGO, ILL.

honey set out for over a week, and so far the bees have not touched it. The weather is like the month of May, the buds and a few blossoms are coming out and the indications are for an early dry spring; but if the irrigation waters hold out the honey-flow will be all right.

E. S. LOVESY.
Salt Lake Co., Utah, March 9.

Seem to Winter Well.

Bees seem to winter well. There is but very little sign of diarrhea, and less dead bees on the cellar-bottom than usual. The past 4 weeks we had about one foot of snow, and good sleighing, but the past week the snow turned into ice; river and creeks were full to their banks, but are going down now in this cold snap.

C. THEILMANN.
Wabasha Co., Minn., March 15.

Convention Notices.

Texas.—The Texas State Bee-Keepers' Association will hold its 22nd annual convention in Greenville, Wednesday and Thursday, April 4 and 5, 1900. A cordial invitation is extended to all. No hotel bills to pay.

Blossom, Tex. W. H. WHITE, Sec.

Chicago.—The Chicago Bee-Keepers' Association will hold its regular semi-annual meeting in Wellington Hall, 70 N. Clark St., Chicago, Ill., April 6, 1900, afternoon and evening. The meeting will be called to order at 1 p.m. Dr. C. C. Miller is expected to be present if his health will permit. Mr. E. R. Root has been invited, also Mr. N. E. France, and others. A good time may be expected by all. Let every one come, especially the ladies.

Park Ridge, Ill. HERMAN F. MOORE, Sec.

Utah.—The Utah State Bee-Keepers' Association will hold its semi-annual convention in the City and County Building, Salt Lake City, Apr. 6, 1900, at 10 o'clock a.m. A full program in the interest of the industry will be presented, and all our bee-keepers can help themselves by aiding the Association, and in order to create a closer bond of union among our bee-keepers. As a further incentive to the success of the bee-keeping industry, it is very desirable to have our bee-keepers from all parts attend the spring convention.

J. B. FAGG, Sec.

100 Cards and Card-Case FREE

We have arranged to mail a neat vest-pocket Aluminum Card-Case with 100 printed Business or Visiting Cards—all for sending us ONE NEW SUBSCRIBER to the American Bee Journal for a year at \$1.00. This is indeed a rare offer. You can have anything you wish printed on one side of the card. Your name

alone will be engraved on the Aluminum Case. It is something that everybody ought to have. Be sure to write very plainly what you want printed on the cards, and also the name for the case.

We will mail the cards and case for 50 cents, when wanted without sending a new subscriber, or will club them with the Bee Journal for one year—all for \$1.40.

BEE = BOOKS

SENT POSTPAID BY

George W. York & Co. 118 Mich. St. Chicago.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers, \$1.00.

Bienen-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Bienenzucht und Honiggewinnung, nach der neuesten methode (German) by J. F. Eggers.—This book gives the latest and most approved methods of bee-keeping in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cts.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cts.

Foul Brood Treatment, by Prof. F. R. Che- shire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 20 cents.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about Poultry Business. 64 pages. Price, 20 cents.

HONEY AND BEESWAX MARKET QUOTATIONS.

CHICAGO, March 19.—We quote best white comb at 15c. An occasional small lot of fancy sells at 16c; off grades of white, 12@14c; ambers, 10@12c. Extracted, 8@9c for fancy white; 7@8c for amber; 6@7c for dark grades. Beeswax, 27c.
Receipts of honey are larger and the demand is not as good as it has been.
R. A. BURNETT & Co.

CINCINNATI, March 3.—There is some demand for extracted honey from manufacturers at 7@7½c for amber and Southern; clover, 8@8½c. Comb honey is selling firm at 14@16½c in a small way. Beeswax, 25@27c.
C. H. W. WEBER,
Successor to Chas. F. Muth & Son and A. Muth.

LOS ANGELES, March 1.—1-pound frames, 12½@15c; 2-pound cans, 2 dozen in case, per dozen, \$2.50; 2-pound glass pails, per dozen, \$2.50. Extracted, water white, 60-pound tins, per pound, 8½c; light amber, 7½@8c; dark amber, 7½c. Beeswax, 25@26c.

The prospect for a crop is very bad. Small lots in the hands of wholesale houses are firmly held.

BOSTON, March 9.—Our honey market is showing some signs of lower prices, altho the stock on hand is not large. At the same time prices are so much higher than previous years that the trade have taken it very slowly and the results are that the holders are willing to range prices quite a little in order to move stock on hand. Prices range: Fancy white, 17@18c; No. 1, 15@16c; amber, 10@12c; buckwheat almost unsalable. Extracted, best white California, 8½c.
BLAKE, SCOTT & LEE.

KANSAS CITY, Mar. 19.—We quote fancy white comb, 15c; No. 1, 14c; No. 1 amber, 13c; No. 2 amber, 13½c. Extracted, white, 8c; amber, 7c; dark, 6c. Beeswax, 22@25c.
C. C. CLEMONS & Co.

BUFFALO, March 3.—Market nearly bare of all grades of honey. Probably no more from any source to market, but if so, fancy white comb is firm at 15@16c. Other grades from 14c downward, with the poorest at 8@9c. Fancy pure beeswax continues at 28@30c.
BATTERSON & Co.

NEW YORK, Feb. 8.—During the past 30 days our market has been somewhat slow and easy in both comb and extracted honey. Stocks of comb honey, however, are almost exhausted, and there is a fair demand for all grades. Fancy white selling at 15c; No. 1 white at 13@14c; fancy amber, 11@12c, and buckwheat at 9@11c, according to quality, etc.

Our market is well supplied with extracted, the prices are firm and unchanged. Beeswax sells very well at from 26@28c, according to quality.
HILDRETH & SEGELKEN.

SAN FRANCISCO, Feb. 28.—White comb, 11½@12½c; amber, 8@10c. Extracted, white, 7½@8c. Light amber, 7@7½c; amber, 5@5½c; Beeswax, 26@27c.

Supplies and demand are both at present limited, which is to be expected at the close of a light crop year. Business doing is mostly of a small jobbing character, and at practically the same figures as have been current for some time past.

OMAHA, Feb. 13.—Demand shows some improvement in January, having been much more active, but as anticipated there is no advance in prices. Market remains steady at 14@14½c for fancy white comb and 8½c for white extracted. The latter is pretty well cleaned up along the Missouri River, and it looks as if there would be some shortage before another crop comes in. From present appearances there is about enough comb honey to go around at the present prices, hence we look for no particular change in values.

CONTRIBUTED ARTICLES

New York Bee-Disease or Black Brood.

A NOTABLE contribution to the literature of bee-culture on its pathological side is to be found in *Gleanings in Bee-Culture* for Feb. 15, written by Wm. R. Howard, A.B., M.D., the man to whom we were already indebted for his valuable work upon foul brood and his investigations on pickled brood.

The new disease, which for want of a name was at first called the New York bee-disease, because it made such ravages in that State, is now called black brood, the appropriateness of the name coming from the fact that the disease begins with a dark spot on the larva, which increases in size, becomes darker, and finally black.

In his introduction, Dr. Howard says: "I have received specimens from Messrs. George W. York, of Illinois; E. R. Root, of Ohio; N. D. West, a New York State bee-inspector, and P. H. Elwood, of New York. All of these men have furnished not only material, but have been active in getting data for the investigation."

Besides the specimens thus obtained, Dr. Howard obtained some bees and started the disease on his own account. In all he made more than a thousand microscopical examinations.

Dr. Howard gives a detailed account of his laboratory investigations, and also of his experimental investigations

made with two nuclei into which he introduced *Bacillus milii*, and then proceeds as follows:

Here conclude my investigations, which have been carefully conducted; altho under disadvantages as to season, etc., they have in a great measure been satisfactory. Many points of vital interest have been made clear, while others of equal importance are necessarily obscure. It is clearly not foul brood. It is clearly not pickled brood. It is clearly something new. It is apparently a disease of the pupa stage. The infection is clearly not in the pollen—not due to a fungus but due to bacteria.

All diseases, in animal and vegetal life, are due to the results of parasitic invasion—some by their mechanical presence, some by the ferments produced in the body, and in plants by changes in or taking from them their life juices, causing starvation and immature growth.

In any given case of rotten wood, dead from freezing, starvation, or other causes, being allowed to remain in the cells, much of the poison generated, as well as the germs themselves, or their spores, remain adherent to the sides of the cell. These are like the seeds which "fell on stony ground," and will not grow until the proper soil, such as is furnished by the rich nitrogenous substances supplied to the brood by the nurse-bees is brought in contact with them, when a luxuriant growth obtains. This produces a fermenting, decomposing food unfit for the brood, and sets up a ferment, a decomposition within the bodies of the bees, thus destroying their lives. This might happen to the host with any form of parasitic life, either animal or vegetal.

It might be said, speculatively, that the disease had its origin in starvation, and that in some cases several putrefactive bacteria of similar biological character were responsible for this malady, which, when once started and undisturbed, becomes as destructive as the old-fashioned foul brood. The two germs isolated having similar, or the same, biological characteristics, especially an

alkaline medium in common, are both in a measure responsible for this disease, and perhaps the variations, the malignancy, etc., are due to modifications by their combined

Dr. Wm. R. Howard, Bacteriologist.

Explanation of Plate; Magnified 600 Diameters—Reduced.

Fig. 1.—*Bacillus mili*. *a*, spore formation, showing morphological changes, in agar-agar plate culture; *b*, peculiar arrangement often noticed in cultures; *c*, isolated bacilli, floating in the liquids of the bee or in cultures; *d*, Zo-Oglea, showing the most common arrangement of the spores at the center, and the separation of the bacilli from the mass.

Fig. 2.—*Bacillus thoracis*, *a* showing rods arranged end to end as occurs in cultures; *b*, peculiar arrangement seen in agar-agar drop cultures, showing spores by fission; *c*, Zo-Oglea, showing common arrangement of the mass.

Fig. 3.—*Mucor*, *a* showing the spore-bearing heads; *b*, showing these heads discharging the spores. Common on decaying matter.

Fig. 4.—*Aspergillus pollinis*, the fungus causing "Pickled Brood."

Fig. 5, Fungi.—*a*, *Hendersonia polycystis*. Fungus found on dead twigs, grasses, etc.; very common; *b*, *Dactylium roseum*, appears as pinkish roseate spots on decaying vegetation; very common; *c*, *Massaria*, var.; *d* and *e*, fungi not common—not placed; unimportant.

Figs. 6 and 7, spore-bearing organs of fungi.

Fig. 6, *a*, transparent spore-receptacle intact; *b*, same, showing membrane ruptured and spores escaping.

Fig. 7.—Contains similar spores in size and shape, which escape thru the membranous pouches triangularly arranged at the dentate periphery. Found in pollen. No culture made.

Fig. 8.—*Penicillium glaucum*, common fungus, found on moldy bread and elsewhere; very common.

Illustrations in this article are from Gleanings in Bee-Culture.

action. It is, evidently, now due to a specific germ, *Bacillus mili*: the other, perhaps purely accidental at first, on account of its requiring more oxygen, is now found in the thorax among the respiratory organs.

While it has not been clearly demonstrated by facts, practically, it appears to be true that perfect bees, especially nurse-bees, are injured by the infection.

DIFFERENTIAL DIAGNOSIS.

Foul brood, pickled brood, and black brood. Foul brood, due to *Bacillus alvei*—a specific bacterium.

Pickled brood, due to *Aspergillus pollinis*—a specific fungus.

Black brood, due to *Bacillus mili*, modified, perhaps, by *Bacillus thoracis*, specific bacteria.

Black brood may be introduced into a healthy colony thru infected food or infected combs—combs from which the diseased brood has been removed, or in which particles remain. The food for the young larvæ, either from its chemical reaction or from its lack of nitrogenous substances, is not a suitable medium for immediate growth of the germs; but when the chyle-like food is furnished the older larvæ, a chemical change in the food produces a change in the liquids of the bee, which become a suitable nutrient medium for their rapid development and dissemination. It would appear that, in some cases, *Bacillus thoracis* was the cause of death, as the spiracles, or openings admitting air to the respiratory apparatus, were closed by the products of decomposition or the result of it. In such cases it is usually

nearly matured bees that are choked for want of air. These did not show the discoloration or shapeless mass which always obtains when *Bacillus mili* is found in the abdomen. This latter germ, multiplying rapidly in the rich nutrient medium of the alimentary tract, may destroy younger blood than the former. It is often found in other parts, and is certainly the cause of the dark masses of rotten brood. Both germs are found in the same comb, and often in the same bee, thus insuring a mixt infection.

REMEDIES.

The best time to effect a cure is during a honey-flow.

Adopting a modified McEvoy plan:

Make your colonies strong by uniting; place them upon comb foundation starters, and cage the queen. After five days remove the starters and make them into wax, and give full sheets of foundation—keeping the queen caged five days longer. This will give time for all infected mature bees to have disappeared before any brood is reared.

Don't try to save infected mature bees by drugs. They are not worth the trouble; yet salicylated syrups, [Sodium salicylate one ounce, water 5 gallons, white sugar 40 pounds. Make syrup without heat.] during a dearth of honey in the field, would in a measure prevent a recurrence, but would not cure the disease. It would not destroy the germs, but prevent their growth, by placing them in an antiseptic [Antiseptics prevent germ growth. Disinfectants destroy the life of germs, by actual contact only.] medium.

If a cure is contemplated when little honey is coming in, the above modified McEvoy plan should be observed in every detail, and the bees fed with salicylated syrups until the combs are well filled, so that all food may be rendered antiseptic by the time brood-rearing begins.

Great care should be taken to melt all old combs and removed starters into wax at once. Do not use a solar extractor, but remove the material at once to hot water or a steam extractor. Until further investigations shall reveal the longevity of these germs in open air, I shall recommend a thoro disinfection of the hives, frames, etc., by boiling in linseed oil for half an hour. This would not injure hives or fixtures; besides, the high temperature reached would insure thoro disinfection. Careful, practical, and experimental work, coupled with microscopical investigations in the presence of this disease when at its worst, will, I feel confident, discover some practical plan for its successful eradication.—Gleanings in Bee-Culture.

Painting Apiarian Tools, Etc., Red.

BY GEO. G. SCOTT.

TO "paint the town red" is of too frequent occurrence, tho of doubtful utility. In my practice, however, I find that to paint with red the small implements of the apiary in use out-doors during the summer months, is a remarkable saver of both time and temper. This simple idea, not even worthy of the name "device," will save the bee-keeper who adopts it much fret, as it is a successful remedy against ineffectual search. You bee-keeper, how often after prying open a hive-cover, and in the great interest concentrated for the moment on the contents of the open hive, have you hurriedly and without thought dropt anywhere your chisel in the grass and weeds.

On closing this hive you repair to another to repeat the operation of opening, when you find you have forgotten to bring with you the truant tool. A search is made, and not infrequently you fail to find it at once. In the interval time is pressing, and you rub your scalp with your fingertips, or with nervous, unemployed energy stroke your whiskers, wondering with bulging eyes where that "plagueoned" thing can be. The writer many a time has had such a trial, and as human nature is constituted very much alike along some lines, he has a sneaking thought that this experience has been yours also.

I have lost tools that were not found the same season, and when discovered during the following spring, rust and rot had done their deteriorating work. But and if that implement had been painted red, an ordinary discernment would have quickly found it. Red being in brilliant contrast to the verdant surroundings of the bee-keeper (no insinuation meant), it stands to reason that anything thus daubed will be plainly recognized, not forgetting the rouged cheek, or the nose it has cost so much to permanently stain!

To paint red the screw-driver, grass-hook, grass-shears, scraper, hammer, small blocks, the outside edges of bee-escape boards, the woodwork of the smoker, or whatever

other traps about the bee-yard that may not ordinarily be easily recognized, will aid in a successful hunt, if lost. Any implement painted with crimson and placed on top of a hive will shine like a beacon light to the mariner; or smeared with scarlet and thrown in the grass will glow like a lighting-bug in the dark of the moon. Try it.

Fayette Co., Iowa.

Thirty Years' Experience in Marketing Honey.

BY C. P. DADANT.

IN reply to the following enquiry, I think the best I can do is to give our experience during a period of over 30 years in the matter of marketing honey:

MR. C. P. DADANT:—I am intending to run my apiary for extracted honey, and try to work up a local trade for it, something after the lines laid down in your book; that is, get the grocers to handle it. Now, if you do not think me too impertinent, I would like you to give an article in the American Bee Journal on marketing extracted honey; or, in other words, tell how you go to work in a new field, where people are not used to it, to work up a trade with the dealers; what size or sizes of package, what price you would allow dealers to sell for compared with the price of granulated sugars and other sweets; what percentage would be fair to allow the dealer; and whether you would put it in stores to be sold on commission, or insist on selling to dealers for cash.

I am fully aware that these questions are quite fully answered in Langstroth Revised, but that has been written some time, and you have no doubt had lots of experience along these lines since the book was written. It is very probable that you can give a beginner advice which it would take him years to dig out alone.—PENNSYLVANIA.

It must be remembered that we began the production and sale of extracted honey very shortly after the invention of the honey-extractor. This invention is due, as is well known, to De Hruschka, an Austrian, and dates back to 1865. Very shortly after, Samuel Wagner gave a description of the invention in the American Bee Journal, which he then published in Washington, and in 1867 we were working an extractor made at home, a very bulky and unhandy machine. We began the production on a comparatively large scale in 1868, and I well remember my first attempt at selling extracted clover honey. The druggist to whom I brought my sample flatly refused to touch it, because *it was too nice*. Druggists alone at that time handled honey, and outside of a few "caps," or a few broken combs of honey, there was nothing to be found but a thick, opaque, and brownish-looking liquid—strained honey—obtained by crushing the combs and pressing them to squeeze the honey out, or, worse yet, by melting comb and all in a pan in the oven. The honey that was obtained was very little better than molasses.

For the first two or three years we had a great deal of trouble in getting rid of our crop of extracted honey, even tho we had comparatively little of it to sell, as we then produced more comb honey. But the price was high. I remember that in 1871, the year of the Chicago fire, we sold extracted honey to a Chicago firm at 18 cents per pound, in barrels. On the second day of the fire we were about to make another shipment, when we were informed that the city was in flames, and that it was quite likely that our man was burnt out. So we withheld the goods, and lucky that we did so, for the man was "broke," and could not pay for what he had bought.

Within a very short time the markets became glutted with extracted honey, because not only were people unacquainted with it, but many dealers put a spurious article on the market which did great damage to the true honey. In addition to this the honey granulated, and most consumers thought that it was only sugar, and would not buy it when in that condition. We still find an occasional person who does not know that granulated honey is good, but they are quite scarce.

Our first attempt at retailing honey was in glass jars, but the great cost of the jars at that time, and the fact that the granulated honey did not appear at its best in them led us to try tin packages. So we had a lot of cans made holding 10 pounds each, and the first season we put up honey in this shape we succeeded, by much drumming, in selling some six or eight thousand pounds in that one size of package, which we sold at wholesale at 12½ cents per pound. We found our first ready sales thru a Mississippi steamboat agent, who managed to place for us over a hundred 10-pound cans during the course of a few weeks, in the river traffic.

We then began a systematic drumming of our honey put up in this shape, among all the grocers of our neighboring towns, and very soon found that we could not command a retail business unless we put up the goods in smaller packages. Thus we got to selling 5-pound cans, then 2½, then 1½.

Our manner of proceeding was to go to the grocer, make ourselves acquainted with him, then offer him our honey, guaranteeing its purity, and offering to take back any lot that would not be entirely satisfactory. We ask him to give the same guarantee to his patrons. We never sold on commission. The few times that we tried it we had cause to be sorry for it, either because the goods would remain on the shelves without attention, or because we did not get returns for all we delivered under some excuse or other.

We slowly built up a very good trade, for we always got rid, very readily, of exceedingly large crops, harvesting as much as 45,000 pounds during several single seasons, though we must say that we never but once got two large crops in succession—in 1883 and 1884.

For 25 years we have sold very little comb honey, and the bulk of our crops has been extracted. For 12 or 15 years past the condition of the market, as far as we are concerned, has totally changed, for the home competition of honey-producers has well nigh driven us out of the home market. It appears that the producers in our neighborhood have thought it impossible for them to sell at our prices. So they have, some of them, ascertained our rates, and have invariably undersold us to get the home trade away from us.

As there are a number of bee-keepers who follow our methods in this vicinity, they have produced enough to crowd us almost out. But, of late years, there has been no trouble in getting rid of the crops anywhere, and we have oftener than otherwise sold our honey at very remunerative prices in large lots. The past season, while one of our home bee-keepers insisted on retailing his honey at 7 cents per pound in small packages to beat us out of the home trade, we have not sold a single pound at less than 7 cents wholesale, and have sold some as high as 9 cents. We have bought all the honey we could hear of among our friends, and it is all gone, and more is wanted.

Our advice to beginners is to seek home sales. Sell to your grocers for cash or for trade, as conditions may require. Do not sell on commission, but have it clearly understood that your goods are just what you represent them to be, and that you stand behind them with your guarantee.

Occasionally you will find a man who will be displeased because he got clover honey when he wanted basswood, or basswood when he expected fall honey. Again, some time or other a little of your honey will prove too watery to keep; this happens in wet seasons with the very best of care, and it will ferment and have a sharp taste. Do not hesitate to make this good, if the honey has been sold before you knew it. Fermented honey, unless it is actually soured, can usually be returned to a very good quality by simply heating it to evaporate the gases that have formed in it. We have often done this, and used the honey afterwards.

Does it pay to produce extracted honey? That question has been asked us many a time. It was put to us by our foreman one day, after some four or five bad seasons in succession. He had seen how great were our expenses when the bees had to be fed, and wondered whether there was anything in it. We turned to our books and found that in the eleven years that had just elapsed we had sold some \$16,000 worth of honey of our own crop. An average of \$400 to \$500 per year would have covered the cost of management and labor. So you can see there is something in it. The cost of extracting is very nearly, if not quite, covered by the beeswax in the cappings. During our best season we made some 600 pounds of first-class beeswax from the cappings. At present prices this would make over \$150. Wax from cappings is the very best that can be had.

It is impossible to set a price on honey for any one to use as guide. Prices depend on supply, on demand, on quality, etc., and we can only advise bee-keepers to be ruled by their own judgment. If it is thought best to sell honey on commission, offer 10 percent to the retailer. A wholesale dealer ought to be satisfied with half as much. You can always sell honey in trade to the grocer of whom you buy your supplies, and to many of your townsmen with whom you have any business dealings. But the key of success in selling is in *your guarantee of the quality of your goods.*

"Painted or Unpainted Hives—Which?"

BY H. M. JAMESON.

THE above appeared in the American Bee Journal last December, as a text from which C. Davenport preaches us bee-keepers a truly valuable sermon. There exists, as he says, a diversity of opinions in the matter of painting

bee-hives. I fully agree with him as to the advisability of painting hives, even as fully as to the painting of houses. While some of the greatest bee-masters in our country advocate unpainted hives, on certain grounds which I will not attempt to dispute, no man can successfully hold forth the doctrine that lumber exposed to the weather peculiar to any State of the Union, will endure a longer time unpainted than will such lumber well painted.

Mr. Davenport kindly tells us how to obtain a good base as a preservative, as well as one that's cheap. There is probably none better. However, there are some beginners who will be putting up some new hives; they will have but little or no cash to pay for even the cheapest paints. I will say to these, that I paint all my hives with crude oil, just as it is pumped from the wells in Los Angeles (costs here \$1.50 per barrel). Mix with this enough red ochre to give a good coat, and to each gallon add one pint of coal-oil (or more if it is too long drying); and by giving two coats your hives will stand any kind of weather, and will be in good condition at the end of one or two years to take a coat of white paint.

The bees take kindly to this black crude oil. I have even boiled the lumber of dovetailed hives in this stuff before being put up, and yet the bees like it. More than this, I believe it likes the bees. All will understand that some shade will be needed in summer with these dark red hives.

We have the magnificent redwood here for hives, which, in my estimation, cannot be excelled, and only equalled by Oregon and Washington cedar. One of our trees makes a few hives, too. I have helped cut a giant that would make more hives than the A. I. Root Co. ever sent out in one season; and there would not be a knot or shake in one of them. Covers and bottom-boards could be one piece, and 25 feet square if saws were big enough to cut them.

Riverside Co., Calif.

Is it "Long Idea" or "Long Ideal" Hive?

BY WM. MUTH-RASMUSSEN.

THE Boiler is wrong in his nomenclature, on page 40, and is evidently not conversant with the earlier volumes of the American Bee Journal. There is no "Long Ideal Hive." In the April number for 1873, the "New Idea Hive" was first advertised for sale, and the first mention of it is in an article from the inventor, D. L. Adair, Vol. VII (1872), page 253. Previous to this it was known as "Adair's Section Bee-Hive," but the sectional feature (by cross partitions) was eliminated, and the name changed to "New Idea," not "New Ideal."

On page 250 of Vol. VIII (1873), in an article from R. M. Argo, is a complete description of this hive. Subsequently some one in a joking manner called it the "Long Idea Hive" on account of its shape, and this nickname has clung to it since then. I think that I have recently seen several allusions to the "Long Ideal," and have wondered that the editor or some one of the veterans did not correct the misnomer.

Inyo Co., Calif.

[Upon receipt of the foregoing, and remembering an interview we had with Mr. O. O. Poppleton on this subject, we forwarded to him Mr. Muth-Rasmussen's criticism, and have received the following in reply:—EDITOR.]

EDITOR YORK:—The history Mr. Muth-Rasmussen gives of the "New Idea Hive," and how its name became corrupted into "Long Idea Hive," is, so far as my recollection goes, correct, and agrees with what I have already written in two or three communications. Gen. Adair's hive differed in an essential particular from the long, single-story hives now in use, the outside or shell of the hive only being alike. If the name, "Long Idea Hive," was given to the one described by Gen. Adair, then it doesn't belong to the one now in use, and there is no ready way of distinguishing between the two, unless another name is used for the later form. As a matter of fact, however, the name has been used for both styles of hives, and is an ample reason for making the slight change of name for one of them.

The name "Long Idea" has always seemed to me to be a misnomer when applied to anything. What is its meaning, anyhow? What definition would a dictionary give to a "Long Idea?" I have long thought that this name, which was first given to the hive in derision, was an offense to good taste in nomenclature, and should be changed if an appropriate name could be found, not too dissimilar from the one hitherto in use, and not too long. The proper name would be "Long Single Story Hive;" but that

is too long for common use, and so the old offensive name has been allowed to stick until now.

Last summer, while looking over some copies of an Australian bee-paper, I noticed the name it used was "Long Ideal Hive," and I recognized at once that this was the solution of the name question. This name is so similar to the old one as to create no confusion whatever in making the change, is short, and, above all other considerations, violates no rules of good taste. The name is in common use in Australia, and, if I have any influence with the editors of our American bee-periodicals, it will be the common name here in America.

While in Philadelphia last fall, I requested Editors York and Root to use the word "Ideal" instead of "Idea" when naming the hive, and as the most extensive user of these hives in this country (which, according to Mr. Muth-Rasmussen's statement, are not the same hives to which the old name was first applied), I think my judgment as to which is the best name for the hive should have some weight.

O. O. POPPLETON, Dade Co., Fla.

A Three Years' Experience with Bees.

BY S. B. SMITH.

IN the spring of 1897 I moved from Stevens County to this (Millelacs), and I brought with me six colonies of bees. They did not swarm the year before, but the surplus honey they stored brought \$60. I will now give my experience with my bees for the three years I have been here.

My bees arrived June 10; moving them so late in the season delayed swarming. July 12, 13 and 15 I had a prime swarm issue on each day. I did not wish to have any after-swarms, so I put supers on the old colonies at once. In a very few days all the supers were full of bees, and they were filling the sections with honey. I watch them closely for 15 days, with no signs of second-swarms, and according to bee-laws I supposed they would not swarm again, but in 21 days each of the old colonies cast a second swarm, and in the meantime they had filled all the sections (84 in all).

Notwithstanding the second-swarms and lateness of the season, it being now Aug. 5, they filled nearly all of the second lot of sections I gave them, and capt them in good shape. One of the second swarms filled the brood-frames and 28 pounds of section honey. The other three old colonies swarmed later, and all did well. One swarm absconded, and I had 17 to put into winter quarters. I kept no account of what my bees made that year; all I can say is, it was a profitable year with me.

I put the bees into winter quarters Dec. 5, and put them out March 28, 1898, apparently in good condition, but later I lost two by being robbed. My first swarm issued May 28, and the second prime swarm June 2, both absconding.

The season of 1898 was a poor one for honey, yet the bees in this section had a great swarming fever. My 15 colonies, spring count, stored only 400 pounds of honey, and increased to 24 colonies.

In the spring of 1898 I bought a colony of Italian bees, receiving them about May 15. June 12 they cast a swarm, and at the same time one of my hybrids cast a swarm, both clustering together. I hived them, but as they did not go into the hive readily, I looked in front of the old hive and found the queen and put her into the live, and soon the bees all went in. The colony I bought swarmed three times, and stored 12 pounds of section honey. All the young swarms gathered more honey than they used in wintering. That year I put my bees into the bee-cellar Nov. 26—19 colonies.

The next spring (1899), on April 3, I put them on the summer stands, all apparently in good condition, but after a few weeks some colonies showed signs of weakness, and before I was aware of danger eight colonies died from spring dwindling, leaving a large amount of honey in each hive. None of the Italians died. I think some, and perhaps all, that died were queenless. Our great bee-men will say that my bees did not have proper care after I put them out, to which charge I plead guilty.

My first swarm issued June 3, and they continued swarming until I had 27 colonies, from which I obtained 900 pounds of section honey. I had more bees than I wanted, so I disposed of 11 colonies.

December 8 my bees had a good flight, and Dec. 14 I put them into the bee-cellar—16 colonies, all but one in good condition for winter. I have a bee-cellar dug in the side of a sand-hill, 10x12x7 feet inside, and I think it is the best place to keep bees there is in this county.

I now have 10 pure Italian colonies from the one I bought, and my hybrids are becoming strongly Italian. My Italians are very good-natured, easy to handle, and good honey-gatherers; all the fault I find is, they are too much inclined to swarm. My first Italian swarm issued June 12, and in a few days I put on a super which they soon filled—both hive and sections—and I supposed they were filling the sections with honey, but to my great surprise, on July 24, they cast a swarm, and Aug. 2 cast a second, and Aug. 6 a third swarm. This weakened them so they did not store any honey in sections, and but little in brood-frames, so I drove them out in the fall and took what little honey they had. The old colony I bought swarmed three times, and stored 24 pounds of section honey.

My experience as given in this article differs in some respects from the opinions of apiarists as given in the American Bee Journal, nevertheless I have stated facts just as they occurred. I refer to second-swarms 21 days after prime swarms, and many of these after-swarms have proved to be the best, altho coming out late in the season, while with most bee-men the opposite seems to be true.

I have taken the American Bee Journal for many years, and am largely indebted to it and the opinions of its correspondents for the little knowledge I have of the laws governing the honey-bee; and yet, my experience the past three years has convinced me that those laws and opinions are not infallible.

Millelacs Co., Minn.

CONVENTION PROCEEDINGS

Report of the California State Convention.

BY J. H. MARTIN.

The California State Bee-Keepers' Association met in Los Angeles at 1:30 p.m., Feb. 21, 1900. About 50 bee-keepers were present. Pres. Robert Wilkin, in his annual address, related interesting reminiscences in his experience as a bee-keeper. He caught the bee-fever while attending a fair near his home in Pennsylvania, and there saw a man making a public exhibition of bees. He afterward helped Mr. Harbison prepare 140 colonies for shipment to California, and soon after that, and after losing some 300 colonies during a severe winter, he also came to California, and has been, and is now, one of the foremost bee-keepers here.

In this State bees were first kept in the Sacramento Valley. The first shipments were not very successful, and the bees that did survive the journey were valued at \$100 per colony, and the first honey was sold for \$1.00 per pound.

After the bees had increased to large numbers, many of them were taken to Southern California, and that portion of the State became stocked. In the early days the bee-keeper was not so favored with bee-literature as at present. The American Bee Journal was mentioned as the very first of the bee-papers, and it has been of great benefit to the fraternity.

Mr. Wilkin stated that he had experienced the usual ups and downs common to all bee-men, that the present dry seasons were in line with his former experiences, and that the patient bee-keeper who held to the business would be the one who would reap success in the end. He many times marketed his own honey, and had made many shipments to various parts of the world, his heaviest shipment being 70 tons to London, England.

A great trade could be worked up in California honey, but from the fact that a good season would likely be followed by a bad one, or a total failure, the uncertainty of the supply had a disastrous effect upon the market.

A paper was read from Mr. Thos. Wm. Cowan on foul brood. The subject is so vital to bee-keepers that it was discussed at length, and as the law of this State is defective in many points, a committee of five was appointed to take steps to draw up a new law and get it before the legislature.

The comb-honey subject was treated at length by Mr. Stubblefield. He asked the question, "What is the matter with the comb honey market in Los Angeles?" His idea of the matter was that a fancy grade of comb honey can not be sold here at a satisfactory price. The fourth-grade honey is usually put on the home market, and the best grades sent to the Eastern markets, therefore fancy grades

could not compete with the cheaper grades. He believed that a fancy grade could not be secured without the use of separators, and that a good share of the low-grade honey that was put on the market was produced without separators, or else by those who were not particular enough in their manipulation of the bees for the production of comb honey in the first-class grade. The latter should produce extracted honey.

The discussion that followed brought out the fact that many who extract do not take the care they should in allowing the honey to become thoroly ripened. Many are known to extract the honey and young brood, and the milky substance that surrounds it, and all had a bad effect upon the honey.

Mr. Delos Wood contended that there was no harm in extracting honey before it was capt. He had practiced that plan for years, and had no trouble in selling his honey at the highest market price, and people who buy his honey always come back for more. Mr. Wood said that his honey was very thin when he extracted it, but he left it in the tank until it ripened to the proper consistency.

A paper was read by Mr. W. A. Pryal, on "The Early Bee and How to Get 'Him.'" His idea is to feed in October in order that there may be a large number of young bees reared for wintering.

The discussion brought out the idea that location may make a difference, and that while in Southern California we need to resort to no such measures to get the early bee, in San Francisco, which is more or less windy, and a land of the mist, such feeding might do.

The ant pest was discussed, and the following remedies prescribed: Find the nest and pour into it a tablespoonful of sulphuric acid. It is sure death to all of the denizens. Another remedy was to rake air-slackt lime into the ground all around a hive or other place needing protection. Gasoline, kerosene, buhac, corrosive sublimate and bisulphide of carbon were also recommended.

Mr. Brodbeck described his methods of producing both comb and extracted honey. He uses a hive about the same depth as the Danzenbaker hive, and claims that such a hive is easier to manipulate, and will secure as large a yield of honey as any other hive and system of management. Mr. Brodbeck always secures a first-class grade of honey.

Another paper was read on the great improvements that are sure to come with the development of the honey-industry. If the business would become more certain, with large apiaries and more of them, there is nothing to hinder the introduction of appliances that will greatly lessen the labor in securing the crop.

The automobile was mentioned as a machine that would become a factor in honey-production. Much interest was manifested in this idea, and many inquiries were made as to where such a machine could be purchased. If there was a \$300 machine upon the market adapted to bee-culture it would meet with a large sale.

At the morning session Mr. Clayton read a paper on "Bee-Keepers' Exchanges—Why? Why Not?"

Mr. Colamore, superintendent of the Forestry Station, at Santa Monica, read a valuable paper on the planting of eucalyptus for honey. The robusta, cornuta alpina (a shrub), melidora, sugar-gum polyanthema, were all good and the last mentioned was extra-good, for it bloomed profusely, and held its bloom for fully two months. The trees are easily grown from seed, and easily transplanted. There is an opportunity to set out thousands of acres of these trees in Southern California. All of the mountain sides now covered with a miscellaneous lot of worthless shrubs could be utilized for this purpose. A planting of large areas of trees would have a beneficial effect upon the climate, and in preserving the watersheds in hundreds of canyons.

The subject of moving bees came up for consideration. Many had moved bees during the past season to Central California, and others, owing to the continuation of the dry weather, were contemplating the same. It costs about \$7.30 per ton to move into Central California, ten tons to the car; between 300 and 400 colonies can be placed in a car.

The officers of the Association for the past year were re-elected, at the head of which are Pres. Wilkin, and Secretary and Treasurer McIntyre.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Moving Bees and Combs.

1. Can bees be moved $\frac{1}{2}$ mile in the fall and be celled with safety? or would they need a cleansing flight before they were put into the cellar, to insure their wintering well? If they were allowed a flight would they go back to where they were removed from?

2. Will combs that were built last summer on Langstroth frames be all right to stand shipping by rail if the frames are fastened securely in the hives? WIS.

ANSWERS.—I don't know. I have moved bees 3 miles and put them into the cellar without a flight, and they did not winter as well as others in the same cellar. Others say they have moved bees and put them into the cellar without a flight, and they were none the worse for it.

Yes, they ought to stand it all right. There might be an exception in the case of a comb that had never had brood in, was very heavy with honey, without wiring, and poorly fastened at the sides and bottom. Be sure that the frames while in the car run parallel with the railroad track.

Transferring—Feeding for Pollen, Etc.

1. I have five colonies of bees in old hives. Will the first week in April be too early to transfer them? If I do not do so at that time I must wait till the first of June.

2. Is it best to feed flour or corn-meal for pollen?

3. Can one use the Cowan extractor for both the ordinary and shallow Hoffman frames? COLORADO.

ANSWERS.—1. Unless you have warm weather in the first week of April with bees flying every day and gathering stores, it would be better to wait.

2. I think I should prefer corn-meal to pure wheat flour, but may be mistaken. The little I tried of the flour was not a great success. Better than either, I like corn and oats ground together, of which I have fed many bushels. It is light and gives the bees a good foothold, and when they have gleaned out all the fine parts the balance can be fed to four-footed stock. A nice way to feed it is to have a box perhaps 6 inches deep and as large as a hive-cover. Fill it a fourth or a third full, block up one end 3 inches higher than the other, and when the bees have dug the feed down level, turn the box end for end.

3. Yes.

Management for Swarming-Time.

I have 32 colonies and want to run for comb honey, and can not be at home much of the time in May and June. I have 8 empty hives that I want to fill with new swarms, and that is all the increase I want. I thought of putting on queen-excluders so the queen could not get out, and then the bees would come back to their old home. Then give them room. Would this plan work, or can you give a better one? MINNESOTA.

ANSWER.—Your plan will not be likely to suit you. The bees will come back, to be sure, but that will not be the end of it. They will swarm out perhaps every day for several days, and a week or more after the first swarm issues there will be a young queen in the hive, the old one being killed, and then they will be more fierce to swarm than ever. After a time all the young queens but one may be killed, and there being no chance for her to get out to mate, you may have a drone-laying queen. In the meantime this large amount of swarming will take place with many if not all of the colonies, making a number of swarms out each day, often at the same time, and after the young queens are out

such swarms will sulkily hang on a tree for hours, several of them settling on the same place, and then the whole bunch may enter the same hive, leaving some of your colonies considerably depleted. Some of the young queens will be very likely to get out at some crack that you didn't suspect, and sail away to parts unknown, taking with them one of those mammoth clusters.

I don't know any good way that a beginner would be likely to succeed with 32 colonies of bees so as to have only eight increase and a good crop of honey, and be away from the bees most of the time in May and June. You might come nearer the mark by having Alley queen-traps at the entrance, then when you found a queen in it you could take away all the brood, leaving the old queen and all the bees in the condition of a swarm. Or you could remove or kill the old queen, and then when all the brood is sealed, destroy every queen-cell but one.

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Richards, Ohio.

THE NEW YORK BEE-DISEASE.

If some of the boys feel bound to prove that the New York bee-disease is owing to too much cellar-wintering—why, then, we are going to have "a pretty kettle of fish," sure enough. Page 100.

MR. COGGSHALL AND HIS APIARY.

Here's the apiary we wanted to see—a Coggshall apiary where nothing is done for the looks of things. Hives put down just where it comes handy, not even rank and file. Bottom-boards extempore, sized or oversized, as fate may lead. Weeds *ad libitum*. If ragged-edged quilts stick out, so be it. And, horror of horrors, a ku-klux robe hung right in a prominent tree, where he that passeth by can't help seeing it! (I've got one, but I keep it out of sight mostly.) The heavy villain himself stands right there in the ultra foreground, like one of Rosa Bonheur's horses; and he seemeth to say: "The blood you thirst to shed is not congealed by the artificial terrors with which you menace your victim. It flows smoothly and unruffled in those channels which the Creator made for a noble purpose, etc."

Whatever we may think of the style of the "shebang," we can not afford to sneeze at five carloads of honey per year—neither at that four-frame extractor, in which the frames are swiftly revert without reversing. Thanks for so excellent a view of it. Somebody'll have to put it on the market sooner or later. The hive which is itemized into bits for our benefit has a very rude-looking gridiron of wire in front of it. Wonder if that's his bottom-spacer, or perchance spacer for both top and bottom. Crane smoker, eh? And we are not told that the barrow standing by is needed to tote it about either. Surprised to learn that Mr. Coggshall prefers chaff hives to wintering in the cellar. I train in the same winter company, but not so much of preference as because it would be inconvenient for me to run away. Page 114.

OLD GRIMES' EXTRACTOR IDEAS.

That's a good Grimes idea, to keep the extractor within a boy's power to run it. Another one—lock the handle of the honey-gate which has power to empty a big tank. And I wish lady customers inspected all our extracting outfits; for then there would be decency all 'round. Page 114.

PRANKS OF EXTRACTED HONEY.

The great variety of pranks which extracted honey will play in the course of years is instructively set forth in the Colorado report, page 117. Of especial interest is the gradual blackening of white honey with time. Fifteen years made Pres. Aikin's sample of white honey as black as sorghum. I have been inclined to blame contact with tin for most of this darkening; but quite possibly I am in a mistake, at least to the extent that honey in glass will often get black also. The general trend of these changes is evi-

dently downward, and sometimes in one year, and sometimes in many years, the outcome is a mere swill entirely uneatable. An old bee-keeper of this county took a number of barrels of honey to California just in time to find the price knocked flat by the new broom of apiculture. He wouldn't sell at ruling price, brought it back here when he moved back, and still kept it on until it was totally worthless.

DADANT ON EXTRACTING-SUPERS.

Several of Mr. Dadant's reasons for clinging to shallow extracting-supers have considerable weight; but what he calls the main reason refers to a difficulty that we all (in this enlightened age of the world) ought to extinguish in another way. Keep the queen down with perforated zinc; then decide the size of your super by other considerations. Still, if one has a plan that *works*, and by which no honey is extracted till the close of the season, the main need of the zinc disappears. Page 115.

SOME HONEY KINKS.

On page 117, Mr. Porter of the Colorados, posts us that after having educated a customer's family to alfalfa honey it won't do to change to sweet clover—which same shows the latter to be decidedly the poorer.

And the same page tells us that the candy factories sometimes buy alfalfa honey, and that they know how to utilize honey so as to retain delicate flavors. Room for we'uns to find out something.

MR. PRIDGEN'S DARK 'KERCHIEF STORY.

That's a dark subject, Mr. Pridgen, that dark handkerchief hanging out of a fellow's pocket, and the bees pitching at it. He wasn't a married man, was he? At least his wife had not the control of him she desired. When a man has more independence than is good for him his handkerchief is apt to be dark. And I don't blame the bees. Page 122.

BEE-MOTH IN COLORADO.

Our Colorado brethren seem likely to get into a squabble as to whether the bee-moth is or is not in that State. Peace, brethren! What's to hinder the moth from being carried to the State any day? And while it might not flourish as it does in a different climate, it's not likely it would immediately become extinct. Wise man would extinguish it before it Darwinized itself into a new variety. Page 124.

MR. JOHANSEN'S EXTENSION HIVE AND IDEAS.

Yes, Mr. Johansen, your considerations (four out of five of them) are excellent. Use the bees' natural impulse instead of resisting it; prevent swarming; keep the sections clean; protect the colony with chaff. As to utilizing more than one queen in a colony, that is still among the problematical things. But we fear that the hive resulting from churning these considerations in the Johansen brain will be rickety, and quite lacking in durability, altho quite expensive compared with the standard hives in use. If there is a swift and unmistakable "get there Eli" about it, when tried by others than the inventor, its faults can be borne, otherwise it will go under quickly. Twenty brood-frames below and a hundred sections above, look like business. But run as a side-storing hive pure and simple, that is hardly in accord with the first of the considerations announced. That bees incline to fill the quarters below before going above "depends" (depends tremendously) upon how big the quarters below are. And that all the eight sections in one frame of a side-storing hive "are apt to be in about the same condition," we find some difficulty in getting the conviction down, Mr. J. As to the three-queens-in-a-hive method, talk to us some more after you have actually run a dozen such colonies in your hive. We get tired rather quickly of experiences which are *going to be* realized. Pages 129 to 131.

SPREADING THE BROOD.

Mr. Aikin's plan of spreading the brood without spreading it is an excellent plan—that is, if you wish to do anything in that line at all. Done with sufficient care, the nest is warmer "after taking" than "before taking," and the great objection to that class of manipulations is obviated. The only case I can think of where warning is needed (must bark a little, you know) is a weak colony with an unusual amount of stores. Putting the wintered stores, more or less inclined to drip if a squaw-winter should come along, right next the entrance, and a nest that must have all the bees to keep it warm away back, might result in getting the whole establishment robbed out. Page 132.

VOL. 40.

APRIL 5, 1900.

NO. 14.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

Bees Have Wintered Well, according to the general run of reports, there being quite a contrast between present reports and those given up to this time last year.

A Convenient Bee-Tree is that reported in the British Bee Journal in which the owner of the tree referred to "works" the bees located in it on a plan not generally followed; in fact, he first cut a good-sized hole in the tree so as to lay bare the combs, and by means of his pipe the bees were smoked off, and several slabs of honey cut out and appropriated. This done, the opening was covered by a sack nailed on, and the bees left to repair the loss as best they could. They got on very well, and the owner for several years has in summer helpt himself to honeycomb as wanted as before, and covers up his "honey-cupboard" by again replacing the sack.

Honey-Recipes.—We take the following from Gleanings in Bee-Culture, having been furnished by Mr. W. L. Porter, Editor Root vouching for the excellence of the coffee and taffy:

HONEY-CEREAL COFFEE.—Five pounds of fresh wheat bran; mix with 2 pounds of rye flour, 2 pounds of alfalfa honey. Mix the honey with 3 pints of boiling water. After the honey and water have come to a boil, pour into the bran mixture. Stir thoroly and knead to a *stiff* dough; put thru a domestic meat-grinder to separate them. Dry in a warm

oven. Brown the same as coffee. For a coffee flavor, add 2 pounds of the *best* Mocha and Java. Have it all ground, and put in air-tight cans for future use.

HONEY-TAFFY.—Boil extracted honey until it *hardens* in cold water. Pull until white. Any quantity may be used. One pound requires about 20 minutes' steady boiling.
MARY C. PORTER.

HONEY-PASTE FOR PUTTING LABELS ON TIN.—Take 2 spoonfuls of wheat flour and one of honey; mix the flour and honey, and add boiling water to make right thickness. This is fine for labels, or wall-paper where paper will not stick with ordinary paste.
W. L. PORTER.

The Langstroth Monument.—After \$100 or more had been raised for a monument, the matter was taken up by General Manager Secor, with a result that \$275 has now been reached, which will erect a fine shaft. Mr. E. R. Root, President of the National Bee-Keepers' Association, requested Mr. Secor to add to his good work by writing a suitable inscription for the monument. This Mr. Secor has done in such a fine manner that American bee-keepers will be none the less proud of their poet-laureate. We reprint the inscription which appeared on page 200 of this journal for 1899:

INSCRIBED TO THE MEMORY OF
REV. L. L. LANGSTROTH,

"FATHER OF AMERICAN BEE-KEEPING,"

by his affectionate beneficiaries in the Art; who, in remembrance of the services rendered by his persistent and painstaking observation and experiments with the Honey-Bee, his improvements in the Hive, and the charming literary ability shown in the first scientific and popular book on the subject of Bee-Keeping in the United States, gratefully erect this monument.

Rest thou in peace. Thy work is done.

Thou hast wrought well. Thy fame is sure.

The crown of love which thou hast won
For useful deeds shall long endure.

All Should Join.—Mentioning the fact that the Wisconsin is the first association to come as a body into the National Bee-Keepers' Association, Editor Hutchinson makes a good point when he says, in the Bee-Keepers' Review:

"There is often an advantage even in numbers. When our representative, be he delegate, attorney, or manager, can say: 'I represent an organization of 1,000 bee-keepers!' it has weight."

Care in Breeding is a matter receiving considerable attention nowadays. Not that professional queen-breeders alone are to be careful, but every producer of honey. Upon this point Ebenezer Skies talks some very good sense in the American Bee-Keeper. His statement that any bee that will gather honey will do for extracted honey needs some qualification, but the rest is all right. He says:

"Any bee that will gather honey will do for extracted honey, but not so for comb. Only those colonies should be selected that are nearest perfect as comb-builders, and whose cappings are the whitest. Only such colonies as these must be used as breeders. No drones must be allowed to fly from any colony, except those having these desirable qualities. No queens must be reared from any but colonies having these qualities.

"If this is done persistently, and every queen destroyed, the work of whose progeny falls below the standard you have set, for a few seasons, you will have an apiary of thorbred, fancy comb-honey producers—that is, as far as the bees go."

Honey for Poultices hardly receives the attention it deserves. A prominent British bee-writer, Mr. W. Woodley, gives the following in the British Bee Journal:

"We have here two cases for which I am supplying honey. In one case (a damaged elbow) a blacksmith was screwing a nut on the underside of a wagon, when the

spanner slipped and his elbow struck the wheel, causing injury to the bone. The man was under a medical man for two or three weeks, when, as the arm was still getting worse, his doctor thought it best for him to go to the hospital and undergo a surgical operation, which included scraping the bone of the arm. The hospital being full, and the man having to wait his turn in consequence, he was induced, on my recommendation, to try honey-poultices, which, in about ten days, so far healed the arm that the doctor does not now consider it necessary for him to go to the hospital at all.

"The other a very bad case of a gathered thumb caused by a thorn. In this instance the sufferer received more benefit from honey-poultices than from any other remedy. I mention these facts as connected with usefulness of honey, and if we could get the medical profession to advocate the use of honey either as food or otherwise, we should soon have the demand equal to the supply."

A New Idea in Wax-Extractors.—When Editor Root was in Colorado, among the things he saw at the home of R. C. Aikin was a mammoth solar wax-extractor, in which there was a new departure by way of applying bottom heat, a principle that can equally be employed in the smallest solar extractors. Mr. Root discourses as follows in *Gleanings in Bee-Culture*:

Now, then, for the solar wax-extractor. As will be seen, it looks very much like a small greenhouse. In fact, it is built a good deal on the same plan. The floor or pan of the extractor, so to speak, is built right over a brick oven, so that not only solar but artificial heat may be utilized.

"Why," said I, "Mr. Aikin, what is the sense of having artificial heat when you have so many days of bright, strong sunshine, with an atmosphere so clear that there is neither mist nor rain a greater portion of the year?"

"Well," said Mr. Aikin, "try it for yourself. You will discover that you can not only do better work, but secure much more wax out of the dirt and refuse by such an arrangement than you can by either source of heat independently. The heat from the sun acts only on the top of the mass. The melted wax runs down and lodges in the refuse, collects, and stays there. By my plan I apply a gentle heat *beneath* by means of the brick flue, or oven as you see. The heat from *above* and the heat from *below* cause almost every particle of the wax to flow out of the refuse, and run into the pans in front."

Bees on Shares is considered by Editor Root in reply to a question in *Gleanings in Bee-Culture*, and he asks for an equitable plan, if there is one, whereby all disputes and ill-feeling may be avoided, and for "a form of contract that will be iron-clad, and afford full protection equally to both parties." In the meantime, Mr. Root gives the following as the general custom:

"When bees are kept on shares it is the rule for both parties to share equally in the profits, and in the expenses and losses. The time of the one who contributes the labor is supposed to offset the capital of the other in the form of bees, hives, implements, etc. Carrying this principle out, each party pays for half of the new hives, sections, shipping-cases, honey-barrels, honey-cans, etc.; and each party receives half the proceeds of honey and bees sold. At the end of the season the increase is divided equally between them. For instance, if there is an increase of 50 colonies from swarming, each would have 25 colonies, including hives and a half-interest in the supplies left over. If at the beginning of the season the owner has 25,000 sections, the one who is supposed to work the bees is expected to pay half their cost, including freight.

"But if half the bees die during winter, notwithstanding the fact that the operator puts them up the best he knows how, carrying out the same rule, he should make good half the loss of the bees. And right here is where many troubles arise. The operator is apt to complain, and with a fair show of justice, that he ought not to be expected to pay for bees that were lost during winter that were not his legally. But here comes the owner, and says that, if his partner had taken care of the bees, no such loss would have occurred, and then there is a row. So it is well to have this particular point safely covered."

To Clean Cappings of Honey put them in a vessel of warm water, stir well, then squeeze the wax into balls with the hands. In the evening feed the honey-water to the bees.—*Biene und ihre Zucht*.

Drone-Layers and Foul Brood.—Ludwig says in *Leipz. Bztg.* that colonies with laying workers or a drone-laying queen form good soil for the prompt introduction of foul brood. Another reason, if true, for not fooling away time trying to build up such colonies.

Bees Biting Cappings.—F. Greiner said in the *American Bee-Keeper* he had trouble in this direction when using bee-escapes at the close of the season. Editor Hutchinson doesn't have the same trouble, and Mr. Greiner replies that locality, weather, and strain of bees make the difference.

The Value of Bees to the Horticulturist and fruit-grower, or rather an evidence that their value is becoming known, was shown at this convention by one of the horticulturists, a man who owns extensive orchards, coming into the convention and offering a site for an apiary free, to any bee-keeper who would establish an apiary upon it.—Report of the Wisconsin convention in the *Country Gentleman*.

To Stop Robbing, it is recommended to put sand and sawdust in the entrance of the robbers. A writer in *Praktischer Wegweiser* says the robbers become so intent upon cleaning up their doorway that they forget all about robbing. Would that succeed with Yankee bees? One trouble is, that it is not always easy to find where the robbers are, and their home may be a mile from the scene of their depredations.

Different Colonies Gathering Different Honey.—Being asked why one colony in an apiary produced white honey of a delicate flavor, while another with the same chance produced only amber honey of rather strong flavor, Editor Root in *Gleanings in Bee-Culture*, doesn't pretend to know, but says he found in New York that blacks and hybrids showed partiality for buckwheat, and pure Italians for clover or basswood. He suggests as a possibility that individual colonies, like individual bee-keepers, have individual tastes.

"**Natural Swarming** has a fascination about it that no mode of artificial increase can possibly have."—G. M. DOOLITTLE. I don't in the least doubt that's true from your standpoint, Bro. Doolittle. Years ago the issuing of a swarm meant to you desired increase, and a glamor was thrown over the whole affair that will never fade away. With me there's a fascination about artificial increase; but there never was any about natural swarming. The announcement of a swarm fascinates me just about as the announcement that the cows have broken into the garden.—*Stray Straw* in *Gleanings in Bee-Culture*.

Greasy Sections (in this case meaning sections that look greasy or watery for lack of an air-space between the honey and capping) are having considerable discussion in *Gleanings in Bee-Culture*. It started from advice given in this journal to pinch the head of the queen in a colony producing such sections. W. M. Whitney and Dr. D. A. McLean are confident that the trouble lies, not in the queen, but in conditions and character of the honey-flow, urging that such greasy sections contain the finest honey. On the other hand, Mrs. A. J. Barber is just as positive in holding "the queen responsible for almost everything that goes wrong—greasy sections and all."

"**Advertise Your Honey**," says R. C. Aikin in the *Bee-Keepers' Review*. One of the ways is to put name and address on the case. He does not agree with Mr. Mandelbaum that the name should be there and not the address. The middleman may not want the address there, but it is the right of the producer to have it there. The *retailer* and the *consumer* have a right to know where their goods come

from. A retailer has a right to order direct from the producer if he sees fit, and a producer has a right to the reputation his production gains.

In the same paper W. A. H. Gilstrap says: "Perhaps the strangest part of Mr. Mandelbaum's article is where he wants the cases marked so as to protect *him*, and yet allow him to sell alfalfa and basswood for white clover. I don't know what you call that."

And again in the same journal, Frank Rauefuss says: "We not only want our names on the cases, but also the addresses, so that people will know where the honey has been produced. We recognized that this is the only way to establish a reputation for our product."

Bee-Keeping in Switzerland.—As every traveler knows, honey is much in evidence at almost every meal in Switzerland. The Republic has an excellent bee-school at Zug, where there are usually 25 students undergoing training in the brief honey-producing season, which (as far as commercial production goes) extends to but three or four months—the later stores being always allowed to remain in the hives for winter. The bee most valued is the small brown German variety, which beats the Italian and Carniolan sorts hollow in foraging in hot weather. I regret to see that complaints are rife as to the import of adulterated honey, and need hardly say where the complaint chiefly lies. Scarce one of the old-fashioned straw-skeps is now in use, the most approved bar-hives being almost universal.—Country Gentleman.

A New Bee-Glove, devised by C. I. Graham, is thus described by Editor Root in *Gleanings in Bee-Culture*:

"The wrist portion of the article is made of some stout strong cloth and elastic material the same as shown in shoes. Instead of shortened glove-fingers every other finger passes thru small iron rings; and these are said to be sufficient to keep the protector tightly over the back of the hand. The elastic rubber causes the wrist portion to fit tightly, preventing any bees from getting up the sleeve, and the rings give the freest possible use for the fingers and palms of the hands.

"I have not tried these protectors any more than to put them on. I don't know, but I *think* I would not on a hot day like to have a pair of tight corsets, so to speak, around my wrists. I have used with a great deal of satisfaction a pair of loose straw cuffs to prevent soiling of my sleeves, and to keep bees from crawling up my arms."

Strong Colonies for Comb Honey was the slogan at the Wisconsin convention. A report in the *Country Gentleman* says:

"Mr. C. A. Hatch argued for the 10-frame brood-nest in the spring, in order to rear all of the bees possible. At the opening of the honey harvest he would have every comb in the brood-nest of a colony that was to be worked for comb honey, filled with brood, even if he had to rob some other colonies in order to do this. He would place the unsealed brood at the outside of the brood-nest. This prevents the filling of the outside combs with honey, as the harvest (from basswood) is over before the brood has hatched from the outside combs. The center of the brood-nest will not be filled with honey. In a debate between two members, on spring management, one advocated that all colonies to be run for comb honey should be populous, even at the expense of weaker colonies, by robbing some of the latter of combs of brood if necessary. He believed in concentration instead of equalization."

Cleansing Beeswax is thus given by F. Greiner in the *American Bee-Keeper*:

"I happened to have an old 5-gallon oil-can; from it I cut the top and put in a small brass-faucet about three inches above the bottom. The can was then ready for work. It was first filled with water up to within one inch of the faucet; when the water was hot, the wax, in its crude state, was added little by little as it kept melting, till the can was nearly full. When all was melted, a cover was put on the dish, moved to the back part of the stove, or the wick of the oil-stove pretty well turned down. My aim now was to keep the melted wax in a quiet state for some little time, until the agitation of boiling had subsided. Still I did not want the wax to cool off very much, but give it time that any impurities might settle. After a lapse of about 30 minutes I commenced drawing off the wax, running it into slightly oiled new-tin basins; all of these when full were

set to one side and kept covered so that the cooling process might go on slowly, thus preventing the cracking of the cakes.

"Moulded in new tin the cakes came out much brighter than when using any old rusty basins, as I have done before. I was greatly pleased with the appearance of the wax, and so were others. Having some on exhibition at the fair, some experienced bee-keepers asked me repeatedly how I managed my wax, whether I had varnished it, etc. For that reason I make special mention of this point. All wax that would run from the faucet without tipping the can up, came out perfectly clean, and none of the cakes, when cool, had any sediment. That which did not run out was allowed to cool in the can, slightly tipping the can back, to leave the faucet above the top surface of the wax. As soon as hardened sufficiently, and yet before the wax had become really cold, the slab about an inch thick was taken out and dirt and other impurities were scraped off from the bottom. I melted this cake with the next batch each time, and thus managed I had only one small cake of inferior wax in my whole lot of 150 pounds."

Improved Benton Shipping-Cages were mentioned by Mr. Benton at the Ontario Co., N. Y., convention, as reported in *Gleanings in Bee-Culture*, as follows:

"As stated, the customary cage is made out of an oblong block with three holes bored in it, and overlapping each other. This feature Mr. B. objected to. A thin wall should be left standing between these holes, connecting them by a smaller perforation thru the walls, which may be effected by boring a small hole from the end into the cage. Formerly the sides of the cages were made flat or smooth. Packed tightly in the mail-bags it might cause a lack of ventilation, which can be easily insured by grooving the long sides of the cages, and boring, *not punching*, the little holes for ventilation from the grooves into the cage. By thus *ventilating only chamber 1*, the bees may retreat to compartment II, if they should find it more congenial there. In fact, here they *will* generally be found clustering."

Wet-Sheet Pack for a Severe Bee-Sting.—I want to say a word of comfort to those who suffer from severe itching, resembling hives, all over after being stung by bees, especially in warm weather. My daughter, aged 12, was stung by a bee last summer, and in half an hour her body was as red as it could be, and swelled up in blotches and lumps of all sizes, and she was in such agony that she cried out aloud. My wife got a sheet, wrung it out of cold water fresh from the well, and spread it upon a bed, and, after taking off all of the child's clothes, she laid her upon it and covered the ends of the sheet over her and patted them down very closely. She then covered her up with a lot of quilts. In 15 minutes she was asleep, and slept over an hour. When she awoke she felt quite well, and the perspiration was flowing freely. After wiping herself carefully with a soft towel, she drest, and felt as well as ever.—EDW. SMITH, in *Gleanings in Bee-Culture*.

Some Big Yields of Honey are reported in the *Australian Bee-Bulletin* as follows:

"Some seven or eight years ago Mr. Vogel, of the Peterson, reported that one colony with its swarms had produced 1,000 pounds of honey.

"Mr. Peterson, late of Wattle Flat, asserted that one year his colonies averaged 750 pounds apiece. It was not, however, satisfactorily proved. The year previous he had no honey and had to feed.

"Mr. Maxwell, of Albury, informed us that one year he had an average of 500 pounds per colony.

"Mr. Kelly, last year, had 17 tons from 70 colonies. These big returns, as far as we can learn, are never followed up. The following year, or the previous one, are in most cases poor ones."

Honey and Almond Cake.—Boil one pound of honey. After it has boiled, and while still hot, stir in one pound of flour, $\frac{1}{4}$ pound of coarsely chopt almonds, browned in $\frac{1}{4}$ pound of sugar (heat the sugar *without water*; when it has melted stir in the nuts; allow it to cool, and then separate the nuts so they will mix well). Add one teaspoonful of ground cinnamon, $\frac{1}{2}$ teaspoonful of ground cloves, a handful of chopt citron, and a scant teaspoonful of soda dissolved in a little water. Mix well, spread on a floured tin, and bake. While still warm cut into squares.—E. H. SCHAEFFLE, in *Gleanings in Bee-Culture*.

The South Dakota Convention.

The South Dakota bee-keepers assembled for the purpose of organizing a State bee-keepers' association, at Yankton, Jan. 25, 1900, at 1:10 p.m., with R. A. Morgan in the chair, and E. F. Atwater as secretary.

A committee of three was appointed by the chairman to draft a constitution and by-laws, composed of Messrs. Harmeling, Dole, and Chantry.

A discussion of various points in relation to bee-culture was then taken up. Mr. Danielson opened a discussion in regard to time of putting queen-cells in nurseries; it was generally thought that cells should not be put in nurseries until "ripe," altho the reason for this was not clearly understood. Mr. Hobbs opened a discussion in regard to the best packing for outdoor wintering, chaff or any light porous substance seeming to be preferred. Mr. Burke gave his method of producing comb honey. Some wintered their bees exclusively in the cellar, while others have had more or less success with outdoor wintering.

After a 5-minute recess, the committee on constitution and by-laws reported. The constitution was discussed and adopted article by article, after slight changes in wording, etc.

The chair appointed Messrs. Danielson, Harmeling, and Waterman as a committee on districts. On motion, Mr. Chantry was instructed to write out rules of procedure, which were adopted. The following amendment was carried: "The executive committee shall prepare a program for each meeting, which shall be sent to all members at the time of notifying them of the time and place of the next meeting."

EVENING SESSION.

The meeting was called to order at 7:30 o'clock by Pres. Chantry. The committee on districts nominated Mr. Hobbs for vice-president of the Yankton district, Mr. Chantry the Meckling district, and Mr. Harmeling for the rest of the State. All were duly elected.

It was decided that this association join the National Bee-Keepers' Association as soon as possible, action in the case to be left to the executive committee. Any one may receive and forward money from new members. It was voted that Mr. Morgan and Mr. Chantry represent the Association at the Farmers' Institute at Vermillion, and that the executive committee have the power to act in all such cases.

Mr. Danielson presented and explained several new or improved appliances, combined hive-stand, moving apparatus, and entrance-closers; the Chantry hive-knife, improved by Danielson, was also shown. The Chantry hive-tie was exhibited and explained. Miss Danielson, at the request of the Association, sang "The Hum of the Bees in the Apple-Tree Bloom."

Mr. Morgan offered to secure the

Sharples Cream Separators; Profitable Dairying

WIDE AWAKE WOMEN

everywhere are furnishing their homes without money by distributing a few of our fine soaps, perfumes, extracts and toilet preparations, among their friends and neighbors.

E. F. ATWATER, Sec.

Bees Had a Good Flight.

On March 17 my bees had a grand cleansing flight in the warm sun that for the first time prevailed since last year. Old Sol outdid himself on this occasion as a sort of apology for his prolonged absence in material force.

Yes, sir: the bees had a perfect picnic and fully enjoyed it. I took a peep into their sanctum to see how they fared for commissaries, and found but two frames empty, which I removed and substituted with two good combs that I saved last fall with this very object in view.

They remained all winter on the summer stand with an ordinary box inverted over the hive, which evidently afforded sufficient protection. As soon as practicable—perhaps the latter part of April—I intend to divide it into two colonies, and, by feeding more honey, have a couple of Italian families that, I believe, will give an excellent account of themselves. I am making big calculations on a fine honey season, and I believe that bee-keepers who are discouraged because of recent failures, and hesitate about looking sharply to their bees and needed supplies, will miss it very big. They who expect nothing, generally get what they anticipate. They who try persistently never entirely fail, and often hit it just right.

DR. PEIRO.
 Cook Co., Ill., March 24.

The Extension Hive.

Will "West Ontario, Canada," kindly give us the benefit of his opinions on features of the "Johansen extension hive," which he may think impractical? A full, explicit explanation is desired.

H. JOHANSEN.

Favors Painting Hives.

C. Davenport's views on painting hives, on page 821 (1899) reminded me that it would be only fair to the subject to admit that I am now in favor of painting hives. A few years ago I was induced by a prominent bee-keeper to try unpainted hives. I knew they were more porous than painted hives. The first year I was well pleased with them and soon had about 40 in use. But, alas, time told on the color and other qualities of the hives. In those unpainted, dark-colored hives the heat in those exposed to the sun was much intensified; they crack, pulled apart, and got out of fix generally. Last summer and fall we painted most of them, and the rest will be painted as opportunity occurs.

I have hives that were painted 26 years ago, and repainted once, and they are practically new. I should say that 3 years on an unpainted hive is equal in destruction to 25 if kept painted.

Then, the looks—the appearance—ought to count for not a little. Like Mr. Davenport, I now paint my hives white.

I cannot quite agree with those who advocate painting inside. I have experimented pretty thoroly in that re-

MODERN FARMER,

9Ctf ST. JOSEPH, MO.

spect, but the results have been unsatisfactory. I account for it in this way: The oil absorbed by the wood from painting both inside and out, together with the moisture taken up by the wood in cold, damp weather, make the hive a pretty good conductor of heat, and hence the temperature of bees is severely taxed. I am aware that a hive unpainted inside will at times become saturated with water, but it dries quickly.

S. T. PETTIT.

Ontario, Canada.

Dry Year in Southern California.

The bees will do well if they are able to "keep the wolf from the door" of their own homes. And if they could see what is ahead of them for the long dry year to come, I fear they would emigrate in a body—and it might be just as well for the bee-keeper in the end.

I see by Gleanings in Bee-Culture that Rambler was getting blue over the situation. As that was Feb. 9, I think by this time he must be ready to cut up into chunks for laundry use. And I also note that he has been pestered again by one of those deaf people. I had hoped to be able to meet Rambler some time, as I journeyed to the "City of the Angels," but as I am afflicted by impaired hearing myself, I fear I will have to deny myself that pleasure; but as my wife is a greater talker than I am, I can send her, and I imagine I hear him exclaim in despair, "Merciful heavens!"

The San Diego weather bureau reports the rainfall to date 3.11 inches, and normal seasonal deficiency, 5.81 inches, which explains the conditions here.

F. C. WIGGINS.

San Diego Co., Calif., March 26.

Expect All to Winter.

Our 84 colonies we think are going to pull thru the winter nicely; at least all indications point that way. Bees have had several flights this month, altho at this date there is still good sleighing.

CRAWFORD BROS.

Osceola Co., Mich., March 26.

A Young Bee-Keeper's Report.

We have had a very good winter for bees here. We put into winter quarters 103 colonies and they are all in good condition, except about 12, and they are not bad. We always winter our bees on the summer stands. They are wintered in the 10-frame Langstroth hives. The shell in which they are packed is 4 inches larger each way and 8 inches deeper than the brood-chamber, and that space is filled with chaff which makes it very warm; and for a roof it is in the form of a shanty with shingles on it.

The entrance is the full width of the brood-chamber, and is left open all winter. I tried to contract the entrance when I first commenced, but I soon found out that they didn't get enough air.

I always tip the hive a little to the front so as to let the moisture run out if there is any; the hives are 6 or 8 inches from the ground, as the bees winter lots better that way. I have been wintering a few in two stories (and they seem to come out better than in the single brood-story)—with the

DR. MILLER'S Honey Queens

One Untested Queen Free as a Premium for sending ONE New Subscriber to the American Bee Journal for one year.

We have been fortunate in making an arrangement with DR. F. C. MILLER—the well-known honey-specialist—to rear queens **EXCLUSIVELY FOR US DURING THE**

SEASON OF 1900. These Queens will be mailed in rotation, beginning about June 1, so "first come first served." We are ready to book orders now.

The Queens Dr. Miller will send out on our orders will be precisely the same as those he rears for his own use, so of course they will be from his best stock. His best colony in 1899 had a queen reared in 1898; May 5, 1899, it had brood in 4 frames, and he gave it at that time a frame of brood without bees. It had no other help, but May 25 a frame of brood with adhering bees was taken from it, and the same thing was repeated June 3, leaving it at that time 5 frames of brood. It stored 178 sections of honey, weighing 159 pounds (and that after July 20, in a poor season), being 2 2/3 times the average yield of all his colonies. A point of importance is the fact this colony did not swarm, and an inspection every week or 10 days showed that at no time during the entire season was there even so much as an egg in a queen-cell. Dr. Miller expects to rear queens from this one during the coming summer.

The demand nowadays is for **BEEES THAT GET THE HONEY** when there is any to get, and Dr. Miller has such bees. You will want to have a queen from his best, we are sure.

Do not send any orders to Dr. Miller, as all orders **MUST** come thru us, according to our agreement.

Remember, send us \$1.00 for **ONE NEW SUBSCRIBER** to the American Bee Journal for one year, and **YOU** will get **ONE OF DR. MILLER'S UNTESTED HONEY-QUEENS FREE AS A PREMIUM.** This offer is made *only* to our present regular subscribers. Orders for queens to be filled in rotation, beginning about June 1st.

Address all orders to **GEORGE W. YORK & CO.,**

118 Michigan Street, CHICAGO, ILL.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.10, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO., 118 Mich. St., Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

honey in the top story, and empty combs in the bottom story. All I have to do is to make a rim the same size as the outside shell, to sit on top. If any one wishes to try this experiment in wintering in two stories, we can explain it in another way.

I am 13 years of age.

MISS EMMA BANKER.

Brown Co., Minn., March 19.

A Minnesota Report.

This part of Minnesota (a little south of central) is favorably endowed by nature for keeping bees. Basswood, white clover, and a variety of honey-producing wild flowers abound in the most favored places. Farmers are beginning to sow alsike clover, and find that it grows well. An occasional stalk of sweet clover seen in gardens and elsewhere, stands as proof that their kind will do well here.

I would guess that we have about 1,000 colonies of bees within a radius of 10 miles from here. A great many of these are kept in a rude way. I commenced in the bee-business last spring with 11 colonies. One of these was weak, and "dwindled out," so I had only 10 to begin the season with. These increase to 23, and gave a surplus of about 400 pounds of comb honey. The season for this place was not very good.

We have a good market here at home for comb honey at 15 cents per pound.

Bees seem to be wintering well here this winter. They will need to be in winter quarters about two or three weeks yet.

From my experience last spring I learned that early breeding can be helped along to protect them in some way to keep them warmer. For one thing, use a pad or cushion of some kind over the brood-frames. Perhaps nothing would answer better than a chaff cushion. But since the present age of "blowers," chaff is a scarce article. As a substitute I think of trying bran. I have an excess of supers, and mean to utilize them to hold the bran. I will tack thin muslin on the inside of the super, and let it sag downward to a level with the bottom; then fill in enough bran to make a warm cushion. The brood-frame cloth will intervene so the super-cloth can not be waxt down. In this way it can be put off and on with convenience, and even used over the section super during the early part of the honey-flow to protect the bees during the cool nights, so common in this part until late in the summer. If I am wrong about substituting bran for chaff, I will be pleased if some one will kindly inform me.

I believe bee-keeping is one of the fine arts, and to keep abreast with the times one should take literature on the subject. Another thing, I believe the life and activity of the bees in an apiary will be increased by adding an occasional fine queen from another yard.

E. S. ROE.

Todd Co., Minn., March 26.

Mild Winter, Smelter Smoke, Etc.

Spring is with us once more, the bees are humming, the birds are singing, and the bee-keepers are hopeful. They are looking into the future with renewed confidence, and why should they

not, when all nature is putting on new life? even seedtime and harvest do not exhilarate the human family with as much joy and hope as the glorious spring. The beautiful, balmy spring-time comes as a joyous gladdening of the heart from the winter of our discontent.

But while we greet with pleasure the return of spring, we can not complain very much of grim winter this time, for we have had a mild and not a very unpleasant winter; and the bees in the greater part of the State have wintered fairly well; the indications for good crops and a good honey-flow are encouraging. The weather here now is beautiful, it is like the month of May, but last year the month of May was like March, with rain, snow and frost, or cold weather, nearly the entire month, causing the bees to die off in many parts of the State, instead of building up as they otherwise would have done, and this caused a partial failure of the fruit crop and the honey-flow. But this year it is quite the reverse—the bees are carrying in pollen, the buds are out, and a few blossoms on the hillside, and the outlook for our bee-keepers having strong colonies are favorable; we hope to hear of a successful year for them.

But I regret to say that with all the encouraging indications some of our bee-keepers who had the misfortune to be located in the wake of the smelters, lost the greater portion of their bees in the fall and winter. When other conditions are favorable the bees appear to get along all right in the spring, but along in August the poisonous smoke seems to settle on the bloom, and as the bees visit the blossoms it appears to affect them so that they crawl on the ground and die in such numbers that there is not enough bees left in the hive to stand the winter, and the bees seem to be in such poor condition that to double them up does not seem to help them much. The evidence in regard to the destructive effects of the smoke is pretty conclusive, for we find that near the smelters no bees will live any length of time at any time of the season, that is, within a radius of a mile or two, and it has been proven that cats, dogs and stock pasturing in the vicinity have died from the effects of the smoke; and in the direction that the smoke most often blows, the bees sometimes die from its effects thru the fall and winter, 10 miles off. As I have stated, the bees are not the only sufferers, hence the situation is getting to be a serious one, and something should be done to have this poisonous, destructive smoke consumed, condensed, or settled at the works instead of being scattered broadcast as it now is. To say the least, it is an outrage on the people, and something should be done for its suppression.

E. S. LOVESY.

Salt Lake Co., Utah, March 15.

Convention Notice.

Chicago.—The Chicago Bee-Keepers' Association will hold its regular semi-annual meeting in Wellington Hall, 70 N. Clark St., Chicago, Ill., April 6, 1900, afternoon and evening. The meeting will be called to order at 1 p. m. Dr. C. C. Miller is expected to be present if his health will permit. Mr. E. R. Root has been invited, also Mr. N. E. France, and others. A good time may be expected by all. Let every one come, especially the ladies.

Yellow Sweet Clover Seed

WE HAVE IT AT LAST!

We have finally succeeded in getting a SMALL quantity of the seed of the YELLOW variety of sweet clover. This kind blooms from two to four weeks earlier than the common or white variety of sweet clover. It also grows much shorter, only about two feet in height. It is as much visited by the bees as the white, and usually comes into bloom ahead of white clover and basswood. We offer the seed as a premium

A QUARTER POUND FOR SENDING ONE NEW SUBSCRIPTION.

So long as it lasts, we will mail a quarter pound of the seed to a regular paid-up subscriber who sends us ONE NEW subscriber for the American Bee Journal one year, with \$1.00; or ¼ pound by mail for 30 cents.

We have been trying for years to secure this seed, and finally succeeded in getting it. It is new seed, gathered last season by an old personal friend of ours, so we know it is all right. But we have only a small supply. When nearly out we will mention it.

Rocky Mountain Bee-Plant Seed!

(*Cleome integrifolia*.)

...FREE AS A PREMIUM...

The ABC of Bee-Culture says of it: "This is a beautiful plant for the flower-garden, to say nothing of the honey it produces. It grows from two to three feet in height, and bears large clusters of bright pink flowers. It grows naturally on the Rocky Mountains, and in Colorado, where it is said to furnish large quantities of honey."

We have a few pounds of this Cleome seed, and offer to mail a ¼-pound package as a premium for sending us ONE NEW subscriber to the American Bee Journal, with \$1.00; or ¼ pound by mail for 40 cents.

GEORGE W. YORK & CO.

118 Michigan St., CHICAGO, ILL.

We call the attention of our readers, particularly the ladies, to the advertisement of Crofts & Reed, Chicago, which makes its first appearance in this issue. This firm make a very fine line of toilet preparations, such as soaps, perfumes, extracts, etc., and have adopted a unique plan of selling. As will be seen by the advertisement, they mail free a handsomely illustrated book of premiums—these are chiefly practical household articles, such as furniture, rugs, lamps, etc., as well as watches, cameras, etc., for the boys and girls. The offers based on these premiums are astonishingly liberal. From the fact that Crofts & Reed are willing to send both the goods and the premiums for examination and on trial for 30 days if desired, it would seem that such confidence in their goods on their part ought to beget the confidence of their customers. We are sure many readers of the American Bee Journal will find it advantageous to secure without delay one of the premium lists. Please address Crofts & Reed, 842-850 Austin Ave., Chicago, Ill., and mention this journal.

The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

118 Michigan Street, - CHICAGO, ILL.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, March 19.—We quote best white comb at 15c. An occasional small lot of fancy sells at 16c; off grades of white, 12@14c; ambers, 10@12c. Extracted, 8@9c for fancy white; 7@8c for amber; 6@7c for dark grades. Beeswax, 27c.

Receipts of honey are larger and the demand is not as good as it has been.

R. A. BURNETT & CO.

CINCINNATI, March 3.—There is some demand for extracted honey from manufacturers at 7@7½c for amber and Southern; clover, 8@8½c. Comb honey is selling firm at 14@16½c in a small way. Beeswax, 25@27c.

C. H. W. WEBER,
Successor to Chas. F. Muth & Son and A. Muth.

LOS ANGELES, March 1.—1-pound frames, 12½@15c; 2-pound cans, 2 dozen in case, per dozen, \$2.50; 2-pound glass pails, per dozen, \$2.50. Extracted, water white, 60-pound tins, per pound, 8½c; light amber, 7½@8c; dark amber, 7½c. Beeswax, 25@26c.

The prospect for a crop is very bad. Small lots in the hands of wholesale houses are firmly held.

BOSTON, March 9.—Our honey market is showing some signs of lower prices, altho the stock on hand is not large. At the same time prices are so much higher than previous years that the trade have taken it very slowly and the results are that the holders are willing to range prices quite a little in order to move stock on hand. Prices range: Fancy white, 17@18c; No. 1, 15@16c; amber, 10@12c; buckwheat almost unsalable. Extracted, best white California, 8½c. BLAKE, SCOTT & LEE.

KANSAS CITY, Mar. 19.—We quote fancy white comb, 15c; No. 1, 14c; No. 1 amber, 13c; No. 2 amber, 13½c. Extracted, white, 8c; amber, 7c; dark, 6c. Beeswax, 22@25c.

C. C. CLEMONS & CO.

BUFFALO, March 3.—Market nearly bare of all grades of honey. Probably no more from any source to market, but if so, fancy white comb is firm at 15@16c. Other grades from 14c downward, with the poorest at 8@9c. Fancy pure beeswax continues at 28@30c.

BATTERSON & CO.

NEW YORK, Mar. 8.—During the past 30 days our market has been somewhat slow and easy in both comb and extracted honey. Stocks of comb honey, however, are almost exhausted, and there is a fair demand for all grades. Fancy white selling at 15c; No. 1 white at 13@14c; fancy amber, 11@12c, and buckwheat at 9@11c, according to quality, etc.

Our market is well supplied with extracted, the prices are firm and unchanged. Beeswax sells very well at from 26@28c, according to quality. HILDRETH & SEGELKEN.

SAN FRANCISCO, Mar. 28.—White comb, 11½@12½c; amber, 8@10c. Extracted, white, 7½@8c. Light amber, 7@7½c; amber, 5@5½c; Beeswax, 26@27c.

Supplies and demand are both at present limited, which is to be expected at the close of a light crop year. Business doing is mostly of a small jobbing character, and at practically the same figures as have been current for some time past.

OMAHA, Mar. 13.—Demand shows some improvement in January, having been much more active, but as anticipated there is no advance in prices. Market remains steady at 14@14½c for fancy white comb and 8½c for white extracted. The latter is pretty well cleaned up along the Missouri River, and it looks as if there would be some shortage before another crop comes in. From present appearances there is about enough comb honey to go around at the present prices, hence we look for no particular change in values. PEYCKE BROS.

Wanted! Your HONEY

We will buy it, no matter where you are. Address, giving description and price, 344½ THOS. C. STANLEY & SON, Fairfield Ill. Please mention Bee Journal when writing.

Wanted to Buy Honey Would like to hear from parties having extracted honey to offer, and their price delivered in Cincinnati. I pay cash on delivery. C. H. W. WEBER, Successor to C. F. Muth & Son, 10A 2146-48 Central Ave., Cincinnati, Ohio. Please mention Bee Journal when writing.

MADE TO ORDER.

BINGHAM BRASS SMOKERS

made of sheet-brass which does not rust or burn
out should last a life-time. You need one, but
they cost 25 cents more than tin
of the same size. The little pen
cut shows our brass hinge put
on the three larger sizes.

No wonder Bingham's 4-inch
Smoke Engine goes without puffing
and does not
DROP INKY DROPS.
The perforated steel fire-grate
has 381 holes to air the fuel and
support the fire.

Prices; Heavy Tin Smoke
Engine, four-inch Stove, per
mail, \$1.50; 3½-inch, \$1.10;
three-inch, \$1.00; 2½-inch, 90
cents; two-inch, 65 cents.

BINGHAM SMOKERS

are the original, and have all
the improvements, and have
been the STANDARD OF EXCELLENCE
for 22 years. Address,

T. F. BINGHAM,
Farwell, Mich.

I ARISE

To say to the readers of the
BEE JOURNAL that

DOOLITTLE...

has concluded to sell
QUEENS in their season
during 1900, at the fol-
lowing prices:

- 1 Untested Queen ..\$1.00
- 3 Untested Queens.. 2.25
- 1 Tested Queen 1.25
- 3 Tested Queens.... 3.00
- 1 select tested queen 1.50
- 3 " " Queens 4.00
- Select Tested Queen,
last year's rearing 2.50
- Extra selected breed-
ing, the very best..5.00

Circular free, giving particulars regarding
each class of Queens, conditions, etc. Address,

CONTRIBUTED ARTICLES

A Kansas Apiary—Several Queen Experiences.

BY SILAS HARTER.

THE accompanying is a picture of my 3-year-old apiary from a beginning of one colony, the second year buying four. How is that for central Kansas? The picture was taken on Jan. 19. The bees were flying and a few were bringing in pollen.

It will be noticed that I am in shirt sleeves, and not uncomfortable. My posture would indicate that I have been a laboring man, and that I am a little round-shouldered, nevertheless I am enjoying the best of health. The one in the distance is one of my sons, "Will," who will soon graduate from our college here. The trees you see are cherries, and in summer make quite a cozy place for the bees.

Now, don't think I have a telephone to my apiary—it is only a clothes-line.

If you won't laugh, I will tell a little of my experience at roasting a queen. One bright morning I received a nice Italian queen from a breeder in the East, to give to a queenless colony. As the bees and queen in the cage seemed to be a little chilled, I thought I would place them in the sunshine by the window. I left them there for perhaps an hour, when, on my return, to my astonishment, all were dead as a doornail. So another lesson was learned, and quite a loss sustained, as it was early in the season.

At another time, on receiving a queen I desired to clip her wings, and so opened the cage at the window, thinking all was closed, but to my astonishment the upper window was down a little, and out went the queen. Well, I thought she was gone, but I quickly raised the window and after flying around awhile she flew in. I thought myself more lucky than wise. But another lesson was learned, to be a little more careful. I think this rule should hold good in all our work with bees.

McPherson Co., Kan.

Apiary of Mr. Silas Harter, McPherson Co., Kan.

NO. 5.—COMB HONEY PRODUCTION.

Managing Swarming—Strong Colonies Only for Good Section-Work.

BY R. C. AIKIN.

WHEN swarming begins, what shall be done? Whatever is the method of handling swarms, it should be done in such way as to keep the section-work going right along. The handling of swarms is one of the things I have had only a limited experience in. True, I have had a good many swarms in 25 years of practice, and, comparing my experience with that of the average apiarist, perhaps it would not be strictly true to say that I have not had much experience. Here is how it is:

The first few years after I began bee-keeping I had only fall honey-flows, coming the last of August and first of September, generally about a month of flow, and about equally divided between August and September. Late honey harvests do not cause much swarming, and if one is in a location with no early flow, and the main harvest just before frost in the fall, he has indeed a very easy time of it compared with those of us who have the early flow. Just think of having all spring and summer till Aug. 1 to 15 to get ready for a honey harvest!

That is what I had in my first few years in bee-keeping.

After this came the white clover flows in June—once it began the latter part of May. I think I am safe in saying that swarming was all of four times greater, and equally more troublesome when my harvest came in June. I practiced hiving swarms back, and sometimes uniting two weak ones, or putting small swarms in with weak colonies, the object being to have strong colonies for section-work.

To hive a swarm back to where it came from is like trying to put a fire out by adding fuel. I cut out cells only to have them rebuilt in very many colonies. Some would remain content and do good super work, but many would not. Some would stay a few days till new cells were started, then swarm again, and some would come out without waiting to build new cells.

Neither is it satisfactory to hive swarms in with other colonies, unless both the swarm and the bees of the colony to be united be dumped together off the combs. In later years I often mix up bees from several colonies and put all into one hive, and it can be successfully done, and such

colonies be made to do fine work. The colony into which the others are to be put should be thoroly subdued, and their sacs filled till all the fight is taken out of them, or else they should be shaken from the combs among the others, and all allowed to run in together. Managed in this way small swarms, or small swarms and weak colonies, may be run together for section-work.

With the exception of about two seasons in which I had much swarming in June (this was my first experience with honey-flows and swarming at that time of year), I have very largely increast by division, and kept down swarming to the minimum. However, there are always a few swarms that I have to contend with, some strays, some my own, owing to some colonies becoming queenless and unknown, and some by supersedure of the queens, and sometimes I get behind and let the bees get the start of me. So it comes about that I handle a few swarms almost every season.

To have an average swarm in a 10-frame hive means very little super-work unless the flow be very good. To have in either an 8 or 10 frame hive on ready-made combs also means that very little or no super work is done *except in very good flows*. To have on 5 or 6 frames with starters, and put on a partly-workt super, or one with bait-combs, will be better than the former plan. I practice hiving in a contracted chamber of not to exceed six Langstroth frames—sometimes I hive on about four combs ready built. I also use a half of a divisible brood-chamber for this purpose. As nearly as I know, I should advise to hive on starters and only 6 to 8 frames, and put the supers over from the old hive on the new, hiving on the old stand and putting the old on a new stand. I would also shake out the bees from the old to the new.

Whatever plan is used, if you can not control swarming, when swarms are lived be sure that the brood-chamber room is contracted to correspond to the bees so that they *must* work above if they do much at all. I should be inclined to put two swarms into one, or three into two, and give whatever was my standard brood-chamber, for it is very much better to have one strong colony store 50 pounds than to have two store only 25 pounds each. The 50 pounds stored by one colony will be better finisht than the 50 pounds by two colonies.

My practice is to have every colony that works in sections very strong, and if I can not keep them from swarming I take away enough of their brood to discourage swarming. Have so many bees in the hive that in a reasonable flow they will work two supers at once, and at the same time occupy an 8 or 9 Langstroth-frame brood-nest. Such a colony is a strong one, and here is about how it will work:

If the flow be moderate, about two to three pounds a day gain for such a colony, and lasts 30 days, I would expect about one snper of 28 sections filled—say 25 pounds. The same and the average daily gain about four pounds I would expect two supers finisht. To increase the daily gain, or to continue the flow longer, would mean a proportionate increase in the surplus. According to my way of looking at the problem, a colony should not be expected to work sections unless it be strong enough to handle a 6 to 8 Langstroth-frame brood-chamber, and at least two 24-section supers in a moderate flow. Such a colony will surely go into the sections whether they use them or not, and they will surely use them if there is a flow that would give a crop. Such colonies will give more or less of a crop when those allowed to swarm would give *none*.

It discourages me to try to get a crop of honey from an apiary allowed to swarm freely, for I surely consider a colony that has swarmed not of sufficient numerical strength to do nice section-work in an average season. It also discourages me to try to tell anybody else how to succeed and allow the bees to swarm. I think I will just say if you will succeed in the production of comb honey, you *must* curtail swarming, or else double up swarms and colonies till you have proper masses of bees together.

Take an apiary of 100 colonies, build them up as strong as you can by the time white clover blooms, then if you can take 50 or 75 of the best of them and run them for section honey, and not let one of them swarm, you have my ideas of proper strength of colonies. Do this, and in doing it follow the methods I have been describing to keep off the swarming-fever, then if any get the start of you and swarm, just hive them in a contracted brood-chamber, or take away part of their brood and substitute frames filled with foundation, and put them back into the old hive.

If you want increase, make it by dividing your weak colonies, and not ask them to put up surplus. If you can do this I will guarantee you will get honey to sell when your neighbors do not have any, and when your neighbors

have moderate crops you will have good ones, and when they have good ones you will have at least three to their two. More than this, when others have to feed or lose their bees you will have little or no feeding to do, and when others have No. 1 honey you will have *fancy*.

I have for nearly 10 years controlled swarming by unqueening just about the beginning of the flow, and for a locality having but one flow lasting four to six weeks, or less, I know of no method that will give better results. Now, my locality is somewhat changed, practically having two flows, hence I am changing my method. Abundance of room and ventilation before the flow; flow started, contract the brood-nest to normal, and give plenty of super-room (all you can get them to use) with bait-combs, and remember *always*, that if we can get a colony to *working in two or more supers before they get in the notion of swarming*, they will not swarm much if they are kept with plenty of super-room.

Larimer Co., Colo.

Can a Good Queen be Reared in a Nucleus?

BY DR. C. C. MILLER.

WHEN I first began working with bees I learned that a small number of bees were sufficient to start queen-cells, if furnisht with proper brood, and that they would therefrom secure a laying queen. I was delighted to think with what rapidity an apiary could thus be built up. But I soon learned that sometimes "things are not what they seem." I reared some very poor queens; in one case a queen laid one egg and died; in some other cases they did not even lay as many as one egg before death.

From that I went to the other extreme, adopting the belief that to get good queens the cells must be started in full colonies and left there at least until sealing. I still held that belief as late as a year ago, and in reply to a question, I said:

"If you put in a hive a frame of brood, another of honey, and a pint of bees, they may protect themselves against robbers, and they will be pretty sure to rear a queen, but the chances are that the queen will be a very poor affair. Don't think of having a queen reared anywhere but in a strong colony, at least until after the queen-cell is sealed." (Page 199, March 30, 1899.)

Commenting upon this, G. M. Doolittle said on page 371, "Without any precaution toward making the bees stay on that frame of brood, they would all leave, and if so no queen would be reared at all—a *poor affair* or otherwise; but where bees are taken from an out-apiary and kept in a nucleus-box without any queen for 24 hours, at the expiration of which a *quart* of bees is turned loose on two frames fixt as the questioner proposes, they will rear *just as good* queens as by any of the plans used which deprive the colony of its *queen* while the cells are being built, as I have proven time and time again; for, while in the nucleus-box they do 'so long' for a queen that nearly all of them will prepare royal jelly, and when they have access to brood they will just 'flood' the young larva chosen for a queen with it nearly, if not quite, equal to those being reared in a colony preparing to cast a swarm. And a quart of bees on the two frames will keep up the necessary heat to fully perfect those queens, where treated as I have given, fully as good as will a strong colony whose queen has been taken from them that they may rear queens."

I studied over that paragraph very carefully. If I understood it correctly, it plainly taught that a quart was just as good as a strong colony of queenless bees to rear queen-cells and queens from start to finish. If that was true, I was in error to teach the reverse. Mr. Doolittle was one of the leading queen-breeders of the world, so had had many times the opportunity that I had had to observe the matter, as I was not a queen-breeder, only a honey-producer. But the bare possibility that Mr. Doolittle might be mistaken was still left in my mind, and I thought there was no great need to change my opinion in haste, as my error, if error it was, was on the side of safety. I could afford to wait until the opportunity came either from my own experience or the testimony of others to help settle me on one side or the other.

Such opportunity has now come. In reply to the question, "When dividing bees is it best to rear queens for them, or let the queenless part of the division rear a queen for themselves?" Mr. Doolittle replies (Gleanings in Bee-Culture, page 175):

"I consider any plan of division, which compels the queenless part to rear their own queen, as faulty. Because, in the first place, *good* queens are reared only in a colony

very populous in bees, of *all ages*, with honey and pollen coming in from the fields, enough to supply their wants. Of course, this honey and pollen part can be supplied by the apiarist, if deficient in nature; but the *populous* in bees part can not possibly obtain with a divided colony."

If I understand that correctly, it means not only that a good queen can not be reared in less than a full colony of bees, but that the colony must be "very populous in bees." I can hardly say that I am glad to know the requirements are so exacting, but I am very glad to be left no longer in doubt. If I have been correct in interpreting Mr. Doolittle, he has changed his views in the past 12 months—a thing we must all do occasionally if we are to make any progress.

The important thing about the matter, sufficiently important to be worth while to take up several pages of this bee-journal with it, is to have it clearly and emphatically known that no nucleus will do to rear queen-cells; or, to put it in the words of Mr. Doolittle, that "good queens are reared only in a colony very populous in bees." For if it should be believed that a quart of bees is just as good as a strong colony to rear queen-cells, there are thousands who would rear queens in nuclei, and thousands upon thousands of dollars would thus be lost in the honey-crop by means of poor queens. If we are to have the best in the line of queens, I believe it can hardly be emphasized too strongly, that up to the time queen-cells are sealed they must be in full colonies. From that time on I do not feel so sure about, but I think that a nucleus of good strength will be all right after the cell is sealed.

McHenry Co., Ill.

The Marks Frame and the Case Feeder.

BY F. GREINER.

WITHOUT fear of contradiction I am safe in saying that the physical make-up of man is such that no two persons can be found among the many millions, that represent another in every particular, altho all are built on the same general plan by the Creator. The nose is centrally located in every face, and the other organs bear the same relationship to the nose, are grouped around it the same in one person as in the other, etc. What is true in the physical make-up is also true in the spiritual and intellectual. And that is the reason why we do not all of us see all things alike; why we so often disagree on the things relating to our pursuit; why one man rides this hobby, another a different one; why the deep frame meets the requirements of one, the shallow frame the ideas of another, etc. Just so long as we live this state of affairs will remain, and the bee-keepers will continue to fix, and change, and remodel, and improve.

If I now attempt to say a few words about a new brood-frame and a new bee-feeder, it is with that thought, to perhaps meet the requirements of some one who is still seeking for something better, or at least for something *to suit him* better; for changes are not always improvements.

The Marks frame is not an entirely new thing—it was even mentioned and illustrated in *Gleanings in Bee-Culture* a year or two ago. However, a good thing has many a time to be pushed and brought before the public again and again before it is recognized as such.

The spacers of the above frame are simple pieces of $\frac{5}{8}$ or $\frac{3}{4}$ inch hoop-iron about two inches long. They are inserted at the upper ends of the end-bars into properly cut saw-kerfs, in imitation of the Hoffman frame. Mr. Marks' idea is to place both spacers on one and the same side of the frame. It is plain that the Marks frame with the spacers thus arranged must not be used *revert*, but must be placed spacers against the flat side of the next frame. On this account it has been criticised. But, really, is this a serious disadvantage?

In discussing the merits of this frame with a number of bee-keepers of our county, one of them said: "Why, with that frame one can not possibly get it into a hive the wrong way." Another one of those present took the opposite view.

The fact seems to be the Marks frame *may* be put in wrong side to, but no one with any eyes at all *would* put it in wrong. With the swinging frame—the Hoffman or any other frame—in returning combs to a hive it may occur that we are uncertain as to which way they had been in the hive; we may make a mistake and get one wrong. We do not find this out until we have tried. The frame must then be taken out again and *revert*, for no frame, when one match in, fits exactly in any other place. I confess I have occasionally had some trouble in this direction. With the Marks metal-spaced frame this would not have happened.

However, if any one should like the Marks *spacer*, and not the other feature of the frame, there would be nothing to hinder *changing one spacer over to the other side of the frame*. But from what experience I have had with any of the self-spacing frames, I would to-day rather have the spacers on *one* side than otherwise. We do not nowadays manipulate the frames very much, and when we do, we want to return them in the order they came out, at least in nine cases out of ten, so what's the difference?

FEEDERS AND FEEDING.

In localities where the surplus is gathered mostly from white clover, the practical bee-keeper finds stimulative feeding early in the season of great advantage. Such feeding has to be done every day, and in small doses, and the feeder that admits this kind of feeding without opening hives and disturbing bees, it would seem, would at once find favor among bee-keepers. I herewith present a drawing of such

a feeder as has been in use here among the bee-keepers in the eastern part of this county (Ontario) for a good many years. As I do not know who the inventor is, I will name it the "Case Feeder," as Mr. H. L. Case explained its workings before the Ontario County Bee-Keepers' convention a short time ago.

The drawing almost explains itself. The feeder is a shallow tin box about four inches in diameter. The bottom is removable and perforated. The long spout is to reach clear to the outside of the hive, and the feeder may be filled without opening the hive or disturbing the bees. It is a time-saver.

As Mr. Case says, just go thru a large bee-yard and take all the covers of the hives off and put them back on. Do that with 100 hives, and you will find it quite a job, especially with clumsy chaff hives. This feeder is tucked away under the cushion immediately over the cluster of bees, the spout running to the outside, either at the rear or side of the hive. The filling is done by the help of a little funnel with an elbow to it. As soon as the feed is poured in, the spout must be closed with a tight-fitting cork. There is but little work connected with this kind of feeding, and no heat is lost opening hives.

Ontario Co., N. Y.

Reversible Frames, Beeswax, Etc.

BY G. M. DOOLITTLE.

A CORRESPONDENT writes: "I have been reading up some old bee-literature, and in it I find quite a little about reversible frames. Are they something of value? If so, I shall desire to make some before the swarming season opens. Please tell us something about them in the *American Bee Journal*."

ANSWER.—Reversible frames were one of the disputed questions of the past, they having quite an extended airing some 12 to 15 years ago. Very many of our most prominent bee-keepers gave them a very thoro trial, but so far as I know there is not an apiarist of any prominence using them to-day; or, if any such are using them, they do not consider them of enough value to say anything about them in bee-literature now.

The main thought and object for which they were brought into existence was that of compelling the bees to store all of their honey in the sections, by reversing the frames as often as the bees lengthened out the cells along the top-bars of the frames and filled them with honey. By thus placing this honey in an unnatural position it caused the bees to remove it, and as there was now brood in the upper part of the frames, the bees would be constrained to store this removed honey in the sections.

At first sight this theory looks very nice, but when it was put into practice it was found the bees did not "think" as did the theorist, and colonies so worked accumulated no more in the sections than did others that were let alone, while at the end of the season the colonies let alone showed

a decided advantage, inasmuch as they had honey to winter on, with little or no honey in those whose frames had been reversed several times.

The claim was also made that the reversing of the frames would do away with swarming, as the queens occupying the reversed queen-cells all die. Many queens in the embryo form would thus die; but as swarms were sure to issue from queens not killed by reversing, or by the swarms coming out without any capt queen-cells, or little if any preparation along the line of queen-cells, the reversing of frames for this purpose proved fully as fallacious as for section-honey.

The only advantage I could ever discover by reversing frames was that, by thus doing, the combs would be built as perfectly to the bottom-bar of the frames as to the top-bar, so that the trouble of ridding the frames of bees on account of their hiding in the space between the bottom-bar and the comb was obviated. While this was some gain, yet I never found the gain here to be sufficient to pay for the trouble and cost of reversible frames. This can be accomplished in other ways, such as placing the frames in an upper story for one season, extracting the honey from the same, or using such frames for winter stores. After they are thus filled there is no necessity for placing them in the upper story again, unless it is so desired for some other purpose besides having the frame entirely filled with comb.

RENDERING AND CLEANSING BEESWAX.

Another correspondent writes: "I have a lot of old combs which I wish to render into wax, and a lot of old dirty beeswax which I wish to change to the nice yellow wax usually found in the comb foundation sent out. Will you tell me thru the columns of the American Bee Journal how this can be done?"

ANSWER.—As to the old-comb part, I very much doubt whether there is a better way for the rank and file of bee-keepers to render such into wax than by using the sun or solar wax-extractor. I have tried many plans, such as a kettle of boiling water, with the comb placed in an old burlap-sack, the same being worked with a hoe or plunger till the wax was worked out and rose to the top; and other methods of getting out by water; the Swiss wax, and other steam extractors; the dry oven method, etc., but I have laid all of these aside, and now use the solar wax-extractor altogether. It has a convenience in storing combs and bits of wax, till full, and then in rendering without "fuss or feathers," by simply removing the covering from over the glass on any sunny day, not possess by anything else. Almost any supply dealer keeps them for sale.

It is claimed that *all* of the wax can not be gotten out of the combs in this way, but if any person will take off the glass frame, after the most of the wax has run out, and with a trowel, or something similar, rub down the refuse, so as to break down the cocoons that may remain whole, I think he will have no trouble in securing fully 99 percent of all the wax contained in any comb, no matter how old or tough they may be. At least I never find any such quantities left in the "slumgum" from my wax-extractor as others tell of, and I have boiled and prest it many times to see if I was wasting enough to pay me for putting it thru this process, as many claim they do.

Regarding the cleansing part, wax coming from a solar wax-extractor is more nearly perfect as regards any impurities than that obtained by any other process, and rarely needs any cleansing except straining. At least that is my experience, for it is always nice and yellow, no matter how old and black may be the combs from which it came. Many of the comb-foundation makers use certain chemicals to bleach and cleanse their wax, if I mistake not, and if the questioner has dirty wax to the amount of hundreds of pounds, it may pay him to enquire of them. Regarding the use of these I know nothing, and I doubt whether the ordinary practical bee-keeper, with only a limited quantity of wax, could make it pay to use chemicals for purifying beeswax even were he familiar with their use.

Any plan by which the wax is kept in a liquid state for a long time, the same being perfectly stationary during this time and while cooling, and using quite a body of water with the wax for the dirt to settle into, has a tendency to separate the impurities from the wax, and give it a bright yellow color.

If, in addition to the above, a pint of good, strong vinegar is used for every ten pounds of wax and one quart of water, the result will be more satisfactory. My plan before using the solar wax-extractor was as follows:

Put 10 pounds of wax, one quart of water, and one pint of strong vinegar into a flaring tin dish, and set it on the

stove until the wax is melted and the whole becomes as hot as it will bear without boiling over. If there are impurities of any size it should now be strained thru common cotton-cloth, or these impurities are likely to be partially imbedded in the wax at the bottom of the cake when cold, so as to make the job unsatisfactory. Having this accomplished, spread down two or three thicknesses of old carpet, or two or three horse-blankets, where the wax is expected to stay until cold; then set the vessel of wax in the middle, and wrap over the top and sides the unoccupied parts of the blankets until the whole is well protected from the outside air, so that the whole may be four or five hours in cooling. If you will watch the liquid you have in the vessel before covering it up, you will note that the whole mass seems to be in agitation, rolling and turning about as tho it were alive. This is the work of the vinegar, and that which makes the dirt separate more perfectly from the wax than it otherwise would. If strained as given above, there will be only a fine dross at the bottom of the cake, which is easily separated from the wax by scraping with a dull knife.

Onondaga Co., N. Y.

Breeding Bees for Business.

BY FRANK COVERDALE.

I AM very glad to see that at least a few people in our ranks are beginning to look more thoroly after a good honey-gathering stock of bees, and other good qualities, such as hardiness, non-burr-comb builders, and white cappers, all of which amount to a very great deal to a comb-honey producer in full, and in part to the bee-keeper who extracts.

I must confess that I have heretofore been far too negligent along this very important line. Who would believe me, if I should say that a large portion of the queens sent out by our breeders are behind the average black stock over the country? During the past two years I have purchased upward of 50 queens from different breeders, and nearly every one has fallen short as a honey-gatherer, but for beauty, gentleness and prolificness nearly all were by far ahead of average black bees.

The above fact, in my estimation, doesn't condemn any race of bees, but strains of bees, or in other words, bees that have been bred for a standard which did not take a proper estimate of the honey-gathering quality. Bees left to themselves in the wild state do of their own accord (in the northern climate, at least) perpetuate the honey-gathering qualities to quite a far-reaching degree; because a poor season comes along at intervals, so poor that only the greatest hustlers will have enough stored to carry them thru. Just so among our slipshod bee-keepers of to-day—one year in 20 will use up a whole apiary from starvation except a few of the best gatherers, which leaves good stock to begin with after the poor, or, I should say, very poor season is gone. But can't we make the same selection every year that would take nearly 20 years? Progress is in a rapid state on all lines, and I believe that the queen-breeder of the future must look well after the more weighty matters.

A few years ago, when attending our State fair, and going the rounds of the different bee and honey exhibits, I came across a very beautiful strain of bees, and they appeared to be very gentle; I was assured by the owner of them that they were hustlers both to gather honey and to cap over their combs white. The gentleman did not make a specialty of rearing queens, but he was anxious that I should try his strain of bees, and at once made me a present of one of his queens, which proved to excel all other queens that I ever owned, either before or since. Her workers would gather six and seven supers of honey while no other of the 50 colonies by their side scarcely finished half the above amount, and nearly all the yard gathered only one and two supers each. I would give \$50 for such a queen for my own use for next season, if I knew where she could be found. Her offspring shows up yet wherever it is to be found thru the home yard, but this queen was not made proper use of on account of lack of time, and I am now very sorry for that.

I often think it would pay me to do as the hog-breeders do—go right to the bee-yard where the owner is producing honey, during the main flow, and make a selection, buy a queen from an extra-hustling colony, and take her right home with me.

Jackson Co., Iowa.

The Premiums offered on page 237 are well worth working for. Look at them.

CONVENTION PROCEEDINGS

Report of the Wisconsin State Convention.

BY N. E. FRANCE.

The 16th annual meeting of the Wisconsin Bee-Keepers' Association was called to order Feb. 7, 1900, at 10 a. m., with Pres. F. Wilcox in the chair. Prayer was offered by Rev. H. A. Winters.

Pres. Wilcox delivered a short opening address, after which the secretary read the minutes of the last meeting, which were approved.

CAUSE OF WINTER LOSSES OF BEES.

Next was a paper by Herbert Clute, of Clark Co., on the causes of loss of colonies of bees last winter. A long discussion followed on wintering, several thinking the long-continued cold weather the main cause. Proper ventilation and uniform temperature were advocated by all. Several have underground inlet air-tubes as well as upward ventilators. If stone walls get damp and frosty it is an indication of lack of heat and ventilation. Good feed is as necessary as the cellar. This may be either sealed combs of choice white honey or thick sugar syrup.

Several spoke of heavy losses where honey-dew or sorghum, from sorghum mills, was plenty in the fall. Some members complained of their bees in the spring being bothered with diarrhea, often the result of shortage of good feed—causing the bees to consume an unusual amount of bee-bread.

In making sugar syrup, all use the best white sugar, about 2 pounds to one of water, and if not stirred much in making it is not liable to granulate.

The secretary then read a second paper by Mr. Clute, on "Bee-Keeping in Clark County."

The convention then adjourned to 1:30 p. m., when Pres. Wilcox called the meeting to order, and George W. York gave each one present a copy of the song written by Dr. Miller and Mr. Secor, entitled, "The Hum of the Bees in the Apple-Tree Bloom." After Mr. York sang the first stanza, all joined, and a choir of 35 bee-keepers' voices was heard.

The secretary then read an essay on bee-keeping, by Mrs. Jennie Towle, of Clark Co. This was followed by Miss Ada Pickard, of Richland Co., who was listened to with great interest.

"Dots by the Wayside," a paper by Jacob Huffman, had many valuable suggestions. A lengthy discussion followed on pasturage for bees, advising the sowing of more alsike clover, and also sweet clover, as the latter might better be growing where worthless weeds are found. Extracted sweet clover honey being of a white-greenish shade, and fair quality, it finds ready sale. Some had trouble to get sweet clover seed to grow, but if fresh-gathered seed was sown in early fall, in gravelly or clay soil, a good catch was generally secured. Mr. York spoke of its great importance to Illinois bee-keepers.

Mr. E. D. Ochsner then read a paper on "The Section-Box for Wisconsin Bee-Keepers," advocating the standard $4\frac{1}{4} \times 4\frac{1}{4}$. Messrs. Hatch and York, in the discussion, spoke of others getting more for their tall, fence-separated honey. The majority present favored the use of the standard $4\frac{1}{4}$ section until their markets demanded a change.

The State foul brood inspector then read his annual re-

port to the Governor, and in the remarks following, askt the association to use its influence to have the present law revised—put back as the legislature past it in 1897, adding a section to appraise and pay for property where necessary to burn. A motion was carried empowering the officers to draft such a bill, and take such steps as may be necessary to secure its passage.

A question was askt by Mrs. Towle as to whether the State association protected its members the same as the National. After remarks in reply to the above by Pres. Wilcox, Messrs. York, France, and others, Mr. York informed the association of an offer, that if all the paid-up members of this association would join the National Bee-Keepers' Association in a body, there was a section in the constitution allowing such to join at 50 cents each. This led to a recess, and a lively paying of such dues. Wisconsin has been in the lead in many industries, and at the close of the paying of dues for the National Association, a feeling of National strength and patriotism was shown in every face.

Geo. McCartney was present with his valuable combined foundation fastener and section press.

The evening session was called to order by Pres. Wilcox. The entire meeting was devoted to questions and answers, this being the place where some questions of great value to the one asking—in many instances of as much value as the cost of attending the gathering.

THE QUESTION-BOX AND ANSWERS.

QUES.—How to prepare new graded ground for an apiary.
ANS.—Seed to white clover.

QUES.—How to manage a 10-frame hive for comb honey—which is the best hive and frame?
ANS.—The majority favored the 8-frame Langstroth hive for comb honey, and the 10-frame for extracting.

QUES.—How far do bees fly and gather honey profitably?
ANS.—In general, 1 to 3 miles, but instances were spoken of by W. Z. Hutchinson, where feed being

scarce, they were known to work freely six to seven miles.

QUES.—When to sow alsike clover seed. ANS.—In the spring in soil well prepared, and if not allowed to be smothered by other crops, it will bloom well the second season.

QUES.—Can ladies keep bees with profit? ANS.—Yes, if proper attention and study are given to it.

QUES.—How to get strong colonies by the harvest time. ANS.—By good protection and feeding.

QUES.—How to keep the top of the hives warm on cold nights and days in the spring. ANS.—Put burlap or other cloth covering under the cover, and then tight-fitting cover. At certain times protect the whole hive.

QUES.—When and how to ripen extracted honey. ANS.—All advised keeping it on the hives until ripened by the bees. A majority of the members use queen-excluding honey-bodies.

QUES.—Is a bee-keeper responsible for damages done by his bees? ANS.—Yes; but if bees are near neighbors or a street, and sting people or stock, they should be moved, or a high fence or hedge erected to force the bees high above such street; and where bees are kept near neighbors so as to bother them, and stain their clothes on the wash-line, keep good neighbors by an occasional gift of honey from these bees. The bee-keeper also should belong to the National Bee-Keepers' Association—a cheap and valuable insurance in times when envious neighbors complain.

QUES.—Do old extracting-combs color the honey? ANS.—No, not even combs that have been in use 20 years.

QUES.—Do hives need ventilation in hot weather? ANS.—Yes, by entrances left open the full length, and the cover raised a little at one end.

QUES.—Do bees do as well in the shade as in the sun-

Bee-Supply Factory of G. B. Lewis Co., Watertown, Wis.

shine? **ANS.**—The majority present prefer a light shade in the middle of the day.

QUES.—Will bees work in very hot weather? **ANS.**—Yes, if the flowers are secreting honey.

QUES.—How many sheets of comb foundation to give to a colony at once. **ANS.**—Two are enough.

QUES.—If a colony produces 50 pounds of comb honey per year, how much extracted should be secured from another of the same strength? **ANS.**—75 to 85 pounds.

Too many use an extractor who do not leave honey enough for the bees to winter on.

□ SECOND DAY—MORNING SESSION.

The election of officers resulted as follows: President, N. E. France; vice-president, Jacob Huffman; secretary, Miss Ada Pickard, Richland Center; treasurer, H. Lathrop.

A committee to revise the Wisconsin State fair premium list was appointed as follows: N. E. France, F. Wilcox, and E. D. Ochsner.

The judge of the apiarian department of the State fair was named—N. E. France.

On motion, W. Z. Hutchinson was made an honorary member of the association.

An essay, entitled, "Honey—From the Hive to the Table," by George W. York, was valuable and instructive. It was followed by a long discussion on packages for extracted honey. As many Wisconsin extracted-honey producers have markets that use large quantities of honey, they use barrels; but the soakage and other troubles common to barrels found the 60-pound cans equally good.

A. G. Wilson then read a paper on "Barrels for Honey," and F. L. Murray read one on local associations.

The question-box being full, it was again opened with interest until noon.

At the afternoon session A. D. Barnes, of Waupaca Co., having a large nursery and small fruit farm, offered, free of charge for a term of years, a site for an apiary on his farm, so that his fruit would have the assistance of the bees in fertilizing the bloom.

Aug. Weiss had a large display of hives, smokers, and comb foundation on exhibition. There was also a fine display of the following bakings sweetened with honey, presented by the American Biscuit Company: Honey-jumbles, iced honey-jumbles, iced honey-cocoa jumbles, honey-fingers, iced honey-fingers, honey-cocoa fingers iced, honey-gems, iced honey-gems, iced honey-cocoa gems.

"Resolved, That contraction is better than expansion for spring management of bees," was discussed, H. Lathrop taking the affirmative, and Jacob Huffman the negative. Both debaters being old, experienced bee-keepers, and the large room full of practical bee-keepers to act as judges, all were well pleased with the debate. At the close the secretary presented the debaters with the above choice bakings, which they divided with the members.

Several cities offered special invitations for the next meeting of the association. On motion, the executive committee were authorized to say when and where the next meeting shall be held.

The convention then adjourned, *sine die*.

N. E. FRANCE, Sec.

[The various papers referred to in the above report will appear later.—EDITOR.]

Celluloid Bee-Button.—We have had made to order a very neat 7/8-inch celluloid button to pin on the coat-lapel. Upon it is the picture of a golden queen-bee, and around the edge these words: "Our toil doth sweeten others." It will especially please the boys and girls, and is a neat thing for members of bee-conventions to wear. It is a nice badge or emblem of the sweet industry in which bee-keepers are engaged. Prices, postpaid: One button, 8 cents; two or more, 5 cents each.

The American Fruit and Vegetable Journal is] just what its name indicates. Tells all about growing fruits and vegetables. It is a fine monthly, at 50 cents a year. We can mail you a free sample copy of it, if you ask for it. We club it with the American Bee Journal—both papers one year for \$1.10.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Bees that Swarm the Least, Etc.

1. Which race of bees are supposed or known to swarm the least?
2. What method is generally used by learned bee-keepers to prevent swarming?
3. Are there any better bees than the Italians for the production of comb honey?
4. Are the Adel bees superior to any others?

SUBSCRIBER.

ANSWERS.—1. There probably is not a very great difference, only Carniolans are supposed to swarm more than others. But it sometimes happens that a particular strain swarms less than others of the same race. The Dadants have bees so good in that respect that not more than three to five colonies in a hundred swarm, but they attribute it to their large hives. It is claimed that the Adels are little given to swarming.

2. The answer to that question is what they are all after, but a satisfactory one has not been given. Large hives, abundant ventilation, shade, etc., are among the things that help. The matter is easier when working for extracted honey, and some report entire success by putting all the brood in an upper story over an excluder at the beginning of the honey harvest, leaving the queen below with foundation or empty combs.

3. Very doubtful.

4. They are undoubtedly superior to some others, but are not generally supposed to be superior to all others.

Sweet Clover.

1. Would it pay me to sow sweet clover seed by the side of the road, where there is a dried-up spring? The ground is never dry here, and is about 10 rods from my bees. The ground is used for nothing, and is a heavy sod.
2. Will sweet clover grow if sown on the sod?

MICHIGAN.

ANSWERS.—1. It will probably pay big, as the expense for seed is trifling, and the land is of no value otherwise.

2. Yes, if you simply scatter the seed on the ground you will find a good many of them grow, and the second year the seed will fall and seed more. It will be well for you to sow two years in succession, for sweet clover is a biennial, and if you sow only one year you will have pasturage for your bees only alternate years for the first few years. The seed will catch much better if the ground after sowing is trodden down by cattle or horses, especially when it is a little wet. Perhaps there is enough travel along the sides of the road to tread in the seed.

Lack of Pollen May be the Cause of No Brood.

I had a weak colony of bees that had been queenless quite awhile, and I bought a queen for them. My bees are all hybrids, and the queen I bought was an Italian, and seemed to be a hustler last fall. It was a small colony and had few bees. I fed them granulated sugar syrup for winter stores, and they had their combs full of stores, and had the combs the bees covered, full of brood. I think it took nearly all the pollen they got to feed the young bees. They reared young bees all the while I was feeding, in the forepart of November. They came thru very nicely this winter, stronger than any of the rest of my bees, according to their size in the fall. When I looked at them one warm day last week there was no sign of brood or eggs, but the queen was alive and all right apparently. Now what I want

to ask, Is the cause of no brood the lack of pollen? If so, what is your opinion in regard to a substitute, that is, what is best to use? My other 10 colonies came thru in fair condition, with plenty of honey.

MICHIGAN.

ANSWER.—The absence of pollen is sufficient to account for the absence of brood. Very likely by this time the bees have gathered enough pollen to start brood-rearing. If not, you may be able to give frames of pollen from other hives; or, give them a feed of oats and corn ground together. Put it in a shallow box, say 6 inches deep. Put a stone under one end of the box so as to tip it up facing the sun; when the bees have dug it down level, turn the box end for end. When the fine portion is all taken out by the bees, the rest can be fed to four-legged stock. If more convenient, ground corn, bran, or Graham flour may be used. Set the box in the open air in a sunny place. A few drops of honey may be used to start the bees to work. If they get natural pollen, you can't get them to take the substitute.

Queens with Clipt Wings—Swarming.

I clipt my queens' wings early last spring, so as to be sure to get the first swarms. As I am not always at home I thought this to be a sure plan. I have since been told that queens did not do so well with clipt wings. What do you think about it?

PHOTOGRAPHER.

ANSWER.—So long as a queen stays in a hive, it doesn't make a particle of difference whether she is clipt or not. The difference comes when she attempts to go with a swarm. But clipping a queen is far from making sure that bees will not leave if they have no attention. If the queen is clipt the swarm will return, but in 8 or 10 days a young queen will come out with the swarm, and will be more likely to take French leave than an *old* queen with wings.

Those Divisible Brood-Chamber Box-Hives.

I was very much interested in Mr. Davenport's article on page 179, as I have just made 9 hives for an experiment that almost coincide with his. My top-bars are 1¼ inches wide. They make lath here 1½ inches, and that would leave a bee-space and give 1½ inches between centers, if I figure correctly. I had intended to put in inch starters, but I don't see why full width could not be used with little danger, the same as in frames not wired. Do you think drone-comb would be apt to be a factor if starters were used? I was much pleased to note that the bees did not fasten the combs to the box below when the hives were tiered, for that was what seemed natural to me to expect.

PENN.

ANSWER.—Mr. Davenport no doubt gets lath the same width as you, but of course planes them down to the right width.

It is quite possible that foundation full depth might be used, especially if the foundation is heavy or of such character as to stretch little. Drone-comb will undoubtedly be a factor if starters only are used. Yet you can accomplish a good deal by management. A swarm newly hived builds mostly worker-comb for the first 10 days or more. Give one of these shallow stories to a swarm, and it would be nearly or quite filled with comb before drone-comb would be commenced. Then a second story could be given with combs fully built.

Renewing Brood-Combs, Cleaning Supers, Etc.

1. How often do you change the frames in the brood-chamber, or do the bees, while strong, keep it clean? We have a few bees, and I can not find anything about this question in my paper or books.

2. Please tell a good way to clean bee-glue from supers. I am using salsoda and hot water. With a knife I scrape them all clean. I am cleaning 6 old hives and 9 supers. It takes time, but they look nice afterward.

OREGON.

ANSWERS.—1. In this country bee-keepers do not renew the brood-combs, no matter how old. Some of mine are 30 years old and older, and for aught I know are good for another 30 years. The bees do all that is necessary toward keeping them clean.

2. For cleaning bee-glue from anything of tin, such as T tins, probably nothing is better than to put them in a hot solution of concentrated lye. I have tried the same thing on wood, but it is not so satisfactory. I simply use a com-

mon hatchet, scraping back and forth with a sidewise motion. No washing of any kind is needed. You will probably find that you can scrape a super in much less time with a hatchet than with a knife.

A Queen Question.

A queen was killed and brought out of the hive March 25 by the bees. The hive was examined the 26th and I found two queen-cells about half finished, with larvae about 3 or 4 days old. There is brood in all stages in the hive from 2 to 3 days old to hatching out. What I want to know is, will this colony come out all right this time of the year with the young queen it is rearing, or should the colony have an old queen? There are no eggs in the hive.

TENNESSEE.

ANSWER.—The main question is whether the young queen will be fertilized. As far south as Tennessee the chances ought to be fair, especially if the season be early. As a matter of precaution it may be well to give the colony young brood 2 or 3 weeks after the date of the death of the queen.

Basswood—Introducing New Blood—Anti-Swarming Management.

1. I have in my pasture about 20 acres of brushland unfit for cultivation, which I want to clear and leave the basswood for the bees. The trees stand in bunches from 5 to 15 in a bunch, and are about 30 feet high. How many would you leave in a bunch? I intend to leave nothing but the basswood.

2. How often would you advise introducing new blood in an apiary when your neighbor bee-keepers neglect the same?

3. Would there be any swarming from an 8-frame, 2-story hive run for extracted honey with a queen-excluder and 3 stories added at the beginning of the honey-flow, and a fourth story added if needed?

I am thinking of starting an out-yard and running it in that way, and can be there but once a week.

WIS.

ANSWERS.—1. It depends on how far apart the trees are. Probably 30 feet apart will be a good distance for trees of that height.

2. If your neighbors have bees in all directions about you, there is less need to introduce fresh blood to avoid in-and-in breeding than if your apiary contained the only bees within 10 miles. But if you are trying to keep Italian blood in your apiary, and black bees are all about you, a fresh Italian queen every 2 or 3 years would be a good thing.

3. You would probably have very little or no swarming if a large entrance is open to each story. You might make the matter still more sure by putting all the brood above the excluder at the beginning of the honey-flow, leaving the queen below. This is on the supposition that you work for extracted honey.

Clipping Queens and Their Swarms.

I have 15 colonies of bees, and I wish to run for comb honey especially. I have 12 hives, just purchast, to receive the swarms the coming season.

1. Would you advise me to clip all of my queens' wings? If so, during what part of which month?

2. Does this clipt-wing queen then issue with the first swarm next season?

I am not physically able to climb trees, etc., after swarms. My hives are roomy and very well shaded, and bees mostly Italians.

VIRGINIA.

ANSWERS.—1. Most assuredly, I think it advisable for you to have all laying queens clipt. Then when a swarm issues, instead of having to get it off a tree, here's what you have to do: Watch for, find, and cage the queen. Set the hive to one side and put in its place the hive for the reception of the swarm, putting at or in the entrance of this hive the caged queen. When the swarm returns and is entering the hive, or after it has entered, let the queen run into the hive. Clip queens during any part of any month when it is warm enough for bees to fly freely. The main point with you is to get them clipt before swarming-time.

2. The queens that you will clip, that is, the ones that are now in the hives, are the ones that will issue with swarms this summer.

VOL. 40.

APRIL 12, 1900.

NO. 15.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

What is the Character of the Cyprians?—Editor Hill speaks of an attempt to revive interest in Cyprian bees, his advice being, "Let Cyprians alone." He says:

"We are aware that the Cyprian is regarded with some favor by as high an authority as Frank Benton; but even he assents to the fact that they use their stings with great energy when thoroly aroused. It is our experience that they will do so at all times, and that they appear to be thoroly aroused whether molested or not. The Cyprian will go farther out of its way in search of some poor, inoffensive creature to sting than any bee we know of.

"To those who are fortunately free from Cyprian venom in their apiaries, we would say: Have a care how you experiment with a race whose maliciousness and irritability has called down upon it the condemnation of nearly every one with whom it has come in contact."

On the other hand, M. G. Dervishian gives a clean bill of health for their tempers, in the British Bee Journal, saying they are more gentle than Italians, he himself handling them without veil or smoke. He says Mr. Cowan is in error when he says some Cyprians are gentle and others very vicious, and accounts for it by saying that Syrians are vicious and vindictive, and that many Syrians were sold in America and England for Cyprians. "Indeed, Syrians were often inadvertently kept in the same apiary along with Cyprians, and were often supplied instead of the latter kind to customers. Unfortunately the bees of these two

species are so nearly alike that in outward appearances no one could possibly detect any difference between them."

Mr. Dervishian's residence in the island of Cyprus gives him an opportunity of familiarity with the subject, but if he makes a business of selling Cyprian queens he may not be entirely disinterested.

Ripening Honey.—G. R. Harrison says in the Australian Bee-Bulletin:

"Mr. Doolittle points out, and has been pointing it out for long enough, and the average bee-keeper tells you he knows it if you mention it—that the honey in the combs is as ripe the morning after it is gathered as it ever will be, and very often much riper."

Yet on page 194 of this journal Mr. Doolittle advises, if you must ripen honey out of the hive, to keep it in a temperature of 90 to 100 degrees for a month or six weeks. Why should this be necessary, if each morning the honey is as ripe as it ever will be? Perhaps Mr. Doolittle will throw some light on the subject.

A New Hive-Cover.—Not that one has been made, but one is asked for in the Progressive Bee-keeper by Dr. Miller. The "Higginsville" is a good cover, and it was a great improvement upon it to have the ridge-piece channeled, and the shoulders of the two side-pieces projecting up into it, so that water could only enter by running up hill; but there is still need of a cover that can not twist so as not to fit down close, and to have an air-space in it so as to make it warmer for winter and cooler for summer. He thinks this might be accomplished in this way:

"Take a Higginsville, perhaps a little lighter than usual, and have under it another surface $\frac{3}{8}$ thick or less, with a $\frac{3}{8}$ air-space between, having the grain of the under surface run crosswise, the cover fitting entirely flat upon the hive with no cleat at the end projecting downward."

A \$1,000 Bee (Model).—Mr. Geo. H. Stipp, of California, sent us some time ago a clipping from the San Francisco Examiner, showing pictures of a mammoth honey-bee model that can be taken apart and put together again. The description reads as follows:

A great wooden model or manikin of a honey-bee, one million times larger than the bee itself, is one of the latest pieces of scientific paraphernalia which now furnishes the new building of the Agricultural Department of the University of California. This immense construction is the only one of the kind in the United States, and was made especially for the University, in Paris, France. Its cost was \$1,000.

It is four feet four inches long, the wings are two feet ten inches long, the head is twelve inches broad, the thorax one foot ten inches long, the abdomen is two feet five inches long, and one foot five inches across; the third, or longest hind leg, is two feet five inches long, and the tentacles are ten inches long.

The dummy insect is complete in every respect; every gland, orifice or scale upon it is presented. It can be taken apart, and so breaks up into 16 pieces. The legs, the wings and head come off, but the most interesting part of it is the internal arrangements, revealed by removing the caps or tops of the several departments of the bee. The top of the head comes off, revealing the brain and the air-cushions surrounding it. Then the top of the thorax is removed, and you may take out one of the strong, red, deflector muscles, looking like the pile of fibers which they really are. These are the muscles which lift the wings of the bee.

Farther back the top of the abdomen comes off, exposing the stomach, intestines and entire digestive apparatus, which also comes out as a separate part. Every vein, duct and sac is detailed in the woodwork, each part being painted the color that it bears in nature.

Prof. Woodworth, who lectures on the honey-bee, states that he finds the model more useful for laboratory work than for any service. When any point comes up about the anatomy of an insect, reference is had to the manikin, and illustration is at once made. This may occur a dozen times

a day. The points arising may not always concern honey-bees, but as all insects are much alike, any point could be explained by referring to the bee, which is the most fully developed and perfect of insects. The superiority of the manikin over printed plates or maps is described by Prof. Woodworth, who remarks that "it makes the difference between seeing a man and seeing his photograph."

The International Apicultural Congress at Paris.—

This office is in receipt of an invitation to attend the Congress to be held Sept. 10, 11, 12, 1900. The membership fee is \$2.00. M. de Heredia is president of the committee of organization, and M. Caillas secretary.

The program looks strange to American eyes, being divided into seven sections, with a different president and secretary for each section, as follows:

FIRST SECTION.—APICULTURE PROPER.

- Advantages of bee-culture to agriculture.
- Fecundation of flowers by the bees.
- Quest of proper means to favor the sale and disposition of direct and indirect products of the hive.
- Influence of soil, climate, and altitude upon the production of nectar.
- Means proper to fill vacancies in the supply of nectar in a given country.
- Culture of bees for selection and sale of swarms.
- Culture of bees for the sale of their products.
- Investigations upon swarming.
- Advantages and disadvantages of feeding bees.
- Means necessary to make the manufacture of hydromel a rural industry.
- Study of ferments.

SECOND SECTION.—ANATOMY AND PHYSIOLOGY OF THE BEE.

- Secretion of wax.
- Influence of the length of bees' tongues in gathering honey.
- Parthenogenesis.
- Role of drones in the hive.

THIRD SECTION.—APICULTURAL TECHNOLOGY.

- Hive and frames from an international point of view.
- Advantages and disadvantages of the large frame—of the small frame.
- Comparative study of different hives.
- Which is better, the warm or cold system of frames?
- Remarks upon wintering; ventilation.

FOURTH SECTION.—APICULTURAL INSTRUCTION.

- Instruction in bee-keeping by professors of agriculture and teachers.
- Means to be employed to popularize bee-keeping, thereby bettering the lot of the workman and small farmer.
- Apicultural publications.

FIFTH SECTION.—DISEASES OF BEES; PARASITES.

- Foul brood—its ravages, diagnosis, prevention, cure.
- Bee-moth—prevention, destruction.
- May sickness—does it exist everywhere? diagnosis, causes, treatment.
- Diarrhea—prevention, cure.
- Parasites of bees—description, harm they do, means for their destruction.

SIXTH SECTION.—APICULTURAL JURISPRUDENCE.

- Legislation regulating the location of apiaries in different countries.
- Legislation regarding adulteration of honey, wax, and their derivatives.

SEVENTH SECTION.—APICULTURAL STATISTICS.

- State of apiculture in different countries (hives, honey, wax, derived products).
- Association of the apicultural press and members of the conference, in view of the general and rapid dissemination of discoveries and documents apicultural.

Dr. Miller's Honey-Queens are offered as premiums, on another page, for sending us new subscribers to the American Bee Journal. The offer is limited to our present regular subscribers, and the queens are to be mailed in rotation, beginning about June 1st, so first come first served. Look up a new subscriber, send in his name with \$1.00, and we will enter your order for a Dr. Miller Honey-Queen.

SUCCESS is the name of one of the very best monthly periodicals devoted to young people who desire to make an honored name and fame for themselves in this life. Its moral tone is of the highest, too. We wish it might be in the home of every one of our readers. Its subscription price is \$1.00 a year (easily worth \$10). We will club it with the American Bee Journal—both papers for one year for \$1.75.

THE 1899 EDITION of the "A B C of Bee-Culture" is about exhausted, we learn, and any one expecting to order will do well to wait for the 1900 edition, which is under way. It is being thoroly revised again this year, and a great deal of pains will be taken with the whole book. It is likely to be Sept. 1st, or later, before the new book will be ready, but orders may be entered at any time for the new edition, to be sent as soon as ready. We still have a few of the 1899 edition left, which we will use in filling orders, unless we are requested to hold the order until next fall for the 1900 edition.

MR. S. A. NIVER, of Tompkins Co., N. Y., recently address the high school at Olean, N. Y., on "Bees, their Culture, Habits and Peculiarities." He talkt for about 45 minutes, and of course amazed his hearers with the mysteries of the hive. Later on he had to repeat the talk before a gathering of some 60 teachers. It wouldn't be a bad idea if the National Bee-Keepers' Association would arrange to have some leading bee-keeper and interesting speaker spend some time each year visiting the schools in cities and lecturing on bees and bee-keeping. It would be helpful to the scholars, and might help to extend the demand for honey. Rev. E. T. Abbott, of Missouri, would be a good man to start out on such a mission. He enjoys talking, and we have never yet failed to see him interest his audience—provided he didn't "preach" too long.

SOMNAMBULIST, the "delightful dreamer" of the Progressive Bee-Keeper, whose dreams are nowadays based upon the good things to be found in other bee-periodicals does considerable browsing in the pages of the American Bee Journal, introducing his "finds" by words so kindly, and withal so brightly, spoken, that even at the risk of endangering the editor's hatband, they must find a place here, and are as follows:

"Another bee-keeping sheet bearing upon its title-page the sweepingly comprehensive inscription, American Bee Journal, may be confidently expected to call once a week, and because of this, along with many other reasons, it has honestly earned the now quite familiar cognomen, the 'Old Reliable.'

"I sometimes wonder if in these days of wagging of tongues on the subjects of imperialism and expansion, just according to which of the two great political parties the speaker belongs, ye editor's heart swells with befitting pride as he finds his rightful territory extending into what was formerly foreign islands of the sea. How's this, Bro. Y.? Loose apparel getting tight-fitting? Hatband still sound? At any rate I am convinced, inasmuch as the spirit of reaching out has so far developed as to become dominant, Editor York will not be left out in the cold, but will be found right in the crowd, reaching out for all he can catch, with which to serve the readers of the American Bee Journal. I came near putting it A. B. J., but didn't we catch it for thus abbreviating only a short time ago? Presume he did not want his paper called a bee-jay, as that kind of a bird is one of the worst known enemies to bees. They will dart down and pick a bee from the alighting-board as deftly and surely as a sharp-shooter does his man. Can one condemn them? They know a toothsome or sweet morsel on sight, and are governed by the laws of self-preservation, just as ye editor knows relishable and appreciable articles, and hustles around to secure them with which to maintain life in his journal."

Age at Fecundation.—In *Bienen-Vater* are given dates for 30 queens. One was fertilized at 4 days after leaving the cell; 2 at 4½ days; 4 at 5; 10 at 6; 8 at 7; 3 at 8; and 2 at 9.

Parsley Angers Bees is the report in *L'Apiculteur*. When any of the family plucks parsley for culinary purposes, very often a bee or two resented it, and when a bee had gone to seed and was pulled up, the bees became so furious that there was fear of trouble with the neighbors.

Honey and Horehound Cough-Drops.—Put a handful of horehound into a saucepan, cover it with water, and boil until the liquor is strong. Then strain and add honey to it, boil until the water has evaporated, test it like other sweets, and when sufficiently boiled pour into shallow pans to cool. Then cut up into pieces.—*British Bee Journal*.

To Kill Worms in Combs, the following is given in the *American Bee-Keeper*:

"Place an empty brood-chamber on top of a stack of combs, and therein a dish with a little bisulphide of carbon, then cover up tight; the liquid will transform into gas and kill everything living within the stack of hives."

To Get Much Honey and No Increase, the following is recommended in *Machrische Biene*: Give combs of ripe brood to the strongest colony or colonies; when the young bees hatch, take away all brood, leaving the colony in the condition of a swarm. The brood removed will in turn strengthen other colonies, and the process be continued.

Uniting a Swarm with a Nucleus.—Speaking of the difference of opinion between Mr. Doolittle and Dr. Miller about uniting a swarm with a nucleus, Editor Pender, of the *Australian Bee-Bulletin*, agrees with Mr. Doolittle, and indeed goes still farther by saying: "In all cases where I have tried uniting a swarm with anything but a swarm it has been a failure."

Traveling Bees Need a Queen or Brood, according to Editor Pender. He says:

"When shipped without a queen, unless the distance is short, say under 48 hours, we always send some brood with them. Bees do not travel well any distance unless they have a queen or some unsealed brood, and we would not care to risk it over 48 hours."

Honey-Soap.—Take one pound of best soap, cut it up into thin slices, and put it into a double saucepan and melt. Add two ounces of honey and two ounces of palm-oil, stir it well and boil ten minutes. Then pour into molds. A few drops of oil of cinnamon or oil of cloves may be added to perfume it. A good soap can be made by omitting the oil and using more honey.—*British Bee Journal*.

Effect of Locality on Bee-Moths.—Coloradoans claim they have no bee-moths. Mentioning this, Editor Hill, of the *American Bee-Keeper*, says:

"By way of contrast, we might say in this connection that in South Florida combs that are left in the extracting-room over night are very apt to show webs in the morning, and if left would be completely ruined within a week."

Prevention of Swarming.—C. Davenport says in the *Bee-Keepers' Review* that he thinks more extracted honey, as well as more comb, can be got in the white honey harvest if the queen be confined to one story, but it is likely to induce swarming. If the queen be allowed the free range of three or four stories, the brood will be scattered, making more frames to be handled to extract a given amount of honey, and in the fall there is trouble reducing all to one story; but there is the saving clause that he has never had a colony try to swarm when the queen had the free range of three or four stories. He thinks, however, that this may be partly attributable to the fact that this locality is slightly overstocked.

Thoro Ripening of Honey.—Those Britishers know a thing or two about getting honey in shape to take prizes. Says a writer in the *Bee-Keepers' Record*:

"You extract your honey, you strain it. You fill a bottle and are delighted with its color. You taste it; it is delicious! If you are inexperienced, you think you have nothing else to do but send it to the show and secure a prize. But no, honey for prize-winning is not so easily produced, or prepared for the show-bench in such a rough-and-ready manner. No matter how well 'capt-over' the combs may be, there are a few necessary tedious operations to perform before we may say our honey is 'in condition.' Even if, as I said, your honey is thoroly sealed, a few days standing in a warm place—by the kitchen grate for instance—in the 'ripeners' has a wonderful effect, enhancing not only its flavor, but principally its consistency. And where partly unsealed combs have been extracted, it is doubly important that this ripening process have due attention. In such cases a week at least ought to be given to ripening."

Length of Tongue of *Apis Dorsata*.—Editor Root, of *Gleanings in Bee-Culture*, sent seven specimens of *Apis dorsata* to Prof. B. F. Koons to have their tongues measured. The length of tongue, given in thousandths of an inch, varied from .170 to .240, the average being .195. He then measured the tongues of 12 Italian bees, which varied from .199 to .232, the average being .220. Just as that reads, it doesn't say much for *dorsata*. Its opponents, however, can take a little comfort from these measurements when it is known that the *dorsata* were specimens in alcohol, and the Italians were fresh. Prof. Koons says he does not consider the measurements reliable, as alcohol is a *drier*, and might materially affect the length. Indeed, the testimony is on the side of the big bees, for one of them showed a longer tongue, even after being in alcohol, than any tongue of the Italians, and it is quite possible all were much longer before being put in alcohol.

White Cappings for Best Price.—G. M. Doolittle says in the *Progressive Bee-Keeper*:

"What I believe is, that after the sections are filled with a nice white comb of honey, the sections are rarely looked at, either by the producer or the consumer, but it is the beautiful comb honey that is looked at ever afterward, and it is for this reason that Doolittle has been advocating taking off the honey while the combs are snow white, all these years, rather than "white sections" as Mr. Aikin imputes to me. I don't guess at the matter; I know that snow-white combs will sell both in the New York and Boston market at from 2 to 3 cents per pound above those left on the hives until they are colored, each having the same quality of honey, and an experience as to the selling price of the two during the past 15 years, is the reason of that 'know.'"

Do Bees Made Queenless Prefer Too-Old Larvæ for Queen-Rearing? is a question taking up some space in the *Bee-Keepers' Review*. Hon. R. L. Taylor thinks the experiment made by Dr. Miller is not satisfactory, altho admitting the claim of the latter that, "there is no positive proof that during the first five days any larvæ more than three days old was chosen, and there is positive proof that 17 larvæ under three days old were chosen." If this were the only experiment that could be made, it might be worth while to keep up the discussion, but would it not be the part of wisdom to let it go and institute fresh experiments that would be satisfactory to both? The question is one of some importance, and ought to be settled.

Each Should Improve His Stock.—Here are some words of wisdom from W. H. Pridgen in the *American Bee-Keeper*, that will bear a second reading:

"Permanent improvements come slowly, being the results of persistent efforts and the ability to make wise selections, which each bee-keeper should be able to do, as well as being sufficiently skilled in queen-rearing to perpetuate the desirable qualities of faithful old mothers ready to pass off the stage of action."

"**Shall We Adopt the Tall Sections?**" is asked by J. H. Martin in the *Bee-Keepers' Review*, and in answering the question he thinks it not well to be too much expense in changing. He makes one point that is worth considering. Accounts are given that tall sections bring better prices by comparison with square ones. Now suppose all change to tall. Will the price of honey then be any greater than if all had remained square?

Root's Column

What They Say. WHO?

Some of the largest producers of extracted honey in the United States.

From the Bee-Keepers' Review, January, 1900.
"The extractor we use is the Cowan reversible."

Miss Ada L. Pickard, Richland Centre, Wis.

Miss Pickard produced 16,000 pounds in 1898, so she should be a good judge.

From the March Bee-Keepers' Review.

"I expect to purchase another machine; for I want the extractor always at hand ready for use. Speaking of extractors, I would not trade my two-frame Cowan machine, as made by the A. I. Root Co., for any four-frame machine I ever saw. They work so easily, and I think one person can extract with them as rapidly as another can uncap the combs."

Harry Lathrop, Browntown, Wis.

If Mr. Lathrop had tried one of our 1900 pattern, four or six frame

BALL BEARING

machines he, perhaps, would think differently. However, we recommend the two-frame Cowan Extractor unless one has a very large amount to extract. In that case do not fail to investigate our larger sizes.

Another feature found on the large sizes is the

BAND BRAKE.

These machines are built for two, four, or six frames of any size, and the regular sizes may be had of the following dealers:

- J. M. Jenkins, Wetumpka, Elmore Co., Ala.
- M. R. Madary, Fresno, Calif.
- The Union Hive & Box Co., Los Angeles, Calif.
- The L. A. Watkins Mds. Co., Denver, Colo.
- Geo. W. York & Co., 118 Mich. St., Chicago, Ill.
- Walter S. Ponder, 512 Mass. Ave., Indianapolis, Indiana.
- Jos. Nysewander, Des Moines, Iowa.
- Carl F. Buck, Augusta, Butler Co., Kan.
- Rawlings Implement Co., Baltimore, Md.
- M. H. Hunt & Son, Bell Branch, Wayne Co., Michigan.
- Geo. E. Hilton, Fremont, Newaygo Co., Mich.
- John Nebel & Son, High Hill, Montgomery Co., Missouri.
- C. H. W. Weber, 2146 Central Ave., Cincinnati, O.
- Buell Lamberson, 180 Front St., Portland, Oreg.
- J. H. Back & Son, 235 W. 3rd North Street, Salt Lake City, Utah.
- The A. I. Root Co., 1024 Miss St., St. Paul, Minn.
- The A. I. Root Co., Mechanic Falls, Maine.
- The A. I. Root Co., 10 Vine St., Philadelphia, Pa.
- The A. I. Root Co., Syracuse, N. Y., or
- THE A. I. ROOT CO., MEDINA, OHIO.

Our extractors are also kept by many other dealers in bee-keepers' supplies. If you want to be sure of getting our extractor, be sure to say "Root's Cowan Reversible Extractor" if you order of any other dealer than those named above.

**The A. I. Root Co.,
MEDINA, OHIO.**

GENERAL ITEMS

Never Wintered Better.

Last year winter kept up till June 6, in fact we had no spring weather at all, but we now have had four weeks of continuous fine weather, and some of our people are beginning to get alarmed for fear we may have a drouth; but we can stand it several weeks longer, and then we can fall back on irrigation; but the spring rains are very necessary in some parts of the State. The bees never wintered better than this year, but the poisonous smelter-smoke has killed them in some parts of Salt Lake County by the wholesale. It is a very serious matter, and to fight it would be like running up against a stone wall, because we would have to fight millionaires.

E. S. LOVESY.

Salt Lake Co., Utah, March 29.

Bees Wintering Well.

I have 40 colonies of bees in my house-cellar, all doing well. I am a farmer, and if I live until next harvest, and do not forget, I will send Mr. Dant some wheat and cheat, or chess, as we call it here, to show that cheat grows from wheat, both on the same root.

L. STAHOSKI.

Trempealeau Co., Wis., March 20.

The New Bee-Disease.

I would like to relate some of my experience and cure for the above trouble, for the past 15 years.

Some 12 years ago I was much annoyed with old bees coming out in mid-summer and crawling and hopping about, shiny and unable to fly; also some dead brood much like we had last summer. I fed some beta naphthol, and for many years we never had a single colony affected.

I often thought the bees lookt much healthier for 2 years after. However, last year it was 10 times worse than ever. (We had no old shiny bees dying off, remember, and no dead brood on my first round when clipping queens.) But after the first hatch of brood it seemed to appear almost at once in perhaps 50 hives, some with only 5 or 6 dead larvae. Starving is no good with me. I tried it twice on one colony and failed. I never put in such a summer in my 20 years with bees for a business—culling out brood with a pen-knife and melting combs. There is positively no smell or ropiness.

This letter is written for Mr. P. W. Stahlman, of New York State, out of sympathy, and I am satisfied it can be cured for one cent per hive or colony. Of course, I will have to fall out with all who believe in no drugs. However, no man living dare stand up and say drugs have no effect. It is the careful, jealous hand they are given with that is half the battle. I fed beta naphthol last fall with winter stores so that it would be stored in every cell in the brood-chamber, after all brood was hatched out, and if it does not lose its

INCUBATOR SATISFACTION.

That is what we sell. We don't want your money if we can't satisfy you with the new **NONE BETTER INCUBATOR.**

The None Better is the simplest, most economical, the most durable and the lowest priced incubator made. Only best material used. Don't buy until you have examined our catalogue. Sent for 2c stamp. Hawkeye Incubator Co., Box A, Newton, Ia. Please mention Bee Journal when writing.

virtue every larva will get some, perhaps, in the spring.

I expect to use beta naphthol this spring if the bees are idle. It must be cut with alcohol, about 1/2 pint of alcohol to 2 ounces of naphthol. I then stir it into 4 pounds of hot honey. It will positively have nothing to do with sugar syrup. I feed from 1/2 to one tablespoonful in each gallon of feed. I hope Mr. Thos. Cowan, of California, will say whether the above is any where near the right proportions.

Now, Mr. Stahlman, don't you think that transferring so many colonies and throwing them out of nurse-bees (which feed the larvæ) had a good deal to do with your trouble? (See page 204.)

I think the above disease points to a lack of nurse-bees, just in the heaviest breeding season.

My bees have been confined for 110 days now without a flight; however, I have no fears whatever.

CHARLES MITCHELL, Ontario, Canada, April 20.

Bees Wintering Well.

I put 24 colonies into winter quarters packt 6 to 10 inches apart with straw in between and behind, in a shed open to the south, with a Hill's device of my own make, with super on filled with cushions and old clothes, etc. I let the sun shine full on them. Unless we have the bees where no frost accumulates in the hive, let them have the sun; we won't lose many bees that are worth anything, by flying out. Don't pack too much, and let them have the sun to warm up and dry them out. My bees are wintering well.

NOAH MILLER, Iowa Co., Iowa, March 30.

Wintered Nicely.

I put out part of my bees this morning. They seem to have wintered nicely. E. S. MILES, Crawford Co., Neb., March 22.

Wintering Fairly Well.

My bees are wintering finely so far. I put into winter quarters 37 colonies, and they are all alive yet, and seem to be nearly as strong as they were last fall. I use the Champion winter-case and pack with oat chaff.

H. C. CLYMER, Linn Co., Iowa, March 20.

Stimulating Brood-Rearing—Stopping Robbing—Bee-Sting Remedy.

Last season was a poor one; I believe I was the only one in my neighborhood to get any surplus honey, and I did fairly well for these parts. My bees are in better shape this spring than ever before—I have not lost a colony.

Mr. Aikin, in a recent number of the Bee Journal, advises turning brood-combs end for end to stimulate brood-rearing. What's the matter with turning the brood-chamber on the bottom-board? I have done this a good many times, and always thought it beneficial, but I make no claim to being an expert, and have made no very particular experiments, but I cannot see why my plan is not just as good as Mr. Aikin's, and is a great deal less trouble;

SEED DUE BILL FREE

To get new customers to test my Seeds, I will mail my 1900 Catalogue, filled with more bargains than ever and a 10c Due Bill good for 10c worth of Seeds for trial absolutely free. All the Best Seeds, Bulbs, Plants, Roses, Farm Seeds, Potatoes, etc., at lowest prices. Nine Great Novelties offered without names. I will pay \$50. FOR A NAME for each. Many other novelties offered, including Gladioli, the great money making plant. Over 20 varieties shown in colors. \$1100 in cash premiums offered. but if there are many colonies, look out for robbing.

I have stopt the worst cases of robbing I ever saw with a spray-pump and cold water, in a few minutes; but don't spare the water—give every colony that shows any excitement a good soaking at the entrance.

Last season I used spirits of turpentine as a remedy for bee-stings (external application) on a number of persons besides myself, and even little children; it gave immediate relief in every case, seeming to neutralize the effects of the poison, and not leaving the least sign of swelling.

W. H. LEWIS.
British Columbia, Canada, Mar. 19.

No Loss in Wintering.

I put my bees out of the cellar March 25. I had put in 32 colonies, and carried out 32. To-day was a fine day, and they were just booming.

FRANK E. KNAPP.
Wadena Co., Minn., March 30.

How I Came to Be a Bee-Keeper.

About 13 years ago I was sick and miserable. In my neighborhood lived an old man, a bee-keeper by the name of Solomon Whitaker, and from him I took my first lessons in bee-keeping. He told me if I would get interested in bees that it would divert my mind from my sickness. He gave me a hive, and told me to put it up in a big tree down in his woods, which I did. I soon had the bee-fever, and had it hard, too.

In a few days I saw bees flying in and out of my hive. Supposing of course I had caught a swarm, I slipped up that tree very still, corked up the entrance, and let the hive to the ground with a rope. I took the hive home on my shoulder, with the fever running at its highest pitch. And oh, how disappointed I was the next morning, when I found I had only about a dozen bees ("tree-hunters" I afterwards found out). I then bought a colony from the old man, for which I paid \$4.

My attention was then turned toward hive-making. For tools I used a buck-saw and butcher-knife. Oh, weren't those hives and fixtures things of beauty! Some were tall, some square, and some long ones. The frames were from 6 inches, to 18 inches deep; the spacing from an extra tight fit to three or four inches; the end-bars were made of lath, and most of them were put in edgewise; but they had the desired effect, for my health returned, and I think those were the happiest days of my life, for I loved those bees, and I haven't gotten entirely over it yet. I once heard a man say that "after woman he loved a horse next best;" with me it is bees next best, for how I love to hear their happy hum among the apple-blossoms.

I borrowed "Langstroth on the Honey-Bee" of Warren Longsdon, an old schoolmate, and at that time the leading bee-keeper of this part of the country; and from that book my eyes were first opened to the mysteries and scientific principles of bee-keeping.

I advise all beginners to buy their hives and fixtures, for it is next to impossible to make them right by hand. Also, to get a good text-book, say "Langstroth Revised," by Dadant, or "A B C of Bee-Culture," by A. I.

PROFIT FOR MAKER ONLY

We manufacture 178 styles of vehicles and 65 styles of harness and sell them to you direct from our factory at wholesale prices. In fact, we are the largest manufacturers of vehicles and harness in the world selling to the consumer exclusively. When you buy on this plan you pay only the profit of the manufacturer. No traveling expenses, no losses, no agent's commission and no dealer's profits.

WE HAVE NO AGENTS preferring to deal with you direct. We have followed this plan for 27 years. No matter where you live, we can reach you and save you money. We ship our vehicles and harness anywhere for examination and guarantee safe arrival. We manufacture everything we sell, and we can assure you of good quality from beginning to end; good wood work, good iron work, good finish, good trimmings, fine style and the largest selection in the land. Large illustrated catalogue FREE.

ELKHART CARRIAGE & HARNESS MANUFACTURING CO., Elkhart, Ind.

No. 717—Canopy-Top Surrey, with double fenders. Price, complete, with curtains all around, storm apron, sunshade, lamps and pole or shafts, \$75; just as good as sells for \$40 more.

Please mention Bee Journal when writing.

DR. MILLER'S
Honey Queens

One Untested Queen Free as a Premium for sending ONE New Subscriber to the American Bee Journal for one year.

SEASON OF 1900. These Queens will be mailed in rotation, beginning about June 1, so "first come first served." We are ready to book orders now.

The Queens Dr. Miller will send out on our orders will be precisely the same as those he rears for his own use, so of course they will be from his best stock. His best colony in 1899 had a queen reared in 1898; May 5, 1899, it had brood in 4 frames, and he gave it at that time a frame of brood without bees. It had no other help, but May 25 a frame of brood with adhering bees was taken from it, and the same thing was repeated June 3, leaving it at that time 5 frames of brood. It stored 178 sections of honey, weighing 159 pounds (and that after July 20, in a poor season), being 2 3/4 times the average yield of all his colonies. A point of importance is the fact this colony did not swarm, and an inspection every week or 10 days showed that at no time during the entire season was there even so much as an egg in a queen-cell. Dr. Miller expects to rear queens from this one during the coming summer.

The demand nowadays is for **BEEES THAT GET THE HONEY** when there is any to get, and Dr. Miller has such bees. You will want to have a queen from his best, we are sure.

Do not send any orders to Dr. Miller, as all orders **MUST** come thru us, according to our agreement.

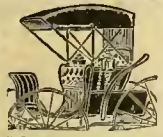

Remember, send us \$1.00 for **ONE NEW SUBSCRIBER** to the American Bee Journal for one year, and **YOU** will get **ONE OF DR. MILLER'S UNTESTED HONEY-QUEENS FREE AS A PREMIUM.** This offer is made *only* to our present regular subscribers. Orders for queens to be filled in rotation, beginning about June 1st.

Address all orders to **GEORGE W. YORK & CO.,**
118 Michigan Street, CHICAGO, ILL.

BUGGIES, Surreys, Stanhopes, Phaetons, Driving Wagons and Spring Wagons, Light and Heavy Harness, Sold Direct to the User by the Maker at Wholesale Prices.

Perfect in every detail of material, workmanship and finish. Any style vehicle sent anywhere for examination before purchase. Wherever you live you can buy of us and **save money.** We make all the vehicles we advertise. Large free book tells our plan in detail. Send for it.

Root, and subscribe for the American Bee Journal, and you will be on the right road to successful bee-keeping.

I now use the Dadant hive, and run for extracted honey, and have made it pay in dollars and cents. To use Mr. Dadant's words, you must know what to do, and do it in time. One spring I work my bees up so strong in numbers that by the last of May the hives fairly boiled with bees. I went away to work for a week, supposing the bees were getting plenty to live on from the fields; when I came home I found them in a fearful condition—the alighting-boards covered with the brood they had thrown out, the young, white-looking bees crawling all over the hives, and the grass in front full of them, some in bundles the size of walnuts. I pondered a long time to know what ailed my bees, but I couldn't make it out. I went to "Langstroth Revised," and I soon found out. I had a case of starvation. I then opened the hives, and there was not a particle of brood, not even an egg, or a drop of honey. I gave them all a good feed of sugar syrup, and in four days the blossoms were dripping with nectar. As strange as it may seem my crop averaged 50 pounds per colony that season.

Once had nearly a whole colony of bees inside of my pantaloons. Yes, sir, inside my trousers. My movements at that time were exceedingly quick, or rapid. My gesticulations were convincing, and with lightning rapidity. I think if the President had been there, yes, and the Mrs., too, I should have disrobed just as I did.

Ogle Co., Ill. BYRON WHITNEY.

Bees in Florida.

Bees have been holding high carnival of late, for fruit-trees and the ti-ti are blooming. Pears, peaches, plums, and dewberries are loaded with bloom, apparently no room for another blossom. I counted 45 blossoms in one cluster. Orange trees are not blooming, for their leaves were killed by frost; the wood was not injured, and some trees are leaving out to their very tips. Lemon trees are more tender and are killed to the ground.

Summer drouths are the "winters of discontent" to bee-keepers here, for many colonies perish by starvation when they are of long continuance, as they have been of late years.

I laid down my pen just now, and went to a neighbor's to look at his bees; they are very diminutive blacks, in movable-frame hives. On my asking the question, "How did your bees do last summer, and how are they now?" He said: "Last spring the ti-ti was killed by frost, and then a severe drouth prevailed, and bees stored no surplus; I've had to feed them to keep them from starving; for a few days they have been doing well—they are a month late; I've had no swarms yet, and I should have had the first of March."

MRS. L. HARRISON.

Washington Co., Fla., March 29.

O Can It Be!

O can it be, that "flies are flies because they fly?"
O can it be, that "fleas are fleas because they flee?"
O can it be, that "bees are bees because they be?"

The Honey-Bee.

Of all the things, in earth or air,
Of wondrous worth or beauty fair,
Few so prized, few could be
So valued, as the honey-bee.

At break of day, it sails away
To scented fields and flowers gay.
And sings its song, and works away
To gather sweets for winter's day.

It fills the hive to hold no more,
With garnered sweets—its winter store—
Then, grateful bee, no lazy sleeper,
A box it fills for its keeper.

Sweet, buzzing bee! so fair to see;
No second place we yield to thee,
In insect life, in earth or air,
Than fairy Queen, of mid-day air.

Arapahoe Co., Colo.

V. DEVINNY.

Buggies on Approval.—No more liberal offer could possibly be made by any manufacturer than appears in the advertising of the Edward W. Walker Carriage Co., Goshen, Ind., elsewhere in this issue. They propose to send any of their celebrated make of vehicles for examination and approval at the reader's nearest railroad station, and quote wholesale prices direct to the buyer, saving middlemen's profits. They also offer light and heavy harness at prices that interest every horse-owner. A large book describing their goods and methods of pleasing customers will be sent free by the advertiser on request. Please mention the American Bee Journal when writing them.

Yellow Sweet Clover Seed

WE HAVE IT AT LAST!

We have finally succeeded in getting a SMALL quantity of the seed of the YELLOW variety of sweet clover. This kind blooms from two to four weeks earlier than the common or white variety of sweet clover. It also grows much shorter, only about two feet in height. It is as much visited by the bees as the white, and usually comes into bloom ahead of white clover and basswood. We offer the seed as a premium

A QUARTER POUND FOR SENDING ONE NEW SUBSCRIPTION.

So long as it lasts, we will mail a quarter pound of the seed to a regular paid-up subscriber who sends us ONE NEW subscriber for the American Bee Journal one year, with \$1.00; or ¼ pound by mail for 30 cents.

We have been trying for years to secure this seed, and finally succeeded in getting it. It is new seed, gathered last season by an old personal friend of ours, so we know it is all right. But we have only a small supply. When nearly out we will mention it.

Rocky Mountain Bee-Plant Seed!

(*Cleome integrifolia.*)

...FREE AS A PREMIUM...

The A B C of Bee-Culture says of it: "This is a beautiful plant for the flower-garden, to say nothing of the honey it produces. It grows from two to three feet in height, and bears large clusters of bright pink flowers. It grows naturally on the Rocky Mountains, and in Colorado, where it is said to furnish large quantities of honey."

We have a few pounds of this Cleome seed, and offer to mail a ¼-pound package as a premium for sending us ONE NEW subscriber to the American Bee Journal, with \$1.00; or ¼ pound by mail for 40 cents.

GEORGE W. YORK & CO.

118 Michigan St., CHICAGO, ILL.

The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

GEORGE W YORK & CO.

118 Michigan Street, - CHICAGO, ILL.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, March 19.—We quote best white comb at 15c. An occasional small lot of fancy sells at 16c; off grades of white, 12@14c; ambers, 10@12c. Extracted, 8@9c for fancy white; 7@8c for amber; 6@7c for dark grades. Beeswax, 27c.

Receipts of honey are larger and the demand is not as good as it has been.

R. A. BURNETT & Co.

CINCINNATI, March 3.—There is some demand for extracted honey from manufacturers at 7@7½c for amber and Southern; clover, 8@8½c. Comb honey is selling firm at 14@16½c in a small way. Beeswax, 25@27c.

C. H. W. WEBER,

Successor to Chas. F. Muth & Sou and A. Muth.

LOS ANGELES, March 1.—1-pound frames, 12½@15c; 2-pound cans, 2 dozen in case, per dozen, \$2.50; 2-pound glass pails, per dozen, \$2.50. Extracted, water white, 60-pound tins, per pound, 8½c; light amber, 7½@8c; dark amber, 7½c. Beeswax, 25@26c.

The prospect for a crop is very bad. Small lots in the hands of wholesale houses are firmly held.

BOSTON, March 9.—Our honey market is showing some signs of lower prices, altho the stock on hand is not large. At the same time prices are so much higher than previous years that the trade have taken it very slowly and the results are that the holders are willing to range prices quite a little in order to move stock on hand. Prices range: Fancy white, 17@18c; No. 1, 15@16c; amber, 10@12c; buckwheat almost unsalable. Extracted, best white California, 8½c.

BLAKE, SCOTT & LEE.

KANSAS CITY, Mar. 19.—We quote fancy white comb, 15c; No. 1, 14c; No. 1 amber, 13c; No. 2 amber, 13½c. Extracted, white, 8c; amber, 7c; dark, 6c. Beeswax, 22@25c.

C. C. CLEMONS & Co.

BUFFALO, March 3.—Market nearly bare of all grades of honey. Probably no more from any source to market, but if so, fancy white comb is firm at 15@16c. Other grades from 14c downward, with the poorest at 8@9c. Fancy pure beeswax continues at 28@30c.

BATTERSON & Co.

NEW YORK, Mar. 8.—During the past 30 days our market has been somewhat slow and easy in both comb and extracted honey. Stocks of comb honey, however, are almost exhausted, and there is a fair demand for all grades. Fancy white selling at 15c; No. 1 white at 13@14c; fancy amber, 11@12c, and buckwheat at 9@11c, according to quality, etc.

Our market is well supplied with extracted, the prices are firm and unchanged. Beeswax sells very well at from 26@28c, according to quality.

HILDRETH & SEGELKEN.

SAN FRANCISCO, Mar. 23.—White comb, 11½@12½c; amber, 8@10c. Extracted, white, 7½@8c. Light amber, 7@7½c; amber, 5@5½c; Beeswax, 26@27c.

Supplies and demand are both at present limited, which is to be expected at the close of a light crop year. Business doing is mostly of a small jobbing character, and at practically the same figures as have been current for some time past.

OMAHA, Mar. 13.—Demand shows some improvement in January, having been much more active, but as anticipated there is no advance in prices. Market remains steady at 14@14½c for fancy white comb and 8½c for white extracted. The latter is pretty well cleaned up along the Missouri River, and it looks as if there would be some shortage before another crop comes in. From present appearances there is about enough comb honey to go around at the present prices, hence we look for no particular change in values.

wide-awake, practical Western farmers, stock-
raisers, poultry people and fruit-growers, to
learn the science of breeding, feeding and man-
agement. Special departments for horses, cat-
tle, hogs, sheep, poultry and dairy. No farmer
can afford to do without it.

It stands for American farmers and produ-
cers. It is the leading exponent of agriculture
as a business, and at the same time the cham-
pion of the Agricultural States and the producer
in politics. Subscription, One Dollar a Year.

The Charms of the Apiary.

Read at the Wisconsin Convention, at Madison, Feb. 7, 1900.

BY MISS ADA L. PICKARD.

PASSING leisurely thru the old meadow white as the driven snow with clover blossoms, we see a bee here, one there, and on every side; but to the average passer it is only a bee, made with a sting, flitting from flower to flower without purpose.

To me, the bee is beautiful, and, like man, it is "fearfully and wonderfully made," showing forth the handiwork of a wonderful Creator.

Some authors have placed the beetle as the highest order of insects; others claim the butterfly and moth entitled to a first place; while others, and with the best of reasons, claim for the bee the highest position.

The moth and butterfly are admired for the glory of their coloring and elegance of their form, and the beetle for the luster and brilliance of its wing-covers; but these only reveal nature's wealth, and live and die without labor or purpose.

The bee, or "white man's fly," as the Indians call it, less gaudy, usually quite plain and unattractive in color, is most highly endowed among insects. It lives with a purpose, and is the best model of industry and economy to be found among animals.

Think of the bees, so frail that they may be deprived of life by the slightest pressure, and how they toil on and on with that untiring energy from dawn until dark, and what an aggregate quantity of the most delicious and wholesome sweet those little insects will store! What beauty the immaculate comb, filled with that golden-colored, sparkling sweet, presents to the eye, making a most luscious and delicate food for the table—a food declared from the most ancient time until the present day suitable for king or queen. Reflect for a moment upon the

wonderfully delicate receptacle the honey is stored in—little waxen cups or cells with walls about 1-180th of an inch in thickness, and also formed so as to combine the greatest strength with the least expense of material and room. It is certainly an enigma within itself.

Apiculture opens the book of Nature to any who love to look upon and study the marvelous pages she is ever waiting to unfold. She is ever presenting the most pleasurable surprises to those on the alert to receive them, and among the insect host, especially the bees, the instincts and habits are so marvelous that the student of this department of nature is moved with wonder and admiration.

By the habit of constant observation one becomes more able, useful, and susceptible to pleasure. The wide-awake apiarist who is so frequently busy with his wonder-working companions of the hive, can never be lonely or feel time hanging heavily on his hands. The mind is occupied, and there is no chance for dullness or languor. The tendency of such thought and study, where nature is the subject, is to refine the taste, elevate the desire, and ennoble manhood. If our youth, with their susceptible natures, become engaged in the wholesome study of nature, we shall have less reasons to fear the vicious tendencies of the streets. Thus apiculture spreads an intellectual feast, furnishing the rarest food for the observing faculties—that which the old philosophers themselves would have coveted.

Must the male sex of our race only enjoy this intellectual feast? Nay! nay! the Creator never intended that the wonder and beauty of nature should be revealed to man only. Man and woman were created equal, and why may not the feminine enjoy the pleasures and fascinations that the apiary may afford? Why may not any person who is cautious and observing take up apiculture either as an avocation or as an amateur? He must however be willing to work with Spartan energy during the busy season, and give prompt attention to all its varied

duties. Enthusiasm, or an ardent love for its duties, is a very desirable qualification, and promptitude is an absolute requisite to successful bee-keeping, as *neglect* is the rock on which too many bee-keepers have wrecked their success.

Apiculture seems especially adapted to those whose life-work is a dull, humdrum routine, that seems to rob life of all zest. If more of our ladies, instead of seeking the office-chair, the place behind the counter, or the position at the

Miss Ada L. Pickard.

school-desk—all of which shut out fresh air and sunshine, until pallor and languor points sadly to departing health and vigor—would seek *apiculture* as an avocation, we might have, instead of pale, wan cheeks, roses and blooming health.

"Ask not for life of ease, but ask
From strength to strength to grow.
Pray not to measure out your task
By powers that you may show;
But ask for powers to meet demands,
For love that knows no strife,
For crystal vision, tireless hands—
A better self for life."

Richland Co., Wis.

How to Raise the Price of Honey.

BY JOHN R. SCHMIDT.

DURING these days of advancement in the prices of material of all kinds, and bee-keepers' supplies being no exception, more ought to be said in the columns of our bee-papers regarding how we may advance the price of honey in order that the ever-advancing prices of supplies, which have already reached an unwelcome figure, may be compensated for.

It is true that within a year or so prices of honey have advanced somewhat, and bee-keepers are rejoicing universally; but so have the supplies advanced, and we are only too willing to look upon one side of the book only where there seems to be a gain. But what has caused this rise in the market, both in the price of honey and also in the supplies? Has there not been a scarcity of honey, and are we not told that the lumber districts are fast diminishing, and monopolies and trusts are controlling almost every useful article that is in demand? We know that overproduction tends to lower the price, and failure to meet the demand raises the price. This is just what has caused the advancement in the price of honey, and is also true in the other case; but will the prices of supplies continue to advance? Most assuredly they will. We can not replace our timber in a few years, which is now rapidly becoming less and less, nor can we hope to abolish monopolies and trusts—they are a "good thing" for the people who form them, and are the natural result of keen competition. So long as manufacturers combine to protect themselves against failure, bankruptcy and the "cut throat" prices which would prevail among them were it not for such an agreement of combination, so long will the prices continue to rise, and trusts continue to form. Therefore, we can not expect to find relief by abolishing, but can only hope to control them.

If prices are bound to advance in supplies, and no hopes are given us of ever expecting to see those much-needed articles cataloged at the old familiar prices, how are we to compensate for this increase in expenditure, and raise the price of our honey accordingly? This is a question which is of vital importance, and one which should ever be in the minds of those interested in the production of honey.

It is true, as I have said, that prices have advanced, but this advancement was the result of a scarcity of honey, and when after a good season the market will again be flooded and prices will drop to their former figure, then there will again be the old complaint of low prices, from all quarters. But how are we to maintain the present price and continue the advancement? There is only one way. Bee-keepers, like farmers, can not form trusts or combines, and it is impossible to corner the honey crop, so we must appeal to the bee-keepers themselves.

It is the unconquerable desire among bee-keepers to market their honey as soon as it is harvested, and "the sooner the better" is the only thing thought of. This is just where a very, very great mistake is made; as a result honey becomes a drug upon the market, and low prices reign. To make matters still worse, "quotations" are given which tend to drop rather than rise. This causes the bee-keeper to ship his honey immediately for fear of losing a few cents per pound if he holds on to it any longer. After it is all sold he begins to realize the low figures which his honey sold for, and often this is where the commission man comes in for a good "raking," if I may be allowed to use the expression.

This year, or the past, has been a good one for the advancement of prices on honey, and owing to the scarcity and the "holding back" of large quantities, a better price was commanded, and it was gladly given. This is the only way we can maintain the price in the future, and the keynote of success has been sounded in some of our periodicals, warning those who have honey to hold on to it and ask a higher price. Some say that necessity compels them to sell

as soon as it is ready for the market. This necessity is the result of the bee-keeper's thoughtlessness in the beginning. Why not sell only in small quantities, and still have a good supply unsold for late winter and early spring demand, instead of rushing the whole crop off at once, getting your money all at once, and, as a result, an empty pocket-book and no bank account later on, which again forces the coming crop upon the market.

Honey that I sold for 13 cents early last fall would now find a ready sale at 18 cents. Hereafter, my small crop of honey will sell at a good price in the beginning, or remain stored until I get my price.

Small bee-keepers who do not depend upon apiculture alone for a livelihood have much to do with setting the price of honey, and it is to them that we must appeal. They are the ones who often supply the grocery trade in the vicinity in which they live. Often in early fall they bargain to supply the small demand of the grocer at a low figure just to have their honey move off quickly; and immediately this price becomes the standard with that grocer, and he is unwilling to give the professional a higher price, because he can buy all the honey his trade calls for at a lower figure.

Now, how are we going to remedy this? It can only be done by calling bee-keepers' attention to this very important question, and keeping it constantly before them. This we can only do thru our papers and conventions. Then when we begin to learn that in union only there is strength, and that we must work together for mutual benefit, and not each one for himself, the time will be near at hand when the fond hopes of the bee-keeper for higher prices will be realized.

Hamilton Co., Ohio.

Detecting the Initial Stage of Foul Brood.

BY F. GORDON.

I AM a member of a reading circle that takes several American bee-papers, the American Bee Journal among them. For long I have been musing, the fire is kindled, and at last I feel I must speak with my tongue—subject, foul brood.

I congratulate you that some parts, at any rate, of your land seem to be so free from it that many bee-keepers do not recognize it in its *incipient* stages. I refer especially to page 819 (1899), in the proceedings of the Utah bee-keepers' convention. "Mr. Lovesy, in giving his experience with foul brood, opened up a new field of investigation," etc.

For the benefit of the craft, let me urge upon you that this field has been investigated long ago, and the "back presentation" of larvæ in their cells that he refers to is the recognized orthodox first stage of foul brood, and the only stage in which drug treatment will be at all satisfactory.

Tho' Mr. Cowan's "Guide-Book" leaves room for more light, still this stage is accurately described therein. I have been to hives, with a spray diffuser of phenyle mixture, searcht their brood-nests thru; and if I found *one single larva*, amid a hive of healthy brood, showing me its back instead of being curled round in the normal manner, I would say to myself, "foul brood," and apply the medicinal spray forthwith. Many times I have had the gloomy privilege of watching the disease develop from such beginnings, thru the yellow to the coffee-color pulp that draws out, and beyond that to the dried-up scale half way down the cell. In cases I have seen the disease arrested at the "restless larva" or "back presentation" stage, but whether by the phenyle sprinkling, or by a good honey-flow, I do not care to say.

Referring to the well-known photograph of a *badly diseased comb* that is published, I am impelled to say that it may, instead of being a help to the novice, become most misleading, in fact is almost bound to be so. The disease depicted there is bad—very bad—and any careful bee-keeper of two years standing or less, who knows the look and scent of a healthy brood-nest, could not fail to perceive something seriously wrong if he discovered one of his hives in such a putrid state as that, even without the aid of any photograph or instruction. But to wait for such an appearance before recognizing foul brood is a most lamentable mistake. The disease has then had *at least three weeks visible run*, possibly several months, and is past the redemption point, fit only for the fire and the spade.

I said "*visible*," for how long the disease had lain dormant nobody knows. But the bee-keeper could have seen it three weeks before, and perhaps saved his combs as well as the adult bees.

Mr. Simmins, editor of Bee-Chat, gives a still more

preliminary stage, viz.: Patchy, irregular brood-nest. That is, where a few of these yellow, restless larvæ have been turned out by energetic workers as soon as affected with the disease, before the eye of the owner ever saw them; this leaving, of course, either empty cells among brood; or cells with different aged larvæ contiguous, supposing the queen finds those empty cells and lays in them. I believe this to be a perfectly correct symptom of the bee-keepers' pest—genine foul brood.

Touching on remedies, izar has been praised of late. Personally, I have found it of no manner of use. Mr. Simmins tells me it is because my bees were blacks. Carniolans and Italians he considers much more immune. After fighting the disease two seasons I finally had to destroy my whole apiary of about 60 colonies to get rid of it.

Some time since there was a case recorded, I think in the American Bee Journal, of a man who sent up a sample of suspected comb to a professor for his opinion, and was told the comb was not diseased, whereas subsequent events proved it was diseased. The professor replied, describing the coffee-colored, stretchy character of diseased matter, and saying he could hardly credit how such a mistake could have been made. I think a very simple explanation would be that the aforesaid comb was in the initial stages of the disease, showing only pale yellow displaced larvæ, and no coffee-colored matter at all, which, of course, developed later in the owner's hive. Cumberland, England.

Separators or No Separators, Etc.

BY EDWIN BEVINS.

ON page 106 is an item headed "Separators and Fences." The first sentence affirms that F. L. Thompson says that "the idea that sections are better filled without separators than with them is a mere notion." Standing alone, this sentence, like some texts of scripture, would leave the reader in some doubt as to what the author was driving at. Further on Mr. Thompson is quoted as saying that "a number of times he tried separators in half of a super, with no separators in the other half, and that the result was always the same—no difference." The last quotation serves the purpose of a key to the meaning of the first one, and altho I have not read the article from which these quotations were made, I conclude that the article in its entirety was an argument against the use of separators.

Now, how many bee-keepers in the United States will stand up and say that they have observed no difference in the weight or smoothness of sections of honey produced with and without separators? I have used supers in the same yard for several years—some with and some without separators—and there has always been a marked difference both in weight and appearance of the sections. A super full of sections when filled with honey would always weigh more than a super with separators. The sections without separators were always unevenly filled and difficult to prepare for shipment. If this is not Mr. Thompson's experience, I believe it is the experience of nine out of ten, if not of ninety-nine out of a hundred, of comb-honey producers. But I will pursue the subject no further, having, as I said before, not read Mr. Thompson's article, and it may be that I have been fighting a man of straw.

CROSSING SWORDS WITH MR. DOOLITTLE.

I am aware of the hazard in differing from Mr. Doolittle about anything pertaining to the management of bees and bee-hives. Armed cap-a-pie with apicultural lore and experience he riots amid the crowd of less well equipped bee-keepers as the armed and armored knights of the middle ages rioted amidst the common herd of the soldiery of the times.

But I will venture to say that I do not quite like his recommendation to use the 10-frame Langstroth and dove-tailed hives in place of the 8-frame sizes, and then contract to seven frames during the white honey-flow. This management may be good for those who do not care to give their bees in 8-frame hives much attention in cold weather, as the after management may be made conducive to successful wintering.

The principal reason for my objection to the change is, that, with this lateral expansion of the brood-chamber there must be a corresponding expansion of the super. I am becoming more and more convinced that a super holding 24 ¼ sections is quite large enough. Observations in recent years have inclined me to the belief that I would prefer a super taking less than 24 sections to one taking more. The

objection to a change to a smaller super is the difficulty of adjusting the double-purpose brood-chamber to the one-purpose super.

FASTENING FOUNDATION ON MOULDED TOP-BARS.

And now I will tell the bee-keepers who use moulded top-bars a trick I have learned about fastening foundation. I use a Daisy foundation roller to roll the foundation on, and this fastening is sufficient if the frames are used immediately, but the foundation in frames not used soon will loosen in places, if not all along the bar. To prevent this, use a splint the length of the foundation, nailing it on with some fine wire nails. The splints may be made from the small branches of willow or other straight-grained wood that splits easily, and the convex side of the splint placed against the rolled edge of the foundation. Supply manufacturers could cheaply furnish splints for the purpose.

Decatur Co., Iowa.

The Principles of Plant Growth or Work.

BY PROF. A. J. COOK.

FROM numerous letters which I have received, I feel quite certain that many readers will not only gain pleasure, but much of value, if I give in this article a simple, plain explanation of the principles of the plant growth. Indeed, every bee-keeper and every farmer can not be too well versed in the principles of vegetable physiology. There are many who think that the plant takes the honey right from the sap. It would seem that simply tasting of the sap would quickly correct this mistake.

One of the most wonderful discoveries of this century was that of Schwann, made about 60 years ago, of the cell. It was shown that the basis of all structure of both animals and plants consists of cells. These cells are very much the same whether in the plant or animal. The plant then consists of cells—little sacs or vesicles, which are not as their name implies, empty vessels, but are always full of a semi-liquid substance known as protoplasm or cytoplasm. This cytoplasm is the great worker in all plants and animals. Thus the cells are the seat of all work done; and all the work is done by this cytoplasm.

As every well-informed person knows, we are constantly wearing out and building up. Whenever we do any work, like moving a muscle, tissue tears down or wears out, and at once builds up again. This is why we must constantly have food to furnish material for this building up, or anabolism as it is called. The plants behave in the same manner. They wear out and build up. The cells which make up the organism act in this respect as the whole organism acts. They are the workers, and in working they wear out, and as surely must build up. Thus, the plant will starve without food, just as surely as will the animal.

We see, then, why plants languish when water, their most important food, is withheld, or when they are in a poor, worn-out soil. These cells perform two important functions. They have the power to absorb liquid substances and pass them on to other cells. In this way the sap goes from the roots far up to the leaves.

The other important work of these cells is to do the work of the plants, taking certain food elements and building up vegetable tissues. They are then carriers and manufacturers. It is the function of the living cell everywhere to take up the liquids that come in contact with it. Thus the cells of the roots of the plants take water and the mineral salts, and, as we have seen above, they pass these up thru the trunk and twigs, even to the topmost leaves.

Perhaps water is the most important element which the roots take, and, contrary to what most people think, practically all water comes from the roots. The mineral elements are quite numerous; but only three need usually be supplied to the soil. These are nitrogen, potash and phosphoric, each of which is always combined as it passes along in solution with or as a part of the crude sap from the roots. As this material passes from the cells usually in the outer sapwood, the cells take what they need for their nourishment. They especially draw heavily on the nitrogen. As stated, this sap passes to the leaves.

The leaf-cells, as also the green part of the bark, have as a constituent of their protoplasm, chlorophyll. There comes into the leaves from small breathing-mouths on the underside, called stomata, carbon dioxide from the air.

The leaves by virtue of the protoplasm in their cells have the power of forming carbo-hydrates, probably from the water and carbon dioxide, the former of which they receive from the roots, the latter from the air. While it is

probable that most of the carbo-hydrates—by which term we mean the starch, sugars and cellulose—is made from the carbon dioxide and water, it is very probably true that the cells have the power of converting their own proteids or nitrogenous elements into these carbo-hydrates, which they might do in case the water or carbon dioxide was not present. We know that animal cells do something very like this.

The material manufactured by the leaves is usually some form of sugar. This is borne away in solution in what is sometimes called "elaborated sap," and taken to the cells, changed into starch often and stored up; as starch is insoluble it will remain until changed again to sugar. Whenever there is excess of the carbo-hydrates, this starch is stored; and when needed it is again changed into sugar and borne away to be used. The cell-walls, and indeed all the woody part of the plant, is formed by changing this sugar into cellulose, which is the substance of all woody tissues.

The growth of all our common trees is always added to the outside in the cambium layer which consists of the outer sapwood and the inner bark. In this way a ring is added to the tree each year. We therefore call such plants exogens, which word means outside growers.

As stated above, the nectar of plants is not sap. At the base of the flower, or wherever nectar is secreted, there are special nectar-cells, which differ not only in appearance from the ordinary cells, but have a different function. These have the power to take sugar from the sap which they may simply deposit, or possibly they may take some element from the sap and change it into sugar. This is almost always cane-sugar. Thus, these cells secrete sugar from the sap, and do not simply pass the sap out into the flower. The sugar of the nectar may be in the sap, or may be formed by the nectar-cells. In any case, the nectar is quite different from the sap.

We have seen that the nitrogen in combination carried up by the sap is used for the nourishment of the cells. The probable use, then, of the nitrogen is to promote the growth of the plant. A soil very rich in nitrogen will show thrifty plants. It is supposed that the potash and phosphoric acid are more needed in the fruiting or formation of fruit and grain of the plant. Without doubt all of these elements are needed in all growth and development.

I have called attention above to the chlorophyll of the leaves. This is what makes the leaves green. In the work of the leaves this is constantly being used up. It must, therefore, be constantly formed, or the plant will become pale and sickly. To form the chlorophyll the leaf must not only have the necessary elements, but also sunlight. We see, then, why plants or grass under a board become pale. The chlorophyll is used up, and in the absence of sunlight can not form again.

I stated above that all the water of plants comes from the roots. Those who have noticed how plants revive on a foggy morning may doubt this statement. As the sap passes to the leaves the water is constantly evaporated from their surface, leaving the salts which it bears for their nourishment. It is probable that the leaves do the hardest part of the work of the plants. By this evaporation an immense amount of water passes off. A foggy morning in time of drouths revives the plant, because it prevents this excessive evaporation.

We should never use the word digestion in referring to plant work. Digestion is the preparing of the food so that it can be absorbed. Plants rarely take any food that can not be absorbed. Therefore, most plants have no digestive organs, and perform no digestion.

Keeping Bees on a City House-Roof.

BY "URBANITE."

EARLY in April, 1899, I became the possessor of two colonies of bees. They were delivered one evening after dark, and in hoisting them up to the roof of my house (for there it is where they were to be located), the hives were bumped against the wall, turned over and over, and the combs, being heavy, old and not wired, broke from the frames, so that it was impossible to lift up one without disturbing all the rest. All the combs in each hive were one solid mass—I might say mess. It was clear they had to be transferred to new hives, and my son and I undertook the job with much misgiving. But we succeeded fairly well and without too much waste.

By the end of the month the breaks in the combs had been repaired, and each frame could be taken out with ease

and comfort. By the middle of May the hives were full of bees—boiling over.

Being away from home during the day it became necessary to prevent swarming. This was managed by the use of entrance-guards, by giving plenty of room, and by dividing. They did swarm, after all, but returned after an absence of about an hour or less.

A third colony was started by taking two frames with brood from each of the two hives, and replacing with frames filled with foundation, and a queen was sent for which did not arrive until June 20. She was introduced the same evening, and reared a hive full of fine Italians; but the colony produced only 39 pounds of honey, having been queenless 32 days. The bees in this hive, however, gave me the satisfaction of allowing me to exhibit them with safety to strangers. Frequently have I taken out one of their frames with crowds of bees on each side, they keeping quietly at work without resenting the exposure, and affording my friends the opportunity to enjoy this novel sight at close range.

In all this there is nothing new, and you may want to know what is the use of going to the trouble to write about it. My object is to show that it is easy to keep a few colonies on the roof of a house right here in this city, and that bees so placed will more than pay for their keep, and that hundreds of men with some leisure on their hands might engage in this most interesting and useful diversion, if they will only make up their mind to it.

An apiary on the roof of a house has its drawbacks—carrying things up and down stairs and ladders in the hottest time of the season is not what you may call "a picnic," but, on the other hand, there are advantages: The bees have perfect quiet, and are not interfered with, anything left lying around loose is not lost, and the small boy is barred out.

When I commenced it was with the apprehension that possibly the neighbors might consider my bees a nuisance, but after the season opened, and it was seen that they were inoffensive, strictly attending to their own business, I had no more fear—they became popular favorites, and when my wife sent to each of our neighbors a tumbler full or so of honey from our first extracting, all became friends and admirers; they take a kindly interest in my bees, and my hives are pointed out by them to visitors as objects of curiosity, well worth seeing.

I had hoped that the bees would produce enough honey to supply the needs of our small household, but when extracting the first time, and getting honey by the bucket full, I was most agreeably surprised, tho I should have known better. It was stored from the white sweet clover, of which there are miles between the West Side and the Desplaines River, and the blossoms were out in considerable quantity by June 15, and continued to the end of October; but I think the bees did not get much nectar out of them after the first of that month. No goldenrod, usually very plenty, was seen last fall. The quality of the honey was superb. It was put up in Mason fruit-jars, and sold to neighbors and acquaintances at the rate of 50 cents a quart. There was no difficulty in disposing of our surplus; in fact, a great deal more than we had was spoken for.

My expenses were \$28—that is, \$8 for the bees, and the balance for new hives, frames, foundation, extractor, comb-basket, smoker, veils, and some few tools. For this outlay we had to show: 194 pounds of extracted, and 24 pounds of comb honey, and an increase of one colony. Should they come thru the winter all right, as I expect, the cash outlay next season, as far as these three colonies are concerned, will probably not exceed one dollar.

I know of but one of my personal acquaintances who keeps bees here on the roof. His is a two-story house on which there are nine colonies, which produced last season more than 110 pounds on an average, one running as high as 200 pounds. He was more successful than I, but then he is an old hand. He tells me he has a number of colonies on his farm in Missouri, and only brought here these few "to keep him company." Chicago, Ill.

The Honey-Extractor—Ancient History—"Honor to Whom Honor is Due."

BY M. M. BALDRIDGE.

THE first honey-extractor put on the market in the United States was the Peabody. It was invented by J. L. Peabody, who now resides in Colorado, and was patented by him in 1869.—(See page 73, No. 5, American Bee Journal.)

No. 11 of the American Bee Journal lies before me. I have waited very patiently till now for some one versed in

"ancient history" to correct the first statement made in the foregoing citation, copied from Gleanings in Bee-Culture, but no one has done so. As I was living in 1869, I will try to show what some of the facts were at that date about the honey-extractor, and to whom belongs the honor of its first introduction to the bee-keepers of the United States.

In the latter part of February or early in March, 1868, L. L. Langstroth & Son sent me their annual printed circular, dated Feb. 20, 1868, in which they say:

"A plan has been devised in Germany for emptying honey from the comb without injuring the comb or removing the bee-bread or any other impurities. By returning the emptied comb to the bees the yield of honey in favorable seasons may be largely increased. An improvement on the German apparatus for effecting this object was devised and patented by L. L. Langstroth and Samuel Wagner, but further experimenting has resulted in so simplifying the machine that, as now made, it is neither patented nor patentable. We annex a cut of the patented machine, which will give a general idea of the principle on which the modified apparatus works. As now made it has been thoroughly tested and found to work admirably. Two full combs in the Langstroth frames can be emptied in less than 3 minutes after the cells are uncapped, to accomplish which we use a knife made expressly for this purpose, and frequently dip it in BOILING WATER to prevent clogging of the edge. We make but one size of machine, holding two of the standard size Langstroth frame (8 $\frac{1}{2}$ x 10 $\frac{1}{2}$ inches INSIDE measurements.) Frames of smaller size, or broken pieces of comb, can be emptied in it. Price of machine complete, including knife and barrel, securely packed and delivered to the express companies at the place of manufacture in Central New York—\$12. The liquid honey, put up in glass self-sealing fruit-cans, we find to sell readily wherever introduced to the market. As we shall have the machines manufactured only as ordered, those wishing them to use this season should order early."

The circular, from which I copy the foregoing, is still in my possession and I will send to the editor the picture or cut of the patented machine referred to by Langstroth & Son, with the request that it be reproduced in the American Bee Journal, so its readers may see and examine it for themselves.

On March 10, 1868, I sent my order for the honey-knife and the improved machine to Messrs. Langstroth & Son, and in a short time thereafter the same were sent to me in this city from Central New York, but from what point I do not just now remember. The machine was tried by me as soon as received, but it did not suit me very well, and mainly because it had no gearing—simply a short, horizontal crank on top of the spindle to make the extracting-box revolve. Otherwise the machine was a good one of the kind. The outer-case was simply a well-made barrel.

In the month of May following, I received an order for a Langstroth machine from A. E. Trabue, of Hannibal, Mo., a practical and extensive bee-keeper near that city, as I was acting as agent for Langstroth & Son. As I thought I could improve the machine in many ways, I sent on to Mr. Trabue the one I got from Central New York. I then got up a number of extractors and added a gearing to each of them. One of those machines I sold to Jas. M. Marvin, of this city, in the summer of 1868, and he used it in his apiary from year to year up to the date of his death. That was a strong, durable, and practical extractor and it is still in good repair and ready to do a fair day's work, so I am assured by a nephew of Mr. Marvin who now owns the same machine. This nephew also resides in this city.

I advertised my make of honey-extractors by circular, and otherwise, in 1868, and for several years thereafter, and sold a number of them to bee-keepers in this and other States.

Now, my main purpose in mentioning some of the foregoing facts is simply to prove, as a matter of history, that my old friend, Peabody, whom I knew personally quite well while he was a resident of Illinois, did not by any means put on the market of the United States the first honey-extractor; and, besides, to bestow honor upon whom the same belongs. Kane Co., Ill., March 16.

Some Excellent Apiarian Suggestions.

BY WM. M. WHITNEY.

TO one contemplating bee-keeping I would say, before you commence actual practice—say during the winter—procure some good work on the subject and study it thoroughly. Make a plan of your bee-yard and mark the places for your hives and number them. With this diagram before you, open your book of instructions and commence manipulating your imaginary hives according to the directions given, noting what has been done with each hive. Thus will be fixed in the mind the different operations, so that when the actual practice begins, you will not feel the degree of embarrassment which you might otherwise experience in an emergency.

In the meantime subscribe for some good apicultural journal—more than one would be better. Then, in the spring, you are ready to take care of 2 to 10 colonies of bees, with plenty of leisure for other pursuits.

Adopt standard appliances—hives, supers, cases, frames, sections, etc.—always keeping in mind your particular locality and its needs. To do this your eyes and ears must be quick to catch every important matter pertaining to your business, then if you have a reasonably good field for operations, and are a live, wide-awake person, as above indicated, you will meet with a fair measure of success.

Let *fads* alone, until those who make it a business to experiment, have tested and proven their efficiency. I am not opposed to those who are experimenting along those lines, for many of our very valuable improvements have been dubbed *fads*, and have met much opposition and ridicule. But the beginner in any enterprise should feel his way carefully, if he would escape the pitfalls that lie concealed along his pathway.

Apiculture—if I may be allowed to digress—in its full significance, includes both science and art, and, to some extent, might be taught in our schools of technology. It is as much a distinct branch of business as horticulture, floriculture, or any other specialty in rural pursuits, and can only be carried on like the others successfully by the specialist; therefore, it is not adapted to the ordinary or average farmer, so many of whom conduct their farm operations in a loose, slipshod manner.

Do not understand me as meaning that farmers should not be bee-keepers, for among the rural population is the proper place for the pursuit, but persons should be trained for it, and many farmers are experts, but unless one intends to study the business thoroughly, and do his work in the best manner, keeping his bees healthy, and everything neat and clean, he should let it severely alone, or he will sooner or later meet disaster, and spread disease and death among the apiaries of the surrounding country.

To emphasize what I wish to convey, let me give one illustration only, among many which might be given, viz.: While talking with a man from the country not long ago about bees, he said to me:

"A neighbor has 18 or 20 colonies. He started with two Italian colonies which he bought in movable-frame hives, but concluded he could not afford to buy such hives, so made common box-hives for the increase. When more honey was needed than could be got from boxes on top of the hives, the bees were killed to get it. I bought two hives of him last summer for the honey, and in the fall I butchered the bees and got over 100 pounds of honey."

Now, I would like to *butcher* all such bee-keeping. If the business was in the hands of expert persons, scattered about among the people of the rural districts to fairly occupy the ground, it would be to the advantage, not only of the manufacturer of bee-keepers' supplies, but of the publishers of bee-literature, and would be much better for all concerned, than the indiscriminate bee-keeping which is so often advocated at bee-keepers' conventions, and thru the medium of apicultural journals. Kankakee Co., Ill.

Celluloid Bee-Button.—We have had made to order a very neat $\frac{3}{8}$ -inch celluloid button to pin on the coat-lapel. Upon it is the picture of a golden queen-bee, and around the edge these words: "Our toil doth sweeten others." It will especially please the boys and girls, and is a neat thing for members of bee-conventions to wear. It is a nice badge or emblem of the sweet industry in which bee-keepers are engaged. Prices, postpaid: One button, 8 cts.; 2 buttons, 6 cts. each; or 5 or more, 5 cts. each. Stamps taken.

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Richards, Ohio.

OVERSTOCKING IN COLORADO.

So it appears that in Colorado an apiary seems disinclined to increase after the 100-colony mark is reached—and this when a small apiary with the same field to itself would increase rapidly. This looks like overstocking, but not necessarily ruinous overstocking. Fairly good crops may be hoped for, I think, even under conditions where swarms are not plenty. Also the stock may be too large for the pollen supply, when it is not too large for the honey supply. As a relief from swarms, I am not sure but some of us would be glad to get into just such a location as the latter. Page 134.

Mr. Lyon, on the same page, strikes into an element of the overstocking question which is usually unconsidered. One colony has 30,000 bees, and 20,000 of them are field-bees. Manifestly a given range could support a thousand of the latter kind of colonies as well as a hundred of the former—that is, so far as honey goes it could.

THAT SNOWBOUND TEXAN APIARY.

A Texas apiary piled with 18 inches of snow—and a good-looking man standing in the midst! Quite unique. (Page 145.) Now let's have a Norwegian apiary shaded by palms, and naked little darkies climbing in them picking the cocoanuts.

A SHORT SERMON ON JUSTICE.

But, Mr. Victor, instead of congratulating you on getting even with the thieves, I fear I must read you a sermon instead. Is it right to keep five men in jail 30 days when only one committed the crime? In dealing with men of another race it's easy to say, "O they're all thieves;" but mostly this is not true. It is not only possible, but more than possible, that one or more of your victims disapproved of the theft, and remonstrated about it. Or, some may have been steadily duped by stories about wild honey from the trees. One of the reasons why this nation was formed in the first place was that accused persons might have a prompt trial. And one of the minor reasons why we went to war with Spain was that Cuban-American citizens (no better a lot than your five, quite likely) were kept in jail without trial. I suppose the Sheldon of it would be: How would Jesus Christ have us proceed toward five men, one of whom had been stealing, and the other four not anxious that their friend be punished?

ACTIONS OF STUNG ANIMALS DIFFER.

So we are to understand, on as good authority as Prof. Cook, that the standard remedy in case of an animal desperately stung, is blankets kept dripping with cold water. But cow as well as man is subject to "locality." The case of one who stood and writhed and died, without thinking of such a thing as running away, does not prove that all would do so. And, by the way, I think we have somewhere evidence that *sometimes* the horse, after receiving hundreds of stings, drops his violence and becomes docile and almost affectionate. Page 147.

A SCIENTIST'S VIEWS ON HONEY.

Scientist Headden's doctrine that ripe honey is one-third water, he must expect us to kick at. Is not one-fifth nearer it? And his surmise that stirring honey does not make it candy any quicker is pretty surely wrong. As to his statement that the relative amount of dextrose and levulose is the same in all samples of honey—perhaps we would better lay that up on a handy shelf, without either believing it or disbelieving it just now. Would rather strain our "believer" to believe that the most solid samples of granulated honey are half fluid, as his statements seem to imply when put together. Page 147.

GETTING AT THE SIZE OF FOUL-BROOD SPORES.

Thanks to Prof. Gillette for his characterization of the foul-brood bacillus. Some longer, some shorter, but the

longest ones proportioned like half a lead-pencil. I would gently remonstrate about the 1,800,000 spores spread to dry on the head of a pin. That kind of illustration does not after all *help* our minds, but hinders and stupefies. Let's see if we can't do better. I find that a book at hand has 384 thicknesses of paper to the inch. Applying this number to the Professor's figures, it appears that 14 fat old bacilli end to end would just reach thru a sheet of thin paper, and that 31 spores would do the same. We can realize this; but few minds *can* realize properly two stout figures multiplied together and the product squared or cubed. Page 148.

TRYING TO IMPROVE BEES.

Yes, Mr. Hutchinson, there is a difference in bees; but the grand trouble is that when we once wake up, and try to improve our stock, we throw away good ones, and buy poor ones at a high price. Page 152.

"YORK'S HONEY" VS. "HASTY'S HONEY."

Thanks for the editorial statement of the honey-dealer's side of the marking dissention, I see. Neither boy is to blame for loving the girl; but they can't both have her. And there *must be* some proper and Christian way to decide things. 'Specks it will have to be the old familiar way—the one that *can* get her gets her, and the other must quietly behave himself like a gentleman. I say this in the sad consciousness that the city chap will usually succeed in the contest. She will be "York's 'Honey'" and not "Hasty's 'Honey.'" Old Adam will tempt us to say "York's a liar;" but if his customers don't understand it to mean that York produced the honey, but only that he inspects and indorses it as a first-class article, veracity does not seem to be broken. Page 152.

MILK A SUBSTITUTE FOR POLLEN.

If Dzierzon says sweetened boiled milk is better as a substitute for pollen than meal, probably there is something in it. As an objection, possibly milk-feeding would leave a certain section of the young workers with nothing to do, while meal-feeding would give all work. Page 154.

WAX-WASTE NOT ALWAYS WORTHLESS.

The 9½ pounds of good wax from one pile of slumgum which Comrade McKown realized, reminds us again that "things are not always what they seem." Wax-waste usually *seems* to be worthless; and most of us need to be prodded up often with the facts to the contrary. Page 159.

FACTS ABOUT FRUIT-FERTILIZATION AND BEES.

Mr. Crane's article on fruit-fertilization and its plate (page 162) came somewhat as a surprise to me. I had rather settled down in the belief that fruit (if it grew at all) would be about the same in size and quality self-fertilized as cross-fertilized, only the seeds being affected. It is easy to see that the fruit, growing for the sake of the seeds, *ought to be* better with normal seeds than with blighted ones; but I had got tainted with the idea that the facts were the other way. Facts seem to be all in our line, I'm glad to see.

A REVERSING EXTRACTOR POINT.

Mr. Dadant makes a good point in calling our attention to the fact that an extractor *without any center rod* admits of the combs being turned without being lifted out. Page 163.

PARAFFIN CANDLES AND SQUASH-SEED BAITS.

Paraffin candle better than a lamp for investigating a bee-cellar. Sounds reasonable, Mr. Doolittle. And possibly, too, the squash-seeds are better than hickory-nut meats as baits for the mouse-trap. Not so brittle and liable to get off. Page 163.

THAT COLOR-CARD CRITICISM.

Mr. Muth-Rasmussen, it was you that didn't "catch on" to Hasty, in reference to the color cards. He was talking about the eternal finalities, whether honey *ought to be* graded by the inward color alone; while you were talking business and present usages. Page 164.

A RETRACTED SNEEZE AT THE ASTER.

When a fellow is too free with his gab he must either have a large supply of cheek, or else be prepared to take back his dicta semi-occasionally. Awhile ago I sneezed at the aster and its honey reputation, and especially at the idea that any particularly rank smell in the apiary came from aster. Now comes good authority, W. H. Pridgen, of North Carolina, and confirms the whole thing. Shake, Mr. Schmidt! Did you ever see such a know-it-all in your life?

A plant that will sometimes give a month of surplus storing late in the fall had better not be sneezed at. Page 165.

BLINDLY CONDEMNING GOOD QUEENS.

How unconsciously and amusingly pat a good writer can sometimes be in stating a fundamental truth! (It's Aikin I'm after this time.) On page 165 we read, "I suspect that many a good queen has been condemned blindly because she did not have a good, strong colony, when she was not at fault at all." Why, comrade, if you live to good old age, and keep studying, you will not only suspect that, but be almost sure of it.

PERPLEXING FOUL-BROOD PREVENTIVES.

How instructive, and also how natural, is the medication experience of the Colorados! One man used solution of salt and carbolic acid as preventive, and kept bees within a quarter mile of a foul-broody apiary without getting the disease. Naturally he would think his remedy splendid. But then another man kept bees for years near foul brood without getting any. He used nothing at all—and there we are. Page 166.

UNCLE SAM AHEAD AGAIN!

What an absurd idea it is to spend good United States money, and time supposed to be valuable, in getting *Apis dorsata*, when this peerless country already possesses a bee 117 feet long! On the whole, I am mildly (very mildly) glad that the chap to whom we are indebted for this news didn't get stung. Page 169.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Painting Hives Two Colors.

How would it do to paint loose-bottom hives dark on one end and one side, and white on the others, then turn to suit the season? KENTUCKY.

ANSWER.—The plan is worth considering. If I understand rightly, the idea is this: If a hive faces southeast, the front and the side to the southwest would be white for the summer and the other end and side dark. That is, the parts toward the sun would be white so as to reflect the heat of the sun, keeping the hive cooler. Then for winter it would be reverse, still having the entrance face southeast, but the sides toward the sun dark, so as to absorb the sun's rays and make the hive warm. It is just possible that on some days in winter the dark color would make enough difference so that bees would fly when they would not fly with white surfaces to the sun. But in Kentucky do you always want to have bees fly out oftener than they do in a white hive? For as one goes south the line is reached where the thing desired is to keep bees from flying as much as possible.

A Swarming Experience.

Are there others who ever had this experience? I purchased a box-hive of bees some time ago, transferred them March 8, or rather I took about 2/3 of them from the box and put them into a frame hive. On March 23 the box gave a 4-quart swarm, leaving as many in the box. Of course I took the old queen when I made the transfer, so the balance had no queen, but would rear one in 15 days; but she came out with her full brood, on her wedding-flight, and this must have been on the very day she came forth from her own cell, as 15 days would be her time. I now have (3) good 4 to 5 quart colonies from one box-hive in just 15 days. Every one of them is bringing in honey from early to late. The swarming took place on a rather cool day—a little

misty—at 2:30 p.m. The bees are a very large black variety, and as gentle as any bees I ever saw. I do not know what kind they are, being quite different from the rest, or any I have seen in this neighborhood. FLORIDA.

ANSWER.—Under the same circumstances you would probably have the same experience repeated. At any time when bees are gathering, take away from a strong colony the queen and some workers, and if enough bees are left in the hive you may be pretty sure the first queen that emerges will issue with a swarm.

It is not at all certain that the young queen that issued with the swarm issued from her cell the day the swarm issued. For in that case the bees must have chosen an egg if they started a queen-cell any time within two days after the old queen was taken. While I believe that bees prefer to select a larva not more than 2 or 3 days old, I do not believe they prefer an egg; and there was a chance that the young queen in question was two or more days old when the swarm issued.

LATER.—My box-hive just gave out another swarm of about 3 1/2 quarts. This makes 4 colonies from one in just 17 days. Is this not unusual? FLORIDA.

ANSWER.—If bees are left to their own sweet will, it is nothing unusual to have 3 swarms issue within 17 days, and even four or five; but it is probably unusual for a third swarm to be strong enough to have 3 1/2 quarts of bees.

Likely Bee-Paralysis—A Suggested Remedy.

I have 60 colonies of bees, and five of them are diseased as follows: The old bees become bright and shiny with bowels much distended. The younger bees are much swollen and have but little use of themselves. Unhatched bees that die have pink eyes. Some of the cappings have holes as if they had been burst by accumulation of gasses inside. The unhatched dead have no smell or ropiness.

For 3 years I have had from 1 to 5 colonies diseased. I have cremated them heretofore, but now I wish to know the name of the disease and a remedy therefor. Only one colony has ever recovered sufficiently to do any good. Is the disease contagious? and how is it communicated from hive to hive? It seems more fatal in spring or early summer.

Giving diseased colonies young queens has failed to cure. Sprinkling sulphur in the brood-nest seems to abate the disease to some extent. TEXAS.

ANSWER.—It seems to be a case of bee-paralysis. As far south as Texas it gets to be a very serious matter. It would be easy to give a list of remedies that have been vaunted as successful from time to time, but the unfortunate thing about it is that no remedy seems yet to have been discovered that proves effective the next time it is tried, and perhaps the best thing is to try to keep colonies strong and hope the damage may be as little as possible.

I don't really know whether the disease is contagious, nor how it is communicated.

The latest cure I have seen is given in the Australasian Bee-Keeper, and it is claimed a number of bee-keepers have succeeded with it. The cure is as follows: To a pound of honey add 1/2 ounce of a mixture of one part sulphurous acid with 4 parts tincture of podophyllin. Heat to 90 degrees, and daily spray combs, bees and all. Three to five days' spraying cures. This may be worth trying.

Bran Instead of Chaff for Packing.

I would like to know if bran will do as a substitute for chaff packing to keep the bees warm? MINNESOTA.

ANSWER.—I don't know. I think no one has reported a trial of bran for packing; but I should be afraid it would not keep so dry and sweet as chaff. Mice would probably like it better than chaff.

Dr. Miller's Honey-Queens are offered as premiums, on another page, for sending us new subscribers to the American Bee Journal. The offer is limited to our present regular subscribers, and the queens are to be mailed in rotation, beginning about June 1st, so first come first served. Look up a new subscriber, send in his name with \$1.00, and we will enter your order for a Dr. Miller Honey-Queen.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY,
118 Michigan Street, Chicago, Ill.

[Entered at the Post-Office at Chicago as Second-Class Mail-Matter.]

EDITOR:

GEORGE W. YORK.

DEPARTMENT EDITORS:

DR. C. C. MILLER, "Questions and Answers." * * E. E. HASTY, "The Afterthought."

LEADING CONTRIBUTORS:

G. M. DOOLITTLE, C. P. DADANT, PROF. A. J. COOK,
F. A. SNELL, R. C. AIKIN, "OLD GRIMES."

IMPORTANT NOTICES:

The Subscription Price of this journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec00" on your label shows that it is paid to the end of December, 1900.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

VOL. 40.

APRIL 19, 1900.

NO. 16

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

The Langstroth Monument, referred to recently in these columns, will likely be erected before June 1. We have just learned from General Manager Secor that a total of \$300 has been raised for the purpose. The one selected is Vermont granite, of very nice proportions, and he feels sure will please the bee-keepers who contributed to it.

We expect to show our readers a picture of the monument after it is in place.

The Chicago Bee-Keepers' Association met Friday afternoon and evening, April 6, as announced. The most prominent bee-keepers present were Dr. C. C. Miller, Ernest R. Root (the president of the National Bee-Keepers' Association), and M. M. Baldrige. There was a fair attendance at the afternoon session, and a goodly number in the evening.

One very enjoyable feature was the supper, which all partook of together around one long table in a near-by restaurant. It seemed more like one large family gathered about the home festal board, and all appeared to approve most heartily of the event, as well as the viands that were so well served, and which disappeared so promptly.

Perhaps the most important action taken at this meeting was the unanimous adoption of a motion that the members of the Chicago Bee-Keepers' Association join the Na-

tional in a body. This added at once the dues of nearly 40 members to the National, and doubtless at least three-fourths of them are new members, so that the National will not only gain in dollars, but will also have its numbers swelled somewhat.

It is the hope of the Chicago Association that every bee-keeper who resides within its territory (say Cook and adjoining counties) will at once send his dollar to Secretary H. F. Moore, Park Ridge, Ill., and request that he be made a member of both organizations. If it is more convenient, the dollar may be sent to the editor of this journal, who will see that Mr. Moore gets it with proper instructions. A receipt will then be mailed by each association.

The arrangement whereby the members of a local association can become members of the National for 50 cents each, when joining in a body (provided the annual dues of the local society are \$1.00), should be the means of increasing the membership in both organizations; and especially should it contribute to an increased interest in the local association. As the writer is mainly responsible for this provision in the new constitution of the National, he naturally desires that it shall prove of much advantage to all concerned, and be used by every local association in the United States. If not mistaken, there are now three local associations that have availed themselves of this new privilege to join the National in a body at half price, viz.: The Wisconsin, the South Dakota, and lastly the Chicago Association.

Co-operation Among Bee-Keepers.—F. E. Brown tells in Gleanings in Bee-Culture how the California bee-keepers are combining to stiffen prices, much in the same way as has already been told of the Colorado association. W. L. Coggshall also urges in the same journal that bee-keepers should combine and fight fire with fire, and shows how combination on the part of purchasers of honey keeps prices down, as follows:

"I knew from the bee-journals I read that the honey-crop was light all over the country. Therefore, early in the season I wrote several letters to the leading bakeries, offering my honey, buckwheat extracted, at 6 cents f. o. b. What was the result? They all wrote me back, offering me 4¾ delivered, saying they were *restricted* to pay only so much (baker's combination or trust, if you please). I tried the same scheme six weeks later. Well, the bakers had found out that the honey market was higher, and they were willing to pay 5 cents a pound. Mind you, the prices were exactly the same at each bakery, and they were *instructed to pay that and no more*. Combination again."

Ten Percent Honey; 90 Percent Fraud.—The following, referring to New York city, appears in Gleanings in Bee-Culture:

"There is a new enterprise started on the East Side in which they are adulterating by the carload honey which will granulate in three days. It has the appearance of and tastes very much like honey; has about 10 percent of the pure article in it. Twelve carloads has been turned out in the last 60 days. It sells for 5½ cents per pound."

Editor Root thinks bee-keepers in the East will do well to turn their attention to comb honey rather than to try to compete with this 5½-cent fraud. He thinks the National Bee-Keepers' Association may do something to stop this villainous work, and considers it a matter of economy for every bee-keeper to become a member. In this last opinion he is undoubtedly correct, whatever may be the kind of honey one produces. A drop in the price of extracted honey can not fail to have *some* influence on the price of comb honey. It is not difficult to believe that a sufficient amount of adulteration like that outlined in the foregoing might reduce the price of comb honey a cent on the pound. Suppose it make a difference of only ½ cent a pound. That makes a

loss of \$1.00 on 200 pounds of honey—enough to pay a year's membership in the National Bee-Keepers' Association. And yet only a comparatively small number have their eyes opened to see that it is a profitable investment to send in that dollar.

Look at what has been done in the past by united action. At the present time the one great foe of bee-keepers is adulteration. The National association can work only as it has "sinews of war." Even with its present small membership it is making itself felt. If you who are not now a member will join, it can do just so much more. Your joining will help to induce others to join. Will you stand idly by, while the battle is being fought, and allow others to pay the cost while you share in the benefits? Is that entirely honorable? True, many honorable men are holding back, but have they correctly weighed what they are doing?

Honey in an Unexpected Place.—Rev. Louis Albert Banks, of Cleveland, Ohio, gave the following incident in the *New Voice* some time ago:

In May, 1898, while one of the volunteers from Dover, Maine, was waiting for the government to call the troops to the front, he went out one afternoon and shot some rabbits. On his return a messenger met him in the doorway and told him he must take the next train for the State capital. As his hunting-coat was wet with the blood of the rabbits, he hung it up on a limb of an apple-tree, remarking that it would be well washed by the time he returned from the war. Upon his return he thought he would try his luck partridge-shooting before settling down to farm-work. The canvas coat was hanging from the limb in the orchard; but when he went to put it on he found that it was already occupied by a swarm of bees, which had taken possession of the garment during his absence. With the aid of a sulphur-smudge fire he expelled the bees and secured 22 pounds of delicious white comb honey.

What are the Best Queens Worth? is a question discussed by W. A. H. Gilstrap, in *Gleanings in Bee-Culture*. He thinks some queens that have been mentioned might produce royal progeny that would raise the average yield per colony 40 pounds, and figures that with 100 colonies such a result would pay the interest on more than \$200. To the objection that such a queen is a freak, not transmitting her desirable qualities, he replies:

"Perhaps Messenger was the greatest desirable freak among horses. His desirable qualities have been intensified by judicious breeding until the world wonders at the result."

Mr. Gilstrap bred from a queen that excelled in an apiary of 100 colonies. The result was a gain in surplus of \$1.00 and \$2.00 per colony, as compared with other colonies. He concludes that the question of hives is a small one compared with the question of stock.

Fool Writers Still Lying.—Mr. E. S. Miles, of Crawford Co., Iowa, sends us the following reprinted in his local newspaper, and credited to the daily *New York Mail and Express*:

FOOL THE BEES AND THE PEOPLE.

"People buy comb honey," said a man from the country, "believing that the fact that it is sealed by the honest little bee precludes the possibility of fraud. The fact is, that the bees of many professional 'honey'-raisers do nothing the livelong summer but pack glucose into their hives from an open barrel that is left standing close by. The bee will not search fragrant flowers the livelong day for a trifling amount of pure honey when it can get glucose. The honey-men see that there is plenty of glucose handy, and instead of one pound of pure honey they aid the bees in putting ten pounds of glucose on the market.

"Human ingenuity has not devised a way for making and sealing the honey-comb, or the bee would be dispensed with altogether. In handling the glucose the bees give it a honeyish flavor, and if you complain to the bee-man that

it is not as sweet and sticky as it should be, he will tell you that it is the early crop, and that the heavy rains make it thin.

"I know a man who keeps 50 hives of bees on the roof of his store in the city, and by hustling up plenty of glucose he gets enough 'honey' out of the buzzing slaves to do a wholesale business in honey. Why, his bees never saw a flower, and would shy at a honeysuckle if they happened to come near one. He will not even let the poor things have a recess to get a drink of water, but keeps a pan of fresh water near the hives for them to drink."

Accompanying the foregoing clipping were these words by Mr. Miles:

MR. YORK:—You have published in times past some queer information (?) about bees, taken from the general newspaper press; I hand you herewith what I think is entitled to the "belt" as the champion lie of the world about bees and honey. It may have been intended only as a "pleasantry" by the writer, but I guess the average editor (not bee-editors) doesn't know enough to think so.

E. S. MILES.

How any self-respecting newspaper can deliberately publish such falsehoods as are contained in the clipping above is more than we can understand. But ten chances to one, should we undertake to show to the editor of the *New York Mail and Express* that one of his reporters had been writing what he (the reporter) knew was only a bunch of lies, that editor would only laugh and call it a fine joke.

The awful degeneracy of the modern daily newspapers is something sad to contemplate. They care not for truth or honor, nor the reputations of men or business interests. We know of nothing else that is so much needed, and of which there seems to be such a limited supply, as honest men—absolutely honest and incorruptible.

Reformed Spelling has attention in the *Inland Printer*, which copies approvingly from the *Dial* an arraignment "of certain eccentric spellings, among which 'thru' and 'program' are typically objectionable examples." That editor takes comfort in the belief that English spelling will not succumb. One smiles at such a belief in the face of the fact that the spelling "programme" is rarely met even now. The *Inland Printer* will no doubt continue to spell the word with nine letters (at least for a time), and as appropriate company also "labour" and "honour."

Per contra, the same paper copies without hostile comment from *Leslie's Weekly* an item headed "Common-Sense in Spelling," which closes as follows:

"Silent letters and fantastic combinations in words impose a useless and wholly unnecessary tax upon the memory and intellect, and they ought to be ruled out of the English language as rapidly as possible. Life is too short and time too precious to be spent in trying to master the absurdities of the spelling-book which have no excuse for existence."

York's Honey Calendar for 1900 is a 16-page pamphlet especially gotten up to create a demand for honey among should-be consumers. The forepart was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample free; 25 copies for 30 cents; 50 for 50 cents; 100 for 90 cents; 250 for \$2.00; 500 for \$3.50. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

Our Wood Binder (or Holder) is made to take all the copies of the *American Bee Journal* for a year. It is sent by mail for 20 cents. Full directions accompany. The *Bee Journals* can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your *Bee Journal* subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it.

To Make Close Joints in Wooden Feeders, it is recommended in Leipziger Bienenzeitung to put a strip of blotting-paper between the parts nailed together.

Dead Bees in Cellar-Wintering.—In Gleanings in Bee-Culture J. L. Anderson gives his estimate of the number of dead bees that will be carried from a cellar in which 100 colonies have wintered, at 60 to 90 quarts, or 3.5 to 9.10 of a quart per colony. He says the number of dead bees in the cellar the past winter has been exceptionally small.

Grading by Pictures.—In Gleanings in Bee-Culture is given a picture of the grading adopted by New York bee-keepers. Three sections are shown, showing respectively the poorest allowed in the three different grades. None of them have any cells sealed next to the wood. Aside from the cells next the wood, the fancy section has 9 unsealed cells, No. 1 has 43, and No. 2 has 68.

Bosnian Bees are now on the market. Bosnia is in southern Austria, and the bees are described in Schles. Imker as very hardy, making successful cleansing flights at lower temperature than other bees. They begin work earlier and close later than other bees, so reaping larger harvests. The workers are smaller than other bees, and gentler than the gentlest Carniolans. But new things do not always live up to their promises.

A Woman's Plan to Avoid Lifting.—Mrs. A. J. Barber is the woman, and she tells about it in Gleanings in Bee-Culture. A little platform big enough to hold a super has casters under it and is put on the wheelbarrow. On this she puts one or more supers and wheels it to the honey-house, where the little platform can be rolled off the wheelbarrow onto a sort of floor in front of the door so made that no lifting is needed to push it right into the honey-house.

Wintering in a Cave.—John F. Millard reports in Gleanings in Bee-Culture the result of wintering 35 colonies of bees in what he considers the best cave in Iowa, said cave being at no point less than 3 feet under the surface of the soil. On putting colonies into the cave, Nov. 4, 1889, the average weight was 57 31-35 pounds. On taking out, April 4, 1890, the average weight was 47 18-35. Average loss during the 5 months' confinement, 10 13-35 pounds. Smallest loss of any one colony, 6¼ pounds. Greatest loss, 15¼ pounds.

Clipping to Mark the Age of Queens is considered advisable by some, if there were no other object in clipping. Without close watching an unclipped queen may be superseded without the knowledge of the bee-keeper. H. Warnke reported in Centralblatt that he had a queen superseded in winter, the young queen taking her wedding flight Feb. 9. Under ordinary circumstances a queen thus superseded out of the usual season would hardly be supposed to be other than the old queen unless there were some special mark such as clipping.

Evergreens as Windbreaks are considered very valuable, by A. I. Root, as a protection for bees. He says in Gleanings in Bee-Culture:

"I would not get evergreens from the woods, even if they were near by, because you can get transplanted trees grown and trained in the nursery so much better and so much cheaper. Trees a foot high cost only \$3.00 per 100. I think our own cost about \$5.00 per 100; they were planted about 20 years ago, and are now almost too large (40 to 50 feet high, and some of them over a foot thru), if anything. We have tried them at different distances. Only one row is necessary if you let the branches come out clear down to the ground, which they will do in a few years.

"The Norway spruce is very hardy, and a very rapid grower. We have not lost one tree in 100, and these would not have been lost had not water been allowed to stand around their roots. Trees 10 feet apart in the row (as ours are) will make a windbreak for bee-hives rather quicker

than if a rod apart; but in a few years, where placed so closely, it will bother you to get thru them if you should happen to want to. One who has not tried it would hardly realize what a difference it makes during a windy time. One can work in comfort when shielded by evergreens, when it would be very tedious if not dangerous to undertake the same kind of work where the wind has full sweep."

Stimulative Feeding is called by the Germans speculative feeding, because it is considered a speculation, and the speculator may lose or gain. Last year Editor Gerstung, of Deutsche Bienenzeitung, got the opinions of 15 able German bee-keepers as to stimulative feeding in spring. They were about equally divided as to its being advisable or otherwise. All were agreed that when practiced it should only be with strong colonies, and in regions where the harvest comes early. The feeding should begin about 6 weeks before the harvest, or about the time of gooseberry bloom. All were agreed that injudicious stimulation might do much harm, and that it was a very good thing for beginners to let alone.

Bottom Starters in Sections.—R. C. Aikin says in the Progressive Bee-Keeper:

"Doolittle said no bottom starters for him. Here again comes in location and methods. If you can crowd your colonies in the sections and keep them so, never letting them have much room ahead, nor yet ever without room; and more, if the honey-flow that is to fill these sections comes freely and work goes steadily on to the close of the flow, and not only so, but comes reasonably rapid, say 3 to 5 pounds daily on the average, then a bottom starter is of little use; but take it in slow and intermittent flows, and bottom starters—or their equivalent by having the full sheet come so close to the bottom that it will be fastened there—is a necessity to obtaining the best shipping sections."

Not Stung to Death by Bees.—The statement that a Mr. Carson owed his death to the stings of bees enraged by burning sulphur is thus contradicted in Gleanings in Bee-Culture by G. E. Martin:

"The facts as told me by a brother-in-law of Mr. Carson are these. Mr. Carson went to his apiary before breakfast, to do some work with his bees. He was stung four times—once on the temple, ear, wrist, and thigh. He went to the house and requested his wife to get a veil, as the bees were cross. In a few moments he said he would go outside, as he felt faint. He went out and sat down on the porch and died there. There was no sulphur burned. Mr. Carson had heart-trouble, which, combined with the stings, upon an empty stomach, the doctor says, was the cause of his death."

Perforated Zinc Against Robbers.—Says G. M. Doolittle in American Bee-Keeper:

"Robber-bees do not like to squeeze thru any hole when there are defenders behind such hole or holes ready to seize them while they are squeezing thru, or immediately after they are thru and while squeezing out again. And for this reason a piece of perforated zinc placed at the front of an 'awning' of wood which juts out from one to two inches from the hive in front of the entrance is an admirable thing to use for the prevention of robbing or to suppress robbing after it has started. As soon as it is placed in front of the entrance, the robbers will all be seen trying to get in where the awning comes up against the hive, rather than out where the perforated metal is; while the loaded robber-bees which are in, and the hive-bees, go out from the perforated metal, and the hive-bees go in there."

The Use of Separators is a topic well considered by R. C. Aikin, in Gleanings in Bee-Culture. For home use, or to sell to families who take a case at a time, there is clearly no need for separators. For the retail trade sections must be nearly of the same weight, and must be so straight that the average grocer's clerk will not set them leaning by lifting them out of a case. In 1889 Mr. Aikin produced 8 tons of section honey so straight and true that not more than 200 of the lot were too bulgy to pack, and he used only two separators in each super of 28 sections. But he has not been able to do the same thing since. Bees, weather, honey-flow, all the conditions must be just right—a thing that may not occur a second time in a lifetime—or separators are indispensable. Even if less honey should be obtained by using separators, a better price will more than repay the loss.

Langstroth on... The Honey-Bee

Revised by Dadant—1899 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the Ameri-

can Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helpt on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.
118 Michigan Street, CHICAGO, ILL.

Rocky Mountain Bee-Plant Seed!

(*Cleome integrifolia*.)

...FREE AS A PREMIUM...

The ABC of Bee-Culture says of it: "This is a beautiful plant for the flower-garden, to say nothing of the honey it produces. It grows from two to three feet in height, and bears large clusters of bright pink flowers. It grows naturally on the Rocky Mountains, and in Colorado, where it is said to furnish large quantities of honey."

We have a few pounds of this Cleome seed, and offer to mail a ¼-pound package as a premium for sending us **ONE NEW** subscriber to the American Bee Journal, with \$1.00; or ¼ pound by mail for 40 cents.

GEORGE W. YORK & CO.

GENERAL ITEMS

Bees Working Nicely.

I bought 5 colonies of bees last spring, and I went to reading the Bee Journal, and I took so much pride in working with and looking at them that I got the bee-fever, so I bought 12 colonies of four persons that were going away. I now have 18 in all.

I am a carpenter by trade, so I live in town and work at my trade.

My bees are all working nicely, bringing in pollen, except two that are queenless. I have sent for two queens for them.

"KEARNEY."

Buffalo Co., Nebr., April 9.

Spraying Caused Loss of Bees.

Our bees have wintered well, and most of them have plenty of honey to carry them thru the spring. Several springs past our bees died off badly in fruit-bloom time, but last spring they did not. It shortened our honey crop materially. One neighbor said he guest he sprayed them. I can't help thinking it was caused by spraying in fruit-bloom time. One spring there were not bees enough to cover the brood. There were lots of brood and bees just hatching out, but scarcely any that could fly.

MRS. L. C. AXTELL.

Warren Co., Ill., April 2.

Prospects Good—Early Breeding.

We are having some spring weather now, and an abundance of rain. The first pollen I noticed March 10, from maple. The winter loss is light thruout this part of the country, I am glad to report. Most colonies have a small amount of brood now. It is too early to predict anything in the way of a honey crop, but indications are seemingly good. White clover was not hurt, I believe. I want to try some sweet clover this year.

I must call one of Mr. Aikin's statements in question, that is, his article on page 132, concerning early breeding. May be it will do for Colorado, but not for Kentucky. I aim to discourage early breeding as much as possible, as far as Nature will allow. I positively agree with Mr. Doolittle on this point. But localities differ, and we must be governed by them.

Prospects are good for an early spring here.

J. WILEY MOUNTJOY.

Anderson Co., Ky.

Rendering Wax—An Experience.

In nearly every copy of the American Bee Journal is an article from some expert bee-keeper, giving his experience and telling what he knows. Now I am going to give my experience and tell what I don't know.

I undertook to render some broken brood-combs, unfinished sections, and pieces of wax, that had accumulated since last season. I hunted up the article written by Mr. Dadant in regard to rendering wax. I found he used sulphuric acid; but also added a caution about using it. So I decided to let the acid go and try using water.

Then I read where some one said, "Use a little soapuds in the pan that is to receive the wax, to prevent it sticking." That had always been the difficulty with me—the cake of wax would stick fast to the pan. Then I thought a man's idea of a "little" must mean an inch deep at least, so I boiled up the wax and took pains to strain it thru two thicknesses of cheese-cloth, as last year when I sold my wax Mr. Rauehufuss said I "should strain it; that there were particles of dirt all thru it;" and in order that it might not all stick to the cloth, I

soapt the cloth also. Now just imagine my surprise when I come to look at my nice cake of yellow wax, to find that it had not hardened, but was a mass of thick, sticky paste! The whole hatch was ruined, and I will caution beginners to use no soap, and then they will take no chances on getting too much.

These experts who tell us how to do the work so nicely, failed to tell us how many failures they made while they were learning.

I am glad to add that I didn't melt all my wax at once, and will try to profit by my own experience in rendering the rest. When I read of mistakes others have made (and there are very few who tell of their mistakes) it makes me feel encouraged to know that I am not the only one, and I feel like trying again.

There are a few things in the apiary that I can do successfully, but I can't render beeswax so it is salable.

Now, I imagine if this appeared in the Bee Journal with my address, I would receive circulars from half the supply houses in the United States, recommending their solar wax-extractor; but what could I do with one now, with 6 inches of snow on the ground? Alas, experience comes high, but is a good investment.

I have read with interest the articles from Messrs. Aikin, "Old Grimes," and always am pleased when an article appears from Doolittle or Dadant; and Dr. Miller's answers to questions are a real treat. I often wonder if he has not the patience of Old Job.

Our bees are doing nicely so far, but the next six weeks will be the hardest on bees here. A little later we will try Mr. Aikin's plan of spreading brood, and if successful I will report—and also if I make a failure of it.

MRS. EMMA WOODMANSEE, Arapahoe Co., Colo., April 9.

Securing Increase Without Surplus.

Bee-keepers here had a good season in 1899. The crop averaged 45 pounds to the colony. I have been here since last March.

I have become nearly blind within the last six months, and as I can not get around to buy any colonies that are for sale, I must rely on increasing the few that I have.

I would like to ask Mr. T. F. Bingham, or some other experienced bee-keeper, to give the best way to secure increase without regard to surplus.

The seasons are backward here in the spring on account of the cool, high winds, and the snow on the mountains. The first alfalfa flow is about June 15. There is not much nectar earlier, as during fruit-bloom the winds and cool weather prevent gathering.

JAMES ANDERSON, Montrose Co., Colo.

A Mississippi Report.

I am home again among the bees after spending the winter trapping.

The home apiary of 97 colonies wintered all right, only 4 having died; at the Mt. Zion apiary 4 miles north, 83 colonies, none were dead; at the Concordia apiary of 77 colonies, 9 were dead. The last apiary came thru better than I expected, as it contained all the weak colonies I had last fall. At the Stokes apiary of 61 colonies, 3 were dead.

Bees are booming now, working on box-alder and elm which are in full bloom, also peach and plum trees. I have bought another apiary of 63 colonies which I shall move nearer home as soon as the roads are settled. I have gone out of the queen-business and will work all my bees for extracted honey.

This Delta valley is one of the best honey-districts in America. There is lots of room for bee-keepers, in a first-class location.

Every colony is in a double-story hive, and on full frames of comb, and not a two-year-old queen in any yard except the last one I bought, so I ought to get some honey this season.

I am trying 3 sizes of hives. In the home

apiary I use 9 frame, in the Mt. Zion apiary 10-frame, and in the Concordia and the Stokes apiaries the 8-frame. If all is well I will write again at the end of the season, when I will tell which of the three sizes is best for this locality, and how much honey I secure from each apiary.

I will give my report for 1892 and 1893 as those are the only seasons that I workt all the yard for honey only: In 1892, from 97 colonies I took 4,800 pounds of extracted honey; in 1893, from the same yard of 113 colonies, 5,200 pounds of extracted.

J. H. SIPLE.

Bolivar Co., Miss., March 25.

All Wintered Well.

November 11, 1899, I put 21 colonies into the cellar, and on April 5 I took them out in fine condition; on the 7th they were carrying in pollen. I raised the hives up one inch from the bottom in front. The previous year I did not raise them thus, and lost 3 colonies, and had considerable mold. This spring there was no mold.

I consider the prospect for honey very good. Clover can't be other than in good condition, unless there is a drouth.

There are not many bees kept around me, and tho I am 70 years old I still like to take care of the bees.

F. HALL.

Fillmore Co., Minn., April 9.

Bee-Keeping Experience—Bee-Trees

My bees are in good condition so far. We have had a fair winter—not nearly so cold as last winter, with very little snow, and no sleighing.

I am 21 years old. I first kept bees in August, 1890. I was herding a drove of cattle, and while sitting in the shade of a tree I heard a noise, and looking up I saw bees flying in and out. The next day I went to look at it again, and found the tree cut. It was a basswood tree, and in a hollow I found some bees and a little honey. I took the bees home, and in about a month they had stored a nice lot of honey. I took it and let the poor bees starve. Of course I didn't know any better, but thought it was all right to rob them the same as I would a bumble-bees' nest.

In 1897 I caught a swarm about two miles from home, and have kept bees ever since. I find a great many bee-trees, and think that it pays to hunt for them. All of them have been well worth cutting, averaging from 75 to 100 pounds of honey. In 1897 I found five trees, in 1898 six, and in 1899 one.

B. F. SCHMIDT.

Clayton Co., Iowa, March 7.

Wintered in Good Condition.

My bees are in pretty good condition so far. I wintered some outdoors in chaff hives of my own invention—a hive especially adapted to the Jumbo order; I use 13 Langstroth frames and contract in winter with division-boards.

E. M. HAYES.

Columbia Co., Wis., April 9.

Honey-Dew and Its Origin.

As the weather is very cold and my 80 colonies of bees are quiet, I will write what I know about the origin of honey-dew in western North Carolina. I have been acquainted with it and its origin for 35 years, and every time it has been produced by an insect of some sort—sometimes a white looking louse at first, then later it has wings and flies away to some other tree where it may lay another lot of eggs. Some of these insects are white, some are dark, and some are a reddish brown. They usually feed on the tender shoots and leaves of the chestnut tree, but the oak and the hickory are not exempt from these honey distillers. They suck the saps from these trees and convert it into sweat nectar, just as the cow does her milk, then the little honey-bee comes along and takes it into the second "still" and carries it to her hive, where she delivers it to one of her sisters for further refinement. This honey-dew is

The Bee-Keeper's Guide

Or, Manual of the Apiary,

—BY—

PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without **THE BEE-KEEPERS' GUIDE.**

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,

118 Michigan Street, CHICAGO, ILL.

not any more filthy than the milk of the cow, for it is produced in the same way.

In the year 1898 we had the most copious yield of this sweet I ever saw. There were not bees enough to gather a hundredth part of it, it being dry and warm thru May and June. The first of July the rains set in and destroyed both the sweet and its producers. Some of these insects produce good honey-dew, while others produce bitter stuff.

This is not guess-work, nor what others say—it is what I have seen and know.

A. J. MCBRIDE.

Watauga Co., N. C., Feb. 18.

Wintered Without Loss.

I put 12 colonies into the cellar last fall and took them out last week without a loss, but some colonies are quite weak. The temperature varied from 35 to 45 degrees. Some of them have young bees, and all have lots of eggs.

For an experiment I took 3 colonies upstairs over the store, and they came thru in good shape. I gave them a flight in January. I had them confined to the hive with a screen in front for ventilation. The temperature varied a great deal—I don't know how much, but nevertheless they came thru all right.

The prospects are not the best in this location for a good honey season. The white clover I am afraid is frozen out, the same as a year ago. There is no basswood nor sweet clover to speak of. **L. J. BERON.**

Dane Co., Wis., April 6.

A Little Bee-Experience.

When only a boy at home in Henry Co., Iowa, we had several colonies of bees in the old-style "gums," and boxes of various kinds and sizes. We got some pretty good honey at times by placing a small box over a hole on top of the hive, but the bulk of it we secured by the robbing system of prying off the cover and cutting out the top part down to the brood, or "taking up" some of the new colonies at the approach of winter.

In the spring of 1876 I came West, and remained almost entirely away from my bees until July, 1897, when, while at work in the field, a swarm of bees past over. I gave a chase, hailing wheat and oats among them, and succeeded in capturing them. I put them in a box 21½ inches long, 17½ inches deep, and 18 inches wide. They did not swarm until June 11, 1898. This was a rousing swarm, and on June 12 another swarm issued, but not so large, tho they filled their 8-frame Langstroth hive and a super besides, and wintered all right; while the prime swarm filled their 8-frame Langstroth hive and a super, but starved out during the winter.

Last summer I took the top off of the hive-box of the old colony, and fit to it a set of slats to support the combs below, the bees attaching the combs to the slats in a few hours. I made the slat work to receive a 10-frame Danzenbaker super. They filled about three supers, and cast a swarm in September that decamped.

I put the bees in a cave the first winter; but since then they have remained on the summer stands. They have an unusual (?) amount of drone-comb; I think I am safe in saying I have killed a half bushel of drones. They were formerly rather dark, but now they are almost as yellow as the golden Italian queen gotten from a queen-breeder in the East. I have somewhere seen it stated that bees become yellower by being inbred, and this colony seems to indicate that the statement is true. I think there are twice as many drones in this one hive as there are in all the other 19 colonies put together, and it seems the chances would favor them in fertilizing queens. I shall try to supersede their queen with one from Dr. C. C. Miller's yard next season, and run them for drones to fertilize as many of the young queens as possible, by keeping drone-comb cut out of the other hives.

I have all the bees in a cave except this

big hive and another old-style "gum" I bought from a neighbor, which is 12 inches square and 22 inches high. They are wintering all right so far. Those in the cave are wintering well with the exception of 4 colonies—one in a Danzenbaker 10-frame hive, which had dwindled away to nothing with plenty of white honey; two in 8-frame dovetailed hives, and one in a box-hive with a late after-swarm. One of the colonies in the dovetailed hives was queenless. I had introduced a yellow queen Oct. 3, from an Indiana breeder, and she had left no signs that she had been successfully introduced. The other had a queen from an Iowa breeder, and no amount of coaxing would induce her to lay after Sept. 15, and on examining them on Jan. 18, there were no signs that she had laid any in the meantime, so far as I could observe. I contracted them to 3 frames, covered them up as warm as possible, put them at the top of the tier of hives in the warmest position I could, and left them until Feb. 24. I then ventured to take a peek at them, and to my surprise they were still living. On March 10, 11 and 12 it was very warm and pleasant, and they all seemed restless, and with the least ray of light were out on the cave floor. So I set them all out in the forenoon of the 10th, and left them out until the forenoon of the 12th, when I put them back. The colony in question was dead.

I have now 13 strong colonies, and 3 which are doubtful. I secured 516 sections of finish honey, and about 50 unfinished sections from 8 colonies, spring count, in 1899.

F. W. HALL.

Sioux Co., Iowa, March 19.

Bees Carrying in Pollen.

I put 92 colonies of bees into the cellar last November, and March 19 I took out 90 live colonies; 4 being rather light I united them, making 2 good colonies, so that I have 88 good, strong colonies, and they are as busy now as I ever saw them, carrying in pollen from soft maple. The weather is all that could be desired, being warm and dry without wind. I have my bees well protected by groves, fruit-trees, blackberry and raspberry vines, on a southern slope open to the sun.

P. G. ABBOTT.

Benton Co., Iowa, April 5.

Methods of Wintering Bees.

My bees have come thru the winter strong, without the loss of a colony. This is my third winter without any loss. I have read all of the books on wintering, and also the experience of hundreds, and the nearer they approach to my plan the more successful they have been. It is safe and sure.

Make your hives like a refrigerator—insuring dry air circulation—and the bees will winter in any climate upon the summer stands. Arranged in this manner the dampness from their breath is all carried above, and, coming in contact with the cold air, is condensate, and remains above the bees. When the mercury runs down to 12 degrees above zero and below, this upper chamber will be filled with frost; without this circulating arrangement, with a low thermometer, the hive would be filled with frost, the bees could not go outside the brood-nest, and would perish with plenty of honey. Any hive can be arranged with this dry-air circulation—even a box-hive. Yet a hive arranged or made expressly will give the best results.

Newman, in his "Bees and Honey," page 141, says: "Disguise the fact as we may, until some method for wintering is devised—that is, a method which will prove as safe and certain for a medium weak colony as a strong one; which will at all times give bees access to their stores let them be in what part of the hive they may; that will be as safe in a long inclement winter, etc.—until then, the success attending bee-keeping will be more or less a matter of chance."

With this arrangement I go contrary to the advice of all experts. The "ABC of Bee-Culture" and all others say, leave the hive open one inch at the bottom. I close

mine tight, or nearly so, with a storm shed or entrance. What would you think of a man who would build an extra-warm house, make a good fire on a cold day, and then leave an outside door open? This states the case exactly. The bees creating the warmth represent the fire—why not keep it warm? Besides, when you open the hive at the bottom you stop the upward circulation. Try your refrigerator—open the door of the provision-chamber and quickly place your hand under the opening in the ice-box and you can feel the current of air downward, and the current soon ceases on account of the door being open.

Others advise packing the bees in the fall for winter and then let them severely alone. To this I say no, arrange them so that you can examine them at any time during the coldest weather; you know then their exact condition at all times, and they will not be left to starve and die unattended.

D. H. METCALF.

Calhoun Co., Mich., April 3.

**100 Cards and Card-Case
—FREE—**

We have arranged to mail a neat vest-pocket Aluminum Card-Case with 100 printed Business or Visiting Cards—all for sending us ONE NEW SUBSCRIBER to the American Bee Journal for a year at \$1.00. This is indeed a rare offer. You can have anything you wish printed on one side of the card. Your name

alone will be engraved on the Aluminum Case. It is something that everybody ought to have. Be sure to write very plainly what you want printed on the cards, and also the name for the case.

We will mail the cards and case for 50 cents, when wanted without sending a new subscriber, or will club them with the Bee Journal for one year—all for \$1.40.

Yellow Sweet Clover Seed

WE HAVE IT AT LAST!

We have finally succeeded in getting a SMALL quantity of the seed of the YELLOW variety of sweet clover. This kind blooms from two to four weeks earlier than the common or white variety of sweet clover. It also grows much shorter, only about two feet in height. It is as much visited by the bees as the white, and usually comes into bloom ahead of white clover and basswood. We offer the seed as a premium

A QUARTER POUND FOR SENDING ONE NEW SUBSCRIPTION.

So long as it lasts, we will mail a quarter pound of the seed to a regular paid-up subscriber who sends us ONE NEW subscriber for the American Bee Journal one year, with \$1.00; or ¼ pound by mail for 30 cents.

We have been trying for years to secure this seed, and finally succeeded in getting it. It is new seed, gathered last season by an old personal friend of ours, so we know it is all right. But we have only a small supply. When nearly out we will mention it.

GEORGE W. YORK & CO.,
118 Michigan St., - CHICAGO, ILL.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, April 9.—There is very little trade in honey of any kind. This is usual at this time of the year, and stocks are well reduced, so that for fancy white comb of the coming crop a good demand should exist. Best white comb now sells at 15@16c, with ambers and dark difficult to dispose of at 3@7c per pound less. Extracted, white, 7½@8c; ambers and dark, 6@7½c. Beeswax firm at 28c. R. A. BURNETT & Co.

CINCINNATI, March 3.—There is some demand for extracted honey from manufacturers at 7@7½c for amber and Southern; clover, 8@8½c. Comb honey is selling firm at 14@16½c in a small way. Beeswax, 25@27c.

C. H. W. WEBER,
Successor to Chas. F. Muth & Son and A. Muth.

BOSTON, March 9.—Our honey market is showing some signs of lower prices, altho the stock on hand is not large. At the same time prices are so much higher than previous years that the trade have taken it very slowly and the results are that the holders are willing to range prices quite a little in order to move stock on hand. Prices range: Fancy white, 17@18c; No. 1, 15@16c; amber, 10@12c; buckwheat almost unsalable. Extracted, best white California, 8½c. BLAKE, SCOTT & LEE.

KANSAS CITY, Mar. 10.—We quote fancy white comb, 15c; No. 1, 14c; No. 1 amber, 13c; No. 2 amber, 13½c. Extracted, white, 8c; amber, 7c; dark, 6c. Beeswax, 22@25c

C. C. CLEMONS & Co.

DETROIT, Feb. 10.—Fancy white comb, 15@16c; No. 1, white, 13@14c; fancy amber, 11@12c; dark and undesirable lots, 8@10c. Extracted, white, 7@7½c; amber and dark, 5@6c. Beeswax, 25@26c. Supply of honey fair with light demand.

M. H. HUNT & SON.

BUFFALO, March 3.—Market nearly bare of all grades of honey. Probably no more from any source to market, but if so, fancy white comb is firm at 15@16c. Other grades from 14c downward, with the poorest at 8@9c. Fancy pure beeswax continues at 28@30c.

BATTERSON & Co.

NEW YORK, April 9.—Market is practically bare of comb honey of all description. Little lots arrive here and there and sell readily at from 10@11c for buckwheat and 12@15c for white, according to quality and style of package. The market is well supplied with extracted, which we think, however, will be moved before the new crop arrives. Beeswax is in good demand at from 27c to 29c per pound.

HILDKETH & SEGELKEN.

SAN FRANCISCO, Apr. 4.—White comb, 11½@12½c; amber, 8@10c. Extracted, white, 7½@8c. Light amber, 7@7½c; amber, 5@5½c; Beeswax, 26@27c.

Very little doing in this line, not only on account of limited demand, but also owing to holdings being too small to admit of anything like wholesale operations. Recent transfers of a small jobbing character are at figures showing values to be practically unchanged.

OMAHA, Mar. 13.—Demand shows some improvement in January, having been much more active, but as anticipated there is no advance in prices. Market remains steady at 14@14½c for fancy white comb and 8½c for white extracted. The latter is pretty well cleaned up along the Missouri River, and it looks as if there would be some shortage before another crop comes in. From present appearances there is about enough comb honey to go around at the present prices, hence we look for no particular change in values.

PEYCKE BROS.

Convention Notices.

DR. MILLER'S Honey Queens

One Untested Queen Free as a Premium for sending ONE New Subscriber to the American Bee Journal for one year.

We have been fortunate in making an arrangement with DR. C. C. MILLER—the well-known honey-specialist—to rear queens EXCLUSIVELY FOR US DURING THE

SEASON OF 1900. These Queens will be mailed in rotation, beginning about June 1, so "first come first served." We are ready to book orders now.

The Queens Dr. Miller will send out on our orders will be precisely the same as those he rears for his own use, so of course they will be from his best stock. His best colony in 1899 had a queen reared in 1898; May 5, 1899, it had brood in 4 frames, and he gave it at that time a frame of brood without bees. It had no other help, but May 25 a frame of brood with adhering bees was taken from it, and the same thing was repeated June 3, leaving it at that time 5 frames of brood. It stored 178 sections of honey, weighing 159 pounds (and that after July 20, in a poor season), being 2½ times the average yield of all his colonies. A point of importance is the fact this colony did not swarm, and an inspection every week or 10 days showed that at no time during the entire season was there even so much as an egg in a queen-cell. Dr. Miller expects to rear queens from this one during the coming summer.

The demand nowadays is for BEES THAT GET THE HONEY when there is any to get, and Dr. Miller has such bees. You will want to have a queen from his best, we are sure, even if she is not pure Italian.

Do not send any orders to Dr. Miller, as all orders MUST come thru us, according to our agreement.

Remember, send us \$1.00 for ONE NEW SUBSCRIBER to the American Bee Journal for one year, and YOU will get ONE OF DR. MILLER'S UNTESTED HONEY-QUEENS FREE AS A PREMIUM. This offer is made ONLY to our present regular subscribers. Orders for queens to be filled in rotation, beginning about June 1st.

Address all orders to GEORGE W. YORK & CO., 118 Michigan Street, CHICAGO, ILL.

CONTRIBUTED ARTICLES

A Satisfactory Shed Apiary in Nebraska.

BY WM. STOLLEY.

MANY years ago a picture of my apiary was reproduced in the American Bee Journal, but it was not anything like the most excellent pictures nowadays brought to view in the "Old Reliable."

The photograph of my apiary shown herewith was taken in August, and gives a view from the northwest side. The building shown in the rear is the workshop and honey-house. In front, to the left, is a winter vault with six colonies in the New Heddon hives for comb-honey production. This picture was taken by a friend (a preacher) who visited me at the time, and who brought his camera along. The one with the white vest is the preacher, the lady is his wife, and the other fellow is myself.

The middle section of the shed is 30 feet in length, fronting due east. The right hand wing, also 30 feet in

length, fronts somewhat to the northeast, and the left hand wing of 30 feet in length fronts to the southeast.

I aim to restrict the number of colonies in my apiary to 30, or even a less number, *which are always in the lower row.* The upper row is manipulated at the proper time for the rearing of queens for my own use only. For this purpose I have single-walled hives carrying only eight combs, while 15 of those in the lower tier carry 11 frames each, and the other 15 have 14 frames each. The combs in the brood-chamber are 11½ x 11½ inches clear within the frames, and all surplus combs for extracting are half the depth of the brood-combs. All hives are provided with two supers, and everything about them is interchangeable.

The 30 hives occupied by bees, as seen in the lower tier, are double walled, but not chaff packed in summer. All hives are well painted with different colors, and are numbered from 1 to 30, on movable zinc plates.

I never move or change the position of the double-walled hives in the lower tier, and aim to retain queens on their stand as long as they are allowed to do service.

All my queens are kept clipped, and only in exceptional cases do I allow queens to do service longer than two years.

I rear my queens from the four best colonies in the apiary, using two colonies for rearing queens, and two other colonies of different strains for drone rearing. By following up of this method for about 12 years I have improved my stock greatly. Every other year I aim to get new blood

Mr. Wm. Stolley and His Shed Apiary, located in Hall County, Nebraska.

infused, by getting queens from reliable dealers, but they are well tested before they are accepted by me as breeders.

I would buy a few of the best queens obtainable every year if it were not for the fear of thus introducing foul brood into my apiary. All my queens are reared when the colony is under the swarming-impulse, and only choice cells are selected for rearing queens.

The superseding of queens, and the culling out of old queens, are attended to as much as practicable early, and before the closing of the fall honey-flow.

I never extract from the brood-chamber, but after contracting for wintering I preserve all honey-filled combs of the brood-chamber not needed for wintering, by storing them in the empty hives in the tier above, to be returned the following spring wherever needed.

When arranging for winter I contract the brood-chamber to 7 or 8 combs, and give side-packing in all large hives. This is followed up by putting on three cross pieces, answering in effect to the Hill's device, when a clean burlap sheet is spread over all, and a super put on. This done, a good woolen quilt is tucked down in the super, followed by a bag filled with dry oats-chaff of about five to six inches in thickness, when a cover finishes the packing. In winter I leave the entrance wide open, but fasten to each entrance a strip of lath, arranged so as to prevent mice from getting into the hives.

Two or three times during the winter (on a very warm day, and when the bees are flying) I take out all top packing for drying, and replace it while it is yet warm.

My bee-shed is about 8 feet wide, thus affording a passage in the rear of the row of hives of 4 feet, and the roof in front overlaps 2 feet. Were I to build a new shed, I would give two additional feet in the rear, and thus make the structure 10 feet wide.

The 30 double-walled hives in the lower tier were all hand-made by myself, as long ago as 18 to 20 years, and they are to-day as good as new.

The four hives seen on top of the bee-shed are so-called "cottage hives," and carry the same frame as all the rest of my hives. They were a patent concern 20 years ago, and while they are very good for wintering bees in, they are no good for the production of honey. I have put them on top of the shed as an ornament, and to get rid of them, and also to catch occasionally a runaway swarm.

In front of the apiary, about 20 feet wide, the ground is covered with fine gravel, and is kept entirely clear of weeds and grass; adjoining this is a blue-grass lawn about 36 feet wide, kept well trimmed with a lawn-mower.

The bees have free flights towards the south, east, and northeast, over low-growing shrubbery and black-locust trees. On the west and north a dense artificial park of 30 acres protects the apiary against high winds in winter and early spring.

The workshop and honey-house referred to before is about 30 feet from the right-hand wing of the bee-shed, and is 18x28 feet.

A sun wax-extractor and watering-trough of my own construction, tho not shown in the picture, are usually kept in front of the apiary.

For bee-keeping carried on as a side-issue and hobby I consider a bee-shed, such as I have, a very practical and convenient thing, as well in winter as in summer, and the success I have had with my bees proves it so. Of course, for hundreds of colonies it very likely would be too expensive to build sheds of this kind. Hall Co., Nebr.

Does Mixing Races of Bees Cause Bee-Diarrhea?

BY G. M. DOOLITTLE.

THE following, taken from among my multitude of correspondence, shows a novel idea regarding bee-diarrhea:

"During the past two or three years I have been purchasing queens from different parties, so that I now have a mixt race of bees, and this winter and spring my bees are having the diarrhea to quite a large extent, while heretofore it was a rare thing that any colony was affected in this way. Therefore, I conclude that mixing the races of bees brings about a state of affairs which tend toward bee-diarrhea. From what I can gather from old bee-keepers years ago, when there were only German bees in this country, bee-diarrhea was a thing not known."

If I mistake not, this idea has been advanced before, but there are some things which stand in the way of such a theory being accepted as truth, and the first is the assertion that years ago when there were only black or German bees in this country, bee-diarrhea was unknown. If any person will turn to pages 287 to 292 of Quinby's "Mysteries of

Bee-Keeping Explained," 1865 edition, he will find there a conversation (between Mr. Quinby and a bee-keeper to whom Mr. Q. went with a neighbor, the purpose being that of buying some colonies for the neighbor) which shows that Mr. Quinby was perfectly familiar with what is now called "bee-diarrhea," but then called "dysentery." And this conversation took place before there were even any Italian bees in this country, to say nothing about the Cyprians, Syrians, Carniolans, etc.

No, this is not chargeable to the mixing of the different races of bees, and, in fact, I doubt if chargeable to any one thing more than to the ignorance of the "fathers" regarding the matter of bee-diarrhea, for in that conversation of the man with Mr. Quinby, it is conclusively proven that he (the man) did not know anything about dysentery, altho he had lost heavily from this disease (if it may be so called) the winter before Mr. Quinby's visit to him.

If the disease is any more prevalent now than in the 50's and 60's, the difference could be easily explained thru the fact that the country was more protected then from the fierce winds we now have, by the abundant forests then in existence, but now cut down to give place to the "onward march of civilization."

When I was a boy, and bees were kept by my father, from 40 to 45 years ago, the woods came close around our dwelling, and the bees could fly every time the sun broke thru the clouds, when the mercury reacht 45 degrees or above. But now everything is different; for four times out of five, when the temperature reaches that degree at the present time, during the three winter months and the first one of spring, the wind blows so hard that no good flight can be had, and the little that is done is at a great loss in numbers in comparison to those which fly. And so the bees suffer on, or die, as the case may be, and the cause is ascribed to the mixing of the different races of bees.

From careful watching for the past 25 years I am confident that the trouble known as diarrhea in bees is caused by confinement beyond the endurance of the colony. The trouble is wholly incident to a continuation of weather unsuited for the flight of the bees, and is more a question of frequent flights, or no flights for months in succession, than of a disease. Many things may conspire to shorten or lengthen the struggle for existence, such as bad food, dampness, weak constitution, etc. Any of these may make the struggle short, and the reverse of these may vary all the way from successful wintering to a long, tedious hanging on to a life that ends in "spring dwindling," or a barely building up for another winter, only to try the same thing over again.

With no return of balmy weather, and no chance of voiding the feces outside of the hives, the end must come sooner or later, and for these reasons I do not see how the word "disease" can be made to apply fully to this case.

COMBS FOR EXTRACTING PURPOSES.

A card from one who says he is a reader of the American Bee Journal lies before me, and on it is the following:

"Which is the best and cheapest way, all things considered, to obtain extra combs for extracting purposes? Heretofore I have workt my apiary for comb honey, so I have no extra combs on hand. I now think of working for extracted honey the coming season."

With the above circumstances I think I should buy comb foundation, putting it into wired frames. I could never make the bees do satisfactory work for me building comb in upper stories, altho I think that where working for comb honey there is greater success in allowing the bees to build their own combs, where an apiary is workt on the swarming plan.

The trouble in trying to have combs built in upper stories lies in the fact that too large a proportion of the comb will be built of the drone size of cells, hence it can not be transferred to the lower story of the hive without producing a host of useles drones as consumers of the honey gathered by the workers.

Looking toward the best results, I would suggest that a few of the stronger colonies be supplied with frames of foundation, two or three weeks before the honey harvest arrives, and fed sugar syrup if you have no inferior honey, feeding quite liberally, so they will work to good advantage drawing out the foundation into combs, and thus you will have some combs to use in the upper stories to alternate with the foundation necessary to fill out the hive. In this way the bees will not have any excuse for idling in waiting for the foundation to be drawn out when the honey-flow is upon them.

For this purpose of feeding to have foundation drawn

out, a cheap grade of sugar can be used; and if you have any inferior honey it can be profitably disposed of in this way.

Now allow a word of suggestion: If you have never worked for extracted honey, would it not be well to devote one-half or less of your apiary for that purpose, working the rest for comb honey as formerly? If you have made a success in producing comb honey, it does not certainly prove that you will be equally successful with extracted honey, altho the prospects may point that way. And should you be successful there is a possibility that you may not like this part of bee-keeping as well as the other, therefore it might be the part of discretion to go a little slow until sure that the new enterprise will be just the thing desired. Many a man has rushed into some new thing, devoting his whole time to it, when, at the end of a year or two he has left it at much loss, because he did not stick to his old business, and enter the new gradually until he became satisfied that the new was more to his profit and liking than the old.

Winter Temperature of a Bee-Cave in Manitoba —Making Straw Skeps or Hives.

BY J. GATLEY.

I OFTEN wonder why bee-writers maintain that it is necessary to keep a bee-cellar at 40 to 45 degrees. Mine never gets above 30 degrees from the middle of November to the middle of March or later. This winter is the warmest for about 10 years, and the temperature has been from 20 to 28 degrees, one day up to 30, and the bees all doing well. Last winter it was from 14 to 28 degrees, and every colony (28 of them) came thru all right, with no dysentery.

Last year some one asked how to make a straw skep or hive, so I enclose instructions with illustration.

Manitoba, Canada, Feb. 26.

[The straw skep or hive matter referred to by Mr. Gatley is as follows, having been taken from some book on bee-keeping.—EDITOR.]

THE IMPROVED STRAW HIVE.

This is the best form of straw hive that can be used; it is made flat on the top, with hole in center, to receive a super. A rim of wood is worked on to the bottom of the stock-hive to preserve the straw, which so very soon rots if allowed to come in direct contact with the floor-board.

Straw hives require some cover, and perhaps the common straw-thatch cover is as good as any, as shown in

illustration; it should be so made as to fit the hive with or without the super. The great objection to straw hives is their extremely perishable nature, and their disposition to harbor vermin, and also the great difficulty in getting them made sufficiently large in size or correct in shape.

There is little difficulty in making a straw hive, as may be seen by the illustration. Provide yourself with some clean straw, and for this purpose the less it has been bruised the better; also a funnel, something in the shape of a cow's horn, for the purpose of drawing and gauging the straw;

lastly, 10 or 15 yards of split cane or split briar, to bind the straw and work one rim to the other, as shown in the illustration. The cane or briar strips are pointed at one end, to enable it to be pushed thru the several bands. A little experience and practice is all that is necessary.

NO. 6.—COMB HONEY PRODUCTION.

About Supers, Separators and Comb Foundation.

BY R. C. AIKIN.

I SHALL not advocate any particular kind of super, for there are many kinds in use, and liked by their owners; but there are a few things about the super that I will insist upon. Provide every super with full separators. Do not tell me you can produce nice enough honey without separators. For your own use, and also for your neighbors who come and buy 5, 10 or 20 sections at a time for their use, separators are not of much value; but if you produce for the retail store, separators are necessary.

It is common custom for people to buy things by littles, a pound each of coffee, butter, and honey, or at most two or three pounds. To meet this custom you must have even-weight sections, approximately. Not only must they be even weight, but they must not be bulged or crooked, protruding beyond the wood. Just as sure as the honey is out beyond the wood, just so surely will some of them be broken and leaking, for even experts in handling honey will damage many when not within the wood. I know that you can have sections so that most of them can be cased by putting in the case as they were in the super, but, after they leave your hands, about the next fellow that handles them does not so place them, then there is a disgusted retailer or consumer, or both, and you lose trade.

I will tell you when you can get fairly straight sections and when not. You can when you have a colony that does not swarm (or for other reason maintains much strength), and a good honey-flow comes, together with the use of full sheets of foundation. Yes, the strong colony and a good flow will often do it with starters only. It may also be accomplished by a careful giving of a very few sections at a time, just so the colony is crowded. The prime factor in this is a very free flow, and continuous. Slow, intermittent and light flows are almost sure to give bulged sections, and if the colony be weak, or the weather cool, or the work should by any cause be interrupted and start again, you will have irregular combs. Control all these things, and you will have fair success; but you can not control all.

Comb honey to be retailed by the piece, or two or three pieces at a time, must be produced between separators. Use separators wide enough to come within 1/4 inch of the top and bottom of the sections, never narrower than this. Produce sections holding an honest pound, too, but never think you can produce a section that will sell for a certain price—prices are always changing, and you can not produce to sell for just so much money—it is a waste of time to try it. A pound, full pound, is a small enough piece of honey for anybody to buy, and the talk of a scant weight is all foolishness.

Suppose I have a horse that jumps my pasture fence, shall I break him by building two fences, or even three or more? The additional fences are but a practice-ground in which he cultivates his jumping capacity. When we get this light-weight section business simmered down to where it really and truly belongs, it is that the producer, wholesaler or the retailer may get an advantage somewhere. That is the essence of the matter, even if many good and honest men have honestly supported the idea. When we produced full pounds some got to putting out "shorts," thereby getting an advantage over the other fellows.

It is the plainest kind of reason that I can sell 3/4 of a pound at a greater profit than you can sell your full pound when we get the same price per case, and if we look into the matter we will find that this is at the bottom of the whole light-weight fad—selfishness pure and simple. I defy any one to come into print and attempt to prove me wrong in this. Where will we stop? Some fellow will drop again to a lower point, and to lower still when the masses have followed, until—until—well, it is all plain. Why cultivate our depravity by seeking methods to take advantage? A square, honest forging thru the mire of corruption is the true principle, not dodging behind some questionable shift.

The use of foundation is somewhat of an evil—a thing to be avoided if we could do so; but like many other things,

we may have to put up with it till we can do better. Under some conditions foundation is thinned and worked out by the bees till it is almost like natural comb, but there is a whole lot left so that the foundation base is very noticeable. I suspect that even natural comb varies considerable, owing to conditions; but there is quite a difference between wax as it comes fresh from the bee and that which has been melted and worked. The fresh product is more of a light, loose, flaky nature, the melted wax more compact and close-grained. The more the bee works over the wax of the foundation the more it is like the original, yet never wholly like it.

But can we avoid the foundation? Let your thoughts go back to what I have said about necessity of strong colonies for good section-work. Recall that a weak colony can not always keep up enough heat to properly *manipulate* wax, and that therefore they will of necessity put it into the comb more in chunks. That temperature does affect comb-building is a commonly accepted idea. Think of the effect of bait-combs—a thing generally conceded of great value, particularly in getting the bees into the super. Comb foundation acts much as a bait-comb; a colony having full sheets of foundation will take to supers more freely than if starters only are used. Going to the supers they crowd the brood-chambers less, relieving pressure both of bees and honey. A large force in the super means a better quality of work done, both in good workmanship in comb construction, either new thruout or from foundation.

Since the foundation acts as bait-combs, and so helps in the control of swarming, and in getting better and more super-work, it seems that we will have to sacrifice a little in the quality of our comb honey, and use the full sheets of foundation. Then, too, the shipping qualities of a section are improved by foundation. While the colony may thin foundation—they do usually thin it some—it never is quite so frail as the all-new comb, and also it enables us to get better attachment to the wood, making *much* stronger sections. Full sheets give us a neater finish than can be had with the same strength of colony and flow when new comb is built. It seems, then, that we will have to use foundation.

Bottom starters also should be used, serving two purposes: They secure stronger sections for shipment, and more even filling and weight. This bottom-starter business is like the separator question—it is possible to get good attachments without them, but in unfavorable conditions we are able to get better with them. The thing to recommend for common practice is not that which gives good results under the most favorable conditions, but that which succeeds in ordinary hands and under ordinary or poor conditions. It is poor policy to adopt that which will succeed only in the best of seasons, and in the hands of an expert. That which will do well in an average season will do proportionately better in the good years.

Another thing about the super is important, and that is, that it shall be covered with a bee-space above the sections. With those weak colonies that will store only a very few pounds in sections, a quilt held down *tight* on top of the sections will do; but where supers are tiered up—and they will and should be with strong colonies in good flows—there should always be a space above the sections as below them, for a quilt laid on with its own weight only will be pushed up, and propolis put in around the openings on top of the sections, till it is a perfect nuisance.

Pull the quilt from the top of a super and put another super over it without cleaning the propolis from it, and the bees will smear the stuff over the section tops and on comb-surfaces and make a bad muss. Have a space in the super top and cover with a board. Larimer Co., Colo.

Laying Workers—How to Get Rid of Them.

BY F. A. SNELL.

LAYING workers are occasionally found in colonies that have been queenless for some time, or until the numbers are much reduced. These workers are capable of laying eggs that will produce drones only. The eggs and the developing drones are cared for with a full degree of tenderness by the bees, and they seem to be satisfied with their condition. This fact has rendered these laying workers a great nuisance and annoyance to bee-keepers new in the pursuit, especially. Many a valuable queen has been sacrificed by their owner in an effort to requeen such colonies, or, more properly, remnants of such.

The trouble with many apiarists has been realized that the bees are so devoted to the laying workers that the good

queen given is considered an intruder, and is destroyed. Many of us have seen this demonstrated in our earlier years of bee-keeping.

Quite a number of years ago the plan of carrying the bees with their combs some distance from their hives and throwing them from their combs and then returning the combs to the hive was practiced, the bees returning, minus the laying worker, to their hive. It was claimed by the advocates of the plan that the laying workers would not know her way back, and be lost, and that then a queen would be accepted. The plan did not at all times work, from the fact that the laying worker had not forgotten her location since last leaving the hive in search of honey.

The plan I hit upon some years ago was to unite these colonies with nuclei or full colonies having queens and brood. When convenient the bees are united with their combs, the bees being put at all times in the hive with the queen. I like this plan better than shaking the bees from the queenless colony at the hive-entrance of the one having the queen, as some at least will return to their old location; while with the other plan I have noticed none to do so. I have practiced the preferred plan for 20 years or more, and have never lost a queen in so doing, and can recommend it to others whose methods have not proved satisfactory, or to the beginner who has not had experience along this line. This method is very easy, and the work quickly done.

I have advised the plan above outlined to be practiced by bee-keepers I have met that had trouble with other ways, and success has been reported with some at least, as they so informed me. The plan is so easy to follow that I believe about every one who will try can succeed with it.

Some one may argue that the bees in the colony having the laying worker are old, and not of much value—not worth the time spent in saving them. That depends largely upon the time of year and the honey-flow at the time. During early summer and a good bloom one or two quarts of old bees will do a good work, and can, with a few young bees, and even one frame of brood, be built into a strong colony by fall, yes, and sometimes do give some surplus besides. These little things must be looked after to meet with the best success possible in our pursuit, or any other in fact.

If one has reason to suspect that a colony is queenless, that colony should be examined at the earliest opportunity, and, if found so, do the work advised herein. Queenless colonies should not be allowed to remain such. As they become weak in numbers, they are almost sure to fall a prey to robbers—a thing to be avoided. Robbing thus started by the careless apiarist at once demoralizes an apiary, and may be carried to weaker colonies, nuclei, etc., to the annoyance and loss of their owner.

Carroll Co., Ill.

Management of the Shallow Divisible-Brood-Chamber Box-Hive.

BY C. DAVENPORT.

IN using the hives described in my last article, on page 179, there are different methods to be practiced, depending upon the results sought, as to whether increase is desired at the expense of the surplus crop, or whether the best possible results in surplus are the object regardless of increase. But in running for comb honey, if it is a fair season it is impossible to prevent some increase for the time being, unless such an amount of drawn comb is allowed for the queen to lay in and range around on that a fair crop of section honey is out of the question. If swarming occurs, and at the end of the season it is desired to unite colonies in order to reduce the number to be wintered, on account of these hives possessing the tiering-up feature, it is fully as easy to unite colonies in them with others in the same kind of hives, or with colonies in frame hives, as it would be if all frame hives were used.

Here in the North, with our short season, I think there is no question but what when natural swarms issue, or, what is practically the same thing, when artificial swarms are made on account of colonies getting the swarming fever just before or during the main flow, but what more surplus can be obtained if the working-force is kept together as much as possible, and the queen of the swarm allowed but a limited space during the flow, for here, if a colony swarms it is the swarm we must depend upon for surplus from the white honey-flow, and if running for comb honey we want the surplus in sections instead of in the brood-nest. By limited space I mean one story of a divisible hive, the same size otherwise as the 8-frame hive, but only 6 or 7 inches

deep. If more room is allowed where there is but a short flow, it decreases the amount of surplus; it might then, by some, be naturally supposed that if the queen was still more confined the results in surplus would be larger yet, but as a rule my experience has been that such is not the case. A colony that has a strong force of both field and house or nurse bees seems to work more willingly, and accomplishes more and better actual results in comb honey if their queen is allowed about the space mentioned, than when she is confined to less room, or caged.

There are a number of methods of keeping or throwing nearly the entire working-force with the swarm, but they are so well known that it is not necessary for me to take space to explain them. I often hive two artificial swarms, and throw most of the working-force of the two colonies into one hive, allowing only one section of these box-hives for a brood-nest, and the number of sections these allied forces will fill in a good season is astonishing; but their force rapidly decreases, so that at the end of the white flow they will often be but a small colony, most of the force having sacrificed their lives in filling super after super of white honey in order to satisfy the greed of their owner, or perhaps a greed of their own.

During the season of 1895 I took off 19 filled supers from one of these shallow brood-chambers. It was the product of three swarms—two were hived together, and another put in with them some time later. This was all white honey, and not a dozen sections in the lot but what would grade No. 1. That season, however, we had, with one exception, the best white flow that there has been here in my time.

If a range is fully stocked, and it is desired to reduce the number of colonies for winter by uniting, the best time to unite is at the end of the white flow; this gives strong colonies for the fall flow, and if plenty of brood-chamber room is given during this fall flow, it insures strong colonies for winter, and some seasons considerable surplus, when any surplus from the fall flow is secured here. I invariably get much more when I unite at the close of the white harvest, if (which is usually the case) I have enough colonies in one yard to stock fully its range. This is owing to the reason that here a range well stocked during the forepart of the season will be somewhat overstocked during the fall flow even with the same number of colonies.

But if increase is desired when using these hives in localities where there is a fall flow, another section can be added to the brood-chamber at the close of the white flow. My practice with these hives usually is to unite at the close of the white harvest what bees there are left in each section, with the weakest colonies in frame hives, and then any honey these shallow hives may contain is used for fall or spring feeding. The combs are rendered into wax.

Colonies wintered in two sections of these hives are allowed to occupy both sections until the commencement of the main flow, then the section containing the least brood is removed, and surplus cases put on. It is an easy matter to get practically all the bees out of one of these sections.

If I wish to get them out of the upper section the cover is removed, then as many of the bees as will go readily are driven with smoke into the lower story. The upper section is then set on end on top of the lower story, and strong volumes of smoke from a cold-blast smoker are driven between all the combs, and it takes the bees left but a short time to decide to come out. A section can be cleared of bees in this way more quickly and more easily than a frame hive can by taking the frames out and shaking and brushing the bees off. If it is the lower story that is to be cleared it is reversed, or put on top, before beginning operations. The removed sections that contain brood can be profitably used to strengthen weak colonies, if there are any such in the yard, or with a queen and a few bees a new colony can be formed with them.

There are different ways in which the queen in these hives can be found, one of which I will describe. If the hive is in two sections, a good volume of smoke is driven in at the entrance, and at the same time the lower section is rapt with a stick, first on one side then on the other, for a minute or two. This on an average of nine times in ten will drive the queen into the upper story. This upper story is now carefully lifted off, and a queen-excluding honey-board placed over the top of the lower section. (An all-zinc board is much better for this purpose than a wood-zinc.) On top of the queen-excluder an empty super is placed; the removed section is then placed on top of it, and what bees will go are smoked down into the super, where they pass thru the zinc into the lower section. If the queen is not now found on the zinc, the upper section is set on end on top of the

super, and such a volume of cold-blast smoke is driven between the combs that the bees crawl out and are brushed down into the super below. If the queen can not now be found on top of the zinc, the lower story is set to one side, bottom-board and all, and the upper story set in its place on a new bottom-board, the queen-excluder and super placed on top, and the lower story treated the same as the upper one was, when, if the queen can not be found on the zinc, she must have fallen off while the sections were being handled, and, if care has been taken not to step on her, she will be found near with a small cluster of bees, for there is no danger of her taking wing unless the colony was just about ready to swarm. If a colony is in only one section, an empty one is placed under it, and the one then treated as the upper one was.

Some may think that if the queen was not readily found so that the full operation described had to be performed, so much smoke as it would subject the bees to might injure them. There is no danger whatever of this if a cold-blast smoke is used; on the contrary, I have often thought that a colony worked with more vim and energy after a thoro overhauling with cold smoke. Unless care is used, tho, a colony may be greatly injured with a hot-blast smoker.

Southern Minnesota.

A Defense of the Queen-Breeders.

BY HENRY ALLEY.

ONCE in awhile some bee-keeper who has purchased a queen and has had bad luck in introducing her, and bad luck in other ways, feels like giving vent to his disappointment, and so he sits down and writes to some of the bee-papers and gives the queen-dealer a "blowing up." The purchaser is disappointed in several ways: He expected a large, golden-yellow queen, and, above all, had no idea that his queen would not be accepted by the bees, as he had adopted a method for introducing that some prominent bee-keeper had recommended, and there could be no doubt about the success of the undertaking!

But the queen was received; she was small, dark-colored, and the accompanying bees "were just like hybrids." About the loss in introducing the queen I will say but little. But does a purchaser expect to get a queen-bee whose condition shall be as good when received as when the queen was put into the cage? Just consider for a moment what a hard time those bees have had while they were cooped up in the little box, and being rusht about for a week or more in a mail-bag while the temperature is nearly up to 100 degrees in the shade. Is it not a wonder that the bees are alive? Just think of a mail-bag being grabbed from a crane while an express train is traveling 50 miles an hour! Then, again, how does it affect the bees when a mail-pouch is kicked out the door of a car and the train going at the rate of 40 or more miles an hour? Sometimes the pouch is left at a station in the hot sun while the temperature is 115 degrees in the clear sunshine; and, sometimes, too, the mail-pouch is placed upon the top of an old stage-coach, and is carried for miles into some back town, and all the while Old Sol is doing his best to cook the contents of the pouch.

Well, now, all these things are done all thru the warm season. Some of the people who handle the mail in the cars have lots of fun with the bees they find in the bags, and many queens meet injury and death in that way.

But these things are overlooked by the purchasers of queens, and they accuse the dealer of sending them inferior queens. Does any one for a moment suppose a queen-dealer would put out and knowingly mail an inferior queen? I do not believe it. The reputation of the dealer is at stake. Every queen-dealer is trying to send out queens that will be superior to those sent out by his competitor.

"Handsome is that handsome does." Well, now, queens when in the nuclei of the queen-breeder do look and appear beautiful; in fact, they *are* beautiful, and give promise—so far as one can judge of appearances and all indications that the queen-breeder must judge quality by—of being superior. I always like to have people come to my yard and select their queens. Then the queens can be seen in all their glory. Of course, all who desire to purchase queens can not avail themselves of this suggestion.

Bee-keepers must not be too hasty to accuse the queen-breeder of wrong doing. Be a little charitable, and treat them as you would like to be treated under the same circumstances. Every advertiser of queens stands ready to make good his guarantee, and there is no need of fault-finding until the dealer refuses to do so.

Now a word about rearing queens. I have seen good

advice given in the various bee-papers in regard to the proper methods for rearing queens. The latest advice and suggestions come from a man who has reared but a few queens. All the things this man has advised and suggested have been practiced nearly 37 years. They are known to all breeders of queens. They are "up" on all points. Yet they do send out some queens that prove on test to be inferior. They do not knowingly do this thing. The queens, when taken from nuclei, seem all right in all respects. No one is trying to see how poor queens he can rear, but how good. The breeders make every effort to please all. Every precaution is taken to guard against injury or loss of queens in the mails. What more can be done? A good many queens are injured in the mail; but more are ruined by the methods used in introducing them to full colonies.

Colony with Virgin Queen—Introducing Queens.

1. I have 4 colonies of bees wintered outdoors in good shape, but in looking them over I found one colony with a virgin queen just hatcht, and no brood whatever. Did the bees supersede the old queen, or did she die?
