HENRY FIELD, J. HARLEY BRADLEY, MURRY NELSON,

To the Executive Committee of the Citizens' Association :

The undersigned, Committee on Smoke, in accordance with the request and instructions transmitted to them in January, proceeded to the investigation of the "smoke nuisance," after due deliberation as to the proper method of conducting it, in the light of past experience and of more recently acquired information. They called to their assistance a mechanical engineer of intelligence and acquirements, who has made a thorough examination of the methods employed for the prevention of smoke in stationary boilers, and has condensed and tabulated his observations, as will be seen by reference to the accompanying statements.

The observations so made extended to 333 establishments where steam is in constant use for various purposes, including 830 boilers, of which 234 places have in use devices for the prevention of smoke, and 99 have no apparatus for the purpose; the particulars are minutely set forth in the tables prepared by the expert. From an analysis of these tables it will be seen that, although the devices in use have a very marked effect on the result, as to whether the smoke emitted from the chimneys is very black or offensive, so much so as to incline us to the opinion that a proper apparatus is almost indispensable for the complete suppression of the smoke nuisance; yet we believe that the greatest amount of good can be accomplished by careful attention to the firing, and the use of a good quality of coal. By combining these three conditions-an efficient smoke preventing device, a fair quality of coal, and careful firing-the offense arising from the chimneys in the business and manufacturing parts of the city can be reduced to insignificance.

Good results have been obtained by mingling coke, or anthracite screenings, with soft coal; but that is practiced to but a small extent, and its beneficial effect is commensurate, after all, with the observance of proper conditions as to use, which are a part of, and included in the general term—careful firing. We see, by examination of the tables given, that the smoke arising from some chimneys where the poorest quality of coal is used, is reported as very light, when accompanied by the observation of careful, or automatic mechanical stoking.

The practice of "crowding the furnaces" with fuel is one of , the most prolific sources of offensive smoke that we have to contend with; this is made necessary, or believed to be necessary from the insufficient size of boilers, or of chimneys, to perform their work. The fires have to be urged to their utmost capacity to keep up the requisite amount of steam, and this is done at a great waste of coal, the custom being to put on as much fuel as the furnace will hold, and then rake it out from below when insufficiently, or not thoroughly, burned, to make room for a fresh supply above; the result being that the outer air gets an amount of deuse smoke that annoys the public, while the proprietor of the establishment pays for a large amount of fuel of which he gets no benefit. The same result occurs from heedlessness of engineers and firemen who, from indolence or ignorance, completely fill their furnaces with coal at certain periods, and pay no further attention to their fires until the time comes to give the furnace a fresh charge of fuel; all chimneys where such practices obtain emit dense smoke more than half the time. Firing should be as intelligently done as any other work; modern requirements call for perfection in most occupations or trades; yet in many cases this important business is left to the discretion, or want of discretion, of men who seem to take no interest in the welfare of their employers, or the convenience of the public. Sometimes a mistaken idea of economy induces merchants to keep a cheap man in the boiler room, who will waste more fuel than the amount of his monthly wages. Instead of crowding the furnaces by heaping up fuel upon half burned coal, the stoking should be done a little at a time, so that the greater surface of the fire will show, at all times, either an incandescent mass, or a bright flame; the last charge of fuel should be pushed back and spread over this, and the new charge put in its place; the ashes should be carefully raked out at fixed and frequent periods ; by this process the steam can be kept up at two-thirds the cost of the fuel used in the practice usually adopted-that of crowding the furnace to its utmost capacity; but to accomplish it there must be intelligence and integrity in the boiler room as well as in the other departments of the establishment.

We are of opinion that the suppression of smoke, as a nuisance, is within the power of those who own the stationary boilers, and of the men who have charge of them; the former have no moral or legal right to subject their immediate neighbors, or the public, to the damage to health and property caused by their own inattention; they should act in unison, and exert their

undisputed authority to compel their employes to do their manifest duty. We have made several attempts to get an ordinance passed inflicting a fine upon engineers and firemen, in cases where the proprietors of establishments have furnished them with a suitable device for the prevention of smoke; but it has been hitherto found impossible to pass such an ordinance, and nothing remains to be done, but to bring about a consensus of opinion, and unity of action in the premises by those interested.

If the proprietors will but insist upon the observance by their engineers of certain conditions, (which should include the constant application of the smoke preventing apparatus, where there is one, under the penalty of suspension or discharge,) and supply them with a suitable device, and the quality of coal found from observation to be appropriate to the set of the boiler, the height of the chimney, and the kind of smoke preventing apparatus adopted, the greater part of this appalling nuisance can be abated. The proprietors must, however, give to this matter the proper measure of their personal attention to insure the desired result.

The principle of smoke prevention is extremely simple; but, as it is not generally understood, it may be well to explain here the cause of smoke, and the method of its prevention. When heat is applied to bituminous coal a gas is generated which is our ordinary illuminating gas in a crude state. It burns freely when mixed with the proper quantity of air. Smoke results from the failure to burn this gas in the furnace. The failure to burn the gas in the furnace results invariably from one of two causes; either, because air has not been admitted to mix with it in proper quantities and in the proper manner—in a thin sheet, or through small perforations—or, because the fireman has so completely covered the grate bars with fresh coal, as to leave no flame or heat to ignite the gas after it has received the proper admixture of air.

Any device which admits air in proper quantities into the furnace will prevent smoke, unless its operation is defeated by bad firing; that is, by piling coal upon the grate until the flames are smothered, or until more gas is created than can be absorbed by the amount of air ordinarily admitted. It is somewhat easier and less troublesome to fire badly than to fire well, because good firing requires that a small quantity of coal shall be applied at frequent intervals; and an indolent fireman prefers to throw a large quantity on the grate, and to have a longer interval of rest. The fireman, or the friendly engineer, persuades the proprietor that any

-7-

device which he may have adopted is a failure, as this excuses the acts of the fireman.

We consider the first step in the direction of an abatement of the smoke nuisance to be the education of the proprietors of steam boilers to the fact that they have in their own hands the cure of the evil, as far as their own furnaces are concerned.

In view of the large percentage of inefficient firemen, and of their ability to defeat the action of most devices, we regard the various self-feeding firmaces as more to be relied upon for the prevention of smoke than any others, as they are automatic in their action, and the best of them seem almost invariably to produce good results. The automatic furnaces commend themselves to those who count the cost of heat and power and of smoke prevention, as they admit the use of the cheapest fuel without making smoke.

Several of the devices mentioned in the accompanying tables are excellent for the purpose required; specimens or patterns of all are within easy visiting distance of every business establishment in the city; the inventors are but too anxious to exhibit their apparatus; inefficient systems should be discarded; and a brief but thorough examination should be made of the most approved patterns, with the object of selecting the device best suited to the existing conditions, which can be readily compared with others. It certainly is not unreasonable to ask for as much attention to this important subject as would be given to the purchase of a carriage, or to the introduction of house-heating apparatus, or a kitchen range.

The City Council has formed a committee to visit and inspect the various devices so that they can report on several patterns, some one of which may be found useful in any given case : it will afford us pleasure to aid them in every way. We shall, ourselves, make such a visit for the purpose of verifying our expert's report.

These remarks and considerations apply equally to the prevention of smoke in tugs and locomotive engines; the law with regard to the offense in their case makes the engineers subject to the penalty imposed; but no regard is paid to it. Observations made after navigation opened, this spring, demonstrated that the greater part of the nuisance can be abated by careful attention to the firing; trips made with our expert on board showed this conclusion; also that soon after he had left the smoke burst forth again without abatement; there are devices on some of these vessels which

--8---

modify its volume when in use; but they are not sufficient, and are seldom in operation. As to locomotives, there is much difference in the degree of annoyance on different roads, depending, as in all other cases, on the care taken by the firemen. Recent observations show, however, that there is an apparatus which will absolutely prevent smoke on locomotives, and probably on tugs, and we refer to the notes of our expert for an account of it.

We have entered into correspondence with the magistrates of some English eities relative to the means of suppression in vogue there; these do not differ very materially from ours; the devices do not vary in principle of construction from those in use here. The powers conferred by law on municipal authorities are, in some instances, greater than ours; they have the authority, which ours have not, to compel the alteration of flues, and the use of appliances. Their mode of procedure in case of offenses is by summons and fine, which apply to the employe as well as the proprietor of an establishment offending.

Our recommendations are: That, as the Mayor has appointed a competent officer whose sole duty it has become to thoroughly investigate the smoke question, with a view to its speedy and permanent solution, the Citizens' Association shall tender to the eity authorities their co-operation in all efforts for the suppression of the nuisance; and that, as a means to the end desired, an ordinance be passed amplifying the seope of the present city law with regard to the liability of firemen and engineers of stationary engines, and enabling the officers to suppress the nuisance at sight; and, that the City Smoke Bureau be so constituted that daily observations shall be made, with the object of pointing out to delinquents how their smoking elimneys ean be remedied, and of enforcing the ordinance in all respects. We would, also, suggest that in any general revision of the Building Ordinanee, provision be made for sejentific construction of the boiler rooms and smoke stacks of factories and large mercantile buildings, with an especial view to smoke prevention.

-9---

Respectfully submitted,

BRYAN LATHROP, JOHN H. LONG, AUGUSTUS NEWELL, FRED. BAUMANN, W. J. CHALMERS, *Committee.*

Снислбо, Мау 20, 1889.

Notes by the Expert Examiner.

A fireman who understands his business, and has a good grade of coal, can prevent a great amount of smoke if the details of his steam plant are proper; in many cases the boiler capacity is entirely inadequate to the demands upon it, and the fires have to be crowded to the utmost; smoke of the blackest kind is thus commonly evolved, without accomplishing the object. numerous other cases the chimney capacity is entirely too small for the number of boilers attached to it; sometimes two, three, or even four boilers are dependent upon a small chimney, projecting but a few feet above the roof of the building, and often surrounded by others much higher; the draft is, in such cases, impeded, and much unneccessary smoke the consequence; a "smoke burner" of the proper pattern will assist materially in increasing the draft. The majority of the smoke preventing devices are of but little benefit, and in some cases have been of positive injury to the boilers; and even where the better style are in use, carelessness in firing, the use of an inferior grade of coal, or the sudden or habitual "crowding" of the fires, one or all together, cause much smoke at times, or at all times; of course, an apparatus will not prevent smoke, if not applied, or improperly handled. One of the first conditions for success is "dou't crowd the boilers"—to use the common expression.

In some establishments in the business district the engineer has to do duty as stoker,—do his own firing; he has also charge of the elevator, and the steam-heating, and of other business; if anything occurs in any part of the building he is sent for to" fix things:" leaving his post to go to the top story, perhaps, without knowing when he shall return, he crowds his furnace full of coal, with the result of sending a deuse volume of smoke ont of the chimney.

These observations show that there are many instances where good apparatus does not prevent smoke, while the same device works perfectly in other cases. The causes are very evident: inadequate chimney capacity, inferior coal, imperfect and faulty setting of the boiler, or careless management of fires: here again

—I0—

there is evidence that unless all details are properly arranged, and the fires carefully attended to,—in short, unless there is careful and judicious management of the whole plant, smoke will be apparent. There were expressions, in some cases, of ill-feeling with regard to the prosecutions by the city anthorities, but, on the other hand, the infliction of a fine has often, confessedly, done good.

Every tng, and nearly every locomotive engine observed, was belching forth great volumes of intensely black smoke; the exceptions were on the Illinois Central suburban trains : on inquiry it was found that this Company uses bituminous coal; but the nuisance was, in their case, much less than on other locomotives, owing to careful firing. A number of tngs have steam jets in their smoke-stacks, which helps to some extent : that careful firing is the best remedy was demonstrated on the trips made, the same tugs were very offensive before and after the trips. The difficulties to be overcome on tugs and locomotives are greater than in the case of stationary boilers.

May 17. Trip on engine No. 93, Wisconsin Central Railway, —accompanied by the inventor of the device attached thereto, W. C. Thayer.

The trip from Chicago to Harlem and return was made without any visible smoke issuing from the stack of the engine, except once, when upon the suggestion of your examiner, the valves leading to the consumer were closed, whereupon dense volumes of black smoke instantly issued from the stack, to be just as quickly dispelled by again opening the steam valves. Observations were made on the following day, and another trip was made as a passenger, unknown to anybody, to see if the device would show equally good results, and it was found to work just as perfectly, as when the writer rode on the engine. There seems to be no further excuse for so much black smoke from locomotive engines in the city of Chicago, while there is such a simple, inexpensive and efficient device within the reach of all, and it would seem that the adoption of this cannot be urged any too strongly, especially as a considerable saving of fuel is said to be effected by its use. The same device is suited to tug furnaces.

ground already gone over; in order to note the effect of the weather upon the smoke production. It gives me pleasure to be able to report that taking it altogether, there was much less smoke produced, than at any time since my observations were begun. A few places were woniting forth the usual amount of smoke, as for instance the Sherman, the Chicago Opera honse block, and some of the factories on the North side, prominent among which were those at Market and Huron streets; and at 56 Birie street, the last of which I have repeatedly observed, and found to emit volumes of smoke at times; they have a consumer, but it is evidently not in use. Other buildings giving forth less smoke than usual, it might possibly be due to the fact, that the day being rather mild less steam was used for heating purposes than usual, and consequently firing was proportionately lighter, and in places visited this was substantiated in every case.

SMOKE OBSERVATIONS, 1889.—Continued.

—32—

												This day was spent in taking observations on the ground gone over, and it was demonstrated that even the heretofore best behaved chim- neys were making a great amount of smoke, due to carelessness in firing in most cases. About forty observations were made, with the result as marked in the "remarks" column in every case observed. There was, this day, a sudden change in the weather, from mild to cold.
