Fleming's British Farmer's Magazine. Lond. 2 vols. 8vo. Continued under the name of the British Farmer's Magazine, 2 vols. 8vo.

1827. *Anon.*

The Farmer's Register and Monthly Magazine of Foreign and Domestic Events. Glasgow. In 8vo numbers, monthly. Completed in one volume.

1828. *Meadows, Arthur, Esq.*

Hints to the Farmers of the Baronies of Forth and Bargo on the Cultivation of Mangold Wurzel, Beans, Carrots, and Parsneps. Westford, 8vo.

1828—1831. *Anon.*, believed to be *David Low, Esq.*

The Quarterly Journal of Agriculture. Edinburgh, 2 vols. 8vo.

The Prize Essays and Transactions of the Highland Society of Scotland are publishing along with this work. See 1793.

1828. *Kennedy, Lewis, Esq.*, son of Mr. Kennedy the late eminent nurseryman of Hammermith, steward to Lord Willoughby De Eresby, author of the *Tenancy of Land in Great Britain*, &c.

1. On the Cultivation of the Waste Lands in the United Kingdom, for the purpose of finding Employment for the able Poor now receiving Parochial Aid, and thereby diminishing the heavy Burden on the Poor Rates; and on the Expediency of making some Provision for the aged and disabled Paupers of Ireland. Lond. 8vo.

2. The present State of the Tenancy of Land in Great Britain; showing the principal Customs and Practices between incoming and outgoing Tenants, &c. Lond. 8vo.

1829. *Lambert, Joseph, Esq.*

Observations on the Rural Affairs of Ireland, or a Practical Treatise on Farming, Planting, and Gardening, adapted to the Circumstances, Resources, Soil, and Climate of the Country. Dublin, 8vo, pp. 327.

1829. *Stephens, George*, drainer, member of the Nerecian and Werlandenska Agricultural Societies in Sweden.

The Practical Irrigator; being an Account of the Utility, Formation, and Management of Irrigated Meadows, with a particular Account of the Success of Irrigation in Scotland. To which is added, a Practical Treatise on straightening

Water-courses, protecting River Banks, and embanking Low Lands. Edin. 8vo.

1829. *Doyle, Martin.*

Hints originally intended for the small Farmers of the County of Wexford; but suited to the Circumstances of many Parts of Ireland. Dublin, 18mo.

1829. *Fall, Thomas*, Surveyor of Roads.

The Surveyor's Guide; or, every Man his own Road maker: comprising the whole Art of making and repairing Roads, Prices for Work. East Retford, 12mo.

1829. *Harley, William*, originally a manufacturer in Glasgow; afterwards a great cow-keeper and builder there. He died in London in 1830.

The Harleian Dairy System, and an Account of the various Methods of Dairy Husbandry pursued by the Dutch. Also, a new and improved Mode of ventilating stables; with an Appendix, containing useful Hints (founded on the Author's ex-perience) for the Management of Hedgerow Fences, Fruit Trees, &c., and the Means of rendering Barren Land fruit-ful. Lond. 8vo.

1829. *Strickland, G., Esq.*

A Discourse on the Poor Laws of England and Scotland, on the Poor of Ireland, and on Emigration. Lond. 8vo.

1829. *Trimmer, Joshua Kirby.*

Practical Observations on the Improvement of British Fine Wool, and the National Advantages of the arable System of Sheep Husbandry; with Remarks on the Saxon and French Systems.

1830. *Anon.*

The Library of Useful Knowledge; Farmer's Series. 8vo, 13 numbers to January 1, 1831.

1830. *Jennings, James, Esq.*, author of the *Family Cyclopaedia*, &c.

A Practical Treatise on the History, Medical Properties, and Cultivation of Tobacco. London.

1830. *Berry, the Rev. Henry*, an extensive farmer in Worcestershire, and undertook to be the principal proprietor of the *British Farmer's Maga-zine*.

Improved Short-horns, and their Pretensions stated; being an Account of this celebrated Breed of Cattle, derived from authentic Sources; to which is added, an Enquiry as to their Value for General Purposes, placed in Competition with the improved Herefords. Lond. pamph. 8vo. 2d edit.

1830. *Broadgign, Thomas, Esq.*

A Botanical, Historical, and Practical Treatise on the Tobacco Plant, in which the Art of growing and curing Tobacco in the British Isles is made familiar to every Capacity, as deduced from the Observations of the Author in the United States of America, and his Practice in Field Cultivation in Ireland. Lond. 8vo.

1830. *Davey, John, Esq.*

Observations on the Disease which has lately been so de-structive to Sheep, called Bae or Coath; particularising the Causes, and minutely describing the Modes of effecting its Cure; and pointing out those Means which ought to be adopted to prevent its Recurrence. Bath, pamph. 8vo.

SECT. II. Bibliography of Agriculture in Foreign Countries.

7899. *Numerous works on agriculture* are published in the French and German languages, and a considerable number in the Italian; but a great proportion of these are translations from British authors. Very few agricultural books have been printed in the Dutch, Flemish, Danish, Swedish, Polish, Spanish, or Portuguese languages, and scarcely any in those of Russia or Hungary. We shall notice the principal French, German, and Italian works, exclusive of translations, and add a few American books.

SUBSECT. 1. Bibliography of French Agriculture.

7900. *Of French books on agriculture* we have given a selection only: those who wish to see a complete list are referred to the *Bibliographie Agronomique*, Paris, 8vo; in which are given the titles of upwards of 2000 works, including translations and books on gardening. A general idea of French culture in all its branches may be obtained from the *Nouveau Cours Complet d'Agriculture*, 16 vols. 8vo (edition of 1821.), compiled by the members of the Section of Agriculture of the French Institute, each of whose names are given to the articles he contributed.

1529. *Etienne, Charles, et J. Liébaull*, physicians, Etienne, i.e. Stephanus or Stephens, in the beginning of the sixteenth century published various small tracts on Gardening and other rural topics; and in 1529 he collected them together and published them, under the title of *Prædium Rusticum*, treating of gardens, trees, vines, fields, meadows, lakes, forests, orchards, &c. Having married his daughter to Liébaull, they afterwards studied agriculture conjointly, and published the *Maison Rustique*, the modern editions of which are still the most popular agricultural works in France.

1. *Prædium Rusticum*; in fol.

2. *L'Agriculture et Maison Rustique*. Paris, in 4to, 1570.

1569. *Hesson, Jacques*, of Dauphiny.

De l'Art et Science de trouver surement les Eaux, Sources, et Fontaines cachées sous Terre, autrement que par les Moyens Vulgaires des Agriculteurs et Architectes, in 4to.

1583. *Hegemon, Philibert*, a lawyer born at Cha-lons-sur-soane. Died in 1595.

La Colombière et Maison Rustique, contenant une Description des Douze Mois et des Quatre Saisons de l'Année, avec En-seignement de ce que le Laboureur doit faire par chaque Mois. Paris, in 8vo.

1600. *Serres, Olivier de*, the Lord of Predel in Languedoc. He was born in 1539, and died in 1619, at the age of 80 years. He was employed by Henry IV. to form a plantation of the white mulberry in the garden of the Tuilleries; and he is generally considered as the father of the culture of that tree in France. He published a great many useful works, the principal of which is his *Théâtre d'Agricul-ture*, the first edition of which was published in 1600, and the 20th in 1675.

Le Théâtre d'Agriculture ou: Mesnage des Champs. Paris, small 8vo. An enlarged edition in 2 vols. 4to, with volumi-nous Notes, and a Historical Introduction, in 1694.

1602. *Letellier*.

Brief Discours contenant la Manière de nourrir les Vers à Soie, &c. Avec des belles Figures. Paris, in 4to.

1604. *Laffemas, Barthélémy de*, valet de chambre to Louis XI.

La Façon de faire et semer la Graine de Mûriers, les élever et replanter, gouverner les Vers à Soie au Climat de France. Paris, in 12mo.

1607. *Vinet, Etie*, a learned professor at Bour-deaux, author of a work on land surveying.

La Maison Champêtre et Agriculture. Paris, in 4to.

1663, *Patin, Charles*, son of a physician of that name.

Traité des Tourbes Combustibles. Paris, in 4to.
1703. *Liger, Louis*, born 1658, died in 1717. In the latter part of his life he seems to have been a bookseller, or an author by profession.

1. Dictionnaire Général des Termes propres à l'Agriculture, avec leurs Définitions et Etymologies. Paris, in 12mo.
2. La Nouvelle Maison Rustique, ou Economie Générale des Biens de la Campagne. Paris, 2 vols, in 4to. 1755.
3. L'Economie Générale de la Campagne, ou Nouvelle Maison rustique. 1762.

4. Nouveau Système d'Agriculture. 3 vols. in 8vo. 1775.
1749. *Boucher d'Argis, Antoine Gaspard*, advocate and author of some works on jurisprudence.

Code Rural, ou Maximes et Règlements concernant les Biens de la Campagne. 2 vols.

1749. *Réaumur, René, Antoine Ferchoult, sieur de*, a leauroed naturalist, born at Rochelle in 1683, died in 1757.

Art et Pratique de l'Art de faire éclore, en toutes Saisons, des Oiseaux Domestiques de toutes Espèces. Paris, Imprim. Royale, 3 vols. in 8vo, avec fig.

1750. *Hamel, Du Monceau, Henry Lewis du*, a famous French writer on Rural Economy and Vegetable Physiology, was born at Paris, 1700; died there 1782.

1. Traité de la Culture des Terres. Par. 6 vols. 12mo.
2. Elémens d'Agriculture. Par. 1764, 2 vols. 12mo.

3. Traité de la Conservation des Graines, et en particulier ou Froment. Par. 1764, 12mo.

4. Traité des Arbres et Arbustes, qui se cultivent en France, en pleine Terre. Par. 1755, 2 vols. 4to.

5. Traité complet des Bois et des Forêts. Par. 1758, 6 tom. 4to.

6. Des Semis et Plantations des Arbres, et de leur Culture. Par. 1760. 4to.

7. Histoire d'un Insecte qui devore les Grains de l'Aragon. Paris. Par. 1762.

8. De l'Exploitation des Bois, ou Moyen de tirer Part des Tailis demi Futayes et hautes Futayes. Par. 1764. 2 vols. 4to.

9. Mémoire sur la Garance et sa Culture, in 4to. 1765.

10. Du Transport, de la Conservation, et de la Force du Bois. 1767. 4to.

1751. *Desbois, Francis Alexander Aubert de la Chesnaie*, a laborious Dictionary-maker; was born at Ernée in the Maine, 1699; died 1784.

Dictionnaire d'Agriculture. 2 vols. 8vo.

1755. *Bouvet*, librarian to the Prince of Conti.

Essai sur l'Agriculture Moderne. Paris, in 12mo.

1755. *Tillet, du*, of Bourdeaux, a zealous agriculturist, author of several works. He died in 1791.

Dissertation sur la Cause qui corrompt et noircit les Graines de Blé dans les E'pis, in 4to.

1756. *Hastfer, F. W.*

Instruction sur la Manière d'élever et de perfectionner les Bêtes à Laine. Paris, 2 vols. in 12mo.

1760. *Alletz, Pons Augustin*, an advocate, and indefatigable compiler.

L'Agronome, ou Dictionnaire portatif du Cultivateur, 2 vols. in 8vo.

1760. *Buch'oz, Pierre Joseph*, a physician, and member of several societies; born at Metz in 1731, died in great distress at Paris in 1807. He wrote above three hundred volumes relative to medicine, agriculture, the veterinary art, and natural history.

A plant (*Buchoziana*) was named after him by L'Héritier.

1. Lettre sur la Méthode de s'enrichir promptement et de conserver sa Santé par la Culture des Végétaux, in 8vo.

2. Lettre sur le Blé de Smyrne, in 8vo. 1768.

3. Histoire des Insectes nuisibles à l'Homme, aux Bestiaux, &c. in 12mo. 1781.

4. Manuel usuel et économique des Plantes, contenant leur Propriétés pour les Usages économiques. Paris, in 12mo. 1782.

5. Histoire des Insectes utiles à l'Homme, aux Animaux, et aux Arts. Paris, in 12mo. 1785.

6. Traité de la Pêche, ou l'Art de soumettre les Poissons à l'Empire des Hommes, précédé de l'Histoire Naturelle de ces Animaux, in 12mo. 1786.

7. Dissertation sur la Betterave et la Poirée, leur Culture, Méthode pour en tirer du Sucre, &c. fol. 1787.

8. Dissertation sur le Cochon, in fol. 1789.

9. Dissertation sur le Lin de Sibérie, in fol. 1789.

10. Dissertation sur la Taupe; les Moyens de la prendre, in fol. 1790.

11. Dissertation sur le Tirage de la Soie, in fol. 1792.

12. Manuel Tabacal et Sternutatoire des Plantes, ou Traité des Plantes qui se trouvent à faire détruire, avec la Manière de cultiver le Tabac, de le préparer, et de juger de ses bons Effets dans la Société, in 8vo. 1793.

13. Manuel Vétérinaire des Plantes, in 8vo. 1798.

14. Mémoire sur le Blé de Smyrne, sur le Blé de Turquie, le Millet d'Afrique, et la Poherbe d' Abyssinie, Plantes Alimentaires pour l'Homme; in 8vo. 1824.

15. Mémoire sur la Manière de former des Prairies Naturelles, in 8vo. 1805.

1760. *Turbilly, Louis François Henri de Menon*, Marquis de, a proprietor in Anjou, who had been in the army, but who retired to his estates and broke up and improved a number of acres, of which he published an account, well known at that time in England. Arthur Young, when in France in

1787, was anxious to visit the Marquis; but after, with difficulty, finding out the estate of Turbilly, he found the Marquis had died in 1776, having ruined himself by establishing a pottery. There is a very interesting account of this visit in *Young's Travels*, part I. p. 294, & seq.

1. Mémoire sur les Déficitheux, in 12mo.

2. Pratique des Déficitheux. Paris, in 12mo. 1701.

1761. *Guillot, Julien Jean Jacques*.

Discours sur les Branches d'Agriculture les plus avantageuses à la Province de Normandie.

1761. *Neveu-Eglite, Louis Joseph Bellepère de*,

an officer in the army.

1. L'Agronome, ou Corps complet des Principes de l'Agriculture, &c. 8 vols. in 8vo.

2. Boussole Agronomique, ou le Guide des Laboureurs, in 8vo. 1762.

1762. *Desplaces, Laurent Bemoist*.

1. Préservatif contre l'Agronomie, ou l'Agriculture réduite à ses vrais Principes. Paris, in 12mo.

2. Histoire de l'Agricultureancienne, extraite de l'Histoire Naturelle de Flinè, avec des Eclaircissemens et des Remarques. 12mo. 1762.

1762. *Despommiers*.

L'Art de s'enrichir promptement par l'Agriculture. Paris, 12mo.

1762. *Lafaille, Clement*, advocate, and member of several societies.

1. Mémoire sur les Moyens de multiplier aisément les Fumiers dans le Pays d'Aunis.

2. Essai sur l'Histoire naturelle de la Taupe; sur les différents Moyens qu'on peut employer pour la détruire. La Rochelle, in 12mo, fig. 1768.

1763. *L'Elong de la-Salle, Simon Philibert de*, of Rheims, a lawyer.

Des Prairies artificielles, ou Moyens de perfectionner l'Agriculture dans toutes les Provinces de France, surtout en Champagne, par l'Entretien et le Renouveauement de l'Engrais; avec un Traité sur la Culture de la Luzerne, du Trèfle, et du Sainfoin, et une Dissertation sur l'Exportation du Blé. Paris, 8vo.

1763. *Barthes de Mormorières*, an officer, secretary of embassy, and member of various societies.

Mémoires d'Agriculture, &c. 8vo.

1763. *Duvergé*, a physician of Tours.

Analyse chimique des Terres de la Province de Touraine, des différents Engrais propres à les améliorer, et des Semences convenables à chaque Espèce de Terre. Tours. 8vo.

1763. *François, Nicholas*, de Neuchâteau, member of the Institute, the Senate, &c., a distinguished member of the Paris Agricultural Society, and author of numerous papers in their memoirs.

1. Avis aux Cultivateurs et Propriétaires de Troupeaux, sur l'Amélioration des Laines. Paris. 8vo. in 7il.

2. Essai sur les Moyens de tirer Part le plus avantageux de l'Exploitation d'un Domaine borné, ou Système d'Agriculture pour les petits Propriétaires. Neuchâteau. 8vo. 1790.

3. Essai sur la Nécessité et les Moyens de s'écarter dans l'Instruction publique l'Enseignement de l'Agriculture; in la Société d'Agriculture de la Seine, &c. 8vo. 1802.

4. Rapport sur le Perfectionnement des Charrues, fait à la Société Libre d'Agriculture du Département de la Seine, Paris, 8vo.

5. Répertoire universel et raisonné d'Agriculture. Paris, 12mo. 1804.

1763. *Préfontaine*.

Manuel Rustique à l'Usage des Habitans de la Partie de la France équinoxiale, connue sous le Nom de Cayenne. 8vo.

1763. *Thierat*. An officer of the royal forests, author of some tracts on gardening.

Instructions familières en forme d'Entretien sur les principaux Objets qui concernent la Culture des Terres. Paris, 12mo.

1764. *Bertrand, Elie*, a clergyman at Orbe, in Switzerland, and member of various societies.

1. Traité de l'Irrigation des Prés. 12mo.

2. Elémens d'Agriculture, fondés sur les Faits et les Raisonnemens, à l'Usage du Peuple de la Campagne. 8vo. 1774.

1764. *Bertrand, Jean*, brother of Elie B.

De l'Eau relativement à l'Economie Rustique, ou Traité de l'Irrigation des Prés. Lyons, 12mo.

1764. *Dupont*, of Vemours, formerly a member of the constituent assembly.

1. Lettre sur la Différence qui se trouve entre la Grande et la Petite Culture. Soissons, 8vo.

2. Journal d'Agriculture, &c. 8vo. 1766.

1765. *Chambroy, Louis*, Marquis de, an amateur apple grower and ciderist.

L'Art de cultiver les Pommiers, les Poiriers, et de faire les Cidres, selon l'Usage de Normandie. Paris, 12mo.

1765. *Sorces-de-Suèvres*, an officer in the army, and a "gentilhomme servant" of the king.

1. Agriculture expérimentale à l'Usage des Agriculteurs, Fermiers, et Laboureurs. Paris, 12mo.

2. Cours complet d'Agriculture, ou Leçons périodiques sur cet Art. 1788.

1768. *Lebrun-de-la-Versane, Louis*, of Marseilles.

Traité de la Garance, ou Recherches sur tout ce qui a rapport à cette Plante. 8vo.

1768. *Marchand, Jean Henri*.

Les Délassements Champêtres. 2 vols. 12mo.

1768. *Palteau, Guillaume Louis Formanoir de*, of Sens, author of a work on bees.

Observations et Expériences sur diverses Parties d'Agriculture. Sens. 8vo.

1769. *Chanvalon*, a clergyman. Manuel des Champs; ou Recueil choisi, instructif, et amusant de tout ce qui est le plus utile et le plus nécessaire pour vivre avec Abondance et Agrément à la Campagne. Paris. 12mo.
1769. *Le Brèze*. Essai sur le Haras; ou Examen des Moyens propres pour établir, diriger, et faire prospérer les Haras: suivi d'une Méthode facile de bled examiner les Chevaux que l'on veut acheter. 8vo, fig.
1769. *Rigoud de l'Isle*, of Crest, in Dauphiny. Mémoire sur la Culture de l'Esparcette, ou Sainfoin. Paris. 8vo.
1769. *Sicure*. 1. Mémoire et Journal d'Observations sur les Moyens de garantir les Olives de la piqûre des Insectes et nous le Méthode pour en extraire l'Huile plus abondante par l'invention d'un Moulin domestique, avec la Manière de la garantir de toute Rancissure. Paris, 12mo. 2. Mémoires sur diverses Constructions en Terre ou Argile, propres à faire jouir les petits Ménages de l'Economie des combustibles. Poitiers, 8vo. 1804.
1770. *Amiot*, *Le P.*, missionary at Pekin. Reflexions sur l'Agriculture, et sur ceux qui s'y consacrent: tirées de l'éloge de Li. Ville de Moukden et de ses Environs. Poème composé par Kien-Lang, Empereur de la Chine et de la Tartarie, actuellement régnant, traduit en Français, par le P. Amiot, et publié par M. Deshayes, Médecin de l'Académie Royale des Inscriptions et Belles Lettres, et Professeur des Langues Orientales au College Royale. Paris, 8vo. Cet ouvrage est curieux sous plus d'un rapport.
1770. *Beauzot*, *Antoine*, an eminent French chemist, was born at Senlis, 1728; died 1805. Mémoire sur les Argiles; ou, Recherches sur la Nature de Terres les plus propres à l'Agriculture, et sur les Moyens de fertiliser celles qui sont Stériles. Paris, 8vo.
1770. *Ricm*. Encyclopédie Economique, ou Système général d'Economie rustique, contenant les meilleures Pratiques pour fertiliser les Terres, la Conservation des Grains, &c.; par quelques Membres de la Société d'Agriculture de Berne. Yverdon, 16 vols. 8vo.
1770. *Rosier*, *François*, born in Lyons, 1734, and killed there on the 29th September 1793, during the siege of that city, by a bombshell, which buried his shattered remains in the ruins of the apartment which he occupied; he began his career as an author, by writing in the *Journal de Physique et d'Histoire Naturelle*, of which Gauthier Dagoty was editor. He next occupied himself with his *Agricultural or Rural Dictionary*, the work by which he is chiefly known. He cultivated a farm near Beziers, which Arthur Young went to see when on his tour in France in 1787; but the Abbé had left it on account of the Bishop of Beziers, who kept a mistress somewhere near, and for his more commodiously visiting her, got a road made across the farm at the expense of the province. This occasioned a quarrel between the Abbé and the Bishop, which ended in the former being obliged to quit his farm. The Abbé, like all other men who depart from common practices, was looked on as a fanciful and wild cultivator; and, because he paved his stables and cow-houses, it was reported by his neighbours that he paved his vineyard. He wrote a great many works, chiefly on agriculture.
1. L'Art du Magon piseur, extrait du Journal d'Observations sur la Physique, in 12mo.
 2. Traité de la meilleure Manière de cultiver la Navette et le Colza, et d'en extraire une Huile Dépouillée de son mauvaïse Gout et de son Odeur désagréable. Paris, in 8vo. 1774.
 3. Cours Complet d'Agriculture, Théorique, Pratique, Economique, etc.; ou Dictionnaire universel d'Agriculture. 12 vols. in 4to. 1786.
1773. *Bezon*, *Gabriel Leopold Charles Ame*, a French miscellaneous writer, was born at Remiremont, 1748; died at Paris 1784; he had a great turn for Natural History, and assisted Buffon in the latter volumes of his great work.
1. Le Systématique, 8vo.
 2. Catéchisme d'Agriculture, ou Bibliothèque des Gens de la Campagne. 1773. 12mo.
1773. *Trother*. L'Art de fertiliser les Terres, et de préserver de la Gelée, commodément et à peu de Frais, les Arbres et Arbrisseaux, les Vignes, &c. Méthode d'Education nationale et particulière. Paris. 3 vols. in 8vo.
1774. *Lerouge*, a friar of the order of Cîteaux, in the abbey of Trisay. Principes de Cultivateur, ou Essai sur la Culture des Champs, &c. avec un Traité abrégé des Maladies des Cultivateurs, de leurs Bestiaux, et des Remèdes pour les guérir. 2 vols. in 12mo.
1778. *Bultiard*, died at Paris in 1793. Aviceptologie Française; ou Traité générale de toutes les Russes dont on peut se servir, pour prendre les Oiseaux qui sont en France. Paris, in 12mo.
1779. *Ametithon*, *Hubert Pascol*, a librarian in Paris, and member of the legion of honour. Journal d'Agriculture, &c. depuis Janvier. 1779; jusqu'en Décembre, 1785. Paris. 16 vols. in 12mo.
1779. *Maupin*, valet de chambre to the queen of Louis XVI. 1. L'Art de la Vigne, contenant une nouvelle Méthode économique de cultiver la Vigne. In 8vo. 2. Avis sur la Vigne, les Vins et les Terres. In 8vo. 1785.

3. Almanach, ou Manuel des Vignerons de tous les Pays. Paris, in 8vo. 1789.
1780. *Bouthier*, advocate at Vienne in Dauphiny. Le Citoyen à la Campagne, ou Réponse à la Question: quelles sont les Connaissances Nécessaires à un Propriétaire qui fait valoir son Bien pour vivre à la Campagne d'un bled utile pour lui et les Paysans qui l'envicommant; dans le Cas où les Propriétaires ne demeurent point dans leurs Biens, quelles seraient également les Connaissances Nécessaires pour que les Curés, indépendamment de leurs autres Fonctions, pussent être utiles à leurs Paroissiens. Genève, in 8vo.
1780. *Copineau*, *Abbé*. Ornithologie artificielle. Paris, in 12mo. avec fig.
1780. *Mallet*, *Robert Xavier*, author of various works on gardening and rural subjects. Précis Élémentaire d'Agriculture, &c. Paris, in 12mo. an. 10.
1781. *Parmentier*, *Antoine Augustin*; born 1757, at Montdidier, in the department of La Somme, one of the most distinguished chemists and careful philosophers which have appeared in France; author of a great number of works, and co-operator in many others, as the *Annales de Chimie, Nouveau Cours d'Agriculture*: he is mayor of Enghien, and has a small garden there, said by some to be more richly stocked with rare plants than any other in Europe of its size. (See *Encyc. of Gard.* p. 1119.)

SUBJECT. 2. Bibliography of German Agriculture

7901. The German agricultural works are as numerous as those of the French, but chiefly translations, and these, for the most part, from the English. We have given a very limited selection, the German language being less generally understood than either the French or Italian. In forest management (*Forstwissenschaft*) the German bibliography is very rich; and it is chiefly these books, and descriptions of local practices, which can be of any interest to the British cultivator. The older German works in rural affairs are enumerated in Haller's *Bibliography*; and the modern ones, and new editions in *Ersch's Handbuch der Deutschen Literatur*, and the *Leipsic Catalogues*, published annually. Thäer of Moeglin is decidedly the highest in repute as an author, and Sickler's *Deutsche Landwirthschaft*, a voluminous work, will give a general idea of every part of German husbandry.

1578. *Heresbachius, Conradus*, counsellor to the Duke of Cleve; was born in 1508, died in 1576. He wrote various theological works, besides his *Rei Rusticæ*, libri iv., which was published in 1570, and his *Legum rusticarum et Operarum per singulos Menses digestæ*, in 1595. The former was translated by Barnaby Googe, of Lincolnshire, with the following title:—

Poure Bookes of Husbandrie, containing the whole Art and Trade of Husbandrie, Gardening, Graffing, and Planting, with the Antiquitie and Commendation thereof. Newly Englished and increased by Barnaby Googe, Esquire. At London, 4to. 1578. Leaves 194, besides the Dedication, Epistle and Table at the beginning; and Old English Rules in Verse for purchasing Lande, at the end.

His authorities extend from the Bible and doctors of the church through the Greek and Roman writers, Homer, Cato, &c. to the moderns as low as Ruellius, Fuchsius, Matthiolus, Cardanus, and Tragus. He subjoins a list of his friends, and others who assisted him. S. Nich. Malbee, M. Cap. Byngham, M. John Somer, M. Nicas. Yetzwert, M. Fitzherbert, M. Willi. Lambert, M. Tusser, M. Tho. Whetenhall, M. Ri. Deering, M. Hen. Brookhu I M. Franklin, H. King, Richard Andrews, Henry Deuys, William Pratte, John Hache, Philip Partridge, Kenworth Daforth.

The work is in dialogue. The persons are Cono, a gentleman retired into the country; Rego, a courtier; Metella, wife of Cono; and Hermes, a servant.

Uebersicht der Europ. veredelten Schafzucht. Prague 2 theile, 8vo.

SUBJECT 3. *Bibliography of Italian Agriculture.*

7902. *A number of Italian agricultural works have been published; such as they are, perhaps more of them are original than of the books of the French or Germans, because the culture of other parts of Europe is but ill adapted for Italy. The vine, olive, mulberry, orange, and the irrigation of lands, have a good deal occupied the Italian writers. Ré may be reckoned their general and popular author, and his *Nouveaux Elements*, 4 vols. 8vo, 1815, and *Annali dell' Agricoltura*, &c. 22 vols. 8vo to 1814, will give a good idea of Italian husbandry and gardening, the two arts in that country being for the most part combined.*

1471. *Crescentino, Crescenzo, or De Crescentino* was born at Bologna about 1233; died 1320.
1. Opus Rurallium Commodorum, sive de Agricultura, libri 3 Augustini. fol.

SUBJECT. 4. *Bibliography of the Agriculture of the other Countries of Europe.*

7903. *Germany and Britain* are the only countries in Europe in which it answers to print agricultural books for the sake of the indigenous readers. In Britain, education is so general among the middling and lower orders, that reading among them is a necessary convenience of life; in Germany, education and reading are equally general and essential: and consequently, in either of these two countries a book will pay by its sale within the country. But this is not the case in any other European country. In France the mass of the people do not read, but books printed there pay, because they are in a language more universal than any other, and perfectly understood by all men of education in Europe. Italian books pay, because they are enquired for by the agriculturists of the south of France, all Spain, and in part of Spanish America.

7904. *Spanish and Portuguese books on agriculture* are in much too limited a demand for production. The earliest Spanish author is Herrera, in 1595; and there are scarcely half a dozen since. After the most particular researches of a book agent at Madrid, he was only able to send a list of translations, and the transactions of the Economical Society of Madrid; who have also published Herrera's work with notes within the present century. In 1815, a professor at Madrid published *Lecciones de Agricultura explicadas en el Jardín Botánico*, 2 tomes 4to. An anonymous author, *Disertaciones sobre varios Plantos Agronomicos*, 3 toms. 4to. Of Portuguese books we could hear of none.

7905. *Of Flemish and Dutch books on agriculture* there are scarcely any. These languages are very limited, and every reader in Holland or Flanders understands French or German. Many works have been published in the Low Countries in Latin and French, but these cannot be considered indigenous. The few Dutch works on culture belong almost all to gardening (*Encyc. of Gard. 7695*). The result of our correspondence with Amsterdam is a *Nieuwe Noamlijst van Boeken, &c.*, from which we see little worth taking. There are several translations from British works on culture, and French veterinary books, and the following seem the latest on husbandry.

Magazijn van Vaderlandschen Landbouw, door J. Kops, Commissaris tot den Landbouw. 6 deelen compleet met register.
Aanwijzing ter verbetering van de Akkerbouw en Landbuishoukunde, in de Nederlanden, door Professor A. Bruchausen. 2 deelen.

De Boeren Goudmijn, of kunst, om van verschillende soorten van Landerijen, het meeste nut te trekken, meer Vee te kunnen houden, en andere Wetenswaardigheden tot den Landbouw, door J. F. Serurier en J. Kops, met platen.

Lichterweldè, J. F. de, Member of the Royal Society of Agriculture and Botany of the city of Ghent: La Bèche, ou la Mine d'Or de la Flandre Orientale. Brussels. 8vo.

Cate's, M. F. M., M.D. at Lige: Instructions sur le Parcage des Moutons; ou, Moyen d'engraisser les Campagnes en faisant coucher les Moutons dans les Champs. Liège. Pamph. 8vo.

7906. *Of Swedish and Danish books on agriculture*, there are necessarily very few; these languages being of very limited use, and the mass of the people too poor to be able to afford to read about ordinary matters, or what they consider as already well known to them. The time such a people give to reading will be devoted to religious subjects, heroic and romantic poetry, or history. The universities of Stockholm and Upsal, every one knows, have produced some useful naturalists: some of these have

written tracts on agricultural improvements, especially on planting fruit-trees (*Frukt-Träd.*) and cultivating culinary vegetables (*Köcks-och Krydd*). A few of such works we have enumerated in our Bibliography of Gardening (709G.), but we can scarcely find any fit to be inserted here as agricultural. *The Natural and Chemical Elements of Agriculture*, by Count Gustavus Adolphus Gyllenborg, a learned Swedish statesman, were translated by John Mills in 1770, and may be considered as the prototype of *Davy's Agricultural Chemistry*. There are several treatises on the culture of the potatoe in the *Swedish Transactions*; also on tobacco, on the management of sandy soils, on the cultivation of the Cerealia; and on the hop and plants for fodder.

1825. *Anon.*: Kongl. Svenska Landtbruks Academiens Annala. Year 9. Part I. 8vo.

1826. *Winstrip, M.*, machinist to the king at Fredericksberg, near Copenhagen: Afbildwinger af de bedste og nyeste Agerdyrkningsredskaber, &c. Copenhagen. 4to.

1797. *Of Polish and Russian books on agriculture*, it may be easily conceived, there are very few. Some translations from French works were made into the Polish language under Fred. Augustus II.; but few or none since that time, the German or French being universally understood by the reading class. Books of agriculture in the Russian language could be of little use. The only things printed in that way there are in the transactions of the Economical Society of St. Petersburg, by foreigners resident there, and in Latin or German. The best informed Russian nobles read French or German like the Poles. There is an agricultural society at Warsaw, which occasionally prints its transactions; and another has lately been established at Moscow, which publishes an agricultural newspaper. (*See Gard. Mag.* vols. i. and ii.)

1825. *Parlat, M.*: Zemliéditsetchkaia Chimia. Moscow. 8vo.

1825. *Aprazin, M.*, a nobleman possessing one of the largest houses in Moscow: Zemliéditsetchsky Journal, &c. Moscow. 8vo.

1825. *Anon.*: Avantages résultant de l'Introduction de la Culture variée des Terres. Warsaw. 8vo.

SUBJECT. 5. *Agricultural Bibliography of North America.*

7908. *There are a few American books of agriculture*, and republications there of most of our best works on the subject. *Dean's New England Farmer's Dictionary* and *Dwight's Travels* may be considered as giving an idea of the husbandry of that part of the country, and *Roughley's Jamaica Planter* of the agriculture of the West India Islands. A number of interesting papers on the subject will be found in the transactions of the American, New York, Philadelphia, and other societies.

1744. *Bartram, John, M.D.*, Philadelphia. On the Salt Marsh Musell: On Oyster Banks and the Fresh Water Musell of Pennsylvania. (*Phil. Trans. Abr. ix. p. 70.*)

CHAP. V.

Professional Police and Public Laws relative to Agriculturists and Agriculture.

7909. *By professional police* we mean those associations which agriculturists have formed, at different times and in different manners, for mutual benefit or instruction; and also those institutions for the same purpose established by the legislature, or of such a nature as to be considered public or national. By laws we allude to those special legislative enactments which affect more particularly agriculture. These are so numerous that we must refer the reader to his lawyer or law dictionary.

7910. *There are few or no agricultural lodges* of the nature of those of masonry or gardening. In Scotland it would appear something of this kind had existed among ploughmen at one time, as the passwords and initiatory ceremonies are talked of in some of the counties by old men. In Forfar, Kincardine, Banff,

&c. it is not uncommon for ploughmen, as well as various descriptions of operatives, to belong to gardeners' sodges. In the southern districts where sheep farming is followed there are some shophers' societies, for mutual interchange of experience, and aid in caso of losses of such sheep as are the shepherds' perquisite. There are some ploughmen's clubs in different places, and various associations among them of the nature of benefit societies; but those do not come under the description of professional.

7911. *Agricultural societies* for interchange of knowledge are of modern date, but they have increased rapidly since 1794: the number at present or lately existing in the British isles is at least equal to the number of the counties. Societies of this description are either general, as the Board of Agriculture and Society of Arts; national, as the Highland Society and Dublin Institution; particular, as the Bath and West of England Society; provincial, as county societies; or parochial, as being limited to a few individuals within one parish. Of this kind are farmers' clubs, ploughing societies, &c. In regard to the end in view, these societies either embrace the arts in general; the rural arts in general; some branch of the rural art, as agriculture; or some department in that branch, as live stock, sheep, wool, &c.

7912. *All these societies hold meetings* at stated periods. Most of them offer premiums for particular objects, — specimens of vegetable or animal culture or produce, agricultural operations, moral and professional merits as servants, &c.; some of them form a library and museum of models or full-sized implements; a few publish transactions; and one or two, as the Dublin Society, send out itinerant ploughmen and agricultural mechanics to instruct practical farmers. These societies are almost wholly supported, and the funds for premiums raised, by the subscriptions of members, and by voluntary donations, legacies, &c.; but some, as the Board of Agriculture and the Dublin Society, have received assistance from government.

7913. *Of English agricultural societies* the oldest is the Society of Arts, founded in 1754 by Lord Folkestone, Lord Komey, Dr. Hales, and Shepley. They have published many volumes of transactions, awarded immense sums in premiums, and on the whole done much good. (See *Rees's Cyc. art. Society.*)

7914. *The Bath and West of England Society* was founded in 1777, for purposes similar to those of the London Society of Arts. They have published some valuable volumes of transactions, and distributed various rewards, &c. (*Rees's Cyc. &c.*)

7915. *The Board of Agriculture* was founded, under the authority of government, in 1793. Much was expected from this Board; but, except the publication of the county reports, and the general attention which it called to agriculture, it may well be asked what advantages arose from it. Their *Communications*, in several quarto volumes, contain fewer valuable papers, in proportion to their total number, than the publications of either the London Society of Arts or the Bath Society. In short it has been ably shown, in *The Farmer's Magazine* and

the article *Agriculture* to the supplement to the *Encyc. Brit.*, that the Board never directed its efforts in a manner suitable to its powers and consequence; and that, instead of discussing modes of culture, its attention ought to have been directed to the removal of the political obstacles to agriculture, and to the eliciting of agricultural talent by honorary rewards, &c. No idea is more erroneous than that of such a Board, or any other, doing much good by a national "experimental farm." The government withdrew its support from this Board about 1816; and there being no longer funds for a handsome salary for a secretary, it soon after fell to pieces, and is now only remembered, at least by us, for its lofty pretensions and its worse than inutilty.

7916. *Of Welsh societies* there are only two or three, of inferior note, which have been already noticed in the topography of the country.

7917. *Of Scotch societies* the principal now existing are the Highland Society and the Dalkeith Farming Society.

7918. *The Highland Society* of Scotland was established in 1715, to enquire into the state of the highlands, to consider the means of their improvement and the preservation of their language; it is chiefly supported by the subscriptions of its mem-

bers, at a games each a year, and soon after its establishment it had a grant of 3000*l.* from government. It has published 7 vols. of prize essays and papers, and now extends its prizes to all the low counties of Scotland. (*Farm. Mag.* vol. 16. p. 316.)

7919. *Of Irish societies* the principal are the Dublin Society and the Cork Institution.

7920. *The Dublin Society* was established in 1751, and incorporated in 1749. Arthur Young observes, that it was the parent of all the similar societies now existing in Europe; but the Edinburgh Agricultural Society, as we have seen (775. and 801.), was established nearly ten years before. The Dublin Society, in its present advanced state, is one of the most complete establishments of the kind. (*Rees's Cyc. art. Dublin.*)

7921. *The Farming Society of Ireland* was established under the patronage of the Dublin Society, in 1800. The object is to improve the agriculture and live stock of the kingdom. (*Archer's Dublin*, 160.)

7922. *The Cork Institution*, for applying science to the com-

mon purposes of life, originated in private subscriptions, about the beginning of the present century. It has since been incorporated, and has received the assistance of government. It possesses a house and a large botanic garden, and under its auspices are delivered lectures on chemistry, botany, agriculture, &c.; it is not, however, in a flourishing state, and has never been of much use.

7923. *The principal county societies* in the three kingdoms have been noticed in the topography of agriculture: many or them were established several years before the Board of Agriculture.

7924. *The only other institutions for the improvement of agriculturists and agriculture* are public professorships. Of these there is one in the university of Edinburgh, established in 1795; one in Dublin, supported by the Dublin Society; one in Cork; and one is destined to be established at some future period in Oxford, agreeably to the will and donation of Dr. Sibthorpe (806. and 7789.), professor of botany there.

BOOK II.

THE FUTURE PROGRESS OF AGRICULTURE IN BRITAIN.

7925. *THE improvement of agriculture*, like that of every art, manufacture, or commodity, necessarily depends on demand and production: a powerful or effectual demand will ensure produce, and excellent produce will, to a certain extent, create demand. A general nicety of taste in coach or saddle horses will call forth a superior description of these animals, and superior animals will tempt purchasers; if the inhabitants of any district who live chiefly on barley or oats indicate a preference for wheat, and a willingness to pay for that grain, wheat will be produced, and so on. Again, as the object of every individual who engages in art or trade is to acquire gain, the advancement of an art will depend mainly on the profits it affords; an art or occupation which affords less than the average profits on capital will only be followed by such as, from habit or other reasons, cannot apply themselves to any thing better, but extra-profits

will command both capital and skill. From these considerations it is obvious, that the improvement of agriculture depends on the profits on capital employed in it, on the taste of those who purchase its products, and on the knowledge of those who are engaged in agriculture as a profession. The first subject would lead us further into political economy than would be of much use in a work of this kind, and therefore we shall limit ourselves to a few remarks on the other topics.

CHAP. I.

Improvement of Agriculture, by refining the Taste of the Purchasers of its Products, and increasing the Knowledge of Agricultural Patrons.

1796. *The desire of being comfortable* is the first step towards improvement; but before any thing can be desired, we must know what it is. Men, when they know of nothing better, rest satisfied with what they have; and therefore one of the main sources of improving the taste both of those who purchase agricultural produce from necessity, and of those patrons of agriculture who purchase from the conjoined impulses of necessity and choice, is the increase of knowledge. However paradoxical it may seem, discontent is the parent of all improvement, as certainly as the acorn is the germ of the future oak, or the time present that of all future times. The grand achievement of the present age, an eminent writer observes (*Examiner*, Jan. 9. 1831.), "is the diffusion of superficial knowledge;" and on this diffusion, superficial though it may be, the progress of agriculture and of every other art depends far more than on any thing else.

1797. *In Scotland and Ireland* could a taste for wheaten bread and butcher's meat be introduced generally among the operative classes, the advantages to agriculture would be immense. Could the same persons be taught to desire a greater degree of cleanliness, light, and warmth in their cottages; a greater variety of pot herbs, salads, fruits, and flowers in their gardens; and handsome dresses for their wives and daughters, how great the general benefit! Much may be done to bring about this change, by the opulent who are willing to reside on their estates and to take a little trouble. Building good and comfortable cottages; attaching proper gardens stocked with trees and plants from the demesne garden; and offering little premiums, or marks of distinction for keeping them in the nicest order, and for decently clothed well-bred children, would soon have a sensible effect. Attending to that kind of education which consists in teaching infants civility and politeness, with mutual respect and restraint as occasion requires; and instructing grown children how to work at almost every thing likely to come in their way, as done in the improved German and Swiss schools, would, independently of reading and writing, do a great deal to soften and humanise the peasant mind. Encouragement should be given to save money for unforeseen wants, or against old age; and the certain effects pointed out of early marriages, followed by a numerous offspring. These and a variety of similar means would be productive of some change of taste in the operative part of rural society.

1798. *The introduction of manufacturing establishments*, wherever it could be properly done, would contribute to the same effect: those who work at manufactures, and even common mechanics, generally live better, and are better clothed and lodged, than the common country labourer; therefore their example would be of use in introducing a salutary degree of luxury. "The endeavouring to impress on the minds of the lower classes the propriety of being contented with the simplest and cheapest fare, is extremely pernicious to the best interests of mankind. Encomiums ought not to be bestowed on those who are contented with mere necessities: on the contrary, such indifference ought to be held disgraceful. A taste for the comforts, the enjoyments, and even the luxuries of life, should be as widely diffused as possible, and, if practicable, interwoven with the national character and prejudices. This, as it appears to us, is the best mode of attempting the amelioration of the condition of the lower classes. Luxuries, and if you will have it so, even wasteful habits, are incomparably better than that cold, sluggish, apathy, which would content itself with what can barely continue mere animal existence." Mr. Peel observed, in the House of Commons that he thought it one of the first duties of the legislature, to do all in its power to excite a taste in the humbler classes of society for those comforts and those enjoyments—those luxuries, he might add—of civilised society, the desire for which, and the habitual possession of which, would form the best guarantee for their good conduct, and the best guarantee that the higher classes could have for the possession of their property and their power, as at present enjoyed." (*Manual of Cottage Gardening, Husbandry, and Architecture, &c.*) "In those countries," Ricardo judiciously observes, "where the labouring classes have the fewest wants, and are contented with the cheapest food, the people are exposed to the greatest vicissitudes and miseries: they have no place of refuge from calamity; they cannot seek safety in a lower station; they are already so low that they can fall no lower. On any deficiency of the chief article of their subsistence, there are few substitutes of which they can avail themselves, and death to them is attended with almost all the evils of famine." (*Sup. Encyc. Brit. art. Corn Laws*.) Such is the case in Ireland, where, amidst the germs of the greatest riches and luxury, the inhabitants are contented to live on less than any other people in the world.

1799. *The taste of the superior patrons* of agriculture is to be improved by visiting the best cultivated districts, reading agricultural works, attending agricultural societies, and, above all, by cultivating a farm, and establishing on it a systematic order and regularity in every detail. Let such observe the hedges, gates, verges of fields, and the beautiful rows of turnips, of Berwickshire or Northumberland; the correctly drilled beans of East Lothian; and the live stock of Leicestershire. But few are the proprietors of lands who either employ a proper bailiff or demesne steward; and of those who do, how few who do not limit and fetter them in their operations, or else neglect them and leave them to sink into that supine state in which the uppermost wish is to enjoy the comforts of the situation with the least possible degree of exertion! Some proprietors desire to have their home farm managed with a view to profit, as the cheapest way of getting hay, straw, mutton, &c.; these are sordid patrons. A home farm ought to combine an elegant orderly style of management, high-kept horses, harness, implements, &c., well clothed servants, and every thing in a superior style to what is seen on common farms. Particular attention ought to be paid to the buildings, which should combine architectural design, fitness, strength, and elegance; the roads ought to be like approaches to a mansion; the hedges like those of gardens, fitness, strength, and elegance; the fields kept mown like lawns or grass walks, and the ditches, bridges, and gates in corresponding neatness; the finest trees ought to be encouraged in proper situations, and correctly pruned; substantial watering places formed and kept supplied; every operation on plants, or the ground, performed in a garden-like manner; and no individual of any species of stock kept, of which a drawing might not be taken and preserved as a beauty. Even the dress and deportment of the servants on such a farm ought to harmonise with the rich culture, orderly display, and high keeping of the whole.

CHAP. II.

Improvement of Agriculture, by the better Education of those who are engaged in it as a Profession.

7930. *By education is generally understood that portion of knowledge which is obtained at schools; but in a more extended sense (as Mills observes), it may be defined the means which are employed to render man competent for pursuing the part which he undertakes to perform in life, with increased satisfaction to himself and others. Education may thus be considered as extending to every thing which operates on the body or mind, from the earliest periods of our existence to the final extinction of life. It is unnecessary here to embrace the subject in its full extent; but we shall offer some remarks on the education of practical men in general, on the professional education of an agriculturist, and on the general conduct and economy of his life.*

SECT. I. Degree of Knowledge which may be attained by Practical Men, and general Powers of the human Mind as to Attainments.

7931. *The kind and degree of education that we think ought to be given to every human being in this and in every country, and in every state of civilisation, may be thus defined:—All the knowledge and accomplishments that a child's body or mind, and the state of knowledge and the art of teaching at the time, will admit, previously to the age of puberty; giving preference to those branches of knowledge considered the most useful, and those accomplishments and manners considered the most humanising, by the wise and good of the age. It seems unreasonable to employ any child in aiding to procure the means of its subsistence, or that of its parents, before the age of puberty. Previously to that age, by means of infant schools, and of the adoption of the various improvements that have been recently made in modes of teaching, all that is worth knowing may be taught more effectually than common reading, writing, and arithmetic are, during the same time, by the common methods. Man, so trained and instructed, and living under an enlightened government, will become as different an animal from what he is at present, even in Britain, as the most enlightened modern moralist and philosopher of Europe is from an African savage. "It is not necessary," says Lequinio, writing in 1792, "to render an agricultural labourer a learned man;" but I am well assured, from my own experience, that the knowledge of every thing useful, and of much that is agreeable, both in knowledge and manners, is perfectly consistent with a life of labour in the fields. But hitherto the education of the labouring classes in the country has proved rather an obstacle to the development of reason than otherwise. Eight or ten years are employed in filling the head of a child with chimeras and prejudices, which twenty years of study will scarcely succeed in entirely rooting out. It remains for national philosophical institutions to destroy this national evil; and we shall one day have under the thatched cottage of the country hamlet thinking men endowed with reason, and capable at once of taking a part in the political and moral affairs of their country, and holding the plough or guiding the cart on their own farm. "Il faut," says this admirable writer, "que les premières leçons soient l'apprentissage des droits de l'homme, et qu'ils soient enseignés sans aucun mélange des perfides principes du fanatisme et des fruits barbares des gothiques préjugés, de quelque espèce que ce puisse être. Les notions de la raison et du bon sens tombent sous tous les intellects. Les droits de l'homme intéressent tous les individus, et l'esprit et le cœur seront bientôt d'accord pour s'en faire une science impérieuse; gravés une fois, je le répète, ils ne s'effaceront jamais; ils se concourent avec aisance, et ils se fixeront bien plus solidement que ces antiques assertions données sur la foi d'autrui, et transmises à travers les ténèbres des siècles les plus obscurs; assertions ridicules, et qui, pour la plupart, n'ont seulement pas en leur la simple vraisemblance; ils se fixeront, sur-tout, parcequ'ils seront aisément et avantageusement comparés à toutes ces faussetés miraculeuses et folles dont le néant alone éclatera pour tous, et parcequ'ils seront encore plus avantageusement mis en parallèle avec ces mystères absurdes que l'homme ne pouvait admettre qu'en rejetant l'évidence, et en se dépouillant totalement de son intelligence et de sa raison. C'est par ce simple enseignement que s'éleva tout d'un coup dans nos campagnes une espèce raisonnable et libre. Sortie, par cette création morale, du cahos ténébreux, et de l'existence léthargique où, depuis le commencement des siècles, elle croupissait sous le joug de tous les impudens habiles qui se permettaient de la dominer, nous la verrons une race nouvelle, intelligente et hardie, laisser un espace incommensurable entr'elle et les générations qui l'ont précédée." (*Les Préjugés détruits, par J. M. Lequinio. Paris, 1792. Parochial Institutions; or, an Outline of a Plan for a National Education Establishment, &c. and Des Etablissements pour l'Education Publique en Bavière, dans le Wurtemberg, et dans le Pays de Bade.*)*

7932. *A high and equal degree of education has some powerful advocates in North America, and, it is thought by many, will, at no distant period, be adopted in several of the states. The New York Daily Sentinel and the Working Man's Advocate are two of several newspapers which support what are called 'working men's measures.' Among these the first and most important is a "republican education, free for all, equal for all, and at the expense of all; conducted under the guardianship of the state, at the expense of the state; embracing every branch of useful instruction, moral, intellectual, and operative, and extending to the entire protection, maintenance, and guidance of children and youth, male and female, without distinction of class, sect, or party, or reference to any of the arbitrary distinctions of the existing state of society." (*Six Essays on Public Education, New York, 1830; Cooper's Lectures on Political Economy, as quoted in the Spectator, Dec. 4, 1830; and Gard. Mag. vol. vii.*)*

7933. *This high and equal degree of education we consider to be as much the birthright of a child in a community where there is a high degree of civilisation, as food and clothes are its birthright in the rudest state of society; because, without it, a man or woman is ushered into society without a fair chance of being able to procure those means of subsistence and of happiness which belong to human nature under the given degree of civilisation; in short, without a fair chance of making the most of life. To introduce an ignorant youth into a highly civilised country, under the supposition that he could obtain the requisite degree of prosperity and happiness, would be more absurd than to turn an educated child into a country of savages. This is one view of the subject, and it is a view on which all who can afford the expense act with respect to their own children. If we regard the subject in the light of humanity, and the sympathy of one part of society with another, this principle will equally dictate the duty of bestowing, as far as practicable, that good on others which we feel to be a good in ourselves, and which we are convinced would add to the general happiness. Viewed as a matter of public policy, and considering that the grand object of every government ought to be, with reference to its subjects, their happiness and prosperity; and, with reference to other governments, its own stability; reason dictates the use of the most important means for gaining these ends; and that it would be prudent, no less than just, in government so to legislate, as that every individual subject should have the degree of education above defined. Let nous,*

therefore, exist in society who have not their minds matured by the care and culture of public teachers, as their bodies are by the nourishment and clothing of their parents. The religious and humane owe this to the poor as a part of human nature; the benevolent, as sympathising with the miseries they suffer; the enlightened, in order to raise them to their rank in the scale of creation; the rich, to give them a greater chance of possessing property, in order that they may respect the property of others; the prudent, that they also may become prudent; and government, that they may not be made the tools or faction, foreign or domestic. (*Parochial Institutions, &c.*)

7934. *Knowledge gives power*; and if one part of society has the degree of cultivation desired, and the other has it not, it is evident that there can be very little sympathy between them. The experience of ages shows the continual tendency of the powerful in wealth or in skill to oppress the weak; and the continual tendency of the weak to re-act by personal force, by cunning, or by numbers, on the strong. Materials so discordant can never form the basis of a sound, healthy, and permanent state of society: the poor and ignorant becoming, under such circumstances, little better than slaves to the rich and enlightened, regard them as their enemies, and often finding them to be such, must and will rebel; and the result is, sooner or later, a subversion of society. It would evidently contribute to the stability and harmony of society to moderate this action and re-action, by a more equal distribution of power; and, as knowledge gives power, the most obvious and effectual way of attaining the end proposed is, by diffusing such a high and equal degree of school education as we have defined. It must be evident, we think, that the state of society which this degree of education will sooner or later produce, will include in it every amelioration and happiness of which human nature, under any given circumstances, is susceptible. (*Ibid.*)

7935. *The knowledge of languages, history, geography, arts, sciences, and literature*, which an agriculturist, whether a ploughman, shepherd, bailiff, steward, or rent-paying farmer, daily occupied with his profession, may acquire by his own exertions, provided he begins at the earliest moment, say at fifteen years of age, and continues to employ his leisure hours in reading till he is twenty or twenty-five, is by no means inconsiderable; not that he can or need become learned; but, if desirous, he may become generally intelligent, render himself fit, as far as conversation is concerned, for good society, prove instructive and entertaining to others by his conversation, and provide a reserve fund of enjoyment, by laying up a store of ideas for reflection in misfortune, disease, or old age.

7936. *The utility of knowledge* to that part of mankind who are doomed to a life of mechanical labour, or rather who suffer themselves to be doomed to it, has been questioned; it is said to render them dissatisfied with their condition, to produce various other evils, and at all events in no way to add to their happiness or the good of society. To a man whose business in life is the mere mechanical performance of operations which any other animal might perform if furnished with hands, education is doubtless less necessary than to a man whose business is to direct the operations of others; but it does not follow, that though less necessary, it may not be highly useful: if, for example, it renders him dissatisfied with his condition, it will, at the same time, be more likely than any thing else to lead him to some proper mode of improving it; or if almost unimprovable, education certainly will be more likely than a state of ignorance to teach patience and submission, by enabling him to reflect on the folly of grieving at what is inevitable, and the consequences of committing what is unjust or criminal to relieve himself. "The low Irish," Marshal remarks, "are sufficiently dissatisfied with their condition; those who know how to alleviate it by emigration, go to Britain or America; those who know nothing, stay at home, commit acts of violence, and are hanged."

7937. *To decide as to the utility of knowledge to the operative parts of society* would perhaps require a previous decision of the question, "What constitutes happiness?" The general answer is, the exercise of all our faculties of body and mind: every one who has lived thirty or forty years in the world, knows that there is no such thing as absolute happiness: the Prince de Ligne, a man of great natural parts, with every advantage of person, birth, and wealth, and in favour at all the courts of Europe; fond alike of war, literature, gallantry, and agriculture, and who lived to be upwards of 90 years of age, has left on record that he was only perfectly happy two or three times in his life, and only for a few minutes each time. Forsyth (*Principles of Moral Science*, vol. 1. chap. 1.) says perfect happiness is a thing not to be thought of; and that all that men and women can do in order to make the most of their existence, is to occupy themselves and make progress in whatever they engage in: progress in enjoyment, or approximation to happiness, is therefore the object to have in view.

7938. *The utility of knowledge to every human being* is consequently, in our opinion, unquestionable, on the mere principle of adding to enjoyment; nor do we believe that there is more danger from excess of knowledge in any particular class of society, high or low, than there is from excess in their eating or drinking. A number of men possessors of property or power by inheritance, favour, or chance, who are very conscious that they never could have acquired those advantages by the common competition of talent and industry, and who are in fact wrapt up in selfishness, are naturally jealous of the progress of knowledge; their secret maxim is to keep down the lower orders, and to impress on their minds only the duties of loyalty, religion, and, as Vancouver adds, hard work. This monopoly of power and knowledge, however, cannot be maintained for ever, and in every country it is found rapidly yielding to the general progress of society. It is only those who have to dread this progress that fear the diffusion of education and liberal principles.

7939. *Education in all countries*, in as far as it has been carried, has had the effect of rendering the poor content. Compare the poor of Sweden and Germany with those of England. The uneducated are prone to consider wealth and happiness as synonymous, a delusion which knowledge quickly dispels; philosophy teaches its fallacy, and history exemplifies it. For our own part, we can see nothing in education but increased security to the rich, and increased happiness to the poor. One of the great evils which at present afflict society in this country is over-production; not only of manufactured goods, but also of human beings. We are apt to believe that even this calamity might be remedied, if every labourer in the country considered a high and equal degree of education as a necessary of life, and no more to be dispensed with in a child than food or clothing; as in that case he would not think of marrying till he could bestow this degree of education on his children. If any labourer acted otherwise, he would bring himself into disgrace among his own class; he would suffer a loss of reputation for good sense and good taste; and his wife and himself would no longer be able to associate with their neighbours, either from the extraordinary exertions which they must make, in order to educate their children up to the general level, or in consequence of not being able to do so, and having it done for them by the parish as paupers. The dread of the reflections and neglect of the children when they arrived at maturity, and found that they were indebted to the parish more than to their parents for their education, and that they had, in fact, to pay the parish for this education themselves, would also act as a powerful inducement to prudent conduct. Besides, when parents themselves have once enjoyed the degree of education defined, they will consider it cruel and unjust not to bestow the same degree of education on their children. This is, in fact, the feeling of all educated parents; and one great object that we have in view is to communicate the same feeling to the very lowest member of society. We are justified in concluding that universal education would do so, by what actually takes place at present among the educated classes. (*Parochial Institutions, &c.*; and *The Objects to be obtained by Reform in Parliament, &c.*)

7940. *The terms knowledge and ignorance are entirely relative*: the knowledge of a modern chemist's porter would have subjected him to be hanged and burned in the days of the first popes; and any brick-layer's labourer of the present day, who reads the London newspapers, has more correct ideas of the principles of political economy than nine tenths of the nobility in Russia and Spain. It is impossible to set limits to the knowledge which may be obtained by those who are destined even to the most severe and constant labour; the intelligence of the miners in Scotland and Sweden may be referred to as proofs

The miners at Leadhills have a regular library and reading society; and the works they make choice of are not only histories, voyages, travels, &c. but even works of taste, such as the British classics, and best novels and romances. The degree to which knowledge will prevail among any class of labouring men will depend jointly on their own ambition, on the demand for knowledge, or the reputation in which it is held, and on the opportunities of acquiring it. A dull, stupid person, with little native activity, will never desire to know more than what enables him to supply the ordinary wants of life; but where the workmen of any art are required to have technical knowledge of any particular kind, they will be found invariably to possess it. Thus carpenters and masons require some knowledge of the mechanical principles of architecture, and working engineers of the strength of their materials; and these kinds of knowledge are acquired by them without an hour's interruption of their daily labour: on the contrary, the habit of evening study renders them more steady, sober, and industrious than other workmen: than bricklayers and paper-hangers, for example, whose employments require much less intellectual skill. If every cook-maid, before she could obtain a first-rate place, were required to be able to read *Apicius* in the original tongue, there would be no want of learned cooks; and if no bailiff could obtain a first-rate situation who had not written a thesis in Greek, or who had not made the tour of Europe, there would soon be found abundance of bailiffs so qualified. A Caledonian, when he comes to the low country, soon acquires the English tongue, and, if he has been taught Latin, thus knows three languages. The servants at the inns on some parts of the Continent, frequented by different nations, often acquire a moderate knowledge of three or four languages: a late custom-house officer on the island of Cronstadt spoke and wrote ten languages; and the bar-maid at the hotel de Londres, at which we lodged in Moscow, in 1814, could make herself intelligible in Swedish, Russian, Polish, German, French, Italian, and English.

7941. *The certain way of obtaining any thing* is to be impressed with the necessity of possessing it, either to avoid the evil of being without it; or to satisfy the desires of others as to ourselves; or our own desires. There is scarcely any thing a rational man can desire that he may not obtain, by maintaining on his mind a powerful impression of the necessity of obtaining it; pursuing the means of attainment with unceasing perseverance, and keeping alive that enthusiasm and ardour which always accompany powerful desires. All may not acquire, by the same degree of labour, the same degree of eminence; but any man, by labour, may attain a knowledge of all that is already known on any subject, and that degree of knowledge is respectable; what many never attain to, and what few go beyond.

7942. *The grand drawback to every kind of improvement* is, the vulgar and degrading ideas that certain things are beyond our reach; whereas the truth is, every thing is attainable by the employment of means; and nothing, not even the knowledge of a common labourer, without it: there are many things, which it is not desirable to wish for, and which are only desired by men of extraordinary minds; but let no man fancy any thing is impossible to him, for this is the bane of all improvement. Let no young ploughman, therefore, who reads this, even if he can but barely read, imagine that he may not become eminent in any of the pursuits of life or departments of knowledge, much less in those of his profession: let him never lose sight of this principle—that to desire and apply is to attain, and that the attainment will be in proportion to the application.

SECT. II. Professional Education of Agriculturists.

*7943. *In order that a professional man should excel as such*, every other acquirement must be kept subservient to that of his profession. No branch of knowledge should be pursued to any extent that, either of itself, or by the habits of thinking to which it gives rise, tends to divert the mind from the main object of pursuit; something, it is true, is due to relaxation in every species of acquirement; but judicious relaxation only serves to whet the appetite for the vigorous pursuit of the main object. By the professional education of agriculturists, we mean that direction of their faculties by which they will best acquire the science and manual operations of agriculture, and we shall suppose agricultural pupils generally to have no other scholastic education than some knowledge of reading, writing, and arithmetic.

794. *All young men who intend embracing agriculture as a profession*, whether as ploughmen, bailiffs, stewards, and valuers, or rent-paying farmers, ought to undergo a course of manual labour for one year or more, in order to acquire the mechanism of all agricultural operations. When the pupil is not destined for any particular county, then he should be sent to a farmer in a district of mixed agriculture; as, for example, East Lothian, where he would, if placed in a wheat and bean culture farm, see at no great distance the turnip system and feeding, and a few miles off, the mountain sheep-farming or breeding: when the pupil is intended to be settled in any particular county, he ought to be sent to a county as near as possible of similar soil and climate, where the best practices are in use; as from all the turnip counties, pupils should go to Northumberland or Berwickshire; from the clay counties to East Lothian, or the Cause of Gowrie; from a mountainous district to the Cheviot hills, and Tweeddale, &c.

7945. *The term of apprenticeship completed*, the future time of the pupil ought to be regulated according to the ultimate object in view: if he is intended for a ploughman, shepherd, or hedger, perhaps to introduce new practices in other counties, he may remain for a year or two longer with other masters in the same district, in order not merely to acquire but to habituate himself to all the improved operations and practices. If he is intended for a bailiff, then, after having been two years on one character of farm, let him engage himself for a second two years in a district of an opposite or at least of a different character; and for a third two years, on a third character. There are, as already shown, only three descriptions of farming in Britain: the bean and clover, or clay-land farming, which includes feeding by soiling; the turnip farming, which includes feeding both by soiling and pasturage; and the hill, or mountain, or pasture farming, which includes all the varieties of breeding. A young man therefore of ordinary intellect, who has worked two years in East Lothian on a clay farm, two years in the lower Berwickshire, or in the low part of Northumberland, and two years on the Northumbrian hills, must have a very competent knowledge of that part of agriculture known as farming or husbandry.

7946. *The higher branches of agriculture*, or what may be called the engineering, valuing, and estate-agency departments, can only be completely acquired by first going through the course above described, as suitable for bailiffs and common stewards, and next placing themselves under an eminent steward, land valuator, drainer, road engineer, irrigator, &c. as the case may be; making choice of a steward who has extensive woods and plantations, and also, if possible, some quarries, fisheries, or even mines under his care, and of a land valuer or drainer in full employment. When a solid foundation is laid by a thorough practical knowledge of all the operations of common agriculture, the higher part is attained with ease, and may be practised with confidence; but, on the contrary, when young men who know nothing of common country work are sent direct from school, or from an attorney's office, to a land steward or agent, in order to acquire the art of managing landed estates, the worst consequences may be dreaded, both to the proprietors and the occupiers of the territory which may be subjected to them. The condition of many estates and tenants, managed by attorneys, may be referred to in proof of our assertion.

7947. *Young men intended as rent-paying farmers*, after two years' labour as common servants, should be kept as assistant bailiffs on other farms, till they are at least 25 years of age: no young man, in our opinion, ought to be put in a farm on his own account, or employed as a master bailiff, at an earlier period.

7948. *In all cases when young men are destined for particular purposes*, they should be sent chiefly to particular districts; as, for example, young men intended for road-surveyors, to where roads are best managed, drainers to a draining country, embankers to Lincolnshire, warpers to the Humber, irrigators to South Corney, hedgers to Berwickshire, woodmen and foresters to Dunkeld, or Blair in Athol, &c. It

would contribute much to the improvement of agriculture in the backward counties, if landed gentlemen would prevail on their tenants to send their sons as apprentices, or even as ploughmen or farm labourers, to the improved counties; or if lads brought up by the parish were sent there with a view to their acquiring the use of the improved implements.

7948. *Whatever is the kind of professional knowledge to be acquired, the means of attainment is the pupil's paying such attention to what he sees and hears as to fix it in his memory.* One of the first things, therefore, that a young man should do is to cultivate the faculty of attention, which he may do every hour of the day, by first looking at an object and then shutting his eyes, and trying whether he recollects its magnitude, form, colour, &c.; whether he would know it when he saw it again, and by what special mark or marks he would know it or describe it. When he goes from one part of the farm to another, or is on a walk or journey, let him pay that degree of attention to every thing he sees and hears, which will enable him to give some account of them when returned from his walk or journey; and let him try next day, or some days afterwards, if he can recollect what he had seen then, or at any particular time and place.

7950. *The attention to be exercised in such a way as to impress the memory, and enable the observer or hearer, not only to recollect objects, but to describe them, must be exercised systematically.* A thing or a discourse must be attended to, not only as a whole, but as a composition of parts; and these parts must be considered not only as to their qualities of dimension, colour, consistency, &c., but as to their relative situation and position. To be able to give an account of a town or village, for example, the first thing is to get a general idea of the outline of its ground-plan, which may be done by looking from a church tower or adjoining hill; next, its relative situation to surrounding objects, as what hills, or woods, or waters join it, and in what quarters; next, the direction of the leading street or streets must be noticed; then the intersecting or secondary streets, the principal public buildings, the principal private ones, where the lowest houses and narrowest streets are situated, and what is the character of the greatest number of houses composing the whole assemblage.

7951. *To treasure up in the mind the characteristic marks of particular varieties and subvarieties of stock is a most important part of an agriculturist's professional education.* To do this effectually, some knowledge of sketching is of great use, and, if possible, ought to be acquired by every person intending to fill the situation of bailiff or steward. The knowledge of soils, plants, and their culture is a very simple business compared with the knowledge of stock, which is not only of difficult and tedious acquirement, but easily forgotten or lost: for one gentleman's bailiff that knows any thing of stock there are at least a score that know nothing.

7952. *In connection with professional studies, the pupil may find it necessary, if his education has been neglected, to go on at his leisure hours with all the usual branches of education, either assisted by books alone, or by books and the best assistance he can procure.* If his school education has extended to arithmetic, mensuration, mathematics, and drawing, he should occupy himself in acquiring a knowledge of botany, zoology, geology, and mineralogy, without a tolerable knowledge of each of which he will ever be in the dark among modern agriculturists, and in reading books on the subject. Next, let him study the various arts and manufactures that have any relation to agriculture, and store his mind with all he can acquire from one of the best general *Encyclopædias*, as that of Rees, or the *Encyclopædia Britannica*, with its excellent supplementary volumes. If he will go farther, and if he wishes to know the extent to which he may go, he may consult what we have advanced on the subject of education in the *Encyclopædia of Gardening*.

SECT. III. *Conduct and Economy of an Agriculturist's Life.*

7953. *A plan for the general conduct of life should be fixed on by every one when he arrives at manhood, and steadily pursued for the time to come: most commonly such a plan is formed by the parents soon after the child's birth, and, at the latest, when the boy is taken from school.* The boy arrived at manhood, however, is entitled to examine this plan, and amend it, or devise another more congenial to his own notions; but the risk of any change of this sort by persons so young and inexperienced is so great, that no youth ought to venture on it without the utmost consideration, and the firmest persuasion in his own mind: where the parent has done his duty, such changes of plan will not often be attempted; for, by the early infusion into the mind of a child of ideas relative to the pursuit that is intended for him, a taste for that pursuit or employment will grow up with him, and become as it were his own natural inclination. This will happen in most cases, but in some children the bias or force of nature for some particular purpose is so strong, that by no parental intreaties or reasoning can it be overcome; even where a sense of duty induced compliance with a parent's wishes for a time, the dormant inclination has at last broke out and taken the lead. In such cases, the parent may generally conclude, that where the pursuit or purpose is not bad, the force of natural inclination will be more likely to command success than the influence of parental authority; and that a pursuit or business, commonly of little profit or repute, will be more profitable and respectable when followed by a genius powerfully impelled to it, than a profitable and reputable business followed by any one against his inclination.

7954. *The plan and conduct of life are in most cases determined by accidental circumstances.* The son of the labouring man grows up without any regular training or education for a particular end, and finds himself at the age of manhood engaged in rural labour, and apparently incapable of any other; his notions and his ambition are so limited that he dare not venture to desire a change for the better; for no man ever desires that which he thinks it impossible to attain, and the mere idea of this impossibility, however erroneous, effectually restrains the attempt at improvement. The life of the ploughman or labourer, much as it differs from that of a man of eminent natural powers and superior education, is capable of much amelioration by being directed to a suitable end or object as the ultimatum, or in other words, by proceeding on a plan; plan indeed, as we have elsewhere observed (*Encyc. of Gard.* 2d edit. 7778.), is predestination, as conduct is fate.

7955. *The greater part of mankind enter on life without any fixed plan, or object in view, or, if they have some general notion of acquiring wealth or distinction, they form no plan by which it is to be accomplished; the consequence is, that such persons, after blundering on through their best years, arrive at the end without having gained any thing but experience, now of no use to them.* No man is born in possession of the art of living, any more than of the art of agriculture; the one requires to be studied as well as the other, and a man can no more expect permanent satisfaction from actions performed at random, than he can expect a good crop from seeds sown without due regard to soil and season. When we look round and observe the quantity of misery in the world, the greater proportion is, or seems to be, the result of a want of plan, or of a bad plan of life. How many parents are unsuccessful in their struggles to maintain a large family, the result of too early marriages: how many find themselves arrive at old age with no other resource for support but charity, the consequence of want of foresight in expenditure: how many are suffering under poverty, brought on by their own want of frugality, or positive extravagance; or under disease from excesses and irregularities committed in the heyday of life: and how many among those not born to inherit property, who, at no period of their life, have any other alternative between hard labour and deficient food, than disease and want!

7956. *Want of plan may not in every case be the cause of all this misery, because accident enters into life for something, both on the unfavourable as well as the favourable side of the question; but we have no hesitation in asserting, that want of plan, as a cause of misery, is as ninety-nine to a hundred: any plan at all, even a bad plan, is better than none; because those who set out on any plan will, in all probability, sooner discover its errors if a bad one, and correct them, than those who set out on no plan will.*

discover the want of one and form a good plan. The young man who is just setting out in life may well tremble at the consequences of proceeding on the journey without the guide of a judicious plan; this plan he must form himself, because he alone feels what he wants, and what he can do to gratify them; all that we can do is to offer a few hints.

7957. *In order to be able to form a plan* it is previously necessary to determine the object to be attained by it. Happiness is the object of every action of human life, and consists in the gratification of certain wants and desires: some of these desiderata are peculiar to youth, and others to old age; but many, as clothing, food, rest, relaxation, entertainment, &c., begin with the earliest, and continue to the latest period of life. All these gratifications are procured by labour; in savage life, by hunting, fishing, and gathering fruits, till the man, no longer possessing strength enough for these labours, is obliged to lie down and die of want: in civilised society, they are also obtained by labour; but here what is called property exists, and man, in the vigour of his days, when the supplies of his labour are greater than the demands of his wants and desires, or when he chooses not to gratify the latter to the full extent admitted by the former, can, as it were, embody a part of his labour, to be made use of when he is no longer able to perform it with ease: a man in this case is said to arrive at independence, instead of want, as in the case of the savage, or of beggary, as in the case of the improvident.

7958. *Independence is the grand object* which every man destined to live by the exercise of his labour or talents ought to have in view. At certain periods of life, when the imagination is vivid, and health and animal spirits in their utmost vigour, some may prefer present enjoyment, more animal gratifications, or imaginary distinctions, amatory conquests, titles, rank, military glory, and high literary or professional reputation: it is a noble attribute of our nature to prefer some of these to the mere accumulation of money; but a great warrior, poet, or painter, arrived at old age and want, if the latter be brought on by common imprudence, will not find himself surrounded by many marks of distinction; and though it may possibly be some consolation to him that the three or four letters composing his name will be sometimes pronounced together after he is dead, yet it will not be much.

7959. *The exercise of his profession* is the most rational mode in which an agriculturist, of whatever grade, can pursue independence. Only extraordinary circumstances can justify a change of profession; in common cases it indicates a want of steadiness of character, or a want of success, and the latter is commonly attributed to want of skill; it is better, therefore, to pursue unremittingly the profession to which we have been educated, even though we should not be very successful in it, than to risk an infringement on character by adopting another. The practice of agriculture, as we have already seen, (7710.) is carried on by three different classes, serving, commercial, and artist agriculturists: on each of these classes we submit a few hints to aid them in forming a plan of life, and regulating their expectations.

7960. *The greater number of agriculturists must ever belong to the lower grades of the serving class*; and act as ploughmen, herdsmen, shepherds, hedgers, woodmen, and labourers of all-work. These form the greater proportion of mankind in every civilised country, and must ever remain the bulkiest material in the social fabric. Comparing one age and country with another, however, there may be the greatest difference in their intellectual and physical condition. The ploughman of Russia is but a remove from his horse. The ploughmen in different parts of Britain are as intelligent as their employers: in Scotland they have the Bible by heart, are familiar with the history of their country, and not ignorant of its literature; they lead a laborious life, but they enjoy the inestimable blessings of health, sound sleep, and peace of mind, till the latest period; they are almost always independent, either from their labour, their savings, or, in old age or sickness, from the assistance they receive of their children in return for what was laid out on their education. These men are as happy, relatively to their capacity for happiness, as any other class whatever: if their measure is smaller, it is as full as the largest; for the essential materials of comfort and happiness are the same in all classes, and in all classes a man's wants and wishes accommodate themselves to the means of gratifying them. The rich have no wants, and their desires for the most part are no sooner expressed than gratified: the pains and pleasures of life are neutralised into a kind of insipidity, till ennui brings on disease, which to this class becomes a blessing, by procuring for them the occupation of taking medicine, the duty of attending to the doctor's regulations, and the pleasures of convalescence.

7961. *Constant labour*, even that of the humblest description in the country, when it is not oppressive, and where it is accompanied with abundance of food, sufficient clothing, and good health, is by no means inconsistent with happiness. It is a common but most erroneous idea, that happiness is confined either to the rich or the independent. Health and activity are the woods, and a rich man who has nothing to do is unquestionably more miserable than any ploughman in the empire. "Happiness," says one who has thought much on the subject, "is the full and vivid satisfaction of the mind; and it consists in content and uninjurious enjoyment, that is, enjoyment not injurious either to oneself or to any other. Among the very first requisites to this satisfaction, it will readily be perceived, is employment, either bodily or mental; and the more energetic, without exhaustion, is the employment, the more full and vivid will be the satisfaction. The human mind is naturally active; and, except in sleep, if even then, cannot with impunity be motionless or torpid. Occupation is as necessary to its health as circulation of the blood is to the body's. Employed it must be, to know content or feel enjoyment; for, by any want productive of pain, either bodily or mental, especially the latter, content and enjoyment are, according to the degree of the pain, destroyed or diminished; and the want, which the unemployed mind invariably feels, is as invariably productive of uneasiness, of listlessness, and lassitude, and their inseparable attendant, mental pain. Indeed this pain is, not unfrequently, altogether unendurable. "All the importunities and perplexities of business," says Dr. Johnson, "are softness and luxury compared with the incessant cravings of vacancy and the unsatisfactory expedients of idleness." "It is this intolerable vacancy of mind," says Paley, "which carries the rich and great to the race-course and the gaming-table." It is this vacuity, says experience, which often arms them against themselves, and hurries them to self-destruction. If, also, employment is necessary to the health of the mind, exercise is to that of the body. Employment to the mind and exercise to the body are in some degree substitutes for each other; but, for the full content and enjoyment which constitute happiness, they both, in due proportion, are necessary." (*Co-operative Magazine*, vol. i. p. 6.)

7962. *The plan of life suitable for the operative agriculturist* may very well be founded on the condition of this class of men in the northern counties of Northumberland, Berwickshire, East Lothian, and others. We have already (7809. and 7834.) described in general terms the manner in which farm servants are hired, lodged, and paid in these counties; and details by an eminent Northumberland farmer will be found in the sixth volume of the *Gardener's Magazine* (p. 589.). The essence of the mode consists in the employer providing the employed with comfortable cottages and gardens, and paying them chiefly in the necessities of life, in so much meal or flour, so much ground to grow potatoes and flax or hemp, a cow's keep, the run of a pig, if a shepherd so much wool or so many sheep, the loan of a team to bring home coal or other fuel, and a certain proportion of money. By this mode of payment the operative countryman is always sure of a comfortable home and food, sure of milk, butter, meal, bread, and potatoes, the produce of a pig, poultry, and bees, and of the produce of his garden; and this, however high may be the prices of these articles in the public market. These good things can only be rendered nugatory by the evil of a bad wife. All country servants hired by the year might be accommodated and paid more or less in this manner; and to this mode of life and payment they ought to look forward as the ultimatum of their grade in the scale of operative agriculturists. By prudent conduct, in regard to the increase of their family, and by frugality, they may live in decency and comfort, educate one or two children, and save something for old age, or unforeseen occurrences.

7963. *The Northumberland ploughman* is the happiest of labourers, and never feels a bad season. His wages are certain; and with frugality and care, his wife may bring up a large family upon this income. The reverse is sometimes the case; but this is attributed to a bad wife, who wastes the produce of the cow. The small stock of the hind being always his own, and the cow generally so, makes him prudent and careful during single service to save as much of his wages as will set him up for himself. To this, and the fact that the wages of labour are never paid out of the poor's rate, the enviable state of the Northumbrian labourer is to be attributed. It appears to operate as a preventive check upon population, and beautifully illustrates Mr. Malthus's theory; or, in the words of Burns, it teaches them to "know that prudent cautious self-control is wisdom's root." They are all anxious to give their children such education as they can command. When they are within the reach of a charity-school they thankfully avail themselves of it, and we find in every hamlet some person who teaches the younger children the rudiments; and several of these, when they get older, work and save the wages of summer to pay for putting themselves to schools in winter. (J. C. in *Gard. Mag.* vol. vi. p. 591. See also *Denson's Peasants' Voice.*)

7964. *The day labourer who has no particular employer*, and probably no fixed residence, is much less comfortable than the yearly servant; in England more especially, under the present system of poor laws and parish management, which is calculated to degrade him, and effectually to prevent any attempt at improving his condition. If, as Slaney observes, "by unremitted industry, he has been enabled to do without parochial relief, and bring up his children decently, it is as much as could be expected; for an attack of illness, or the temporary loss of employment, he is in general totally unprepared; he thinks not much of the morrow, and, as it stands, it is perhaps well for him that he does not anticipate evils which he cannot prevent. Every one knows how beneficial to the community, how advantageous to the individual, the hope of bettering his condition in life is: it cheers him in adversity, encourages his industry, promotes his content, yet from this hope the major part of the agricultural labourers of England are excluded; they toil indeed, but it is to continue, not to better their existence." (*Essay on the beneficial Direction of Rural Expenditure*, p. 170; see also the succeeding chapters of these judicious and intelligent essays.)

7965. *The condition of the labouring classes* has lately been considered by the editor of the *Scotsman*, in an article in his xvth volume (Nos. 1131, and 1132), which is also published separately in a tract entitled *The Scotsman's Advice to the Labouring Classes*. The condition of the labouring classes, it is observed in this tract, may be deteriorated in two ways; "by increasing their numbers too rapidly, and by diminishing the capital which provides them with employment. Now capital is either diminished, or its natural growth is impeded, by the enormous sums paid to the government, by the tax on corn imposed for the benefit of the aristocracy, and by the many absurd restrictions on industry, which have arisen from the ignorance or misconceptions of our legislators. To repeal or reduce taxes, and relieve industry from the restrictions which fetter it, benefits the working classes by enlarging the fund which creates a demand for their labour. The sufferings of these classes are therefore, in no small extent, imputable to the exactions and misconduct of the government. Culpable and injurious, however, as the extravagance of the government has been, I am convinced that were all the public burdens annihilated, and all the obstacles to freedom of industry removed, the relief given would be but temporary. The misery of the working classes might be mitigated by such means, but it cannot be eradicated by legislation, nor by any human means except such as shall put some check on the increase of their numbers. Scientific thinkers regard this conclusion as established on the clearest evidence; how then is the principle of increase to be checked? Only in one way: by enlightening the minds of the working classes; by inspiring them with feelings of self-respect; by teaching them the immense importance of habits of prudence, forethought, and self-control to their own happiness; by giving them true notions of their situation as moral agents, responsible for the consequences of their acts, and endowed with powers which, if rightly used, would make them to a great extent masters of their own destiny."

7966. *A radical evil in human conduct*, is that "in the article of marriage men consider life as a lottery, and they rush into the most important of all ties, without making any provision for discharging the obligations it lays upon them. This applies to the middle ranks as well as to the lower." Thousands and tens of thousands marry every year whose earnings hardly suffice for their own subsistence; and multitudes throw their offspring on the world "with as little rational consideration about its future well-being, as the crocodile shows when she drops her egg in the sand, and leaves it to the sun and the winds to hatch her young into life." Such persons shelter their thoughtless conduct under the plea of trusting to Providence: but what is trusting to Providence but trusting to chance? Nature has endowed us with reason to regulate our conduct, and in most of the common concerns of life has enabled us to foresee the consequences of our acts. After making all the use of our reason that we can, enough will still be left for chances, which may turn out, as every day shows, as much against us as for us. "To neglect the admonitions of reason, and then trust to Providence to free us from the evils induced by our own thoughtlessness, is to call upon the Deity to work a miracle in our favour; and this, instead of promoting our improvement, is only to harden us in our folly."

7967. *There are two truths of vast importance to the well-being of the labouring classes*; the first is, that as no efforts of legislation can lift them out of their misery, their happiness must always depend on their own habits of prudence, forethought, and self-control. The second is, that no man has a right to bring human beings into the world, who is not able to provide for their support and education. The law punishes severely the act of exposing a child; but the man who marries and becomes the father of children, without having any reasonable prospect of being able to keep them from beggary with all its attendant miseries, is guilty of the same crime in a lower degree.

7968. *To convert the burthens which marriage brings with it into money*, the *Scotsman* suggests the following scheme: he takes the case of an industrious mechanic beginning to earn 16s. per week at the age of eighteen, and he shows what he could accomplish by living economically, and deferring marriage till he was twenty-eight: he supposes him able to live upon 12s. 6d. per week, and to place 3s. 6d. per week in a savings' bank, by which his stock, including interest, will amount in ten years to about 100l. At his marriage he is supposed to spend 30l. in this 100l. in furnishing a house, &c. and to dispose of the remaining 70l. to provide against the following casualties.

7969. *The first casualty after marriage* which he has to provide against is sickness, which may be done by a weekly contribution of 4d. for himself and his wife.

7970. *The second casualty* is the infirmity of old age. This is to be provided against by an annuity from government, or a benefit society; and 17l. 1s. 9d. paid at once, or an annual payment of 9s. 6d. by a man at the age of twenty-eight, will obtain an annuity for him of 20l. per annum for whatever number of years he may live beyond the age of sixty-eight.

7971. *The third casualty* to be provided for is the possible widowhood of his wife: this he may do by paying down 32l. 12s., for which a man of twenty-eight may secure for his wife, supposing her age to be the same, an annuity of 10l. for life, in the event of her being left a widow, at whatever period it may happen. On this subject the benevolent and philosophic author of the scheme observes, "When society is more enlightened, it appears to me that a provision against the chance of widowhood will be considered as indispensable at marriage as a suit of wedding clothes."

7972. *The fourth casualty* is the chance of the death of the father before his child is able to shift for itself; that is, before it is fifteen or sixteen years of age. To ensure each child against this casualty, it is proposed to secure a small annuity to it in the event of his death, of say 3s. per week, up to its fifteenth year. This, the father being aged thirty, he calculates may be purchased for 5l. paid down the first year of the child's life. "A similar deposit of 5l. would be requisite at each addition made to the family; and as a marriage is assumed to produce on an average four children, the whole sum expended under this head would be 20l." Those who have more than four children must make extraordinary exertions.

7973. *A reasonable degree of security against the casualties of life* may be afforded to a working man about to enter into the married state and his family for the sum of 100*l.*, which it is shown he might save by the age of twenty-eight. That sum would be disposed of thus :

Furniture, exclusive of what was provided by the wife	-	-	-	£30
Annuity for himself in old age of 30 <i>l.</i> per annum	-	-	-	17
Annuity of 10 <i>l.</i> per annum for his widow	-	-	-	33
Provision for four children	-	-	-	20
				£100

Therefore, let no man whatever, not even the most humble country labourer, think of marrying before he has saved 100*l.*; and let him beware of spending any part of this sum, even that part which is allotted for his furniture, before he has provided for the four casualties of the married state.

7974. *To carry this scheme into effect*, mutual assurance societies by the working classes themselves, or benefit societies, would probably be the best mode, and government and the more wealthy members of society ought to lose no time in assisting in their formation. It is justly observed, however, that it cannot be too often inculcated upon the working classes, that the improvement of their condition must be their own work. Were this scheme carried into practice, "it would diminish their numbers relatively to capital, and as a consequence, *their wages would rise*. Secondly, it would rescue them and their families from extreme poverty, give them independence of character, secure to all of them the advantages of education, and thus break down the barrier which confines them to the sphere they are born in, and precludes them from obtaining any of the higher prizes in the lottery of life. To society the system would be equally beneficial: poor's rates, with all the abuses they engender, would be done away; crimes would be rare when pauperism was eradicated; and by the universal diffusion of education, all the talent in society would be made available. And last, not least, when every grown-up man had either a small stock of savings in hand, or investments in a common fund, we should have the very best guarantee for the public tranquillity. Did the working classes fully understand this scheme," its excellent author continues, "nine tenths of all the poverty, misery, and crime which we see around us would disappear; we should in fact find ourselves in a new world, full of intelligence, peace, and good order, in which life and property would be ten times more secure, happiness more equally distributed, and an admirable foundation laid for the further amelioration of the lot of mankind." (*Scotsman*, Nov. 13, 1830).

7975. *The plan of life for the directive class of agriculturists* need hardly be pointed out; the rise from a farm bailiff to a steward or bailiff, or to a domestic bailiff or steward, and thence to the general steward or factor of an estate, is an obvious object of ambition. In another direction he may rise through the different gradations of the commercial agriculturist, or, adopting the rank of counsellor or artist, he may become a salesman, appraiser, timber or land-surveyor, land-valuer, agent, or agricultural engineer; rarely, however, can he attempt the veterinary profession, or that of draftsman, author, or professor.

7976. *The remuneration to which a directive agriculturist is naturally entitled*, should be regulated by his professional abilities and experience; that which he will commonly receive will be regulated by the quantity of agricultural talent and experience in the market; it ought always to be such as will render it worth his while to be honest, assiduously attentive to the interest of his employer, and of polite and obliging manners. A handsome salary to such a servant is wise economy.

7977. *The object of the artist or counsellor agriculturist* may be either to ascend to the rank of author or professor, conditions of more honour than profit; or to realise property and become a proprietor cultivator. For a rent-paying farmer, no artist or author is at all adapted.

7978. *The legitimate object of a commercial agriculturist* is to rise in the different grades of his class, and become either a large farmer, a gentleman farmer, or, best of all, a proprietor cultivator.

7979. *The profits to which a commercial agriculturist is entitled*, comparatively with those of other commercial men, are theoretically determinable by the risk attending the employment of his capital, and the skill requisite to prosecute his art; but, practically, this remuneration will depend on the quantity of skill and capital in the market. The risk attending capital employed in the culture of the useful products of the soil, is evidently less than the risk of capital employed in many or perhaps most manufactures; and the skill requisite to enable any one to become a farmer, according to the customary practices of the country surrounding him, is less than that required for almost any branch of manufacture. In consequence of these things, there are men every where ready to become farmers; hence the profits of farming are naturally less than those of most other pursuits; but, to counterbalance this, the farmer has several advantages peculiar to his profession. First, the nature of his residence in the country, which assumes a certain degree of consequence from its connection with a considerable group of out-offices, surrounded by a garden, orchard, fields, woods, and other rural scenery, all in his occupation, and inhabited by servants in cottages, horses, cattle, sheep, and other domestic animals, in subjection to him, gives him a degree of consequence both real and apparent; and assimilates him more nearly to a lord of the soil, and to the possessor of that sort of rural retirement and independence which is the object of almost every commercial man's ambition, than any other mode of life could do. Secondly, many trades and professions preclude (according to general prejudices) their followers from being gentlemen: whereas, though every farmer is not a gentleman, yet any gentleman may become a farmer, without in any degree lowering his rank and character; a farmer may, therefore, if he chooses to adopt the habits and manners of a gentleman, be reckoned as such. Thirdly, the farmer's products are in universal demand, and he is sure of a market at some reasonable rate, a fact otherwise with many manufactures. Fourthly, he is sure of a home, of the necessities of life, and, in general, of most vigorous health. Fifthly, he is generally a man of more parochial influence than the tradesman or manufacturer.

7980. *Scarcely any farmer makes a fortune by his profession*: the utmost exertions of the most skilful and industrious men, in the most improved districts, seldom do more than enable them to keep pace with the times; and the great majority, in all countries, lead a life of great labour and anxiety, and end as they began. No farmer, in a general way, can raise more than one corn crop in a year, and in this respect the farmer of Russia and Poland has the advantage of the British farmer; for the lands of the former being from five to eight months under snow, all root-weeds are destroyed, and the ground so loosened by the frosts and thaws, as to require very little stirring for the seed: the rapid summer which succeeds ripens all annual plants that will grow there, nearly as well as in England, and better than in many parts of Scotland and Ireland. The British farmers, however, have the great advantage of perpetual pastures, owing to the mildness of our winters; but still no art of man will shorten the period of animal gestation, and originate a lamb or a calf in shorter periods than five months and forty weeks. How often does the tradesman or manufacturer turn his capital in that time! There are three varieties of professional farmers, however, who occasionally realise some property: the grazier who feeds with oil-cake, grains, and other artificial foods; the dealer in corn or cattle, who has the art to buy at a falling and sell at a rising market; and the dealer or jobber in farms, who sublets or sells his lease, or in purchases of land, who subdivides and sells estates. The profits of the first are not great, and those of the last two are attended with great risk: the only farmer whose lot is to be envied, lives under a landlord who does not take the full marketable price for his lands: such as Burdett, Coke, Bedford, Northumberland, and many others in the south; but few in the north, or in the west.

CALENDARIAL INDEX.

Though agricultural operations, in general, require less nicety as to the exact time of performing them than many of those of gardening, yet there are exceptions in respect to some field crops; for example, beans and turnips. It is proper to observe, therefore, that the *almanac time* in this Calendar is calculated for the meridian of London; but as a *Calendar of nature* is given for the metropolitan district, the almanac time may, in every part of the empire, be varied to suit the local climate and vegetation.

In general, other circumstances being alike, four days may be allowed for every degree, or every 70 miles north or south of London; in spring, operations may be commenced earlier in that proportion southwards, and later northwards; but in autumn the reverse, and operations deferred as we advance southwards, and accelerated as we proceed to the north. In every case allowing a due weight to local circumstances.

Our notices under each month extend only to a few of the leading features of country-work; — to attempt to insert every thing, or even most of the things that require attending to, we conceive impossible; and, if it could be done, quite useless. A man will always act better when guided by his own judgment, than when following implicitly that of another. Calendars should only be considered as remembrancers, never as directories.

JANUARY.

Weather at	Average of the Thermometer.	Greatest Variation from the Average.	Average of the Barometer.	Quantity of Rain.	REMARKS.
London	35 9	6	29 56	1.957 inch.	A cold January is reckoned seasonable; the air being drier during a low state of the thermometer than when it is a little above or below the freezing point; winter-cold is generally less felt by animals than that of March. Winds often prevail during this month. The calendar of animated nature is much more to be depended on than the vegetable calendar; for except the catkins on trees, the state of the other plants during this month depends much on the character of the preceding autumn.
Edinburgh	34 3	-	29 194	2.994	
Dublin	39 92	-	29 721	2.697	

1. Calendar of Animated Nature round London.

In the first week: shell-snails (*Helix*) and earth-worms (*Lumbricus terrestris*) appear.

Second week: redbreast (*Monticola Rubicola*) whistles, nut-hatch (*Sitta europæa*) chatters, missal thrush (*Turdus viscivorus*) sings, and wagtails (*Motacilla alba et flavæ*) appear.

Third week: the common lark (*Alauda arvensis*) congregates.

Fourth week: snails (*Helix hortensis*) and slugs (*Limax ater et hyalinus*) abound in the sheltered parts of gardens; the hedge sparrow (*Motacilla modularis*) whistles, the large titmouse (*Parus major*) sings, and flies appear on windows.

2. Calendar of Vegetable Nature round London.

In the first week: some plants accidentally in flower; and others, as the *Laurustinus*, continued from December.

Second week: winter aconite (*Eranthis hyemalis*), Christmas rose (*Helleborus foetidus*) in flower, and hazel (*Corylus Avellana*) catkins beginning to appear: common honeysuckle (*Lonicera Periclymenum*) buds begin to appear.

Third week: primrose (*Primula vulgaris*) flowers in sheltered places; daisy (*Helis perennis*) and chickweed (*Alopecurus media*) begin to flower.

Fourth week: mezerion (*Diaphne Mesereum*) begins to flower; and sometimes spurry (*Spergula arvensis*), pansy (*Viola tricolor*), white scented violet (*Viola odorata*), archangel (*Ammann rhubarum*), and coltsfoot (*Tussilago purpurea et odorata*) show blossoms.

3. Farm-yard. (2902.)

Attend to cattle, whether in the open yard on straw and a few turnips (5411), in hammels for feeding (6855), or in stalls (6852). See that the weak are not driven from their proper share of green food by the strong; notice any in bad condition, and put them in a place by themselves for a few weeks. When the hay or straw is of inferior quality or flavour, sprinkle with salt water, which will make it more palatable.

Threshing (3199) goes on pretty regularly at this season for the sake of a supply of straw. In some districts it is common to thresh an hour every morning by candle-light during the three winter months, the candles being hung up in lanterns. See that the gudgeons and other places are kept oiled, and the teeth of wheels greased or soaped, or coated with anti-rustion.

Implement not now in use may be repaired, also harness greased, ropes spliced, and various regular jobs executed, where it is customary to work a part of the winter evenings.

Men's lodges. (4160.) In some districts the unmarried farm-servants have a common living-room in the farmery, with a sleeping-room over, or sleeping-rooms over the house. It is the duty of the farmer or bailiff to see that these young men are properly occupied during the long winter evenings. A portion of every man's time will be taken up in mending his clothes or shoes, and sometimes in oiling and cleansing horse harness; the rest they ought to be encouraged to pass in reading, or otherwise instructing themselves. One may read aloud

to the rest; one may instruct the others on any subject; a master may be got in for an hour or two every evening, who would teach them all. A master suitable for this purpose will often be found among the married servants, or among the village mechanics. To serious studies may be joined recreative ones, such as the flute, violin, story telling, singing, speech-making, dramatic attempts, &c. The bailiff or farmer should occasionally come and examine each lad, and bestow some mark of approbation on the most deserving.

4. Live Stock. (6216.)

Store farms (7191.), whether of sheep or cattle, require considerable attention during the winter and spring months to supply straw and hay, with such green food as can be spared, to stock on scanty pastures; and to shelter during storms, especially of snow.

Lambs are dropped during this month by the Dorset sheep, and near London are generally kept in the house and fed. (7224.) These require regular attention.

Cattle fattening at this season (6843.) should be kept very clean, and their supplies of milk liberal. Calves to be reared as stock should never be dropped sooner than April.

Pigs (7235.), poultry (7453.), and stock in general, should be kept in good heart at this season, otherwise in the spring months they will be fit for nothing, and half the summer will elapse before they recover the bad effects of winter starvation.

Fish, when the ponds are covered with ice, require attention, to break holes to admit air. (7572.)

Bees if dormant do not require to be fed; but if the weather is so mild, or they are placed in so warm a situation as to occasion their flying about, they should be examined, to ascertain if feeding be requisite. (7602.)

5. Grass Lands. (5643.)

Dry soils and uplands should alone be stocked with cattle or young horses at this season. (5839.) Sheep should not be allowed to graze either on wet marshy meadows or on young clovers. (5645.) Grass lands, under a system of irrigation, may not be kept covered. (4387.) Clayey soils, and others not properly drained should now have that operation effectually performed on the surface (4294.) or under it (4282.), according to circumstances.

Worms (7104.) on some soils do considerable injury to grass. Where the labour is not considered too much, and there is a water barrel at any rate, they may be killed by mixing powder of lime with the water, at the rate of one pint to ten gallons. On lawns, and in small paddocks, or in the cases of *ferrous ornées*, getting rid of worms casts is an object worth attending to; and this month, February, and October, are the best seasons for the operation.

6. Arable Lands. (4025.)

Plough when the soil is not too wet. Lead out dung and farm field dungills, also compost heaps, with peat or other matters. See that drains, ditches, and water-furrows run free, and answer their respective ends.

Beans (5922.) are in some dry situations planted in the last week of the month; and also peas, and sometimes oats, are sown. On the whole, however, it is better to defer the beans and peas till the first and second weeks of February, and the oats till the two last weeks of that month.

Spring wheat of the common kind (5025.) may be sown where the soil is suitable.

7. Fences (2960.), **Roads** (3523.), and **Drains** (4213.)

Hanthonas may be planted in fence-lines, in any of the different modes. (2972.) Ditches, walls, palings, and all other fences of the common kind may be formed; but one where hollies or other evergreens are to be used. Repair by the different modes. (2967.) Roads and drains may be formed at all times and seasons.

8. Orchards (4079.) and **Hop-grounds**. (5997.)
Prune trees and free them of moss. Where digging round each tree is practised, this is a good season. Stake and the newly planted trees. Plaut orchards. Trench ground for hop plantations. (6007.)

9. Wood-lands and Plantations. (3906.)
Prepare the soil for planting. Plant deciduous hard-wooded trees in mild weather. Plant and sow the larger tree seeds, whether in places where they are finally to remain, or in nursery-grounds.

Fell timber and coppice not valuable on account of its bark. Stock up roots, stack them, and char them.
Prune deciduous trees; fill up vacancies. Cut hawthorn hedges. (2953.) Gather any tree seeds not before gathered.
Drain wood-lands and cut paths or other openings required through them, the leaves being now off the deciduous sorts.

FEBRUARY.

Weather at	Average of the Thermometer.	Greatest Variation from the Average.	Average of the Barometer.	Quantity of Rain.	REMARKS.
London -	42 3	5	29 94	0.873 inch.	This month (the <i>spring or sprout kale month</i> of the Saxons) is usually subject to much rain, or snow; either is accounted seasonable: the old proverb being, "February fill dike with either black or white." Round London, the sap in vegetables shows evident symptoms of motion about the middle of the month, and sometimes a week earlier. The animal calendar, and influence of native trees for this month, will generally be found very correct.
Edinburgh -	38 6	-	29 56	1.269	
Dublin -	43 78	-	30 091	2.24	

1. Calendar of Animated Nature round London.
In the first week: bees (*Apis mellifica*) come out of their hives, gnats (*Culex*) play about, insects (*Insecta*) swarm under sunny hedges, and the earth-worm (*Lumbricus terrestris*) lies out; hen-chaffinches (*Cathartes*) are seen, and the ring-necked or throated (*Turdus musicus*), and common lark (*Alauda arvensis*) sing.

Second week: the buntings (*Emberiza alba*), and finnets (*Fringilla linata*), appear in flocks; sheep (*Ovis Aries*) drop their lambs; geese (*Anas Anser*) begin to lay.

Third week: rooks (*Corvus frugilegus*) begin to pair, and resort to their nest-trees; house-sparrows (*Fringilla domestica*) chirp, and begin to build; the chaffinch (*Fringilla coelebs*) sings.

Fourth week: the partridge (*Zetras Perdix*) begins to pair, the stockbird (*Turdus Merula*) whistles, and the wood-lark (*Alauda arvensis* et *arboræa*) sings; the hen (*Phasianus Gallus*) sits.

2. Calendar of Vegetable Nature round London.

In the first week: the snowdrop (*Galanthus nivalis*), which (*Ulex europæa*), white deadnettle (*Lamium album*), polyanthus (*Primula veris*) flowers; and the elder (*Sambucus nigra*), and some roses and honeysuckles, begin to expand their leaves.

Second week: common crowfoot (*Ranunculus repens*), dandelion (*Leontodon Taraxacum*), and the female flowers of hazel (*Corylus Avellana*) appear.

Third week: *Veronica agrestis* in flower; many of the poplar and willow tribe show their catkins; and also the yew (*Taxus baccata*), alder (*Alnus communis*), the tulip (*Tulipa*), crown imperial (*Fritillaria imperialis*), and various other bulbs, boldly emerging from the ground.

Fourth week: the *Erica carnea* wood strawberry (*Fragaria vesca*), some speedwells (*Veronica*), the groundsel, and sometimes the stocks and wall-flower (*Cheiranthus*) in flower. Some sorts of gooseberries, apricots, and peaches, beginning to open their buds.

3. Farm-yard. (2902.)

See last month. In taking in stacks to thresh, destroy vermin as much as possible. (6632.) Clear away the bottoming of straw, faggots, or other temporary matter, and leave the site perfectly neat and clean: the poultry will pick up what grains may have dropped. Be vigilant in keeping stock of every description in order; wintering cattle by frequent supplies of fresh straw and turnips, or other roots; horses by sound corn, and good peat-straw, or clover-hay, dispensing as much as possible with wheat and oat straw. The evening food should, occasionally at least, be of carrots or potatoes.

Poultry now lay freely; and if some indicate a desire to incubate, so much the better where an early brood is an object.

Men's lodge. There are still a good many hours for mental improvement.

4. Live Stock. (6216.)

Sheep generally begin to lamb during this month, and re-

quire unremitting attention from the shepherd. (7112.) Attend to feeding lambs as before (7224.), and to milch cows (6865.) and fattening calves. (6845.)

5. Grass Lands. (5643.)

See last month. Manure, where applied to grass lands, may be laid on at this season; and such old mow lands as are to be broken up may now be pared with a voss to burning next month.

The watering of meadows in warm situations may be partially left off towards the middle of the month, to encourage the growth of the grass. (4385.)

6. Arable Lands. (4925.)

Beans should be put in during this month. (5222.) Peas for podding, and for a ripened crop, may be sown at different periods (6114.) and tares for soil, &c. (5257.) Oats sown from the middle of this month to the middle of March (5160.) unless on very old turf, where they may be sown later. It is a common but erroneous opinion, that old grass lands intended to be broken up and sown with oats or beans, should be ploughed as early as possible, so as the frost may have some effect on the furrow before seed-time. But this, though most plausible, is a most dangerous doctrine, it being found from experience, that lands so ploughed and sown are always more subject to have the plant of corn destroyed by the grub, wire-worm, or other larvae. The only safe mode with such lands, is not to plough them till about the middle of March, and then to plough, sow, and roll immediately afterwards. It would appear that by this practice the larvae of insects are buried so deep, that they have not time to reach the surface before the grain has germinated and grown out of the reach of their attacks, or probably they may be so deeply buried as to be obliged to remain another season under ground; it being known to naturalists, that the eggs, larvae, and chrysalides of many insects, like the seeds of many plants, will, when buried too deep, or otherwise placed in circumstances not favourable for their immediate hatching or germination, remain there, retaining their principle of life, till they can make their way, or are by accident placed in circumstances favorable for their development. The safest plan, however, to break up old grass land is to pare and burn. (5865.)

Spring wheat of the common kind may now be advantageously sown (5004.) and barley is also sown in some warm spots in the last week of the month.

7. Fences (4213.), **Roads** (3523.), **Drains**, **Ditches** (2960.), **Ponds**. (4467.)

Hedges may be planted (2978.), grown ones pruned (2981.), old ones plashed or cut down (2987.), and imperfect ones repaired. Walls built (3036.), water-fences and ponds formed. (4467.)

8. Orchards (4079.) and **Hop-grounds**. (5997.)

See last month.

9. Wood-lands and Plantations. (3906.)

See last month. Where there is a nursery store, nut and kernel tree seeds may now be sown.

MARCH.

Weather at	Average of the Thermometer.	Greatest Variation from the Average.	Average of the Barometer.	Quantity of Rain.	REMARKS.
London -	46 4	4	29 20	0.716 inch.	The beginning of March usually concludes the winter; and the end of the month is generally indicative of the succeeding spring; according to the proverb, "March comes in like a lion, and goes out like a lamb." The Saxons called this month <i>the lengthening month</i> , in allusion to the increasing of the days. This is a laborious and trying month, both for men and cattle engaged in field operations.
Edinburgh -	41 7	-	28 886	1.455	
Dublin -	44 09	-	29 707	2.354	

1. Calendar of Animated Nature round London.

In the first week: the ring-dove (*Columba Palumbus*) coos; the white wagtail (*Motacilla alba*) sings; and the yellow wagtail (*Motacilla flava*) appears. The earthworm (*Lumbricus terrestris*), and the small Helix and slug (*Limax*) engender.

Second week: the jackdaw (*Corvus Monedula*) begins to come

to churches; the tortit (*Parus cruentus*) makes its spring note; brown wood-owls (*Strix Uta*) hoot; and the small tortoise-shell butterfly (*Papilio urticae* L.) appears.

Third week: the marsh titmouse (*Parus palustris*) begins his notes. Various flies (*Musca*) appear. The fox (*Canis Vulpes*) smells rank. The turkey-cock (*Meleagris Gallo-Pavo*) struts and gobbles.

Fourth week: the yellowhammer (*Emberiza Citrinella*) and green wood-pecker (*Picus viridis*) sing; rooks, ravens (*Corvi*), and house pigeons (*Columba*) build; the goldfinch (*Fringilla Carolinæ*) sings. Field-cricket (*Scrabonæ*) open their holes; and the common fly (*Pulex irritans*) appears.

2. Calendar of Vegetable Nature round London.

In the first week: various species of the pine, larch, and fir tribe in full flower; the rosemary (*Roosmarinus officinalis*), the willow (*Salix*) and bay (*Laurus nobilis*) in blossom; various trees and shrubs beginning to open their buds.

Second week: the common honyeucackle (*Lonicera Periclymenum*), and some roses in leaf; *Cercus verna*, and other subspines, and some Scelline in flower. Pilewort (*Ficaria*), and creeping crowfoot (*Ranunculus repens*), Hepatica, and elder (*Sambucus nigra*), sometimes in leaf.

Third week: *Saxifraga oppositifolia*, *Draba verna*, *Daphne ponicata*, and collins; and *Lonicera nigra*, in flower.

Fourth week: the peach, nectarine, apricot, *Cercoborus japonicus*, *Pyrus japonica*, crows in blossom; *Saxifraga crassifolia*, *Buxus sempervirens*, and other plants, in warm situations, in flower, or just advancing to that state.

3. Farm-yard. (2902.)

Wintering cattle should be liberally supplied with food from this time, till they can be wholly turned to grass: as straw and hay gets drier at this season, more should be given, and the supply of turneps, or other roots, rather increased than diminished. Where oil cake, brewers' grains, and similar articles can be obtained, they are valuable auxiliaries. Fasting cattle (5852) and milch cows (5863) require continued attention to food, cleanliness, and moderate exercise. Working horses must be kept in good condition; if they fall off now, they will not recover themselves for several months. Potatoes may now be cut into sets preparatory for next month.

4. Live Stock. (6216.)

Sheep now drop their lambs freely; and none pay better than such as are turned fed at this time, and finished off in April, on forward pasture. As turnips begin to run to flower about this time, they are apt to prove more than usually laxative, and therefore the stock supplied with them should have an extra supply of hay.

5. Grass Lands. (5643.)

Meadows intended for mowing (5768.) should now be shut up, their surface having been freed from stones or other extraneous matters, the furrows or water gutters made completely effective, and, if the weather will permit, the surface bush-harrowed, and rolled. Meadows which have been flooded during winter will, in favourable situations, show a considerable crop of grass by the beginning of this month. Turn off the water a week or ten days, till the surface gets firm; then feed with ewes and lambs, giving a little hay in the evening. Calves may also be turned on these meadows, but nothing heavier. The best mode is to hutch off the grass in strips, in the manner of eating turnips or clover in the places of their growth. Moles (7651.) and worms (7704.) are best destroyed at this season.

6. Arable Lands. (4925.)

There are few hardy seeds, whether of agriculture or gardening, that may not be committed to the soil during this month. Spring wheat of the common kind (5004.) may still be sown; but if possible, not later than the middle of the month; oats (5120.), rye (5069.), barley (5080.), canary corn (5169.), buck-wheat (5111.), beans (5222.), peas (5121.), tares (5207.), &c.

Clover and rye grass (5021.) may now be sown among young wheats after naked fallows, or among spring corn in lands in good heart and fine tilth.

Field beet (5982.), carrots (5423.), parsneps (5471.), and Swedish turnips should be sown the last fortnight of the month, provided the land is dry enough to be sufficiently cleaned, and pulverised to the depth of at least a foot. It more frequently happens that this cannot be got done till the beginning of April, and hence this class of seeds is seldom got in before the middle of that month. The carrots should be first sown, and the Swedish turnip will bear to be the latest. Lands intended for potatoes, carriagees, turnips, transplanted Swedish turnip, and other plants of the *Irdisca* kind should be brought forward by such ploughings, cross ploughings, and workings with the grubber, as their nature and state may require. It is one great advantage of the common white turnip, that it admits of two months more time for preparing the soil than either root or *Irdisca* crops. Summer or wheat fallows require at least one furrow in course of the month.

7. Fences (2960.) Roads (3523.), and Drains. (4213.)

Thorns and other hedge plants may be put in, but the earlier in the month the business is completed the better. This is an excellent season for making or repairing roads (3727.), drains, ponds, embankments, &c., the ground being still moist, and the days sufficiently long to admit of a man's labouring ten hours, or from six to six. In January, the ground is often too wet, or frozen, or covered with snow, and the days too short for advantageous day labour. In July and August the ground is too dry and hard for spade work, and day labour high on account of the proximity of hay-time and harvest.

8. Orchards (4079.) and Hop Grounds. (5997.)

Finish pruning fruit-trees (4111.), and also digging round their stems, if that is practicable (4194.). Where young orchards are in grass, see that the guards or fences to the single trees are in repair.

Form plantations of hops (5997.), and open up and dress the hills of established plants, returning the mould to their roots. (5025.)

9. Wood-lands and Plantations. (3906.)

In the tree nursery, finish sowing acorns, keys, nuts, mast, berries, stones. Sow also the lighter trees, as poplar seed (where it can be got), willow, birch, alder, elm, &c. Transplant from the seed bed, or from narrow to broader intervals, and attend to other parts of the usual routine culture.

New plantations may still be planted, endeavouring if possible to finish putting in deciduous trees with the month; using the puddle in dry weather (3940.), and fixing by water. (3952.) Where large trees are introduced, the latter generally require to be staked.

Evergreens of the harder kinds, as the Scotch pine, spruce fir, &c. may be transplanted in the last week of the month, but not earlier before. They are often put in during any of the winter months, but the result shows the impropriety of the practice.

Fill up blanks (3983.) in young plantations and hedges, and fell timber, cut over coppice woods, and thin out young woods as in last month. When plantations are to be raised from seed where they are to remain for timber (3926.), this is the month for best seed, but April is better for the pine and fir tribe. Sow the others in the second or third week of the month; and if resinous trees are to be mixed, a sprinkling of their seeds can be sown over the others in April.

APRIL.

Weather at	Average of the Thermometer.	Greatest Variation from the Average.	Average of the Barometer.	Quantity of Rain.	REMARKS.
London	49 9	3	29 77	1.460 inch.	The weather of this month is distinguished by the rapidity of its changes. It is generally stormy, interspersed with gleams of sunshine, hail, snow, some frost, and occasionally violent storms of wind. It is a month of the utmost activity to the cultivator of arable land, who during its course finishes the sowing of spring corns and grasses, and begins that of roots and leaves.
Edinburgh	46 3	-	29 873	2.414	
Dublin	51 125	-	32 909	2.561	

1. Calendar of Animated Nature round London.

In the first week: the viper (*Cobaber berus*) and woodlouse (*Oniscus Asellus*) appear; the missoleet thrush (*Turdus viscivorus*) pairs; frogs (*Rana*) croak and spawn, and moths (*Pleuro*) appear.

Second week: the stone curlew (*Charadrius Edolenemus*) clamours; young frogs (*Rana temporaria*) appear. The pheasant (*Phasianus*) crows, the trout (*Salmo Trutta*) rises, and spiders (*Aranea*) abound.

Third week: the crested wren (*Motacilla Regulus*) sings; the blackbird (*Turdus Merula*), raven (*Corvus Corax*), pigeon (*Columba domestica*), hen (*Phasianus Galline*), and duck (*Anas boschas*) sit; various insects appear; and the fieldfare (*Turdus pilaris*) is still here.

Fourth week: the swallow (*Hirundo rustica*) returns; the nightingale (*Motacilla Luscinia*) sings; the bittern (*Ardea rotellaria*) makes a noise; the house martin (*Hirundo arctica*) appears; the blackcap (*Motacilla Altricapilla*) white; and the common snake (*Cotuber Natix*) appears.

2. Calendar of Vegetable Nature round London.

In the first week: the daffodil (*Narcissus Pseudonarcissus*), the garden hyacinth (*Hyacinthus orientalis*), the wallflower (*Cheridanthus Cheiri*), the cowslip (*Prunella officinalis*), the periwinkle (*Vinca*), sloe (*Prunus spinosa*), and various other herbs and trees in flower.

Second week: the ground-ivy (*Glechoma hederacea*), gentianella (*Gentiana acuta*), *Pulsinellia virginica*, the auricula, *Iberis sempervirens*, *Omphalodes verna*, and most of the common fruit-trees and fruit-shrubs in flower.

Third week: some of the American, *Ranunculus Kalmii*, and other American shrubs; *Diphne auriculata*, *Ulmus campestris*, *Chrysosplenium oppositifolium*, *Mercurialis perennis*, and other plants in flower.

Fourth week: the beech (*Fagus*) and elm (*Ulmus*) in flower; ivy-berries drop from the racemes; the larch in leaf, and the tulip and some white narcissi and fritillaries in flower.

3. Farm-yard. (2902.)

This month will in most situations terminate the wintering of cattle in the straw-yard. Straw is now very dry, therefore turnips, or other green food or roots, should be added in proportion.

Horses should be kept in high order, on account of the hard work and extra exertion often required of them during this month. If there are carrots or potatoes to steam for them once a day, that will greatly aid hay and corn; if not, steam a part of the hay.

The accidental supplies of food for store pigs and poultry are less abundant during this month, because less time can be spared for threshing. There are fewer wintering cattle, and the yards are generally now cleaned out for the field dung-hill.

4. Live Stock. (6216.)

The end of this month is a good time for mares to foal (6629.), and they should have the horse accordingly. (6631.) Attend at the proper periods, first to moulture working, and then to entire case before foaling time. (6641.)

Cows must still be well fed with roots or steamed food, within doors, letting them taste the grass occasionally towards the end of the month. (6853.)

Sheep and lambs generally require a good deal of artificial food during the first half of this month. When the turnips are expended, clover hay, grains of barley which have been malted, rape cake, or linseed cake, are the next resources. (6094.) About the end of the month the ewes may be turned on the pastures, and then it is that nutren generally drops in price—a hint to the farmer to sell all he can in the early part of April.

Where there are water-meadows, the sheep and lambs will have been fattening on these during the whole of the month, — an immense advantage to a farmer.

Poultry of most kinds have now hatched their broods, and require looking after, to see they do not injure one another, nor are attacked by stronger enemies.

5. Grass Lands. (5643.)

See that the fences are kept up, and the gates regularly shut and fastened; as cattle newly let out are very apt to wander, and more ready to break through fences than when the herbage is more abundant.

Water-meadows (4371.) are generally shut up for hay about the end of the month, the ewes and lambs being then turned on young artificial grasses, or common provincial pastures, in a sufficiently far ward state.

Mowing-meadows of the common kind (5768.), and clovers, and mixed grasses for hay, should be hand-picked, bush-harrowed, and rolled, early in the month, and then shut up for the scythe.

6. Arable Lands. (4925.)

Finish sowing all the spring crops (5080.), peas, tares, lucerne (5674.), sainfoin, and all other herbage, plants, and grasses (5643.).

Summer wheat (5004.) may be sown during the whole of the month, also barley in late situations (5080.), peas for late podding, and under peculiar circumstances, tares for cutting green in October and November.

Manufactures of wool, cord, madder, flax, hemp, mustard, &c.; oil plants, as rape, poppy, and such plants as are grown for medicinal purposes or peculiar uses in domestic economy, as rhubarb, liquorice, buck or beech wheat, &c., may all be sown or planted from the middle of last to the middle of this month. The first week in April will, in the greater number of seasons, soils, and situations, suit the most of them.

Carrot (5443.), fluid beet (5482.), parsnep (5417.), and Swedish turnip (5408.) not sown the last week of March, should be finished during the first ten days of April. A bed of Swedish

turnips should be sown in the garden for transplanting in the field by the end of the month, or the first week in May.

The last fortnight of the month is the best season for planting potatoes (5316.); in the earliest situations this is soon enough for a full crop; in the latest, the middle of May will answer dry rich sheltered fields may be planted in March. In the moors of Scotland they often plant in June, and still have a crop; there the potato is alike obnoxious to late spring and early autumnal frost.

* 7. Fences (3960.), Roads (3523.), and Drains. (4213.)

All these should have been put in order before, so as to leave the hedger of the farm (7714.), and the labourer of all work (7711.), time to assist in getting in planted crops, as potatoes, cabbages, &c. in the fields, cropping the garden, mowing, or otherwise dressing the orchards, shrubberies, lawn, or such ornamental or enjoyment ground as the farmer indulges in round his house.

8. *Orchards* (4079.) and *Hop-grounds* (5697.). In some cases fruit-trees may be so over-run with insects towards the end of the month as to make it worth while to burn wet straw under them; but this rarely happens before the middle of May, and even then farm orchards may almost always be left to the birds and vigour of the trees. Hops are generally potted in this month, and the ground between the hills afterwards stirred with the cultivator or nudget as it is called in Kent. (6026.)

9. *Wood-lands and Plantations*. (3906.) All planting and pruning of deciduous trees should be finished the first week of the month. Afterwards the planting and pruning of evergreens may commence; first the common pine and fir, and afterwards the holly, yew, and other forest evergreens. (3937.) If these can be watered, and staked, so much the better. Barking oaks may in some warm situations be done the last week of the month, but May is the more general time. (4050.)

MAY.

Weather at	Average of the Thermometer.	Greatest Variation from the Average.	Average of the Barometer.	Quantity of Rain.	REMARKS.
London	56 61	2 5	30 02	0.794 inch.	Vegetation now goes on with great vigour, though there are often very cold and even frosty nights, which materially injure the blossoms of fruit-trees, and sometimes the young shoots of the hop and potato. Many, in common with other animals, being now full of life and vigour, the consummation of animal desire is frequent; but marriage is better deferred till September, when the offspring will be born in the May or June following, a season the year when the poor man can better support the expenses of an accoucher than in the cold month respondent to marriages in May.
Edinburgh	50 4	- -	29 585	1.945	
Dublin	52 195	- -	30 061	1.812	

1. Calendar of Animated Nature round London.

In the first week: the titlark (*Alauda pratensis*) sings, the cuckoo (*Cuculus canorus*) is heard; the gadgeon (*Cyprinus Gubio*) spawns; the redstart (*Motacilla Phoeniceus*), swift (*Hirundo Alpestris*), whitethroat (*Motacilla Sylvia*), and singing-ly (Cinops edictricus) appear.

Second week: the turtle-dove (*Columba Turtur*) coos; the red ant (*Formica ruginosa*), the laughing wren (*Motacilla Curvica*), the common fox-glove (*Antirrhinum*), the lady-cow (*Coccinea bipunctata*), grasshopper lark (*Alauda Locustæ vesis*), and willow-wren (*Motacilla Salicaria*) appear.

Third week: the blue flesh-fly (*Musca vomitoria*) appears; black snail (*Helix nigra*) abound, and the large bat appears.

Fourth week: the great white-cabbage butterfly (*Papilio brassicae*) and dragon fly (*Libellula 4-maculata*) appear; the glow-worm shines, and the fern-owl, or goat-sucker (*Caprimulgus europæus*), returns.

2. Calendar of Vegetable Nature round London.

In the first week: Gêum urbanum, *Artemisia campestris*; lily of the valley (*Convallaria majalis*), water-violet (*Hottonia palustris*), tulip-tree (*Liriodendron tulipifera*), and numerous other plants in flower.

Second week: the oak, ash, sweet chestnut (*Castanea vesca*), hawthorn (*Mespilus Oxycantha*), the common maple (*Acer campestre*), horse-chestnut (*Aesculus Hippocastanum*), hawberry (*Berberis vulgaris*), and the *A. Jugo repians* in flower.

Third week: the water scorpion-grass, or forget-me-not (*Myosotis scorpioides*), lime-tree (*Tilia*), milk-wort (*Polygala vulgaris*), nightshade (*Solanum tuberosum*), and various American shrubs in flower, and rye (*Secale hybridum*) in ear.

Fourth week: oaks, ashes, and beeches now generally in leaf, and the mulberry (*Morus nigra*) beginning to open its buds. The cismarine rose and some other hardy roses in flower; and also the bramble (*Rubus fruticosus*), moneywort (*Lysimachia Nummularia*), columbine (*Aquilegia vulgaris*), and various other trees and shrubs in blossom.

3. Farm-yard. (3902.)

Feeding and wintering on straw and roots generally ends, and soiling (5642.) or pasturage (5663.) commences, in the first fortnight. Where high-flavoured milk and butter are preferred to quantity, then pasturage on dry-bottomed uplands is to be preferred; but where quantity and richness is the object, soiling with clover and tares, and two or three hours pasturage per day, for the sake of exercise, is the preferable system. Even on farms where there is nothing to mow but old meadow, soiling with that will be found more economical than pasturing it. A field of meadow in good heart, mown and eaten green, will, at a rough estimate, produce treble the quantity of milk it could have done if pastured, and four times as much as it would do in the form of dry hay.

The yards and pits are generally cleared of dung, urine, &c. in this season; and if no soiling goes on, they should be kept

clean during the summer, excepting what room is required for the dung of the few stock which are there constantly, as pigs and poultry, or occasionally, as horses while harnessing, &c.

4. Live Stock. (6216.)

In turning cattle to grass, consider the different systems of pasturing (5816.); adopt what suits your circumstances, and pursue it regularly. See that water is not wanting to each field (4465.); nor shade, rubbing posts, and shelter (5888.) — *Lean stock* are generally dead during this month, from the number of persons who lay in and feed off on grass. When cattle or sheep are very numerous, they are found to feed better, and do less injury to the grass, in small herds or flocks, than in large ones.

Mares may have the horse during the first week, but not later considering the season of parturition. (6637.)

5. Grass Lands. (5643.)

As most grasses send up their flower-stalks during this month, it is of importance so to stock pastures, as to eat these down. This is only to be accomplished in recently sown down lands by overstocking, and not then completely if rye grass prevails. When grass lands are to be mown, the best crop of hay will be obtained by not pasturing after the middle of April. Some may think that where cattle and sheep are fed till May or June, the stalks left will come in as hay; but as such fields cannot be mown till the end of July, the stalks have long before shed their seed and become dry, and so shrivelled as to be unfit for food.

Watering and burning are wanted, this is a favourable season (3000.)

Water-meadows, having been eaten down in April, are generally watered for the first three or four weeks of this month, to bring forward the crop of hay. (4429.)

6. Arable Lands. (4925.)

Summer wheat (5004.) and *grass seeds* (5873.) may still be sown, but not profitably after the first week or ten days. Swedish turnip (5408.), marrow, and yellow turnip may be profitably sown, and also early crops of common white turnip where the soil is clean and dryly prepared. (5394.)

The preparation of *turnip fallows* is the great business of this month, and the seed of maked fallows (4044.), and the culture, by horse and hand hoes, of corns and pulse in drills. In late situations potatoes may be planted during the whole month (5316.); and hemp and flax sown during the first fortnight (3980. and 3992.) Tares for successional sowing. (5267.)

7. Fences (3960.), Roads (3523.), and Drains. (4213.)

The young hedge-rows (3982.) Drains may now be advantageously designed, as the springs show them-elves more conspicuously during winter. The rest in this department is mere routine.

8. *Orchards* (4079.) and *Hop-grounds*. (5997.)

Grafted trees should be looked over occasionally, and any that the clay has dropped from re-covered. Remove suckers and superfluous side shoots.
 Stir and clean the hop-plantations; place the poles, tie the vines where necessary; and towards the end of the month, when the number of shoots wanted have taken the lead; cover

the stool or centre of the plant with a small hill of soil, to prevent it from sending up more shoots.

9. *Wood-lands and Plantations*. (3906.)

Continue to bark oak trees, and also the larch, and such others as are adapted for the farmer (4044.), but finish, if possible, by the middle of the month. Keep newly planted large trees properly staked, and all kinds of cultivated ground clear of weeds.

JUNE.

Weather at	Average of the Thermometer.	Greatest Variation from the Average.	Average of the Barometer.	Quantity of Rain.	REMARKS.
London -	65 22	2	29 97	0.332 inch.	The weather is sometimes cold at the beginning, but is generally agreeable and steady towards the middle of the month. By observing the columns indicating the greatest variation of the thermometer in each month, it will be seen that it varies, in London, only two degrees in June, which is less than in any of the preceding months. In July and August the variation is the same; but in March and October it is twice as much.
Edinburgh	57 2	-	29 666	1.935	
Dublin	55 76	-	30 06	0.860	

1. *Calendar of Animated Nature round London.*

In the first week: the sedge-sparrow (*Passer arundinacea*), the fly-catcher (*Muscicapa atricapilla*), the wasp (*Vespa vulgaris*), and several species of the bee and butterfly appear.

Second week: the burnet moth (*Sphinx filipodulæ*), and forest-fly (*Hippoboscæ equina*) appear; bees swarm.

Third week: several flies, butterflies, moths, beetles, and other insects appear.

Fourth week: insects abound; and singing-birds begin to retire to the woods, and leave off singing.

2. *Calendar of Vegetable Nature round London.*

In the first week: water-lilies (*Nymphæa et Nuphar*) flower; also *Fris Pseud-acorus*, *A'rhensis Côtius*, *Polygonum Persicaria*, *Melva rotundifolia*, and numerous other plants.

Second week: the vine, raspberry, and elder in full flower; also various Scotch roses (*Rôsa spinosissima*), broom (*Spartium*), nettle (*Urtica*), and wheat in the ear.

Third week: the *Orchis*, *Epilobium*, *Fris Xiphium* and zephyllides, the hardy *F'xim* and *Gladioli*, and a great variety of garden and field plants in flower; also the wheat and many of the pasture grasses.

Fourth week: some black and red currants ripe, strawberries in abundance; young shoots of trees and shrubs have nearly attained their length. Oats and barley in flower: blue-bottle, scabious (*Centaurea Cyathus*), and numerous others in bloom.

3. *Farm-yard*. (2902.)

Soiling is the principal operation now going forward (5542), and requires the utmost attention to the cleanliness of the animals, whether fattening cattle, feeding milch cows, or horses.

4. *Live Stock*. (6216.)

Wash and shear sheep (7201.); examine flocks individually as to the fly (7175); see to shade for every description of stock when the weather is hot. Bees swarm during this and next month.

5. *Grass Land*s. (5648.)

Hay-making is now a principal business (5544. and 5792.) Any tussocks or flower-stalks (*benia*) which appear, notwith-

standing the close feeding of April and May, should now be mown (5772); thistles and similar weeds cut out close by the root (6202); pare and burn as in May (3208.); clean out ponds, water-courses, wells, &c. See that clovers, tares, or other soiling crops are mown close to the soil.

6. *Arable Land*s. (4925.)

Great part of the turnip process goes on during the three first weeks of this month and the latter half of May (5375.) Dung fallows and otherwise bring them forward (4568.), draining (4213.), levelling, altering ridges, &c. as the case may require; weed broad-cast crops, and stir the soil between such as are in rows. Warming, when it can be practised, may now be commenced (4450.); thin out the first sown turnips (5406.)

7. *Fences* (2960.), *Roads* (3523.), and *Drains*. (4213.)

Weed hedges, but avoid clipping them, which only creates a close surface of feeble shoots, that in the end becomes so thick as to exclude light and air from the central stems, and occasions their languishing and death. (2985.)

Dig and otherwise prepare materials for roads (3635.) and drains. (4284.)

8. *Orchards* (4079.) and *Hop-grounds*. (5997.)

Insects, or other effects of what are called blights, can seldom be destroyed on so large a scale as that of the farm-orchard or hop-garden. Burning weeds or wet straw, litter, &c. will do something; and on a small scale, washing with lime-water, soap-suds, tobacco-water, or a mixture of these, will prove effectual. (6056.) Those who tie the binds or vine of the hop to the poles, instead of leaving them to nature, have generally completed the operation by the middle of the month. In some early spots the superfluous shoots are cut off about the end of the month.

9. *Wood-lands and Plantations*. (3906.)

The woodman is now chiefly employed in trussing up the branches of barked trees, and otherwise disposing of what is unfit for timber purposes. (4099.) Old copes or stools of trees, woods, or hedges, may now be systematically stocked up, stacked, and when dry, charred for fuel. (4068.)

JULY.

Weather at	Average of the Thermometer.	Greatest Variation from the Average.	Average of the Barometer.	Quantity of Rain.	REMARKS.
London -	66 3	2	29 89	2.194 inch.	This was called <i>hay month</i> by the Saxons; and though hay-making near London is generally finished in June, yet in places where manure is less abundant, it is chiefly made in this month. The farmer's prospects as to crop may now be determined as to almost every article cultivated.
Edinburgh	60 6	-	29 445	2.546	
Dublin	61 15	-	29 929	2.614	

1. *Calendar of Animated Nature round London.*

In the first week: the cuckoo (*Cuculus canorus*) leaves off singing; the stone-curlew (*Charadrius Edicnemus*) whistles occasionally late at night, and the golden-crested wren (*Monticola Régulus*) now and then chirps.

Second week: the quail (*Tetrax ferrugineus*) calls; and the cuckoo-spit, or frog-hopper (*Cicada spumaria*), abounds.

Third week: young frogs migrate. Hens moult.

Fourth week: the great horse-fly (*Tabanus bovinus*) appears; and partridges fly.

2. *Calendar of Vegetable Nature round London.*

In the first week: enchanter's nightshade (*Circæa lutetiana*) and lavender (*Lavandula spica*) in flower, and pinks and carnations in full bloom.

Second week: the fallen star (*Tremella Nodosa*) appears; also puff-balls (*Lycoperdon Bovisæ*), and sometimes the common mushroom (*Agaricus campestris*).

Third week: raspberries and gooseberries ripe, potatoes in flower, asparagus in berry, the thistles in perfection.

Fourth week: the truffle (*Tuber cibarium*) now hunted or dug up in commons and forests; nightshade (*Solanum nigrum*), devil's bit (*Scabiosa succisa*), burnet saxifrage (*Pimpinella Saxifraga*), and a great number of plants in flower.

3. *Farm-yard*. (2902.)

As in June; between hay and corn harvest is generally a very good time for the farmer to make a tour to observe more extensively the practices of his own district, and to witness those of other districts.

4, 5. *Live Stock* (6216.) and *Grass Land*s. (5648.)

Lembs are now weaned (7161.) when not fattened off; at first they require the richest keep. As green food will now be abundant, every animal about a farm that can live and thrive or answer its end by a milking system, should be so treated. The weather being hot, cattle or sheep in fields must be frequently looked to, as to shade, water, and abundant keep. Suffering from thirst, or a want of food, they are very apt to break through fences, which at this season is more than usually injurious, on account of the state of the corn crops.

6. *Arable Land*s. (4925.)

Attend to weeding, hoeing, and otherwise moving the soil between rowed crops, more especially potatoes and turnips. Towards the end of the month, the first-sown white turnips will be in a state to thin out; and a farther thinning may be advantageously given to field peas, carrots, &c. at this season. Where peas are sown for podding, they will now be in abundance for gathering; in warm situations sooner. Buck-wheat may now be sown for autumnal food for game. (6111.)

7. *Fences* (2960.), *Roads* (3523.), and *Drains*. (4213.)

As in June.

8. *Orchards* (4079.) and *Hop-grounds*. (5997.)

Cherries, strawberries, gooseberries, &c., where grown as field-crops, are now in gathering, and towards the end of the month, fallen apples and plums for tarts. Hop-grounds are looked over, and the superfluous vine pruned off, &c. In Kent

and other places these prunings are often a requisite of the pruner, who lays them aside as fodder for cows.

9. Wood-lands and Plantations. (3906.)

As in June; and prune the gear, which at other seasons is apt to bleed. (3995.) This season answers perfectly for pruning

all sorts of trees; and if their leaves and spray were an object for fodder, as in Sweden and Italy, no doubt it would be preferred. (3994. and 3996.) Wounds in trees do not now bleed, as they sometimes do in spring and autumn; and they heal, and are in part covered over with bark, before the approach of winter. (3993.)

AUGUST.

Weather at	Average of the Thermometer.	Greatest Variation from the Average.	Average of the Barometer.	Quantity of Rain.	REMARKS.
London -	65 85	2	30 06	0-824 inch.	This is the barn or harvest month of the Saxons; and, as every body knows, the busiest month of the agriculturist. It is, in consequence, the most profitable season for the labourer and his family, who are generally in full employ, and at an increase of wages, or perquisites, for four or six weeks at this season.
Edinburgh	60 66	- -	29 82½	1-996	
Dublin -	62 82	- -	30 172	5-858	

1. Calendar of Animated Nature round London.

In the first week: flying ants (*Formica*) appear; bees kill their drones; and the swallow-tailed butterfly (*Papilio Machaon*) appears.

Second week: young martins (*Hirundo tiberica*) and swallows (*Hirundo rústica*, *Hirundo cælestis*, and *Hirundo apus*) depart; the wharne, or burrel-fly (*Æstrus bôvis*), lays eggs on horses.

Third week: the black-eyed marble butterfly (*Papilio Semele*) appears. Various birds re-assume their spring notes.

Fourth week: the nuthatch (*Sitta europæa*) chatters, the stone-curlew (*Charadrius œdicnemus*) whistles at night, the goat-sucker (*Caprimulgus europæus*) and young owls (*Strix Uta*) make a noise in the evening; robin-redbreast (*Merula rubicola*) sings; and rooks roost on their nest-trees.

2. Calendar of Vegetable Nature round London.

In the first week: melilot (*Trifolium officinale*), rue (*Ruta graveolens*), yellow sucoory (*Pteris hirsutioides*), burdock (*Arctium Lappa*) in flower; the bread-corns ripe.

Second week: wild clary (*Salvia Fernencas*), meadow-rue (*Thalictrum flavum*), ploughman's spikenard (*Conjuga squarrosa*), and various other natives in flower.

Third week: the mallow (*Malva Lavatera*), hollyhock (*Alcea rosea*), and lobelias, among the garden-flowers; and the polygonum and potamogetons among the wild plants now in blossom.

Fourth week: the autumnal crocus (*Colchicum autumnale*), *Aster Solidago*, *Senecio paludosus*, *teazel* (*Dipsacus fullonum*), and various other plants in flower. The earlier varieties of all the hardy kernel fruits ripe.

3. Farm-yard. (2902.)

The rick-yard should now be attended to (2906.); stacks-stones repaired or put in order; bottoming of faggots, and straw or rape haulm got together; thatch in readiness, and ropes made. (3184.)

At any spare period the teams may be employed carting out the summer-made dung to the wheat fallows, or to form field dunghills for spring crops, &c.

4. Live Stock. (6216.)

Select the stock of lambs to be kept as breeders. (7170.) Swine commonly bring their second litter of pigs in this month; which, owing to the dropping corn, is generally one of abundant keep, both for them and poultry. Farmers in some places look to the stubbles as a source of good food for their cows, as

others do to the fallows for keep for their sheep. Where either is the case, the culture must be of a very inferior description.

5. Grass Lands. (5643.)

Where meadows are manured, that operation generally goes on after the hay is removed, or during winter; the surface in the former case being hard with drought, and in the latter by frost. After grass should in general be shut up and reserved for later use, and in some cases as a winter resource. Keep down weeds, tussocks, ant-hills, &c. Turn the water on meadows as soon as the hay is removed, and let it remain till a third crop is in forwardness. (4387.)

6. Arable Lands. (4925.)

Weed and stir among green crops, earth up potatoes (5636), but by no means turnips, unless the soil is very dry indeed, as that operation only prevents them from attaining a full size. Heavy commences in all the southern districts in the first week of this month, and in some by the middle of July. When the operation is executed by day-work, the most unremitting inspection of the master is necessary; and even when the greatly preferable mode of renting by the acre is adopted, he should be continually in motion from one party to another, to see that the operation is performed low and clean.

Naked fallows in late situations receive the seed furrow during this month, excepting in cases where the seed is ploughed in an operation generally deferred to the middle of September. Sow cabbage-seeds (4497.) for plants to put out in April next. Sow turnips after early peas which have been podded (5209), or early cut wheat, faves, cabbages, &c., or after hemp and flax, which are generally ploughed by the middle of this month. (5880. and 5922.) Grass seeds sown alone at this season (5692.) will generally succeed better than at any other; they germinate as well in spring; but the heats of July often burn up the tender plants.

7. Fences (2960.), Roads (3523.), and Drains. (4218.)

As in the two preceding months.

8. Orchards (4099.) and Hop-grounds. (5971.)

Apples and plums of some sorts are now ripe. Grapes may in general be untied. Budding performed, and pruning, if desirable, as observed last month under woods and plantations.

9. Wood-lands and Plantations. (3906.)

See last month.

SEPTEMBER.

Weather at	Average of the Thermometer.	Greatest Variation from the Average.	Average of the Barometer.	Quantity of Rain.	REMARKS.
London -	59 63	3 5	30 09	0-482 inch.	The temperature begins now to decline and to vary; the nights begins to lengthen, and heavy dews and diminished transpiration and evaporation promote the growth of grass, herbage, plants, and especially turnips. This is still a busy month with the agriculturists; in the warmest situations he is finishing harvest-work, and in the latest commencing it. Animals of most sorts are now fat; fruits are ripe; honey abundant; and most products of the earth in perfection and plenty.
Edinburgh	54 3	- -	29 739	3-470	
Dublin -	59 35	- -	30 239	3-021	

1. Calendar of Animated Nature round London.

In the first week: young broods of goldfinches (*Tringilla Carduelis*) appear. The linnet (*Tringilla Linbta*) congregates. The bull (*Bos Taurus*) makes his shrill autumnal noise; and swallows (*Hirundo rústica*) sing.

Second week: common owls (*Strix Alamma*) hoot. The saffron butterfly (*Papilio Hyale*) and willow red under-wing moth (*Phalaena picta*) appear. Herrings (*Clupea Haréngus*) are now cheap.

Third week: the ring onuzle (*Turdus torquatus*) appears. The fly-catcher (*Muscicapa Atropilla*) withdraws.

Fourth week: the store (*Strus vulgaris*) congregates. The wood-lark (*Alauda arborea*) sings. The woodcock (*Scolopax rusticola*) and fieldfare (*Turdus pilaris*) appear; and the swallow (*Hirundo rústica*) departs.

2. Calendar of Vegetable Nature round London.

In the first week: some fungi and *Balbala diba* appear, traveller's joy (*Clematis dila*) and *Farnesida palustris* in flower.

Second week: catkins of the hazel and birch formed; blossoms, and green, red, and black berries found on the bramble at the same time. Leaves of the sycamore, birch, lime, mountain-ash and elm, begin to change colour.

Third week: the ivy (*Hedera Helix*), laurel (*Prunus Lauro-cerasus* and furze (*Ulex europæa*) in flower.

Fourth week: hips, haws, and nuts ripe. Leaves of plane-tree (*Platanus*) of the hazel, yellow; of the oak, yellowish-green; of the sycamore, dirty brown; of the maple, pale yellow; of the ash, fine lemon; of the elm, orange; of the hawthorn, tawny yellow; of the cherry, red; of the hornbeam, bright yellow; of the willow, hoary.

3. Farm-yard. (2902.)

The rick-yard is now the chief scene of operations, in getting earlier crops thatched (3185), and later ones stacked. (3276.) In all operations in this department attend, as far as circumstances will permit, to neatness. In the case of a proprietor or amateur, neatness, order, and high keeping are essential in every department.

4. Live Stock. (6216.)

There is generally abundance of fat cattle and sheep in the market during this and next month. Lean stock, especially crones and widders, are now brought in, and wintered or fed on turnips. Wintering cattle (6835), also about the end of the month. Poultry and pigs are now fat, and honey may be taken from bee-hives.

5. Grass Lands. (5643.)

As in August. Newly sown grass lands should now be sparingly fed, in order to strengthen the plants for the winter.

6. *Arable Lands.* (4925.)

This is the chief season for sowing wheat, whether on naked fallow or after clover, rye, or early crops of peas and beans. Potatoes are generally not taken up till the end of the month, in which case the sowing after that crop is later. (5015.) Sow tares to stand the winter (5257), and grass seed, for permanent pasture; or a hay crop next season will succeed on good soils, if sown before the middle of the month. (5533.)

7. *Fences* (2960.), *Roads* (3523.), and *Drains* (4213.)

Routine operations of mending, &c. as before.

8. *Orchards* (4079.) and *Hop-grounds.* (5997.)

Gather fruits for immediate sale, the keeping sorts not being yet ripe. (4085.) Walnuts for pickling not later than the first week. (4102.)

Hop-picking and drying, in the districts where this plant is much cultivated, is the great business of the month. (6036.)

9. *Wood-lands and Plantations.* (3906.)

Routine operations as in the two or three preceding months. Plant evergreens during the three last weeks, and deciduous trees the last ten days. (3957.)

OCTOBER.

Weather at	Average of the Thermometer.	Greatest Variation from the Average.	Average of the Barometer.	Quantity of Rain.	REMARKS.
London	52 81	4	29 69	2.027 Inch.	The weather of this month is very uncertain. Before these rains, snows, or frosts which constitute the practical commencement of winter, there is generally two or three weeks of settled weather; sometimes these weeks are in October, sometimes partly in November. These weeks afford a last resource for bringing forward neglected operations.
Edinburgh	49 7	-	29 350	3.334	
Dublin	51	-	29 76	2.798	

1. *Calendar of Animated Nature round London.*

In the first week: the red-wing (*Turdus iliacus*) arrives. Snakes and vipers bury themselves.

Second week: hooded crows (*Corvus cornix*) and wood-pigeons (*Columba Palumbus arvensis*); hen-chaffinches (*Fringilla coelebs*) congregate, and prepare for migration, leaving their males in this country.

Third week: the snipe (*Scolopax Gallinago*) appears in the meadows. Wild-geese (*Anas platyrhynchos*) leave the fens, and go to the rye-lands.

Fourth week: the tortoise (*Testudo graeca*) begins to bury itself in the ground; and rooks visit their nest-trees. Some larks (*Alauda*) sing, and of the woodcock (*Scolopax rusticola*) returns. Spiders' webs abound.

2. *Calendar of Vegetable Nature round London.*

In the first week: strawberry-tree (*Arbutus Uva-ursi*), holly (*Ilex Aquifolium*), China hollyhock (*Alcea chinensis*), and China aster (*Aster chinensis*), in bloom.

Second week: cactins of some species of *Salix* formed; leaves of the asp almost all off; of the Spanish chestnut, yellow; of the sugar-maple (*Acer saccharinum*) scarlet; of the common birch, yellow and gold; and of the weeping-birch, gold and bright-red coloured.

Third week: *Gemmatia calycina* in flower. Some horse-chestnuts and acacias quite denuded of leaves.

Fourth week: various plants, especially annuals, continue in flower. Leaves of marsh-elder (*Sambucus Ebulus*), of a fine pink; of stag's-horn sumach, of a purplish-red; of the American oak, of fine shades of yellow, orange, red, and purple.

3. *Farm-yard.* (5902.)

This is the season of rural plenty, affording an opportunity, both to men and animals, for laying in a large stock of health, to enable them to support the severity of the coming winter. Operatives should now buy in the winter stores of potatoes, fuel, &c. and ridge up their garden ground, not to under crop for the winter.

Cows ought being generally in the rick-yard by Michaelmas, and the root and herbage crops not taken being at or near their maturity, the first of October is the most suitable season for a farmer to take stock and ascertain his annual profit or loss. Michaelmas being also the most general term of entry and removal, especially in the case of arable farms, is another reason why agricultural accounts are conveniently made up to this period. (4883.) Examine your household accounts, and if your expenses have exceeded your income, or even come up to it, look over the particulars with your wife or housekeeper, and see on which you can retrench. This is an essential process for all who would proceed in life with any thing like peace of mind, or the permanent respect of their neighbours. (4921.) Remember that very small indeed is the net income of a rent-paying agriculturist.

Michaelmas is also the general term for hiring farm-servants by the year; but the seldom agricultural operatives are changed the better, unless in the case of senseless, indolent, or viciously inclined persons, who degenerate unless frequently removed.

4. *Live Stock.* (6216.)

Cattle when not sufficiently fattened on grass or herbage, whether by pasturage or soiling, should not be put on other food, to complete them for the butcher. Oil-cake, grains, turnips, carrots, or, in default of these, bruised corn may be used. The same observations may be applied to hogs, which are generally in good condition at this season. (7518.)

Hog porridge. A mixture of oatmeal and water, or any other meal and water, left till it becomes sour, as practised by the millers in the northern counties, will feed hogs rapidly; but milk and peas meal make the finest pork in the world.

The teams which have been soiled during summer, may now be put on hay, straw, and carrots, or other roots, by degrees. (6782.)

5. *Grass Lands.* (5643.)

Where these are manured, this is a good season for the operation (3782); choose dry weather.

6. *Arable Lands.* (4925.)

Potatoes (5991), carrots (5443), field beet (5482.), parsneps (5474.), and Swedish turnips, may now be taken up and housed, and the ground sown with wheat. This grain (5001.) rye (5069.), barley (5080.) in some situations, and tares (5257.) may still be sown in the milder districts. Embrace every opportunity to give the first furrow to fallows (4944.), whether for green crops or otherwise. In general all lands that are to have two or more furrows before they are sown or planted, should be ploughed as soon as possible after harvest; but not so lands that are to be sown on one furrow, which are better ploughed in January and February. It is a great mistake to suppose that ploughing land in autumn destroys the eggs or larvae of insects (7695.), or the seeds of weeds; on the contrary, it may often, by giving them a deeper covering, preserve them better from the winter's frost, or what is much more destructive, from being devoured by birds. There are few subjects less generally understood than the economy of nature in regard to the eggs of insects and worms. (Turn to 7644. and 7704.) See that water furrows and drains run freely, and that fences and gates are in repair.

7. *Fences* (2960.), *Roads* (3523.), and *Drains.* (4213.)

Hedges may now be advantageously planted (5978.), grown ones pruned (2983.), old ones plashed (2985.), and imperfect ones repaired. (2995.) The Northumberland practice as to hedges (7809.) well deserves the study of the more southern agriculturist. Roads and drains may be made or repaired at this season, and in spring, will better effect than during the heat and drought of summer. Road materials now bind better, and land-springs show themselves more distinctly.

8. *Orchards* (4079.) and *Hop-grounds.* (5997.)

The winter fruits may now be gathered, and either spread in an airy loft or upper floor, there to remain till used, or swested in heaps, to extract a part of their moisture, and then buried in dry sand, or packed in close boxes or casks, to be kept in a cool and dry cellar. (1854. and *Encyc. of Gardening*, 2d Edit. 2289.)

Fruit trees of every kind may now be planted (4105.) and pruned. (4111.)

Hop-picking is generally completed the first week of the month; and as soon afterwards as convenient, the vine and poles removed, and the latter stacked till next spring. (6047.) Young hop plantations may be formed (6005.), and the soil among established grounds manured and ploughed. (6019.)

9. *Wood-lands and Plantations.* (3906.)

Hedges and plantations of evergreen trees may be made during the first week of the month; and no period of the year is better for transplanting all kinds of hardy shrubs.

Timber and coppice may be felled, and in general every operation preparatory to planting, as well as the operation itself, may go forward.

NOVEMBER.

Weather at	Average of the Thermometer.	Greatest Variation from the Average.	Average of the Barometer.	Quantity of Rain.	REMARKS.
London	44 44	4	29 68	2.527 Inch.	This is the windy month of the Saxons; it is generally also cold and moist, and one of the most disagreeable for the labouring agriculturist; but he may console himself with the shortness of the day, and half the approach of evening, when he may lay aside his wet dress and fortify his mind by converse with books, or enjoy the comforts of his fire-side, and the solace of his wife and children; reading to or otherwise instructing them; or mending his boots or shoes.
Edinburgh	41 1	-	29 638	4.514	
Dublin	45	-	29 74	0.294	

1. *Calendar of Animated Nature round London.*
In the first week: the buck (*Cervus Capreolus*) grunts.
Second week: the golden plover (*Charadrius pinnialis*) appears.
Third week: snails (*Limas*) and slugs (*Hélix*) bury themselves.
Fourth week: greenfinches (*Fringilla Montifringilla*) flock. The winter moth (*Gedretra frumaria* Sum.) and the common flat-body moth (*Geometra appalana* Sum.) appear in gardens about the end of the month.
2. *Calendar of Vegetable Nature round London.*
In the first week: a few plants in flower, by accident, chiefly annually, according to the season.
Second week: the fungus *Helvella mitra* appears. *Laurus* in flower.
Third week: *Chimonanthus fragrans* in flower.
Fourth week: some primroses show flowers at this season; and some plants, unnaturally in flower, still continue if the weather is temperate.
3. *Farm-yard.* (2902.)
Wintering cattle are now introduced to the straw-yards (2902.) or hammels (2831.), and others to stalls for feeding or fattening. Live stock in general ought to be kept in good condition at this season, otherwise they are apt to fall off towards spring. Thrashing goes on at intervals to supply straw. (3195. and 2773.)
4. *Live Stock.* (6216.)
 See Farm-yard.

5. *Grass Lands.* (5643.)
 Manure in dry weather (5782.); turn the water on meadows adapted for irrigation (4387.); destroy ant-hills (5776.); drain by surface gutters, or other means, where that operation is requisite; clear out water furrows for the same purpose; admit cattle and horses only on the driest pastures; see that sheep have shelter, and especially Dorset ewes likely to lamb next month.
6. *Arable Lands.* (4925.)
 See that water furrows and drains run unobstructed; plough and cart out manure, as weather and other circumstances permit.
7. *Fences* (2960.), *Roads* (3523.), and *Drains.* (4213.)
 As in last month; and see that they are in effectual repair, and fairly used.
8. *Orchards* (4079.) and *Hop-grounds.* (5997.)
 Complete the operations of last month, where interrupted, deferred, or neglected.
9. *Wood-lands and Plantations.* (3906.)
 As in last month, excepting when the weather is unfavourable. Selling all kinds of timber and coppice not adapted for parking for the tanner, may now go on freely. (4073.) Saw-logs for baskets may be cut over (4042.), and baskets, hampers, crates, and hurdles, made by the woodman and hedger.

DECEMBER.

Weather at	Average of the Thermometer.	Greatest Variation from the Average.	Average of the Barometer.	Quantity of Rain.	REMARKS.
London -	41 4	3	29 64	1-124 inch.	<i>Winter month.</i> Sax. Cold but dry. The agricultural operations are chiefly of the laborious kind; but the days are short and the nights long. In the last week the young operator should examine himself as to his professional and intellectual progress during the last year, and form plans for further improving himself for the year to come. Knowledge is a lever by which a man may raise himself as high as he desires.
Edinburgh	28 9	- -	29 66	2-598	
Dublin -	36 34	- -	29 723	2-916	

1. *Calendar of Animated Nature round London.*
 The mole (*Talpa europæa*) throws up hillocks. The December moth (*Eriogaster populi* Sum.) appears about the beginning, and the yellow-line quaker (*Noctua flavilinea* Sum.) about the end of the month.
2. *Calendar of Vegetable Nature round London.*
 Some of the last month's plants continue in flower, according to the weather.
3. 4. *Farm-Yard* (2902.) and *Live Stock.* (6216.)
 Thrashing, and otherwise preparing corn and straw for the market, and the use of the working, fattening, wintering, and store stock are the main operations. Next, the regular supply of live stock with food, and cleaning and littering them. Fattening stock should be particularly attended to, especially house lamb (7227.) and calves. (6855.)
 The supply of turnips for cattle and sheep is liable to be interrupted by severe frosts; if the precaution of housing a quantity (3420.), or setting them (5121.), is not taken in time. Where oil cake, rape cake, or dot (6094.), brewer's or distillers' grains (5112.) are used, supplies must be secured; and where hogs or cattle are fed on meal and water mixed and soured, a quantity must always be kept in mixture; as a week or ten days in temperate weather, and a longer period during frost, is requisite to induce the fermentation.
5. *Grass Lands.* (5643.)
 See that they are not poached; that water furrows, gutters, drains, and ditches are in repair; and where manuring is practised, cart it out in frosty weather where there is no danger of injury from the feet of horses or cart-wheels. Unless labour is very cheap, carting earths or earthy composts on grass lands will not pay the expenses; they produce more effect on arable lands.
6. *Arable Lands.* (4925.)
 See that all the modes of drainage are effective. (4278.) Plough and cart out manure according to weather and other circumstances.
7. *Fences* (2960.), *Roads* (3523.), and *Drains.* (4213.)
 Plant hedges of trees or bushes, and walls only in temperate weather, as frosty air injures the roots of plants; and freezes humid mortar, thereby effectually preventing its setting. Roads and drains may be made and inclosed in all weather that admit these operations.
8. *Orchards* (4079.) and *Hop-grounds.* (5997.)
 Clear old trees of moss or mildew; but prune only in mild weather. Dig and dung at any time.
9. *Wood-lands and Plantations.* (3906.)
 Fall timber or copse of sorts not adapted for banking. (4044.) Stock or grub up tree roots, stacking them for fuel or charcoal. (4068.) Trench, dig, or otherwise prepare ground for planting; but lift plants from the nursery, and re-insert them in plantations only in mild weather, and when the soil does not parch by treading, &c. The rest as in November.

Evergreens, as Mr. McNah has ably shown and proved by experience, may be planted at any period during winter, when the weather is mild. He says, "I have planted evergreens at all seasons of the year with nearly equal success, except from the middle of June to the middle of August, and even during this period I have planted some; but unless the weather is very dull and moist, and even with such weather, it is difficult to prevent the plants suffering considerably, and in many cases it is years before they recover. Although, however, I have planted evergreens ten months out of the twelve, with little difference in the success, yet one season has a preference over the others with me; and when there is the power of choice, I would recommend late in autumn, winter, or early in spring; that is, any time from the middle of October to the middle of February, and in general the beginning of this period is the best; that is, from the middle of October to the middle of December, always providing that the weather and the ground are favourable; that is, supposing there is no frost, no drying wind, nor much sunshine, and that the ground is not too much saturated with wet, either from continued rain, or from the nature of the soil. One of the principal things to be attended to in planting evergreens is, to fix on a dull day for winter planting, and a moist day for spring and autumn planting. There can be no secret in the proper treatment of evergreens; if there were, I should say, that it is in preventing their roots becoming dry when out of the earth; to choose moist and cloudy weather for planting; and still better, if we had the power, by foresight or otherwise, to secure a continuance of such weather some time after they have been planted." (*Mr. McNah's Essay on the Planting and General Treatment of Early Evergreens in the Climate of Scotland*, &c. p. 17.)
 Mr. Crutchebank has shown that poor waste ground, which, if trenched or ploughed would not bear a crop of grain, will, after being planted and kept under wood for some years, become fit for every purpose of agriculture. "On a rising ground, not far from the village of Ellon, a piece of ground of a dry gravelly nature, which has lately been cleared of a crop of fallow-Scotland hirs, was trenched in a very partial and imperfect manner; the roots of the trees being scarcely eradicated. It was then sown with oats, without receiving lime, dung, or manure of any other description; yet the crop was so luxuriant, that a great part of it lodged. The following spring, the ground was again sown with the same species of grain, without receiving any enrichment; and, when harvest arrived, the crop was unequalled by that of the richest fields, in a neighbourhood which is generally considered fertile. The experiment was tried a third time, still without manure, and the return was again considerably above an average. The soil, as has already been remarked, was dry and gravelly, and far from possessing any natural qualities that could have been the cause of such extraordinary productiveness. When planted, it had been covered with heath, and in that state had not been superior to those waste lands which we occasionally see improved at a vast expense, and which will produce no kind of crop till they receive a great quantity of manure." (*Crutchebank's Practical Planter*, &c.)

GLOSSARIAL INDEX.

* * * In this Index both Pages and Paragraphs are referred to; the letter p. is prefixed to the former, to the latter the letter a.

- A**
ABRADING earth, earth crumbling down from the effects of frost, page 483.
Absorbent soil, soil so constituted as to absorb moisture from the atmosphere, 779.
Absorbent system, explained in a. 6352. p. 968.
Acclimatising vegetables or animals, inuring them to a climate in which they are not indigenous. The term naturalising is sometimes substituted, but erroneously. See *Naturalising*.
Accevent, entering a state of acid fermentation, s. 6978. p. 1036.
Aération, exposing the soil to the air, p. 507.
Aërometric beads, hollow beads of glass containing air, for ascertaining the specific gravity of milk, s. 7008. p. 1039.
After-grass, the second crop of grass from lands which have been previously mowed the same year, p. 905.
Aftermath, the second mowing of perennial meadow lands in the same season, p. 515.
Agriculture is used in its most extensive sense in the third line of the title-page, and generally in the historical part of the work (Part I.), as including territorial economy and husbandry. In most parts of this work, for example, in the words of the title-page, "animal and vegetable productions of agriculture," as synonymous with husbandry. In several places as synonymous with aration; that is, the culture of arable lands, as opposed to pasturage, or what may be called agriculture proper. In every case the reader will be able to gather, from the scope of the sentence or paragraph containing this term, in which of these three senses it is meant to be understood.
Aigrettes, tufts of feathers, p. 1088.
Aits, small islands, or islets, in streams.
Alburnous parts, soft woody parts, p. 661.
Alburnum, the soft sappy wood just under the inner bark, p. 646. See *Lindley's Outlines of the Principles of Botany*, p. 17.
Alien waters, a brook or stream passing from one area through another, which has been embanked from a river or the sea, p. 715.
Altitudinally, independently of any superior, p. 552.
Alluvial soil, soil deposited by streams, p. 747.
Aloetic purge, a purge composed of the scocotorine aloes, p. 1035.
Alterative, alterative medicines are those which induce a change in the blood and juices for the better, without any manifest operation or evacuation, p. 977.
Alveolar sockets, sockets like the cells in a honey-comb, p. 972.
Ambling, explained, a. 6665. p. 1002.
Amercement, a pecuniary punishment arbitrarily imposed, p. 769.
Ammoniacal gases, s. 6701.
Amorphous stones, without regular shape, a. 3005. p. 483.
Andrus, an excrecence in some plants of the natural order Crucifere, and chiefly in the turnip, produced by the puncture and depositing of the eggs of an insect, s. 5437. p. 861.
Anima, a chemical product obtained from plants, s. 1468.
Anomalous, irregular, p. 692.
Aorta, the great artery of the heart, p. 967.
Arteria ascendens, the ascending great artery of the heart, p. 967.
Arteria descendens, the descending great artery of the heart, p. 967.
Appui, a reciprocal action between the mouth of the horse and the hand of the rider; the bit and rein forming the line of communication. Thus a horse with a sensitive mouth has a good appui, and the same may be said of the rider if his hand be good, s. 6663. p. 1002.
Aqueous humour, the watery humour of the eye; the first or outermost, and thinnest of its three humours, p. 970.
Aration, ploughing or tillage, a. 3562. p. 573.
Arenarious grasses, grasses suitable for sandy soils, p. 749.
Averruncator, a pruning instrument, consisting of two blades fixed on the end of a rod, acting like scissors, by means of a line fixed to one of them, and pulled by the operator, s. 3155. p. 512.
Avns, the beards or long bristles which project from the chaffs; they are plentiful on spring wheat, and on barley, p. 812.
Azillaries, explained, s. 6344. p. 967.
Azote, the radical principle of the atmospheric air, p. 814.
- B.**
- Backing** a horse, explained, s. 6657. p. 1000.
Back-taking, an operation in farriery, by which hardened feces are withdrawn from the rectum, s. 6543. p. 990.
Back-rents, rents paid subsequently to reaping, p. 768.
Bagging, explained, s. 3173. p. 575.
Bails, a substitute for fixed standings or stall divisions, s. 6799. p. 1006.
Band-win ridges, ridges formed of such a width as to be reaped by what in Scotland is called a band of shearers or reapers; s. 3250. p. 526.
Barbs, explained, s. 6382. p. 972.
Bastard-cocks, small preparatory haycocks, a. 5797. p. 904.
Battering, as applied to fences, leaning inward, s. 4594. p. 754.
Baulk, in Scotland, ground left unturned between the furrow-slices in ploughing, p. 711.; in England the same thing, and also strips of ground usually in grass between ploughed ridges, as in common field lands.
Bavins, brush-faggots, s. 3626. p. 584.
Bear, an iron instrument used in the Isle of Ely to eradicate weeds in water-courses, s. 5686. p. 892.
Bents, the dead stems of grass in pasture grounds which have borne seeds.
Bigg, a variety of winter barley, s. 5085. p. 823.
Billet, a term variously employed. A wooden billet is often used in docking a horse, and often forms a separation between carriage horses, s. 6733. p. 1009.
Binding and stooking, binding sheaves of corn, and placing them in shocks or stooks, s. 3175. p. 515.
Binot, a variety of double mould-boarded plough, s. 2620. p. 396.
Blanch holding, a mode of legal tenure in Scotland, s. 3401. p. 552.
Blast, a disease in the stomach of sheep and oxen from wind; also a term for the mildew in wheat, p. 1065.
Blinding, filling up interstices between stones on roads with gravel, &c. s. 3654. p. 589.
Blood spavin in horses, 961.
Blowing lands, lands whose surface-soil is so light as to be liable, when dry, to be blown away by the wind, p. 870.
Blowing sand, p. 749. See *Blowing lands*.
Boles of trees, the trunks of trees, p. 656.
Boll, a measure for corn in Scotland; in wheat and beans, equivalent to four Winchester bushels; in oats, barley, and potatoes, to six bushels, p. 842.
Bone spavin, explained, s. 6507. p. 986.
Boulder stones, large round stones, p. 481.

- Bout* of the plough, the going and returning with the plough along a land or ridge under ploughing, s. 3266. p. 529.
- Box drains*, explained, s. 3607. p. 581.
- Boyn*, a vat or tub, s. 7064. p. 1045.
- Bratrs*, from braird, to spring up, s. 5397. p. 857.
- Brake*, a large harrow, s. 2664. p. 405. In machinery, a constraining wheel divided into joints, which stops when needed another wheel that revolves within it.
- Bramble bands*, bands made of the long shoots of the bramble or blackberry, s. 5191. p. 518.
- Braxy*, explained, s. 7258. p. 1065.
- Breakshare*, explained, s. 7259, 7260. p. 1065.
- Breasting over a hedge*, cutting it down, p. 459.
- Braechin*, that part of the horse's harness attached to the saddle, and hooked on the shafts, which enables him to push back the cart or other machine to which he is harnessed.
- Breeding in the line*, or in the same line, explained, p. 301.
- Breeding in and in*, explained, p. 301.
- Breeding cross*, explained, p. 301.
- Broken tigger*, a quarter-cleft rod, as thick as the finger, and four feet in length, used in thatching, p. 518.
- Brose*, a Scotch dish made by pouring boiling water on oatmeal, and sometimes on the meal of peas, and immediately mixing them by stirring; leaving the meal in small knots or lumps about the size of marbles. It is afterwards eaten with milk or butter, s. 5217. p. 857.
- Burghage-holding*, explained, s. 3404. p. 552.
- Butts*, short angular ridges, short irregularly shaped lands or ridges in the corners of fields, s. 3253. p. 527.
- Byre*, cow-shed, s. 6777. p. 1015.
- C.
- Cadence*, as applied to horsemanship, an equal measure or proportion observed by a horse in all his motions when he is thoroughly managed, and works justly at a gallop, *terra a terra*, so that his motions or times have an equal regard to each other, s. 6672. p. 1003. See *Crabb's Technological Dictionary*.
- Caissons*, temporary chests in which foundations in deep water are built, s. 4357. p. 715.
- Calcareous soil*, soil abounding with lime, p. 775.
- Callipers*, or calibers, explained, s. 4075. p. 663.
- Calorifer*, from calor, heat, and fero, to bear, explained, s. 7464. p. 1087.
- Camping potatoes*, explained, s. 5345. p. 851.
- Canon* of the horse, explained, s. 6232. p. 959.
- Cantle*, the protuberant part of the saddle behind, s. 6675. p. 1003.
- Capillaries*, the hair-like extremities of the arteries and veins, s. 6352. p. 968.
- Cap of straw*, explained, s. 5195. p. 518.
- Caprioles*, leaps made in one and the same place without advancing forward, s. 6672. p. 1003. See *Crabb's Tech. Dict.*
- Capulet*, explained, s. 6512. p. 997.
- Carotid arteries*, two principal arteries which carry the blood to the head, s. 6398. p. 972.
- Carotids*, 967. See *Carotid arteries*.
- Carpus*, explained, s. 6317. p. 965.
- Carriage* in irrigation, explained, s. 4408. p. 726.
- Carse*, explained, s. 4554. p. 747.
- Caruncula lactarymatis*, explained, s. 6370. p. 970.
- Cassova*, of the nature of cheese, s. 6979. p. 1036.
- Castrate*, to incapacitate male animals from engendering offspring, s. 7306. p. 1069. See *Spey*.
- Catch-drain*, explained, s. 4419. p. 727.
- Catch-work meadows*, explained, s. 4428. p. 727.
- Cavesson*, a sort of nose band, either of iron, leather, or wood, fastened round the nose of a horse to forward the suppling and breaking of the horse, s. 6657. p. 1001. See *Crabb's Tech. Dict.*
- Cellular membrane*, an important membrane in animals in which the fat is lodged, p. 785.
- Cereal grasses*, the kinds producing corn, p. 723.
- Cerebral hyatids*, explained, s. 7267, 7268. p. 1066.
- Cervical ligament*, an aponeurosis or strong bandage of packwax, which runs along the neck and upholds the head, p. 972.
- Chambrière*, a kind of long whip used in riding horses, s. 6662. p. 1001.
- Char wood*, to, to partially burn it to enable it to resist wet, s. 3039. p. 492.
- Charlock*, the *Sinapis arvensis*, a wild species of the mustard family, p. 890.

- Chloride of calcium*, quicklime, s. 4988. p. 810.
- Chyle*, a milky fluid secreted from the alicants in the lacteal vessels.
- Chyme*, that poultice-like mass to which the food is reduced in the stomach of every animal, s. 6404. p. 975.
- Cicatrise*, to heal over with a scar, p. 513.
- Cilia*, eyelashes, p. 970.
- Claveats*, explained, s. 7248. p. 1065.
- Clinches*, cramps or holdfasts; to clinch, to turn the points of nails which have been driven, as in the shoeing of horses, s. 6710. p. 1007.
- Clough*, explained, s. 4455. p. 732.
- Cob*, a kind of wicker basket, made so as to be carried on the arm; hence a seed-cob, or seed-lip, is a basket for sowing from, p. 378.
- Cochle oast*, a kind of kiln for drying hops upon, s. 6043. p. 927.
- Coff*, a Cornish term for offal pilchards, p. 1172.
- Coffin bone*, a bone in the foot of the horse, s. 6417. p. 976.
- Coherent soil*, a soil whose parts stick together, p. 772.
- Collar-blade* or *hairs*, short segments of wood or metal, embracing the neck of the horse, to which the traces are attached, s. 3235. p. 524.
- Coltop*, explained, s. 7871. p. 1200.
- Commutation* of tithes, the substituting a fixed money payment, or a portion of land, instead of a tenth of the produce.
- Concha cartilages*, the gristles of the ear, s. 6764. p. 1013.
- Condition* of a horse, the state of health and strength, p. 977.
- Consecutive*, following, p. 525.
- Copyhold*, explained, s. 3395. p. 552.
- Chorde vocales*, or *chorde vocales*, tendons called into action by braying in the ass, s. 6765. p. 1013.
- Cornea*, the first or outer coat of the eye, s. 6371. p. 970.
- Cornetti*, a mode of riding, s. 6672. p. 1003.
- Corollary*, a consequent truth gained from some preceding truth or demonstration, s. 4961. p. 804.
- Coronal roots*, explained, s. 4983. p. 808.
- Coronary*, explained, s. 6417. p. 976.
- Cotyledon*, the first or seed leaf or seed lobe of a plant.
- Couples*, chains, collars, or mechanical contrivances, by which dogs, &c. are coupled together.
- Courses*, explained, s. 3189. p. 518.
- Crest*, upper part of a hedge-bank, p. 483.
- Croppers*, a variety of pigeon, p. 1095.
- Cross-breeding*, explained, s. 2023. p. 301.
- Crown* and *furrow-ploughing*, explained, s. 3256. p. 527.
- Crown scab*, a disease in the horse, p. 1007.
- Crystalline humour*, explained, s. 6374. p. 970.
- Culms*, stems of grasses, p. 1167.
- Culmiferous crops*, crops of plants whose stems yield straw, as wheat, barley, &c., p. 768.
- Curb*, explained, s. 6513. p. 987.
- Curl*, explained, s. 5371. p. 854.
- Curvilinear*, formed of curved lines.
- Cut ower*, to cut off the top crop, s. 4043. p. 658.
- Cutting* in horses, explained, s. 6523. p. 988.
- Cut-water* of a bridge, the projecting part of the pier of a bridge, which is opposed to the current, and divides it, s. 3612. p. 582.

D.

- Dandriff*, scurf, s. 6738. p. 1006.
- Dashing*, or dashed. See *Lipped and harled*.
- Dead hedges*, hedges made with the prunings of trees, or with the tops of old hedges which have been cut down.
- Dead timber*, any timber not growing, p. 502.
- Deciduous*, shedding the leaves in autumn.
- Decorticated*, deprived of the bark, p. 655.
- Defecation*, explained, s. 4591. p. 867.
- Dendrometer*, an implement invented to ascertain the quantity of timber in standing trees, p. 663.
- Deportation*, carrying away, removal, p. 519.
- Dew-retting*, spreading hemp or flax on grass to expose it to the action of the dews, which expedite the separation of the fibre from the feculent matter, s. 5904. p. 916.
- Dewstone*, the name of a species of limestone in Nottinghamshire, s. 3639. p. 587.
- Diagram*, an explanatory sketch, p. 757.
- Diarrhæa*, explained, s. 6473. p. 983.
- Diastole*, explained, s. 6351. p. 968.
- Digging his toes*, in horses, explained, s. 6289. p. 960.
- Dike*, explained p. 496. In Cambridgeshire a ditch is called a dike.

- Ditaceous plant*, a plant bearing its male blossoms on one plant and its female on another, s. 3181 p. 517.
- Disbarked timber*, timber deprived of its bark, s. 4053, p. 680.
- Dishes*, applied to a wheel, explained, s. 3732, p. 605.
- Dishes*, in farming, hollow places in the fields, in which the water lies, p. 802.
- Diuretics*, food or drink causing a copious discharge of urine, s. 6410, p. 975.
- Docking and nicking*, cutting off part of a horse's tail, and cutting a notch or nick on the under side of what remains, for the alleged purpose of making him carry it well; now almost obsolete, s. 6639, p. 1002.
- Domical*, shaped like a dome or an arch, s. 4507, p. 740.
- Dorsal vertebrae*, joints of the back bone, s. 6764, p. 1013.
- Double broaches*, broaches or splits are two-feet lengths of split hazel branches, employed in thatching, p. 578.
- Double wind-rows*, double ranges of new-made hay, s. 5797, p. 904.
- Dowel together*, to join so closely as to form a smooth surface, s. 3710, p. 600.
- Down shores*, breast ploughs to pare off the turf on downs, s. 3215, p. 521.
- Dragoon*, a variety of pigeon, p. 1095.
- Drain sluice*, explained, s. 4409, p. 726.
- Draw cut*, explained, s. 3151, 3152, p. 512.
- Droschkeys*, the name of a four-wheeled carriage in Russia, s. 6741, p. 1010.
- Dry stone walls*, walls built without mortar; a common practice in stony countries, s. 3065, p. 497.
- Duodenum*, the first of the intestines, and connected with the stomach, s. 6405, p. 975.
- Duct*, a passage through which any thing is conducted.
- Dynamometer*, or draught machine, explained, s. 2563—2565, p. 385.
- E.
- Earth*, as applied to the surface of the globe, one or more of the earths, as lime, clay, sand, &c., in a friable or divided state, and either alone or mixed; but without the addition of much organic matter.
- Empysematous swellings*, swellings filled with a windy humour, s. 6946, p. 1033.
- Enteritis*, explained, s. 6456, p. 982.
- Ergot* of rye, spur of rye; a disease in the kernels of that grain, p. 822.
- Eruca*, the larva state of insects, p. 1112.
- Estuary*, an arm of the sea, the mouth of a lake or river in which the tide ebbs and flows, s. 3425, p. 555.
- Etiolated*, drawn out into a weak state, p. 808.
- Eustachian tube*, explained, s. 6385, p. 972.
- Evolue*, to unfold, disentangle, develop, or separate.
- Eye in plants*, a bud.
- Eyes in cheese*, explained, s. 7067, p. 1046.
- F.
- Fagri*, or shagreen, ass's skin, s. 6757, p. 1012.
- False ribs*, explained, s. 6312, p. 964.
- Farcy*, explained, s. 6495, p. 985.
- Farmer* (from *fermier*, Fr.), farming agriculturist, farming cultivator, professional farmer, commercial farmer, rent-paying farmer, &c.; a proprietor cultivating his own estate is not correctly speaking a farmer; to be such he must pay a rent. A proprietor who cultivates his own soil may be a gentleman or yeoman agriculturist or husbandman, a *propriétaire cultivateur*, but not a farmer.
- Farmery*, the homestead or farm-yard, p. 677.
- Farming*, renting land and cultivating it, or employing it for the purposes of husbandry.
- Feather boarding*, sometimes called weather boarding, boarding, in which the edge of one board overlaps a small portion of the board next it.
- Recurrence* of cider, the lees or dregs, p. 673.
- Fee farmhold*, explained, s. 3394, p. 551.
- Feeding pastures*, pastures used for feeding stock, p. 905.
- Féring*, explained, s. 3251, p. 527.
- Felon*, a disease in cattle, explained, s. 6942, p. 1032.
- Femur*, the thigh bone, p. 965.
- Ferruginous waters*, water impregnated with iron, p. 724.
- Few-holding*, explained, s. 3402, p. 552.
- Few a house*, to hold a house on a few right, s. 3861, p. 624.
- Fibula*, explained, s. 6327, p. 955.
- Filouse*, explained, s. 7599, p. 1105.
- Finched*, explained, s. 6779, p. 1015.
- Fingers and toes*, explained, p. 861.
- Finkins*, a variety of pigeon, p. 1095.
- Finos*, the second best wool of Merino sheep, s. 7140, p. 1052.
- Firrot* of tares, a measure used in Scotland, in wheat and beans, equivalent to the English bushel, s. 5968, p. 842.
- Flakes*, hurdles or portable pales for fencing, s. 3046, p. 493.
- Fleaking*, explained, s. 3190, p. 518.
- Flecked cattle*, explained, s. 6780, p. 1015.
- Flight*. See *Glume*.
- Flooders*, explained, s. 4449, p. 731.
- Flaw bog*, or flow moss, a peat bog, the surface of which is liable to rise and fall with every increase or diminution of water, whether from rains or internal springs, s. 3628, p. 585.
- Flowing meadows*, explained, s. 4427, p. 727.
- Fluke*, a disease in sheep, p. 1049.
- Fluke worms*, animals of the genus *Fasciola*, s. 7271, p. 1066.
- Fetus*, a young animal in the womb, p. 976.
- Fogging pasture lands*, explained, s. 5837, p. 908.
- Foliage crops*, plants cultivated for their leaves to be used green, and which will not make into hay, as the cabbage tribe.
- Foot rot*, explained, s. 7366, p. 1066.
- Forage plants*. See *Herbage plants*.
- Fore-rents*, rents paid previously to the first crop being reaped, p. 767.
- Fors and scudda*, explained, s. 7137, p. 1052.
- Forsing*, explained, s. 7137, p. 1052.
- Founder* of the feet of horses, explained, s. 6517, p. 987.
- Free martin*, explained, s. 6824, p. 1021.
- Freehold*, explained, s. 3323, p. 551.
- Frieze*, colic, gripes, or gullion.
- Friable soils*, crumbling soils, p. 802.
- Frondeux branched trees*, full of branches, which are flat and spread horizontally, like the fronds of ferns, as in the spruce fir, s. 3687, p. 648.
- Frontal worms*, explained, s. 7270, p. 1066.
- Frustum*, a piece cut off from a regular figure, s. 5732, p. 695.
- Furnished*, explained, s. 6247, p. 955.
- Fusiform root*, shaped like a spindle, as the carrot, parsnep, &c. p. 865.
- G.
- Goites*, single sheaves tied in a particular manner, p. 516.
- Gaiting*, explained, s. 3176, p. 516.
- Gangs*, courses or slips in thatching, p. 518.
- Gastric juice*, the juice of the stomach of any animal, p. 974.
- Gaw furrows*, explained, s. 4266, p. 803.
- Gelding out-hills*, explained, s. 5778, p. 902.
- Geau*, wild cherry, s. 3994, p. 650.
- Gibbous*, protuberant, bearing excrescences, s. 6775, p. 1014.
- Git*, explained, p. 1066.
- Glair*, the mucous evacuation in the scouring of horses, s. 6950.
- Glanders*, explained, p. 985.
- Glennoid*, the hollow or socket in one bone at a joint which receives the knob, boss, or head of the approximate bone, p. 965.
- Glumes*, the husks or chaff of corn. Oat flights are the glumes of the oat, p. 838.
- Gluten*, a tenacious, ductile, and elastic substance, forming a constituent part in wheat flour and other vegetable bodies, p. 771.
- Go-downs*, explained, s. 6736, p. 1010.
- Goggles*, explained, s. 7267, p. 1066.
- Grass-cocks*, hay-cocks, p. 904.
- Grasses*, all the natural order of Gramineæ, of Linnaeus and Jusieu. Cereal grasses, those grown for bread corn. Pasture grasses, those grown chiefly for pasturage. Fœneous or feniferous grasses, those grown chiefly for hay.
- Grassing flax*, bleaching it on the ground, p. 915.
- Grease*, a disease in horses, explained, s. 6514, 6516, p. 987.
- Great rot*, explained, s. 7261, p. 1065.
- Green acres*, land capable of tillage, p. 1206.
- Grounding*, filling up, s. 3711, p. 600.
- Gutta serena*, explained, s. 6441, p. 980.
- Gutter*, a furrow-channel or drain, s. 4418, p. 726.
- Gypsum*, a genus of calcareous earths, consisting of carbonate of lime, and united with sulphuric acid. The principal species is the *Gypsum Alabastrum*, plaster of Paris, or alabaster. See *Crabb's Tech. Dict.*

H.

- Ha-ha*, a sunk fence, p. 474.
Hacking and picking. See *Picking*.
Hainault mowing, explained, s. 3172. p. 515.
Hammel, a small shed, with a yard for feeding one, or at most two animals, p. 469.
Hands of tobacco, leaves tied up by their footstalks, so that the leaves spread out like the hand, s. 3945. p. 641.
Hangs, slopes, s. 3945. p. 641.
Harled, p. 497. See *Lipped*.
Hash, explained, s. 2716. p. 419.
Hatches, flood-gates, p. 756.
Hated kill, explained, s. 7105. p. 1048.
Hattocks, shocks, s. 3173. p. 515.
Hautm, the base of the stalks or stems of all crops, after the seeds are reaped or gathered. The haulm of peas is in some places called pea ryse.
Heat and heel of gates, explained, p. 501.
Heading down trees, lopping or cutting off the heads of trees, p. 651.
Heading sheaves, the hood sheaf or sheaves of shocks of corn, p. 515.
Headmain, explained, s. 4411. p. 728.
Heckles, iron combs, p. 923.
Heckling flax, combing, p. 916.
Helmets, a variety of pigeon, p. 1095.
Hepatic affections, affections of the liver, p. 1037.
Herbage plants, forage plants, such as clover and other plants cultivated chiefly for the herb, to be used either green or made into hay.
Hide-bound, a disease in horses and cattle when the skin cleaves to the sides, s. 6425. p. 977.
Hink, explained, s. 5171. p. 832.
Hiary, explained, s. 6768. p. 1013.
Hirsel, a Scotch term of the same meaning as the English term "herd," s. 6793. p. 1017.
Hoars, thick mists, p. 772.
Holmes, small islands, but larger than aits.
Hood-sheaf, a sheaf placed on the summit of other sheaves for a covering, p. 516.
Hook bones, bones in the hind quarter of cattle, s. 6799. p. 1018.
Horny frog of the horse, the prominence in the hollow of a horse's foot, p. 976.
Horsemen, a variety of pigeon, p. 1095.
Horses, pieces of wood used in barking trees, p. 659.
Hot fur, explained, s. 5906. p. 824.
Hot yellows, explained, s. 7256. p. 1065.
Hove, explained, s. 7254. p. 1065.
Huckaback, a kind of cloth, s. 5933. p. 917.
Humerus, the arm bone, p. 965.
Hummelling machine, explained, p. 440.
Hunger rot, explained, s. 7264. p. 1066.
Hungry soil, barren soil needing much manure, p. 773.
Husbandman, one who farms generally; that is, who both produces corn and cattle, and attends to the dairy, the poultry, the woodlands, and the orchard. A farmer may confine himself to grazing, or to breeding or haymaking, or milking or raising green crops for the market, &c., but in none of these cases can he with propriety be called a husbandman. This term husbandman, therefore, is not exactly synonymous with farmer.
Husbandry, the culture of arable grass and woodlands, the management of live stock, the dairy, poultry, &c., and, in general, what constitutes the business of the head of a family living by agricultural industry in the country.
Hybrid, bastard or spurious, p. 1013.
Hyaloid, the *Tænia globulus*, an insect occurring in the skull of the sheep, p. 1049.
Hydroptic rot, explained, s. 7261. p. 1065.
Hygrometer, an instrument for ascertaining the degree of moisture in the atmosphere, p. 773.

I.

- Imago*, the perfect state of insects, p. 1112.
Impinge, to strike against, s. 4361. p. 719.
In and in system of breeding, p. 301.
Incision of objects on roads, the marks, traces, tracks, or ruts made, s. 3571. p. 575.
Increments, proportional rates of increase, s. 3552. p. 572.
Indigenæ, peculiar to, springing out of the nature of, p. 1012.
Induration, hardening, p. 717.
Infield, an obsolete Scottish term for enclosed lands near the farmstead, as opposed to such as are at a distance from it, and uninclosed, s. 802. p. 130.
Ings. See *Sittings*.

- Iris*, the coloured circle in the eyes of animals, s. 6371. p. 970.
Isometrical perspective, explained, p. 472.
Isosceles triangle, a triangle which has only two of its sides equal, p. 503.
Itinerating libraries, libraries, the books of which are carried from one place of deposit to another, and thence issued, p. 756.
Jacobines, a variety of pigeon, p. 1095.
Jammer, a tool used by masons for boring holes in hard stones to be refit by gunpowder, p. 743.
Jumping pole, a long stiff pole, by which persons in the fens are enabled to jump across ditches or drains twenty feet wide, by planting the pole towards the middle of the drain, and springing from bank to bank: a small piece of board, called a quant, is fastened to the bottom of the pole to prevent its sinking into the mud. See *Quant*.

K.

- Kelp*, the ashes of any description of *Fuci* or other seaweed, p. 1805.
Knees for ship-building, crooked pieces of timber, having two branches or arms, and generally used to connect the beams of a ship with her sides, s. 3034. p. 491.
Knuckering, explained, s. 6387. p. 972.
Kyloes, the name given to the cattle of the Hebrides, s. 6796. p. 1018.

L.

- Lachrymal gland*, the gland which secretes or supplies the *lachryma* or tears, p. 970.
Lacteals, the absorbents of the mesentery, which originate in the small intestines, and convey the chyle from thence to the thoracic duct, p. 968. See *Crabb's Tech. Dict.*
Lactometer, explained, s. 7008. p. 1037.
Lampas, a swelling of the wrinkles or ribs in the roof of the horse's mouth; analogous to the gum-boils in man, p. 980.
Land, a term employed in Cambridgeshire and other counties, to designate what more generally is termed a ridge; that is, one of those compartments which lie between gutter and gutter in arable fields. The ridge, in Cambridgeshire, is the highest part or central line of the lands, just as the ridge of a house is the highest part of its roof. In Scotland, a ridge includes the whole of the surface between gutter and gutter. Land appears the fitter term.
Land, ground, earthy surface in opposition to water or rocks. The term ground is generally applied to a comparatively limited extent of surface, as garden grounds, hop grounds, &c. in opposition to arable lands, wood lands, &c.
Land-fast stones, stones fixed or imbedded in the soil, p. 483.
Land-reeve, explained, s. 4638. p. 760.
Larvæ, the grubs, maggots, or caterpillars of insects, 803.
Laryngeal sonorous sacs, hollows in the windpipe which modulate the voice of animals, s. 6764. p. 1013.
Larynx, the windpipe or trachea, p. 972.
Lateral shoots, shoots emitted on the sides of branches; laterally; quite distinct from latter shoots, with which they are occasionally confounded, p. 478.
Laying in hedge-planting, laying down the sets or plants horizontally on the bed prepared for them, s. 3944. p. 640.
Laying an old hedge, explained, s. 3026. p. 490.
Leaping ill, explained, s. 7253. p. 1065.
Leasehold, property held on lease, p. 552.
Legget, explained, s. 3193. p. 518.
Leguminous crops, crops of the various kinds of pulse, as peas, beans, tares, saintfoin, lucern, clover, &c., p. 800.
Levelling, explained, p. 535.
Leverage, the act of using levers, or the power acquired by the use of them, p. 575.
Light-lyered, the dew-lap of a light colour, s. 6738. p. 1018.
Ligneous plants, woody plants, as trees or shrubs, p. 476.
Lipped and harled, a wall built of stones without mortar, but which has the joints afterwards filled with mortar, and the whole wall plastered over with what is called rough-cast, or harling in Scotland. The mixture used for harling is lime, sand, and small stones about the size of peas. Dashing in England is the forcible casting of small stones

- like the above, only washed quite clean, into the soft recent plaster of exterior walls, in order to resist the action of rain.
- Loom**, any soil in which clay and organic matter exist in considerable proportions, and so as to render it neither very adhesive or hard, nor soft and loose.
- Lock spit**, explained, s. 3823. p. 620.
- Longe**, a long leather thong, used in the process of longing or lunging horses, p. 1001.
- Lymph**, a clear, colourless, rather viscid humour, separated from the blood, and specifically heavier than water, s. 6350. p. 967.
- Lymphatics**, lymphatic vessels, are the absorbent vessels that convey the lymph into the thoracic duct, and form, with the lacteals, what is called the absorbent system. The use of these vessels is to draw in by a capillary attraction the fluids contained in the circumjacent cavities, p. 968. See *Crab. Tech. Dict.*
- Lymphatic absorbers**, 968. See *Lymphatics*, and *Lacteals*.
- M.
- Maceration**, the act of steeping or soaking in water, p. 863.
- Malic acid**, an acid obtained from apples, by saturating the juice with alkali, and pouring in the acetous solution of lead, until it occasions no more precipitate. See *Crabb's Tech. Dict.*
- Malindres**, a disease in horses, s. 6710. p. 1007.
- Manege riding**, explained, s. 6672. p. 1003.
- Martingal**, a thong of leather, fastened at one end to the girths under the belly, and at the other to the noseband of the bridle, to prevent a horse from rearing, p. 1001.
- Maturation**, the process of ripening, p. 816.
- Mazillary glands**, the glands belonging to the jaw bones, p. 972.
- Meal** of milk, the quantity yielded at one time of milking: thus, the morning meal, the evening meal, s. 7103. p. 1048.
- Medulla**, marrow, p. 967. In plants it signifies the pith.
- Mees or merca**, cattle ponds in Derbyshire, p. 735.
- Memel timber**, fir timber from the port of Memel in Prussia, in the Baltic, p. 504.
- Mere**, a lake, pool, or pond.
- Mesentery**, a membrane in the cavity of the abdomen attached to the vertebrae of the loins, and to which the intestines adhere, p. 975.
- Meslin**, a colony of flocks, s. 736. p. 118.
- Meslin, mesling, mesecin, mastin, or mesclidine**, corn that is mixed, as wheat, rye, &c., to make bread. This term occurs in old acts of parliament for the regulation of rivers, as that of the Cam; mescelin being in former days a frequent lading in that neighbourhood.
- Mesta**, explained, s. 736. p. 118.
- Metcacripus**, the shark, p. 965.
- Metal bed** of a road, explained, s. 3630. p. 585.
- Metaliferous ores**, ores which contain metals, p. 629.
- Metals** of a road, the material of which a road is formed, as broken quarry stone, boulder stones, and other kinds, p. 612.
- Metayer system**, the system of farming lands in many parts of the Continent, in which the produce is equally divided between landlord and tenant, p. 184.
- Midden**, dungbill, p. 807. "The midden is the mither o' the meal kist."
- Milsey**, a provincial term for a sieve, in which milk is strained, s. 7064. p. 1045.
- Mortices**, holes, cells, or receptacles made in posts, &c. to receive the tenons of rails, &c., p. 493.
- Mould**, organic matter in a finely divided and decomposed state, with a little earth mixed, as vegetable mould, leaf mould, peat mould, &c.
- Mowat**, explained, s. 7137. p. 1052.
- Mow**, a compartment in a barn, into which corn in the straw is stacked or packed.
- Mow-burn**, to heat by fermentation in the mow, p. 825.
- Mourrain**, a wasting, contagious, and most fatal disorder among cattle, s. 6943. 7250.
- N.
- Naked disease**, explained, s. 7964. p. 1066.
- Naturalising animals and vegetables**, introducing them to a new climate, in such a manner that they shall in future perpetuate themselves in that climate without the aid of man. See *Acclimatizing*.
- Navicular** or **nut bone** of the horse, explained, s. 6417. p. 976.
- Nicking**. See *Docking*.
- Nicotianing membrane**, explained, s. 6370. p. 970.
- Nuns**, a variety of pigeon, p. 1095.
- Nurses** for young plants, plants of an inferior and rapidly growing kind, planted round those which are choicer and of slower growth, both to shelter them and expedite their growth, p. 653.
- O.
- Obstetrics**, considerations appertaining to the foaling, calving, yeating, &c., of animals, s. 6969. p. 1035.
- Odometer**, from *odos*, a way, and *metreo*, to measure, an instrument by which the quantity of space passed over on foot, or in a conveyance, may be ascertained, s. 2506. p. 376.
- Oesophagus**, the weasand or gullet, p. 972.
- Omentum**, the caul, p. 973.
- One bout stitch**, a ridgelet formed by the going and returning of the plough, s. 5235. p. 839.
- Ophthalmia**, an inflammation in the coats of the eye, proceeding from arterious blood got out of the vessels, and gathered together between the coats, s. 6756. p. 1012.
- Optic nerve**, a nerve which perforates the bulb of the eye, and communicates with the brain; so that every sensation derived from sight depends on the optic nerve, p. 970.
- Outfall**, the lower end of a water-course, p. 714.
- Outfield**, uninclosed farm lands at a distance from the farmstead, s. 802. p. 130.
- Owls**, a variety of pigeon, 1095.
- P.
- Pacing**, one of the motions taught the horse, s. 6672. p. 1003.
- Pancreas**, the sweet bread. It is composed of innumerable small glands, the excretory ducts of which unite and form one duct, called the pancreatic duct, that conveys a fluid very similar to saliva into the intestines, called the pancreatic juice, which mixes with the chyle in the duodenum.—*Crabb*.
- Pane** of ground, a four-sided compartment of grass ground, adapted for irrigation, p. 726.
- Panicle**, an irregularly divided branch of flowers, as in the oat, p. 826.
- Pantile**, a gutter tile, p. 708.
- Papier maché**, mashed paper, which, when mixed up with glutinous substances, may be moulded into various shapes, p. 810.
- Paring and burning**, taking off the turf or surface of grass or waste lands, and incinerating it by means of fire, in order to prepare the soil for aration, p. 520.
- Parotid glands**, explained, s. 6388. p. 972.
- Passaging**, one of the motions taught the horse, s. 6672. p. 1003.
- Pastern**, explained, s. 6319. p. 965.
- Patilla**, explained, s. 6325. p. 965.
- Paucity**, fewness, p. 784.
- Peelers**, the same as barkers. Persons employed to deprive trees of their peel or bark, p. 662.
- Pellicle**, little skin or coat, p. 822.
- Pelt rot**, explained, s. 7264. p. 1066.
- Pendro**, explained, s. 7367. p. 1066.
- Penultimate**, the last but one, p. 801.
- Percolate**, to strain, or trickle through, p. 581.
- Percolation**, the act of straining, purification or separation by straining, p. 522.
- Perforans** of the horse's foot, explained, s. 6420. p. 976.
- Perichondrium**, explained, s. 6336. p. 967.
- Petricrinium**, explained, s. 6356. p. 967.
- Peridæmium**, explained, s. 6336. p. 967.
- Periosteum**, a general uniting membrane to bones and their appendages, s. 6336. p. 967.
- Periphery**, the circumference or orbit, p. 429.
- Peripneumonia**, explained, s. 7251. p. 1065.
- Peristaltic motion**, the vermicular, worm-like, or creeping motion of the intestines; by which they contract their spiral fibres so as to propel their contents, p. 975.
- Petits**, a variety of pigeon, p. 1095.
- Pharynx**, explained, p. 972.
- Picking and hacking**, loosening with a pick-axe or mattock, and by separating with some cutting tool, s. 5382. p. 538.
- Picking** of hop plantations, explained, s. 6025. p. 956.
- Piccework**, work done and paid for by the measure of quantity, or by previous estimation and agreement,

- in contradistinction to work done and paid for by the measure of time, p. 976.
- Pigeon-cat**, explained, s. 7540. p. 1096.
- Piggery**, the compartment in a farm-yard, with sties and other accommodations allotted to pigs.
- Pile**, the shag or hair on the skins of animals. Each hair may be called a pile, s. 7140. p. 1052.
- Pillow-slip**, pillow-case, p. 1049.
- Pining**, explained, s. 7372. p. 1066.
- Pinning**, explained, s. 7280. p. 1065.
- Pip**, explained, s. 7525. p. 1095.
- Pipe drain**, explained, s. 4296. p. 710.
- Pith and Pilting**, by butchers, explained, s. 6308. p. 964.
- Plane table**, a square board with lines drawn on its upper side, used in taking angles and in measuring land, s. 2998. p. 481.
- Plashing** an old hedge, interweaving the stems in hedges, s. 3025. p. 490.
- Plumassier**, one who prepares feathers for ornamental purposes, p. 1088.
- Pluviometer**, rain gauge, s. 4742. p. 773.
- Pneumonia**, an inflammation of the lungs, p. 981.
- Podders**, persons employed to collect the green pods of peas off the plants, p. 837.
- Polders**, salt marshes in Holland and Flanders, p. 774.
- Pole cut**, or poll cut, a disease of the poll or head, usually at its hind part, or in the nape of the neck, s. 6442. p. 980.
- Polled**, hornless, devoid of horns, s. 6786. p. 1016.
- Pompage**, the pulpy mass to which apples are reduced by grinding in the cider counties, preparatory to pressing out the juice, p. 672.
- Pommel**, the prominence in the front or fore part of a saddle, p. 1003.
- Potato pie**, explained, s. 5344. p. 851.
- Pouters**, a variety of pigeon remarkable for its habit of pouting, p. 1095.
- Preventive pruning**, explained, s. 3990. p. 649.
- Probang**, a flexible piece of whalebone with a sponge fixed to the end, used occasionally in probing the throat, s. 6953. p. 1033.
- Puddling**, explained, p. 620.
- Pulls**, hills or elevated parts of a road, requiring extra pulling in draught animals, s. 3237. p. 525.
- Pulmonary artery**, explained, s. 6345. p. 967.
- Pultaceous**, of the consistence of a poultice, p. 1005.
- Puncted foot**, explained, s. 6521. p. 987.
- Puncta lachrymalia**, explained, s. 6370. p. 970.
- Pupa**, the chrysalis state of insects, p. 1112.
- Purchase** of the bridle, the command or control of it, s. 6676. p. 1003.
- Pursiveness, pursiness**, shortness of breath, s. 6693. p. 1005.
- Pyrites**, firestone, s. 3228. p. 523.
- Pyroigneous acid**, acid produced by distillation of the spray of trees, p. 493.
- Q
- Quadrant**, a mathematical instrument; the fourth part of a circle, s. 3350. p. 544.
- Quant**, a small piece of board at the bottom of a jumping pole to prevent the pole sinking into the mud by the weight of the jumper's body.
- Quarter-cleft rod**, a measuring staff having four sides, s. 3195. p. 518.
- Quartering**, the division of planks of wood lengthwise into small four-sided pieces.
- Quarters** of the horse's hoof, explained, s. 6420. p. 976.
- Quick**, a live fence or hedge formed of some growing plant, usually hawthorn.
- Quick bends**, sharp turns, p. 578.
- Quicken tree**. See *Roan tree*.
- Quickset hedge**, a hedge formed of sets or plants that are quick; that is, alive.
- Quincunx**, trees planted in rows, at the same distance between the rows that the trees are in the rows, and the trees of one row opposite the vacancies in the other, s. 3928. p. 638.
- Quit-rent**, a small rent or acknowledgement payable by the tenants of most manors, s. 1117. p. 179.
- Quittor**, explained, p. 988.
- R
- Rabbit**, a moulding, s. 4334. p. 715.
- Rabios**, explained, s. 7140. p. 1052.
- Rafter**, a piece of four-sided timber used in roofs.
- Raftering** land, ploughing half of the land, and turning the grass side of the ploughed furrow on the land that is left unploughed, p. 1166; as applied to timber, sawing up planks of trees into pieces of greater depth than width for rafters to roof buildings.
- Rake hot**, or reek hot, s. 6723. p. 1608.
- Ramos-headed trees**, trees whose heads abound in branches, p. 649.
- Ramos-rooted trees**, trees whose roots are much branched, p. 634.
- Rath ripe**, the property of being early ripe, s. 5082. p. 823.
- Rut's tail**, a disease in horses, which causes the hair of the tail to fall off, and not be again produced, s. 6710. p. 1007.
- Ray**, a discomb in sheep, explained, s. 7625. p. 1066.
- Rectangular fields**, fields whose angles arc right angles, p. 680.
- Rectangular parallelogram**, a figure of four sides, whose opposite sides are equal, and all its angles right angles, p. 443.
- Red roan**, explained, s. 5106. p. 825.
- Redwater**, explained, s. 5106. p. 1064.
- Rete mucosum**, p. 968. A mucous membrane deposited in a net-like form, between the epidermis and the cutis: it covers the sensible cutaneous papillae, connects the epidermis with the cutis, and gives the colour to the body. — *Crabb*.
- Retina**, the true organ of vision, formed by a net-like expansion of the pulp of the optic nerve, p. 970.
- Rhomboid**, a figure whose opposite sides are parallel and equal, but all its sides are not equal, neither are its angles right angles, p. 414.
- Ribbing**, explained, s. 3255. p. 527.
- Ricking**, explained, s. 3176. p. 516.
- Riddle**, a large coarse sieve, s. 3655. p. 589.
- Ridging**, laying the soil up in ridges, p. 508.
- Riffling** by gunpowder, riving, splitting, or dividing, s. 4065. p. 661.
- Right angles**, where a room is exactly square, each of the corners of it is called a right angle: in scientific language it is thus defined, as the fourth of a circle; or thus, when one straight line, standing on another straight line, makes the adjacent angles or corners equal to one another, each of the angles or corners is called a right angle.
- Ring-bone** in horses, a disease in the feet of the horse, p. 960.
- Ripping** of flax or hemp, the operation of separating the boles or seed pods, by striking them against a board, or piece of iron, p. 915.
- Ristle-plough**, explained, p. 1197.
- River-meadows**, explained, s. 5769. p. 901.
- Roan tree**, the mountain ash.
- Roguish plants**, spurious varieties, s. 5220. p. 838.
- Roset**, explained, s. 3195. p. 519.
- Root crops**, esculent plants cultivated for their tubers, bulbs, or other enlarged parts produced under or immediately on the ground, and chiefly connected with the root, as the potato, turnip, carrot, &c.
- Roots**, the fibres and other ramifications of a plant under ground, and by which it imbibes nourishment. Tubers, bulbs, and other fleshy protuberances under ground, are employed by nature for the purposes of propagation or continuation, and therefore ought never to be confounded with common roots, which serve to nourish these tubers, bulbs, &c., in common with other parts of the plant.
- Rot**, explained, s. 7245. p. 1064.
- Rouen**, the aftermath, the lattermath, or second crop of hay cut off the same ground in one year, s. 3169. p. 515.
- Rough pile** in cattle, coarse hair or wool, p. 784.
- Roup**, explained, s. 7526. p. 1095.
- Rouvels**, explained, s. 6538.
- Rubbers**, a disease in sheep, explained, s. 7265. p. 1066.
- Rubble stones**, loose stones, brick-bats, and the like, which are put together to conduct water; so called because they are rubbed together.
- Rumbling drains**, drains formed of a stratum of rubble stones, p. 581.
- Rusner**, explained, s. 4140. p. 675.
- Rusks**, a variety of pigeon, p. 1095.
- Rural economy**, rural affairs, geponics, agronomics, terms considered as synonymous with husbandry.
- Rust**, a disease to which the cereal and other grasses are subject, and which occasions their herbage to be of a rusty colour, s. 5741. p. 893.
- Rut**, to cut a line on the soil with a spade, p. 482; also the copulation of deer in the rutting season; also the track of a cart-wheel.
- Rutting**. See *Rut*.

S.

- Saccharo-saline*, partaking the properties both of sugar and salt, p. 1039.
- Saddle-grafting*, explained by figures, p. 1143.
- Satin*, explained, s. 5860. p. 853.
- Sativa*, the spittle of animals.
- Salt-cat*, a mixture given to pigeons to promote their digestion, p. 1096.
- Saltings or ings*, salt-water marshes, p. 747.
- Sandcracks*, explained, s. 6525. p. 983.
- Sauer kraut*, explained, s. 5507. p. 808.
- Scab*, explained, s. 7265. p. 1066.
- Scalene triangle*, a triangle with three unequal sides, s. 4343.
- Scantling*, all quartered timber under five inches square, s. 4002. p. 652. In masonry, a term expressive of the size of stones.
- Scarcement*, a rebate or set-back in the building of walls, or to raising banks of earth, p. 481.
- Scarification*, cutting through the bark and soft wood of a thick branch with an edge tool, previously to sawing through the hard wood, s. 3164. p. 513.
- Scipula*, the shoulder blade, p. 994.
- Scurfiter*, a machine to excoriate and disturb the surface of soil, p. 528.
- Sclerotic coat*, a coat of hard consistence, p. 970.
- Scoop wheel*, a large wheel with numerous scoops fastened in its periphery, s. 4277. p. 706.
- Scoria* of founderies, the refuse or dross of the metals, s. 3643. p. 588.
- Screening*, the act of sifting earth or seeds through a large oblong sieve or riddle, called a screen, p. 509.
- Scudder*. See *Fors and Scudder*.
- Scuffler*, a kind of horse-hoe, p. 528.
- Scutching flax*, breaking the woody part of it preparatory to separating it from the fibrous parts, p. 915.
- Sea-ooze*, the alluvial deposit, the mud or slime left by the sea where its waters have subsided, p. 746.
- Sea-lobes*, the cotyledons, or very first leaves displayed on a seedling plant.
- Sellenders*, in horses, explained, s. 6293. p. 961.
- Seminal roots*, the first roots, those emitted from the seed itself, p. 808.
- Sensible frog* of the horse, explained, s. 6420. p. 976.
- Sensible idminax*, explained, s. 6421. p. 976.
- Septic*, causing putridity, producing putrescence, s. 6844. p. 1023.
- Serum*, whey, or the remainder of milk after its better parts have been taken away; also, the yellow and greenish fluid which separates from the blood when cold and at rest, s. 6980. p. 1036.
- Sesamoids*, little bones found at the articulation of the toes (in man); so called from their supposed resemblance to the seeds of the plant called sesamum, s. 6319. p. 965.
- Setons*, explained, s. 6537. p. 990.
- Set-sod*, explained, s. 3014. p. 486.
- Sets and eyes* of potatoes, slices of the tubers of the potato, each slice being furnished with at least one eye or bud, p. 948.
- Shab*, explained, s. 7265. p. 1066.
- Shagreen*, or *fagri*, the prepared skin of the ass, s. 6757. p. 1012.
- Shakes* in the holes of trees, fissures, clefts, or rents, p. 656.
- Shakers*, a variety of pigeon, p. 1095.
- Shaking quags*, shaking bogs; wet spongy soil, p. 694.
- Shaly soil*, explained, s. 4750. p. 774.
- Shearer*, a reaper, s. 3250. p. 526.
- Shearing*, reaping, p. 515.
- Sheath*, land guard of embankments, s. 4362. 4366. p. 719, 720.
- Shearing rivets*, the process of mowing the plants which abound in rivers; the instrument with which this is effected is formed of a line of scythe-blades, rivetted together by their extremities, and which line of scythe-blades is worked or moved along over the surface of the mud by levers attached to the line, operated upon by men in boats, s. 3171. p. 515.
- Shift of crops*, an alternation or variation in the succession of crops, p. 814.
- Shifting beach*, a beach of gravel liable to be shifted or moved by the action of the sea, or the current of rivers, s. 4332. p. 714.
- Shingles*, pieces of thin board used as tiles, a common practice in timber countries on the Continent and in America, s. 3051. p. 495.
- Shocks*, stooks or hattocks, assemblages of sheaves, never of more than ten sheaves in those places where the tithes is paid in kind, as this arrangement facilitates the taking of the tithes; in Scotland, from six to twelve, independently of the two or four hood or roof sheaves, p. 515.
- Shoughed*, earthed in, p. 640.
- Siddow peas*, such as boil freely, s. 7791. p. 1140.
- Silicious*, of the nature of sand or flint, p. 587.
- Siloes*, repositories, explained, s. 4988. p. 810.
- Single wind-rows*, a single range of new-made hay, before it is packed into cocks, p. 903.
- Skirting or peat turning*, explained, s. 3210. p. 520.
- Skrreen plantations*, plantations made for the purpose of skreening or sheltering, p. 753.
- Slab*, the outer board sawed from the trunk of a tree.
- Sleepers*, explained, s. 3785. p. 613. In Suffolk the root stocks, when left in the soil, of such trees as are sawed off level with the surface.
- Strip-coat cheese*, explained, s. 7085. p. 1047.
- Slit planting*, explained, s. 3263. p. 642.
- Slob farrow*, explained, s. 3213. p. 521.
- Sludger*, explained, s. 2514. p. 378.
- Snaffle*, a bridle with a single rein, and without a curb, s. 6734. p. 1009.
- Snag pruning*, pruning or cutting off branches so as to leave snags, s. 4027. p. 655.
- Snags*, stumpy bases of branches left in pruning, s. 3993. p. 650.
- Sob*, a convulsive spasm of the air passages to relieve congestion, s. 6723. p. 1008.
- Soil*, earth, either of one or of several sorts, mixed with decomposed organic matters.
- Soiling*, feeding horses or cattle in houses or sheds with clover or other herbage in a green state, p. 874.
- Sough*, a box-drain, s. 4254. p. 700.
- Sovens*, explained, s. 5146. p. 828.
- Spay*, to incapacitate a female animal for producing young, s. 7306. p. 1069. See *Castrate*.
- Sphaclated*, withered, blasted, mortified, gangrened, s. 6945. p. 1032.
- Spinous processes*, projections resembling spines or prickles, s. 6764. p. 1013.
- Spired*, grown, shot out into spires, s. 5108. p. 825.
- Spitful of earth*, a spadeful of earth, p. 507.
- Splint*, in horses, a preternatural excrescence of bone, or a hard tumour, s. 6293. p. 961.
- Spots*, a variety of pigeon, p. 1095.
- Spray drain*, a drain formed by burying the spray of wood in the earth, which keeps open a channel, s. 4284. p. 708.
- Spray of a tree*, the twigs of the branches of a tree, p. 649.
- Spring feed*, herbage produced in the spring, p. 905.
- Squeakers*, pigeons under six months of age, p. 1096.
- Stacking stage*, explained, s. 3289. p. 633. In Cambridge, the object of the stage is effected by a stage hole left in one side of the upper part of the rick.
- Stack sword*, explained, s. 3288. p. 632.
- Stades*, explained, s. 3796. p. 903.
- Stake and rice*, a fence composed of stakes driven into the ground and interwoven with branches retaining their spray, or with rods without their spray; the latter is frequently called a wattled fence, p. 487.
- Stagers*, a disease of the horse, explained, p. 978.
- Straw mow*, a stack or rick of straw formed in a barn, s. 5045. p. 818.
- Steining a well*, lining it with stone or brick, s. 4479. p. 735.
- Stife of the horse*, explained, s. 6276. p. 959.
- Stire*, a sort of cyder apple, s. 4082. p. 665.
- Stock*, the animals of agriculture called live stock; also, the implements and other lifeless articles of property on a farm, called dead stock.
- Stocking a pasture*, putting in as many head of cattle as the pasture will maintain, s. 5285. p. 906.
- Stolones*, the creeping rooting shoots of some grasses, and other plants, by which they increase, p. 904.
- Stoloniferous grasses*, grasses producing stolones, p. 887.
- Stone-brash*, a sub-soil composed of shattered rock or stone, s. 4519. p. 742.
- Stooks*, shocks or hattocks, p. 817.
- Stools of a coppice*, the stumpy root-stocks of trees previously cut down, p. 662.
- Stoney of rape*, the pods and points broken off in threshing, p. 932.
- Strull*, a bar so placed as to resist weight, p. 498.
- Stubs*, stucky stumpy portions of the stems of trees and shrubs, p. 1005.
- Stud*, a post, a stake, an upright, in a building, p. 500.; a collection of breeding horses and mares.

- Stumming*, explained, s. 4132. p. 674.
Sturdy, explained, s. 7267. p. 1065.
Sudcarbonate of soda, a salt in which soda predominates, p. 837.
Sublingual, under the tongue, s. 6388. p. 972.
Succedaneum, a substitute, p. 846.
Swath, the bands or ridges produced by mowing with the scythe, p. 903.
Swath balk, the line between two swaths where the stubble is cut less closely, presenting a little ridge of stubble, p. 514.
Sways, long hramble rods used in thatching with reeds, p. 518.
Sweating of hay, a slight fermentation, p. 904.
Swing plough, any plough without wheels, p. 390.
Switching bill, an instrument used in pruning hedges, p. 485.
Switching hedges, cutting off the one year's growth which protrudes from the sides of hedges, s. 4005. p. 652.
Synchronous, at one time, at the same time, contemporary, p. 1002.
Synopsis, the seeing all at once, or at one view; a comprehensive volume, p. 881.
Synovia, joint oil, p. 965. 967.
Systole, explained, s. 6351. p. 968.
- T.
- Tag-bell*, a disease in sheep, explained, s. 7260. p. 1065.
Tail drain, explained, s. 4414. p. 726.
Tapetum, explained, s. 6373. p. 970.
Tarsus, explained, s. 6328. p. 966.
Teatling, explained, s. 5824. p. 906.
Tecreros, explained, s. 7141. p. 1052.
Tedding hay, scattering, spreading, turning, and, in short, making hay, p. 903.
Tenon, a projection in a rail, &c., made to fit a mortice.
Tenon joint, a joint formed by a tenon and mortice, p. 598.
Tenure, a holding or occupying, p. 179.
Territorial economy, whatever relates to the valuation, purchase, sale, exchange, arrangement, improvement by roads, canals, drainage, &c., of territorial surface, including interposing waters, as rivers, lakes, and also mines and minerals. Territorial improvements are mostly effected by the proprietors of lands or their agents and stewards, and not to any great extent by renters of land, or farmers.
Tetanus, a spasmodic affection, accompanied by rigidity, one species of which is known by the popular name of a locked jaw, s. 6370. p. 970.; s. 6432. p. 978.; s. 6965. p. 1035.
Tethering, restraining grazing animals by a rope or chain, fastened to the animal at one end, and to the earth at the other, s. 5560. p. 876.
The line of draught, the direction in which an animal is pulling or drawing, s. 2592. p. 390.
Theodolite, an instrument used in surveying, and chiefly in taking angles, p. 544.
Thill, the beam or draught tree of a cart or waggon.
Thiller or Thill horse, the horse that is put under the thill, or into the shafts or draughts, p. 1139.
Thoracic duct, the trunk of the absorbent vessels, so called from its being placed in the thorax or chest, p. 968.
Thorough-pin, explained, s. 6293. p. 961.
Threave, twenty-four sheaves of straw or corn, s. 3168. p. 517.
Thrush paste, explained, s. 6554. p. 988.
Tibia, the leg bone, p. 965.
Ticks, a variety of bean, called the tick bean, s. 5225, 5226. p. 838.
Tie, a bar so placed as to resist a drawing or twisting power, p. 498.
Till, coarse obdurate land, p. 746.
Tiller, to send forth numerous stems from the root; applied only to culmiferous plants, s. 4384. p. 808.
Tillering. See *Tiller*, s. 5130. p. 826.
Tith, the degree or depth of soil turned by the plough or spade, that available soil on the earth's surface, into which the roots of crops strike, p. 803.
Typlling, as applied to hay-making, explained, s. 5549. p. 875.
Tithe, the tenth of the produce of the soil, paid to the clergy of England.
Tithing-man, a person employed by the clergyman in a village to set out and collect his tithes.
Torrefied earth, earth subjected to the action of fire, p. 522.
Trächen, the windpipe, p. 972.
Tracking flax, breaking the woody part in the stems of flax, s. 5912. p. 915.

- Tramp*, an instrument used in making hedges, p. 481.
Tramroad, explained, s. 3795. p. 615.
Transparent, transparent, diaphanous, allowing light to shine through, p. 811.
Tremblings, explained, s. 7253. p. 1065.
Trench, explained, s. 4412. p. 726. To trench, to turn over and mix soil to the depth of two, three, or more spades, or spits.
Trench drain, explained, s. 4413. p. 726.
Trindle, to allow to trickle or run down in small streams, p. 641.
Trochar, an instrument resembling a pipe, used for making incisions, when water or air is received out of the incision through the trochar, p. 1034.
Truncheons, large sets, stakes, or poles, of willow, poplar, &c. planted to form trees speedily, p. 749.
Trumpeters, a variety of pigeon, p. 1095.
Tubers, knobs, fleshy bodies at the roots of plants, as in potato, yam, pignut, &c., p. 511.
Tumblers, a variety of pigeon, p. 1095.
Turbits, a variety of pigeon, p. 1095.
Turners, a variety of pigeon, p. 1095.
Turnsick, explained, s. 7267. p. 1066.
Tussocks of grass, clumps, tumps, tufts, or minute hillocks of growing grass, p. 518.
Twibil and hink, explained, s. 5171. p. 832.

U.

- Urinarium*, a receptacle for urine, s. 6998. p. 1038.

V.

- Velum palati*, explained, s. 6382. p. 972.
Vena cava, explained, s. 6348. p. 967.
Vena cava ascendens, explained, s. 6348. p. 967.
Vena cava descendens, explained, s. 6348. p. 967.
Vena porta, explained, s. 6349. p. 967.
Vinuish. See *Pining*.
Viscid, thick, glutinous, gummy, p. 1086.
Vivacious, living, sprouting, very lively, very free of growth, p. 803.
Vives, explained, s. 6388. p. 972.

W.

- Wads*, explained, s. 5208. p. 836.
Walls dashed with lime. See *Harled*.
Walls en pisé, walls built of mud rammed in between a frame of boards, p. 457.
Wardles, explained, s. 6489. p. 984.
Ward-holding, explained, s. 3402. p. 552.
Warping, explained, s. 4452. p. 732.
Watering of hemp, the maceration, steeping, or immersion of the stems of the hemp plant, in water, s. 677. p. 107. 917.
Water-ratted, watered, s. 5929. p. 917.
Water tables across a road, sunk panels, which conduct the surface water into drains, p. 582.
Water-tabling, explained, s. 3014. p. 486.
Water head, explained, s. 7967. p. 1066.
Wattle, to weave, to interlace, or plat branches or rods.
Wattled fence. See *Stake and Rice*.
Wattled hurdles, hurdles wattled with rods.
Way pane, explained, s. 4416. p. 726.
Wear, a dam made with stakes and osier twigs interwoven, as a fence against water, p. 722.
Well-bred, explained, s. 2064. p. 305.
Whethring, explained, s. 6971. p. 1035.
Whin, furze, gorse, gorse, or goss, p. 510.
Whinstone, explained, s. 3654. p. 589.
Whipping out grain, striking the ears against a stone or the edge of a board, till the corn is separated from the straw, p. 519.
Whipping in plants, to bruise, abrade, or injure, by rubbing or striking against another, as the competing branches of neighbouring trees, s. 4014. p. 638.
Whirlbone of the horse, the articulation of the thigh bone with the pelvis, 959.
Whitlen, the small-leaved linn, p. 1141.
Wilding, trees sprung up from seeds naturally distributed, i. e. by winds, birds, running waters, &c., p. 675.
Winestraws, the withered flower-stalks of grasses standing in the fields; in English, bents, s. 5058. p. 820.
Wormals or puckeridge, explained, s. 6968. p. 1035.
Woodward, a land-revee or ground officer, s. 4638. p. 760.
- Y.
- Yellows*, explained, s. 6480. p. 984.
Yerking, one of the motions taught to horses, s. 6672. p. 1003.

GENERAL INDEX.

* * * The Numbers refer to the Paragraphs, not to the Pages, except in the case of the List of Authors, where they refer to the page and the year in which the Author published: in such cases the word page and letters A. D. are prefixed.

- ABBATE**, Antonio, his work on agriculture, page 1921. A. D. 1808.
- Abelle**, F., his work on agriculture, page 1217. A. D. 1791.
- Aberdeenshire, statistics of, 7852.
- Abortion in plants, 1683.
- Abyssinia, climate, surface, and soil of, 1067; agricultural products of, 1068; live stock of, 1069; agriculture of, 1070.
- Acclimating of plants, 1764; the more tender animals, 7390.
- Account books, farmer's, 4886.
- Accounts, keeping and auditing, 4708; keeping, 4883; necessity of a regular system of, 3381.
- Acid, fluoric, in animals, 1924; muriatic, in animals, 1925; pyroligneous, distillery of, at Milburn in Dunbartonshire, 7843.
- Acids, 1423; oxalic, 1424; acetic, 1425; citric, 1426; malic, 1427; gallic, 1428; tartaric, 1429; benzoic, 1430; prussic, 1431; vegetable, constituents of, 1432; animal, 1953.
- Adam**, James, his work on agriculture, page 1210. A. D. 1789.
- Adam**, of Blair Adam, 7847.
- Adams**, George, his work on agriculture, page 1212. A. D. 1810.
- Adanson**, Madame Aglaë, her work on agriculture, page 1218. A. D. 1822.
- Adansonia digitata*, 1109.
- Africa, general description of, 1066.
- After-grass on meadows, 5810.
- Agricultural Institution of Moegelin, 576.
- Agricultural Society, Australian, 1043.
- Agricultural Societies of Hanover and Celle, 593.
- Agriculture among the Romans, decline of, 178.
- Agriculture, as influenced by climate, 1948; by temperature and light, 1259; by elevation, 1860; by soil, 1263; by moisture, 1264; by the state of society, 1270; by civilisation, 1271; by political circumstances, 1272; by religion, 1273; by the character of a people, 1274.
- Agriculture, bibliography of, 7896.
- Agriculture during the seventeenth century, 234.
- Agriculture, earliest Spanish works on, 713.
- Agriculture, history of, in the ages of antiquity, 5; in Egypt, 8; among the Jews, 17; of the Greeks, 24; of the Persians and Carthaginians, &c. 56; among the Romans, 42; during the middle ages in Italy, 180; in France, 185; in Germany, 192; in Britain, 195; in ultra-European countries, 47.
- Agriculture, improvement of, by refining the taste of the purchasers of its products, and increasing the knowledge of agricultural patrons, 7926; by the better education of those engaged in it, 7930.
- Agriculture in England during the thirteenth and fourteenth centuries, 210; in the fifteenth century, 211; in the sixteenth century, 216; early in the sixteenth century, 221; during the reign of Elizabeth, 222.
- Agriculture in ultra-European countries during the middle ages, 257, 258.
- Agriculture may be practised without any knowledge of its theory, 1286; object of the art of, 1287; study of the science of, 1283.
- Agriculture of Britain, classification of the, 1280; improved by the Norman conquest, 204.
- Agriculture of irrigation, geographical extension of the, 1254; of manures and irrigation, 1255; of draining and manures, 1256; of science, 1276; of habit, 1277; barbarian, 1278; of savages, 1279; of water-fed lands, 1260; of sun-burnt lands, 1267; of mountains, 1268; common, 1269.
- Agriculture, origin of and importance; practice of, in early times; recent discoveries in, arrange-
- ment of the subject in this work, pages 1 to 3; the operations, 3111; the physical circumstances affecting, 1258; traditional history of, 1, 2; works on, during the commonwealth, 250.
- Agriculturists, commercial, the different kinds of, 7942; itinerant, 7725; professional education of, 7942.
- Aigou**, his work on agriculture, page 1218. A. D. 1805.
- Ainslie**, John, his works on agriculture, page 1212. A. D. 1806.
- Air, fresh, proper for domestic animals, 2076; noxious in wells, 4480.
- Aiton**, William, his works on agriculture, page 1212. A. D. 1805.
- Alamanni**, his work on agriculture, page 1221. A. D. 1764.
- Alamanni**, Luigi, his work on agriculture, page 1221. A. D. 1546.
- Albania, agriculture of, 758.
- Albertazzi**, Jacopo Antonio, his work on agriculture, page 1222. A. D. 1811.
- Abrecht**, J. F. E., his work on agriculture, page 1219. A. D. 1775.
- Albumen, 1344. 1406; in animals, 1939; use of, 1940.
- Atterson**, John, M. D., his work on agriculture, page 1211. A. D. 1802.
- Age, utility of the, 1333.
- Algiers, description of the territory of, 1095.
- Alkalies, vegetable, 1500; utility of, 1501.
- Allets**, Pons Augustin, his works on agriculture, page 1215. A. D. 1760.
- Almond tree, the, at the Cape of Good Hope, 1122.
- Aloe, the, in Spain, 723; of the Cape of Good Hope, 1123.
- Amazonia, agriculture of, 1244.
- Amhergris, 1949.
- Amethon**, Hubert Pascal, his work on agriculture, page 1216. A. D. 1779.
- America, agricultural operations of, 1170; field labours in, 1171.
- America, North, temperature of the eastern parts of, 2352.
- Amoë**, Le P., his work on agriculture, 1216. A. D. 1770.
- Ammonia in animals, 1929.
- Ammoniac, 1474.
- Amoretti**, his works on agriculture, page 1221. A. D. 1785.
- Amorceux**, his works on agriculture, page 1216. A. D. 1787.
- Amos**, William, his works on agriculture, page 1210. A. D. 1794.
- Amphibia, 7589.
- Analysis of plants, mechanical and chemical processes for the, 1392, 1393.

SUPPLEMENT
TO
LOUDON'S ENCYCLOPÆDIA
OF
AGRICULTURE :

**BRINGING DOWN IMPROVEMENTS IN THE ART OF FIELD CULTURE FROM
1841 TO 1843 INCLUSIVE.**

By J. C. LOUDON, F. L. G. Z. & H. S. &c.
**AUTHOR OF THE ENCYCLOPÆDIA OF GARDENING, AND CONDUCTOR OF THE
GARDENER'S MAGAZINE.**

INTRODUCTION.

THE improvements in agricultural science and practice, which have been either discovered, or brought more conspicuously into notice, since the publication of the last edition of this *Encyclopædia* in 1831, may be thus briefly enumerated.

1. The functions of the leaves of plants are beginning to be more generally understood; and hence, also, the importance of allowing sufficient space for their exposure to the sun and air, by wider sowing or planting, by judicious thinning, and by pruning.

Hence, also, when plants are to be destroyed, this may be effectually done by cutting off their incipient leaves as fast as they appear. In this way ferns and other perennial weeds in pastures may be more easily destroyed than by any other mode; and the same may be said of weeds growing up from the bottoms of ponds.

As a proof that the use of leaves was not understood by practical men, and even by the officers of the Highland and Agricultural Society of Scotland, so lately as 1836, we may refer to the *Transactions* of that body; in which we find the Society giving a premium for an essay on the destruction of ferns in pastures, to a candidate who recommends as the best mode the irrigation of these pastures. The irrigation of pastures on which ferns abound may be considered impracticable in ninety-nine cases out of a hundred.

2. Growth and maturation in plants are two separate processes, and when either is the main object of culture, the other should be prevented or checked; thus when seeds or fruits are maturing, the elongation of shoots and the production of leaves should be checked, by pinching them off as fast as they appear. Hence the use of topping beans, tobacco, woad, and even potatoes; not to mention vines, gooseberries, raspberries, peaches, and other garden fruit shrubs and trees.

3. By preventing the formation of seeds or fruits, more strength is thrown into the plant generally; and if it is a plant which produces bulbs, tubers, or underground stems, as substitutes for seeds, these will be increased in size. Hence the use of picking off the blossoms of potatoes.

4. Plants imbibe nourishment from the soil, chiefly from the points of the fibres at the extremities of their roots. Hence the practice of banking up hedges, beans, potatoes, and other plants in drills, and of watering, stirring the soil, and laying manure close to the stems of trees and plants, is erroneous in principle and often injurious in effect; by cutting off the fibrils, or, in the case of potatoes, the underground shoots on which the potatoes are formed. In some cases, however, cutting off the extremities of the roots is useful by increasing the number of fibrils, and consequently of the spongioles or mouths by which nourishment is imbibed.

Hence the Berwickshire practice of tabling hedges so much recommended, and so generally followed by Scotch bailiffs, foresters, and hedgers, is for the most part a waste of labour; unless, indeed, the object be to stunt the growth of the hedge, and prevent its roots from robbing the soil of the adjoining fields. The practice of earthing up turnips was once in vogue, but it is now ascertained to be a certain mode of instantly checking the swelling of the turnip, by the pressure of the soil which is thrown up to it by the plough.

5. The properties of the fruit of any plant, for example, the gluten of Leguminosæ or wheat, or the starch of potatoes, or the sugar of the beet-root, are more or less diffused over the entire plant: and hence sugar may be made out of the leaves of the beet, as well as the roots, and starch out of the stems of the potato, as well as out of its tubers; it being understood that the leaves or stems are in a nearly mature state.

6. The progress of the ripening of seeds and fruits in general goes on in a geometrical ratio, and hence the great nicety required to determine the moment when seeds or fruits should be gathered, which period varies according to the purpose to which the seeds or fruits are to be applied. The last change which takes place in the ripening of wheat is an increase of bran or husk, and a relative diminution of farinaceous matter or flour; and hence the immense difference in the produce in flour, between that of the grain of a field of wheat cut down at the proper time, and a field of wheat allowed to be over ripe. Too much importance can hardly be attached to this subject.

7. Running water is found to contain oxygen, potash, carbonic acid gas, and ammonia, all which serving as manures for plants, it follows that irrigation, even in cold climates, is beneficial to grass lands, altogether independently of supplying water as an element of growth, which in cold climates is seldom wanted in that capacity.

8. More importance is now being attached to the ascertaining of the mineral constituents of plants, such as alkalies and alkaline earths, phosphorus, sulphuric acid, silica, &c., than was the case before the appearance of Liebig's *Organic Chemistry*.

9. The permanent fertility of a soil is found to depend more on the inorganic substances which it contains, (for example, on the proportion of alkalies and alkaline earths which it holds in combination with the silicic, phosphoric, sulphuric, and other acids,) than on its organic constituents, such as humus or decaying vegetable matter: for all organic matter in soil, whether that soil be naturally good or bad, is sooner or later exhausted by the growth of plants; and if the supply is not kept up, the soil reverts to its original state, except in so far as it may have been improved mechanically by draining, levelling, shelter, &c.

10. Plants absorb their carbon chiefly in the form of carbonic acid, and not, as was supposed till lately, solely in the form of a solution of humus.

11. Plants derive their carbonic acid principally from the atmosphere in the form of carbonic acid gas; and the chief use of humus or mould in the soil, is to combine with the oxygen of the atmosphere, and thus to supply an atmosphere of carbonic acid to the roots. Hence the inutility, and often dead loss, of burying putrescent manure to such a depth as to exclude it from the air, and the more immediate return made by manure spread on the surface of the ground among the leaves of plants, as in manuring meadow lands, and top-dressing spring crops of corn, or artificial grasses.

12. The process by which carbonic acid is generated by oxygen from humus, depends on the soil being permeable to air and moisture; and hence one of the principal uses of draining and pulverisation.

13. Alkalies are the most important inorganic constituents of soils, and when a soil has been exhausted of them by cropping, no manure that does not contain alkalies will restore their fertility for agricultural plants.

14. The poorest soils are almost invariably those which contain least alkalies and alkaline earths.

15. Animal manures contain a much greater proportion of the inorganic constituents of plants, than vegetable manures; and the most powerful of animal manures are those of carnivorous or omnivorous animals; for example, of the human species.

16. The most valuable part of manure is ammonia, from which plants derive their nitrogen, which, though formed only in small quantities in plants, is yet essential to the ripening of their seeds; and hence the great value of urine.

17. Next to ammonia, the most valuable manure is potash, which in the form of silicate is the principal constituent in the straw of wheat.

18. In consequence of knowing the ingredients which constitute a good soil, all lands the slope of the surface of which is not so great as mechanically to prevent their being readily cultivated, may, by the addition of the ingredients wanting, and by proper culture, be raised to the highest point of production that the climate in which they are situated will admit of.

19. To know what can be effected in the worst soils in any given climate, it is necessary to have a conception of what can be done on the best soils in such a climate. Twelve bolls (48 Winchester bushels) per statute acre is not an uncommon crop in the best soils and situations in the Lothians; and less than 10 bolls (40 bushels) per acre is not considered a full crop. The average produce of wheat in England and Wales, however, is only $2\frac{1}{2}$ bolls, or 26 bushels, per acre! It is believed by most scientific agriculturists that every soil and situation in Britain, capable of growing wheat at all, is capable of growing from 8 to 10 bolls or sacks (32 to 40 bushels) per acre, if properly cultivated.

20. Next to animal manures, the most important ingredient that can be added to soils is the ash of plants, because it contains all their saline constituents.

21. Saline manures not only supply food, but, acting as stimulants, enable plants to derive more food from the soil and the atmosphere than they otherwise would do. (*Chatterly in Phil. Mag.* 1843.)

22. Plants containing the smallest quantity of alkaline salts flourish in the greatest variety of soils, and the contrary.

23. The office of food is two-fold: to supply the body with nutriment or flesh, and to supply heat and fat.

24. Only those substances can supply flesh which contain nitrogen; and starch, sugar, gum, and other substances which contain carbon, oxygen, and hydrogen, without nitrogen, only supply heat and fat.

Hence neither pigs nor human beings who live chiefly on potatoes can derive flesh from that kind of food, without the addition of milk, or some other animal matter, or of corn, pulse, or meal of some kind which contains gluten. Hence the Irishman's cow is as essential to his existence as his potato ground.

25. Hence a knowledge of the chemical constituents of plants is useful, not only in

ascertaining the manures proper for being applied to them, but also for knowing their application to the feeding or fattening of animals.

Hence, also, no system of agriculture or horticulture can be considered complete which does not give an analysis of the chemical constituents, not only of the plants of cultivation, but of the weeds of the locality. In a word, the chemical constituents of every individual plant are just as essential to be known as its physiology and systematic character; and indeed a great deal more so. A century hence, or in less time, it will be wondered by scientific cultivators how the present generation could go on without this knowledge.

26. Warmth, to a certain extent, is equivalent to food; and hence the great benefit derived from sheltering cattle during winter.

27. Exercise is for the most part a waste of food, and hence the advantage of stall-feeding cattle, and confining pigs and poultry in a limited space; it does not follow from this, however, that confinement should be carried so far as to render the flesh of the animals unwholesome.

28. In the case of milch cows, rich pastures, or other food abounding in carbon, produce the greatest proportion of butter; while poor pastures, by requiring the cow to take more exercise, increase the proportion of the caseous part of the milk.

29. The various new manures which have been introduced are either of organic or inorganic origin. The action of inorganic manures, such as nitrate of soda, common salt, &c., is not uniform, and in some cases is not perceptible; but the action of organic manures, such as guano, poudrette, rape or oil-cake, and vegetable alkalies, such as potash, is certain, and always beneficial if not applied in too great doses.

30. All clays contain potash, and also all soils produced from rocks containing felspar, zeolite, albite, and mica; and hence one cause of the value of basaltic and granitic soils.

31. The application of burnt lime to clay, independently of other effects which it may produce, liberates potash.

32. The action of burnt clay (which generally contains oxide of iron) to soils, independently of its mechanical properties, is as an absorbent of ammonia from the atmosphere.

33. The addition of clay to sandy soils containing calcareous matter, increases the quantity of potash which they contain; but if the sand contains no calcareous matter, it merely improves their mechanical texture.

34. The ammonia of liquid or other manures may be fixed by gypsum or sulphuric acid; or, in default of these it, may be prevented from evaporating by mixing with soil or diluting with water. In general the most convenient and economic mode for the British agriculturist is to mix it with farm-yard manure, or, what is better in our opinion, plenty of surface soil.

35. The chief practical advantages which have as yet resulted from the recent discoveries in chemistry, as applied to agriculture, are, the employment of saline manures, and the recognition of their importance, the mixing of azotised (nitrogenised) with unazotised (unnitrogenised) food in feeding and fattening cattle, and the procuring greater warmth for the domestic animals of the farm.

36. The most useful practices which have obtained extended diffusion within the last ten years are, the frequent drain system, long practised in Essex and Suffolk, but recently brought conspicuously into notice by Mr. Smith of Deanston, the use of draining-tiles instead of stones, the use of the subsoil plough, and of the cultivator as a substitute for the plough in various cases, the greater eagerness to procure improved implements, machines, and buildings generally, the mixture of soils, the greater value set on urine and liquid manure generally, the use of single-horse carts, the selection of improved varieties both of animals and plants, and the employment of land agents conversant with agriculture, instead of lawyers or others who have little or no agricultural knowledge.

The details which have led to the above summary will be found in Liebig's *Organic Chemistry*, and *Animal Chemistry*; Johnston's *Agricultural Chemistry*; Trimmer's *Practical Chemistry for Farmers and Landowners*; Solly's *Rural Chemistry*; Dr. Playfair's Lectures on rearing and feeding Cattle, published in the *Journal of the Royal Agricultural Society*, vol. iv.; Donaldson's *Manures, Agricultural Grasses, and General Management of Landed Property*, &c. The greater part of this Supplement consists of extracts from these works; and from the *Quarterly Journal of Agriculture*, the *British Farmer's Magazine*, the *Gardener's Chronicle*, and the *Gardener's Magazine*.

SUPPLEMENT

TO THE

ENCYCLOPÆDIA OF AGRICULTURE.

PART I.

AGRICULTURE CONSIDERED AS TO ITS ORIGIN, PROGRESS, AND PRESENT STATE, ETC. (p. 4.)

ITALY.

7981. — 274. *An oil*, not fit for the table, but useful for burning and other purposes, has been obtained by expression from the fruit (keys) of the *Negundo fraxinifolia*. The experiment is of some importance with reference to Britain, as it shows that in all probability an oil may be obtained from the keys of the common sycamore, *Acer Pseudo-Platanus*; and also from the common maple, *Acer campêtre*. See the details respecting the oil obtained from the negundo in *Gard. Mag.*, 1842, p. 40.

7982. — 288. *The olive*, we are informed by Mauetti, is propagated by cuttings, by seedlings, and by grafting. By cuttings is the most valuable mode when the soil is good, as the plants come soonest into a bearing state. Where the soil is poor, and especially if it be rocky, seedlings are to be preferred, because they send down their tap-roots into the crevices of rocks, and thus derive nourishment and support, where plants raised from cuttings would not live. In Tuscany, the olive is very generally raised from seed, and in many situations it is grafted. In Lombardy, on the Larian Hills, trees raised from cuttings are always used, and this is the reason Mauetti alleges why these trees have their trunks perpendicular to the sides of the hill, instead of perpendicular to the horizon. Some interesting discussion on this very singular appearance will be found in *Gard. Mag.*, vol. viii. p. 68. to 70.

7983. — 289. *The cause of malaria*, in this and other pestilential districts of Italy, has generally been supposed to be the decomposition of vegetable matter on a moist surface. This, however, is to confound the malaria with the marsh fever. The former is now thought to proceed from a very different cause, and to be analogous to what in England is called the hay fever. It is found that, while the corn or hay crop is in a growing state in the pestilential districts, they are as healthy as any part of Italy; but that the moment the crop is cut down, or withers on the ground, the malaria commences, and continues through the autumn and winter, till vegetation becomes vigorous in the following spring. The neighbourhood of Rome, where malaria is so prevalent, "is very billy, dry, and entirely without vegetation. For days together, one sees nothing but desolate dried-up cornfields without trees, bushes, or wood of any description. In early times, Rome was surrounded by extensive sacred woods, which were not suffered to be destroyed. At that period malaria was unknown, though intermittent fevers were well known in the Pontine marshes." (*Jameson's Journ.*, vol. xvii. p. 167.) In several districts in England, the country people are liable to attacks of fever immediately after the removal of the hay crop, some individuals much more so than others. This may be considered as a species of malaria of a comparatively mild description. See on the agriculture of Italy generally, an extract from the agricultural part of the *Atti della Terza Riunione degli Scienziati Italiani*, Florence, 1842, &c., in the *Gardener's Chronicle* for 1842. "No kind of potatoes has hitherto succeeded in Tuscany, owing to the great drought and heat, which destroy the herbage in the month of August. In mountainous situations they succeed better; but they are for the most part grown only in gardens, where they can be constantly watered. The sweet potato, *Convolvulus Batatas*, succeeds much better, as it naturally can stand a greater degree of heat, while its copious herbage covers the ground, retains moisture, and affords a superior fodder for cattle." (*G. C.*, 1842, p. 679.)

FRANCE.

7984. — 380. *The backwardness of agriculture in France* "is mainly attributable to the very partial spread of education in the rural districts, there being out of 40,000 communes, according to M. Dupin, 15,000 destitute of teachers; and out of 25,000,000 inhabitants who have reached a teachable age, 10,000,000 only are able to read. Now as the small independent proprietors of land amount to 4,000,000, and their families to 12,000,000 or 14,000,000 more, it is obvious that this state of ignorance must, under such circumstances, be attended with far more prejudicial effects upon production than if it existed in England, where the labourers are under the orders of about 32,000 large proprietors, and the success of cultivation consequently does not so mainly depend upon the general diffusion of knowledge. It is gratifying to find, however, that the large proprietors in France are universally desirous for the instruction of the rest, and that societies, rural schools, and model farms have been established under very favourable auspices." (*For. Quart. Rev.* 1829.) A national system of public instruction was established in 1832, and the various details will be found in the *Bulletin de la Société pour l'Instruction Élémentaire*, for that year. An account of the present state of French agriculture, and of the state establishments in that country, such as sheep farms, model farms, veterinary schools, haras or studs, will be found in the *Journal of the Agricultural Society of England*, vol. i. for 1839, p. 262.; and the statistics of French agriculture is given in the same work, vol. i. p. 411.

7985. — 381. *Present state of French agriculture*. In *L'Agronome*, a monthly agricultural journal published in France, at the low price of five francs a year, it is stated in the first number, published in January, 1833, that in France "the colonies afford no longer the means of making a fortune; the convents do not provide a remedy for the want of foresight of parents; the system of peace, which is every day procuring more advocates among the most highly civilised of the people, no longer offers a brilliant

prospect in the profession of arms; commerce and manufacture suit only particular characters; the sciences and the professions only minds privileged by nature; while agriculture alone offers unlimited scope for employment and for improvement." After enlarging on this subject, the writer goes on to state, that the business of a farmer must no longer be that of men who are not fit for any thing else; but it must be adopted by men of education, and pursued assiduously and systematically. It appears, from this and other French publications, that extraordinary exertions are making in France for the territorial improvement of that country. Among other points to which the attention of the cultivator is directed, is the necessity of feeding his men well, no less than his horses. As a proof of the advantages of doing so, it is stated that when Messrs. Manby and Wilson, from England, established their iron works at Charenton, the French workmen were not able to support labour for the same number of hours as the English did, till they adopted, like them, the practice of eating butcher's meat. Exactly the same thing has been proved respecting the Irish labourers, as compared with the English, and British soldiers, as compared with those of other nations.

7986. *Agricultural Societies in France.* This, and some of the following paragraphs are taken from a very interesting article, understood to be by Professor Macculloch, which appeared in the *Foreign Quarterly Review*, just after the historical part of our 2d edition of this Encyclopædia was printed. "The Agricultural Society of the Seine and Oise, which comprises many extensive landed proprietors, bestows annually medals and prizes on the small cultivators who turn their hereditary estates to the most profit, and upon the hired labourers and servants employed in large farms, who perform their work with the greatest intelligence and fidelity. A model-farm has been lately established at Renville, in the Valley of the Meurthe, about six leagues from Nancy, by M. de Dombasle, a skilful practical agriculturist. It comprises clay, sand, and gravelly soil; and the proper modes of culture are applied to each. By the improvements in ploughs and instruments of husbandry, five horses and nine oxen now accomplish at Renville more work than thirty-five beasts of burthen used to do on the same ground. With the aid of the Scotch threshing-machine, M. de Dombasle beats out, with three horses, three hectolitres and a half (upwards of an imperial quarter) of wheat, and other grain in proportion. Potatoes are cultivated with attention, and a distillery has been established for extracting their spirit. M. de Dombasle has proved what will, we think, excite some surprise, that land of a middling quality, planted with potatoes for fattening beasts, will be more productive than the richest meadow. No stronger encomium can be made on the skill of M. de Dombasle, than the fact that he has more than doubled the produce of the land: the average annual return of Renville being 59 francs per hectare (of 2½ acres), while that of the rest of the department of the Meurthe is but 2½ francs per hectare. At Moucey, in the department of the Moselle, the model-farm of M. Bouchotte is famous for its breed of horses." (*For. Quart. Rev.*)

7987. "The *Agricultural Society of Strasburg* in 1828 commenced an experimental plantation of fruit and forest trees in Alsace; a want observable not merely in that department, but throughout the whole country, except, perhaps, Normandy and parts of Brittany. In Franche-Comté, and the department of Doubs, the government has taken the breeding of cattle under its peculiar care, and established annual exhibitions and prizes. In these parts, as also in Montbéliard, the useless practice of feeding off the land is beginning to be discontinued, it being ascertained that a hectare of inclosed ground produces one third more if not subjected to this ceremony. The arrousisement of Montbéliard has abandoned the system of fallows in use in the rest of the department, and cultivates with success both flax and the turnip. In Franche-Comté the very beggars are becoming industrious; they go about collecting manure till they have accumulated a certain quantity, when they take it to a proprietor, who allows them in return to plant on his soil, and receive the crop of a proportionate number of potatoes. In Picardy, the increase of the sheep-flocks, and the improved system of manuring, have added to the fertility of the soil. At Nouvion, in the department of the Aisne, the farms have been ornamented by hedges and plantations, in imitation of the adjoining country of Hainault. It is here that the making of sabots, and wooden utensils called bois-jolis, is chiefly carried on; the supply sent to Paris annually is valued at 17,000. At Origny, in the neighbourhood of Vervins, the children of the husbandmen are employed in fan-making, baskets, &c. of willow, to the value of 40,000. per annum. In Champagne, the example of M. Richardot, a small proprietor, has given an impulse to plating, and to a systematic irrigation of the land." (*Ibid.*)

7988. — 390 & 414. "The *culture of the vine* is a department of their husbandry of which the French have, perhaps, a right to boast more than any other people. The same grape, when tried in countries under the same latitude as the south of France, has never been brought to an equal degree of perfection. The plantations of vines have been and are subject to severe discouragements, but have, nevertheless, increased very considerably over their extent in 1789. In that year their surface was estimated at 1,200,000 hectares of land; in 1808, it amounted to 1,600,000; and in 1824, it covered 1,728,000 hectares. In 1828, the vines occupied about 2,000,000 cultivators, and their annual produce was computed at 40,000,000 hectolitres; the value of which, at fifteen francs per hectolitre, is 600,000,000 francs, or about 24,000,000 sterling English money." (*Ibid.*)

7989. — 391. *The olive climate.* Strabo (lib. iv.) says, that the line of the Cevennes, in Gallia Narbonensis, was the northern limit, beyond which the cold prevented the growth of the olive. The limit is still in the same position. (*Jameson's Jour.*, April, 1834, p. 233.)

7990. — 398 & 399. *The breed of cattle and sheep in France.* "with the exception of parts of French Flanders, Normandy, and Alsace, is yet very degenerate. But their improvement, like that of mankind, depends upon their rearing; and, if the example of the Roville and other studs be followed, there seems no reason to doubt that the French horses may one day equal those of England or Spain. The company lately formed for recovering the 4,000,000 hectares of marsh land now uncultivated, and converting them into pasture, will greatly further the amelioration of the cattle, as well as the augmentation of their numbers. 2,500,000 horses, 7,000,000 horned cattle, and 42,000,000 sheep and goats, are certainly not a large stock for a country covering 53,500,000 hectares of land. The most experienced of the agriculturists have shown that the fleeces may be brought to almost any desired degree of perfection. When the merinos of Spain first appeared in France, the partisans of the coarse mattress-wool were continually alleging that Spanish sheep would never thrive in the French climate; their success has, however, been complete. The celebrated M. Ternaux (deceased in 1832) imported wools of what are called the electoral race, and placed the goats of Thibet in his park of St. Ouen, near Paris. The rugged declivities of the Jura have been adorned with the magnificent naz breed of MM. Girod and Perrault, and their rams are now attesting in New Holland the march of science in the management of flocks in France." (*For. Quart. Rev.*)

7991. — 403. "The *French pigs*, although they have excited many factitious observations from travellers, and have not infrequently been compared to greyhounds, may be fattened, we are assured, at a small expense; and the method of doing this is now beginning to be better understood. The Chinese and English breeds are also getting into use for crossing. The fact that 4,000,000 pigs are killed yearly in France, shows of how great importance they are to the small agriculturist." (*Ibid.*)

7992. — 407. *The most extensive of the branches of French agriculture, as connected with the manufactures,* "are the culture of beet-root for sugar; of oleaginous plants, particularly at Lille and Dijon; and of the mulberry for silk-worms, in Languedoc and the southern provinces. It has been the habit in England to consider the former of these as merely a fanciful amusement of national vanity; but it appears by the amount of its consumption (between 7,000,000 and 8,000,000 lbs. a year), that at all events it is become an article of some practical magnitude." (*Ibid.*) The process of obtaining sugar from the beet-root has been given in all its details, with a view to adopting the practice in Britain, in the *Brit. Farm. Mag.*, vols. x. & xi. for 1836 & 1837.

HOLLAND.

7993. — 426. *The greatest part of the land in Holland, it is observed by Mr. Alton, of Hamilton, being under the level of the sea, and of the great rivers and canals which intersect that country, and consequently, being unfit for arable culture, is generally kept in meadow.* "Part of the grass produced is cut for hay, to supply the stock in winter and spring, and the rest of it is eaten off by a few sheep and horses, but chiefly by cows. Some of the cows are fattened for the shambles, but most of them are kept as dairy stock. In those parts where the surface of the ground is above the level of the water, it is cropped with wheat, rye, rape, beans, oats, flax, hemp, and potatoes; and even where the soil is a little lower than the level of the sea and rivers, part of it is dug up in some places, and cropped with potatoes, hemp, &c. But the greatest part of North and South Holland is so often overflowed with water, as to render it improper to raise winter wheat crops to a great extent." (*Quart. Jour. of Agr.*, vol. iv. p. 328.) — *The soil "being generally rich, the herbage is luxuriant; but, owing to the moist condition of the land, which is frequently inundated in winter, the herbage it produces is rather coarse, and many moist plants arise from the richer natural grasses."* (*Ibid.*)

7994. *There are few large estates in Holland, and "but few large farms. The land being remarkably level, it is generally divided and subdivided by ditches, or narrow canals, that receive the surface water, and serve the purposes of a fence."* (*Ibid.*)

7995. — 428. *The farm-houses in Holland "are of dimensions suited to the extent of the land in the farm, and they are more or less elegant or comfortable, as the wealth or taste of the occupant may dictate; but they very much resemble each other. They are generally of only one story in height, but placed on so broad a base, as to afford accommodation not only for the boor, or farmer, and his family, but also their live stock, dairy, cheese-house, threshing-floor, the whole crop, and fodder for cattle. In short, the whole farmstead is frequently comprehended under one roof. Besides a kitchen, in which the family sit and eat, as well as cook their food, and from which they can see their cattle during winter and spring, these houses contain at least one elegant and well-furnished room, with a bed-room or two, into which they seldom enter, except on days of festivity. Their kitchens are much more tastefully fitted up than those of the farm-houses in Scotland. They have a stove of an elegant figure, which is kept wonderfully clean. The wall near to the fire-place is covered with plates of flowered earthenware; and the mantel-piece is richly, though rather heavily, fitted up. There are some concealed beds and closets in this part of the building; while a pump-well, and a horse-gio for washing and churning the butter, are both at hand, near the centre of the building. The floor of the kitchen generally consists of marble; the rest of the building is of brick. The gincourse is laid with sand, and is covered with boards when the horse is not in yoke. The whole building is roofed with tiles, and the roof rises in a somewhat pyramidal form. The walls are generally built of brick, but sometimes of mud or boards; but the roof is supported on frames of wood, round which the walls form only a covering. There is no urine tank as in Belgium. Indeed, little attention seems to be paid to manure in Holland, probably on account of the soil being naturally rich."* (*Ibid.*)

7996. *The cow byre is "paved with hard bricks, or clinkers, as they are termed, set on edge; and the stakes to which the cows are bound are made to be removed in summer, when the cattle are turned out to pasture. A passage before the cow's head is convenient for giving them their meat, and a trough of clean water is placed before the cows, from which they can drink at pleasure. The water is let off once a day by means of a plug, and a new supply from the well pumped into the trough. A passage behind the cows, serves to remove the dung."* (*Ibid.*, p. 330.)

7997. *Dutch cows. "The Vriesland and Gröningen cows are the largest and most esteemed races in Holland. They are short-necked, broad and deep-chested, deep bodied, and broad-backed, with well-made limbs, fine small horns, and stand well upon their feet. The greatest number of these cows are either black or white, or dark brown and white."* (*Highland Soc. Trans.*, vol. x. p. 169.)

7998. *The general practice in Holland is, "that the cow should calve in her second year. The bull is employed when it is two years old, and is fattened and sold to the butcher when four or five years old, and the cow at seven or eight. Some cows are, however, kept for milking till the tenth year."* (*Ibid.*)

7999. *The most improved method of treating the calf in Holland. "It is immediately after its birth taken from the cow, put in a separate place, and laid on dry straw. A little salt is given, and the tongue and mouth are rubbed with it. It is also rubbed clean with straw. After the lapse of six or eight hours, the first heating of the mother cow, diluted with one third water, is given to the calf to drink, and this treatment is continued for some days, the liquid being given thrice a day. Thereafter, during two or three weeks, they give the calf the milk as it comes from the cow, diluted with one fourth water, in which now and then a small handful of salt is put; then buttermilk is gradually given, and it is supplied with hay; the age of ten weeks it is brought out into the meadow, where it is also supplied with skimmed milk, buttermilk, or whey. In this way each farmer raises the proper number of heifer calves to fill up vacancies; but calves fattened for sale have milk from the cow three times a day. For some days after calving the cow is milked thrice a day, after which they return to the usual practice of milking twice a day."* (*Ibid.*)

8000. *Treatment of milch cows in Holland. "The cows are turned out to grass generally by the end of March, or the beginning of April. They are, when first sent out, furnished with a very thick cloth of tow, covering the back and sides, from the shoulders to the tail, to prevent diseases from cold. They remain out, night and day, about thirty weeks. In the winter months the general food is hay, and most farmers give their cows nothing else; distillery grains are sometimes given, when they can be obtained. At the great establishment of Baron Van Palink, near Leyden, boiled beans, with rape cake, spread over the hay, were given at night, and ground linseed cake in the morning, which, it was stated, enabled the cow to give more and better milk than hay alone. Raw potatoes and dry linseed cake are also sometimes given, and most farmers give the buttermilk, either diluted with water or not, to the cows, as well as to the calves and pigs. Mangold-wurtzel is also given, but turnips never."* (*Ibid.*)

8001. *The byres or cow-houses in Holland "are generally lofty, airy, paved with large square bricks [Aiton says "clinkers," see § 7996.], and kept perfectly clean. The roof is generally about ten feet high. There are no racks or mangers. The cows stand in two rows, generally facing the centre, and sometimes the sides of the byre, along which is a brick pavement slightly elevated in the middle. On the edges next the cows, and on a level with them, is a trough, perfectly clean, into which the meat or drink is put, and the hay laid down. Each cow has about five feet of space, and is tied to a railing of three small posts in front, which separate them from one another. There is a little straw used for bedding; on the place where the cows stand, there is a hollow part at the fore feet, into which are now and then put dry horse dung and straw; at the hind feet, generally nothing is laid but a little dry sand. From the narrowness of the space divided into stalls, the back always projects so far as to cause the dung droppings to fall into a gutter about eighteen inches deep, and eighteen inches wide, which is regularly and carefully swept and cleaned, so that there is very little trouble in clearing away and collecting the manure. The cows are always kept quite clean; and, to prevent the tail occasioning filth, the lower end is always tied up by a string attached to the ceiling."* (*Ibid.*)

8002. *Process of milking in Holland. "The cows are always milked by the men, and the butter and cheese made by the women. One man is considered necessary for every ten cows. At Vier Leide, the well-managed dairy establishment of Baron Van Palink, there are ninety milch cows, 1'er men, and a Boerinn (or female farmer), the maker of the butter and cheese, who has a female assistant. At Klinkenburgh, near Sasenbeim, there are forty cows; the farmer and three grown sons do all the milking, and his wife and one female servant make all the butter and cheese. At Schoote, near Haarlem, there are*

twenty cows; the father and son milk, and the wife and a female servant make the butter and cheese." (*Highland Soc. Trans.*, vol. x.)

8003. *Butter*. "There are three distinct kinds of butter manufactured in Holland; the butter made from the cream, when the cow is at grass in the summer, called grass butter; the butter from the whey of the new milk cheese, called whey butter; and the butter made in winter, when the cows are in the cow-houses, called hay butter." (*Ibid.*)

8004. *Grass butter*. "The cows being carefully milked to the last drop, the copper pitchers lined with brass, or pitchers entirely of brass, which contain the milk, are put into an oblong water-tight pit, which they call a *roelbak*, built of brick or stone, about six feet in length, three feet in breadth, and two feet in depth, into which cold water had been previously pumped; there being generally a pump at one end of the pit. In this pit or cooler, the pitchers stand two hours, this milk being frequently stirred. The cooling process is of great advantage in causing the cream to separate rapidly and abundantly from the milk. After this, the milk being run through horse-hair sieves or strainers, is put into the flat milk-dishes, which are of earthenware, copper, or wood, as will be afterwards described; it remains in a cool dairy or cellar for twenty-four hours. It is then skimmed, and the cream is collected in a tub or barrel. When soured, if there is a sufficient quantity from the number of cows, they churn every twenty-four hours, the churn being half filled with the soured cream. A little boiled warm water is added in winter, to give the whole the proper degree of heat; and in very warm weather the cream is first cooled in the *roelbak* or cooler. In many small farm-houses, or when the cows give little milk, the milk is not skimmed; but the whole, when soured, is put into the churn. The butter, immediately after being taken out, is put into a shallow tub called a *vloot*, and carefully washed with pure cold water. It is then worked with a slight sprinkling of small salt, whether for immediate use, or for the barrel; there being none made entirely without salt, as in Scotland. When the cows have been only eight or ten days out, the difference between grass and hay butter is slightly perceptible; but the grass butter, after the cows have been three weeks at grass, is delicious. This new butter is highly esteemed in Holland; it is made in fanciful shapes of lambs, pyramids, &c., or stuck with the flowers of the polyanthus, &c., and sells very high. If intended for barreling, the butter is worked up twice or thrice a day with soft fine salt, for three days, in a flat tub, there being about two pounds of this salt allowed for fourteen pounds of butter; the butter is then hard packed in thin layers into the casks, which casks are previously carefully seasoned and cleaned. These casks are always of oak, well smoothed inside; and, before being used, they are allowed to stand three or four days, filled with sour whey, and are then carefully washed out and dried. Each cow, after being some time at grass, yields about one Dutch lb. (17½ oz.) of butter per day." (*Ibid.*)

8005. *Hay butter* "undergoes the same process as grass butter; being, of course, the butter made in winter, when the cows stand in the cow-house. But, although inferior in flavour and colour, it has none of the disagreeable taste which the turnip imparts to the winter butter of Britain." (*Ibid.*)

8006. *Whey butter* "is made from the whey of the new milk cheese. The whey, being collected from the curd and the pressed cheese, is allowed to stand three days or a week, according to the quantity; the cream is either skimmed off and churned, or the whey itself is put into the churn, and the butter is formed in about six hours. In winter the butter obtained by the process is about one lb. per cow per week; and in summer about one lb. and a half per cow per week." (*Ibid.*)

8007. *Cheese*. There are four kinds of staple cheese made in Holland: the round or bullet cheeses, called Edam (from their having been first principally made in that neighbourhood); and Stokker (so called from the village of Stolkwijk), which are called in Britain, Gouda, and are fat and broader and larger than the Edam, both kinds being made of unskimmed milk; Leidsche or Leyden (being so called from this kind of cheese being principally made near Leyden), which is made of milk once skimmed; and Graaawshe, which is made in Vriesland, of milk twice skimmed. Both the latter kinds are called Kanter cheese in Britain, and are larger and flatter than the two first named." (*Ibid.*)

8008. *Edam cheese*. "The process of manufacture of the Edam cheese is as follows:—The rennet is put into the milk as soon as it is taken from the cow; when coagulated, the hand, or a wooden bowl, is passed gently two or three times through the curd, which is then allowed to stand a few minutes; the bowl or finger is again passed through it, and it is permitted to stand some minutes longer. The whey is taken off with the bowl, and the curd is put into a wooden form of the proper size and shape of the cheese to be made. This form is cut out of the solid wood by a turner, and has one hole in the bottom. If the cheese is of the small size (about 4 lbs.), it remains in this form about fourteen days. It is turned daily, the upper part, during this time, being kept sprinkled with about two ounces of purified salt of the large crystals. It is then removed into a second box or form of the same size, with four holes in the bottom, and put under a press of about 50 lbs. weight, where it remains from two to three hours, if of the small size; and four to six hours, if of the large size. It is then taken out, put on a dry airy shelf in the cheese apartment, and daily turned for about four weeks, when Edam cheeses are generally fit to be taken to market. Alkmaar, in North Holland, is the great market for Edam cheese. It is not uncommon to see 800 farmers at this market, and 470,000 cheeses for sale on one day." (*Ibid.*)

8009. *Gouda cheese*. "This kind of cheese is also made from the milk, immediately on its being taken from the cow. After gradually taking off the principal part of the whey, a little warm water is put upon the curd, which is left standing for a quarter of an hour. By increasing the heat and quantity of the water, the cheese is made harder and more durable. All the whey and water is then taken off, and the curd is gradually packed hard into a form, cut out by the turner, flatter and broader than the form for the Edam cheese. A wooden cover is placed over it, and the press, with a weight of about eight lbs., put upon it. It is here frequently turned, and remains under the press about twenty-four hours altogether. The cheese is then carried to a cool cellar, and put into a tub containing pickle, the liquid covering the lower half of it. The water for the pickle is boiled, and about three or four handfuls of salt are melted in about thirty imperial pints of water. The cheese is not put in until the water is quite cold. After remaining twenty-four hours, or, at most, two days, in the pickle tub, where it is turned every six hours, the cheese, being first rubbed over with salt, is placed upon a board slightly hollowed, having a small channel in the centre to conduct the whey, which runs off into a tub placed at the one end. This board is called the *zouttank*, and several cheeses are generally placed upon it at a time. About two or three ounces of the large crystallised salt is then placed upon the upper side of the cheese, which is frequently turned: the side uppermost being always sprinkled with salt. It remains on the zouttank about eight or ten days, according to the warmth of the weather; it is then washed with hot water, rubbed dry, and laid upon planks, and turned daily, until perfectly dry and hard. The cheese-house is generally shut during the day, but must be open in the evening, and early in the morning. Each cow at grass in Holland is calculated to give about three or four lbs. of new milk cheese per day." (*Ibid.*)

8010. *Kanter cheese*. "The skimmed milk is poured out of the *stoep*, copper, or wooden milk-dishes, into a tub or tubs, in which it remains to settle half a day. About the fourth part is gently poured over into a copper boiler; which boiler, by the most careful farmers, is oiled with sweet oil, to prevent burning the milk, or giving it a stoged taste. This is heated till the hand can hardly bear the heat, and then taken out and mixed with the other three fourths, the whole being stirred about; the rennet is then put in, and when coagulated, the whey is taken out with a wooden bowl, the curd is hard worked and pressed out with the hands, and then put into a cloth, the four corners being folded on the top, and the whey pressed out. The curd is next put into a broad tub, called a *porteltable*, and hard worked, and trodden upon by the bare feet; for although there has lately been a plan introduced to obviate this disagreeable practice, this is generally the mode used in making common or kanter cheese. The next process is to mix among the curd a shuf handful of soft fine salt to every thirty lbs. of cheese. The curd is then put into a strong circular form (of staves, and hooped, about three inches thick, with holes bored in the bottom), with the

cloth round it. It stands in this form twenty-four hours, the cloth being taken off and wrung dry three or four times a day during these twenty-four hours: this form is placed upon a hand-barrow, or open stand, over a tub, which receives the whey; a cross plank is laid over the lid of the cheese form, and it is frequently pressed by the weight of the body. The cheese is then taken out and put into a cheese-well, or form, equally strong, having a cover called a *voelirt*, and put under a heavy press, the weight being about 360 lbs., where it remains twenty-four hours more. After this process, or when taken out of the press, the cheese is washed, and in some places it is smoothened by rubbing it frequently with sour skimmed beatings preserved for the purpose; it is then rubbed with a reddish-coloured substance, called *kaasverf* or *kaasmeer*, which the apothecaries sell in Holland, for the purpose of giving it a smooth outside, and good colour. The cheese is then put into a cool cheese-house or cellar, and frequently turned, until brought to market. It is into this kind of common or kanter cheese that various spices are put, although few of the spiced cheeses come to this country. This operation takes place when the curd is put into the first form: the curd is put in layers; the first layer has no spices in it, but upon it is sprinkled some cummin seed, and then follow regular layers, with cloves intermingled, until the upper layer is placed which has no spices in it." (*Highland Soc. Trans.*, vol. x.)

8011. *Graawse kaas*, or *inferior kanter cheese*. "This inferior kanter cheese is made of milk twice skimmed, in Vriesland and Groningen; and is prepared in a similar way to Leidsche, or the best common or kanter cheese to which it is much inferior." The Dutch farmers reckon that thirty cows at grass will give from 100 lbs. to 200 lbs. of fine butter, and about 300 lbs. of kanter or common cheese, per week." (*Ibid.*)

8012. *Dairies*, or *milk-houses*. "There is great variety in the arrangements of the milk and cheese-houses; but the most frequent form is this:—Between the dwelling apartments and the cow-house, and of the breadth of the house, is a square apartment for churning and other similar operations; at one corner is the cooler, built of brick, as already described, and generally having a pump at one end, for the purpose of introducing the cold water to cool the milk. This apartment is airy, roomy, and paved with square bricks. Descending a few steps from it, is the milk-house, or rather cellar; it is always three or four steps below the level of the house, paved with brick, and having an arched ceiling, almost always of brick or stone, and two or four windows, according to size. The milk dishes, or pans, which are daily first hand-scrubbed and washed with boiling hot water, and then with cold, are ranged along the floor, (not on shelves), in such a way as each pan may be reached by the dairy-maid. The windows are opened or shut according to the state of the weather, to which particular attention is paid." (*Ibid.*)

8013. *The cheese-houses* are also generally cellars, and adjoining the milk-houses; but in summer the byres are used for the Leidsche or kanter cheese; the floor being kept quite clean. All the windows and doors being open, abundant air is afforded. In winter the windows of the cheese-houses are generally kept shut; and, if any intense frost exists, they put in one of the wooden boxes, containing a pan with burning turf. The cheeses are placed in rows on the wooden shelves." (*Ibid.*)

8014. "The sweet and delicious flavour of the Dutch butter is said to be principally owing to the excellence of the Dutch salt. The butter, though salted, is always well flavoured, and hardly tastes of that acrid quality which the muriate or sulphate of magnesia frequently imparts to butter in this country. This acidity will be found very obvious, when comparing the Dutch salted butter to the best salted butter of Britain. It appears that in the manufacture of salt more time is allowed for evaporation and crystallisation, and that the crystals are nearly an inch square. In Britain the process of evaporation is hurried on by artificial heat, so that the crystallisation is never perfect. This is owing to our excise laws, which it is to be hoped will be removed, or regulated in such a manner as to admit of applying the modern improvements in chemistry in this manufacture." (*Ibid.*, vol. x, p. 184.)

8015. *The great cleanliness everywhere observable in the farmeries of Holland* is "another cause of the general excellence of the dairy produce. This seems to be the result of a well-regulated division of labour. The men attend to milking and feeding the cows, and the women to making the butter and cheese. As to cleanliness, every dwelling-house is a model and a pattern; the inhabitants seem to vie with each other on this point. The cow-house is pure and clean, not a particle of filth being to be seen in it; the cows are as clean as if they were in a dining-room; the milk and cheese-houses, and, in short, every part of the house, are free from dust and dirt of any kind; the manure is placed at a convenient distance from the cow-house, behind the house, and every particle is carefully collected together. The whole apartments, even the byre and bay-house, are generally under one roof; and the cleanly system, and the admirable arrangements, give that comfort and pleasure which are too often wanting in Scotland." (*Ibid.*)

8016. *As an example of a Dutch dairy farmery*, we copy the plan fig. 1139. In this figure "a is the kitchen or living-room of the family, during the greater part of the year; b, a temporary apartment in which the family take their meals during the warmest weather in summer; c, the cow-house, in which the cows are seen from both apartments; d, a large room used for various purposes; e, bed-room; f, shed; g, dairy; h, dairy scullery; i, cooler; k, a place for drying cheese; and l, hay and straw room in the centre of the building." The farmeries in Holland are generally of one story, and thatched with reeds, one immense, lofty roof covering the whole. The highest part of this roof is in the centre, over the hay and straw room. (*Ibid.*) Mr. Aiton of Hamilton, who also visited Holland with a view of studying its dairy husbandry, gives a similar account of the Dutch farm-houses. See § 793.

In the school gardens or fields, in Cousin's work already (§ 79. 81.) referred to.

8019.—873. "The farmers about Bonn," says Williams, "have neither a good plough, nor a good cart, and their hay-fork is like Neptune's trident." (*Williams Travels*, &c.)

8020.—624. *Screens or narrow barns* are used in many parts of Carniola for hanging buck-wheat

upon. The screen is composed of two upright posts, twenty-feet in height. Through holes in the upright posts, horizontal poles are placed, reaching from one upright to the other. On these poles, the buck-wheat and other kinds of fodder are placed. A narrow roof of boards covers the whole, passing from one upright to the other. The sheaves of buck-wheat are also sometimes fixed on an upright post. (*Cadell's Travels*, p. 24.)

8021.—625. *Gourds* are cultivated in considerable quantities in Carniola and Styria: cut in slices, they are given to the hogs and cows. (*Cadell's Travels*, vol. i. p. 25.) In Hungary sugar has been lately made from them.

8022. *The rural economy of Schleswig, Holstein, and Lauenburgh*, has been given at length in the *Journ. A. E.*, vol. i. p. 37., and of the agriculture of Denmark and Sweden by James F. W. Johnston, F. R. S. in the same work, vol. iv. p. 196. et seq.

RUSSIA AND POLAND.

8023.—662. *Roads in Poland*. By far the best specimen of that kind of road usually called macadamised, for want of a more explicative term, is to be found between Warsaw and Kalisz, a distance of thirty-three and a half Polish, or one hundred and fifty-six English miles. Throughout this distance it is uniformly hard, level, and as smooth as a billiard table, quite straight, planted with a double row of trees on each side, and with very tolerable inns at each post station. It is doubtful whether a better road is to be found in England; certainly not on the Continent, except, perhaps, between Milan and Cremons, or even as far as Vicenza. The Warsaw road is perfectly new, and owes its existence to the grand duke Constantine, whose efforts to improve the internal communication of the country in every direction were incessant. One feature of the Polish road in question deserves notice, because it tends to give it the appearance of a carriage-road in a gentleman's park kept in the highest order; namely, the manner in which the sides are dressed all along with green turf, which looks like mossy banks, cut smooth, and perfectly level. This method of flanking a macadamised road that has been cut through hills, or prominent undulations in the ground, offers, besides its neat appearance, a great advantage; for it prevents, in a great measure, the carrying away of the loose earth and denuding of the roots of trees during heavy rains, both which inconveniences, very injurious to the road itself, take place when the sides are not covered with turf. (*Granville's Russia*, p. 580.)

8024. *British Farmers in Poland*. Since the peace of 1814, some Scottish farmers have settled in different parts of Poland, and chiefly in the neighbourhood of Warsaw. The soil and the climate are found much more favourable, both for agriculture and gardening, than might naturally be imagined. Though the winters are more severe than they are at Edinburgh, yet the summers are much warmer, and corn and fruits ripen much sooner and better. The cucumber grows freely, and bears abundantly in the open air during the summer months. The estate or farm of Wilga, on the river of that name, a view of which is given in *fig. 1140.*, consists of 1,800 acres, and was purchased by a near relative of the author in

1140

1832. The buildings consist of a dwelling-house (a), with a detached kitchen (b), a brewery (c), a distillery (d), a machine for raising water to supply both (e), a corn-mill (f), sheds for feeding cattle (g), an ice-house (h), in which ice is kept above ground by means of thick double walls and doors; and large barns, a threshing-machine, coach-house, stabling and all other offices, including a carpenter's shop and house, blacksmith's shop and house, bailiff's house, &c. Besides these there is a small colony of cottages for the common labourers. Behind the house there are a large garden and orchard, with summer-house green-house, &c., the estate having been the property and residence of a Polish nobleman, considered a man of taste. The situation of this property is about thirty miles from Warsaw, in a flat country, and there is good communication between it and that city, both by land and water. The soil is light in most places, but in others it is loamy. About half the surface is covered with wood, chiefly birch, poplar and Scotch pine, which is felled at stated intervals, and is floated down the Wilga and the Vistula to Warsaw, where it is sold as fuel. The culture pursued on the arable land is the convertible system of—1. turnips; 2. corn, chiefly barley and wheat; 3. clover; and 4. oats. The turnips and clover are consumed in the feeding-houses by milk cows, or cattle for the butcher. The corn is either ground-into flour or malted and brewed into beer, or distilled into spirit; for both of which there is an ample market at Warsaw. Butter and cheese are made, for which there is also a great demand. Pigs are fattened, but the Polish towns being chiefly occupied by Jews, and trade of every kind being chiefly in their hands, it is found that pigs cannot be driven to market, and sold there alive as in Britain; but the carcases are salted, or cured as bacon, and sold in that state, to Christian consumers. The fattened cattle are sold by private

contract to Jewish dealers, who dispose of them, either to their brethren in Warsaw, Cracow, and other towns in Poland, where they are killed in the manner peculiar to the Jews; or to Christian butchers either in Poland, Prussia, or Russia. Numbers are sent to Dantzic and other sea-port towns. An unlimited supply of manure may be obtained from Warsaw at present, though it cannot be expected that this will long continue to be the case; but bones are abundant, not only in Warsaw, but all over the country, and the supply of this manure will, probably, for many years, exceed the demand. A crushing-mill has been, or is about to be, added to the corn or flour-mill on the estate. It is also in contemplation to establish a steam-boat between Wilga and Warsaw, which will add greatly to the rapidity of conveyance between the two places. The flour might then be converted into bread, and the cattle, for Christian consumption, slaughtered on the farm; for it is chiefly by manufacturing farm produce, that it can be at all disposed of to advantage in such a country as Poland. The great drawback to farming in Poland, is the want of moral principle in the labourers, who require continual watching both to keep them at work, and from stealing and drinking; but as this has arisen from the harsh treatment to which, as slaves, they have been subject from their masters through many generations (see § 650.), it may be diminished by kindness to the adults, and the education of the children.

8025.—672. *Food of the peasantry in Russia.* Rye bread is the chief support of the peasants in the north of Russia; but, in order to save the rye flour, and to make it last the longer, the inhabitants, when compelled by necessity, mix with it fine ground oatmeal, the meal of buck-wheat, and the husks of the field mustard seed (*Sinapis arvensis*). Brandy is, in general, distilled in Russia from rye meal, with a more or less additional quantity of barley, oatmeal, and barley malt; but very seldom from wheat, or buck-wheat. The Russians also distil brandy from potstoes, juniper berries, and *Sorbus aucuparia*, at all times with an addition of meal and malt. They distil, in Astrachan, a sort of French brandy from damaged wines, prunes, kernels of cherry-stones, and wild almonds (*Amygdalus nana*). Some of the distillers make use of the skin and stalks of pressed grapes, raisins, and the waste in sugar refineries, with which they make good brandy. To the worst and common sorts of brandy belongs the dram of Kamtschatka, of *Heracleum Sphondylium*, and another used by the Kalmucks, made from sour distilled mare's milk, which is spirituous, but rather of a disagreeable flavour. (*Com. Board. Agr.*, vol. i.)

8026. *Agriculture in Livonia.* The country, before reaching Volinia, offers a tolerable specimen of the present state of agriculture in this part of Livonia. Forests, both old and new, in considerable numbers, are met with here and there, succeeded by corn-fields; barren heaths; farm-houses, consisting of one or two wooden buildings, and a yard, in tolerably good condition; small horses, and diminutive horned cattle; no inclosures, except a kind of palisade, marking the divisions of property or protecting the farm-houses from intrusion; and extensive buildings serving as granaries to hold the crops. These are the most prominent agricultural features of the country. The Livonians have the reputation of being good farmers. (*Granville's Russia*, p. 337.)

8027.—673. *Agricultural products of Russia.* The hop is indigenous in the district of Petersburg; a few are also cultivated in gardens, and the crop gathered the end of September. Hemp is sown about the middle of May, and pulled in the beginning of September. Flax is sown in the beginning of June, and pulled in the middle of August. Both these plants are grown only in small quantities for private use. Red clover is sown along with barley and oats, and cut the following year, about the end of June, and the second in September; the plants are frequently destroyed by the early frosts. The farinaceous plants grown in the district of Petersburg are the following:—Some winter wheat upon good soil, sown in the latter end of August and the beginning of September, is reaped about the middle of August. Spring wheat is sown on newly cleared lands in the beginning of May, and reaped about the middle of August. Rye is sown, more extensively than any other grain, on most descriptions of soils, and in the latter end of July and the whole month of August; it is reaped the latter end of July and the beginning and middle of August. Spring rye is sown upon high and sandy ground in the beginning of May, and reaped the latter end of August. Barley is sown in the beginning and middle of May, and reaped about the middle of August. Oats are sown the latter end of April and beginning of May, and reaped from the middle of August to the beginning of September. Buck-wheat is sown upon high sandy lands in the month of May, and reaped in the beginning and middle of September. No oleaginous plants are cultivated, except the sesamum and the white mustard in a few gardens. The following are the leguminous plants of the same district:—White and gray peas are sown in the beginning of May, gathered green the latter end of July, and ripe the latter end of August. Beans are sown in the beginning of May, and reaped in the middle of August: French beans are sown in gardens, but they seldom do much good. (*Com. Board Agr.*, vol. i.)

SWEDEN.

8028.—688. *General appearance of the country in Sweden.* A bishop of Bergen is said to have given the name of Northern Italy to some districts of Norway and Sweden. The pine forests are very beautiful, especially when the pale green of the young shoots contrasts with the older foliage. From the appearance of some of these trees on lofty cliffs, it is easy to perceive how in alpine countries the descent of the roots of the pine and the mountain ash, through fissures, contribute to the splitting of the rocks. The Swedish mistletoes are raised on plinths to keep them above the snow. The roads, winding through extensive pine forests, are picturesque in the extreme. (*Brooke's Travels in Sweden*.)

8029.—693. *The cottages of the peasants in Norway have double fronts.* This additional protection renders them warm and secure against the blasts of winter. The manner of building these cottages is the same as in Sweden: and on the roof of each, a luxuriant crop of grass was generally growing, though some were loaded with a thick coating of pebbles, and above them were two or three large fragments of rock, to secure the whole from being blown away by the winter storms. (*Brooke's Travels*, p. 105.)

8030.—704. *Stakes for drying newly-cut corn are also used in Sweden.* They are generally made of young pine trees, eight feet long, about one inch and a half in diameter at the top, and four inches at the bottom. Both ends are pointed, and the thick end is let into the soil by the aid of an iron crowbar. The first sheaf is put on the stake with the root ends of the corn downwards, and the other sheaves, to the number of fifteen or sixteen, are placed in an inclining position. (*Quart. Journ. Agr.*, vol. iii. p. 638., and Professor Johnston in *Journ. A. S. E.*, vol. iv. p. 196.)

BRITAIN.

8031.—800. *The progress of agriculture in Britain, more especially in England, since the second edition of this Encyclopedia was published in 1831, has been singularly rapid; though it must be acknowledged that it has hitherto been more in the direction of discussion than of actual improved practices; the introduction of the latter require time.* The first great stimulus to agricultural discussion in England appears to have been given by the *Report to the Agricultural Committee* by Mr. Shaw Lefevre, which was printed in 1836. In this Report the frequent drain system, introduced in Scotland by Mr. Smith, of Deanston (§ 8299.), is mentioned as capable of reclaiming every acre of cold wet land in the country, and raising it in a short time to a par with the very best soils. According to Mr. Lefevre's idea, if this system were applied, whether with or without a corn law, the produce of Britain would become so abundant, that there would be no danger of prices rising for half a century to come. Mr. Lefevre counsels the British agriculturist to accede to a total repeal of the corn laws, and to stand on the field of free competition with all the world; trusting to his improved skill and improved modes, to his capital, and to the aptitude of the soils of his country for improvement, to enable him to do so.

In two years after the publication of this report, the Royal Agricultural Society of England was formed; partly from the increasing interest taken in agriculture by the landed proprietors, but principally from their having observed and remarked on the great good effected by the Highland and Agricultural Society of Scotland. The idea of the Agricultural Society of England was first suggested by Lord Spencer at the dinner after the show of the Smithfield Club in the beginning of 1839, and a meeting was held for that purpose on the 9th of May following, when the foundation of the Society was laid. Its progress since has been so extraordinary, that it now reckons upwards of 7,000 members, including all the great landed proprietors of England. The society holds annual meetings in different parts of England, as the Highland Society does in Scotland; and its journal, which is published quarterly, contains a great number of valuable communications from scientific men and eminent landed proprietors. The desire for scientific knowledge, mainly brought about by the British Association for the advancement of Science, has called forth several eminent chemists who have directed their attention to agriculture; and in this the British Association have taken a prominent part. It is to this Association that we owe the volumes of Liebig on Vegetable and Animal Chemistry, which have thrown so much new light on the subjects of which they treat. The establishment of a Professorship of Agriculture in Oxford, and one also in the University of Durham, have seconded the efforts of the Agricultural Society; and much good continues to be effected by the model farms on the estate of Lord Ducie, in Gloucestershire, and by the lectures of Professor Henslow, and his exertions in various ways among the farmers of Suffolk. In a direct and practical view, perhaps the greatest service to agriculture, next to the frequent drain system, has been the introduction of new substances as manures, or the more frequent use of such as were previously little known. Among these may be mentioned bones, guano, gas liquor, and a variety of saline substances, all of which, under particular circumstances, have been found to add materially to the produce of the soil. The Agricultural Society of England, like the sister society in Scotland, have wisely abstained from experimenting themselves, but have offered ample prizes for experiments made by others, and Professor Henslow has drawn up a scheme (detailed in his *Letters to the Farmers of Suffolk*, 1843, 8vo.) by which the same experiment may be repeated in any number of places all over the country. Excellent works on the Chemistry of Agriculture have been published by Professor Johnston, of Durham, Mr. Solly, the Professor of Chemistry to the Horticultural Society; and important essays or treatises on some departments of the subject with reference to Agriculture, by Professor Daubeny, Dr. Madden, Dr. Lyon Playfair, Mr. Trimmer, Mr. Johnson, Mr. Lyburn, and others; and the stimulus given by these works and the societies mentioned, has given such an impetus to improvement, that there can be no doubt of its rapid progress for a long period to come.

8032. *In Scotland*, though the agriculture is far in advance of that of England, yet advantage has been taken of the new manures; and the point in which the country was most deficient, the breeding of domestic animals, has received general attention, and the consequence has been great improvement in this department.

8033. *Ireland* has established its Royal Agricultural Society, which continues the exertions begun in 1831. No one has contributed more to the improvement of the agriculture of small farms in Ireland than Mr. Blacker, of Armagh, whose essays on the subject ought to be in the hands of every proprietor in Ireland. (See Catalogue, and also *Q. J. A.*, vol. v. p. 386.)

8034.—801. *In the literature of Agriculture*, as it may be supposed, considerable progress has been made since 1831. The *Mark Lane Express* is the most popular farmer's newspaper in England; but we have also the *New Farmer's Journal*. There is no paper of the kind in Scotland; but in Ireland there is the *Farmer's Gazette*, and *Journal of Practical Horticulture*, a very excellent weekly paper. In England we have the *Farmer's Magazine*, the papers in which generally appear first in the *Mark Lane Express*; the *British Farmer's Magazine*, and the *Journal of the Agricultural Society of England*. The only agricultural periodical in Scotland is the *Quarterly Journal of Agriculture*, which continues to maintain its high reputation. For the other works published since 1831, we must refer to the Catalogue in continuation of that given in the *Bibliography of British Agriculture*, p. 1206. As this Catalogue is arranged in the order in which the works were published, a glance over it will form a very good chronological history of agriculture from 1831 to the present time.

ASIATIC TURKEY.

8035.—861. *On the agriculture of Asia Minor* some interesting notices will be found in the *Journal of the Geographical Society*, vol. x. It appears that on the banks of the Lake Van, the drill husbandry has been practised from time immemorial, with rude, but yet ingenious implements.

PERSIA.

8036.—864. *The general appearance of the country in Persia* is characterised by its chains of rocky mountains, its long arid riverless valleys, and its still more extensive salt or sandy deserts. The northern provinces form an extensive table land, which rises from a lower plain, and is interspersed with numerous clusters of hill, chains of rocky mountains, and barred deserts. The lower ground, under the name of Dushistao, or the level country, exhibits a succession of sandy wastes, where the eye is occasionally relieved by a dark plantation of date trees, and a few patches of corn, in such places as are blessed with a freshwater rivulet or a copious well. On the banks of the Tigris this tract becomes more fertile. Wherever water abounds, vegetation is most luxuriant; but the country generally suffers from excessive drought. The mountains present masses of grey rock, and the only trees that are found in abundance are the tall poplar and stately chimar (*Plátanus orientalis*), and the fruit trees which surround every border. These hovels are clean and comfortable; and wages are high, while food is cheap. (*Fraser's Persia, Edin. Cab. Lib.*, vol. xv.)

INDIA.

8037.—893. *To give some idea of the present state of agriculture in India*, Mr. W. Carey, one of the missionaries, states, in the *Transactions of the Agricultural and Horticultural Society of India*, vol. ii. part 1., 1832, that, in many parts of the country, the same crop is invariably raised on the same ground year after year; hay is never cut till the grass has died or withered on the ground; scientific rotation of crops is a subject to which Indian cultivators are strangers; and the manure produced by animals is generally consumed for fuel. No attempt to improve stock appears ever to have been made in India; though there is every reason to believe that all the animals used in the husbandry of Europe are capable of as high a degree of improvement in India as they are in more temperate regions. The quantity of waste lands in India is said to be so large as almost to exceed belief. Extensive tracts on the banks of numerous rivers are annually overflowed, so that they produce little except long and coarse grass, seldom turned to any useful account. During the rainy season, these tracts are the haunts of wild buffaloes, which in the night come up from them and devour the crops of rice on the high lands. In the cold season, wild dogs, tigers, and other noxious animals, unite with the buffaloes in occupying these extensive tracts of alluvial soil; which, though now so pernicious, might, by embanking and draining, become the richest lands in the country, and contribute greatly to the improvement of the climate. Similar observations might be made respecting immense tracts now wholly covered with wood, and producing nothing whatever to civilise man, but, on the contrary, proving a nuisance to the surrounding districts by affording a shelter to noxious animals. The oppression of landowners, and petty officers, on the cultivator is so great, that in some parts of the country no farmer can reasonably promise himself secu-

city for a single night. "Thus," concludes Mr. Carey, "one of the finest countries in the world, comprising almost every variety of climate and situation, diversified by hills and valleys, intersected in every part by streams (most of which are navigable six months in the year, and some of them through the whole year afford every facility for carrying manure to the land, and every part of the produce to market), is, as far as respects its agricultural interests, in a state the most abject and degraded." (p. 10.) This is a most forbidding picture; but it is incident to all countries in a particular stage of their progress in civilisation. Time was when the low districts of England were ravaged by the wolves and bears from the mountain forests, and when the crops on the alluvial vales of her rivers were annually swept away, or at least greatly injured, by floods. As to oppression by superiors, and thieving from others, there will always be abundance of such evils, till mankind are brought to something like equalisation in point of knowledge, and consequently power; till, in short, the mass of society become fit for self-government. (*Trans. Agr. Soc. of India.*) The potato has at length been effectually introduced into India, and as good potatoes are to be had in Calcutta as in London. Baron Hügel introduced them into Cashmere and Little Tibet. (G. C. 1842, p. 607.) A copious account of the agriculture of Hindostan, will be found in the *Q. J. A.*, vols. viii. ix. x. xi.

AUSTRALIA.

8038.—1037. *The whole territory of New South Wales*, Dr. Lang, writing in 1834, informs us, "is divided, like that of Great Britain, into counties and parishes; but these divisions are scarcely ever referred to in the common intercourse of colonial life. Except in government deeds or legal documents, the grand natural divisions of the country are the only ones recognised by the colonists." These divisions are the districts of the Hawkesbury, of Hunter's River, of Bathurst, of Illawarra, and of Argyle. The district of the Hawkesbury, which is let out in small farms of from 30 to 100 acres each, has been long considered the granary of the colony, from the extreme fertility of its soil, though the system of agriculture practised in it is as slovenly as can be well imagined. The surface of the ground is "for the most part merely scratched; and nothing like a proper rotation of crops is ever dreamt of. Wheat, year after year, for twenty years together, and sometimes wheat and maize in succession on the same ground, during the same year, is the Sangrado system of husbandry that prevails on the Hawkesbury." The district of the Hunter's River is let out in farms of from 500 to 2000 acres each. "Dairies are frequent throughout this extensive district; and large quantities of butter and cheese, of superior quality, are forwarded regularly by the steam-boats to Sidney." The vast plains of the Bathurst are chiefly tenanted by black cattle and sheep, and the farms are generally 2000 acres each. This may be considered the wool district. The cultivated land of the Argyle district is almost all in pasture, but there are interspersed extensive tracts of the most barren country imaginable. The district of the Illawarra consists of a narrow strip of arable land of the first quality, let out to "small settlers, who cultivate grain, potatoes, pumpkins, &c. for the Sydney market, their produce being conveyed to the capital by water in small coasting vessels." This is also the timber district, great numbers of the red and white cedar trees growing here, and that wood being generally used for cabinet and joinery work all over the colony. Besides these, there are several large tracts of pastoral and alluvial land, which cannot be properly classed in any of the above-named districts; and a very great extent of country remains unexplored. The rich alluvial land on the banks of rivers is called interval land. It is very productive, but is difficult to clear. Norfolk Island has a soil of the richest vegetable mould, even to the tops of the highest hills, and appears well adapted for the culture of coffee, if not sugar. It is now (1834) occupied as a penal settlement for the colony of New South Wales. (*Dr. Lang's Historical and Statistical Account of New South Wales*, vol. i.)

8039. *General aspect of the country*. The principal town, Sydney, is beautifully situated on Sydney Cove, one of the romantic inlets of Port Jackson, about seven miles from the entrance of that harbour, the headlands at the mouth of which constitute one of the grandest and most interesting features in the natural scenery of the country. Many of the most interesting localities on the shores of Port Jackson, between Sydney and the headlands, are in the hands of private proprietors. On Woolloomooloo Hill (*fig. 1141.*), which is an elevated projection of the land, about a mile from Sydney, most of the officers of the colony have houses. The second town of the colony is at present Paramatta, but Maitland will, probably, soon supersede it, as the latter place is situated at the head of Hunter's River, in the centre of the most extensive agricultural and grazing district in the colony. Between Sydney and Maitland there are two steam-boats, and a company has lately been formed, called "The Hunter River Steam Navigation Company." With the exception of the large open plains in the interior of the country, the territory of New South Wales is, in its natural state, one vast forest. On the banks of the rivers, and especially on the alluvial land within the reach of their inundations, this forest becomes what the colonists call a thick scrub or jungle. Immense trees of the genus *Eucalyptus*, such as the stringy bark, the Blue gum, *E. piperata*, and the Iron bark, *E. resinifera*, tower upwards in every direction, to the height of 150 or 200 feet; while the cedar, and other trees of inferior elevation, with innumerable wild vines and other parasitical plants, fill up the interstices. In the sterile region, the trees are stunted in their growth, and of a most forbidding aspect; their trunks and naked branches being frequently blackened by the action of fire, as in the *Eucalyptus*. The soil of these regions is a white sand, and nothing can exceed the loneliness and desolation of the scene. (*Ibid.*)

8040. *The settled portion of New South Wales*, in 1833, Sturt tells us, extended from the 36th to the 32d parallel of latitude. The population of the colony is said to consist of 45,000 free settlers, and 25,000 convicts. Its imports, in the year ending January, 1833, amounted to 602,032*l.*, of which 144,793*l.* was the value of commodities imported from foreign states, the rest being the produce of Great Britain, and her colonies. The exports amounted to 384,344*l.*, of which 81,969*l.* consisted of British and foreign merchandise re-exported, and the remainder was the produce of the colony, the New Zealand fisheries, and the South Sea Islands. The chief articles of export, which were shipped to the mother country, were:—New Zealand flax, 806 tons, value 15,393*l.*; sperm and black oil, 3186 tons, value 142,921*l.*; and wool, 1,515,159 lbs., value 73,559*l.* In 1831, no less than 150 vessels entered the harbour of Port Jackson from foreign ports, the amount of their tonnage being 31,259 tons. (*Sturt's Expedition into the Interior of Australia.*)

8041.—1038. *The mineral productions*. Marble of a good quality, and which takes a beautiful polish, has been obtained in Argyle. In one part of its course, Hunter's River flows for a considerable distance over rocks of jasper; and beautiful agates, opal, and chalcodony, besides innumerable petrificactions, are found on its banks. (*Hist. and Statist. Account, &c.*)

8042.—1040. *Natural productions of New Holland*. A peculiar character is given to the woods of the extratropical parts of New Holland, and to the woods of Van Diemen's Land, by the species of trees of the order *Proteaceæ*. These are numerous, and the leaves of the generality of them have a vertical position, and a similar aspect on both surfaces. These surfaces, a close inspection teaches, are distributed, by a reticulation of the fine veins of the leaf, into numerous small compartments or areolations, within each of which, on one face of the leaf, and very generally on both faces, is lodged a minute gland. (See *Brown's Supp. prim. Flor. New Holl.*)

8043. *The vegetable productions of New Holland*. Some of the most common trees in the neighbourhood of Sydney are several of the different kinds of *Eucalyptus*; what is there generally called the honey-suckle (*Banksia integrifolia*), the apple tree (*Angophora lanceolata*), the forest oak (*Casuarina torulosa*), and the grass tree (*Xanthorrhoea arborescens*). The last is particularly beautiful. There are also the broom (*Jacksonia scoparia*), which is called the dogwood at Port Jackson, and the wood of which is very difficult to burn, and the tea tree (*Melaleuca linariifolia*). The name of tea tree is given

almost indiscriminately to several kinds of *Melaleuca* and *Leptospermum*, because it is supposed that the first colonists made tea from the leaves of some of the species of these genera. The terms *hina*, red, or white gum trees, as applied to different species of the genus *Eucalyptus*, refer to the colour of the bark. The wood of trees of this genus is very durable; as a proof of which,

1141

of a species of *Eucalyptus* (blue gum tree) remained quite sound for thirty-five years in the ground, after having been cut down. When it was necessary to remove it, it took a fortnight to burn out the root. The circumstance of this trunk remaining quite sound for such a great length of time is very remarkable; and reminds us of what Dutrochet states respecting the stump and roots of the silver fir (*Gard. Mag.*, vol. x. p. 408.); viz., that they will continue to live, and even grow, during a great number of years after the tree has been felled. (*Lang's Hist. and Statist. Account.*)

8044.—1041. *Agriculture in Australia* appears to be making considerable advances, from the more frequent influx than formerly of emigrants with capital. Some Scotch farmers have settled in the interior of New Holland; a good many have located themselves in Van Diemen's Land, and there are some even on the Swan River. In 1830, the Cashmere goat was imported into the colony by Mr. Riley, and about the same time a German gardener, that Mr. Riley took with him from England, established vineyards in different parts of the country, which, from accounts received in 1834, have already produced wine. (*See Gard. Mag.*, vol. x. p. 159.)

8045. *The principal agricultural products of New South Wales* are wheat and maize. The cost of clearing heavily timbered alluvial land is about 5*l.* an acre, but sometimes a single crop of maize clears the expense. The return of wheat varies from 15 to 40 bushels an acre, and in the Argyle district it has reached 45 bushels; but the system of husbandry is, generally speaking, wretched in the extreme. The staple article of Australian produce is wool, of which Dr. Lang says, 1,515,156 lbs., and Sturt, 2,500,000 lbs., were exported in 1833. It is generally supposed that John Macarthur, Esq. was the first to introduce fine-wooled sheep into the territory; and, though the honour is also claimed by another individual, there is no doubt that Mr. Macarthur had the merit of having demonstrated their adaptation to the climate, and the capability of the colony to produce wool to almost any extent. This has been effected in comparatively a very short space of time. About 1792, Mr. Macarthur commenced sheep farming, and in a year or two, he had an opportunity of crossing his coarse-bleeced sheep with merino blood. So prolific was the mixed breed, that in ten years, a flock, originally consisting of not more than seventy Benal sheep, had increased to 4000. In 1803, Mr. Macarthur went to England, carrying samples of his wool, which was so much approved of by a committee of manufacturers, that government were induced to encourage him in his attempts to produce fine wool in the colony, by directing that he should receive a grant of land for that purpose, in the low pastures, which is now named the district of Camden. In 1806, Mr. Macarthur returned to New South Wales with two ewes and three rams, purchased by him from the merino flock of George III.; his flock was removed to the low pastures, and since that period, the wool of New South

Wales has been rapidly increasing in value in the home market. (*Dr. Lang's Hist. and Statist. Account, and Stuart's Exped. into the Interior of Australia.*)

8046. *Fruits and other vegetable products cultivated in the colony of New South Wales.* Vines, which are the most important of the fruit-bearing plants to a young settlement, have only been cultivated a few years to any extent. "There are now, however, many acres of vineyard throughout the country;" and wine and brandy have been manufactured from grapes grown by Mr. Macarthur's sons at Cambden. The wine is very similar to the light wines of France and Germany. Tobacco has been grown to great extent, particularly on the rich alluvial lands, and is only inferior in point of manufacture. Olives, hops, indigo, and opium, are beginning to be cultivated: the castor-oil tree (*Jicinus communis*) grows luxuriantly, and oranges and all the genus *Citrus*, and figs and peaches, bear abundantly. The hedges to the fields are generally formed of quince or lemon trees. There are several orange orchards, producing annually from 12,000 to 20,000 dozen each. The fruit of the loquat (*Eriobotrya japonica*) is sold in great quantities in the Sydney market. Cotton, coffee, tea, and sugar have been tried, and found to answer, though their cultivation has not yet been attempted on a larger scale. (*Hist. and Statist. Account, vol. i. p. 375.*)

8047.—1042. *As a country for emigrants.* During Sir Thomas Brisbane's administration, any respectable person, who pledged himself to government to maintain and employ ten or twenty convict servants, could obtain 100 acres for each such servant. This occasioned a great demand for convict labourers; and, instead of government being obliged to establish penal settlements in order to employ them, there was, during the government of General Darling, "applications for no fewer than 2000 convicts lying unsatisfied at the office of the principal superintendent of convicts." There is no doubt that New South Wales is an excellent country for the agriculturist; but it is subject to some drawbacks. A season of drought, which continued three years, began in 1827, and it appeared from the statements of old natives, that the country was subject to periodical visitations of that nature. It is also subject to inundations, particularly from the Hawkesbury River. From the imperfect state of husbandry throughout the country and the fertility of the soil, much may, however, be done by an experienced agriculturist. For eight months in the year, from March to November, the climate is delightful; but during the Australian summer, the heat is considerable. The most unpleasant part of the year is during the prevalence of the hot winds. "These winds occur on an average four times every summer, and continue from twenty-four to thirty-six hours at a time;" the atmosphere feeling like a current of heated air from a furnace, and the thermometer generally standing at from 90° to 100°, and sometimes even reaching 112° of Fahrenheit. The extreme dryness of the air, however, prevents this degree of heat from being so intolerable as it would be in a moist climate like England. The hot wind is generally succeeded by a violent gust from the southward, and very often by a shower of hail. (Vol. ii. p. 186.) Very few persons live to attain old age; but they generally enjoy excellent health and spirits while they do live. In short, observes Dr. Lang, "the lamp of life in the salubrious climate of New South Wales is like a taper immersed in a vessel filled with oxygen gas; it burns more brightly than in the common air, but it is sooner extinguished." To persons possessing property to the amount of from 2000*l.* to 5000*l.*, "New South Wales presents a most eligible prospect for effecting a comfortable settlement. They may put out part of their capital at interest for ten per cent. on excellent security, and 1000*l.* will not only purchase 1000 acres of land at 5*s.* an acre (the selling price in 1833), but will be amply sufficient to stock it." (*Lang's Hist. and Statist. Account, vol. ii. p. 200.*)

8048.—1044. *Van Diemen's Land.* This colony may be considered as the most prosperous in Australia, and the suitability of its climate for Englishmen is every year more and more confirmed. "The colony," Mrs. Prinsep observes (*Journal of a Voyage from Calcutta to Van Diemen's Land*), "contains every source of wealth and health, in short, every thing but money. Interest on mortgages, with the very best securities, is 15 or 20 per cent. Bank shares pay 16 per cent. There is no immediate prospect of any check to that rise in the value of land which is now observable. Money well invested in land here, and allowed to accumulate, will be tenfold its original value in fifteen years. 200*l.* would purchase a noble property here. 1000*l.* will buy a fine, healthy, and beautiful estate of 1200 acres, 200 of them already in cultivation, and the whole becoming more valuable every year. Corn and potatoes are exported to Sydney; and wool to England. Wool averages 6*d.* per pound. The whole colony is on the advance, and its resources remain to be developed. Fresh lands are granted in square miles, in the proportion of the square mile, or 640 acres, for every 500*l.* sterling of capital; which is the largest grant that is made to any settler without purchase, as the smallest is 320 acres. The total territory in acres is 15,000,000, of which about one half is rocky, or thickly wooded; the rest arable and pasture; the proportion of arable being as one to six of nature. The total number of acres granted to individuals, up to December, 1829, is 1,323,5/3; consequently there are 13,676,447 unlocated acres."

8049. *The wool of Van Diemen's Land* is of peculiar softness, and, from the greater attention now paid to cleaning and packing, the price is rising. Wheat is of a very superior quality, weighing generally about sixty, and sometimes as much as sixty-five pounds per bushel. Oats are beginning to be raised; barley has not yet succeeded; peas, and other species of pulse, are plentiful. Skins are also valuable; seal-skins the most so, being worth about 2*s.* each in England. Kangaroo skins are essentially useful in the colony for hats, and also for shoes, which are remarkably durable: when well packed, and of a good size, these skins fetch nearly 6*d.* a pound in London. Shoemakers make 100 per cent. on the raw material. (*Cape of Good Hope Lit. Gaz.*, vol. iii. p. 187; see *Backhouse's Narrative of a Visit to the Australian Colonies*, 1843, 1 vol. 8vo., with maps and etchings.)

8050.—1054. *New Zealand*, from its climate, which resembles that of the south of England; from its soil, which is in most places good; and from the inhabitants, which may be described as at least half civilised; appears to be one of the most desirable countries in the world to which a native of Britain can emigrate. (See *Dicffenbach's New Zealand*, 1843, 2 vols. 8vo.; *Gard. Chron.*, 1840, p. 99; *Gard. Mag.*, 1843, pp. 126 and 325; and *Butler's Emigrant's Handbook of Facts concerning Canada, New Zealand, Australia, Cape of Good Hope, &c.*, 1843, 1 vol. 12mo.)

EGYPT.

8051.—1077. *Egypt, under the government of the present pasha*, is undergoing extensive political improvements, among which agriculture, Mr. St. John observes, is not altogether forgotten. The culture of cotton has been commenced on a large scale by government; and an extensive tract of country round Cairo, which was long rendered useless by prodigious mounds of rubbish, many of them exceeding seventy feet in height, has been cleared, the mounds having been levelled, and planted with olive trees, which bore fruit the second year. The teak tree has been introduced from India, and is found to thrive near Cairo as well as in its native country. The mango, the pine-apple, and other tropical fruits, have been tried; and there is an English garden of naturalisation, under the direction of Mr. Trail, an English doctor. On the whole, there can be no doubt, that, if the present comparatively liberal policy of the Egyptian government be continued for another generation, the face of the country, and the condition of its inhabitants, will be entirely changed. Nature has supplied an excellent soil, and abundance of water, under a climate sufficiently hot to mature the fruits of tropical countries, and yet not so much so as to prevent the grains of temperate regions from being profitably cultivated. (*Egypt and Mohammed Ali*, p. 443.) In Dr. Bowring's *Report on Egypt*, presented to parliament in 1840, that country is shown to be making gigantic strides in civilisation, through the efforts of the present viceroy, Mahomet Ali. Agriculture is improving, though not very rapidly. The principal agricultural produce of the country is clover, corn, beans, barley, peas, and various other seeds. Watering is an essential element of culture.

and by means of it the soil, which in many places is excellent of itself, is made to produce enormous crops. The various details of Egyptian agriculture, as extracted from Dr. Bowring's Report, will be found in the *Gardener's Magazine* for 1840, p. 645. to 655.

Monocco.

8052.—1098. *Agriculture in Morocco.* The farmers plough and sow at the same time. The ploughing is performed by one man, who, while he guides the plough, which has a single handle, with his right hand, holds the reins, which are made of the palmetto twisted, and a long, thin, pointed stick to goad the oxen, in his left. When he sows, he leaves the plough, scattering the grain very sparingly with his right hand, and harrows it in by passing the plough again over the surface, the furrows being straight, narrow, and very shallow, without any ridge. The ploughshare has merely a simple tip of iron, which is taken off when the husbandman ceases to work, to prevent its being stolen. (*Brooke's Travels in Spain and Morocco*, vol. i. p. 303.) Some account of the progress of agriculture in Algiers will be found in the *G. C.*, 1842, p. 67.

CAPE OF GOOD HOPE.

8053.—1133. *Albany.* At the close of 1824, when this new settlement was hastening to dissolution, the commissioners of enquiry removed certain political evils, and the country at once commenced a march of success, which John Cuddeville Chase believes "the most unparalleled in the history of colonisation." In August, 1833, the Caffre trade, chiefly in ivory, amounted to about 34,000*l.* annually; and the exports increased from 32,273*l.*, their amount in 1829, to 51,290*l.*, their amount in 1832. Hides, horns, skins, tallow, butter, salted provisions, and ivory, formed the principal items. Cultivation is extended. Oats, barley, and oat-hay are the chief commodities; wheat has also been raised, and Indian corn, fruit, and vegetables grow most luxuriantly. Cattle, sheep, and horses are abundant, and every necessary of life is extremely cheap. There are about 26,000 sheep, the wool of which sells at upwards of 1*s.* per pound. Graham's Town has increased from 22 houses to 600; and eight villages, eleven places of worship, and fifteen schools have been built. Hat, blanket, and tile manufactories, numerous limekilns, three water and six wind mills, two tanneries, and two breweries, have been established. There is an infant school, a savings bank, a public reading room, and a commercial hall. A newspaper was commenced in January, 1832, and it is prosperous. The population, in 1833, was 9913; and, as a proof that the country is favourable to human life, only 24 out of 248 persons, who landed in 1820, had died in 1830. "Such," says Mr. Chase, "is the result of thirteen years' settlement, nearly five of which were those of failure and distress. From what has been related, it may be seen, whether success has attended the efforts of the immigrants or not, their only difficulty, in as far as my own knowledge goes, is that of a want of additional labourers to gather in the harvest of growing prosperity; and, as a proof of this want, I refer to the many and frequent appeals to the home government, successively made since 1825, for a new emigration." (*The Cape of Good Hope Lit. Gaz.*, vol. iii. p. 182.)

AMERICA.

8054.—1153. *Climate of North America.* Over the whole extent of North America, it is universally admitted that the clearing of the country has modified the climate; that this modification becomes every day more manifest; that the winters are now less severe, and the summers less hot; and, in other words, that the extremes of temperature observed in January and July annually approach each other. (*Jones's Jour.* Ap. 1834.)

8055.—1159. *The soil of the United States* is adapted to almost every species of culture. Wheat grows every where; and tobacco, hemp, and flax between the Potomac and Roanoke and Mexican Gulf. All the grains flourish in the valley of the Mississippi; but it is particularly in the delta of that river (which, like that of the Nile, is the work of the waters) that the sugar-cane and indigo succeed best. Almost every where, the earth abounds in pasturage, but is not adapted to the growth of fruit trees, or only produces fruit tart and without flavour. The most productive kinds of culture are those of colonial articles and vegetables; a species of cultivation for which the Americans are indebted to the French of St. Domingo, who have taken refuge among them. They are also indebted to them for some seed and kernel fruits. The territories of the United States, with regard to agriculture, may be divided into two parts, perfectly distinct from each other. The lands bordering on the Atlantic are generally bad or middling; but those on the other side of the Alleghanies, in the basin of the St. Lawrence and the Mississippi, are not exceeded by the best lands in Europe; and have, besides, the advantage of being nearly all virgin, and easily cultivated. Vegetation is hardy, but prompt, which is occasioned by the humidity of the soil. (*Beaujour's Sketch of the United States*, p. 81.) From the increase in the number of agricultural periodicals in the United States, the progress of the art would appear to be as rapid as it is in any part of Europe. Sugar has been extracted from the maize, to such an extent as to become an article of commerce; and Mr. Colman, who has been deputed by the state of Massachusetts to make an agricultural tour in Europe, has stated as his opinion to the Royal Agricultural Society, that the process of extracting sugar from the maize might be carried out in England with as much success as in America. (*Morn. Chron.*, June 22d, 1843.)

8056.—1192. *Climate of the Canadas.* John Young asserts, "that, 2000 years since, the climate of Europe was precisely similar to that of British America at the present day; in support of which he quotes many authors of antiquity. He attributes the change, first, to the extirpation of the forests and the draining of the morasses; secondly, to the increase of population, and consequent evolution of animal heat, and the warmth communicated to the atmosphere by the fires within the houses; thirdly, to the extension of tillage, the process of putrefaction alone generating considerable heat." (*Brit. Firm. Mag.*, vol. vi. p. 196.)

8057.—1195. *Emigration to British America.* Mr. Ferguson, who visited Canada in 1831, says, "that Upper Canada certainly is blessed with all the solid appearance of human happiness, independence, and comfort." The notes of this gentleman are given at length in the *Quarterly Journal of Agriculture*, vol. iii., and well deserve to be consulted by all emigrants. In a work on *Emigration to British America*, by John McGregor, Esq., published in 1831, the British possessions in North America are stated to be the Island of Newfoundland, Cape Breton, and Prince Edward Island; the province of Nova Scotia, New Brunswick, and the Canadas; the region of Labrador, and the territory west of Hudson's Bay. Newfoundland bears a striking resemblance to the Western Highlands of Scotland, and is chiefly adapted for the rearing of cattle and sheep. Prince Edward Island possesses an excellent climate and soil, and is, taken altogether, a most desirable spot for emigrants. "The society in the island is good, and the inhabitants consist of Europeans from all nations, but particularly from Scotland. Cape Breton is a small island, peopled by between twenty-five and thirty thousand souls, chiefly from the Western Highlands of Scotland." The climate, though humid, is salubrious; the general aspect of the country romantic and mountainous, and covered with forests; and the valleys contain extensive tracts of excellent soil. Nova Scotia is an extensive country, fitted to receive "thousands, perhaps millions, of emigrants." The winters are severe, but the air at that season is generally dry. This peninsula abounds with extensive fields of coal, with ironstone, with gypsum, and, it is believed, with rock salt. New Brunswick has a climate particularly suited to the constitution of Britons. The country is covered with immense forests of evergreen and deciduous trees, and it is everywhere intersected by rivers fit for navi-

gation. Coal, iron, gypsum, and sandstone abound. The Canadas include an extensive territory, with a climate which is on the whole salubrious. The thermometer, in summer, rises as high as 80° in the shade, and in winter sinks below zero. The winter in Lower Canada is two months shorter than that of Upper Canada. The geology of Canada is little known; the principal rocks appear to be trap and limestone. There are soils of every description, but the largest tracts are either alluvial, or of a lighter character, approaching to sand. Labrador, and the territory west of Hudson's Bay, Mr. McGregor does not consider as suitable to emigrants. We can only refer the reader, who is desirous of emigrating, to Mr. McGregor's book; or to a very copious abstract of it which will be found in the *Quarterly Journal of Agriculture*, vol. iii. p. 890. to 924.

8058.—1197. *The culture of wheat in the West India Islands* may be mentioned as a comparatively new agricultural feature. The kinds which succeed best are the summer varieties, which have been cultivated to advantage in Jamaica, Barbadoes, and several other islands. Great exertions have been made with a view to introduce the best varieties into these islands from Europe, and to make known the success which has attended their culture by Dr. Hamilton of Plymouth. (See *Gard. Mag.* and *Gard. Chron.*)

PART II.

AGRICULTURE CONSIDERED AS A SCIENCE AND AS AN ART. (p. 208.)

8059.—1285. *The present state of agricultural science* has been treated of in a prize Essay by Dr. Madden, published in the *Highland Society's Transactions* in March 1842, from which, as taking the latest and most comprehensive view of the subject, we submit the following abridgment:—

To the question, "What has science done for agriculture?" Dr. Madden answers that scientific agriculture has been investigated by an extremely limited number of individuals, and this chiefly since the commencement of the present century; that a great drawback to the advance of agricultural science is to be found in the want of confidence in it of practical men, and that among practical men there is a great want of scientific knowledge.

"If by the question, 'What has science hitherto done for agriculture?' we are to understand which of the new improvements owe their origin to scientific investigation, we feel obliged to confess that as yet we know of none extensively in operation. But if, on the contrary, we are to understand it in the wider sense, as requiring an account of what science has effected towards establishing agriculture upon a sure basis, so that the farmer may be enabled to apply his practical knowledge in whatever situation he may be placed, and will be at once capable of determining what changes in his arrangements, &c. will be necessary if called upon to change his farm, so that his operations will no longer be so much the sport of chance that each farmer can be considered as knowing only the treatment fitted for his own farm, we can confidently assert that much, very much has been accomplished; and although there is no point upon which we have as yet by any means perfected our knowledge, still there is scarcely any upon which science has not already thrown sufficient light to enable those, who are at all capable of appreciating her services, to derive great benefit and direction in cases of difficulty." To prove this, he takes a general view of what science has effected under the heads of, 1. Soil; 2. Effects of Vegetation upon soil; 3. The Art of Culture, and 4. The Economy of Husbandry.

8060. 1. SOIL. Science has already proved, in the most satisfactory manner, the following circumstances regarding soil:—

8061. *In order that it may be fertile, it must contain all the mineral matters found in the ashes of the plants destined to be cultivated upon it, in such a condition as to be available by the plants, and in sufficient quantity to enable the supply to be kept up by some economical mode of cultivation.* "The necessity of this condition depends upon the well-established fact, that plants cannot make for themselves any of the elementary substances which they contain, but are only capable of changing the form in which these are combined with one another. Thus, the organic portion of plants, or that which is destructible by fire, is composed of four elementary substances; namely, carbon, or charcoal, and three gases, named oxygen, hydrogen, and azote. Now plants cannot produce any of these four substances under any circumstances whatever; but if they are supplied with them, in almost any state of combination, they can, by their vital processes convert them into starch, gum, woody fibre, or whatever else they may require. The same is the case with the constituents of their ashes. They must be supplied with the requisite elements in some state of combination, and then they will be able to produce for themselves the particular compound which they require." Dr. Madden admits that a considerable increase of knowledge is required among farmers before this part of agricultural science can be brought to perfection; though he believes that much of the future progress of agriculture depends upon increased knowledge in this department of agricultural chemistry.

8062.—2. *Soil must consist of a due admixture of impalpable matter and larger sized particles, so that it may be porous and easily permeable by air and moisture, while, at the same time, there is a sufficient supply of matter in a state capable of undergoing chemical changes.* "All the useful organic matter of soil is in a combination with the impalpable earths which it contains; though the larger particles are necessary for the admission of air and water. Till these larger particles are reduced to powder, they exert no direct influence whatever upon the vegetation of the soil of which they form a part."

8063.—3. *Soil must contain a sufficient supply of organic matter mingled with it in a state capable of decomposition by the action of air and water.* "In general, the quantity of vegetable and animal matter in a soil is a direct index of its fertility."

8064.—4. *Soil, to be fit for profitable cultivation, must be free from any mineral substance which is destructive of fertility.* "This is a case in which no farmer will doubt the utility of chemical knowledge; thus, if the injurious matter be an acid or a soluble salt of iron, it may be neutralised by lime; or if it should be some compound of magnesia, it may be rendered innocuous by exposure to the atmosphere."

8065.—5. *Soil must be capable of being reduced to a sufficiently fine tilth, without an undue amount of labour, in order that its culture may be profitable.*

8066.—6. *Soil for a good farm must either be naturally capable of letting off any superabundance of water, or it must be capable of being made to do so artificially by draining.* "The advantages of draining a soil naturally moist can hardly be over rated. It not only admits air to the roots of plants, but admits the temperature of the atmosphere, so that a drained soil will always be found to produce an earlier vegetation than the same soil undrained."

8067.—7. *Soil, to be useful to the cultivator, must possess a structure which will allow the decomposition of organic matter mingled with it to proceed at a regular rate, being neither so fast as to waste the manure, nor so slow as to keep it too long fresh.* "Hence gravels, coarse sands, or strong clays, are to be improved by the addition of soils of an opposite texture, by the use of suitable manures, and by appropriate mechanical treatment; such as exposing strong clays to the frosts of winter, or the intense heat of summer, compressing loose gravels or sands, &c."

8068.—8. *The situation of soil must be such as to admit of all the operations of husbandry being per-*

formed in a proper manner, without occupying too much time; and the climate must permit of the plants arriving at perfection.

8069.—9. In order that soil may be advantageously subjected to continued cropping, the farmer must keep up its essential qualities by ploughing, harrowing, and any other operations necessary to pulverize it.

8070.—10. Soil intended for continued cultivation must have its supply of organic matter, and part also of its mineral ingredients, renewed by returning to it, from time to time, in the shape of manure, what has been removed from it in the form of crops.

8071.—11. The condition, as well as the composition, of the manure, must be attended to, because soil must have its activity preserved by adding to it, at certain periods, substances in a state of fermentation. Numerous facts tend to prove that the success of many crops depends upon the existence of fermenting matter in the soil, and that however rich it may be in other respects, these crops can only be advantageously cultivated after a fresh addition of manure; this is particularly the case with the turnip. Without dung the richest soil will bear but an indifferent crop; while with manure, very poor soil, if it be not too wet, will at all times give a good return. Science has not as yet been able to account for this satisfactorily, although many of her votaries are willing to acknowledge its truth, and it is obvious that an acquaintance with the fact must be of the greatest value in assisting the farmer in his arrangements, for he will of course apply dung when he intends to raise a crop requiring the existence of fermenting matter, and thus insure its success, while he does no injury to the following crops, whose growth is, to a certain extent, less dependent on the condition of the soil.

8072.—12. To correct any natural faults which the soil may possess, it must be subjected to various processes which have been proved by experience to cure the faults in question. "The chief of these are draining, liming, and burning."

8073. *Drainage.* The importance of draining, and especially of furrow draining, is now very generally understood, and the practice is so widely extended that it is in some danger of causing the advantage of deep draining to be overlooked. "A soil which is naturally capable of easily getting quit of surface-water, may be rendered quite marshy by the existence of a spring. Now, to furrow-drain a field of this kind would, in many cases, be absurd, for in all probability the spring would be missed, and after all the expense of laying the drains, the soil would remain almost as wet as at the first. The proper treatment, in such a case, is to search for the rise of the spring in the highest part of the field, and having found it, one good drain will frequently have the effect of drying the whole field. Again, when the wetness arises from both causes conjointly, viz., spring and surface-water, it is obvious, that however free an exit be given to the spring, the soil cannot be made dry without having recourse to furrow-draining to a greater or less extent, according to the stiffness or porosity of the soil and subsoil."

8074. *Liming.* "Lime has three distinct great effects, in addition to several minor ones: 1st, It greatly hastens the decomposition of the organic matter in the soil, and in doing so renders it much more valuable to the crops. 2d, It alters the texture of the soil to a certain extent, proportioned to the quantity applied. 3d, It adds, of course, calcareous matter to the soil. From these considerations, it follows that lime is applicable to all cases where there is an accumulation of undecomposed vegetable matter, as in poor old pasture, heath, peat, moss, moorland, and the like." Lime is not required in soils which are poor for want of organic matter, nor in such as abound in chalk. Lime does not add directly to the fertility of the soil, but only increases it, by calling into activity organic matter. Lime exhausts the soil by bringing the organic matter which it contains into action; and hence many lands will yield for a year or two after liming heavier crops than they did before, but afterwards their productive powers fall as much below the natural standard, as they had been artificially raised above it by liming.

8075. *Burning.* "The immediate effects of this process are fourfold. 1st, It destroys a large quantity of organic matter. 2d, It alters entirely the texture of the portion to which the heat is directly applied. 3d, It reduces to a caustic state the alkalis and alkaline earths contained in the burnt portion. And 4th, By means of those alkalis it acts upon the remaining organic matter of the soil exactly as lime does. To arrive at a just conclusion as to the true economical merits of this process, we must bear all these four facts in mind: 1st, As it destroys a large quantity of organic matter, it of course exhausts the soil to the extent of the quantity destroyed; this is, therefore, in one respect, a disadvantage. 2d, As it completely alters the texture of the portion burnt, viz., by giving to the clay the feeling and texture of sand, we must consider how far this would be advantageous to the soil. 3d, and 4th, As it produces alkali which acts upon the remaining organic matter of the soil, and thus further detracts from its supply of organic matter, it becomes of importance to decide whether the soil will bear the deterioration without a real loss of value."

8076.—11. THE EFFECTS OF VEGETATION UPON SOIL. Science explains, more or less satisfactorily, the causes of the following facts.

8077.—1. *Uncultivated soil, however rich, becomes gradually less and less fertile until it has attained the condition either of moor or marsh.*

8078.—2. *Uncultivated soil retains its luxuriance for the greatest length of time, when covered with forest trees and other large vegetables.*

8079.—3. *Land not disturbed by the plough produces successive crops of different kinds, or, in other words, a sort of natural rotation is, to a certain extent, maintained.*

8080.—4. *On cultivated land, when any species of plant disappears, its place is supplied by one of less value as an article of food, and thus the richest pasture comes in time to produce only the coarsest and most worthless species of grass.*

8081.—5. *Although the natural produce of uncultivated soil thus uniformly decreases in value, the soil itself becomes progressively richer; so that when brought under the plough, it will yield much larger returns than could be expected from its spontaneous produce.*

8082.—6. *Soil continually ploughed, yields its nourishment in much greater abundance, and with greater ease to plants growing upon its surface.*

8083.—7. *The facility with which the productive powers of well cultivated land are diminished depends on its organised matter being more easily converted into compounds soluble in air and water.*

8084.—8. *The decrease of fertility in carelessly cultivated soil depends, in addition to the above circumstance, upon a diminution in the proportion of its impalpable matter.*

8085.—9. *Cultivated land, when properly taken care of becomes gradually richer and richer, notwithstanding the increased quantity of produce annually removed from it.*

8086.—10. *If the same plant be cultivated for several years successively upon the same spot, the soil much more rapidly decreases in fertility than when a variety is kept up.*

8087.—11. *Some of the most valuable mineral constituents of soil decrease in greater rapidity in proportion to the greater care bestowed upon its cultivation, altogether independent of the portions removed by the crops.* "The more you pulverise a soil, the more alkali will be annually removed by the rain-water."

8088.—III. THE ART OF CULTURE, or the means necessary for keeping up the fertility of the soil, requires—

8089.—1. *Manure added in proportion to the weight of the crops removed.*

8090.—2. *A judicious rotation of crops.*

8091.—3. *Fallowing, at least in some soils.*

8092.—4. *Resting, by laying down in pasture.*

8093.—1. *Manure must be added in proportion to the weight of crop removed.* "It is believed that careful examination will prove that there exists between the crop and the active organic matter in the soil, a proportion so constant and definite, that to keep up the fertility of the soil, we must keep up this

proportion; and if we do this by manure, of course it follows that there is a certain fixed proportion between the manure and the crop. Calculation will show us that although at first sight the gross weight of the crops of a rotation is considerably above that of the manure applied, still, in reality, the amount of the various elementary matters is much nearer an equality, in fact, are generally most abundant in the manure. Let us, for example, suppose the following case:—an imperial acre of turnip soil receives 2½ tons of farm-yard dung, and yields, 1st, 30 tons of turnips; 2d, 42 bushels (of 53 lbs. each) of barley, with 2000 lbs. of straw; 3d, 200 stone of hay; 4th, 48 bushels (of 42 lbs. each) of oats, with 2500 lbs. of straw. Now, the gross weight of these crops would be 80,342 lbs. whereas the manure would weigh only 56,000 lbs.; and consequently, the soil has yielded 24,342 lbs. more in four years than it received in the form of manure, or at the rate of 6085½ lbs. more annually. If, however, we compare separately the relative quantities of carbon, azote, and saline matter contained in the crops and manure, we shall obtain the following results:

	lbs.			lbs.
Carbon in the crops	- 8,183.04	-	In the manure	- 12,734.4
Azote in the crops	- 248.61	-	In the manure	- 280.
Saline matter in the crops	- 1,191.24	-	In the manure	- 6,104.
	9,622.89			19,118.4

So that, in fact, there is a considerable excess in the manure, of all the elementary ingredients of the crops, if we except the elements of water, viz., oxygen and hydrogen. We trust that this calculation will be sufficient to satisfy all, that there exists a certain proportion between the weight of the elements of the crop and that of the constituents of the manure.

8094. *A rotation of crops is required, not merely because it tends greatly to lessen the expense of cultivation, but because the more azote a plant contains, the less frequently can it be cultivated upon the same spot in uninterrupted succession.* "The precise chemical principles upon which a rotation depends are somewhat obscure."

8095. *A naked summer fallow only becomes necessary when soil cannot be cleaned and brought to a sufficiently fine tilth between harvest and the following seed time, without interfering with other operations.*
8096.—IV. THE ECONOMY OF HUSSANDAY, or the particulars regarding each individual crop, which are necessary to be known in order to its successful cultivation. The following general facts in vegetable physiology will assist us in understanding this part of the subject.

8097.—1. *All plants in a highly artificial state require a larger supply of nourishment during the first period of their growth than is supplied by the seed alone; and hence the necessity of a rich soil, or of a supply of putrescent manure.*

8098.—2. *Plants which have more than one method of propagating themselves should be limited to the method which is most suitable.* The potato should not be allowed to produce seed, because it is most conveniently propagated by the tuber.

8099.—3. *Plants lay up a store of nourishment for the next year, either in the wood or roots, as in trees and perennials, or in the seeds as in annuals.*

8100.—4. *The starch of plants is always contained in cells, formed of a substance containing azote; and consequently there exists a fixed proportion between the quantity of azote composing the cells and the amount of starch contained in them; hence it follows, that to increase the quantity of starch in a plant, you must increase its supply of azote, although starch itself contains no trace of this element."*

8101.—5. *In all parts of a plant there is an exact proportion between the various elements entering into its composition, so that an addition to one of them is necessarily followed by a relative addition to them all.*

"If, for example, a plant possesses one part containing 2 grs. of azote, combined with 18 grs. of other elements, and another portion containing 2 grs. of azote combined with 48 grs. of other elements; if we, by any means, prevent the development of the more highly azotised portion, viz., the 2 to 18, we shall produce a proportional increase in the other; so that, by preventing the formation of 20 grs. of the highly azotised portion, we obtain 50 grs. of that which contains proportionally less azote."

"These facts will assist us in the following explanations regarding individual crops."

8102. *The turnip.* "The fusiform, or globular part of the root of the turnip, contains the supply of nourishment required for the development of the flower and seed in the following year. The turnip has a large system of leaves; contains much water; is not highly azotised; the seed possesses a very small supply of nourishment; the whole success of the crop depends, within certain bounds, upon the rapid development of the large absorbent leafy surface. Hence the culture of the turnip must be conducted as follows:—the soil must be sandy; first, because it is a law that plants make preparations for retaining in their own texture most water when the soil around them is capable of retaining least; second, because its development must be rapid, and hence the decomposition of manure must be rapid likewise. There must be a good supply of very active manure, so that the seed may be provided with abundance of food in the first period of its growth, and thus have its leaves developed as rapidly as possible (within certain limits of course). As the plant is not highly azotised, it can draw the greater portion of its nourishment from the air, provided the absorbent surface of the leaves be sufficiently large; hence it is more necessary to attend to the quality than the quantity of the manure for this crop. A small quantity in a very active state, will prove much more valuable here than a large quantity which is too fresh. As the size of the bulb is regulated by the size of the surface of its leaves, this crop must not be too crowded, but plenty of room should be left to permit of the full development of the leaves."

8103. *The potato.* "The potato differs essentially from the turnip, in that the portion used is a perfectly developed part, that is to say, a part which is perfect in itself; for instance, the bulb of the turnip is merely a deposit of nourishment for the use of the plant during the ensuing spring, and if removed from the soil, cannot be made to produce a new individual; whereas the tuber of the potato is as much a perfect individual as any seed, for it contains within itself all that is requisite for the propagation of the species. On this account, therefore, the potato may be considered as perfectly developed when the tuber is ripe; whereas the turnip has merely advanced a certain way towards perfection, which cannot be said to occur until the seed is formed. Now, the importance of this distinction will be seen, when we remember that all plants deteriorate the soil most during the latter periods of their growth, and hence it follows that, *caeteris paribus*, the potato is a more exhausting crop than the turnip. The potato, like the turnip, has a large system of leaves, and contains much water. It is more azotised than the turnip, but the portion containing the greatest quantity of azote is not developed until during the latter periods of the growth of the plant. It possesses two ways of propagating its species, viz., by seeds and tubers, and whatever prevents the development of the one, increases proportionally that of the other; this proportion being regulated by the quantity of azote. The success of the potato depends greatly upon a due balance between the quantity of nutriment afforded respectively by the soil and the air, because the tuber consists of a large deposition of starch in cells, composed of an azotised matter. Now, as the soil provides the material for the cells, and the carbonic acid of the starch is derived chiefly from the air, it follows, that if one or other of these supplies be in excess, a due proportion will not exist between the two ingredients of the tuber. Thus, if the soil be very rich in azotised matter, so many cells are produced that the leaves cannot eliminate starch sufficient to fill them: on which account, the potato is of that peculiar consistence termed 'waxy.' If, again, the soil is deficient in azote, only a few cells are formed, and these are completely filled with starch, and the potato consequently becomes 'mealy.' With regard to the order of development of these parts, the cells are first produced, and become filled with starch subsequently, and as this is formed by the leaves, any thing which injures them, such as frost, &c., checks the

production of starch, and the potato remains either waxy, or, what is worse, soft and watery. Now, a review of these facts would lead to the following suggestions regarding the culture of this plant:—"

8104. 1st, "There must be an abundant supply of manure, because, not only must the leaves be quickly developed, but the soil must be in a condition to yield azote abundantly, even during the latter period of the growth of the plant; hence, small quantities of active manure will not succeed nearly so well with this plant as with the turnip."

8105. 2d, "The manure need not be so well prepared, as the greatest supply of azote is not required until some time after the plant has risen above ground; but it must not be too fresh, for fear of retarding the development of the leaves, nor too hot, for fear of acting injuriously on the seed or tuber."

8106. 3d, "We must not give this crop too much rich manure, for fear of making a greater demand upon the atmosphere than it is capable of answering."

8107. 4th, "The plants should be placed far apart, so as to permit of the free increase of the leaves."

8108. 6th, "As the potato has a spreading root, and the tubers are nearly all developed upon the under surface of the fibres which run most horizontally, it is very injudicious to earth up the plants, as this of necessity renders the roots more perpendicular. Experiment has proved that this practice occasions considerable loss."

8109. 6th, "To obtain the largest number of tubers, the flowers should be plucked off to prevent the formation of seed, while every thing should be done to protect the leaves from injury."

8110. 7th, "The soil for the potato should be loose, although this plant will grow in a much greater variety of soil than the turnip. This also depends upon the tubers being a completely developed portion, destined for the production of a separate individual; whereas, the bulb of the turnip is for the purpose of supplying the plant during the most important period of its growth; viz., during the development of the seed, with abundance of moisture and nourishment, when growing in a soil which cannot naturally retain these: and therefore, if we attempt to grow the turnip upon stiff soil, it either does not flourish at all, or else the bulb is very imperfectly developed, for in this case the soil can supply all that is required, without the assistance of this artificial reservoir."

8111. *Wheat, oats, and barley.* "All of the cerealia agree in so many respects, that it will be advantageous to consider them together."

8112. 1st, "As they are cultivated for their seed, they are perfectly developed before harvest, and, therefore, exhaust the soil to a much greater extent than green crops."

8113. 2d, "As their system of leaves is very much less than that of the plants before considered, they are much more dependent upon the soil even for those elements which larger leaved plants obtain from the air."

8114. 3d, "As the seed is, in all instances, the most highly azotized portion, and as it is the last part developed, it follows, that these plants require more a general richness of the soil than a supply of newly added manure. On this account, it is with propriety, therefore, that they are seldom made to follow close after the application of manure, but are either preceded by a green crop, or are sown after summer fallow."

"These crops differ among themselves chiefly as regards soil and climate; wheat requiring clay, barley a lighter soil, and oats succeeding pretty equally on all good soils, of whatever texture they may be. The same is the case concerning climate, and the richness of the soil;—wheat requires the best climate and the richest soil, then barley, and then oats. It is not easy to explain this satisfactorily, for although we can produce many circumstances which appear to explain the differences in question, more careful examination will prove that they can merely be considered in the light of probabilities, and by no means as certainly ascertained facts. For example, if we examine the ashes of these three plants, we find that their quantities amount proportionally to three, two, and one, wheat containing the most, and oats the least; and if we examine still further, we shall find that clayey soil is more capable of yielding the ingredients of these ashes than land of a lighter texture. This renders it probable that one of the causes of wheat requiring clay, depends upon the necessity of a larger supply of these earthy particles; but accurate calculation also proves, that many plants which grow best on sand remove from it a greater quantity of these very substances than would be required to supply the heaviest crops of wheat. It cannot, therefore, be considered as proved, that the cause of wheat preferring clayey soil, depends upon the greater quantity of earthy matter required for its perfect development, although we may venture to advance as a probability, that it depends upon an increased facility of obtaining this supply. Again, these three crops require a considerable supply of azote during the latter periods of their growth, the proportion being, wheat 2·13, barley 1·76, oats 1·96; so that here again, since we know that decomposition proceeds more slowly in clay, and the azote of the manure is hence not so quickly given off, we might argue that clay would be better fitted for wheat. Chemical analysis, however, proves in this case also, that some crops peculiarly suited to sandy soils contain a much larger absolute quantity of azote, although it must be admitted that the relative proportion is much less. Our conclusion here, also, must therefore be, that the cause of wheat thriving best upon clay, depends probably upon its receiving azote in a greater degree of concentration."

8115. *Beans, peas, and other leguminous plants.* "Very little can be said regarding these in the present state of our knowledge, as but little particular attention has hitherto been paid to them by the scientific inquirer; and there are so many peculiarities exhibited by them, that it would be very imprudent to risk an opinion upon so meagre a collection of facts. Beyond all doubt these are the most hazardous crops we cultivate, as they are so very much influenced by the weather. Clover, for example, is a plant the success of which we can scarcely in any instance predict, as, no matter what the state of the soil may be, a few days of unfavourable weather may destroy at once all prospect of success. We may, however, notice one fact in this place, although we shall not attempt its explanation, viz., that the nitrates of potash and soda, two very favourite manures, appear to exert an almost magic influence over clover in rendering it much more certain and luxuriant."

These observations complete Dr. Madden's review of the facts in agriculture, which are already explained by science: he regards them as showing that considerable advances have of late been made, and he hopes soon to see the farmer and the philosopher pressing forward hand in hand in the field of agricultural improvement. He subjoins the following tables:—

I. Table showing the relative nutritive Powers of various Articles of Food, deduced from the Quantity of Azote which they contain. Arranged from M. Bousingault's Tables.

Name.	Various kinds of Fodder.		
	Amount per cent of Solid Matter.	Amount per cent of Azote.	Value compared with Hay as 100.
Hay, from red clover in flower	83·4	1·76	60*
Vetch hay	89	1·41	74
Lucern hay	83·4	1·35	75
Common hay	88·8	1·04	100
Green clover	—	·50	208

* That is to say, that 60 lbs. of red clover hay contain as much nourishment as 100 lbs. of common hay, and as 612 lbs. of turnips.

Potatoes	7.7	.37	281
Green lucern	—	.30	347
Carrot	12.4	.30	
Wheat straw	80.7	.20	520
Barley straw	89.	.20	
Oat straw	79.	.19	547
Rye straw	87.8	.17	611
Turnips	8.2	.17	612
Beans	92.5	5.11	20†
Vetches	85.4	4.37	24†
Kidneybeans	95.	4.08	25†
Lentils	91.	4.00	26†
Yellow peas	83.3	3.40	31†
Wheat flour	87.7	2.27	46
Wheat grain	89.5	2.13	49
Rye	89.	2.04	51
Oats	87.6	1.96	54
Barley flour	87.	1.90	55
Barley grain	86.8	1.76	59

† Leguminous plants alone will not prove so nutritious as the cerealia, because they do not contain a sufficiency of phosphates which are required for the production of bone; they are therefore most useful when conjoined to some of the following grains.

11. Table showing the Composition of the Ashes of our most frequently cultivated Crops. From Saussure and other Authorities.

Name.	Ashes in 1000 Parts.	Constituents of 100 parts of the Ashes.				
		Soluble Salts.	Phosphates.	Earthy Carbonates.	Silica.	Metallic Oxides.
Wheat { grain	13.	47.16	44.5	-	.5	.25
{ straw	43.	22.5	6.2	1	61.5	1.
Oat grain	31.	1	24.	-	60.	.25
Barley grain	18.	29.	32.5	-	35.5	.25
Vetches	33.	69.23	27.92	-	-	0.5
Turnips	5.8					
Potatoes	5.9					

111. Table showing the Quantity of Alkali associated with the various Minerals entering into the Constitution of Soil. From Liebig.

Name of Mineral.	Per Cent of Alkali.	Name of Alkali.
Felspar	17.75	Potass.
Albite	11.43	Soda.
Mica	3 to 5	Soda.
Zeolite	13 to 16	Soda and Potass.
Basalt	5.75 to 10	Soda and Potass.
Claystone	2.75 to 3.31	Potass.
Clinkstone	14.	Potass.
Loam	1.5 to 4.	Potass.

Analysis has proved the existence of more or less potass in all clays, as also in marls. From this table it would appear that by far the best soil would be that originating from the disintegration of felspar; and we think that observation will often prove this to be the case.

BOOK II.

THE ANIMAL KINGDOM WITH REFERENCE TO AGRICULTURE. (p. 281.)

8116.—1836. *Animals*, according to Liebig, are subject to the action of two powers which are constantly at work: vitality, which is the cause of life; and chemical affinity, which is the cause of death. The object of vitality is to sustain and increase the mass of the body in which it resides; the object of the chemical forces is to destroy and waste that body. Vitality resides in every part of the fortress which it has to defend; the chemical forces are encamped in the atmosphere which everywhere surrounds it. In fact, the chemical power is the gas oxygen, one of the principal constituents of common air; and its affinity for the elements of organic matter is so great, that it constantly endeavours to destroy it. The whole life of an animal consists in a conflict of these rival powers; in the endeavour of vitality to sustain and increase; in that of chemical affinity to waste and destroy. In health, vitality possesses the ascendancy, and modifies the destructive efforts of the chemical powers. Disease, on the other hand, is a temporary conquest of the chemical over the vital forces; while death is the victory of the former, and annihilation of the latter." (*Journ. R. A. S. E.*, vol. iv. p. 221.)

8117.—1863. *The food of all animals*, and particularly of those employed in agriculture, Liebig has shown to consist of two elementary substances: gluten or albumen, composed of carbon, hydrogen, nitrogen, and oxygen, which constitute the nutriment of the body; and starch, sugar, gum, and other substances containing carbon, hydrogen, and oxygen, but from which the element nitrogen is absent. It is only the substances containing nitrogen, or which in other words are azotised, which produce flesh, while the other elements are for the production of heat by the combustion of carbon in consequence of its union with oxygen. The heat generated in this combustion in the body of an animal, is exactly equivalent to that produced by burning the same amount of carbon in a fire or a candle. As the heat

of an animal body is the same in all regions, it follows that more carbonaceous food is required to keep up the animal heat in a cold region than in a warm one, and hence the great importance of protecting animals from a greater degree of cold than is natural to them in every stage of their growth, and for obvious reasons it is equally important to protect them from extreme heat. This subject has been beautifully illustrated by Lichtig, who says, "were we to go naked like certain savage tribes, or if in hunting and fishing we were exposed to the same degree of cold as the Samoyedes, we should be able with ease to consume 10 lbs. of flesh, and perhaps a dozen of tallow candles into the bargain, as warmly clad travellers have related with astonishment of these people. We should then also be able to take the same quantity of brandy or train oil without bad effects, because the carbon and hydrogen of these substances would only suffice to keep up the equilibrium between the temperature of the external air and that of our bodies." (*Chemistry as applied to Physiology, &c.*) The only use of clothes, says Dr. Playfair, is to economise food by retaining heat. (*Lecture on the Applications of Physiology to the Rearing and Feeding of Cattle, in Journ. R. A. S. E., vol. iv. p. 221.*) The animal body is a furnace which must be kept up to a certain heat in all climates. This furnace must, therefore, be supplied with more or less fuel according to the temperature of the external air. If, then, in winter we wish to retain the vital functions of our cattle in a proper degree of activity, we must keep up the heat of their bodies. This we may do in two ways. We may either add more fuel (food) to the furnace, or we may protect their bodies from the cold. Warmth is an equivalent for food, and as a proof, Dr. Playfair cites the following experiment, which was made by the Earl of Ducie at Whitfield farm. One hundred sheep were folded by tens in pens, each of which was 22 ft. in length by 10 ft. in breadth, and possessed a covered shed attached to it of 12 ft. in length by 10 ft. in breadth. They were kept in these from the 10th of October to the 10th of March. Each sheep consumed on an average 20 lbs. of Swedes daily. Another hundred were folded in pens of a similar size, but without sheds attached. They were kept during the same time, and their daily consumption of Swedes amounted to 25 lbs. each. Here the circumstances were precisely similar with respect to exercise, the only difference being that the first hundred sheep had sheds into which they might retire, and thus be partially protected from the cold. This partial protection was equivalent to a certain amount of food, and consequently we find that the sheep enjoying this protection consumed one-fifth less food than those sheep which were left entirely exposed to the cold. In the last case the consumption of the additional food arose wholly from the necessity of adding more fuel (food) to the furnace of the body, in order to keep up its normal temperature. This was proved from the circumstance, that those sheep which enjoyed the protection had increased 3 lbs. each more than those left unprotected, although the latter had consumed one-fifth more food. (*Journ. A. S. E. 1843, p. 222.*) The honey stored up by bees is for the purpose of serving as fuel to keep up the heat of their bodies during the winter. Now it has been found that when two hives of bees are placed in one hive during winter, they actually consume less honey than each hive would have done separately.

8117 a. *The assimilative power of the graminiivora* is enormous, and the quantity of food which they consume is proportional. In summer, when the temperature of the air approaches more nearly to that of the body, the heat generated by the combustion of this food is more than is sufficient to retain the normal temperature of the system: Hence it is that we find oxen so much inconvenienced by hot weather, and that we observe them standing in streams of running water, or exposing themselves, with evident satisfaction to a shower of rain. The cold water serves to carry off the redundant heat, and, consequently, matter, from the body; for heat is produced by the combustion of matter. This practice, therefore, although agreeable to the cattle, can scarcely be a profitable one for the grazier: and hence, as before hinted at, the advantage of a shed in summer to exclude the heat, as in winter to retain it. The air in summer being so much expanded by heat, much less air is taken into the system in an equal number of respirations than in winter; consequently less oxygen is consumed. But oxygen is the principal acting chemical force; it is, therefore, the cause of waste. The case of cattle now feeding is the very reverse of what it is in winter. In cold weather, the vital force (cause of supply) is reduced in energy, whilst that of the chemical force is augmented; but in summer the vital functions are elevated and the chemical powers depressed. Vitality, having now a diminished force in antagonism to its action, exerts all its powers in increasing the mass of the organs in which it resides; it therefore converts into blood all azotised parts of the food taken by the animal, except those which supply the small amount of waste. All the excess of blood is converted into flesh (*i. e.* muscular tissue and cellular tissue). The animal now becomes fleshy and plump. The other constituents of the food, such as starch, sugar, and gum, are converted into fat, and deposited as adipose tissue. The cause of the deposition of fat is this: that sufficient oxygen does not enter the system to consume the food, or to convert it into carbonic acid and water; it is, therefore, only partially consumed, or in other words, converted into fat (Liebig). Fat is not a part of the organism; it is a chemical compound arising from an unnatural state. The fattening of cattle is similar to the growing of corn plants, or to agriculture generally. The object of agriculture is to produce an abnormal increase of some particular constituent of a plant, such as of gluten in the wheat. This we do by chemical means, by manure. The fattening of cattle is similar. Our object is to produce an unnatural increase of some particular parts of the body; and to do this we must put the cattle in an unnatural state. (*Journ. R. A. S. E., vol. iv. p. 224.*)

8118. *Exercise* The most favourable conditions to the development of tallow, are, food destitute of nitrogen, warmth, want of exercise, and in some cases darkness. Motion diminishes the tendency of an animal to fatten, "by increasing the number of its respirations, and therefore by giving to the system an increased supply of oxygen gas, which consumes the tallow. Hence our practice of stall-feeding cattle. Liebig asserts, "that every motion, every manifestation of force, is the result of a transformation of the structure or of its substance; that every conception, every mental affection, is followed by changes in the chemical nature of the secreted fluids; that every thought, every sensation, is accompanied by a change in the composition of the substance of the brain. There is a constant conflict in the body between the two antagonist powers, vitality and chemical affinity. In the state of health, vitality retains the ascendancy, and subdues the chemical powers; but this subjection is the result of much effort on the part of vitality, for the strength of the rival forces is nearly equal. The moment, therefore, that vitality leaves undefended a single point in the fortress of the body, that moment the chemical forces begin the work of demolition on the unprotected part. Thus, if vitality be called upon by the superior power, volition, to execute some purpose of its will, — to move the arm for example, — the vitality residing in the muscles of the arm obeys this command, and occasions the desired movement. Before the production of motion, all its powers were exerted in preventing the encroachment of the chemical forces (*i. e.* of the oxygen of the air). But when it is employed in effecting a vital movement, such as that of the arm, it is no longer in a position to resist the attack of its antagonist power. This, therefore, immediately acts upon the muscles which obey the will, destroys part of their substance, and occasions its separation from the tissues. Poultry-feeders confine their poultry when it is necessary to fatten them quickly. The ravenous feeders to prevent the expenditure of a particle of the food by the motion of the animal. The greatest part of the food consumed by an animal thus deprived of the means of motion goes to the production of fat. When pigs are put up to be fattened, they are removed from the yard, in which exercise now expended in the production of motion, the pig rapidly increases in size. Sheep fed in sheds consume from one-fifth to one-half less food, and increase one-third more in weight, than those fed in the open field. The cause of these results is two-fold: — first, the sheep in the sheds are subjected to less motion, and therefore exhaust less food in its production, than those in the field; and, secondly, the sheep are kept warm in the sheds, and therefore expend less food for the support of animal heat than those

exposed to a cold atmosphere in the open fields. It is well known that the more bodily labour to which a man is subjected the more food must he receive to supply the tissues wasted in that labour. In the late distress in Lancashire, the poor sufferers, who often were unable to obtain sustenance for themselves and families, discovered, through the force of necessity, both the theories which we have endeavoured to expound, viz. that warmth is an equivalent for food, and that motion is always accompanied by a change of matter. We are informed by the daily press that whole families remained in bed for days together, covered with as many clothes as their small stock could furnish. In this state the animal heat was artificially retained, and little matter being expended in motion, a small amount of food was sufficient to support the vital principle." (*Journ. R. A. S. E.*, vol. iv. p. 227.)

8119. *The importance of knowing how much water each kind of food contains*, has been forcibly pointed out by Dr. Playfair, who has furnished the following table :

	Water.	Organic Matter.	Ashes.
100 lbs. of Peas - - - - - contain	16	80½	3½
— Beans - - - - -	14	82½	3½
— Lentils - - - - -	16	81	3
— Oats - - - - -	18	79	3
— Oatmeal - - - - -	9	89	2
— Barley meal - - - - -	15½	82½	2
— Hay - - - - -	16	76½	7½
— Wheat straw - - - - -	18	79	3
— Turnips - - - - -	89	10	1
— Swedish turnips - - - - -	85	14	1
— Mangold-wurzel - - - - -	89	10	1
— White carrot - - - - -	87	12	1
— Potatoes - - - - -	72	27	1
— Red-beet - - - - -	85	10	1
— Linseed-cake - - - - -	17	75½	7½
— Brau - - - - -	14	81	5

Thus, in giving a pig 100 lbs. of potatoes, we actually give it only 28 lbs., because 72 per cent. of this food consists of water.

8120. *The comparative values of different kinds of food*, as far as the production of flesh or muscular fibre is concerned, is not less important ; because, as we have before seen, those kinds of food which do not contain nitrogen are only productive of fat or heat. The following table is given by Dr. Playfair :

	Albumen.	Unazotised Matter.
100 lbs. of Flesh - - - - - contain	25	0
— Blood - - - - -	20	0
— Beans - - - - -	31	51½
— Peas - - - - -	29	51½
— Lentils - - - - -	33	48
— Potatoes - - - - -	11	25
— Oats - - - - -	14	68½
— Barley meal - - - - -	8	68½
— Hay - - - - -	11	63
— Turnips - - - - -	1	9
— Carrot - - - - -	2	10
— Red-beet - - - - -	1½	8½

In a cold day animals ought to be furnished with food containing a considerable amount of unazotised ingredients, in order to protect them from the effects of the cold. Potatoes are of great use in keeping up the heat of the body, and in forming tallow ; but are in the highest degree unprofitable for forming flesh. " It will be seen by the table, that 1550 lbs. of potatoes would be required to form the same quantity of flesh that 100 lbs. of beans would do ; whilst little more than 200 lbs. would suffice to form the same quantity of tallow ; hence the great advantage of mixing food, so as to supply in smaller bulk those constituents, of which one kind of food is deficient. Sheep fed on oil-cake increase in weight faster than on any other kind of food, but they feel quite soft, and when fat handle like a bag of oil. This is because they receive food which contains very little albumen to form flesh, so that tallow is the only product. But if with the oil-cake they receive oats or barley, they are firm to the touch, and possess plenty of good flesh, and the fat lies equally distributed amongst the muscular fibre. The reason here also is obvious ; for both oats and barley contain much albumen (or, chemically, gluten). In an experiment made by Mr. Merton at Lord Ducie's farm, twenty-eight pigs, put up in pens of seven each, and fed on an average on 15½ lbs. of potatoes and 4 lbs. of barley-meal each, gained 15 or 16 lbs. weekly. In this quantity, the pigs actually consumed nearly equal quantities of the two kinds of food, or exactly 30 lbs. of dry potatoes, and 22 lbs. of dry barley-meal weekly. The increase in weight being 16 lbs. for each pig, 37 lbs. of the food were lost in supporting respiration, and the necessary muscular movements, even without taking into calculation the water contained in the flesh of the animal, which amounts to 75 per cent. If these animals had been deprived of muscular movement, by being placed in narrow warm cribs, it is reasonable to suppose that less food would have been lost, because less would have been consumed in the production of force, and in sustaining the animal heat. The barley-meal contains the constituents for furnishing firm flesh, as well as for producing tallow, or supporting respiration. The economy of using potatoes, consisted in their supporting the respiration of the animals at less expense than barley. The 108 lbs. of potatoes used in the week for this purpose, and for the production of tallow, contain 26 lbs. of unazotised matter. In order to replace this, 33 lbs. of barley-meal would be requisite. It does not invalidate the conclusion, that 33 lbs. of barley-meal would produce a greater return than 108 lbs. of potatoes, because the former contains much more albumen and less water than the latter." (*Journ. R. A. S. E.*, vol. iv. p. 233.)

8121. *The equivalent values of different kinds of food*, if they could be correctly ascertained, would be of great value to the farmer, and the following table, translated from the French by Mr. Rham, may be considered as near an approximation as can be obtained in the present state of our knowledge. On this table Dr. Playfair observes that an animal in a hot day will require much less food than in a cold day ; that equivalence of food may be correct as far as the same animal is concerned, but may be of little value as regards other animals, because the size of the lungs of an animal occasions a great difference in the amount of food consumed.

	lbs.		lbs.
Of good hay	- 100	Boiled potatoes	- 175
<i>is equal in nourishment to,</i>		White Silesian beet	- 220
Of Lattermath hay	- 102	Mangold-wurzel	- 330
Clover hay, made when the blossom is completely developed	- 90	Turnips	- 504
Clover hay, before the blossom expands	- 88	Carrots	- 276
Clover, second crop	- 98	Colza	- 287
Lucerne hay	- 89	Swedish turnips	- 308
Sainfoin hay	- 91	Ditto with the leaves on	- 350
Tare hay	- 98	Grain, rye	- 54
Spergula arvensis, dried	- 146	wheat	- 45
Clover hay, after the seed	- 410	barley	- 54

		Canada poplar leaves	- 67

(*Journ. R. A. S. E.*, vol. iii. p. 80.)

8122. *The form in which food is given to cattle* is far from being a matter of indifference. If the food be in a state in which it is either difficult to attain, or difficult to masticate when obtained, much of it will be lost in the production of force necessary to adapt it for the organs of digestion. The cutting of hay and straw to chaff is unwittingly done with a view to prevent any unnecessary expenditure of force. Less mastication is requisite, and consequently less of the tissues of the body are expended in grinding down the food. The use of saliva, according to Liebig, is to form a receptacle for air or oxygen, by which means it is mixed with the food and carried to the stomach. The use of mastication, then, is not only to comminute the food, but also to mix it with air or saliva. We find that a larger size of chaff is given to those animals which chew the cud, than to those that do not. One great object of rumination is, to obtain a repeated supply of oxygen to the food. Hence, in our ordinary practice, we cut the hay-chaff one inch in length for oxen, half an inch for sheep, and only quarter of an inch for horses. The two first being ruminating animals, require it longer than the horse, which is not one. When we consider that fresh grass is much more easily masticated than hay, the economy of force exhibited in cutting the latter is well judged. Straw, except when new, is not a very nutritious food, for we find a great part of it unchanged in the faces of the animal fed upon it. Its principal use is to give a bulk to the food taken. Even in the case of turnips, a food of considerable bulk, straw is necessary, because they contain nearly 90 per cent. of water, which becomes soon separated. Thus it is that cattle fed upon turnips voluntarily take 2 or 3 lbs. of straw daily, or as much as will serve to give the necessary bulk to the food. Rumination is requisite in order to keep an ox in health. A little straw or hay is accordingly necessary to enable it to chew the cud. We know a case in which barley-meal and boiled potatoes were given to cows without hay or straw. Constipation resulted, and the cattle nearly perished from the ignorance of the feeder. From these considerations, we are induced to consider that a greater return will be made by food partly, but not too much, reduced. The turnip-slicer is known to save food, and this arises from the fact, that the sheep expend less force in eating sliced, than whole turnips, and to their being enabled to lie down more constantly. On similar grounds are we to ascribe the advantage of steaming food, or reducing it to the state which the first three stomachs would otherwise have to do at a great expenditure of force, and consequently, of food to produce it." (*Journ. R. A. S. E.*, vol. iv. p. 235.)

8123. *The use of salt in food.* "Respiration is carried on by means of the combustion of those constituents of the food which are destitute of nitrogen. But before this combustion is effected, they are transformed by the liver into the fluid called bile. Bile is a compound of the alkali soda, with a resinous or highly carbonaceous substance derived from the food. The bile, after being formed, is absorbed by certain vessels of the intestines, and there meeting with oxygen, is consumed and converted into carbonic acid and water, which are expired by the lungs. The combustion does not take place in the lungs themselves, as is generally supposed, but in the intestines. Now, as bile is the medium through which respiration is supported, it is necessary that it should be properly and regularly formed. This can only be done by supplying the animal with a constant amount of soda: this we do in common salt. The soda of the salt aids in the formation of the bile, whilst its muriatic acid assists the digestion of the food. A proper formation of the secretions is necessary to the health of an animal, and a supply of salt is highly favourable to their production. But whilst it is admitted that a limited supply of salt is very useful to the health of the animal, a large supply is highly prejudicial, and prevents the formation of fat. An experiment was tried upon a goose, which was crammed with maize, and allowed to eat salt. The salt taken by the goose was less than that necessary to produce a purgative action, and yet the goose did not fatten. This arose from the excess of food being formed into bile, and not into fat. As much bile was consumed as corresponded to the oxygen inspired, whilst the remainder passed out with the excrement, and was detected therein. On this account, it is a bad practice to give fattening sheep as much salt as they will take in summer." (*Journ. R. A. S. E.*, vol. iv. p. 237.)

8124. *In the rearing and feeding of cattle,* it is important to bear in mind that the process of nutrition differs in a young animal from that of an adult, and that no substitute has yet been found for the milk of the cow in rearing calves, though sugar, treacle, and flour of different kinds, have been added to milk in order to make a smaller quantity serve. The great point in the rearing of stock is to take care that the vital powers are always predominant over the chemical. "Attention to these considerations will easily point out the kinds of food which are best adapted for a growing animal. Thus potatoes, without an admixture with other food, would be highly improper, because they do not contain sufficient albumen to supply the materials necessary for the growing frame. But it would be quite proper to mix potatoes with other food rich in albumen, for its starch might support the respiration and heat of the animals with more economy than another food containing much albumen, but a less abundant supply of substances fitted for respiration. It is a mistake, into which many breeders fall, to deprive the young animal of exercise by confining it entirely in the stall. Such a procedure is perfectly correct with a fattening calf, but not with one which is rearing. The muscular apparatus of a young animal requires a certain degree of exercise, without which it cannot increase. Unless the vitality residing in the various organs be called into action,

it becomes enfeebled; and as vitality is the cause of increase in the body, any diminution of its power is highly prejudicial to growth. The amount of exercise must of course vary with the age of the animal." (*Journ. R. A. S. E.*, vol. iv. p. 242.)

8125. *That warmth is equivalent to food in feeding animals*, has been already shown. Mr. Morton found that sheep will consume more turnips in the cold wet days of winter, than when the weather is dry and warm, and in frosty weather than in mild dry weather; the difference being equal to one fourth of the whole of their food. Pigs fatten faster in summer with the same food, than they do in winter. The protection of a shed has saved one fourth of the whole food; and Mr. Chivers has shown (*Journ. R. A. S. E.*, vol. i. p. 407.) that where motion was at the same time prevented, the saving amounted to as much as one half. The protection from cold, and the deprivation of exercise, are the great advantages of stall feeding. "The true state of health of an adult animal is, that the supply of food to the body should be equal to, but should not exceed, the waste of matter expended in the production of motion. This state is exhibited in a healthy adult man, who is found to weigh the same at the end of the year as he did at the beginning. This is not the state desired in a fattening animal. We wish a diseased condition, or the state in which the increase of the body is far greater than the waste. We can best throw an animal into this condition by removing or diminishing the causes of waste." (*Journ. R. A. S. E.*, vol. iv. p. 243.)

8126. *Should cattle be fed in stalls, or in small yards with sheds attached?* Certainly the former would appear at first sight to be most preferable, because less motion is permitted. But it is also possible that, the health of the animal being impaired by this treatment, the energy of the vital principle may be so far subdued as to prevent a rapid increase of the body; while, the health being better in the latter case, and only a small amount of exercise permitted, the increased energy of the vital powers may more than compensate for the loss experienced by the motion of the animal. The flesh of the cattle in the yards must also be firmer and more fitted for the butcher; while the cattle tied to stakes will, in all probability, be possessed of more tallow." (*Journ. R. A. S. E.*, vol. iv. p. 245.)

8127. *The feeding of cattle for dairy purposes*, has occupied Liebig and Dr. Playfair, but it would require more space than we can afford to explain their views, and we must, therefore, refer to the original sources. The same remark will apply to Dr. Playfair's remarks on the diseases of cattle, and on the recognised signs of fattening, and of early maturity. The theory of fattening adopted by Liebig and Dr. Playfair is, or appears to be, in total opposition to all opinions at present entertained. According to them, "the peculiar aptitude of any animal, or of a breed, to fatten, must arise from a peculiar smallness and fineness of texture of the lungs. Although Liebig has not announced in his work the opinion, that smallness of lungs is an indication of a tendency to become fat, still he conceives that it is so. On consulting some eminent physiologists in our own country, I find that they also entertain the same view. Cline asserts quite the contrary, and agriculturists have generally needed to his opinion. He says, 'an animal with large lungs is capable of converting a given quantity of food into more nourishment, and therefore has a greater aptitude to fatten.' Mr. Youatt holds a similar doctrine; and both he and Mr. Cline uphold their opinion by reference to the capacity of the chest. 'On the roundness and capacity of the chest,' says Mr. Youatt, 'depend the size and the power of the important organs which it contains the heart and the lungs; and in proportion to their size is the power of converting food into nourishment.' (*Journ. R. A. S. E.*, vol. iv. p. 257.)

Those who would wish to pursue this subject will have recourse to the original, the interest of which would be in a great measure destroyed by abridgment, and it is too long to quote. We can, however, recommend these two lectures, as next to the volumes of Liebig, the most interesting and instructive discourses with reference to agriculture which have appeared in our time.

8128. *The nutriment afforded to animals by seeds, and roots* depends on the rupture of the ultimate globules which constitute their meal or flour. These globules vary in different roots, tubers, and seeds; those of potato starch are usually from the fifteen-ten-thousandth to the four-thousandth part of an inch; those of wheat rarely exceed the two-thousandth part of an inch, and so on. From experiments made on these globules, by M. Raspail, the author of *Chimie Organique*, and M. Biot, of the French Academy of Sciences, celebrated for his researches in the polarization of light, the following conclusions have been drawn.

1. "That the globules constituting meal, flour, and starch, whether contained in grain or roots, are incapable of affording any nourishment as animal food till they are broken.
2. "That no mechanical method of breaking or grinding is more than partially efficient."
3. "That the most efficient methods of breaking the globules is by heat, by fermentation, or by the chemical agency of acids or alkalies.
4. "That the dextrine, which is the kernel, as it were, of each globule, is alone soluble, and therefore alone nutritive.
5. "That the shells of the globules, when reduced to fragments by mechanism or heat, are insoluble, and therefore not nutritive.
6. "That, though the fragments of these shells are not nutritive, they are indispensable to digestion, either from their distending the stomach and bowels, or from some other cause not understood; it having been proved by experiment that concentrated nourishment, such as cane-sugar, essence of beef, or osmazome, cannot long sustain life without some mixture of coarser and less nutritive food.
7. "That the economical preparation of all food containing globules of fecula consists in perfectly breaking the shells, and rendering the dextrine contained in them soluble and digestible, while the fragments of the shells are at the same time rendered more bulky, so as the more readily to fill the stomach." (*Q. J. A.*, vol. vii. 456.)

8129. *Comparative advantages of feeding live stock on raw, or on prepared food.* In 1833, the Highland Society of Scotland offered handsome premiums for reports on this subject. Five of their Reports are published in the Highland Society's *Transactions*, vol. x., by which it appears that no benefit whatever is gained by the practice in the case of cattle, but, on the contrary, a loss equal to the amount of fuel and the cost of labour. Swine, on the other hand, afford a greater profit when fed on prepared food than on raw food. In three months pigs on steamed food increased 173 lbs., being 67 lbs. more than double; while those on raw food increased only 115 lbs., being 7 lbs. more than double their first weight. Hence there can be no doubt that steamed food is more profitable for feeding pigs than raw food; more especially raw potatoes, which when given alone are found insufficient for bringing a pig to a fat state. (*Trans. H. S.*, vol. x. p. 280.)

8130—2068. *Progress of education in rearing and training brute animals.* The effect of gentleness in teaching the human species had not long been observed, before (generalising on the subject) it was applied in the case of brute animals in a state of domestication; and it has been found that the domestic animals used in agriculture, and for military and commercial purposes, may be trained to do their work much more effectually, and with far less labour, by gentleness than by force. This has been lately beautifully exemplified in the education of cavalry horses. The principal object in the treatment of young horses is to render them docile; and the same gentle means are now used for that purpose which are found to answer best in the treatment of children. They are rendered quiet and tractable by frequent patting, handling, and rubbing them, and by taking up their feet. They are reared about the barrack yard to accustom them to the sight of mounted horses, and to the glitter of arms; and, in the course of four or five months afterwards, they are transferred to the riding-school to be trained. The good old plan, like that preferred by our ancestors for teaching boys Latin and Greek, was to whip all fear and shyness out of them; but kindness and common sense have at last gained the ascendancy, to the great delight of the organs of sensation in both boys and horses. (*G. M.* 1838, p. 343.)

8131. *Training calves and horses.*—In Ellis's *Horse Training*, reviewed in the *Athenæum* for April 2 1842, it is shown that breathing into the nostrils of calves, horses, and various wild animals, renders them quite tame. The experiment has been tried in England with success; and Mr. Ellis is of opinion, that this is the secret of the celebrated Irish horse charmers, who pretended to whisper to the animal and play with his head, and thus, probably, breathed into his nostrils. The experiments made by Mr. Ellis are founded on the following passage in Mr. Catlin's work, *On the Manners and Customs of the North American Indians*:—"I have often, in concurrence with a well-known custom of the country, held my hand over the eyes of the calf and breathed a few strong breaths into its nostrils; after which I have, with my hunting companions, rode several miles into our encampment, with the little prisoner busily following the heels of my horse, the whole way, as closely and affectionately as its instinct would attach it to the company of its dam. This is one of the most extraordinary things that I have met with in the habits of this wild country; and although I had often heard of it, and felt unable exactly to believe it, I am now willing to bear testimony to the fact, from the numerous instances which I have witnessed since I came into the country. During the time that I resided at this post, in the spring of the year, on my way up the river, I assisted (in numerous hunts of the buffalo with the Fur Company's men) in bringing in, in the above manner, several of these little prisoners, which sometimes follow for five or six miles close to our horses' heels, and even into the Fur Company's fort, and into the stables where our horses were led. In this way, before I left for the head waters of the Missouri, I think we had collected about a dozen. In the same way the wild horses are tamed. When the Indian has got him well secured with the lasso, and a pair of hobbles on his feet, he gradually advances, until he is able to place his hand on the animal's nose and over his eyes, and, at length, to breathe in its nostrils, when it soon becomes docile and conquered; so that he has little more to do than to remove the hobble from his feet, and lead or ride it into camp." In confirmation of what has just been stated, we quote the following:—"The taming of horses," says the *Newbourn Advocate* (a North Carolina newspaper), by breathing in their nostrils, seems to be gaining friends. Mr. David Clayton, of Tyrrel county, having seen an article in our paper stating that horses had been rendered gentle by breathing into their nostrils, determined to try it on a young mule belonging to him, who would suffer no person to handle him. Mr. Clayton fastened him in a stable, and, after considerable trouble, succeeded in breathing several times in his nostrils. Before he left the stable the mule became gentle, and would stand still and suffer himself to be rubbed, and would nose and smell around him. He followed Mr. Clayton out of the stable, around the yard, and wanted to go into the house. We advise our friends who have colts to break to try the experiment; if it does no good, it can certainly do no harm." (*G. M.* 1842, pp. 328, and 574.) The subject of training horses in this way is said to be mentioned by Meric Casaubon, in his *Treatise on Equestrianism*, published in 1655; who refers to one Sullivan, a blacksmith at Cork, who practised the art. The same statement will be found in Stewart Rose's translation of *Parthenopez de Blois*, and in a note in Borrow's *Bible in Spain*. We have introduced it in this Supplement in the hope that it may induce such experiments to be made as may set the matter at rest.

BOOK III.

THE MINERAL KINGDOM AND THE ATMOSPHERE WITH REFERENCE TO AGRICULTURE.

CHAP. I.—*Earths and Soils.* (p. 312.)

8132.—2100. *Humus or mould* exists in all soils, and indeed is necessary to constitute soils as distinguished from earths, which consist solely of inorganic matter. It was formerly thought that humus was soluble in water, and in that state was taken up by the roots of plants; but Liebig has shown that it is insoluble in water; that if it were, it would soon be washed out of the soil by rains and melting snow; and that it only supplies food through the action of the oxygen of the atmosphere, with which it forms carbonic acid gas. "The complete, or it may be said, the absolute insolubility in cold water of vegetable matter in progress of decay, (humus), appears on closer consideration to be a most wise arrangement of nature. For if humus possessed even a smaller degree of solubility than that ascribed to the substance called humic acid, it must be dissolved by rain water. Thus, the yearly irrigation of meadows, which lasts for several weeks, would remove a great part of it from the ground, and a heavy and continued rain would impoverish a soil. But it is soluble only when combined with oxygen; it can be taken up by water, therefore, only as carbonic acid. When kept in a dry place, humus may be preserved for centuries; but when moistened with water, it converts the surrounding oxygen into carbonic acid. As soon as the action of the air ceases, that is, as soon as it is deprived of oxygen, the humus suffers no further change. Its decay proceeds only when plants grow in the soil containing it; for they absorb by their roots the carbonic acid as it is formed. The soil receives again from living plants the carbonaceous matter it thus loses, so that the proportion of humus in it does not decrease." (*Liebig's Chemistry of Agriculture*, &c., 2d ed. p. 114.)

8133.—2212. *Irrigation.* Sir Humphry Davy was unable to satisfy himself as to the cause of the benefits derived from irrigation, ascribing it chiefly to the protection of the grass from early spring frosts; but if we admit, with Liebig, that inorganic salts are necessary to the well-being of plants, and promote an increased development of them, the explanation of the effects of irrigation with clear water becomes easy. The clearest spring water holds in solution carbonate, sulphate, and chloride of lime, with silicate and other salts of potash and soda. "Reeds and equisetaceæ thrive in ditches and streamlets, because a large portion of silicate of potassa enters into their composition, and, by the frequent change of the water, dissolved silica is largely supplied. The meadow grasses likewise require silicate of potassa, and they are furnished with it by the water which flows over them while under irrigation. The carbon also, and the carbonaceous excrements of plants contained in the soil, require abundance of oxygen to promote their decay and conversion into carbonic acid. Now the water of rivers and streams holds oxygen in solution, and if, during the process of irrigation, the water be frequently renewed, no matter how thin the sheet of it with which the meadow be covered, it will communicate large supplies of oxygen, and promote the decomposition of the organic matters contained in the soil. Stagnant water, on the contrary, retards their conversion into carbonic acid by preventing the access of air, and hence arises the sterility of bogs and marshes. In order to convert them into luxuriant meadows, it is only necessary to remove the stagnant water by draining, and, where practicable, to irrigate them by means of water rapidly renewed." (*Trimmer's Chemistry for Farmers and Landowners*, p. 199.)

8134.—2217. *Rotation of crops.* The theory of the rotation of crops adopted by Liebig is thus ably given in an abridged form by Mr. Trimmer. Formerly the soil was supposed to contain a variety of substances, some only of which could be assimilated by one family of plants, others by another; and that each plant absorbed those substances which were suited to it, and rejected the rest. "Subsequent observations caused the following modification of this theory; viz., that plants absorb indiscriminately whatever is presented to their roots in a state of solution, retaining that which is suited to assimilation by them, and expelling as excrement that which is unsuited. Some experiments were made by Macaire Princeps, in which plants were made to vegetate in a weak solution of acetate of lead, and were sprinkled

with nitrate of strontian. In each case they absorbed the substance thus presented to them, for it was detected by analysis in their structure, and they expelled it again. These experiments offered strong confirmation of the above views, and afforded a satisfactory explanation of the fact, that a plant like wheat, which contains much potash, will not flourish after another crop likewise requiring potash, and that it thrives after clover, beans, peas, or other leguminous plants, which scarcely contain any alkalies; but they did not explain how land becomes fertilised by fallowing, nor how leguminous plants cause an increase of carbonaceous matter in the soil. Other experiments, however, made by him have established the fact, that most if not all plants expel whatever their organs are unable to convert into woody fibre, starch, gluten, &c., and that these substances are of two kinds, inorganic matters derived from the soil, which are incapable of assimilation, and organic compounds formed in the plants by the vital process. He found, for instance, that when leguminous plants were grown in water, it acquired a brown colour; that other plants of the same kind would not grow in this water, but that the plants of corn thrive in it and removed some of the colouring matter. He ascertained, too, that of the organic matters thus expelled, some were of an acrid resinous nature, some mild, like gums; the former of which he regarded as poisonous, the latter as nutritious to succeeding crops. These organic matters, thus expelled by the roots, and deposited in the soil, restore to it the carbon, which in the early stages of their growth the plants had extracted from it in the shape of carbonic acid. Before they can be converted into nutriment for other plants, they must undergo decomposition: their preformation must be converted into decay by the access of air, which tillage produces, and thus they become capable of performing the functions of humus, by affording a supply of carbonic acid. In calcareous soils, the process of decay is accelerated by the presence of lime, while argillaceous soils are those in which the longest time is required for its completion. The excrements of a given crop must be thoroughly decomposed before the land will produce another of the same species; and on those soils on which the longest intervals are required between crops of the same kind, it is found that the time cannot be shortened by the most powerful manures. Now calcareous soils are those on which peas, clover, &c. will bear to be repeated at the shortest intervals, and argillaceous soils are those on which the longest periods are required between them. But though these excrements, undecomposed, either wholly or in part, are injurious to plants of the same species as those which expelled them, they are not so, nay, are even capable of affording nutriment, to those of other species; and therefore the introduction into cultivation of every new plant which can supply the place of another, such as clover or turnips, which will not bear frequent repetition, confers a great benefit on the farmer, by furnishing him with the means of varying and extending his rotation." (*Trimmer's Chemistry for Farmers, &c.*, p. 196.)

CHAP. II. — Manures.

8135. — 2224. *The use of all manures* is to increase the natural fertility of the soil, or to restore that which has been diminished by vegetation. The idea of a universal pabulum for all plants is nearly exploded; and all the attempts to discover it are, by many considered to be on a par with the finding of the philosopher's stone or the universal medicine. The improvements in chemistry have discovered various and different substances in every different family of plants; not only such as are peculiar to organised matter, and are the result of the decomposition of vegetable and animal substances, but others likewise, which belong to the mineral kingdom. These can be exhibited unaltered in the residue of chemical decomposition, whether in the dry way, by means of heat, or in the humid way, by means of the action of other substances, which destroy the cohesion of the parts, or change their affinities. Thus the earths, silica, lime, magnesia, alumina, and several of the metals, especially iron, are found in the ashes of plants which have been burned; and from the regular proportions of these in plants of the same kind, whatever be the nature of the soil in which they are raised, we must conclude that they are in some measure essential to their formation. However involved in darkness and doubt the growth and nourishment of plants is in the present state of science, there are certain principles which may be considered to be fully established by experiment: of these one is, that whatever enters the body of a plant, whether by the roots or the pores, which are distributed along its surface, especially in the leaves, when they are developed, must be so minutely divided, that its particles are invisible, not only to our naked eyes, but even assisted by the high magnifying powers of the microscope; that is, they must be fluid, whether in a liquid or aeriform state. It is useless, therefore, to present to the pores, or mouths, if we may so call them, of plants, substances which cannot enter into them, however well adapted they may be to serve as nourishment or increase. Mineral substances must, therefore, be dissolved in suitable menstrua before the plants can imbibe them. Organic substances naturally decompose in the state of gas, and these gases may contain various matters in solution. It is more than probable that water and atmospheric air are the chief menstrua in which the food of plants is dissolved; as we well know that, without the presence of both, plants soon become diseased, and die. (G. C. 1843, p. 67.)

8136. *The modern theory of manures*, as founded by Sprengel and lately established by Liebig, is thus ably and concisely stated by Mr. Pusey. "Plants consist in the main of several vegetable substances, which are, however, all composed of four kinds of air variously combined; these gases are named oxygen, hydrogen, carbon, and nitrogen. Dr. Liebig supposes that the two first are derived by the plant from water; the third, which is charcoal, from the air; and the fourth, nitrogen, which constitutes the most nutritious part of our food, from ammonia; which substance he has found not merely in the dung of animals, but in the water of rats,—a new and remarkable fact. But there exists also in crops a considerable quantity of earthy matter; in every ton of oat-straw, for instance, nearly one cwt. of flint; whence, if a hayrick be burnt, lumps of a substance like glass are often found in the ashes. These mineral substances vary in different plants as to quantity, but eight are generally to be found in their ashes, four of the eight being acids, namely, that of flint, which is silica; of bones, phosphorus; of limestone, sulphuric acid; of common salt, muriatic acid; and also four alkalies, potash, soda, lime, and magnesia. A very small quantity of alumine, or the earth of clay, is also usually detected in the ashes of plants. These, Dr. Liebig says, cannot of course be formed in the plant, but must be derived from the soil; and accordingly there they are generally to be found when the soil is examined by chemists, but in limited quantity, so that the soil may become exhausted of one or more of them. But further, all these eight mineral substances are to be found in farm-yard dung, besides ammonia, the source of nitrogen; hence the excellence of dung for all crops indifferently. Some crops, however, require more of one ingredient than of another: hence the good effect of bones upon turnips, which contain a great deal of phosphorus; and of gypsum or peat-ashes, which contain sulphate of lime, upon clover; of Epsom salts also. Dr. Liebig states, which contains magnesia, upon potatoes. Some soils, again, may contain so much of one of these eight minerals, that it may be useless to add any more. Thus gypsum is found to be useful in one part of a field and not in another, and bones are useless in Mecklenburg, where the fields are dressed with a marl full of phosphorus; or, on the other hand, a tract of country may be deficient altogether in some one of the eight ingredients which is necessary for all crops, as in lime: in such a district lime will be a standing manure. This new theory of agriculture, though but a theory at present, certainly promises important results. In order to test it first, and, if it hold good, to apply it afterwards, two courses of inquiry are requisite: 1, as Dr. Liebig informed Mr. Pusey, "a more minute examination of the ashes of plants in which these mineral substances are found, and further a more accurate analysis of our

various soils, in which last particular English science is sadly defective: for, Dr. Liebig observes, Davy has made several analyses of various fertile soils, and since his time numerous other analyses have been published, but they are all so superficial, and in most cases so inaccurate, that we possess no means of ascertaining the composition or nature of English arable land. This reproach on our science ought certainly to be removed; and it is easy to see how varied a field of inquiry is opened by the new theory." (*Journ. R. A. S. E.*, vol. iii. p. 214.)

8137. *On the practical application of manures*, Mr. Pusey has given the following summary as the result of recent experience. On this most difficult subject in agriculture, manures, "it may be said that we have learnt a great deal in the last four years, but know nothing; for we have learnt many of the chemical principles on which manures act, but we do not yet know how to apply those principles to the daily work of the farm. It is now established, that the most important ingredient of farm-yard dung is ammonia; the same substance as common smelling salts; known to escape very readily in the air; and there is a growing opinion that a great deal of it does so escape from our farm-yards; which is doubtless the case; though I am not sure whether the alarm on the subject be not somewhat exaggerated. For ammonia arises chiefly from the urine of the cattle, but it does not form itself until after some days; and by that time, in a well-littered yard, it has sunk from the surface, and has been trampled down fast, so that it can less easily evaporate. Whilst it is forming itself, too, the straw begins to decay; and it is the opinion of Sprengel that an acid, called the humic acid, formed from the decaying litter, has the property of combining with the ammonia, and removing its volatile property. This must be doubtful, of course, and various means of fixing the ammonia have been proposed. Sulphuric acid is one, either in the shape of gypsum, which has been found not to answer, or in that of green vitriol, or as a pure acid; but these are at present only suggestions. We have been also strongly urged to imitate a foreign practice of using liquid manure, spread from a water-cart; but this I believe to be a very doubtful innovation; for if the urine be collected separately, it is the opinion of Sprengel that a still greater escape of ammonia takes place, unless some substance, which is not yet ascertained, be added to fix it, or unless it be largely diluted with water, which occasions great labour in its application. This last objection lies also against the other form of liquid manure, the runnings from the yard collected in a tank; for after heavy rains they sometimes do not contain above two per cent. of salts, and are then not worth the labour of carriage. It appears that this foreign practice has arisen from two causes: one, the want of litter, and where the same cause exists, as on some of our dairy-farms, the method might be well introduced; the other motive is, the desire in Flanders of applying a liquid top-dressing in May to the corn growing on sandy land, or else to a second crop, such as carrots sown amongst beas; but this last case does not arise in England. Some loss, however, must arise by the runnings from every farm-yard; for whether the ammonia be fixed or escape in the air, there is no doubt it is still soluble and runs away in the water." But "if the yard be well littered, and the dunghills be covered with earth, I doubt whether, excepting on grass farms, where the tank may be necessary from the want of straw, the present management of dung can be greatly improved, though in many districts the quality certainly may be."

8138. *Artificial manures or hand-tillages*. Besides farm-yard dung, we have an infinite variety of artificial manures or hand-tillages; indeed, it may be said that there is no refuse of any trade, provided it be animal or vegetable, except tanner's bark, which is not or might not be used for this purpose. It would be useless to enumerate all, as they are well known, and the supply of many is very limited. The two principle articles are bones and rape-dust, the former suited for light land, and used chiefly for turriops. It is remarkable how very local is the use of both these manures; that of bones, indeed, is spreading, but rape-dust is not so much known in the south; and certainly where artificial manures are new, there is some unwillingness to lay out money upon them, though dung perhaps is bought at 5s. the cart-load, and carted with great labour at a long distance. When bones were first used, it was thought that unboiled bones must be better than those from which the animal oil had been extracted; but the reverse appears now to be true — not that animal oil is useless, but that it sheathes probably the bone, and checks its action upon the plant. There remains, however, in the bone another animal compound, gelatine, or the matter of jelly; but Sprengel states he has repeatedly found that bones act as strongly after they have been burnt, when the jelly of course is removed; and this is well worth remarking, because the body of the bone consists of phosphate of lime, evidently another powerful principle, which is found also abundantly in urine, and consequently in dung. But though the character of bones is established upon light land for turriops, even this manure fails on some soils of that quality, which shows that we cannot be too cautious in prescribing even the most approved remedies for the first time upon land.

8138 a. *Rape-dust* appears to be established chiefly among the farmers of Nottinghamshire, Yorkshire, and Lincolnshire. As it is one of the few hand-tillages which can be applied to clay, and as some of our south-country clays are much in want of assistance, I may mention that, according to an excellent price essay of the Wetherby Agricultural Society, by Mr. John Hannam, the best mode of using it is drilling with autumn-sown wheat at the rate of 4 or 5 cwt. to the acre, the price being about 7s. per cwt.

8139. *Rags*. Mr. Hanoam states, "20,000 tons of rags are said to be used annually by the farmers of Kent, Sussex, Oxford, and Berkshire. The price is about 5s. per ton. They answer extremely well for hops and wheat. They are usually cut by a chopper into shreds, and applied by the hand at the rate of half a ton per acre." Six or seven cwt. is considered a fair dressing for wheat upon light land; on heavy land rags are not used at all.

8140. *Nitrate of soda*, from which so much was once expected, has given various and contrary results. "There are the most undoubted proofs from numerous quarters of an enormous increase in the produce after its use; there are as undoubted instances of its utter failure: nor have we any clue to the mystery. A full statement of all the recorded experiments on nitrate of soda is contained in Professor Johnston's *Chemistry and Geology applied to Agriculture*, the most complete account of agricultural chemistry that we possess. On the same land where it gave Mr. Pusey 8 bushels of wheat one year, it gave barely 3 in the following; and having tried it largely at that time on four different farms, nowhere with success, he has given it up. Still there is evidently a principle of fertility in it, which will some day be found out, and some farmers continue to use it; but in several cases it has produced mildew in wheat and barley by forcing the crop beyond the strength of the land. By the side of the nitrate Mr. Pusey tried on several fields the sulphate of ammonia, extracted from gas-water, for the first time. It acted precisely as the nitrate of soda, darkening the colour of the plant, and lengthening the straw and the ear even more than the nitrate, but it certainly did not pay. Again we have the principle, and we must learn to combine it."

8141. *Guano*. "I can speak with more confidence of the last new manure, guano, having used it on a small scale last year, and to the extent of 5 tons in the present season. There are two circumstances in its favour before-hand: one, that it is in fact dung, though of very ancient origin, still birds' dung, which is known to be the most powerful of all manures; the other, that it has experience in its favour, 360 years. It appears to be best calculated for root-crops. On a light loam, where it has been used here this year for turnips at 3 cwt. to the acre, costing 45s., it has nearly equalled 20 loads of very good dung, and has beaten 20 bushels of bones costing 65s., as well as several other artificial manures, beyond any comparison. It has failed as a top-dressing on corn and on clover. On the whole, guano seems an excellent manure for root-crops, if rightly applied, and, as it is now sold at 12s. the cwt., a very cheap one; but I should be sorry to hear of it being tried largely on a different soil than light loam without success."

8142. *Quichlime* is so largely used on the west side of England that it bears there the name of

manure. Whether it could be adopted elsewhere, with the same advantages, is a very interesting question, as is the mode of its operation. "Sir H. Davy's theory, that it dissolves vegetable matter, is given up; in fact, it hardens vegetable fibre. Some persons think that it should be applied hot to the soil, founding their view upon chemical principles, but at present it seems better to follow practice; and where it has been mixed heretofore with five times its bulk of earth, and left so in heaps for some weeks before it is applied to the surface, it would be well to do so still. Dr. Liebig has recently discovered that lime has the power of decomposing clay, and producing potash and soda, which are manuring principles. Now, if this be the mode in which lime acts, there could not be a better course than to mix lime with earth before it is thrown upon grass land, and the old practice would agree with the true theory, as is often the case. Of all things we must guard against premature inferences from abstract science; but, be the cause what it may, the effect of lime in sweetening sour pastures is wonderful throughout the districts where it is used; and it is well worth inquiry whether it could be applied in those districts where it is at present unknown." (*Journ. R. A. S. E.*, vol. iii. p. 213.)

8143. *The new saline and other manures.* Numerous trials have been made within the last seven years with salt, nitrate of soda, ammoniacal liquor, and other ingredients of comparatively little bulk, as manures. An estimate of the value of the present state of our knowledge on the subject has been made by an eminent practical agriculturist and rent-paying farmer, Mr. Oliver, of Locheud, from which the following extracts are taken. Mr. Oliver has long been of opinion, that, "by the discovery of new fertilising substances, a great and fresh impulse may be given to agriculture."

8144. *The great desideratum in agriculture hitherto* has been to keep up and increase the fertility of the soil by returning to it, in the form of manure, more food for plants than has been carried off in the form of crops; and the progress of agriculture has been in proportion to our means of accomplishing this object. The introduction of turnips and other green crops has, within the last 100 years, added to the weight of materials produced by a farm capable of being converted into manure in the proportion of 13 to 1. Notwithstanding this, the proportion of grain crops which can be advantageously taken from land of the first, second, and third degrees of fertility, in situations where no considerable supply of extraneous manure can be obtained, does not exceed two-fifths, two-sixths, or two-sevenths respectively; whereas, on lands in the immediate vicinity of large towns, from which an abundant supply can be had, one half, and, in some instances, such as frequently occur in the neighbourhood of Edinburgh, three-fifths are advantageously devoted to that purpose. If, then, fertilising substances which can be transported at a moderate expense to those districts distant from large towns are discovered, the proportion of land so situated which may be annually allotted to the production of corn will be greatly increased. If, for instance, by means of a cheap top-dressing, such as nitrate of soda or ammoniacal water, land which is now under the six shift-course, and consequently three years under pasture in each rotation, can be made to fatten three bullocks instead of two, it is obvious that such land will be nearly as much enriched, though left only two years in pasture, as it was formerly when three years, and might therefore be brought under the five instead of the six shift-course, by which two-fifths would be annually devoted to corn crops instead of two-sixths. In like manner, if, by means of a similar top-dressing, land which formerly required to be two years in pasture can be made to maintain double the number of sheep or bullocks, the period of pasture might be reduced from two to one year, by which means one-half, instead of two-fifths, would be annually under corn crops; and in the case supposed, 50 bullocks would be grazed on a farm of 100 acres instead of 40, while the extent of land under corn-crop would be 50 instead of 40 acres, with little or no chance of the acreable produce being diminished.

This, it will be observed, would be the result simply of discovering substances adapted for top-dressing grass lands, and having the effect supposed in the preceding remarks. But if we should be fortunate enough to discover also other substances equally efficacious when applied to potatoes, turnips, and corn-crops, the means of human subsistence would be still farther augmented in proportion to the fertilising powers of the substances applied.

Mr. Oliver next inquires, 1st, What probability exists of obtaining the object sought? and 2d, By what means are we likely to prove successful?

As to the probability of discovering new fertilising substances, it may be observed, 1st, That the recent and rapid progress which has been made in chemistry and vegetable physiology, as regards their application to agriculture, has drawn the attention of several distinguished scientific gentlemen to the subject; 2d, We are not in search of a substance, such as putrescent manure, possessing fertilising powers in almost every soil and situation, and for all and every description of crop; we are (thanks to the suggestions of science) in search of specific substances adapted to specific soils, situations, and crops: thus increasing our chance of success in discovering the object of our search, and diminishing the chance of its becoming exorbitantly high-priced, if found. 3d, The experience of practical agriculturists, so far as it goes, is at least encouraging. Of several new substances tried as manures of late years, two at least, rape and bone dust, may be said to have fully succeeded. Others are under trial, with greater or less probabilities of success; and it may not be uninteresting to give the results of some recent experiments as illustrative of the progress already made in that department.

An account of experiments by Mr. Bishop, overseer to Mr. Smythe, of Methven, shows the effect of nitre, nitrate of soda, rape dust, ammoniacal water, and a mixture of nitrate of soda and common salt, applied as a top-dressing to three years old pasture in summer 1841. Five Scots acres were subjected to experiments, and, for the sake of ascertaining the comparative effect of the manures applied, the whole was reserved for hay, and the produce contrasted with that of an adjoining acre, to which nothing was applied. The expense of the top-dressing in each case was about 1*l.* 15*s.* per Scotch acre. The effect of the three first-mentioned substances was so nearly the same as to render any distinction unnecessary. The result per Scotch acre may therefore be thus stated:—

The three acres to which nitre, nitrate of soda, and rape dust were applied, produced on an average each 272 stones of hay; the acre to which ammoniacal water was applied, 410; and the acre with no top-dressing produced 136.

It thus appears that the additional produce from the three former manures was 136, and from the ammoniacal water, 274 stones per acre; being in the former case exactly double, and in the latter nearly treble, the produce yielded by the acre to which no manure was applied; and taking the value of such hay at 6*d.* per stone, gives a profit of 1*l.* 13*s.* on each of the former, and 5*l.* 2*s.* on the latter per acre. The profit from the ammoniacal water is very striking; but Mr. Bishop in some measure accounts for it, by stating the interesting fact, that the growth of timothy grass, of which the pasture partly consisted, was promoted to a remarkable degree by its application; whereas the other manures did not seem to promote its growth more than that of the other grasses in the field. This result tends to strengthen the opinion, that specific manures applicable to specific crops exist, and that the discovery of them will prove beneficial to agriculturists.

In an account of experiments furnished to Professor Johnston, of Durham, in consequence of suggestions printed and circulated by him last spring, results, on the whole satisfactory, and, in many respects, highly encouraging, were also obtained; a few of which it may not be uninteresting to state shortly, referring those who take an interest in the subject to the pamphlet (*Suggestions for Experiments in Practical Agriculture*, pamph. 8vo. 1841) for a more detailed account, and Mr. Johnston's remarks on the experiments individually.

Near Aske Hall, on the property of the Earl of Zetland, six bushels of common salt, which cost 13*s.*, applied to clover and rye-grass hay, gave one ton of hay of additional produce per imperial acre, which, at 8*d.* per stone, is worth 3*l.* 6*s.* 8*d.*, leaving as profit, after deducting the cost of the manure, 2*l.* 13*s.* 8*d.* per imperial acre, 3*l.* 7*s.* per Scots acre: 20 bushels of sout, which cost also 13*s.*, gave an increase of 18

cwt., or 90 stones, worth, as above, 3*l.*: 112 lbs. of nitrate of soda, which cost 1*l.* 2*s.*, gave 12 cwt., or 60 stones additional produce. The same quantity of sulphate of soda, which cost 20*s.*, gave 6 cwt., or 30 stones.

In a similar set of experiments made at Erskine, the property of Lord Blantyre, near Glasgow, with a variety of substances applied also as a top-dressing to clover and rye-grass hay, partly on light and partly on clay soil, favourable results were obtained, especially on the light land, 120 lb. of nitrate of soda having given an increase of one ton of hay per imperial acre; the same quantity of saltpetre or nitrate of potash gave 16½ cwt. The effect, however, on the clay land was less in every instance, 10 cwt. being the greatest additional weight of produce obtained, and that from nitrate of potash. Nitrate of soda yielded 9 cwt. 1 qr. 12 lbs., being rather less than half the quantity obtained from its application to light lands.

Mr. Fleming, of Barochan, obtained also nearly equally favourable results from the application of nitrate and sulphate of soda to clover and rye-grass hay; though he seems to have applied the latter in only half the quantity suggested by Professor Johnston: 160 lbs. nitrate of soda gave 1 ton of additional hay per imperial acre, and the same quantity of sulphate of soda about 8 cwt. only.

Mr. Fleming gives also a tabular view of experiments on a field of wheat with a considerable variety of manures, on which Mr. Johnston makes the following remarks:—"This table presents us with two remarkable results; that obtained by the use of common salt, and that from a mixture of soda and rape-dust. Thus, exclusive of the straw,

"Nitrate of soda alone gave 152 lbs. of wheat for 3*s.*, or 12*s.* 2*d.* per bushel.

"Nitrate with rape-dust gave 400 lbs. of wheat for 43*s.* 6*d.*, or 6*s.* 9*d.* per bushel.

"Common salt gave 472 lbs. of wheat for 3*s.* 6*d.*, or 6*d.* per bushel.

"The increased produce by the use of common salt is by far the most valuable result to Mr. Fleming, in an economical point of view, and plainly indicates the kind of application he can most profitably make to his wheat crops, at least on land similar to the above, and in the district where he resides.

"Neither the nitrate of soda, nor the mixture of this salt with rape-dust, gave such an increase as to repay their own cost, unless when corn is very high. It is interesting, however, to observe, that the mixture with rape-dust gave so large an increase, though the value of this particular experiment is lessened by the absence of any trial with rape-dust alone, by which the effect of each of the ingredients ought to be judged of. I have reckoned the rape-dust at 7*l.* a ton, so that 5 cwt. would cost 28*s.*; and we know that a top-dressing of this substance alone, in a somewhat larger quantity, gives a remunerating return in many of our wheat lands."

Mr. Fleming's experiments on oats, potatoes, &c. afford equally interesting results, and are deserving of the attention of all who feel an interest in agriculture; but I shall confine myself at present to that made on early potatoes in 1841, which cannot be more clearly or shortly stated than in Mr. Fleming's own words.

"All were dunged in the usual manner with farm-yard manure, at the rate of about 30 cubic yards per acre. The potatoes were all planted on the 25th of March, on the same heavy black soil. The several dressings were applied on the 20th of May, and the potatoes were all lifted on the 28th of September.

No.	Description of Top-dressing.	Rate per Imperial Acre.	Produce per Imperial Acre.	Weight of Produce of 18 Yards Drill.	Increase in Bolls.
		<i>lbs.</i>	<i>bolls.</i>	<i>lbs.</i>	<i>bolls.</i>
1	Nothing	-	66	77	-
2	Nitrate of soda	160	80	93	24
3	Sulphate of soda	200	73	86	7
4	Ditto and nitrate of soda	200	107	124	41

Note.—The peck is 35 lbs. weight, and 16 make a boll, or 5 cwt.

"This break of ground consists of a piece of poor clay, mixed with moss, about 9 inches deep; subsoil a very stiff blue till. The dung was old from the farm-yard, about the ordinary quantity (30 cubic yards per acre), spread upon the land and dug in. The potatoes were drilled in with the hoe; as the ground was wet, the plants came up but weak. The nitrate of soda was sown before the other top-dressings, and had remarkably quick effect, as it showed the third night after being sown. The sulphate of soda does not occasion the dark green colour which is seen upon the potato after the dressing of the nitrate; but there is not the smallest doubt of its beneficial effects, although not in so great a degree as the nitrate. The mixture, which is composed of two-thirds of sulphate of soda and one-third of nitrate, has a wonderful effect in strengthening the growth (which it keeps longer than with nitrate alone), and the mixture has the same effect in producing the dark green colour as the nitrate alone."

Professor Johnston, in remarking on this and similar experiments furnished by Mr. Fleming's gardener, observes: "Those who are the most sceptical in regard to the benefits to be derived from agricultural experiments, when well conducted, will scarcely question the importance of this result; the most backward in making experiments will be anxious to repeat this upon his own potatoes. The cost of the mixture to be applied, in the quantity used by Mr. Fleming, is as follows:—

Sulphate of soda, 75 lbs. <i>dry</i> , at 10 <i>s.</i> per cwt., or 150 lbs. in crystals, at 5 <i>s.</i>	-	-	£	0	6	9
Nitrate of soda, 75 lbs. at 22 <i>s.</i>	-	-	0	14	9	
			£1	1	6	

"The return for this 21*s.* 6*d.* was in each of the above cases upwards of 8 tons of potatoes."

Though the number of experiments made, and inferences which can be safely deduced from them, are far too scanty to admit of our feeling confident of success, yet it may perhaps be admitted, that they are such as to hold out sufficient encouragement for further prosecuting the inquiry.

This, I apprehend, can only be successfully done by the united efforts of the practical and chemical agriculturists; the former by instituting and carefully conducting experiments on a systematic plan; the latter by tracing the facts so obtained to the laws of nature on which they depend, and the progress will, in all probability, be in proportion to the number of practical men who can be induced to engage in making the experiments with precision and accuracy. It would be advantageous, I apprehend, in all cases to analyse the soil to be experimented on; and to ascertain by weight the kind and quantity of the material to be applied, as well as the quantity and quality of the produce obtained from the application of each description of manure. This, however, is an inquiry which cannot be successfully prosecuted by a few individuals, nor can satisfactory results be obtained from a small number of experiments. Diversity of soil, climate, situation, season, and a variety of other circumstances, combine to throw doubts on results so obtained, however carefully conducted. But this should not deter us from prosecuting the inquiry; on the contrary, it is an additional reason for all who have it in their power, whether owner or occupier, contributing their share."

Mr. Oliver concludes: "Assuming, then, that the object in view is of sufficient importance to merit the attention of this Society, and that the few experiments which have already been instituted hold out sufficient encouragement for expecting a successful result, I trust I shall neither be considered pre-

sumptuous nor over sanguine in expressing my hope that the Society will give the subject their best consideration, and afford such aid as may seem to them best calculated to secure the co-operation of practical agriculturists, in instituting and reporting the results of experiments, carefully made on a regular and systematic plan. We may not succeed to the full extent; but I cannot help thinking that a wide, fertile, and unexplored field in agricultural improvement lies before us; and although it would be rash to venture an opinion as to the results which the combined effect of science and enlightened practice may arrive at, it would be equally rash and less politic, I apprehend, to rest satisfied with our present knowledge. Let practical men, therefore, establish facts by experiments, carefully made, whether from the suggestions of their own mind or those of others; and let the duty of tracing these to the principles of nature on which they depend, be zealously discharged by men of science; and perhaps the progress may be more rapid, and the success greater, than it would be either wise or prudent to anticipate at present." (*Trans. H. S.*, vol. xiv. p. 526.)

8145. *Experiments with saline manures*, made on a farm in Essex, gave the following results, which may be depended on for their accuracy. "A field of wheat was chosen, which in the latter end of April, 1842, presented a thin plant; the salts were top-dressed over the land, by hand, on the 12th of May, and the crop mowed on the 10th of August. The soil was rather poor, consisting of a heavy clay upon a sub-soil of the London clay. 1. No manure; corn per acre, 1413 lbs. 2. With 28 lbs. of sulphate of ammonia; corn, 1612 lbs. 3. With 140 lbs. of the same salt; corn, 1999 lbs. 4. With 112 lbs. of nitrate of soda; corn, 1905 lbs. 5. With 112 lbs. of nitre; corn, 1890 lbs. The increase in the straw was also considerable in all cases, except with the small proportion of sulphate of ammonia. The total increase in the four manured crops was, per cent, in the order in which they were enumerated, 14.1, 41.5, 34, and 33.5; the cost of the manure for the three last did not greatly differ, being 21s. 9d., 24s. 6d., 27s. 6d. The profit on the outlay was, with the small dose of sulphate of ammonia, 294 per cent; with the large dose, 212 per cent; with the nitrate of soda, 138 per cent; and with the nitrate of potash, 92 per cent. The principal conclusions drawn by the author are, that the increase of the nitrogen in the crop is greater than is accounted for by the nitrogen of the manures, showing that these manures have a stimulating effect, or enable the plants to draw additional nitrogenised food from the soil and atmosphere; the considerable superiority of sulphate of ammonia over the other salts, and the greater proportional efficiency of a small than of a large dose of that salt. The sulphate of ammonia costs 17s. per cwt. It appears best to apply this salt in the proportion of about 1 cwt. per acre, at three different dressings, the first quantity when the crop, if wheat, makes its spring growth, or if of oats, wheat about two inches above the ground; the second quantity about a month afterwards; and the third quantity at the time of the formation of the ear. To meet the practical difficulty of distributing so small a quantity as one third of a cwt. over an acre, about twice the quantity of common salt or of soot may be mixed with the ammoniacal salt. These, and most saline manures, when used as top-dressing, should be supplied to the plant, when dry, some time after a shower of rain, or during hazy weather." (*G. C.* 1842, p. 839.)

8146. *Ammoniacal salts as manures*. In Switzerland, water is poured over the fresh stable-dung, so as to wash it; the fluid thus obtained is saturated with sulphate of iron, or sulphuric acid, and a liquid manure of great power is the result. It has for many years been the custom in Switzerland to preserve stable urine, to wash the fresh manure, and to collect the fluid in reservoirs, where, after fermentation has taken place, the ammonia is saturated and converted into sulphate of ammonia by sulphate of iron (green vitriol), sulphate of lime (gypsum), or sulphuric acid (common vitriol). The fluid thus obtained, when employed for watering land, produces a strong vegetation, an effect that is ascribed to the sulphate of ammonia, which is not volatile, like the carbonate, if acted upon by the sun. Fresh manure, like urine, contains ammonia, which it is important to preserve, but which is generally wasted by the common modes of managing manure. (*G. C.* 1842, p. 191.)

"Dr. Sprengel, after describing the various methods of employing liquid manure, uses these strong words:—'Whoever is obliged for want of straw to collect the urine separately,—whoever, if he be compelled to do this, mixes no water with it, or who falls also to employ some neutralising substance to combine with the ammonia, which is produced in so great a degree during the summer,—suffers a loss of manure which exceeds all belief. It is, indeed, only a gaseous substance, and not a solid material visible to the eye, which thus escapes and is lost; but for all that, it is of greater importance to the plants than any other portion of the droppings.'" (*Journ. A. S. E.*, vol. iii. p. 208.) The quantity of sulphuric acid required to fix the ammonia of urine in a state of putrefaction is 12 per cent; of muriatic acid, 34 per cent; or by weight, 12 lbs. of sulphuric acid, 34 of muriatic acid, or 19½ of sulphate of lime to fix the same quantity of ammonia. (*G. C.* 1842, p. 51.)

8147. *To ascertain whether or not a liquid contains free ammonia*. Take a tea-spoonful of common turmeric powder, and mix it into a thin paste, with a little water; keep aside one-half of the greenish yellow paste thus formed, and mix the remainder with three or four times its bulk of the liquid to be examined. If it contain any free ammonia, the liquid becomes immediately of a reddish brown colour; the depth of the colour depending on the quantity of free ammonia it contains; upon the addition of a few drops of any acid the ammonia will be neutralised, and the turmeric will return to its original yellow colour. The value of any acid or other substance as a fixer of ammonia may be well tested in this manner; the liquid must be mixed with a little of the powdered root, which it will immediately redden. The value of the fixer, or the quantity of it required for any quantity of the manure, is known by observing how much of it must be added to bring back the original yellow colour of the turmeric. Turmeric root may be procured at almost any chemist's; if only the whole roots can be obtained, they are readily rubbed to powder on a common grater, like ginger. (*E. Solly* in *G. C.* 1842, p. 868.)

8148. *Test for the presence of Ammonia*. A strip of paper previously rubbed over with petals of the common mallow will be turned green, if the ammonia predominate in the liquor. The absence of the ammoniacal smell is a very uncertain proof of the saturation of the ammonia by the sulphuric acid, and the use of the test will save the waste of acid. (*G. C.* 1842, p. 742.)

8149. *Nitrate of Soda*. The effect of this manure in increasing the value of the hay crop, has been strikingly exemplified in numerous instances. Mr. Grey, of Dilston, dressed one portion of a field with nitrate of soda, another portion with manganese and nitrate of soda in equal quantities, and a third portion was left without any dressing. This was done in May, at the expense of 26s. per acre for the nitrate of soda, and 21s. for the nitrate and manganese, and when the hay was made the produce was found to be 3 tons 88 stone in the former case, 3 tons and 21 stone in the latter, and only 2 tons and 37 stone on the space which received no dressing. (*Trans. H. S.*, vol. xiv. p. 330.)

8150. *Natural silicate of potash for manure*. Potash being drawn from the soil by every crop, requires constant renewal. The ordinary resources are, vegetable ashes of different kinds, such as wood, some kinds of peat turf, weeds, leaves, and even straw. The potash in the food both of man and beast is restored chiefly in the form of liquid excrement, which runs to waste in our town sewers, or in our farm-yard drainings. Liebig proposes to procure the silicate of potash from the ashes of burnt wood, but Mr. Frideaux, an eminent Plymouth chemist, suggests the idea of obtaining it from Dartmoor or other granite, by burning and mixing with lime. The details of the process will be found in the *Brit. F. M.*, N. S., vol. vii. p. 102.

8151. *Effect of mixed manures*. "It is probable that one of the reasons why natural manures are so much more valuable than any of the simple manures, is their consisting of many different ingredients, so that if one does not take effect upon a crop, another may. Thus we see that farm-yard dung, guano, cloacine, and compost-heaps, produce invariably a good effect; while nitrate of soda, sulphate of soda, and the other saline ingredients now so extensively employed, sometimes succeed, sometimes fail, and always succeed best when used in addition to the ordinary manures. Experiments show that plants are but little

Improved by simple substances when they can get nothing else, and that it is only when the soil in which they grow has been manured, and still retains a quantity of the organic matter so introduced, that the effects of simple substances become advantageous. This is to some extent exemplified in certain valuable experiments made by Mr. Fleming, of Barochan. On a soil which, without being recently manured, produced 6½ tons of the red don potato, 50 bushels of wood-ashes (which may be regarded as a simple manure) raised the crop only three quarters of a ton at the expense of 25s.; but 4 cwt. of natural guano, a very compound substance, added more than 7½ tons, at the total cost of 48s. (reckoning guano at its present price). But when 25 bushels of wood-ashes were added to 4 cwt. of guano, the crop rose about 1½ ton further, at the additional cost of 12s. 6d. So that, where wood-ashes were used alone, the small quantity of potatoes obtained by them cost 33s. 4d. a ton, while, in combination with guano, the same substance furnished potatoes at the expense of only about 8s. a ton. To the guano and wood-ashes 20 bushels of charcoal were added, at a cost of 7s. 6d., and the effect was to add 1½ ton more to the crop; so that now the additional crop cost scarcely more than 4s. a ton. This may be stated a little differently in the following manner:— Where wood-ashes (a simple manure) were used alone, the potatoes, obtained beyond what the land would yield without any manure whatever, cost 1l. 13s. 4d. per ton. But where wood-ashes were used in addition to more complicated manures, the crop was largely augmented, at an expense in manure amounting only to from 6s. 3d. to 6s. 8d. per ton of extra produce. These things seem to prove conclusively that the best way of using saline or simple manures for the potato-crop is to apply them in addition to common manure, and not on any account to trust to them by themselves. (G. C. 1843, p. 243.)

8152.—2258. *Guano in South America* is scarcely used but on land where maize and potatoes are cultivated. It is applied to both maize and potatoes when about 2 ft. high, at the rate of a single handful to three different stools of plants. Water must be let on within two or three days after the guano is applied. (*Mark Lane Express*, as quoted in G. C. 1843, p. 175.)

8153. *Potter's artificial guano*. Mr. Cotton, of Hildersham, Hall, near Cambridge, used it for barley, and obtained 6 quarters per acre; on grass land the ordinary produce of hay was doubled. On orange mangold wurzel the result was still more striking; a square yard dressed with common farm-yard manure produced 27 lbs.; another, dressed with Potter's guano, 40 lbs.; the heaviest root of the latter weighed 15½ lbs.; others 12 lbs. and 13 lbs. The soil was light, with chalk close to the surface. At the rate of weight obtained by Mr. Cotton, 87 tons an acre of mangold wurzel were produced, which is more than double the usual maximum; and the result of an experiment by Lord Zetland, showed that artificial guano may be employed on grass land with very decided advantage. (G. C. 1843, p. 3.) Potter's guano is commonly mixed with two or three times its bulk, with cinder siftings, charcoal powder or peat, soil, or other mould.

8154.—2259. *Cloacine may be disinfected* by earth which is very rich in vegetable matter, and by mud from ponds. (G. C. 1843, p. 260.)

Cloacine and Epsom salts, recommended by Liebig as a powerful manure for potatoes. One ton of cloacine without Epsom salts equal to six tons of the best farm-yard manure. (G. C. 1843, p. 26.)

8155.—2270. *The treatment of stable dung* by M. Schatteumann, of Bouxwiller in Alsace, is thus described by himself: "I have for many years been in the habit of treating stable-dung in a manner entirely different from that commonly in practice. At Bouxwiller I have had for several years the control of the stable-dung of 200 artillery horses quartered there in a single building, at the back of which lies some laod of my own. There I have formed a trench for manure occupying 800 square yards superficial, and divided into two equal parts. This trench is an inclined plane which rises forward and right and left, so that all the water which enters it runs down to the middle, where it collects; at that place I have a pump, by means of which I am able at pleasure to return to the manure the water which runs away from it. What water I want, I obtain from a well and pump placed by the side of the manure trench. By these means, at a trifling expense, I obtain that great quantity of water which stable-dung requires, while at the same time I do not lose a drop of the saturated fluid, which eventually is altogether absorbed by the manure by the time that it is taken away, unless I prefer employing it directly, and to replace it by pouring more pure water over the manure. Two halves of my trench are alternately filled from the stables. The litter is made up six or eight yards high over the whole surface of the excavation, trod down by the feet of the men who bring it and spread it, and abundantly watered by the pumps. In this way I have it thoroughly made up, and as much water as I want; two conditions which I consider indispensable, in order to counteract the violent fermentation of the stable-dung, which would destroy the most active parts of the manure, which are volatile. I add to the saturated matter, and I scatter over the manure green vitriol in solution, or gypsum, so as to change into a sulphate the ammonia as it is produced, and which readily flies off at a slightly elevated temperature. By means thus simple and cheap, I obtain in two or three months a mass of manure thoroughly made, as soft and pasty as that of cattle, and of great energy, as is proved by the remarkable results I have obtained both on arable and meadow land for several years. When this manure, or the liquid which flows from it, is applied to land, the most striking effects are apparent. Litters formed upon a meadow, by pouring it from the spout of a watering-pot, speedily acquire a deep rich green, remarkable among the surrounding herbage. It is, however, necessary, in forming such dunghills, that they should be so placed as to allow the water to run completely off them, and that they should be frequently drenched. Farmers do not employ anything like the quantity of water required to decompose stable-dung. Care also must be taken that the litter is thoroughly trodden down by men and horses, as the dunghills are made, partly in order to enable it the better to retain its moisture, and partly to check the excessive heating, which drives off the best parts of the manure." (G. C. 1842, p. 191.)

8156.—2284. *Calcareous manures*. Mr. Ruffin, a scientific agriculturist of great repute in the United States, has made many experiments with calcareous manures, and has proved the following propositions, which would appear to contribute much to the clear elucidation of the causes of the fertilising effects of lime:

1. That soils naturally poor, and rich soils reduced to poverty by cultivation, are essentially different in their powers of retaining putrescent manures; and, under like circumstances, the fitness of any soil to be enriched by those manures is in proportion to what was its natural fertility.

2. That the cause of the natural sterility of the soils of Lower Virginia is their being destitute of calcareous earth, and their being injured by the presence and effects of vegetable acid.

3. That the fertilising effects of calcareous earth are chiefly produced by its power of neutralising acids, and of combining putrescent manures with soils, between which there would otherwise be but little, if any, chemical attraction.

4. That poor and acid soils cannot be improved durably or profitably by putrescent manures, without previously making them calcareous, and thereby correcting the defect in their constitution.

5. That calcareous manures will give our worst soils a power of retaining putrescent manures, equal to that of the best.

The proofs of these five propositions will be found at length in the *Brit. F. M.*, new ser., vol. vii. p. 141.

8157.—2307. *Universal compost*. The following ingredients and quantities, it is said, will afford a sufficient dressing for an acre of laod:— Fifty pounds of vegetable alkali, viz., English, Russian, or American potash; thirty-six pounds, viz., four gallons, of oil of any kind; one hundred and twelve pounds, viz., two bushels, of common salt; fifty pounds, or about a bushel, of quicklime. Mix the whole together, the alkali and salt having been previously dissolved in water, and reduce the whole to such a degree of liquidity that it may be poured from the rose of a watering-pot on as much light porous soil as will absorb it. After this compost has lain some time, it may be carted out, and spread over the acre

to be manured ; but if there is a proper water cart, this manure may be sprinkled over the land in its liquid state. (See *A Dissertation on Soils and Manures.*)

8158. *List of hand manures* offered for sale at the present time (July 1843) in London : —

Agricultural salt
 Agricultural salt, fine
 Alexander's compost
 Bleaching powder
 Bone dust, and half-inch bone
 Brimstone
 Clark's desiccated compost
 Daniell's Bristol manure
 Guano, foreign
 Guano, Potter's English
 Gypsum
 Humphrey's inodorus soluble compound
 Hunt's new fertiliser
 Imperial compost
 Muriate of ammonia
 Muriate of lime
 Nitrate of soda
 Petre, salt, 4l. per ton (See Saltpetre.)
 Phosphate of ammonia
 Phosphate of soda
 Phosphate of lime

Super-phosphate of lime
 Poittevin's disinfected manure
 Poittevin's concentrated manure
 Rape-dust
 Rock salt
 Saltpetre per cwt. (duty paid) 24s. 6d. (See Petre, salt.)
 Silicate of potash
 Soda ash
 Sulphate of ammonia
 Sulphate of iron
 Sulphate of soda
 Sulphur
 Sulphuric acid
 Trimmer's composition for clover
 Trimmer's composition for wheat, with silicate of potash
 Trimmer's compost for turnips
 Urate
 Watson's compost for turnips.
 In all, thirty-eight sorts !

8159. *Estimate of tillage manures.* "Liebig," says Professor Johnston, "broadly announced 'that wheat grows well in this soil, because it contains much potash, refuses to grow in that, because potash is wanting, and that the efficacy of a fallow consists in its allowing the potash of decaying minerals to accumulate in the soil, and thus to provide a sufficiency for an after crop of corn.' What was this, but to say that, by adding potash to the soil, you may grow wheat after wheat for an unknown period? How important, and yet how simple, a discovery this! No wonder that it attracted the attention, and excited the hopes, even of the more instructed farmers; and that a kind of potash monomania should have spread among the distressed agriculturists from one end of the island to the other. Then was the flood-gate opened for new varieties of quackery, and every large town speedily produced its own chemical manure manufactory." (*Q. J. A.*, vol. i. N. S., p. 7.)

BOOK IV.

MECHANICAL AGENTS EMPLOYED IN AGRICULTURE.

CHAP. I. — *Implements of Manual Labour used in Agriculture.* (p. 369.)

8160.—2444. *Lindon's patent spade* has the blade case hardened, so as to remain much longer sharp than the common spade, which is apt to wear round, get blunt, or become broke. The price is little more than that of the common spade.

8161.—2444. *The under foot spade* (fig. 1142.) should be made very strong; the shaft, or handle, should be square, with the angles rounded off, and strongly plated over where it is joined to the cross-angle at top, and to the blade below. The blade is about fourteen inches across, and twelve inches deep; quite perpendicular, with sharp cutting edges, and a hilt or piece of iron (a) rivetted on for the feet. For the stocking up of hedges, taking the top sods off drains, and various uses where strength is wanted, this spade will be found a most powerful instrument. (*Gard. Mag.*, vol. vii, p. 86.)

1142

1143

8162.—2451. *The corn rake.* (fig. 1143.), for using after the scythe, differs from the common rake both in form and dimensions. The head (a) of the corn rake should be made of fine ash; as light as possible, but strong enough to bear the driving in of a number of iron teeth; and it should be at least five feet in length, and feruled with iron at both ends (bb). The teeth should be seven inches in length, and four inches apart, and so curved at their points that the weight of the rake may rest upon the curve, with the points of the teeth quite free of the ground when the rake is held in a working position. The points of the teeth should be thin and broad. The handle of the rake may be of light fir, and it should be full six feet in length. An iron (c), passing from the handle on each side to the head, will prevent the latter

from being twisted out of its position. A short handle (*d*), like the left handle of the scythe, and fastened at a convenient spot on the shank with an iron wedge, will facilitate the passage of the rake over the ground. (*Quart. Journ. Agr.* vol. iv. p. 363.)

8163. *Cottam's improved dibble* has two wheels which move on the axle so as to be set at any distance apart; and the dibblers on the tire can also be set at any distance, so that the implement is singularly complete for dibbling wheat, beans, mangold wurzel, &c. Figured in *Johnson's Agr. Imp.* 1843, p. 15.

Cottam's portable weighing machine may readily be carried by two men, and any description of farm produce can be weighed by it accurately and expeditiously. Figured in *Johnson's Agr. Imp.* 1843, p. 16.

8164.—2481. *The reaping-hook.* It is observed by the author of an excellent article on reaping with the scythe, published in the *Quart. Journ. Agr.*, vol. iv. p. 350., as a remarkable circumstance in the history of mechanical science in Britain, that the art of cutting down corn crops should be so inadequately supplied with instruments. The reaping-hook, unlike every other mechanical instrument, depends entirely for its efficacy on the physical powers and dexterity of the labourer. The knife and the spade are as simple in their forms as the reaping-hook; and yet the former has been displaced by many mechanical contrivances, while the reaping-hook remains in all its primitive simplicity. Its continued use in the field is attended with immense loss of time and money; and therefore, till an efficient reaping-machine is invented, it is proposed to substitute, in many cases, the scythe in its stead. The scythe is used, for this purpose, in France, Switzerland, and in many parts of Aberdeenshire, and it appears to be gaining ground everywhere.

8165.—2489. *Houden's two-edged bill-hook* (fig. 1144.). This hook is something like the letter S; it is all round sharp, and combines the powers of the carpenter's axe, the gardener's knife, the hedger's hook, the Highlander's broadsword, and the joiner's chisel. The blade is twelve inches in length, and three inches broad; the socket is eight inches long, and serves instead of a wooden handle when the instrument is used as a knife, bill-hook or axe; when it is to be used as a chisel, it must be placed on the end of a long handle; and will then, either by pushing or drawing, remove small branches from the stems of tall trees. The long socket is made a little oval in the direction of the two edges, in order to let the operator feel where the edges are. The chief use of this instrument, however, is for dressing hedges, and for that a wooden helve, or handle, of about two feet in length, is best. (*John Houden, April 30. 1830.*)

8166.—2489. *To preserve hedge-bills, scythes, sickles, and other steel instruments, from rusting,* wipe them quite dry, heat them sufficiently to melt common bees' wax, and then rub them over with it so as to cover the whole of the steel with a thin coating. The wax, completely excluding the air, prevents any decomposition from taking place on the surface of the steel; and when the instrument is wanted for use, the wax is readily removed by the application of heat. (*G. M. 1839, p. 186.*)

8167.—2505. *Grazier's sliding rule* for showing the weights of fat cattle, was invented by Dr. Wollaston for Lord Spencer, and may be considered an essential article for every cattle dealer. (*Journ. A. E.*, vol. iii. p. 337.)

8168. *Cottam's dynamometer* is so arranged as to obviate the continual vibration of the pointer usual in such instruments. This is effected by a cylinder filled with oil, which is furnished with a piston with small apertures in it, the rod of which is attached to the pointer. The obstruction caused by the oil to the quick passage of the piston, prevents any slight alteration in the draught from influencing the pointer; unless the increase or decrease is continuous, when it will immediately indicate the mean draught of the machine on trial, and not the draught of any temporary impediment, or cessation of resistance. (*Johnson's Agr. Imp.* for 1843, p. 15.)

8169. *Clyburn's dynamometer*, records on a roll of paper the distance which the plough or other implement may have passed over, and the weight necessary to draw it through all its variations. (See *Johnson's Agr. Imp.* for 1843, p. 37.)

8170.—2523. *A seed sifter*, or machine for cleaning rye grass seed, or other grass seeds, is described and figured in *Trans. H. S.*, vol. xii. p. 202.

8171.—2525. *Wire turnip baskets*, as a substitute for those of willows, in carrying turnips to feeding cattle, are recommended by Mr. Buiist in *Q. J. A.*, vol. xi. p. 112.

8172.—2560. *Slight and Lillie's straw-cutter* (fig. 1145.) is considered to be the most perfect machine of

is done by elongating the cutting-box into a nozzle, which is twisted until its orifice assumes an angle of about thirty degrees. By this arrangement, the entire efficiency of the machine is retained, while its construction and keeping in order are simplified, and its price is proportionately reduced. The framing is made entirely of cast iron: *a* is the feeding-trough, the rollers being only partially seen; *b* is the nozzle or cutting-box; *c*, *c*, the cutting bearers, with the cutters attached by their bolts; *d* is a lever and weight, which, through the medium of the bridge *e*, keeps a constant pressure on the feeding-rollers to counteract any inequality of feeding; *f* is the fly-wheel for equalising the motion; and *g*, the handle to which the power is applied. The small pinion on the fly-wheel shaft gives motion to the spur-wheel, which is mounted on the shaft of the lower feeding roller, and carries also the lower feeding-pinion. This last pinion works into the pinion of the upper roller; and, both being furnished with very long teeth, they thereby admit of a limited range of distance between the rollers according to the quantity of feed. With one of these machines, a man, assisted by a boy to feed in the hay or straw, can cut

this description that has hitherto been invented. In most of the other machines, the oblique position of the cutters, relatively to the hay or straw which they have to pass through, is found to be attended with difficulties to the workmen when replacing them after they have been taken off for sharpening. Messrs. Slight and Lillie have obtained the advantages of passing the knives in an oblique direction through the body of hay, without occasioning the slightest difficulty when these knives are removed to be ground. This

at the rate of eight stones per hour; and that quantity of cut hay is found to be sufficient for sixteen horses for twenty-four hours. (*Quart. Jour. Agr.* vol. iv. p. 349.)

8173.—2568. *Taylor's tub for measuring and weighing corn*, represented in *figs.* 1146. 1147. The tube (a) has a movable bottom (b), which, when it is desired to let the corn drop out, is raised by putting the

foot on the pedal (c) which operates on the lever (d). The valve is worked by a spindle, which passes through the collar (e). The angles at the bottom of the tube are bevelled off to allow of the free egress of the corn into the sack below it. Of course the tub should be suspended high enough above the floor to allow the corn to escape; and for this purpose a platform (f), ascended by steps, is required, which may be either fixed or movable. Up this platform the man walks who bears the sack of corn; and the mouth of the sack being previously untied, he shoots the contents very gently and gradually into the tub. The precaution of shooting the corn into the tub gently and gradually is essentially necessary, as otherwise there will not appear to be full measure. The mode of weighing may be either by Marriot's dial engine, or by a steelyard beam; the former is the most simple. This tub was invented by Mr. Samuel Taylor, and is used in the extensive malting establishment under his care at Stokeferry, Norfolk. (*Gard. Mag.*, vol. viii. p. 467.)

8174.—2571. *Baird's turnip-slicer* (*fig.* 1148.) is considered one of the best turnip-slicers in use in

Scotland. It is made, when of full size, entirely of cast iron, and consists of a standard or frame to which is attached a hopper; the frame bearing a circular plate of cast iron mounted on a horizontal axis, to

which the winch-handle is attached. This plate is cast with a thickened edge or rim, which gives it, when in motion, the effect of a flywheel. It carries two thin cutters or knives, set parallel to the face of the plate, and radiating from the centre. The thickness of the slices is regulated by the distance of the knives from the face of the plate. Each knife is preceded by three or more lancet-pointed studs, which, by slitting the turnips in passing, prepare the slices for falling in pieces when they are detached from the knives, at each revolution of the plate. This process goes on so long as the hopper is replenished with turnips, their own weight being found sufficient to hold them within the stroke of the knife. When potatoes are to be sliced, the disc above described is to be removed, and another substituted, differing from the first in having the cutting studs set closer together. In the figure, A represents the hopper filled with turnips; B, the disc of cast iron that carries the cutters; C, one of the cutting knives, the opposite one being concealed by the framework; D, the lancet-pointed studs; E, the winch-handle, partially seen from behind the machine; F F, the framework of the machine; G G, two bars which slide into staples, and serve as handles by which it can be removed from one place to another. (*Highland Soc. Trans.*, vol. x. p. 51.)

8175.—2571. *The lever turnip-slicer* (fig. 1149.) has lately been much improved, and in Scotland is

1149

taking the place of more elaborate machines. "The advantages of this form of slicer are, 1st, the certainty of cutting turnips free of even the smallest portion of waste, a property which few of the revolving machines possess in such perfection; 2d, its cheapness, the price being only from 26s. to 30s.; 3rd, its portability, being easily carried about by one person, or it may be mounted on wheels at a small additional expense. It has the disadvantage of being only capable of cutting slices, and therefore not so well adapted for sheep feeding, but it is quite as expeditious as some of the revolving machines, as a man or a boy will slice 10 cwt. of turnips in ten minutes with this machine."

8176.—2578. *A turnip-sowing machine*, which sows two rows at a time, and deposits along with the seed a regular train of hone-dust, is described in the *Quarterly Journal of Agriculture*, vol. iii. p. 718.

8177. *A machine for sowing carrots* was invented in 1833, by Mr. Daniel M'Naughton, farmer, near Irvine, in Ayrshire. Fig. 1150. exhibits the general appearance of the machine, which is similar to those in common use for sowing turnips; the essential difference lying in the apparatus adopted for discharging the carrot seeds from the seed-boxes. To the lower part of the framework is attached, in the

usual manner, the great roller (a) serving to compress the prepared ridgelets, and also to communicate motion to the other parts of the machine. This is effected by means of a leather belt or a pitch chain,

1150

passing over a pulley at the extremity of the roller, and another of the same diameter at the extremity of the axle (b); which last, in the common machines, always carries the seed-boxes, but in this performs a double purpose. The first of these purposes is, that by means of two pulleys, which are not seen in the figure, it gives motion to two other pulleys (c) of the same diameter, mounted on small axles, which pass through the seed-boxes, and are each mounted with three plain wooden pulleys; the middle one is about six inches diameter, one inch thick at the centre, and is diminished to about half an inch thick at the edges; the other two are three inches in diameter, and of proportional thickness. The middle pulleys, unseen, are armed with six stout wire prongs, the extremities of which describe a circle of twelve inches in diameter; while the smaller pulleys (at c) are similarly armed with five prongs, extending to seven inches in diameter. The revolution of these armed pulleys keeps the seeds in continual agitation preparatory to their being propelled from the box. The second purpose to which the axle (b) is applied is, to carry a small wooden cylinder, placed immediately under each seed-box, of five inches in length, and three inches in diameter, armed with four prongs or claws, extending to a radius of three inches. In the revolution of these claws they penetrate successively into the orifice of the seed-box, and perform an operation of picking or scratching out the seeds in a regular succession. The seeds are received into the funnels (f f), and pass from thence down the tubes in the usual manner to the ground, where a rut is prepared for them by the coulters. The seed-boxes are made of sheet iron, or of tin plate, of an elliptical form in the mouth; the diameter being about eighteen inches and twelve inches, with a depth of twelve inches; the cross section, taken either longitudinally or transversely, being also elliptical. The bottom of the box terminates in an oblong orifice of about six inches long by half an inch wide in the clear; the latter dimension being capable of extension, or diminution, by means of two pinching screws. Each box is covered with a movable lid, to prevent the seeds from being thrown out by the agitators. The funnels, with their seed tubes, are attached to the hind part of

the coulters, and are provided with an adjustment, by means of the slits and pinching screws in the collar bar (*k*) of the framework, enabling the operator to regulate the distance between the rows, while, by means of the slits and pinching screws (*m m*), he can regulate the depth of the rut for the seed-bed. The machine is convertible into a turnip drill by a very simple alteration. The seed-boxes and the claw cylinders are removed; and, in place of the latter, two barrel-shaped seed-boxes of the common construction are substituted upon the axle (*b*). It is then a complete turnip drill-machine. When, again, it is required for sowing onions, the turnip seed-boxes are removed, as also the collar bar (*k*). The axle (*b*) is then mounted with five barrel-shaped seed-boxes, similar to, but smaller than, those for turnips. A collar bar, with five permanent coulters, is placed in the slits (*l l*) of the frame. The coulters are perforated from top to bottom for the passage of the seed, terminating in the hind part of the lower extremity. Five funnels, corresponding to the seed-boxes, are inserted, one into the upper orifice of each coulters, and thus the machine is prepared for sowing five rows of onion seed. (*Highland Soc. Trans.*, vol. x. p. 303.)

8178.—2578. *Crosskill's improved turnip drill, with apparatus for sowing bones, ashes, &c.*, is considered a very efficient implement, and is much used by those who apply the manures commonly called hand-tillages. The price for one row drill, 6*l.* 10*s.*, and for two rows, 9*l.* 10*s.*

8179.—2581. *A press for compressing flour or meal into casks* is employed in North America, and it will be found described in the *Quart. Jour. of Agr.*, vol. iii. p. 559.

8180. *A machine for compressing peat* (*fig. 1151.*) has been invented by Mr. Walter Tod, of Longhepe,

near Hawick. The same machine might also be employed for compressing earth for building walls, and for other purposes. A more powerful and elaborate machine has been invented by Mr. Slight, the Curator of the *Highland Society's Museum of Models*, and figured and described in the fourth volume of their *Transactions*; but the simple machine of Mr. Tod, we think, will be more useful in countries where the fuel is peat; and in new countries, where the emigrant might think it advisable to build the walls of his house of dry earth. This machine consists of two strong planks of wood fixed together at each end by cross bars, and mounted upon four wheels. Two pieces of wood (*c, d*) at the distance of two inches from one another, are mortised into the plank (*a, b*) at the end *a*, and at right angles to *b*. Between the upright posts (*a, d*) there is inserted a strong beam (*a, e*) twelve feet long, and secured with an iron bolt passing through the pieces (*c, d*), which have numerous holes to admit of raising and depressing the beam (*a, e*) at pleasure. Two boxes are then made, one of wood, and one of sheet iron fourteen inches in length, three and a half in breadth, and three and a half deep. These boxes have lids which just fit them, about three inches in thickness, to allow them to sink in the boxes by the pressure. Each box is to be alternately filled with peat newly dug, the lid adjusted, and the box placed in the machine at the point *f*; a man stands at the end (*e*) of the beam (*a, e*); and, as each box is placed in the machine at the point *f*, he bends his whole strength and weight upon the end of the beam. By this means, an immense pressure is applied to the box by a single effort, and in an instant of time. Two women may fill and remove the boxes. To this way a man and three women could compress about eight cart-loads of peat in a day. One man digging, and a woman throwing out the peats, could keep the machine in full operation. The peats, when taken from the machine, are built up like small stacks of bricks, but so open as to admit a free circulation of air. The stacks put up in this way become perfectly dry, without being moved till they are taken hence. If the machine just described were to be adapted for compressing earth, boxes of cast iron, full of small holes, would answer the purpose best. The pressure is so great, that the wooden boxes frequently give way, though strongly made, and secured with iron at the ends; and even the one of strong sheet iron has been bent. (*Highland Soc. Trans.*, vol. ix. p. 374.)

CHAP. II. — Implements and Machines drawn by Beasts of Labour. (p. 389.)

8181.—2598. *Swing ploughs on Small's principle.* Notwithstanding the numerous swing ploughs that have been brought into notice within the last seven years, the best practical agriculturists who follow the Scotch system, such as Morton and Donaldson in England, and Oliver, Professor Low, and Mr. Stephens in Scotland, seem to be of opinion that the improved Small's plough has not yet been surpassed. It would appear, however, from experiments reported in the *Journal of the English Agricultural Society*, vols. iii. and iv., to be afterwards quoted, that there are some ploughs, both with and without wheels, which are drawn through the soil with less power than the best Scotch ploughs. We do not, however, consider the result of the trials which have been made as warranting us in recommending any other swing plough in preference to Small's. The best forms of this plough, according to Mr. Stephens are: the East Lothian or Small's plough, the Lancashire or Wilkie's plough, and the Mid-Lothian or Currie plough. The best makers in Scotland are Wilkie of Uddingstone, near Glasgow, and Clarke of Stirling. (*Stephens's Book of the Farm*, vol. i. p. 407.)

8182.—2609. *Wilkie's turnvest or hill-side plough* (*Trans. Hort. Soc.*, vol. xii. p. 484.) (*fig. 1152.*) as always used by Mr. Smith of Deanstou, whose fields, being thoroughly drained, have a regular uniform appearance without furrows. Each of the two mould boards in this plough is attached to the rod *b*, by two bands of iron, *c, e*, by which, with the end of the handle *d*, they are alternately raised or depressed; while the one is in a working position, the other is carried above. The rod *b*, extending to the coulters at *f*, in moving the mould-board, moves also the coulters one inch at the point, so as to give it the proper position with the point of the sock at *g*.

8183.—2616. *The Deanstou subsoil plough* (*fig. 1153.*), as designed and used by Mr. Smith on the farm of Deanstou, has been found peculiarly efficacious in rendering productive a sterile soil upon a tenacious

1152

bottom. It has been constructed so as to be of easy draught, and to penetrate to a depth of from sixteen to eighteen inches from the surface. It has no mould-board, and is intended merely to break and stir up the subsoil, without bringing it to the surface, or mixing it in the first instance with the incumbent soil. It is, in fact, a *horse-pick*, and readily loosens and throws out all stones not exceeding seventy pounds' weight. It is drawn by four horses, two and two abreast, and it is held in the usual way by one man. In working, the common plough goes before it, taking a furrow ten inches by six inches, the subsoil plough following in the bottom of that furrow, and going deeper by ten or twelve inches. When this plough is applied on a tenacious bottom, and in conjunction with parallel drains about two feet and a half deep, and distant from twelve to twenty feet from each other, it produces wonderful effects in attaining a deep and dry soil; and even on gravelly and sandy bottoms, its effects are considerable, and are especially apparent in the succeeding pasture. The cost of such a plough, with a team, or main

1153

chain for the leading horses to draw by, is about 9*l*. The ordinary swingle-trees and harnessing suit, with straps over the quarters of the leading horses to bear up the swingle-trees to their buttocks, and a chain from the collars of the hind horses to bear up the soam chain. This plough, with four horses, a ploughman, and a lad to drive, will do about an acre Imperial per day, at a cost of about 1*l*.; no charge being made for the common plough, as the land would require a furrow at any rate. Such ploughs are made by Robertson Smith, at Drip (by Stirling), on the estate of Blair-Drummond. (*Highland Soc. Trans.*, vol. viii. p. 206.) On July 7th, 1843, Mr. Smith gave a lecture on this plough in Willie's rooms, London, in which he exhibited the first subsoil plough which he had made, and which after twenty years use had not required the slightest alteration in the construction. A modification of the subsoil plough by Mr. Pusey, is known as the Charlbury subsoil plough; and another was made in Stirlingshire by Mr. Armstrong, whose implement combines a common plough and a subsoil plough, and is considered an important boon to small farmers, as facilitating among them the system of subsoil ploughing.

1814.—2637. *Wilkie's improved friction wheel plough for two horses.*—The invention of the friction wheel plough is claimed by Mr. Morton, an implement manufacturer of Leith Walk, Edinburgh, who "conceived the idea of introducing a wheel into the body or bosom of the common plough, about fifteen inches in diameter, to act as the sole," so far back as 1813. The average draught of the ploughs when the wheel was applied was reduced about one fifth, or to about two cwt. and three quarters. He manufactured a number of these ploughs both for home and foreign use; but in a short time, the farmers in the neighbourhood of Edinburgh left them off, giving as a reason for so doing, that they required more attention from the ploughmen to grease the axle of the wheel, than the latter were willing to give. (*Gard. Mag.*, vol. vi. p. 209.) We may notice it, as a remarkable circumstance, that Professor Low, in his *Elements of Practical Agriculture*, published in 1834, describes only Small's plough, without mentioning Morton, Wilkie, or any other improver, and without once introducing the subject of wheel ploughs of any kind. The invention of the friction wheel is also claimed by Mr. E. Elliott, who lately managed a farm near Shepperton, in the county of Middlesex. In the *Farmer's Journal* for August 1, 1831, an account of an experiment is given in which Wilkie's improved plough without a friction wheel was tried against the same implement with a friction wheel, and both against the common swing plough in use in Middlesex. Wilkie's plough, without the friction wheel, required four cwt. two quarters; with a friction wheel, three cwt.; and the common Middlesex swing plough, six cwt. Notwithstanding experiments of this kind, it is an undecidable fact, that the old, heavy, clumsy Middlesex plough, which it appears requires twice as much strength to draw it as Wilkie's friction wheel plough, is still that commonly used in the county! We cannot suppose that any class of men would persist in a practice which they knew to be decidedly opposed to their own interest, and therefore we unavoidably conclude that in ignorance, or prejudice, or both, we must seek for the cause of these men so obstinately adhering to the practice of their forefathers. The truth is, as we have elsewhere observed, the farmers are the only class of Englishmen who do not read.

1815.—2647. *Pearson's draining plough* has been used extensively by Sir C. M. Burrell in clayey soil, at Knapp Castle, near Horsham, in Sussex, by which the land has been increased in value one third. The drains are made in parallel lines about $\frac{3}{4}$ feet apart; they are from 24 inches to 26 inches deep; a tile is laid in the bottom; and, charging at the rate of 2*s*. a day per horse, the total cost, the tiles being made on the spot, is about 52*s*. per acre. (*G. M.* 1840, p. 102.)

1816.—2649. *Comparative estimate of ploughs by English agriculturists.* Scotch agriculturists, with scarcely any exceptions, consider the Scotch swing plough as preferable to all others; but since the establishment of the Agricultural Society of England, a number of experiments have been tried with wheel ploughs and swing ploughs of various kinds, and the general results are, that certain wheel ploughs are of easier draught than swing ploughs, and that some English swing ploughs are of lighter draught than the most approved Scotch swing plough. The progress of the inquiries of the English Agricultural Society is thus summed up by Mr. Pusey in an article published in November, 1842:—"At the time of our foundation, four years back, the Scotch iron swing-plough was stated to be the most perfect form of plough. Lord Spencer having remarked that, from his observation of ploughing-matches, he doubted whether swing ploughs had any advantage over those with wheels, a prize was proposed by our council for the best essay upon the subject, which was won by Mr. Handley, who applied the

draught-gauge for measuring the strain arising to the horses from different ploughs, and found that those wheel ploughs he tried inflicted the least labour upon the cattle. Following his example, I tried several ploughs in the same manner, and with the same result. It further appeared that there was a much wider difference in the draught of ploughs than had been suspected, and even that, of two ploughs used by two farmers in the same parish and on the same soil, one was heavier for three horses than the other for two; the old Berkshire plough costing the cattle a muscular strala of 23 stones, while Hart's improved one-wheeled plough was drawn by them with an exertion of 14 stones only. One of Messrs. Ransome's was hardly surpassed by Hart's in lightness, and it certainly made better work. The Scotch were the heaviest of the swing ploughs. The next trial was by Mr. Freeman at Haverfordwest in South Wales, who set an old Welsh plough of the country against Hart's. Here again the old plough was more severe for three horses than Hart's was for two. The old plough stood at 20 stones; Hart's at 13. The next experiments were made by Lord Tweeddale, and in these the Yester plough equalled Hart's plough in lightness. The next trial was before our judges at Liverpool, whose words I will quote from their report: "It appears that in almost every case the draught of the wheel ploughs was less than that of the swing kind; and it must not be concealed that the wheel ploughs in every case actually turned over more soil than the swing, for the share and sole of the former maintained a flat, horizontal position, whereas all the swing ploughs leant more or less to the load side, cutting to a less depth on the right than on the left-hand side. Consequently the furrow-bottoms left by the wheel ploughs were more even than those excavated by the swing ploughs." On this occasion, a wheel-plough by Messrs. Barrett, of Reading, was the lightest, marking 22 stones; Hart's the next, 24 stones; a Scotch and a Northampton swing plough the heaviest, standing each at 40 stones. I cannot but remark how little our mechanists yet know of the draught of their ploughs, when implements could be brought forward to compete for a prize at a great public meeting, some of which gave as much work nearly for four horses as others for two. The latest published record of trials is a very careful set of experiments by Mr. Hannam, of Dorchester, in Oxfordshire. Here again, as in Wales, and in Berkshire, the lightest plough stood at 13 stones, the old Oxfordshire plough at 22 stones, the Scotch swing-plough at 20 stones. The lightest plough in this instance was Messrs. Barrett's. There only remains the interesting report of our judges on the ploughs which competed at our Bristol meeting. There, again, it will be seen that the lightest plough was a wheeled one, Mr. Howard's of Bedford, which stood at 22; the heaviest, a Scotch swing-plough, which marked 44; the next heaviest, another Scotch swing-plough, which marked 36; and, in the words of our judges, it is worthy of note that the resistance of Mr. Howard's two-wheel was less by 4 stones than that of his swing plough. From these repeated trials, which have arisen out of Lord Spencer's remark, we may now come to the conclusion that wheel ploughs, as he suspected, are superior to swing ploughs, in ease for the cattle, and are also superior in the work they perform; that the Scotch swing plough in particular is very severe for the cattle; that, since in three country trials the draught of the ploughs was found to differ as two to three—that is, as two horses to three—more attention is required on the part of our ploughwrights to the easiness of their draught; and, lastly, that, since in our two public competitions at Liverpool, and again at Bristol, the draught of some competing ploughs doubled that of the winning plough, it appears very clearly that our ploughmakers, as a body, are not thoroughly acquainted with the qualities of their own implements, otherwise the race could not be so unequal." (*Journ. A. E.*, vol. iii. p. 187.)

1817. *Comparative estimates of ploughs by Scotch agriculturists.* Notwithstanding the experiments made in England under the auspices of the Agricultural Society seem to prove the superiority of wheel ploughs in many instances, yet the prejudice in favour of swing ploughs seems to remain unabated in Scotland. Mr. Slight, in Stephens's *Book of the Farm*, observes, writing in 1842, "no ploughman who has been able to wield the swing plough, will ever suffer himself to be incommoded with the addition of wheels to his plough (for he will always consider wheels an inconvenience), and this he does not from a conviction that wheels increase the labour of his horses, but because to himself they appear a source of annoyance; and here it may be further remarked, as regards wheel ploughs, that, since the wheels must always have a tendency to increase the draught, and on that account are objectionable, so also, if a plough can be wielded with equal and perhaps better effect without wheels than with them, the excuse that a wheel plough may be wielded by a man of inferior qualifications is of small value. Any man may be trained to handle a plough, though every man will not be equally successful; and since in the whole of Scotland not a wheel plough is to be found, except as a curiosity, while her ploughing is at least not inferior to that of any part of the kingdom, and as the chances are surely equal that the ploughman are not all equally good, it is evident that ploughing can be satisfactorily performed without wheels. If ploughing can thus be performed over one part of the kingdom with an implement of the simplest form and in a satisfactory and economical manner, there can be no necessity for using a more complicated, and more expensive machine to perform the same work in another part of the kingdom, where it is at least not better done or done at less expense." (*Stephens's Book of the Farm*, vol. i. p. 643.)

1818.—2664. *The Uley Cultivator.* One manufactured at Lord Ducie's iron-works at Uley in Gloucestershire, and known as Lord Ducie's, or the Uley cultivator, is recommended as the best, and, from the description, it appears to be an admirable implement, and by far the best of its kind which has yet appeared. It has been tried for paring as well as stirring, and is found to move the whole surface of the ground most perfectly. "The implement is altogether about 6 cwt. in weight. It is supplied at Uley at prices varying according to the size, weight, &c. at which it is ordered, certain forms of the implement being intended for two horses and others for four." According to the *Trans. H. S.*, the iron work is chiefly cast, the weight about 10 cwt., and the price 15*l.*

1819. *Huckvale's horse-hoc, for hoeing and thinning turneps* (*fig. 1155*). The idea of an implement of this kind occurred so long ago as 1778 to Mr. Skirving, of Strathruing in Fifeshire, one of the Scottish

1155

1156

martyrs, but we are not aware that it was ever before realised. A set of revolving blades in this hoe work across the rows of turpits, leaving the plants at regular distances. (*Johnson's Agr. Imp.* for 1843, p. 57.)

8191.—2690. *Crosskill's broadest manure sower* (fig. 1156.), which is drawn by one horse, will contain 8 bushels of manure in a state of powder. It is 6 feet wide, and can be regulated so as to deposit the manure at any given rate per acre. By placing the drill box in a vertical position the quantity of manure sown is increased, and the contrary by placing it in a horizontal position. Price 12*l.* 12*s.*

8192. *Cottam's improved scyated chain harrow* (fig. 1157.) consists of a number of serrated iron discs interwoven and linked

together with iron rods, the whole forming a surface of thirty superficial feet, interspersed with nearly four hundred points or discs. It is said that no clod can escape the influence of this harrow, and that it will be found particularly serviceable in harrowing after seed has been sown. (See *Johnson's Agr. Imp.* for 1843, p. 17.)

1157

8193.—2709. *Crosskill's clod-crusher roller* (fig. 1158.) is intended to effect the same objects as the spiky roller. It consists of a number of segments fixed on an iron axle six feet six inches long. Ploughed land once rolled by this machine is said to be reduced to a finer state than by two or three rollings and harrowings with the ordinary machines. It is drawn by three horses, and cleans itself, even when land

1158

is in the very roughest state. A number of these machines have been manufactured by the inventor at Beverley, and used by the farmers of the surrounding country. The price of a machine, including two iron road wheels to attach to it when not in use, is from 17*l.* to 19*l.* delivered in Hull. Mr. Crosskill

informs us (June 22, 1843) that the demand for this machine is from 150 to 200 annually. For the first two or three years after he invented it, he did not make above 2 or 3 annually.

8194.—2711. *Crosskill's liquid manure cart* (fig. 1519.) holds about 200 gallons. The body *a*, is made of cast iron; there is a brass valve lever, *f*, by which the liquid

1159

can be let out by the iron spout *e*, upon the spreading board *d*, and a patent iron pump *b*, which cannot easily choke or get out of order, with a flexible leather pipe *c*, 7 feet long, with a 3 feet copper pipe at the end for drawing up the liquid from the manure tank. Altogether this seems an excellent machine. The price delivered in Hull is 25*l*. Dean's liquid manure cart figured in Johnson's *Agr. Imp.*, p. 32., appears also to be a very excellent machine; cost, complete, 35*l*.

8195.—2711. *A cheap and useful water-cart* is thus described by Mr. Donaldson in the *Farmer's Magazine*, vol. viii., p. 61.:

—A barrel, holding 100 to 200 gallons, is placed on a pair of wheels and shafts in the usual way. A pump, three inches in diameter, is placed close by the side of the barrel; and to the under end of the pump is made fast a leather pipe of indefinite length, with a rose copper end, and in the pipe small copper or tin rings are placed, two inches distant, to prevent the external air from pressing together the sides of the pipe, and thus excluding the water. The cart being placed on the bank of a river, brook, or pond, and the pipe thrown into the water with the rose end immersed, a man will pump 150 gallons in ten minutes, without the trouble of having a road into the bottom of the river, and with the great advantage of the horse standing dry, and not plunged into three feet of cold water on a winter day, in the usual way of filling by ladle and standish. A stop-cock is fixed behind for discharging the water. When the cart is travelling, the leather pipe lies over the barrel, fastened by two iron catches. The barrel being filled, and driven to the place required, the leather pipe is immersed in the barrel by a hole in the top, sufficient to admit the rose end. A small iron rod screws down by the side of the piston rod, upon the upper valve, and shuts in fast. A rising main, with a check valve, is opened between the two buckets in the pump, upon which is screwed fast a leather pipe with a copper tube on the end. One man directing this pipe, and another pumping, converts the cart into a sort of fire engine, that may be very useful in cases of emergency, throwing the water forty feet horizontally, and over any house of two stories, any haystack or corn-rick; it is also very useful for garden walls and fruit trees. By increasing the size of the barrel, and by applying more power, a very sufficient engine may be made, and answering other purposes at the same time.

8196.—2731. *Mann's reaping machine* was invented in 1820, but neglected till 1826, when it was improved; and in 1832 it was exhibited at an agricultural meeting at Kelso. It differs from Bell's reaping machine in being drawn instead of being pushed, and in depositing the corn in a continuous swathe nearly at right angles with the line of direction, and on the side opposite to the standing corn. Both these are advantages which we hope will not be lost sight of by the mechanist who may at some future time make such a reaping machine as shall come into general use. An engraving, with descriptive details, of Mann's reaping machine will be found in the *Quart. Jour. Agr.*, vol. iv., p. 250.

8197.—2752. *Crosskill's improved Scotch cart* is made entirely of iron, and is peculiarly adapted for hot climates; with narrow iron wheels, having the tire $\frac{3}{4}$ in. wide, by $\frac{1}{2}$ in. deep, the cost is only 12*l*. The cart made of wood, in the usual manner, costs 10*l*. 10*s*.

8198.—2756. *An improved corn and hay cart* is exhibited in fig. 1160., and is in general use in the neighbourhood of Alloa. The advantages are, "great simplicity of structure, and, what constitutes its chief excellence, the load takes its full breadth at the very commencement, by which the centre of gravity of the load is brought lower than in either the common corn-cart, or the dung-cart with top-frame, whereby a greater degree of stability and safety against the risk of upsetting is acquired, and a greater facility of loading. Another advantage may be pointed out, in the case with which it is converted into a cart frame from the shafts, and in its place laying two single cross bars, one before, and another behind the wheels." (*Trans. H. S.*, vol. xi., p. 396.)

1160

for the conveyance of timber, by simply unholting the frame from the shafts, and in its place laying two single cross bars, one before, and another behind the wheels." (*Trans. H. S.*, vol. xi., p. 396.)

8199.—2773. *The construction of threshing machines* is everywhere very imperfect, even in Scotland, where they were first invented, and where machines of the largest power, impelled by water or steam, are erected at great expense. The editor of the *Quarterly Journal of Agriculture* has the following judicious observations on this subject:—"Were threshing machines constructed on correct and unerring principles, like the machinery of a timepiece or of a steam-engine, or even of a flour-mill, the advantage to the farmer would not only appear in the shape of cleaner threshed straw, and of economy of time and labour, but the millwright himself would derive great advantage in the certain possession of *materials*, which would enable him to erect threshing machines that would suit the particular localities in which they were to be placed. There is no way of arriving at this perfection, but by the institution of experiments to ascertain what may be the simplest construction of the threshing machine, and the best mode of applying the least quantity of moving power to execute the desired work satisfactorily. These desiderata would produce the advantage of threshing the corn at the least cost. Threshing machines are of so durable a nature that they are not often renewed; but for that very reason they should be constructed in the best manner at first. A set of patterns could be made from the results of these experiments, and lent out to those makers in the country who could grant security that they would only erect machines which were conformable to these patterns. In the course of time the country would be stored with efficient and easily moved threshing machines. The ill-judged desire of the farmer to have a machine that will not cost much money often leads the millwright to adopt expedients in its construction which he is conscious are not suited to work well together. This is one reason, among many others, to prove the propriety of landlords erecting threshing machines at their own expense, upon their farm-steadings, and of giving the tenants the use of the mills, as well as the steadings, and of obliging them to keep the machines in repair, as in the case of the buildings." (*Quart. Jour. Agr.*, vol. iii., p. 986.)

8200. *The threshing machine at Wynnstay*, the seat of Sir Watkin Williams Wynn, Bart., is considered one of the most complete in Britain. It was erected by the late Mr. John Gladstone, of Castle Douglas, Kirkcudbrightshire, about the year 1812. This machine separates the corn from the straw, and delivers both straw and corn into their proper places, without the assistance of manual labour, with the exception of feeding. The site of the mill is on a declivity, and the barn has three floors or stories; the uppermost of which opens into the stack-yard, making it very convenient for carrying in the sheaves; the second one contains the first winnowing machine; with a chaff-house, partitioned off under the stair, and

descending to the floor below, with a door into the straw-house, and one into the stieble-yard. When the corn is only to be passed through the first winnowing machine, the corn elevators and second machine are thrown out of gear, and the corn delivered on the second floor, where the bruising machine is fixed. The under floor contains the second winnowing machine with the lower end of the corn elevators. If necessary, the clean corn may be delivered on this floor, instead of into the elevator trough: the ends of both machines are inserted in the chaff-chamber. The corn is put between two grooved rollers, when the grain is beaten out of the ear by four beaters fixed on the threshing cylinder, and thrown into the rake or first shaker, when it falls through the sparred bottom into the winnowing machine hopper, while the straw is raked forward and thrown upon the travelling shaker, where it is thoroughly shaken, and conveyed into the straw-house. The corn passes through the first winnowing machine, when it is cleared of its chaff, short straws, &c.: the latter is thrown into a set of elevators which carries them up to the feeding-table, to be threshed over again with the unthreshed corn. This is a very useful appendage to a threshing-mill; it takes all the refuse from the fanners, which generally accumulates about a barn floor (or is carried up by head), whereas the elevators carry all away, and thereby leave a clean baro. The corn passes through another pair of fanners, and from thence into the corn elevator trough, and is carried from thence into the granary and thrown into the weighing machine, which is connected with an ludex in the barn on the partition walls facing the man at the feeding-table, which shows the quantity threshed very nearly. The machine occupies part of three floors. The water wheel is in a house beside the barn, and in a room above the wheel is a Scotch barley-mill, and beyond it is a very complete saw-mill, both driven from the same wheel, which can be detached when the threshing part is at work, and

the threshing part, when the saw or harley-mills are wanted. In the middle floor is an oat bruiser driven from the upright shaft; it can be put out of gear if wanted.

8201. *Description.* In *figs.* 1161, 1162, 1163., *a* is the water-wheel, eighteen feet in diameter by four feet wide; *b*, a pit wheel, eight feet in diameter, which works into a pinion, *c*, of fifteen liches in diameter, fixed on the upright shaft; *d*, a bevel wheel, five feet in diameter, which turns the drum pinion, *e*, of nine inches in diameter; *f*, the drum, or threshing cylinder, three feet four inches in diameter outside of the beaters, and four feet and a half long, with four beaters turning upwards with a velocity of 300 revolutions per minute; *g*, a bevel wheel, twenty-one inches in diameter, turning a pinion of five inches and a quarter diameter, on the axle of which is another pinion five inches in diameter, working in the face wheel, *h*, with two rows of teeth, one of thirty and the other twenty-four teeth; this pinion slides along its axle into either set of teeth; for instance, into the one of the smallest number if the straw is long, and into the other if it is short, loose, and irregular. The rollers are about three inches and a half in diameter; the wheels *i* and *j* are each twenty-one inches in diameter, working into the pinions *k*, *l*, five inches and a quarter in diameter, which gives motion to the rake or first shaker at the rate of forty-five turns per minute: it is four feet in diameter to the extremity of the teeth; *l*, two wheels, each twenty-one inches in diameter, with pinions, *m*, *m*, five inches and a quarter each, which drive the travelling shaker that receives the straw from the rake, and conveys it into the straw-house. This shaker is composed of two endless pitch chains, worked by two stud wheels ten inches in diameter, with eight studs on each, on the same shaft as the wheels *m* and *n*, revolving at forty-five times per minute. These chains are kept stretched by two smooth wheels at the further end in the straw-house: between the chains are fixed round wooden rods about two inches apart. *m* is a wheel with large teeth on its circumference, which, as it turns round, depresses the point of the lever *o*, and raises the end *p*. The lever is fixed on an axle which passes through to the other side of the shaker, with a short lever fixed on it to correspond with the lever *p*; on these levers, *p*, *p*, rests a small shaft, on which is fixed on each end, under the chains, a small drum four inches in diameter, which supports the shaker in the middle, as the wheel, *z*, moves round. The point of the lever, *o*, strikes the loose corn out of the straw, which is drawn back by the under returning rod into the winnowing machine hopper; *q* is the first winnowing machine; *r*, the second winnowing machine; both driven by a small water-wheel, six feet in diameter, and four feet wide: the water from the large wheels supplies this one. The motion of the machine requires to be uniform, which cannot be the case if connected with the threshing part. It answers better to have a separate wheel for

the machines. The clean corn passes into the elevators *s*; from thence it is carried up into the granary, and delivered into the weighing machine, *1*, by small elevators made of sheet iron, with wooden backs and bottoms fixed to a pitch chain, revolving round a studded wheel ten inches in diameter, and with eight studs at the upper end, and a small wooden roller at the bottom, at eleven turns per minute.

The corn is delivered into the weighing-machine box, 1, and accumulates until there is the weight of a measure, when the box turns on its axle, and the corn is emptied into the spout which conveys it into whatever bin it may be wanted in. At the same time the part 2 turns up, and is filled as the other, and, when full, descends as the other, and so on, while the threshing is going forward: 3 is a weight which slides up and down a rod fixed at right angles from the bottom of the weighing machine: if the corn is heavy, slide this up until it will balance a bushel of corn similar to what is to be threshed; if light, slide it downwards. From the axle of this box, a small rod proceeds to two small wheels behind the index, *u*, which turns two fingers that revolve round the face of this index; it is figured from 1 to 10. For every movement the weighing bucket makes, the longest finger moves over the space of one, and for every ten, the other finger moves one. At the end of the threshing, this finger will denote pretty accurately the quantity threshed: for instance, were the long finger at 5, and the short one at 9, there would be ninety-five bushels of corn in the bin; *x x x* are pinions five inches and a quarter in diameter, each working in wheels (*y y y*) twenty-one inches in diameter each, which give motion to the corn elevators; and likewise to the tail elevators by a pitch chain revolving round the stud-wheel *v v*, giving motion to the shaft of the elevators at eleven times per minute. The buckets are made of thin boards fixed on two pitch chains by two stud wheels ten inches

in diameter at the upper end, and a wooden roller at the lower. (*J. Gladstone, Lead-works, Chester, Oct. 29, 1831.*)

8202. *Mr. J. Gladstone, civil engineer, Chester, to whom we are indebted for the foregoing plans and description, with reference to the improved form of the threshing machine, says, "I have always understood that it was to my father we are indebted for it in its improved state.*

1163

Mr. Andrew Meikle produced the first machine of the kind, for which he took out a patent. (See *Repository of Arts*, vol. x. No. 58.) This was simply a threshing cylinder with the beaters turning downwards, throwing straw and corn into a moving screen, which separated them in a very imperfect manner; so much so, that I have heard the machines were given up, or going into disuse, simply on account of the beaters striking downwards; if the ears escaped the beaters immediately on passing through the rollers, they were bent under them, and laid close to the interior of the cylinder case, and thereby evaded the stroke of the beater. In 1793, my father made his first machine, similar to that of Mr. Meikle, with this difference, that the threshing cylinder turned upwards, and as the corn came through the roller, it lay upon the cylinder, and, being exposed to the stroke of each beater, none escaped being threshed." (See *The Stewartry of Kirkcudbright Agricultural Report of 1810.*)

8203. *The late Mr. Gladstone, of Castle Douglas, added the shaker to the threshing machine in 1794, and what he called a fetterer, for breaking off the awns of barley, soon afterwards. In 1798, he made a threshing machine, to be driven by windmill sails. In 1799, he invented the draught chains used in threshing machines, to*

equalise the pressure of the draught on the horse's shoulder. In 1805, he added a travelling shaker to the threshing machine, and soon after, a contrivance for conveying the corn from the fanners into the granary, and weighing it at the same time. By another piece of machinery the corn may be accurately measured. "On reviewing the whole," the writer, in the *Report of the Stewartry of Kirkcudbright Agricultural Society for 1810*, observes, "it is impossible not to perceive how vastly superior the machines of Mr. Gladstone are to those first contrived by Mr. Meikle, and what distinguished services he has thus rendered to the interests of agriculture. The machine is now competent to the threshing not only of one, but of every, species of grain. It is adapted of itself to separate the straw from the corn, and convey it perfectly shaken into the straw-house; to clean the corn effectually; to weigh and measure it accurately; and to lodge it securely in the granary. If driven by water, the adoption of the chain bucket under wheel saves an inner one, formerly deemed indispensably necessary, and simplifies the machinery; if by horses, the person feeding it can manage without a driver from within, and assign to each horse an equal share of the draught, or such a proportion of it as may be supposed adequate to his strength. Much diminution in the expense, as well as much improvement in the mode, of farm management has thus taken place. What was the work of several months, can be performed more perfectly, and with more ease, in as many weeks; and the labour of the winter season can now be devoted to more valuable purposes, to the collecting and formation of manures, and the better preparation of the land for the reception of the seed."

8204. *One of the most complete threshing machines in England has been erected at the Duke of Gloucester's farm at Bagshot Park; for the following description and drawings of which we are indebted to Mr. Anderson, an experienced agricultural engineer. This machine threshes the corn, hummels barley, winnows, sifts, and cleans corn, grinds it into flour, cuts the straw into chaff, and grinds bones for manure; and any one of these operations can be performed without the other. The different parts of this apparatus are chiefly taken from machines already in existence, but some also are original. It may be mentioned as a singular and melancholy sign of the times, that the parties who have the chief merit are afraid of giving their names to the public. The agriculturists of a future, and, we trust, no distant day will hardly believe it possible that the destruction of threshing machines should have been popular in England in 1830. It is worthy of notice as an argument in favour of the diffusion of knowledge among the labouring classes, that, so far from threshing machines being destroyed in Scotland, they are so much in repute among the labourers of that country, that a farmer who is without*

one is obliged to pay higher wages to his servants. This fact is well authenticated by a correspondent in the *Examiner* newspaper of February 13, 1831. (See the examination of Joseph Forster in No. 1. of *The Working Man's Companion*, and also in *Mech. Mag.*, vol. xlv. p. 323.)

The mechanical part of the machinery was executed and erected chiefly by Mr. George Miller, now residing near Bagshot. Fig. 1164. is partly a section, and partly a side view; fig. 1165. is partly a cross

1164

section, and partly an end view; and fig. 1166. is partly a vertical section, and partly a vertical profile. The same letters are applied to the same parts in all the figures.

8205. *Description of the machinery.* (figs. 1164. 1165. 1166.) *a* is an overshot water wheel 15 feet diameter, which makes from six to eight revolutions per minute according to the supply of water; on the arms of the water wheel is fixed a bevel wheel, *b*, of 128 cogs (seven feet four inches diameter), working into the pinion *c*, of 26 cogs (twenty inches diameter), on the upright shaft *d*: these wheels are below the ground floor, and entirely hid from the view.

On the shaft *d* are two driving wheels, *g* and *f*: *g* is a spur wheel of 119 cogs (six feet two inches diameter), driving the pinion *e*, of 22 cogs (fourteen inches diameter) on the shaft *h*, which leads to the floor above, and turns the upper millstone; *f* is a mitre wheel of 40 cogs (two feet diameter), working into two wheels, *i* and *k*, of the same dimensions.

On the same shaft as the mitre wheel, *i*, is a spur wheel, *l*, of 200 cogs (six feet eight inches diameter), working into the threshing machine drum pinion, *m*, of 20 cogs (eleven inches diameter); the spur wheel, *l*, also drives a wheel, *n*, of 39 cogs (twenty-two inches diameter), on the same axis of which is a small wheel, *o*, of 26 cogs (ten inches diameter), working into the wheel *p*, of 121 cogs (three feet four inches diameter), on the axis of the first rake or shaker: the wheel *p* gives motion to the intermediate wheel *q*, of 72 cogs (two feet diameter), which works into the second shaker wheel of the same dimensions as the first shaker wheel *p*.

On the spindle on which the wheel *n* is mounted is a small shifting pinion, *r*, of 17 cogs (seven inches diameter), working into the faced wheel *s*, on which are two rows of cogs, one of 20 and the other of 30 cogs each. On the same axis as the faced wheel *s* is a bevel wheel, *t*, of 20 cogs (eight inches diameter),

upper pair of crushers are driven by the wheel 6, working into a wheel, 7, in the upper crush or spindle. The crushing rollers are set to or from each other as the nature of the work may require. When the bones are large, the upper pair of crushers only are used in passing the bones the first time through, an inclined board being placed to prevent them from falling into the lower set; this board is removed at the second time of grinding, and the bones pass through the two sets and fall into the revolving circular screen 16: any bones that will not pass through the mesh of the screen are again put into the mill. The screen is set in motion by the wheel 6, working into a pinion not shown in the drawing, and by a shaft and universal joint connecting with the axis of the screen.

On the shaft 2 is a bevel wheel, 8, of 46 cogs (twenty-one inches diameter), driving the pinion 9, of 16 cogs (nine inches diameter), on an inclined shaft leading to the floor above; on the upper end of this shaft is a bevel wheel, 10, of 52 cogs (twenty inches diameter), driving a pinion, 11, of 17 cogs (nine inches diameter), on the spindle of the chaff-cutting machine.

When the threshing machine only is at work, the mitre wheel *k* is thrown out of gear by the lifting screw 12; the pinion on the flour mill spindle is raised above the spur wheel *g* by the screw 13.

When the threshing machine is not at work, the mitre wheel *i* is thrown out of gear by the lifting screw 14.

1168

8209. A portable hand corn mill with French burr stones, capable of being worked by one man, is shown in fig. 1169. The cost of this machine is 10*l.*, but there are various others adapted for being worked by two men, or by horse or engine power, at various prices, from 10*l.* to 30*l.* When made entirely of iron, they are comparatively of little use. The manufacturer of these machines is chiefly Dean of Birmingham. (*Johnson's Agr. Imp.* for 1843, p. 29.)

1169

8210. Brick and tile making machines have recently been invented by various persons. One by the Marquis of Tweeddale is in most general use, and he has recently invented a hand drain-tile making machine, which was honoured with a premium in 1843. Messrs. Ransome have also brought forward a new machine for making tiles and bricks, which received a silver medal at the meeting of the *English Agricultural Society* at Derby in 1843.

8211.—2797. A barley hummelling machine, of a simple, but very efficient construction, is described in *Trans. H. S.*, vol. x. p. 334. "The machine consists of a deal box (fig. 1170.) in the form of a truncated square pyramid, 30 inches on the side at the base, 20 inches at the smaller end, and 48 inches in length. In the interior of the box, the two lower angles are filled up with wood, so as to form the half of an interior conical surface; while the two upper angles are left void, except that their surface is thickly studded with iron spikes, driven into the wood of the box. An iron axle, or shaft, *a, b*, as seen in the longitudinal section (fig. 1170.), passes through it, in the line of the axis of the conical surface, and is supported on bearings at each end, formed in the bars crossing the ends of the box. The shaft is armed with two rows of blunt iron beaters, seven in each row, all lying in one plane; the beaters on the one side of the shaft being placed alternate with those of the other.

When the hummeller is in the working position, the opening *d*, in the smaller end is brought under the corn spout of the threshing-mill faners, supported on the foot *e*, to bring the axis to the horizontal line. The vertical lines bounding the space *f*, represent a transverse section in outline, of the faners, the prolongation *b, c*, of the shaft passing through it, and attached to the principal shaft by a coupling box at *b*. The journal at *c*, is supported on a bearing formed either on the faners or a separate framework.

The pulley *g*, giving motion to the beaters, is driven by a strap from the fan-shaft, or from such other motion as may be found convenient, giving the beaters a velocity of about 400 revolutions per minute.

"The grain received from the spout of the faners is violently agitated in its progress among the revolving beaters, and, the lower side of the case having a considerable inclination, the grain is advanced during the process towards the lower orifice, through which it is ultimately discharged; that opening is made capable of regulation by means of the slider *h*, which serves, at the same time, to retain the grain within the box until it is divested of the awn, and prevents also its being scattered about by the agitation of the beaters. The hummeller having no permanent fixture, it can be removed with great facility when a change of grain comes to be threshed.

"Hummelling machines, on this principle, are certified to have been constructed in different situations, and to have given decided satisfaction." (*Trans. H. S.*, vol. x. p. 336.)

8212.—2802. Application of steam to purposes of husbandry, showing the saving in horse corn that might be made by employing locomotive engines instead of horses. (*Quart. Jour. Agr.*, vol. v. p. 84, and p. 479.; vol. vi. p. 411.; and vol. vii. p. 225.)

1170

CHAP. III.—Edifices used in Agriculture. (p. 442.)

8213.—2811. Edifices in use in agriculture. In the *Encyclopædia of Cottage, Farm, and Villa Architecture*, we have gone into this subject in greater detail than could with propriety have been done in a

work embracing so extended a view of agriculture as the present volume. In that work, including the *Supplement* to it published in 1842, we have not only given a great variety of the very best plans for farmeries, or farm-houses, which have been executed in Britain within these few years; but we have given detailed plans, sections, and specifications of all the component buildings of a farm-yard, and of their fittings up, fixtures, and furniture.

8214.—2816. *Stables in Sweden* have the floors laid with perforated planks, so that no wet will lodge on them, and no litter is allowed. The same thing was practised in Harley's dairy. The Swedes attribute the soundness of their horses' feet to their stable floors. (*Brit. F. M., N. S., vol. iv. p. 405.*)

8215.—2819. *Doors*, which are likely to meet with obstructions on opening inwards, or themselves becoming obstructions to things passing outwards, should be mounted on crooks and bands, so as to open and throw back against the wall, or what is better, into a recess in it protected by a lintel. The door may be held in its place in the recess by a bolt. (*Book of the Farm, vol. i. p. 118.*)

8216.—2847. *Barn floors*, to be proof against the ascent of rats from beneath, should be formed of wood, or covered over with asphalt, which is found to be proof against every kind of vermin, and also to bear the action of the flail. "The sleepers upon which the floor is laid, should rest upon stone and lime building, raised two feet from the ground, close to the barn wall; and the mortar and stones must be packed close to the upper edge of the sleepers, up to the deals of the floor. According to the width of the barn, the sleepers should rest also upon one or two supports of stones, so hewn as to permit no footing to any vermin; and which will support the middle of the floor. By this contrivance, the space from the floor to the ground is made too deep to permit any small animal staiding on its hind legs and gnawing the floor, while dogs or cats can easily pass under it." (*Quart. Jour. Agr., vol. iii. p. 995.*)

8217.—2856. *Hay barns* are little used in Scotland, notwithstanding the moisture of the climate compared with that of England. In making meadow or natural hay, they have lately been found of great advantage in Scotland; where meadow hay of the same degree of dryness that would rot if put into a rick, will keep perfectly if put in a hay shed. This arises probably from an increased evaporating surface, and the hay being put in loosely. Were landlords sufficiently alive to the value of the hay barn, one would be built on every steading in districts where meadow hay is made. (*Trans. H. S., vol. xiv. p. 697.*)

8218.—2876. *Labourers' cottages*. Having entered on this subject at length in our *Encyclopædia of Cottage, Farm, and Villa Architecture*, and there given numerous plans, accompanied by descriptions, specifications, estimates, and critical remarks, we shall not here repeat any thing which has appeared in that work. Nevertheless, as the improvement of the dwellings of country labourers is what we have most at heart, next to the education of their offspring, we cannot let pass this opportunity, without contributing something farther to the subject; we shall, therefore, give one article, entitled the *beau idéal* of an English labourer's cottage, by a most benevolent and enlightened clergyman, who adopts the signature of Selim; and another on building cottages with mud walls, by a professional man, Mr. Wilds of Hartford. This gentleman, having been in North America, is deeply impressed with the importance of this kind of knowledge to emigrants, who, at present, too frequently build their houses of wood, and consequently, sooner or later, suffer from accidents by fire, or, what is almost as bad, live in continual fear of doing so. To these we shall add the design of a stone-walled agricultural labourer's cottage, recently built, along with a number of others of the same kind, on the estate of William Laurence, Esq., in Gloucestershire.

8219. *The beau idéal of an English labourer's cottage*. The leading feature in the exterior of a labourer's cottage should be a picturesque simplicity, which is a sort of medium between superfluous decoration and unmeaning plainness. This appears to be the only character of which a cottage is susceptible; for, as plainness is uninteresting, so it offends our sense of propriety to see a building of this description bedecked with costly fantastic ornaments, which are evidently unsuited to the simple unrefined habits of humble life. But a picturesque simplicity is seldom the pervading character of modern ornamental cottages. They are often decorated with turrets and battlements in the castellated style of Gothic, or in the monastic style, with elaborate painted windows, crosses, and pinnacles; nay, instances have occurred where the two styles have been united in the ornaments of a cottage dwelling. It cannot be denied, that a picturesque effect is produced by this mode of embellishment; all I contend for is, that such ornaments are altogether unsuited to a dwelling of the lowest order. Should it be objected, that, if we reject this mode of decoration, we must have recourse to ruin and decay to produce a picturesque effect; I answer, that as much of this effect as we may require may be produced, I think, by irregularity of form and outline; and irregularity is, in fact, the only effect aimed at by the use of Gothic ornaments. But as my object would be only a picturesque simplicity, I should discard useless and inconvenient irregularity. In so small a building as a cottage, a slight irregularity would be sufficient to give it a picturesque character, and the simplest embellishments would give it an ornamental effect; and this, I conceive, is all we require to produce what I understand by picturesque simplicity. Though I am an advocate for simplicity, however, in cottage architecture, I would in some measure sacrifice even simplicity to the picturesque; because the beauty of a neighbourhood frequently depends upon the style of the labourers' dwellings. These are the prevailing buildings in all rural scenery. They are occasionally so placed and associated with surrounding objects, that they present the most striking features in the landscape; and the effect of particular scenes is not unfrequently produced by the forms and situations of the cottages. Hence, a picturesque exterior is one of the chief requisites in an ornamental cottage; but it should be a simple pleasing style of picturesque, which does not interfere with internal comfort and convenience; produced by slight irregularity of form, and by unobtrusive and appropriate ornaments. I am not at all disposed to sacrifice internal comfort to outward effect. I think a picturesque exterior may always be united with a comfortable interior; and I now proceed to give the description of a cottage in which I shall endeavour to exemplify the union above alluded to.

8220. *Site of the cottage*. As the comfort of the inmates and the general effect of a building depend materially on its site, the situation of a cottage is the first thing connected with it that requires consideration. A general rule for the situation of a cottage is, that it should be properly supplied with water; be dry, airy, and sheltered; and admit of a sufficient allotment of garden ground adjoining the house. And I am an advocate for rather a scattered village, because, among other advantages, it affords an opportunity of erecting the cottages in proper situations. A damp situation is the principal thing to be avoided. It is a nuisance in all cases; but especially to a labouring man, who cannot afford to spend any thing in draining, or much in fuel; whose health is his only source of wealth, and to whom it is necessary, both for health and comfort, that he should have a dry home to come to after long exposure and severe exertion in the open air. Besides being dry, the site of a cottage should be airy and sheltered. Every dwelling should have a proper circulation of air around it, or it cannot be dry; and a cottage should be sheltered, that it may be warmed with less expense of fuel: the shelter should be so placed, however, as not to interfere with a full exposure to the sun. We will, therefore, suppose our cottage placed on a gentle eminence in the neighbourhood of other dwellings; and sheltered, in part, by higher ground at a distance, by a wood, or by groups of trees, and in part by its own orchard and outbuildings; some of these so placed as to appear above the roof, but leaving it fully open to the south. The situation would be more desirable if a stream of water happened to run near, or if it adjoined a common, or a public road; and it would thus possess the advantages of dryness, shelter, and cheerfulness, besides others which are of consequence to the general effect of the building to be erected upon it.

8221. *Style of the cottage*. Having fixed upon the site of the cottage, the next thing to be considered is, in what style is the building to be erected; for even a cottage, I think, should present some appearance of architectural style. I have already contended that the Gothic is inappropriate to a dwelling of

this description, and a building in the Grecian or Roman style, upon so small a scale as a cottage, must be plain and formal, and deficient in picturesque effect, unless it be an elegant and costly edifice. There remains, therefore, only what is called the old English style, which is, I think, the proper style of architecture for an ornamental cottage. It admits of great irregularity and variety of form; and is suited to houses of all dimensions. Its ornaments may be adapted to the smallest dwellings; and the irregularity it allows in the exterior, may be made conducive to infernal convenience; and it has this peculiar advantage, that we have many beautiful models of old English cottages in all parts of the kingdom. It has, also, this additional recommendation, that it is not an expensive style, and may be executed in almost any kind of material. A cottage in this manner may be built of stone, brick, flint and chalk, or even of wood and plaster; and the building may be so formed, and the materials so disposed, as to give a picturesque and decorated effect, without the use of any expensive ornaments. The desired effect will be given by the tall chimneys; by the high pointed gables, with, perhaps, small-pinnacles at the angles; by the mullioned windows and the labels over them; by a projecting porch of one or two stories; and by the stringcourses round the building. In this style much of the ornamental work might be of wood. For instance, the whole of the upper story might be formed of a wooden framework, filled in with brick or plaster. This wooden framework would project beyond the wall which supported it, and produce a pleasing effect of light and shade, and a variety of ornament might be given by the form of the frame itself, which shows on the outside, and by the arrangement of the bricks, or by the patterns impressed upon the plaster, with which the interstices of the frame are filled up. In these half timber houses might be introduced a kind of wooden oriel window, which is one of the most striking ornaments in many old cottages. The gables over such a building might have handsome barge boards with carved pinnacles at the points. These pinnacles, if small and in good proportion, would be in keeping with a mode of building which admits of a great variety of embellishment, and is well suited to a district where stone and other substantial materials are scarce and expensive. As it possesses these recommendations, we will adopt the old English style for our present purpose, and suppose the cottage erected on a dry, airy site, well protected from the prevailing winds, and surrounded by its garden, orchard, and out-buildings. It would, of course, present one regular front. This we will suppose divided into two equal parts by a porch of two stories to the centre; in the ground story of the porch might be an arched entrance; in that above, a neat mullioned window of two lights, with its proper label; and over this a low gable terminating in a simple ornament. On each side of the porch might be a mullioned window of three lights, placed immediately under the stringcourse, which divides the house into two stories; the low wall above these windows would be plain, as the windows of the rooms to the chamber floor would be most conveniently placed in the gables at the ends of the house. In the centre of the roof, behind the porch, would be the stack of chimneys, which should be tall, and rather the handsomest member of the building. It is the most conspicuous part of it, and the general effect of the whole would depend materially upon the form of the stack of chimneys. This front would afford an example of what I understand by picturesque simplicity. There would be a certain symmetry and unity about it; it would present no superfluous ornaments, nor any unmeaning irregularity. But still it might be made a highly ornamental cottage, and might contain many internal conveniences which are not always found in buildings of more pretension; and it would possess enough of the picturesque character to make it harmonise with the surrounding scenery.

§222. Interior accommodation. Such, then, would be the exterior of the cottage: what are the accommodations it should contain within? A comfortable labourer's dwelling should, in my opinion, consist of an entrance porch, kitchen, washhouse, pantry, and small cellar, a parlour or spare sitting-room, and at least three bedchambers. These apartments are all necessary for the comfortable accommodation of a family, even in humble life; and, as we are attempting to describe the *beau idéal* of a cottage, we must suppose it to contain all these conveniences, which we proceed to describe in their order. A porch, besides being an important ornamental appendage to a cottage, is necessary for the comfort of the inhabitants, to which it contributes by sheltering the entrance from wind and rain, and thus assisting to warm the interior. A cottage porch should be of small dimensions, the floor on a level with the rooms within, and raised a step or two above the surrounding surface. It should be paved and ceiled; and if it had a seat on each side, it would form a kind of summer-house, where the females would often sit at work in fine weather. Over the seats might be shelves, on which small tools might be put away, and seeds, onions, &c. placed to dry. There should, of course, be a scraper at the steps, and a mat within the entrance.

§223. Kitchens. From the porch you should pass through a small lobby to the kitchen, or common sitting-room of the family, which should be a sufficiently spacious, light, and airy apartment. The object of the lobby is, that there may be two doors between the living-room and the outer air, which will assist in keeping the room warm with a less expense of fuel. There are some defects, usually found in the interior of old cottages, which ought to be avoided when new ones are erected. I allude to the lowness of the rooms and doorways, damp floors, and smoky chimneys. If we were to judge of the people by the houses they inhabited, we might suppose the former generations of our "bold peasantry, their country's pride," to have been absolutely a race of dwarfs. For, if you would avoid a broken head, you must actually creep through the doorways of ordinary cottages; and, after escaping the perils of the doorway, a man of good stature can seldom stand upright in the house without being in danger of knocking his head against the bare rafters of the floor above, or against the bacon-rack, the scythe-blade, the reaping-hooks, and twenty other things commonly suspended from the ceiling. Now these low rooms and doorways must be a continual source of annoyance to the inhabitants; and, therefore, I would lay it down as a general rule, that no cottage kitchen should be lower than eight feet, and every cottage doorway above six feet. Another common defect in cottages, is the dampness of the ground-floor. In the case of old cottages, the ground-floor is usually much below the level of the surrounding surface, and you generally descend into the house; and, even in modern cottages, the floors of the lower apartments are seldom sufficiently elevated. The consequence is, that, in many situations, the cottages are damp and uncomfortable for five or six months in the year; indeed, I know several cottages in which springs of water regularly break through the kitchen floors during the winter season. To avoid this inconvenience, I would propose, as another general rule, that the ground-floor of every dwelling in this description should be eighteen inches or more above the surface, and that the earth on the outside should be the same distance below the level of the floor. Under every brick or stone floor there should be a substratum of broken stone or flints, varying in thickness according to the nature of the soil and situation. On a damp site, it may be necessary to have this substratum two or three feet deep, with drains and air passages through it; and the earth should have a good slope from the walls on every side, so that the water from the roof may escape rapidly, and not sink into the foundation. Another prevailing misery in cottages is, a smoky chimney. This is a proverbial nuisance to every one; but it is especially so to a cottager, because, over and above the dirt and discomfort occasioned by the smoke, half the fuel is wasted in a fireplace which has not a proper draught. This nuisance in cottages generally arises from the large size and straightness of the flue, and from the lowness of the chimney on the outside, or from the currents of air occasioned by the bad positions of the doors and windows, which seldom fit close. From whatever cause it arises, a smoky chimney is a prevailing misery in labourers' dwellings, which a judicious builder may generally contrive to avoid; and I refer the reader to some sensible observations upon this subject in the *Encyclopædia of Cottage, Farm, and Villa Architecture*. After this digression, let us return to the cottage kitchen. As this is the common sitting-room of the family, in which most of the household operations are to be performed, it should be a light warm apartment, of a good size. We will suppose it sixteen or seventeen feet square, and eight feet high, having a window in the east and one in the west side. It would

thus have the benefit of the morning and midday sun; an important advantage to a cottager, in whose domestic expenditure coals and candles are considerable articles. Stone is, I believe, the best material for the floor, as being most durable and easily kept clean, and in these respects greatly to be preferred to brick. Boards, besides that they are liable to occasional accidents by fire, could scarcely be kept clean in a cottage living-room, and would soon be worn out by the iron-bound shoes of the inhabitants. Of course the walls and ceiling should be neatly plastered and whitewashed, and there should be a proper skirting-board round the room, and attached inside shutters to the windows. The fireplace should be so situated as to be well lighted by one of the windows; and it might be a close or open fireplace, according as wood or coal happened to be the common fuel of the district. I observe that the old-fashioned open fireplaces are generally preferred by cottagers, on account of the snug warm seats they afford in the chimney corner, as it is called, and which is too often the only warm place in the house. I am aware that these fireplaces do not economise fuel, or afford the best means of warming the room; but they present some advantages to the cottager; that is, they are capital places for drying bacon and wet clothing. Either wood may be burnt in them on the hearth, or coal in a moveable grate; and, as the fire is on or near the ground, it certainly diffuses a considerable heat around it. The mouth of the brick oven also generally opens in the back, or side, of the chimney, so that all the ashes and litter, together with the heat produced, are confined to one place; and, should this place be near the centre of the building, the mass of warm masonry must have the effect of raising the general temperature of all the apartments. In the coal countries these open fire-places are not usually met with; but, where wood is the principal fuel of the peasantry (as it is in the district from which I write), I would indulge their prejudice in favour of an open chimney, and will suppose one in the cottage kitchen, with the mouth of the oven on one side of the back, and on the other a small copper set in an arch, having a flue through the arch by which the steam might escape up the chimney. It would be tedious to describe minutely the various articles of useful and ornamental furniture found in the kitchen of a thriving cottager; indeed, to those unacquainted with rural life it would be difficult to convey an idea of the multifarious collection often displayed in a room of this kind. A tidy labourer's wife is sometimes as fond of knick-knacks, and as proud of displaying her various stores, as the richest lady in the land. The peasantry have, in fact, many of the prevailing tastes of their superiors in wealth and refinement, and love to ornament their houses with plants and flowers, prints, and plaster casts, and ornamental china. The kitchen is frequently as much crowded with useful and ornamental furniture as a modern drawing-room. The mantel-shelf displays a range of flower-vases, images, and painted busts of the favourite heroes of past and present times, mixed with some of the bright cooking utensils. The walls are sometimes thickly hung with coarse engravings, ballads, and printed papers, moral, religious, and political, and with various other things; among which are conspicuous the labourer's club rules, and his staff, or some peculiar implement denoting his occupation, such as the polished head of the shepherd's crook, the market-day carter's whip, or the spare flail of the thresher. The window is seldom without its collection of exotics, thriving surprisingly, some of them in spoutless teapots and other discarded vessels; and on the window seat, or on a shelf near, a little heap of books; the bible, in a neat cover, reverently placed apart from the rest. Even the ceiling is usually furnished with that desirable ornament, a well-stored bacon-rack, shoes, tools, bags of seeds, and a host of other things. But the pride of the cottage housewife is her dresser and shelves. Here she displays her little store of glass and earthenware of the better kinds, with her best plated spoons, her bright pewter plates, and clean wood trenchers, frequently arranged with considerable taste and effect. Some of the conspicuous articles will not, perhaps, bear a close examination; and are, in fact, useless; though wisely kept for show; but she contrives to hide defects, and the shelves often exhibit specimens of old glass and china, which a collector of such rarities might covet. There are, indeed, few more picturesque interiors than that of the well-kept kitchen of a thriving labourer who happens to have a tidy wife; and I have often been much pleased at the air of decent comfort, and at the decorated effect produced by the miscellaneous collection seen in a room of this description.

824. *Furniture of the kitchen.* Among the more prominent articles of furniture in a thriving labourer's kitchen, the clock, I think, takes precedence of the rest in the owner's estimation, and its well-polished case is generally a conspicuous object. Next to this we may rank the best dining-table, often one of those interesting old oak tables with rounded leaves, and as many curiously-turned legs as a spider. The best tea-table, turned up, with its pillar and claw, in a corner; and the dough trough with its clean white cover, would next attract attention. To these we may add the great arm-chair, with a patchwork cushion in the bottom, for the *man*, as he is emphatically called here, in which he sits in the evening in a sort of rustic dignity, surrounded by his wife and children, forming, in many cases, a happy, interesting group: the wife and elder girls at work, perhaps, while one of the boys is standing by the father, reading, or repeating what he has learnt at school during the day. I hope there are many such evening groups still to be found in our cottages, in spite of politics and the beer shops. This reminds me of another piece of furniture which I should wish to see in every cottage; I mean, a shelf of useful and instructive books. You seldom enter a cottage without finding some books; indeed, as far as my observation extends, I should say that a taste for reading is becoming more general among the labouring classes; and it ought to be encouraged, as a source of instruction and enjoyment, which has a tendency to improve the morals and better the condition of the peasantry. What a wide field of knowledge and enjoyment is cut off from the labourer who is unable to read, or who has no taste for reading! Half the leisure time of such a person must be spent in drowsy indolence, or in the debasing scenes of the ale-house, to which he is almost driven in self-defence, to relieve the tedium of idleness and the oppressive vacancy of his mind: the want of this resource and comfort is severely felt by the uneducated labourer in times of sickness and old age, when a long active life is necessarily exchanged for a state of total inactivity. There are few of the rising generation entirely without education. The stores of knowledge will therefore soon be opened to all the labouring classes, and they should be encouraged to use them to their own advantage, by having their attention directed to useful and improving books. "A little learning," if not properly directed, "is a dangerous thing."

825. *Back-kitchen and washhouse.* Besides the kitchen, or common living-room of the family, every complete cottage should have a small washhouse, in which the brewing and washing, the dirty and all work of the family, may be done. Here I would have shelves for the saucepans, and other unsightly articles, used in cooking; also a set copper; and a proper sink, communicating, by a drain, with the dung pit or a cess-pool. Most cottages are without a washhouse; but a small place of this sort is absolutely necessary to every dwelling; as, without it, the living-room can never be tidy or comfortable, and I may add, wholesome. For want of a washhouse, the cottager is compelled to hang up his dead pig, and even to salt it, in the living-room; and as there is no other place in which to do the dirty work, and put away the dirty things which must be used in every family, the room is generally in a litter, and has an unwholesome, disagreeable smell, which must be prejudicial to the health of the inhabitants. But what I would chiefly insist upon in the washhouse is a proper sink to receive the slops and dirty water. Very few cottages have any convenience of this kind; and consequently all the slops are thrown out at the door; and you can scarcely approach a cottage, in many cases, for the abominations that surround it. Besides this, the entrance is commonly surrounded by a sort of impure air, which is extremely offensive, and a drain, which may carry the dirty water to a sufficient distance from the house. Even a pretty cottage will have a squalid, miserable appearance, when the door is surrounded by filth; and I have seen villages, with the houses built on each side of a narrow road, which were absolutely disgusting in consequence of the nuisance referred to.

8226. *A small larder or pantry*, having a window in the outer wall, should communicate with the kitchen or wash-house. This is a necessary convenience not often found in labourers' dwellings, in which the provisions are generally kept in nasty close cupboards, or on shelves in the living-room, where they are liable to get spoilt, and are exposed to dust, smoke, and all sorts of impurities. For want of a better place, even the beer or cider barrel is kept in the warm kitchen, and in such a situation the liquor, of course, soon becomes sour and unfit to drink. No cottage, therefore, should be without a cool airy larder; and a small place of this kind might be easily contrived in every dwelling, with little or no addition to the cost of building. As I am describing the *beau idéal* of a cottage, the owner of which might keep a cow, I will, in the present case, suppose the larder of a sufficient size to contain both the milk and provisions. We can scarcely expect a distinct place for each in a labourer's cottage, and it would be unnecessary. There might be separate shelves for the milk and provisions, &c.; hanging shelves for the small cheeses, which a mausing woman would of course make during the summer season, even from her single cow.

8227. *Cellar*. If the floor of the larder were sunk the depth of a yard below the surface, the beer might also be kept in it; but a cottage would not be quite complete without a small cellar, to contain the beer, and the potatoes and other roots. A cottage with land would grow a large supply of potatoes and other roots, for his cow and pigs; and it would save a great deal of time, and prevent waste, to have the roots always at hand in the cellar, instead of burying them out of doors in pits, which, when once opened, are not secure against frost and wet. I would also recommend a cellar in every new cottage; because I look forward to the time when every labouring man will be able to brew his beer at home. A hard-working labourer requires a certain quantity of wholesome beer; and if he has not this at home, he is sure to go to the alehouse, where he gets into the worst company, spends in intemperance what is required for the maintenance of his family, and in many cases becomes a confirmed drunkard. It would be a work of charity, therefore, to encourage brewing among the labourers; and, as a means of promoting it in country villages, I would suggest a plan of having a small set of brewing utensils, for the use of the cottagers, in the care of a fit person, who would lend them, in the parish, under proper regulations. The cost of the tubs, &c., would be inconsiderable, and might be easily raised by subscription among the wealthy inhabitants, or even among the cottagers themselves. A penny or two paid for the use of the tubs would be sufficient to keep them in repair. The want of tubs is one of the chief obstacles in the way of cottagers brewing, which this plan would remove. And I am persuaded it would succeed, as I find that even a whitewashing brush, kept to lend out, has been a great promoter of cleanliness.

8228. *The parlour*. Should this paper ever fall into the hands of a labouring man, he would probably smile when he came to this part of it, in which I am to speak of the parlour. Many persons will consider a parlour an unnecessary luxury in a labourer's dwelling: it would be seldom used perhaps as a sitting-room, but as a spare room it would be a great convenience in the case of a large family, and should not be omitted in an attempt to describe a complete cottage. Most thriving labourers are in the habit of receiving their distant friends and relations, at certain seasons, such as the village feast, at "the tides," at christenings, &c. The parlour would be useful on such occasions, both as a sitting-room and additional bedroom, as it would be also in case of sickness, or death. If for no other reason, I should be an advocate for a spare room of this kind in every cottage, as a receptacle for the dead. As cottages are at present, there is seldom any possibility of separating the dead from the living, when one of the inmates dies: when such a calamity occurs, the corpse must be placed either in the sitting-room or bedroom; and I have known instances of a large family sleeping for several nights together in the same room with a corpse, even when death has been occasioned by an infectious fever. To my feelings there is something unspeakably terrible in this dreadful mixture of the living with the dead; and if the idea be so appalling, what must the reality be to those who suffer it! A small parlour, therefore, containing an occasional bed, would prevent the necessity for this most disgusting consequence of death in a labourer's family; as, with the possibility of making up an extra bed for some of the inmates, one of the bedrooms might generally be appropriated for the reception of the body, between the death and the funeral. I would have the parlour a plain comfortable room, ceiled and plastered, with a stone or boarded floor. It should, of course, have a small fireplace, and attached inside window-shutters. Besides the chairs and table, the furniture should comprise a closet bed complete, as the room would probably be more used as a bedroom than as a sitting-room. A corner cupboard to receive the best china and glass, a few groceries, &c., would also be useful; and a chest of drawers for the linen of the family would not be out of place. I should whitewash the walls, because it could be done by the cottagers themselves when requisite, and colour-washing is, of all things in this way, the most difficult to do well to the uninitiated. The cottager's wife would decorate the walls and the room generally with some of her best knick-knacks, books, flowers, &c.

8229. *Staircase*. As we proceed to the upper story, we must say something of the staircase. This, in old cottages, is generally the most awkward thing possible, and placed in the most awkward situation; a narrow, twisting, dark, and, to a stranger, a dangerous ascent, compared with which a common ladder would be luxurious, and usually leading into a bedroom which is a passage room to another, when there happens to be two. Our cottage must have a proper light staircase, ending above in a small landing, to which all the bedroom doors should open.

8230. *Bedrooms*. Every cottage for a family should have at least three bedrooms, so that the parents, and the children of each sex, might sleep in separate apartments. The rooms need not be large, but they should be light, airy, comfortable, each having a window that will open. They ought to be ceiled, plastered, and whitewashed; with boarded or plaster floors; and, if possible, a fireplace in each, in case of sickness, or merely for ventilation. I am rather an advocate for the plaster floors used in the north of England for cottage bedrooms, as they are a security against accidents by fire; and, when properly made, are more comfortable, and have a more cleanly appearance, than the rough ill-jointed boards commonly found in cottage chambers. I have seen these floors nearly as hard as stone, and, when washed over with pipeclay, they have a very neat effect. It is unnecessary to describe the furniture, which, of course, should comprise the requisites for comfortable repose and cleanliness in a humble way. You seldom find bed-curtains in a cottager's chambers; I have heard them express a dislike to bed-furniture; and, in a tolerably warm room, it is, I think, a luxury we might all dispense with, as being rather prejudicial to health than otherwise. Cottagers generally use stump bedsteads, with head-boards, and I have observed in cottages ancient specimens of oak bedsteads, with curiously carved head-boards and legs. Old carved oak clothes-chests are also frequently met with, which would be valued by the antiquary. There are few things connected with labourers' dwellings, which so much need reform as the bedrooms. In this neighbourhood half the cottages have only one chamber, and this sometimes a low miserable apartment in the roof, open to the thatch; with the walls unplastered, and without a window that will open; in fact, a place little better than a hay-loft. And here the whole family sleep; old and young, married and single, without even a curtain to separate the sexes. Can we wonder at the gross immorality which is so lamentably common among the young peasantry, when the sense of delicacy is destroyed even from infancy? I would therefore press this subject on the attention of all benevolent owners of cottages, and especially on our great landed proprietors, who are generally well disposed to contribute to the improvement of the peasantry. The first step towards the improvement of their morals must be to increase the number of bedrooms in cottages. Let me, then, urge this upon those whom it concerns, in the words of "Nature's sternest painter, yet the best," the poet Crabbe: —

"These thoughtless people part,
Nor let the ear be first to taint the heart."

8231. *General remarks on the interior.* Having described the interior of the cottage, let me pause and enquire, whether there is any thing in the description which can be justly considered superfluous, and not absolutely necessary for the comfortable accommodation of a labourer with a large family. I am not aware of any thing to which a reasonable objection can be offered unless it be the parlour. The idea of a cottage parlour may lead some to exclaim, "The man must be a fool! Who is to do the work, if labourers are to be fine folks, and sit in parlours?" My friend, are you not offended at a name? Let us change the high-sounding title of this room of all works, and perhaps you will not object to it. Call it the spare room, for instance; a place to be used for all sorts of purposes: for such it would be, in fact. Unless when the wife was confined, or any of the family happened to be recovering from illness, I will answer that it would not be used as a parlour above six times in the year. It would frequently be let as a lodgino for an occasional labourer in the parish. In rainy weather, it would be degraded into a drying-room, and be filled with wet linen; and the floor would often be found half-covered with onions and seeds laid there to dry. Do not the various uses to which such a room may be applied make it a desirable addition to a cottage, even though it may be called a parlour? If such an apartment would have a tendency to give the peasantry fine notions, I should be the last to recommend it. For I hate fine people of all sorts, and fine poor people above all others, because they have not even an excuse for finery. But though I would not give them notions unsuited to their station, I should be glad to see their habits improved, and I know, from painful observation, that our cottages stand in need of improvement. They are, in fact, to bind the ties; and while the pious of every other class of society have been gradually increasing in comfort and convenience, the dwellings of the labourers are little better than they were a hundred years ago. Many improvements and conveniences in cottages have been suggested by others, which I forbear to notice; for this reason, that while such conveniences are unattainable by persons of small independent property, it is in vain to expect that they will be provided for cottagers. My object has, therefore, been to describe the accommodation required in what would be called a comfortable labourer's dwelling, and to suggest practicable improvements which are likely to be effected; and I hope that there is nothing in the foregoing description which can be considered impracticable.

8232. *External appendages to a labourer's cottage.* I am next to speak of the external appendages to a complete labourer's dwelling, including the yard and out-buildings, the garden, orchard, and allotment of land. To account for some of the out-buildings which will be mentioned in the following description, I must remind the reader that, as I am speaking of a cottage of the first class, I must, of course, suppose the cottager to keep a cow; and that, besides a quarter or half an acre of land, for spade husbandry, (the quantity should be proportioned to the spare time of the labourer, and the quantity of manure he can collect,) he would also be the occupier of about three acres of pasture. I am of opinion that it would have a beneficial effect upon the general conduct of the agricultural labourers, if there were a certain number of cottages, with land attached to them, in every parish, to act as a sort of stimulus to industry and frugality. Formerly the small farms presented this stimulus. The industrious, saving cottager had then a chance of rising a step above his original station in society; and a natural desire to improve his condition would act as a constant inducement to carefulness and activity. But now he has no such inducement. In most parts of England, parishes which were once divided into ten or twelve farms, of various extent, are now thrown into two or three large ones; the waste lands are enclosed or appropriated; and even the bare-worn common is, in many cases, denied to the hard-working frugal labourer, who happens to have saved enough money to set up a cow. How can we wonder, then, at the careless improvident habits of the peasantry, when they have scarcely an inducement to be otherwise? But, under all their disadvantages, there are still a few labourers who save money; and is it not rather hard that they should be deprived of the opportunity of employing it profitably in the only business with which they are acquainted, that is, agriculture? Let us suppose a working man to be possessed of 50*l.* Almost the only way in which he could invest it safely, would be in a savings bank, where it would produce him an interest of about 2*l.* a year. Now this is all very well; the principal sum is secure, and a certain 2*l.* a year is a desirable addition to a labourer's income. But it would take nearly his whole life to save up 50*l.*; and half that sum would produce a much greater income, and much improve his condition, if employed in some sort of business. In short, though the savings banks have been a great benefit to the working classes, the small income produced by a sum of money placed there does not afford a sufficient stimulus to frugality. The interest upon their savings can add little to the comforts of the depositors; and, as to having a sum of money against the time of sickness or misfortune, they know that the parish must then support them; and though they might be induced to save, if by saving, they could materially improve their condition, we must not expect them to save for the relief of the parish. But let us suppose a man to have saved only 25*l.*, and to have an opportunity of taking a cottage, with land enough attached to it to support a cow. He would probably invest his little capital in a cow, a couple of pigs, some poultry, perhaps, and a hive or two of bees; and, if he had tolerably good luck, and were a good manager, he would soon be placed in circumstances of comparative affluence, and would be infinitely better off with his 25*l.*, thus invested, than the other would be with his 50*l.* in the savings bank. The great improvement in his condition would also be apparent to all around him, and would act as a general spur upon the carefulness and industry of his neighbours. Money in the savings bank would not produce this consequence, because its effects are less apparent; in short, its effects are unimportant when compared with the comforts derived to a labourer's family from keeping a cow. But, besides being prizes to excite the diligence and reward the good conduct of the labourers, a few cottages, with land attached, would be a general convenience to the villagers, as a means of supplying them with milk; a luxury which, in my neighbourhood, is seldom tasted by the poor. The girls who live in the country, they are worse off than townspeople in this respect, as they cannot get it for money, unless on some particular occasion. The cause of this inconvenience is the large farms, and the want of cottager's cows. A rich farmer is, of course, above selling milk, and there is no one else to sell it, unless there happens to be a small farmer in the parish, or the rich farmer lets his cows to the farmer or dairyman. It would not answer to sell milk in small quantities, and, as we have no cottage cowkeepers, the peasantry are deprived of a nutritious article of food, which it is almost impossible to do without. Wherever there are no cottagers' cows, the peasantry in general must be ill supplied with that important necessary, milk. I offer these reasons for the opinion I have ventured to advance, that in every village a few cottages with land to keep cows would be desirable on many accounts. I do not say that every cottager should have a cow. Perhaps it would be better if all had them who can manage them; and it would be found, upon trial, that the number of these would not be large. A cow would be thrown away upon dirty, indolent cottagers, and there are many respectable ones so situated, that it would be more an inconvenience than an advantage to them to keep a cow. But I think there should be a few cottages with land in every parish, that the steady and industrious, and those who have an opportunity, may at least have a chance of improving their condition.

8233. *The yard.* After this long digression, let us proceed to speak of the yard, a very necessary convenience to a labourer who keeps a cow. The washhouse should have a door opening into the yard, which ought to contain the pump, dung-pits, and all the out-buildings. The pump I would place as near the washhouse door as convenient; the dung-pit in the corner of the yard farthest from the house; and to this pit the surface of the yard should have a gentle fall. It should, of course, be properly drained.

8234. *The fuel-house.* The first out-office to be mentioned is the fuel-house, a place in which the coals and dry wood may be kept, if necessary, under lock. The tools and hng-wash tubs, and many other things may also be placed in this building, which is a necessary appendage to every cottage. It would be most conveniently placed joining the back part of the house, so that it might be approached under cover from the washhouse door.

8235. *The cow-house and pigsty* should be near the dung-pit, that the drains from both may be laid into it at little expense, and to save the cottager's time in cleaning out the cow-stall, &c. The cowhouse need only contain one roomy stall and a calf-pen, with a small loft over both for the hay brought in for use. The pigsty to a cottage where a cow is kept should be divided into two, that the store-pig, which a good manager would never be without, might be separated from the fattening pig.

8236. *If a poultry-house* should be required, I would place it either over or adjoining to the cowhouse, for the sake of warmth. But I am not sure that it would answer to a cottager to keep much poultry, unless in situations where there is a ready sale for eggs and chickens, and where poultry can be kept without being a nuisance to the owner and his neighbours. In a widely scattered village this may sometimes be the case, but where the houses are near together, the cottager's fowls are a continual source of dispute and annoyance. They are ill-fed at home, and cannot stray anywhere in search of food without trespassing upon a neighbour's ground, where, in the absence of the family at work, they may devour or destroy half the produce of the garden. Where the houses are scattered, and a cottager has land of his own, or is near a common, on which they could have a run without trespassing upon others, perhaps it would answer his purpose to keep a few fowls; that is, if he can keep them out of his garden, but not otherwise. If water is near, ducks would be most profitable to a labourer, and more easily managed than hens.

8237. *Privy.* I do not recollect any other out-building actually necessary for the cottager's convenience, unless it be the privy, which might be either in the yard or in the garden, and if desired, I see no objection to one in each place. But it is useless to talk of a separate convenience of this kind for males and females, till every labourer's dwelling has one. I believe that nearly half our cottages are without any place of the kind; at least it is so in my neighbourhood. For instance, out of sixteen dwellings near me, six only have the convenience alluded to, and three of the six conveniences have been erected within these two years. The want of such places must be a terrible nuisance to the cottagers; and I particularly recommend the subject to the attention of cottage owners.

8238. *General observations on exteriors.* As the fence of the yard and the outbuildings would add something to the cost of the cottage, I choose here to meet objections that I suppose, and recommend only the least expensive out-buildings, such as the cottagers, with trifling assistance, would very frequently erect themselves. The cowhouse would be the chief expense, and that would be little better than a common shed, walled up with any thing on three sides, and open to the south. But I would have a strong fence and gate to the yard, to be fastened well at night, that all the stock may be secure, as it would probably cost the owner at least a day's work, when his cow or pig happened to get astray. I do not mention any place for pigeons in the yard, because a cottager could not keep them without constantly trespassing on his neighbours. There is an increasing prejudice against pigeons, which are certainly very troublesome to the farmer at certain times in the year. Dovecots are now much less frequently seen in farmyards than they were formerly, at least in the corn-growing districts; and if the farmers can no longer keep pigeons, of course the labourers must not. Where the cottage stands near a common, or among open green lanes, it would answer the cottager's purpose to breed a few geese, which are a profitable kind of stock, because, after a certain age, they almost take care of themselves. They would require to be secured at night; and, if the cottager keeps geese, he must add a house for them to his out-buildings in the yard.

8239. *The garden,* if well managed, is commonly the most striking feature about a labourer's dwelling, and there are many reasons why it should adjoin the house. In the present case we will suppose the cottage to be surrounded on two sides by the garden, and I would approach the front of the house through a narrow part of the garden which divides the house from the road; and this part of it I would devote chiefly to flowers and shrubs. I would train some ornamental climbing plants against the walls of the house, and a vine or pear trees, if there were proper situations for them, where the fruit would ripen, and be out of the reach of the children. I observe, however, that, excepting vines, fruit trees seldom thrive much against the walls of cottages; there are few labourers who know any thing of the art of pruning, and, being improperly pruned, the trees bear little, and seem not worth the time and trouble they require. Vines, however, do remarkably well against the cottage walls in this neighbourhood, and bear profusely in many situations, apparently with very little care or pruning. I am not qualified to lay down rules for the management of a cottager's garden, but I would venture to suggest, that it should not be too large; a small garden well cultivated, being more profitable than a large one half cultivated. In fact, if he have an allotment of potato ground elsewhere, the cottager has no use for a large garden, as he grows and uses none but the commonest vegetables, which take up little room. He does not ever cultivate much small fruit. Strawberries and raspberries are very seldom seen in a cottage garden; and currants and gooseberries are not often abundant; so that a large garden is not requisite. I used to wonder formerly why the cottagers did not cultivate the small fruits in greater abundance, as they require so little trouble, and are so extremely useful. The reason for this neglect, given me by several labourers, is, that the children devour the fruit before it comes to perfection; in fact, they begin upon it as soon as it is formed, and very little is left to ripen. As cottage children are, of course, left a great deal to themselves, I believe it would be useless to attempt growing fruit where there is a large family, or in a closely built village. Where a cottager, therefore, cannot grow fruit, he ought, I think, to keep bees as a substitute for the profit of fruit. Indeed no cottage garden should be without bees, placed in some warm retired corner, at a short distance from the house, for they are not agreeable neighbours. Bees are, I believe, the most profitable of all stock for a cottager, as the whole of their produce is valuable, and, except at swarming times, they are no trouble.

8240. *Orchard.* Besides the garden, it is desirable that every cottage with land should have a small orchard attached to it, especially in the cider countries; and, in extensive allotments of land, there are generally rough places, which, being of little value for any other purpose, might be converted into small orchards. Where there is no waste place of this description, I would plant the orchard immediately behind the garden, and contiguous to the house, that it may be easily overlooked by the owner; I would also rear a good hedge round it to keep out intruders, for young cottagers are as fond of sour apples as they are of sour gooseberries; and though they can scarcely clear an orchard of apples as they would a garden of small fruit, they will do a great deal of mischief, if not guarded against. As it is scarcely possible to have too much fruit, and a peasant's orchard is not likely to be large, I would plant some fruit trees in the hedges of the garden and fields. Damsons and cider apples, and other common fruit trees, would do very well in the hedgerows, and would be very ornamental. I think a cottage orchard should produce apples, pears, and plums of various kinds, but chiefly apples. Fruit will sell every where; and it is desirable that a cottager should have as many ways as possible of making a little money. The landlord ought to furnish the cottage grounds with fruit trees, and a gentleman of landed property would do this at a very trifling expense, by having a small cottage nursery, in which his gardener might graft and rear fruit trees of good kinds, to transplant, when fit, into the cottagers' gardens and orchards. Many labourers are fond of grafting; and, if the ground were planted with fruit trees at first by the landlord, the tenants would generally keep it stocked. I wonder our landowners do not see the advantages of planting their cottage grounds with fruit trees; by which they would increase the value of them, and place in the hands of the tenant the means of paying the rent. They would also give their cottagers an additional comfort, and greatly increase the beauty of our villages, by surrounding the houses with fruit trees, which are the most interesting of all trees. What can be more beautiful than a handsome apple tree covered with rosy blossoms in the spring, or loaded with golden fruit in autumn? It is picturesque even in winter, when its rugged massy stem and irregular branches are exposed to view. Indeed, a village with many small orchards about it is generally a pretty village.

8241. *Potato-ground.* The next thing to be spoken of is the allotment for potatoes, &c., without which no cottage would, in these days, be thought complete. But, of course, this allotment would be much smaller in the case of a cottager keeping a cow, than in that of a labourer with only a garden to attend to. The cowkeeper would have many little odd jobs to do connected with his cow and land, which would leave him not leisure enough to cultivate an extensive potato-ground besides his garden. Nothing pays a labourer so well as working for a master; consequently, a garden cannot answer to a cottager if he is obliged to lose time, as they express it, in order to cultivate it. A cowkeeper's ground for potatoes, &c. should therefore be smaller than that of another labourer, because the man will not have much leisure, and the wife will have less, as she will have the produce of the cow to manage, in addition to the ordinary cares of the family. But if the cowkeeper have not constant employment with a master, the case would be altered, and he would require as large an allotment as other labourers. He would probably cultivate his ground on a different plan from that followed by ordinary cottagers. He would not have space for a plot of corn, and it would answer his purpose better to grow cabbages, Swedish turnips, man-gold wuzel, or something that would be useful for the cow, on that part of his ground not occupied by the potato crop; indeed, a man who has a cow and pigs should consider their wants in his gardening almost as much as he does those of his family, and his pigs should nearly live on vegetables during the summer.

8242. *Grass land.* We conclude with a few observations upon the grass land which the cottager is to occupy for the use of his cow. This should be about three acres, divided into two enclosures. I believe three acres of fair grass land are generally considered the quantity required to summer and winter a cow; but, if a less quantity would be sufficient, of course the cottager would not desire more, as it would cause an unnecessary addition to his rent. He had better have rather too much land than too little, as the profit of a cow depends in a great measure on its being well fed. He would probably mow his fields for hay alternately, as he would not be able to manure very freely. He must, however, manure a portion of his grass land every year, or it would go back; and, if he were a good manager, he would be able to do this; for it is surprising what a heap of compost a managing person will collect who keeps a cow, and two or three pigs, and gathers every thing that can be converted into manure from the garden, the yard, the drains, and the roads about the premises. If he had not too large a potato-ground, a cottager, situated as I have described, would not be a good manager if he could not contrive to dress over an acre of his grass with compost every year; and this would be sufficient to keep it in heart if it were mowed every alternate year. There is one thing connected with allotments of land to labourers, which I would press on the attention of cottage owners, that whatever land is let to a labourer should be adjacent to his house. It should be remembered that the cottager's land is to be cultivated during the leisure time he has after having done an honest day's work for his master. His land, therefore, should be near his abode, that he may make use of all his time, half of which would be wasted in walking backwards and forwards if his land happened to be at a distance. If, also, his land were at home, he would spend many a half hour spudding thistles, or spreading dung in the field, or doing many little odd jobs, which would be left undone if the field were some way off. Moreover, it works a man too hard to have to walk a quarter of a mile, or more, to his extra labour, after, perhaps, walking a much greater distance from the place where he works for a master. He would do half as much more work, and do it with more pleasure to himself, if he could do it at home, where he could immediately retire into his house when he felt fatigued. In short, if a cottager is to do any good with land, it should be within an easy distance of his home. Imagine the extra labour occasioned to the cottager when he has to wheel out the manure, and bring home the produce of his land, distant, perhaps, a quarter of a mile from his house. Where the cottages belong chiefly to one proprietor, who is the principal landowner in the parish, it may generally be contrived that the allotment of land may adjoin the cottage, or be at least a convenient distance from it. A cottager can generally afford to pay as good a rent for land as an ordinary farmer; and, if he can afford to pay for it, he may reasonably expect to have it conveniently situated.

8243. *General observations.* I believe I have noticed most of the conveniences, internal and external, which in these times would be thought requisite to form a complete labourer's cottage. I am aware that the description given goes very far beyond the ordinary run of cottages, as they are at present. My aim has been to make it so; but I hope I have suggested nothing but what is absolutely necessary for the decent comfort of a family. My aim has also been to speak of practical improvements; and to show how the domestic accommodations of the peasantry may be increased at a moderate expense. There are many desirable improvements and luxuries suggested by writers on cottage architecture, which I have forbore to mention, for this reason; because costly improvements are not likely to be applied to cottages; and it is useless to recommend luxuries for labourers' dwellings, which are not found in the houses of wealthy farmers and tradesmen, and even in those of the smaller gentry. Our peasantry, however, have no desire or taste for luxurious habitations. They wish for comfortable cottages; that is, dry, warm, and, above all, sufficiently roomy dwellings, in which their families may be conveniently accommodated, without violating the common decencies of life. If they had houses of this description, they would have every reason to be satisfied, and would be so, without unnecessary luxuries. And I hope the time is fast advancing when the improvement which has taken place in the habitations of all classes above them will be extended to labourers' cottages.

8244.—2884. *Asphalte*, as the upper layer of the floors of cottages, effectually prevents the rising of damp; as it also does when introduced in a thin layer in a wall, a little above the surface. (*G. M.* 1840, p. 564.) It has, as we have already mentioned (8216.), been found to form excellent barn floors.

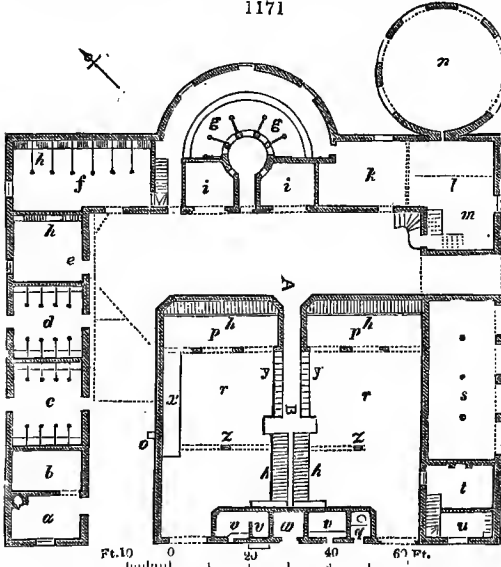

8245. *Design for a three-plough farmery*, by Mr. Mckenzie of Perth. *Fig.* 1171. is a ground plan; *fig.* 1172., an isometrical view; and *fig.* 1173., a vertical profile. This three-plough farmery is understood to be built upon level ground; with the straw-yard cut out hollow in the centre of a basin figure; that being the best form for retaining the moisture among the manure. In fixing the position of the different ranges of the buildings, the highest are put down to front the north and east, as best suiting the purposes to which those parts of the farmery are to be applied; and at the same time adding to the comfort of the cattle in the sheds and straw-yards, by sheltering them in the directions which are generally the coldest.

8246. *The byres* (*c, d*), which are low buildings on the west, and the pigsties (*e*), which are on the south, do not shade the straw-yard and cattle-sheds, but admit the rays of the sun to all parts of them. The farm-house is supposed to be situated on the south-west of the farmery, with the kitchen court adjacent to the cow-byre, calf-yard, &c.; thus keeping the offices which are managed by the house servants in one division, and those under the management of the farm servants in the other division of the establishment.

8247. *The threshing machinery* (*I*), being placed in a corner of the square, discharges the threshed corn into the clean corn-room (*m*), in the direction of the granary, which occupies the upper story of that side of the square; and the straw is thrown from it into the straw-house, which is in the direction of the straw-chambers, over the feeding-byre, stables, &c., on the other side of the square. The clean corn-room thus communicates with the granary, which extends from this point over the cart-shed. In this way the clean corn-room and granary occupy a side of the square apart from the offices allotted for the cattle, and the other apartments connected with them; and, as the corn-room can be locked up the moment the operation of threshing is finished, no opportunity is left for the grain being pilfered or injured. The granary in this situation has not only the advantage of the ventilators in the side walls, but it has also the benefit of the free air from the open cart-shed under it, which acts upon the grain through the joints of the floor. The cart-shed under the granary, besides being beneficial to it for air, is convenient, particularly where a farm is situated at a considerable distance from a market-town; or in the winter season, when the carts require to be loaded on the evening preceding the market-day; as it can be done before yoking (putting the horses in), and without moving the carts from under their cover, by

means of the trap-door in the centre passage of the granary: which passage must at all times be kept

- w, Water-house.
- x, Tank for liquid manure.
- y, Turnip-boxes.
- z, Gratings over the drains leading to the liquid manure tank, to prevent the straw from the yard from choking up the drains.

clear from grain. In the straw-house, a trap-door is placed over the straw-rack: and, when the lower part of the house is packed full, this trap-door can be shut, and the straw carried along the upper floor to the straw-chambers over the stable and feeding-byre. These apartments will contain the straw of two ricks, which will enable the farmer to keep different kinds of straw under cover, and in separate divisions. A door is placed opposite the passage which extends along the centre of the straw-yard for taking out straw for the cattle-sheds, cow-byres, &c., if at any time required; but in general these are supplied from the low straw-house. The threshing-machine is one of six horse-power, and is impelled by horses; but where water can be had, it is a great improvement, as the men may be employed threshing, while the horses are resting: this is advantageous in a still greater degree at certain times, when the field operations exhaust all the horse power.

2248. The circular byre (g), which will contain ten head of cattle, is by far the most commodious and convenient arrangement; and, for a farm double this extent, the same form may be introduced, with equal advantage, by carrying the stalls wholly round the circle where the sheds are. The figure of the stalls, being broad behind, gives more space for the cattle when lying down; and, as a greater quantity of litter is requisite, more manure, of course, will be made: at the same time it admits from behind a more abundant supply of fresh air, and has also the advantage of one large ventilator in the centre of the circle serving the whole. The ten head of cattle are put up in double stalls in pairs; they are bow'd up, one on each side of the partition, which is made high enough to prevent the horned cattle from touching one another; at the same time keeping the heads of each pair at such a distance apart, as to prevent them from injuring each other, or eating each other's turnips. The bends, or cow-ties, are fixed to upright iron rods about three quarters of an inch in diameter, which are screwed through the partition. The lower part of the windows in the back wall of the byre are filled with luffer-boarding, which can be

1172

opened to any degree for admitting air, or shut altogether at pleasure. The feeding-ports, or openings which surround the feeding-chambers, have small doors hung with pulleys, lines, and weights, similar to those of a common window, which, by moving upwards, do not interfere with, or occupy, any part of the chamber. The wall at the heads of the cattle surrounding the feeding-chamber is built to the full height of the joists; which keeps the turnip barrow out of the view of the cattle, and does not disturb the one

division of them, while the man is in the act of feeding the other. This is important, as the quieter cattle are kept the better, quietness being, no doubt, essential to quick fattening.

8249. *A commodious straw-chamber* is obtained over the byre, in a connected range with the straw or hay chamber over the stable: the roof, which is of considerable width, serving the double purpose of covering the feeding byre, and of containing a very large quantity of straw immediately over it. Racks are placed over the several stalls, which are filled from the straw-chamber above. By this arrangement, the cattle have it in their power to eat straw and turnips alternately, if inclined. The access to the straw-chambers over the byre and stables is by a stair, which is common to both; and upon the plate (first landing-place) of this stair is placed a door, which divides the stable from the feeding-byre; the upper flight of the stair is understood to be a hanging one, having a useful space under it for holding the byre implements. By the whole arrangement much labour in feeding and attending the cattle will be saved.

a, Platform forming the upper part of the roof of the feeding-shed.
b, Ventilators to the stables.

c, Ventilators to the byres.
d, Inclined plane between turnip boxes.
e, Racks for hay or corn.

Although the under racks appear the most natural for the horses to eat from, it is found that they do not eat the straw or hay so clean out of them, as they do out of the upper racks; but these under racks are the most convenient for the grass, as it should always be put in from the stall above, without passing through the hay-chamber; being, in its damp state, very hurtful to the wood floor above. Part of the three-stall stable is set apart for a mare and foal.

8251. *The turnip-shed (f)*, adjoining the feeding-hy, is also conveniently situated for supplying the cattle in the straw-yard; and, as it is not required for turnips in summer, it may be used for and serve the double purpose of a turnip-house and a grass-house.

8252. *Ventilators*. The cow-byres have ventilators placed over each line of heads; these cross the ridge, and are formed of lead of a triangular figure; the sill piece being overlapped by the sides far enough to prevent the rain from getting in. (See c in fig. 1173.)

8253. *The calf-house and ward*, and the cow-byres (c, d), which fall under the class of offices more immediately connected with the farm-house, have doors facing the kitchen-court, which makes the access to them convenient and clean. The opposite doors are for driving out the cattle, and for wheeling the manure into the straw-yard. The causewayed court, in front of the byres, besides being convenient for carting in the turnips, affords space for the cows to move about in, or to stand in for a short time; and, as the cattle always dung when they are driven out, by allowing them to remain for a few minutes in this passage or court, the manure, that might otherwise be wasted on the roads, is preserved, and thrown into the straw-yard.

8254. *The several drains* leading from the byres, stables, and straw-yard, have such declivities as are sufficient to discharge the liquid manure into the tank, which is constructed on one side of the straw-yard in a central situation for the byres, stables, &c. It is thirty feet long, three feet broad, and seven feet deep; and, if the nature of the soil be porous, it should be plastered with Roman cement, to prevent the thin liquid manure from escaping. Being of this long and narrow figure, the tank can easily be covered with flagstones, which are much cheaper than arching, and take up less space. The drains should have holes fitted with cast-iron plugs, placed about fifteen feet apart; so that at these openings a jointed rod fifteen feet long could be put into the drain, with a hoe, or a piece of plate iron the shape of the drain, fixed to the one end of it. By these means the drains may be cleaned without breaking up any part of the causeway; but, if the drains are properly constructed, they will not require cleaning for several years. They should have a fall, towards the tank, of at least four inches to the ten feet, and be nine inches wide, six inches deep at the sides, and nine inches in the centre. By having this kind of triangular bottom, the smallest quantity makes a current, and forces everything along with it. The drains through the straw-yard should have openings with grates (z z) over them, situated in the lowest part of the straw-yard, to draw off the surplus water after heavy falls of rain or snow. When these drains are not required, the grates may be easily covered over with dung; and if, at any time, the manure is found too dry, movable spouts may be attached to the pump which is placed in the tank, by which means the liquid manure can be regularly spread over the whole straw-yard. A waste drain extends from the tank to an open ditch near the buildings; by which means, the liquid manure in the tank, if neglected, is carried off when it rises to that level, and is thus prevented from injuring the drains.

8255. *The cattle sheds (p)*, from their situation, face the south, which is of great advantage to the cattle, though often overlooked in laying out farm buildings, and they are divided in the centre by a passage adjoining the turnip-shed, and opposite the straw-house. This passage rises like an inclined plane four feet from A to B; the sides or parapets may be of wood, two inches thick (which forms a back to the turnip boxes), and be four feet in height, forming a fence to both yards. All the manure from the feeding-byre and stable is wheeled into the straw-yards by this passage; which, from its central situation, admits of the stable dung being equally distributed through both yards, and this by the rising passage can be done without opening a door, which prevents the one class of cattle from intermingling with the other, or getting out. Straw-racks (h h h h) are placed in the sheds; but, by also having them in the centre

of the yard, and connected with this passage, they can be conveniently filled, and the cattle are induced to divide, which mixes the dung more generally through the yards.

8256. *The piggeries (w)*, from their situation, may be conveniently supplied from the kitchen or boiling-house, and are in both yards. Pigs are very beneficial to the manure, from their turning it over, and mixing it; they also eat up any particles of corn among the horses' dung that may not have been digested. One small enclosure is provided with a trough for feeding young pigs, and they are thus protected from the cattle while eating; but they have no house or sty, that they may be induced to go out among the cattle, and to lie down about the sheds. By this arrangement, they have healthy exercise, and are enabled at the same time to provide a part of their food, and to be beneficial to the manure in both yards. Another sty is provided for putting up a pair to feed.

8257. *The gates to the straw-yard* may either be of the common form, or be hung, like sash windows, with stout ropes, pulleys, and weights. This last is perhaps the best plan as it secures them from the risk of damage when the dung is being carted out of the yard; and also enables them to be raised as the straw in the yard rises.

8258. *The cistern-house (w)* is of such a height that pipes may be taken from it to the dwelling-house, hoiling-house, calf-ward, &c. It may be either supplied from a spring, if one is to be found in the neighbourhood; or a well may be dug, and a pump placed within the cistern-house. A water-trough is placed in the division wall between the straw-yards; and a ball-cock is fixed in the centre of the said trough, and shut in by boarding, overlapped by the upper part of the wall, which thus protects it from injury by the cattle. By this self-acting supply, the cattle at all times have the command of water, and none of it is wasted; if supplied from a spring, no attention is necessary, as the supply may be regulated by having a ball-cock in the cistern. Two troughs are placed on the outside, for the horses and the milch cows, and are also supplied with ball-cocks. The roof water, in the inside of the court, is carried round with eave-spouts, and with rainwater pipes at the south extremities, leading it into drains. It is a material object to carry off the roof-water, without allowing its admixture with the manure in the courts.

	£	s.	d.
8259. <i>Estimate.</i> —Masonwork, excavations, and paving -	-	-	373 0 0
Carpenter's, glazier's, and smith's work -	-	-	470 0 0
Slater's and plumber's work -	-	-	145 0 0
Plaster work -	-	-	5 0 0
			£993 0 0

The above estimate is made out upon the supposition that stone may be got for the working, at a distance not exceeding one mile from the building; and that the land carriage of the timber (which is all foreign) and of the lime should not exceed from five to ten miles, and that of the slates from ten to fifteen miles.

8260.—2976. *Whin or furze fences* strongly recommended as occupying less ground, and being ultimately cheaper than thorn fences. "Quick in growth, hardy, easy of culture in all dry, lightish soils, of unknown longevity, prospering under the knife, affording as an evergreen a pleasing object to the eye, the best shelter for stock, adapted for food, and not suffering, but rather benefiting from being cropped." Impressed with this conviction, W. Bell, Esq., of Hunthill, Roxburghshire, planted this fence, extensively, and after a great number of years he is entirely satisfied with them. (*Trans. H. S.*, vol. xi. p. 471.)

8261. *Wire and netting fences.* An excellent substitute for hurdles or cords is manufactured of wire at Whittington, Stoke Ferry, under the direction of Mr. Taylor, in the form of netting, and sold at very low prices. Messrs. Cottam and Hallen, of London, also manufacture a cheap netting for sheep folding from cocoa nut fibre. Mr. Taylor's wire netting is particularly valuable for rendering garden and poultry-yard hedges impenetrable by rabbits, foxes, &c.

8262.—3075. *Field gates.* The most advantageous forms, and the lightest and cheapest materials, are pointed out by Mr. Buist, who recommends the ties or stays to be made of iron, and the struts or stiffening pieces of wood. He recommends wire gates of a very light construction, which cost from 1*l.* 8*s.* to 1*l.* 16*s.* These are figured and described in the *Gard. Mag.* vol. for 1840, p. 198; and in *Trans. H. S.*, vol. xiv. p. 603.

8263.—3104. *A fall-down gate-stopper* (*fig. 1174.*) has lately been invented, which deserves adoption wherever double gates are fastened in the middle by a bolt attached to the lower bar, and entering a hole in a stone or other body fixed in the road. This gate stopper is formed of cast iron, and is sunk in the ground till its upper surface is level with the road, its lower end being placed on a stone to prevent its sinking too deep. The gate-stopper has an ear (*a*), which is raised up when the gate is shut, so as to form a stopper and a hole for the bolt; and it is put down (*b*) when the gate is open, so as not to present an obstruction to the feet of horses. Sold by Messrs. Cottam and Hallen.

BOOK V.

THE OPERATIONS OF AGRICULTURE. (p. 506.)

8264.—3239. *The use of ploughing* is for the purpose of loosening the texture of the soil so as to admit the free circulation of air and moisture, in order to promote the decomposition or disintegration of the stony parts of the soil, and facilitate the extension of the roots of plants in it. "However well you may manure your land, however thoroughly you may drain it, you will never obtain the crops it is capable of yielding, unless you pulverise it; nay, so important did Jethro Till think this, that he felt firmly persuaded that if you pulverised your soil well, you need not manure at all. Always bear in mind that the impalpable powder is the active part of soil, and that no other portion has any direct influence upon vegetation; and you will then, at all times, be sufficiently impressed with the necessity of thorough plowing, harrowing, &c.; indeed, you may rest assured that, except upon some few very light sands, you cannot pulverise the soil too much: economy alone must fix the limit of this useful operation. Several chemical processes of considerable consequence as respects the fertility of soil, occur after it has been ploughed, which either take place very slowly, or not at all, while it lies undisturbed; and, moreover, some of these take place to the greatest advantage during winter. This is especially the case with the disintegration of mineral masses, nothing tending so powerfully to reduce even the hardest stones to powder as sudden changes of temperature, combined with the presence of much moisture. During rain or thaw after snow all the clods of earth and the

pores of the more loosely aggregated stones become filled with water, which, of course, freezes, if the temperature is sufficiently reduced; and from its expansion during solidification, a peculiar property possessed in a marked degree by water, the particles of earth or stone, as the case may be, are pushed so far asunder, that when the thaw returns, it crumbles into fragments, which are again and again acted on until reduced to the state of soil. This crumbling by frost is of the greatest importance in the case of stiff clays, for two reasons:—1st, because they are thus rendered much more easy to work; and 2d, which is of far greater consequence, they are enabled to give up their alkalies more readily to water; and clayey minerals are fortunately the quickest to disintegrate, or rather to decompose, by the action of the weather; and hence every means that facilitates that process is valuable, because, as we have already seen, those most valuable ingredients of soil, potash and soda, are of no use to plants, unless they are soluble in water, and they do not obtain this property until the mineral with which they have been associated becomes completely decomposed." (*Dr. Madden in Stephens's Book of the Farm*, vol. i. p. 641.)

8265.—3240. *Disadvantages of irregular ploughing.* As there is a certain stage in the progress of the grain, at which, when cut, it produces more flour than any other, that is, when it is full but not ripe, it follows that a field of corn which, in consequence of bad ploughing, does not come regularly into flower, must be attended with decided loss to the farmer. Those seeds which have been buried too deep will be the last to flower, and consequently the last to ripen; so that, if he waits till the whole crop appears ready for the sickle, all the early seeds will be too ripe, by the time that the late ones are sufficiently dry to cut; so that by this error in ploughing there is a direct loss, by the production of less flour from the early seeds, while the farmer is waiting for the late ones to ripen. (*Trans. H. S.*, vol. xiv. p. 629.)

PART III.

AGRICULTURE AS PRACTISED IN BRITAIN.

BOOK II.

GENERAL ARRANGEMENT OF LANDED ESTATES. (p. 558.)

8266.—3751. *A machine for cleansing public roads*, described in *Q. J. A.*, vol. iv. p. 876. Another in *Trans. H. S.* vol. x. p. 349.

8267.—3759. *Keeping parish roads in repair* on the mile system. This system consists in putting "a certain portion or district of road under the sole care of one man, from which he is never removed so long as he conducts himself properly, and that the materials, instead of being carted and laid on the road, at the time of repairing, should be contracted for so as to be brought and laid on the sides of the road and trimmed up in one uniform way ready to be measured up some months before they are wanted for use." (*Journs. A. E.*, vol. ii. p. 354.)

8268.—3947. *Slit planting.* Mr. Gorrie lays in all resinous plants, particularly larches, at an angle of 20° with the horizon, their tops pointing to the south-west, and finds this an effectual preventative to wind waving. (*Q. J. A.*, vol. xiii. p. 211.)

8269.—3950. *The perforator* (fig. 1175.) is used as a substitute for the spade, in planting young taprooted trees in rough ground. It was invented by Mr. Munro, of the Bristol Nursery, and, in that

neighbourhood, in 1828, cost about eight shillings. In using it, one man employs the instrument, while another man, or boy, holds a bundle of plants. The man first inserts the instrument in the soil, holding it up for the reception of the plant; round which, when introduced, he inserts the iron three times, in order to loosen the soil about the roots; he then treads down the turf, and the plant becomes as firmly set in the ground as if it had been long planted. Two men may set from five hundred to six hundred plants in a day with this instrument. (*Gard. Mag.*, vol. iii. p. 215.)

8270.—3987. *Pruning forest trees.* A digest of five essays on this subject, by Grigor, Gorrie, Cree, Fowle, and an anonymous author, is given in *Trans. H. S.*, vol. xii. p. 141—179, which may be considered the most satisfactory article on the subject of pruning that has hitherto been published. All the writers agree in recommending a system corresponding with that of Mr. Cree's, but in some respects less definite.

8271.—4038. *Increasing the durability of timber*, by causing growing trees to absorb certain liquid solutions was tried by Dr. Boucherie in France, and Mr. Hyett in England. (*Trans. H. S.*, vol. xiv. p. 535.) The subject cannot be considered as yet settled: creosote and sulphate of copper appear to have been found most effectual preservative substances.

8272.—4052. *Sawing machines for selling timber*, of four different kinds, will be found described in the *Highland Soc. Trans.*, vol. ix. p. 275. The most powerful of these appears to be a circular saw (fig. 1175.) which consists, first, of a ground frame (a a), in form of the common hand-barrow, eight feet and a half in length by two feet and a half in width; on one side of which is erected a vertical frame (b b), of three feet and a half in height. The second compartment comprehends a traversing frame or carriage (c c) about five feet in length, and two feet in height; the vertical bar (d) being prolonged upward, and having its top and bottom ends formed into pivots, on which the carriage, carrying all the working machinery, is made to swing. The saw (e), of twenty-four inches diameter, is fixed on the lower end of a vertical spindle, and immediately above it a bevelled pinion (f), which is driven by the wheel (g); the wick handle, by which the power is applied, is fitted upon the same spindle. The saw pinion and the

wheel (g) are in the proportion of one to five, so that, when the handle is turned with the ordinary velocity of forty revolutions a minute, the saw will make 200 revolutions in the same time. In order to keep

the edge of the saw in contact with the saw-draft, a vertical spindle (h), carrying the pulley (f), of one foot in diameter, is placed at the outward extremity of the carriage; the pulley (f) is put in motion by the band (j) passing over a smaller pulley on the winch axle. On the spindle (h) there is also fitted a small drum (k), capable of being disengaged at pleasure from the motion of the spindle by means of a clutch. The cord (l), which passes round the pulley (m), in the ground frame, has one end attached to the carriage; while the other end, being attached to the drum, is coiled upon it when revolving along with the spindle, thereby carrying forward the saw with a slow and uniform motion. When the operation is completed, the small drum is disengaged, and the cord is allowed to uncoil, while the carriage is moved backward to prepare for the next cut. For the support and guidance of the carriage, an iron segment (n) is fixed upon the lower part, which slides through eyes in the ground frame; and the machine is kept steady while at work, by two iron dogs (grappling irons), the hooks of which are driven into the roots of the tree. The certificates accompanying the model of this machine bear ample testimony to its successful application on the large scale; and show that it can be worked, and carried from tree to tree, by two men. The machine here described is calculated for felling trees from eight to twelve inches in diameter. (*Highland Soc. Trans.*, vol. ix. p. 276.)

8273. *Species and varieties of the larch.* That extensively cultivated by the Duke of Athol is the common white larch, *Lärix europæa* Dec.; but the following other species or varieties were tried:— 1. The Tyrol larch, with white flowers; those of the common variety being pink flowers. 2. The Tyrol larch, with white flowers; the cones also remarkable for their whiteness, and for being erect, not cernuous. The shoots of the Tyrol larch are generally stronger than those of the common larch; but the foliage of both kinds is similar. 3. The weeping Tyrol larch, a variety of the common, with pendulous branches; but distinct in botanic characters from the *Lärix pénédula*, or black larch of North America. 4. The red larch of North America, or *Lärix microcarpa*. This species is remarkable for the great specific gravity of its wood, which is so ponderous that it will scarcely swim in water. Its cones are shorter or smaller than those of the common larch, its branches weaker, and its leaves narrower. 5. The Russian larch, raised from seed procured by the Duke from Archangel, about the year 1806. The bark is cinereous, not yellowish-brown; the leaves come out so early that they are liable to be injured by spring frosts. The *Lärix pénédula*, or black larch of North America, and *Lärix daurica* of Dr. Fischer of Petersburg, are distinct species, no examples of which exist at Dunkeld or Blair. (*Hort. Trans.*, vol. iv. p. 416.)

8274. As an Appendix to the chapter on Planting, we shall here give some account of the larch plantation of Athol and Dunkeld, from the *Transactions of the Highland Society*, vol. xi. p. 165. to p. 219. It appears that the late Duke of Athol planted 15,573 acres, which contained 27,431,600 plants. Of these 8,604,842 plants were larch. All these were planted in the slit manner, as by far the best. It is stated in that paper that the larch will supply timber fit for ship-building, at a great height above the region of the oak; and that, while a seventy-four-gun ship would require the oak timber of seventy-five acres, it would not require more than the timber of ten acres of larch; the trees in both cases being sixty-eight years old. The larch in the neighbourhood of Dunkeld grows at the height of 1300 feet above the level of the sea; the spruce at 1200; the Scotch pine at 700; and deciduous trees not higher than 500. The larch, in comparison with the Scotch pine, is found to produce three and three quarter times more timber, and that timber of seven times more value. The larch, also, being a deciduous tree, instead of injuring the pasture under it, improves it. It is remarkable that the woolly aphid, which affected the larch plantations in most parts of Scotland for a number of years about the beginning of the present century, never extended higher than about 600 feet above the level of the sea. The late Duke John the Second planted, in the last years of his life, 6500 Scotch acres of mountain ground solely with the larch, which, in the course of seventy-two years from the time of planting, will be a forest of timber fit for the building of the largest class of ships in his Majesty's navy. It will have been thinned out to about 400 trees per acre. Each tree will contain at the least fifty cubic feet, or one load of timber, which, at the low price of 1s. per cubic foot, only one half of its present value, will give 1000*l.* per acre, or, in all, a sum of 6,500,000*l.* sterling. Besides this, there will have been a return of 7*l.* per acre from the thinnings, after deducting all expense of thinning, and the original outlay of planting. Further still, the land on which the larch is planted is not worth above 9*d.* to 1*s.* per acre. After the thinnings of the first thirty years, the larch will make it worth at least 10*s.* an acre, by the improvement of the pasture, upon which cattle can be kept summer and winter. (*Highland Soc. Trans.*, vol. iii. p. 168.)

8275. *Soil for the larch.* It is an error to suppose that the larch will thrive in all soils and in all situations. There are many kinds of soils in which it will not thrive, and ought not to be planted. It has been found that, in soils which have been turned up by the plough, and which have borne white crops, the larch cankers. It cankers in wet situations also. In soils resting on a wet tilly subsoil, it decays at the heart, after arriving at forty years of age. In situations where water stands for a length of time about the roots, it becomes fogged, or covered with lichens. But in all rocky situations, and particularly those which are composed of mica slate, containing crystal of garnets, among the fissures and fragments

of which they can push down their roots, larches thrive to admiration. The geognostic character of the country from Dunkeld to Blair is primitive. At Blair is gneiss; at Dunkeld, clay slate; and the intermediate space is occupied by mica slate; they lie conformably to one another.

8276. *Situation.* The advantages resulting from planting mountain ground appear at first sight, in the greater number of trees that may be supported on the acclivity of a mountain than on a surface equal to its base. Trees derive nourishment from the soil immediately around the place in which they are fixed; and, as the superficies of that soil must, of course, be greater on an acclivity than on the base, a greater number of trees will be there supported. Practically speaking, 100 trees, at six feet apart, can be planted on the hypotenuse of a right-angled triangle, whereas the base would only permit eighty at the same distance. Another and a great advantage derived from planting mountain ground is, that, on an acclivity the trees expose a greater surface to the influence of the sun, and air, and rain, than they can do on a level surface. That trees derive much nourishment from the air, through the instrumentality of their leaves, there is no doubt. The experiment of taking the bark from fifty standing larches, in May, 1814, at Dunkeld, did not prevent their vegetation, and even forming wood for two years after. The outside trees in a forest are always the strongest. On an acclivity, they all possess the advantages of outside trees; and at the same time, most of the shelter enjoyed by those in the interior." (*Highland Soc. Trans.*, vol. xi. p. 185.)

8277. *Nurses* were not used by the late Duke in his larch plantation. The gardener, in the Duke's absence, planted some acres with a mixture of Scotch pine and larch; but so far were the former from nursing the latter, that at the end of seventeen years they had not attained a height exceeding three feet; while the larches which they were intended to nurse were from fifteen to twenty feet high.

8278. *The growth of the larch.* Taking the average height of an average larch, of eight years from the seed, at eleven feet, it will be nearly accurate to allow sixteen inches as the annual growth, till the tree is fifty years old, and after that only ten inches per annum for twenty-two years longer; as the length of the tree lessens in growth as the bulk of the wood increases. These data give a larch tree of seventy-two years of age a height of ninety-three feet four inches; a fair average, agreeing with actual experiment. The shoots of larches beyond thirty-five years of age are heavier, though they are not so long as those of younger trees. The larch, like the oak, puts forth two shoots every year, the one in spring, the other in autumn. The spring shoot has no lateral branches: the autumnal shoot pushes out like the spring one; but, at the time this process is going on, the spring one is throwing out lateral branches which are firm and woody.

8279. *In regard to the growth of the girth,* a larch tree, on an average, will acquire an inch in girth per annum, till it be twenty-four years old; and from that time, till it has acquired the venerable age of seventy-two years, it will grow one inch and a quarter in girth every year; thus:—

In 24 years, it will be 2 feet in girth, at 1 inch per annum.
48 years more, 5 feet in girth, at 1½ inch per annum.

In 72 years, it will be 7 feet.

8280. *The larch begins to make wood* at twenty-four years of age,
At 50 years old it will contain 26 cubic feet of wood.
60 ————— 14 ditto more.
72 ————— 20 ditto more.

In all, 60 ditto, or one load of 50 cubic feet, and 10 feet more.

8281. *These results* correspond exactly with the quantities which the Duke obtained at these respective ages. Larch appears to be on its greatest increase for timber from fifty-seven to seventy-two years old. A larch containing fifty cubic feet, or one load of timber, is quite fit for naval purposes. At half that size it is suitable for every country purpose.

8282. *Thinning larch plantations.* The great object of the Duke, in planting the larch, seems to have been to raise timber for naval purposes; and, finding that larches grow to a great size at only twelve feet apart, he thinned accordingly. This distance gives 360 trees to the Scotch acre, or about one fifth of the 2000 originally planted. "The first thinning should consist of a light one of about one fifth of the whole, by removing only those trees that are of least value or worthless. After twenty-four years from the time of planting, the spines fall off the lower branches, which are, of course, no longer useful to the soil below. From twenty to thirty years old, then, the thinning is carried on so extensively, as to remove two thirds of that which was left standing by the first thinning. In thinning, it is necessary to observe that all the strongest and healthiest trees should be left, even if two or three of them should be closer together than twelve feet. These small clumps happening to light on a favourable situation, they will thrive well, as the air has access to each tree, around two thirds of its circumference. This thinning being delayed so long, the trees thinned out will be valuable for a variety of purposes. One of these purposes is the profitable use which may be made of the bark. The last thinning should be given when the trees are from thirty to thirty-five years old, which will leave from 380 to 400 trees per acre."

8283. *Pruning the larch.* Little or no pruning was used in the larch plantations at Dunkeld. The 380 trees left in the acre, it is observed, "will require a little pruning and trimming of the lower branches, in order to give head room to the cattle, which are to browse on the grass below. The whole prunings and thinnings will cost about 5*l.*, and their produce will fetch about 12*l.*, leaving a profit on them of about 7*l.* an acre." (*Highland Soc. Trans.*, vol. xi. p. 190.)

8284. *Thin planting the larch* is recommended by the late Duke of Athol, because it allows the lower branches to extend to a greater size; and on these depend the thickness of the base of the trunk of the tree, and the strength of its roots. He therefore seldom planted more than 2000 plants per acre, more especially in elevated regions.

8285. *The process of the thickening of the soil, and the improvement of the pasture, by the larch,* being very important in its results, it deserves to be particularly described. The lower and stronger branches meet together in six or seven years after planting, so as to form a complete matting over the ground. The air and light being excluded by them, all plants that are under them die. At the same time, the annual deposit of leaves from them, by means of decomposition, forms, in the course of time, a soil of considerable depth. At the age of twenty-four, the larches lose the spines on the lower branches altogether, and that is the natural mark of their being ready to be removed by thinning, to a considerable extent. On the air being readmitted by the removal of the trees, the surface of the new-made soil, wherever it has been formed, even among the rocks, becomes immediately covered with natural grasses, of which the *Holcus mollis* and *H. lanatus* seem to predominate. These grasses continue to grow, and to thicken into a sward, by the annual top-dressing which they receive from a continued deposition of leaves. The improvement of the natural surface of the ground for pasturage, by means of the larch, appears to be a property peculiar to this tree. This pasturage is quite capable of improving the condition of cattle, either in winter or summer.

8286. *With regard to other trees effecting a change of the ground,* the following are the results of many experiments made by the Duke on the subject. In oak copses, the value of the pasture is only 5*s.* or 6*s.* per acre for eight years only in every twenty-four years, when the copse is cut down again. Under a Scotch fir plantation, the grass is not worth 6*d.* more per acre than it was before it was planted. Under a beech and spruce it is worth less than it was before; but the spruce affords excellent shelter to cattle, either from the heat of summer or the cold of winter. Under ash the value may be 2*s.* or 3*s.* per acre, more than it was in its natural state. But under larch, where the ground was not worth 1*s.* per acre, the pasture is worth from 8*s.* to 10*s.* per acre, after the first thirty years, when all the thinnings have

been completed, and the trees left for naval purposes, at the rate of about 400 to the acre, and twelve feet apart. Nay, so impressed was the Duke of the value of larch as an improver of natural pasturage, that he makes a statement to show that the pasture alone, independent of the ship-timber on it, would increase the value of land, by increasing its annual rental, so that it itself would repay the whole outlay of fencing and planting, at five per cent. compound interest, thus :—

3000 acres of land in its natural state, not worth above 1s. per acre, at 25 years' purchase,	£	s.	d.
will give	-	-	3,750 0 0
Plants and planting, at 6s. per acre	-	-	900 0 0
2400 rods of fencing, at 5s. per acre	-	-	600 0 0
Sundry expenses, at 3d. per acre	-	-	37 10 0
			£5,287 10 0

5287. 10s., at five per cent. compound interest, for twenty-nine years, the period at which the land is fit to be begu to be depastured, gives 21,150*l.*; but 3000 acres, at an improved rent only of 6s. per acre per annum, at twenty-five years' purchase, yield 22,500*l.* (*Highland Soc. Trans.*, vol. xi. p. 189.)

8287. *The value of larch wood*, exclusive of the value of the pasture under it, may be estimated in this manner :—Suppose the plantations are thinned out by thirty years to what they are to stand for ship-timber; that is, to 400 trees per Scotch acre;—suppose, after that period, the whole were cut down at the following respective ages; the value of the whole, per acre, at the different periods, would be as follows :—

400 trees at 30 years old, at 2½ cubic feet each tree, = 1000 cubic feet, or 20 loads at	£	
1s. 6d. per foot profit, =	-	75 per acre,
400 trees at 43½ years old, at 15 cubic feet each tree, = 6000 cubic feet, or 120 loads,		
at 1s. 6d. per foot profit, =	450	—
400 trees at 59 years old, at 40 cubic feet each tree, = 16,000 cubic feet, or 320 loads,		
at 2s. 6d. per foot profit, =	2000	—
400 trees at 72 years old, at 60 cubic feet each tree, = 24,000 cubic feet, or 480 loads,		
at 2s. 6d. per foot profit, =	3000	—

The average of these prices would be 1381*l.* 5s. per acre; so that 1000*l.* per acre is not too high a calculation of the value of the Duke's larch plantations.

8288. *On felling large trees of larch*, care must be taken to use plenty of rope, and to take advantage of the direction of the wind: but a very windy day should be avoided. It was found, in digging the Scotch fir out by the roots from among the larch, that the ground was so much shaken about the roots of the larch, as to endanger their stability; ever after, the fir was cut over by the ground.

8289. *The seasoning of larch timber* is accelerated by stripping off the bark before felling. In May, 1815, the Duke experimented on fifty trees of larch at Dunkeld, that were growing in a situation, among other wood, that was nearly inaccessible for want of a road or path to it. In 1816 they were cut down and used for several purposes, and they appeared to be completely seasoned. They contained twenty-five cubic feet of wood each. Larch trees that had been only ten months cut down were built into a steam-boat in the river Thames, but they had not been seasoned enough, as the planks above water, near the deck, shrunk a little. In this case, however, the scantlings were made the same as of oak, which were of too slight dimensions for larch.

8290. *Uses of the larch*. These are very various. Larches have been grown by the Duke as nurses to spruce firs. The thinnings of larch plantations, "which take place from twenty to thirty years of their age, supply useful materials for various purposes. Posts and rails for fencing may be made either out of the tops or the trunks of young trees. While fir-posts and rails last only about five years, and are worm-eaten after that period, the larch-posts stand for twenty years, and never get worm-eaten. But the trunks of young trees are preferable for this purpose to the tops, as they have less sap-wood. In 1807 the Duke fenced a nursery-ground with young larch trees cut up the middle, made into a railing seven feet high. In three years after, the sawn side assumed a leaden grey colour, and in 1817 the whole railing was quite sound. Larch tops which had lain cut for four years, and were, of course, well worn, were found useful in filling drains where stones were at a distance, and they continued sound in them for many years. The larch was used for axles of different kinds of mills from 1793 to 1802, and up to 1817 they continued quite sound, though constantly in water.

8291. *For buildings*, too, the larch is found equally desirable. In 1779, the Duke built the shooting-box in Cleitill, called Forest Lodge, the floors and joints of which were made of larch. The wood was under forty years old, and, as an experiment, some of the deals were cut up narrow, and others as broad as they could be wrought. In 1817 the narrow boards continued quite close together. After the bridge was thrown over the Tay at Dunkeld, the Duke altered the course of the great northern road to Inverness, which caused him to build a new porter's lodge, stables, and offices to Dunkeld House, near the new line of road. The whole wood-work of these buildings was executed with larch. They were finished in 1812. In 1813, part of Athol House was burnt down, and the repairs of wood, consisting of joists, floors, doors, and windows, were all made of larch. This wood was so red in colour that it looked like cedar. Several houses were also repaired in the town of Dunkeld with larch. At Dunkeld 271, and at Blair 170, larch trees had been used by 1817 for building purposes.

8292. *The first attempt to use the larch for the purposes of navigation* was in the construction of fishing-boats on the Tay in 1777. In 1809, 8491 cubic feet of larch timber were sent to Woolwich dockyard. The greatest quantity which was employed was in the repair of the *Serapis* store-ship, and the state of its soundness was favourably reported on in 1817. One beam of it was put into the large frigate *Sibylle*, in 1816, after it had lain six years in the dockyard. The next trial of larch in shipbuilding was in the Sir Simon Clerk, merchant vessel, of 375 tons register, built by Messrs. Symes and Co. of Leith, in 1810. They got eleven trees, containing 1066 cubic feet, and they were formed into the first four or five planks, of three inches and a half in thickness, on the bottom of the vessel from the keel upwards. This vessel was soon afterwards taken by the Americans, and no account could therefore be got regarding the durability of the timber."

8293. *The elasticity, durability, strength, and resilience of larch timber, relatively to oak and Baltic fir*, has been determined by experiment. The details, in a tabular form, will be found in the article quoted; and the following are the general results :—The Riga timber and American white pine are about one fifth part less strong than the larch. The larch is superior to the oak in stiffness, in strength, and in resilience, or the power of resisting a body in motion; and it is inferior to Memel or Riga timber in stiffness only. The larch tree, while growing, may be uprooted by wind, but it seldom breaks over by the stem, either by wind, or a weight of snow lodging on its upper branches. The durability of the timber, in every stage of its growth, is superior to every other, even to oak itself. When speaking of all the above properties as belonging to the larch, it is always to be understood to be grown in an alpine region, on dry soil. In low rich soils the wood is of a very inferior character.

8294. *The large roots of larch trees fit for ship timber* may be used as knees; and this was first done at Leith in 1811. These roots have been used for the same purpose on various occasions since that time.

8295. *The larch has been tried for masts*; but, the vessels which were fitted up with them having left the Tay, it is uncertain how far larch timber will answer for that purpose. It was the Duke's practice "to plant spruce in all the wet parts of the ground, which he planted to the amount of about one tenth, expressly for the purpose of raising masts and spars, for which he conceived the spruce peculiarly well adapted."

8296. *The larch as piles.* Two hundred and twenty-three trees, forty-two years old, were converted into piles, and driven into the river Thames in the front of the works of the Woolwich dockyard in the year 1810. A report on their state was made in 1817, when they were found to be as fresh as when they were driven in. It is impossible to peruse this paper without being strongly impressed with the patriotic views entertained by John, the second Duke of Athol. Living in a period when the country was involved in a war with almost all other countries, he dreaded, in common with other patriots and statesmen, a scarcity of timber fit for naval purposes, and he contemplated the idea of planting so extensively as to provide against this scarcity for centuries to come. In all his plans and operations we see little or nothing of the merely selfish principle at work; his great object was to provide a regular yearly supply of ship timber, the commencement of which supply could not take place till many years after he was dead. The following table shows the Duke's own calculation of the supply which would be afforded by the woods of Athol, from 1832 to 1904.

12 years cutting from 1832 to 1844 will give	1,250 loads annually from	50 acres.
10 — 1844 - 1854 —	8,000 —	300
8 — 1854 - 1862 —	18,000 —	650
8 — 1862 - 1870 —	30,000 —	1050
16 — 1870 - 1886 —	52,000 —	2000
18 — 1886 - 1904 —	120,000 —	3000

8297. *The relative duration of timber* has been thus determined by M. Hartig, an eminent German professor of forestry. Small posts of lime tree, black American birch, alder, and trembling poplar, inserted in the soil, decayed in three years; the common willow, horse-chestnut, and the platanus, in four years; the purple beech, and the common birch, in five years; the elm, the hornbeam, the ash, and the Lombardy poplar, in seven years; the acacia, the oak, the Scotch pine, the Weymouth pine, and the spruce fir, at the end of seven years were only decayed a little to the depth of a quarter of an inch; the larch, the common juniper, the Virginian juniper, and the arbor vitae, were, at the end of the same period, untouched by decay. Thin boards of the same woods decayed in the following order: platanus, horse-chestnut, lime tree, poplar, birch, purple beech, hornbeam, alder, ash, the maple, the spruce fir, the Scotch pine, the elm, the Weymouth pine, the acacia, the oak, and the larch. (*L'Agronomie*, tom. i. p. 315.) It thus appears that the larch, whether as posts with the bark on, or sawn up into boards, is by far the most durable of our timber trees.

BOOK III.

IMPROVING THE CULTURABLE LANDS OF AN ESTATE. (p. 690.)

8298.—4213. *Draining by steam power.* The application of steam power to the draining of land which the ordinary means of draining are insufficient to accomplish, is among the most important improvements of the time. Land which, otherwise, either could not be cultivated, or with the uncertainty of reaping what was sown, is now cultivated with profit and certainty. Beyond the localities in which steam power draining is in operation, little is known of it. In the *British Farmer's Magazine* for 1839, and also, in the *Transactions of the Society of Arts* of that year, will be found a detailed account of the steam power draining which has lately been effected in Cambridgeshire and Lincolnshire. It will be found of the greatest interest to those possessing similar tracts of land. The water is lifted with wheels, and raised about 3½ feet higher than the surface, at which height it flows off to the rivers or main drains.

8299.—4207. *The frequent drain system.* The great importance of thorough drainage, and deep ploughing, has lately been placed in a striking point of view, by James Smith, Esq., of Deanston, in Stirlingshire, in an article contained in a *Report of the Exhibition of Agricultural Productions*, &c., published in 1832, by Messrs. Drummond, seedsmen, of Stirling. Mr. Smith observes, "that the practical drainers of the old school cannot see how a field should be drained, unless by deep cross drains, to cut off the springs. The portion of land, however, wetted by water springing from below, bears but a very small proportion to that which is in a wet state from the retention of the water which falls upon the surface in the state of rain, and a vast extent of the arable land of Scotland and England, generally esteemed dry, is yet so far injured by the tardy and imperfect escape of the water, especially in winter, and during long periods of wet weather in summer, that the working of it is often difficult and precarious; and its fertility is much below what would uniformly exist under a state of thorough dryness. A system of drainage, therefore, generally applicable, and effecting complete and uniform dryness, is of the utmost importance to the agricultural interests, and, through them, to all the other interests of the country. By the system here recommended, this is attained, whilst the expense is moderate, and the permanency greater than on any other system yet known. The drains, as applied to the case, have been named *wedge drains*, from their form, and being filled with wedges or keys to preserve the opening in their bottoms. They are sometimes called *furrow drains*, from their being placed under the water furrows of the ridges; but these terms give no exposition of the principle upon which the effect of this mode of draining depends. The principle of the system is, the providing frequent opportunities for the water rising from below, or falling on the surface, to pass freely and completely off; and, therefore, the most appropriate appellation for it is the *frequent-drain system*."

8300. *Main drains.* In proceeding to apply this system of drainage to land, the first object is to obtain a sufficient fall, or level, as it is commonly termed, for a main drain to receive the water flowing from the various smaller or ordinary drains. This drain should be directed along the bottom of the chief hollow or valley of the grounds, where the whole or greater portion of the drains can be led into it. If any lesser hollows occur in the extent of surface, they must also have their proportional mains or leaders. The bottom of the main should be at least three feet; and, if possible, three feet and a half or four feet under the surface where it passes along; and it should have throughout as uniform a fall as the nature of the ground will admit. It should be flagged at the bottom; or, where flagstones are expensive, built as an inverted arch, to prevent the possibility of rain, &c. washing away the earth under the side building. The dimensions necessary will depend on the fall or declivity, and the area of land from which the drain has to receive water. With a fall in no place less than 100 yards, a drain ten inches wide, and eighteen inches deep, will receive the rain water from 100 acres. It is of great importance to make the openings of such drains narrow and high; as they will thus require smaller bottoms and covers, and be less liable to give way; the current of water being also more confined, mud and sand will be less apt to settle in the bottom. Let the sides be smoothly and securely built with flat stones, either with or without mortar; and let strong flat covers be placed over the drain; or, where such are not to be found, a rough simple arch, with thin stones and mortar, may be built, packing the haunches of the arch well up to the sides of the cuts with earth beaten in firmly. Where lesser hollows occur, crossing the fields, it is necessary to cut submains along their bottoms, about three feet or three and a half feet deep, and having openings of suitable dimensions formed by stone couples (two flat stones placed together at the top and apart at the bottom, like the two sides of a triangle), or with drain tiles; or, where a very large flow of water has to be provided for, with inverted tiles, and covering tiles placed above the bottom one, or with larger tiles made on purpose.

8301. *Submain drains.* There should be a cross submain at the bottom of every field or stretch of drains, to receive the water from all the parallel drains; and such submain drain should always be cut six inches deeper than the drains running into it, that the water may have a free drop, which will prevent the lodgment of mud or sand at their junctions or mouths. Open cuts or ditches, either as mains or sub-mains, should never, except from necessity, be adapted, being apt to get filled with mud and grass, by which the water is thrown back into the drains, and often chokes them; besides, the loss of land, annoyance in ploughing, constant expense of cleaning, and unsightly appearance of such drains, are serious objections.

8302. *Parallel or frequent drains.* Having thus provided a main drain, with submains flowing into it, matters are prepared for setting off and for executing parallel or frequent drains in the field. These drains can be executed at any season when the weather will permit; but spring and summer are most suitable for the work. It is best to execute the drains when the field is in grass, as they can then be cut in all kinds of weather, and in a more cleanly manner.

8303. *In setting out the drains,* the first object for consideration is, the nature of the subsoil: if it consists of a stiff strong clay, or a dead sandy clay, then the distance from drain to drain should not exceed from ten to fifteen feet; but if there is a lighter and more porous subsoil, a distance of from eighteen to twenty-four feet will be close enough. When the ridges of the field have been formerly much raised, it suits very well to run a drain up every furrow, which saves some depth of cutting. At whatever distances the drains are placed, they should be run parallel to the ridges, which is commonly in the steepest descent. They should always be run quite parallel to each other, and at regular distances, and should be carried throughout the whole field without reference to the wet or dry appearance of portions of the field; as uniform and complete dryness is the object, and land, which may be considered dry in its natural state, will show wet when compared with properly drained land. A three feet drain should be carried along the ends of these drains at the top of the field, and at a distance of about nine feet from the fence, especially if it is a hedge fence. Such a drain is necessary for the growth of the hedge; but if made nearer than nine feet, the roots are apt to get into the drain, and choke it up by degrees. It is of importance to be accurate in setting out the drains as described, as it secures uniformity of dryness, and in all future operations, or at any time, it is easy to ascertain the line of any drain.

8304. *Excavation.* The lines of drains having been marked off in the field, the drainer begins by cutting with a spade on a line; then removing the first layer to the depth of a spitful of about thirteen or fourteen inches wide all along, another follows with a narrower and tapering spade, made for the purpose, taking out another layer; and, when picking becomes necessary, a third man follows with a pick; and a fourth with a large scoop shovel to cast out the earth, and a smaller scoop shovel is used to clean out the bottom, which should be cut as narrow as will allow the last drainer a footing, generally about three or four inches. From two to two feet and a half from the surface are the best depths for such drains; the latter always to be preferred. The bottom should be cut as straight and uniform as possible, so that the water may flow freely along at all places, and it is better to cut a little deeper when there is any sudden rise of the surface than to follow it; and where sudden hollows occur, the cutting may, on the same principle, be less deep: attention to this also admits of after straightening or levelling of the surface, without injury to the drains. The workmen, in cutting, should throw the earth to the right and left from each alternate drain, as that allows the plough to go regularly and fully occupied *boutings* (a Scotch term for a rotation or traverse of the plough) in filling in the earth, whilst each alternate ridge or space is left for getting in the stones free from the earth thrown out.

8305. *Filling.* The stones may either be laid down at intervals, by the sides of the drains, to be there broken; or, being broken in masses at some convenient spot, can be brought by the carts, ready to be filled in. No part of any drain should, if possible, be filled in, till the whole line is cut out and inspected, but the sooner drains are filled, after having been cut, the better. Sometimes, when there is much tendency of the sides to fall in, it becomes necessary to fill in going along. Cutting at the end of summer, when there is little water in the soil, or in a dry season, saves much of this. In soft or sandy bottoms, by cutting the drains to half the depth in the first instance, and allowing them to remain in this state until the water has drained from the upper stratum of the soil, the lower part may be cut out with more safety from falling in. The stones covering the drains should not be filled in nearer to the surface than eighteen inches, leaving sixteen inches free for deep ploughing.

8306. *Covering the stones.* The upper surface of the stones having been made straight and uniform, the whole should be neatly and closely covered with thin turfs, cut from the adjoining surface, or brought from some suitable place. Strict attention to the correct execution of this operation is of the greatest importance, as many drains are ruined at once, from the rinning in of the loose earth. Thick turfs are objectionable, from the difficulty of getting them to fit close. Straw, rushes, broom, whin, and other like material, are very objectionable, affording no certain or uniform security, and forming a receptacle for vermin. Peat may be used to advantage. Where the deepest ploughing has been executed, there should always remain a firm crust of earth undisturbed over the stones of the drain; and no surface water should ever have access to the free way of a drain by any direct opening, but should find its way, by percolation or filtration, through the subsoil, and should always enter by the sides of the drains. For this purpose, it may be of advantage to tread or beat down closely the first two inches of soil put over the turf, in order to form the permanent crust.

8307. *The cost of executing such drains* varies, of course, according to circumstances: the cutting cost (in 1832) from 1s. 6d. to 2s. 6d. per rood of thirty-six yards, according to the hardness of the subsoil; the stones, if collected on the adjoining fields, will cost from 1s. to 1s. 6d. per rood, the breaking from 9d. to 1s. per rood; about one and a half cubic yards of broken stones will fill a rood of a well cut drain; the putting in of the stones may be calculated to cost about 3d. per rood, and the turving about 1d.; the filling in of the earth over the stones with the plough will cost about 1d. per rood. The whole cost, per rood, of common drains, may be taken at 4s. 8d., or, including a charge to cover proportion of main drains, 5s.

8308. *The following table exhibits the cost per Scotch acre of draining in this method, at various distances between the drains; and as this method of draining forms a permanent improvement of the land, it is presumed the proprietor should defray part of the expense. The table is constructed to show how much it will cost the landlord in money to do the cutting, carrying, and (when necessary) breaking of stones, filling in, and turving; and how much the horse-work, &c., which can be performed by the tenant, will cost, charged at the ordinary rates:—*

8309. *Remarks.* In cases where time or capital are wanting to complete the draining, each alternate drain may be executed in the first instance; and the remainder can be done the next time the field is to be broken up. After the drainage has been completed, a crop of oats may be taken from the field; and immediately after that crop is off the ground, the field should be gone thoroughly over with the subsoil plough, crossing the line of drains at right angles.

8310. *The subsoil plough* has been constructed on principles appearing the best fitted to break up the subsoil completely to a depth sufficient for most thorough cultivation, say fourteen to sixteen inches, allowing the active soil still to remain on the surface; to be of the easiest possible draught, in reference to the depth of furrow and firmness of the subsoil; and to have strength and massive weight sufficient to penetrate the hardest stratum, to resist the shocks from fast stones, and to throw out all stones under 200 lbs. in weight. All this has been accomplished, and practically proved, over an extent of at least 200 acres of various soils. This plough requires four good horses, an active ploughman, and a lad to drive the horses and manage them at the turnings. Six horses, yoked three and three abreast, may be necessary in some very stiff or stony soils. A common plough drawn by a pair, goes before the subsoil plough, throwing out a large open furrow of the active soil. The subsoil plough following, stirs up thoroughly and breaks the bottom, when the next furrow of the active soil is thrown over it; the stones brought to the surface by the subsoil plough being thrown aside, on the ploughed part of the land, by a boy or lad; and so on, till the whole field is gone over. The boy should carry a bag of wooden pins, that he may mark the site of the large fast stones which the plough cannot throw out, and which must afterwards be dug out with the pick, and, perhaps, blasted. This large plough is a sort of horse-pick, breaking up without raising to the surface the subsoil. Channels are thus regularly formed for the water to flow from all parts towards the drains. The atmospheric air being also by this means freely admitted to the subsoil, the most sterile and obdurate clay becomes gradually ameliorated, and the common plough may ever after be brought to a depth of from fourteen to sixteen inches without obstruction; and with the power of three horses yoked abreast, and managed with ease by the ploughman, without any person to drive. By being thus yoked together, and near the point of resistance, the horses have great power; and, the furrow turned over being broad in proportion, nearly as much ground will be gone over in a day, as with a plough and a half drawn by a pair of horses. The cost of subsoil ploughing an acre may be estimated at 30s., being one sixth of what a similar depth would cost with the spade; and, upon the whole, as effectually done. A subsoil plough with apparatus cost, in 1832, from 7l. to 8l.

8311. *The effect of this mode of draining and deep working on close-bottomed land* is quite wonderful. After one turn of green cropping, with the usual application of lime and dung, the formerly quite sterile surface soil becomes a deep rich loam, carrying, without fail, crops of wheat and barley, producing from nine to twelve bolls per acre of wheat, and from eight to twelve of barley; the hay and pasture following being also very fine. When fields have been thus dried and worked, it is recommended to plough them at all times without ridges, or water furrows, preserving one uniform sheet of soil over the whole field. By this means every superficial inch is allowed to be productive. There is no carrying away of the surface by accumulated currents of water; and the water falling as rain, is left to percolate through the soil where it falls, thereby uniformly enriching the whole extent. There is a powerful process of nature much facilitated by complete draining and deep working, viz., the constant circulation of air to and from the bottom of the soil, produced by the constantly varying relative temperatures of the atmosphere and the earth. When heavy rain falls, the air is completely expelled from the interstices of the soil, the water taking its place. Also, when the rain has ceased to fall, the water gradually subsides to the level of the drains, or, at all events, to the level of the bottom of the subsoil that has been moved by the plough, and fresh air takes its place throughout the soil; thereby promoting doubtly a chemical action vastly conducive to the decomposition of the soil and the manure it contains; and, of course, to the nourishment of plants. When land is uniformly and completely dry and deep in the soil, it is more easily wrought; it can be wrought at any time when it does not rain; it comes to a state proper for sowing earlier, and more uniformly; a circumstance of great importance in our climate; it affords a wide and uninterrupted range for the roots of plants; it resists the evil effects of long droughts, as well as of long periods of wet; it never honeycombs, as it is called; it seldom throws out plants of any kind in frosts; it never suffers from the treading of cattle in removing the green crop; for, although apparently puddled or poached on the surface, yet, being dry below, a single ploughing restores the soil to a proper tilth; and it gives an earlier harvest, and affords a dry bed for cattle when in pasture. In the conclusion of his article, Mr. Smith observes, that the subject of the rough under-draining, and of deep ploughing, is one of so much importance, and so extensive in its parts, that volumes might be written on it to the advantage of the country. (*Report of Dr. Drummond's Agricultural Exhibition, &c.*)

8312. *4267. Thorough draining* has been practised in Suffolk for many years; a narrow gutter being cut in the bottom of the drain, which is not filled up with any material through which the water drains in the usual manner, but with such materials as will support the earth above till the arch is formed; by which time the supporting material is for the most part perished, and a clear channel for the water left. The materials used are haulm, heath, a coarse rope of straw or of hop-binds. The practice is exceedingly well described in *Journ. A. E.*, vol. iv. p. 23.

8313. *The direction of frequent drains with reference to the inclination of the ground*, is a subject on which at one time there was some difference of opinion. Deep drains to cut off springs are unquestionably most effective when carried across a declivity; but drains made in the furrows to carry off surface

water, will best attain their object when made straight up and down the slope. The reason is thus given by Mr. Smith of Deanston: "Drains drawn across a steep, cut the strata or layers of subsoil transversely, and as the stratification generally lies in sheets at an angle to the surface, the water passing in or between the strata, immediately below the bottom of one drain, nearly comes to the surface before reaching the next lower drain. But as water seeks the lowest level in all directions, if the strata be cut longitudinally by a drain directed down the steps, the bottom of which cuts each stratum to the same distance from the surface, the water will flow into the drain at the intersecting point of each sheet or layer, on a level with the bottom of the drain, leaving one uniform depth of dry soil." (*Remarks on Thorough Draining*, p. 9.)

8314. *Tile draining* has the great advantage of suiting every soil, from the poorest to the richest, and of being used at any depth, and where stones cannot be applied, as in morasses or flur-moss. It is less expensive than stone draining, and equally, if not more, durable; for if a tile should give way, it can easily be replaced, or a whole drain reopened and renewed at pleasure; which is impracticable with stones. Besides, being more portable, tiles can always be had of any size, shape, or strength desired, in those clay districts where stones are with difficulty procured, and may therefore safely be taken as the best substitute for stones in ordinary draining. Shut up from the influence of the weather, and secured from every injury, it is impossible to limit their duration, or conceive anything better calculated for the purpose of draining. In all cases where the bottom of the drain has very little slope, tiles are decidedly preferable to stoe, and ought, therefore, to be used in such situations, even though they should prove more expensive than stones. (*Trans. H. S.*, vol. xii. p. 81.)

8315. *Concrete drain tiles*, have been made by Lord James Hay, and the mode of operation is most distinctly described and illustrated by figures in the *Trans. H. S.*, vol. xiv. p. 592. It can only be attempted with any prospect of success where there is strong quick setting lime and sharp sand. Perhaps peat may be advantageously compressed into draining tiles.

8316. *Peat cut like draining tiles* by means of a peculiar spade, and dried in the sun during summer, and stacked like peats ready for use, is found an excellent substitute for clay tiles. (*Q. J. A.*, vol. vii. p. 246.)

8317. *The substitution of larch-wood tubes for drain tiles* has been adopted by W. Scott, Esq., Craigmoy, Kirkcubright. The tubes are 4 inches square externally, with a clear water way of 2 inches. They are put together with wooden pins or nails, as may be found most economical. (*Trans. H. S.*, vol. xiv. p. 104.)

8318.—4330. *A tide sluice*, invented by the Rev. George Cruden, is represented in figs. 1177. and 1178., the first a vertical profile with the cover removed, and the second a vertical section; the same letters applying to both figures.

a, the spout of the apparatus laid in the embankment, constructed of wood.

b, the descending nozzle of the spout in which is placed the float valve, also made of wood.

c, the float valve, being a hollow wooden box capable of rising and falling in the nozzle b, from its buoyancy in the tidal water, so as to shut or open the passage a.

d, openings for the escape of the collected water which is discharged during the recess of the tide.

The mode of the float's operation is thus: "During the recess of the tide, the float, by its own gravity descends until its upper surface is on a level with the sole of the spout, thus giving free egress to the fresh water collected in the reservoir, until the flood-tide has risen so high as to envelope the float in its water. The float in the tidal water, and so closes the passage through the spout a, preventing either the ingress of the tidal water, or the egress of the drained water until the tide has again fallen below the level of the float. Perhaps a more uniform and more permanent action would be obtained by constructing the float, and the chamber in which it operates, of thin sheet copper, or of sheet iron, and giving it a cylindrical, instead of a cubical form." (*Trans. High. Soc.*, vol. xii. p. 137.)

8319.—4406. *Sluices, trunks, and valves for embankments* are now made of cast iron, on an improved principle; and, when properly fixed in by a mass of masonry and cement, they are found to retain the water of a pond, and admit it at pleasure, with as much accuracy and ease as a brass cock does the contents of a beer barrel.

8320.—4485. *Artesian wells*, or those produced by boring, are so named from their having been first used in the neighbourhood of Artes in France. Upon a review of the appearances observed in these wells, it is quite evident that they must always succeed where an inclined stratum of a fissured or porous limestone, or other porous stone, is included between two waterproof beds of clay; one of which sets a limit to the sinking of the water downwards, and the other prevents it from rising above the surface. The existence of such a cover is evinced by all boring works. A waterproof stratum of clay must always be penetrated, before reaching the spring water; and it may easily be conceived that the undermost layer is never wanting. Although, for the most part, some thioner strata of limestone supply its place, yet the strata, which conduct the water, always contain it in crevices, which are much more numerous on the surface than in the centre of the beds. Thus, there is a demonstration, as in a boring work at Bleng, that, even in the limestone itself, beds of clay occur. From these circumstances it is easily explained how we can never hope to sink Artesian wells in granite, gneiss, porphyry, serpentine, &c. Even in schistose mountains, it would not be advisable to sink these wells, because, if water were found there, it would be very easily impregnated with sulphuretted hydrogen, from the abundance of pyrites occurring in these strata, and thus be unfitted for many uses. Limestone, on the contrary, which is very insoluble, experience teaches us, yields a very pure water. These observations especially relate to the Pés de Calais.

8321. *Other districts*, where water has been bored for, show a similar geognostic constitution to the Pés de Calais. M. Garnier, in his *Manuel du Fontanier-sondeur*, &c., notices this, with regard to Boston in America, and Sheerness in England. Loudm (where many sugar-works, distilleries, and breweries have, for a long time, been principally supplied with water from Artesian wells) lies in the middle of a basin-shaped hollow, the fundamental rock of which is a limestone belonging to the chalk formation; which also forms the heights in the vicinity, and which is covered with clay, though at times not immediately. The wells, which are not sunk to this Loudon clay, give abundance of clear, but mostly very hard, water; while those which penetrate through the Loudon clay, into the subjacent plastic clay, a formation immediately covering the chalk, and consisting of alternating beds of sand, clay, and boulders, yield a very soft and pure water, which, on piercing this clay, often ascends with such violence that the workmen have scarcely time to escape. Here the plastic clay seems to be either the conducting medium, or the reservoir of the water yielded by the chalk. Paris is known to be situated in a district whose geognostic relations are most identical with those of London; and therefore we cannot wonder that there, as well as in many other parts of the north and east of France, Artesian wells may everywhere be sunk; nor can we doubt of the extension of this very useful discovery. (*Jameson's Phil. Journ.* for July, 1830.)

8322. *We must not, however, expect to be able to sink Artesian wells in every description of country*, as has been thoughtlessly asserted. On the one hand, the nature of the ground sometimes absolutely prevents it, as in granite districts; and on the other hand, it is possible that a perforation, if made too near

a bored well affording water, may not yield any; should the latter, for example, be fed by a subterranean current, in place of being supplied by a sheet of water; or should the perforation be made upon the extremity of a basin with inclined strata, resting upon a formation of a very different nature. M. Garnier's *Manuel du Pontanier-sondeur* contains all that can be desired on the subject of boring these wells. (*Ibid.*)

8323. *General observations on Artesian wells.* Great subterranean sheets of water exist at various depths. These sheets are more commonly met with in the plane of superposition of strata of different formations. They, however, frequently occur at various heights in the great masses of earth; such as those of clay, chalk, and even marine limestone containing corals, when these masses are entire and of great thickness. According to the slope, the undulations, or the declivities which are presented by the plane of superposition of the permeable deposits in which the waters flow between impermeable strata, these great sheets of water are met with at all depths; but it is impossible to lay down any constant rule with respect to them. (*Ibid.*)

8324. *In order that these waters may be capable of ascending, it is necessary that the formations among which they occur be entire, in the state in which they were originally deposited; and that they be not intersected by large valleys, or deep ravines, through which the waters would find a free and easy exit.*

8325. *It would be in vain to search for springs in deposits which, at no great distance from the place of boring, are intersected by deep valleys, or when the formations are internally crooked, filled with tortuous separations, and greatly disturbed, whether by the contraction attending the desiccation of the mass, or by internal shocks, swellings, or earthquakes; or, lastly, when these Neptunian formations, such as plastic clay, chalk, oolite, and shell-limestone, are raised up, and present precipices at the surface. In such localities, we need not expect success in boring for springs, unless by penetrating deeply into the mass of the chalk, in search of the sheets of water in its lower part; or even by traversing it entirely, in order to come upon those in the clays, oolites, and shell-limestones; or, lastly, unless by penetrating deeply into the latter, when they happen to be raised to the surface, and to present cliffs, or are intersected by valleys of greater or less depth.*

8326. *In a country composed of elevated plains, if, in place of boring to the necessary depths for reaching the different water-sheets which are commonly the most abundant, and, at the same time, those which rise highest, the boring is stopped at higher levels, less distant from the surface, it is more than probable that the ascending waters will stop more or less beneath the surface of the ground, according to the depth of the borings. When this occurs, we ought to be far from considering the operation as having failed; because in this case the water does not rise above the surface, and in most instances, according to the localities and the nature of the ground, steps may be taken to remedy the deficiency. Thus, for example, when the water of a boring only rises to within a certain number of yards from the surface, but in sufficient quantity, it might be conducted from the point to which it reaches, by a small gallery, into some neighbouring well, or into one dug on purpose; and there might thus be produced a kind of artificial fall, which might be employed to make the water ascend to the surface of the ground, and even beyond it, by employing for this purpose either the hydraulic ram (bâlier hydraulique), which would always give a third of the volume of water, or a wheel, which might be placed at the point of the fall, and which, working a pump suitably placed, might raise the third, or perhaps even the half, of the volume of water; or, in short, any other hydraulic machine of the kind. But these means would be practicable only in so far as the wells into which the waters should be precipitated might not allow them to run off into strata of permeable deposits.*

8327. *Circumstances which it is necessary to examine and appreciate before resolving upon boring a well.* It is necessary to examine the physical constitution or the nature of the ground, and the disposition of the surface of the country, with reference to the mountains which overlook it, the valleys by which it is intersected, and the springs which rise in those valleys. The latter it is particularly necessary to examine, before deciding upon boring a well, as many of them are natural wells. It is of importance to select a fit person for boring; the art not being merely mechanical, and such as can be practised by any borer. Besides attending to these circumstances, it is necessary to be possessed of perseverance and courage, which will lead us to disregard the delays and difficulties often unavoidably connected with the operations of boring. (*Hérisart de Thury, as quoted in Jameson's Journal for July 1830.*)

8328. *Boring for water in deep sand.* Mr. David Greenley of London, has been lately (August, 1834) very successful in obtaining "an abundant supply of pure water," at Diss in Norfolk, at a depth of upwards of 600 feet below the surface. A well had been previously sunk in the same place; but, in consequence of an immense quantity of sand rising whenever the pump was worked, it was almost useless. (See *Arch. Mag.*, vol. i. p. 210.)

8329. — 4512. *The improvement of waste lands, whether moss, bog, or wet clay is exemplified in seventeen different cases reported on in the Highland Society's Transactions, vol. x. p. 281.* The article embodies an immense amount of valuable practical information on the subject.

8330. — 4524. *Bending rocks or stones.* A newly invented apparatus for this purpose has been brought into notice by Mr. D. Millar, road contractor and builder in Edinburgh. The apparatus appears to be a more efficient boring instrument than any hitherto in use. It is calculated to bore or tap to the depth of 100 feet or upwards, and may be put in operation either by manual labour or steam. (*Scotsman*, Feb. 22. 1834.) An instrument for the same purpose was invented by Mr. Mallet of Dublin in 1832. Mr. Mallet's object was to split all rocks that could be separated into laminae, by the application of the male and female screws; instead of blasting, as heretofore practised, with gunpowder. The process is as follows:—Jumper holes are formed in the direction of the proposed fracture, as at present; but, instead of filling them with gunpowder, a split female screw is inserted in each hole, and the fracture is effected by the insertion of a conical or male screw. (*Arch. Mag.*, vol. i. p. 93.)

8331. — 4541. *Draining and bringing into cultivation moss-lands or peat-bogs.* The Liverpool Agricultural Society having awarded its premium to Mr. Reed, late of Chat Moss, but now a professional drainer, we give the following as the essence of his paper. We may premise that we had the pleasure of inspecting Mr. Reed's farm at Chat Moss, near Liverpool, in August, 1831, and were much gratified and instructed by what, when there, we saw and were told by Mr. Reed.

8332. *Draining.* The water, to a considerable depth from the surface, being held in a great degree by capillary attraction, drains should be frequent, and more or less distant according to their depth. Open drains to divide the fields may be placed at any distance not exceeding 100 yards. The covered drains should run at right angles to the divisional drains. Sixty-six yards, or three chains, Mr. Reed has found the best width between the open drains; and, consequently, as the covered drains are at right angles to these, their length will be sixty-six yards. The open drains may be four feet wide at the top, from three feet six inches to four feet deep, and fourteen inches wide at the bottom. The covered drains should not be more than five or six yards apart, and three feet deep. No material is wanted to cover them but the moss itself. The form should combine the principle both of the shoulder and the wedge drain, and the somewhat square clod, which is first taken out, when dried to a certain extent by the weather, becomes the cover.

8333. *Preparing the surface.* "Moss, or peat bog, is not a soil, but an accumulation of dead, dying, and living plants growing in water." To form a soil, therefore, it is necessary to destroy, to a certain depth, the original structure of the moss, both for the purpose of destroying vegetation, and facilitating the passage of the water to the covered drains. Digging is perhaps the best mode of destroying the structure of the moss, and afterwards, a cutting machine formed by fixing circular knives on the cylinder of a common roller, may be applied. In due time, the surface may be harrowed, and afterwards manured,

and sown with a crop. Any description of earth ls useful, as tending to consolidate the moss, and to facilitate its decomposition : but, to obtain a good crop the first year, putrescent manure in a considerable quantity is absolutely necessary.

8334. *After cultivation.* "Manure of some sort being applied, almost any description of crops may be had; but potatoes are perhaps the best article to begin with; 2d, wheat; 3d, clover, without grass seeds; 4th, oats. The rotation may be varied, so as to include almost every crop."

8335. *The preparation of coke or charcoal from peat or moss* has been effected in different parts of Scotland, and in Ireland, and the charcoal thus produced has been found superior to many kinds of coal for smelting iron, and the use of smiths' forges. This arises from the total absence of all sulphuric matter in the peat, which renders it almost equal to the charcoal of wood, to which it is well known the Swedish iron owes its principal excellence. The charring of peat for use in smelting iron has been strongly recommended as a means of giving employment to the labouring population. (See *Brit. Farm. Mag.*, vol. v. p. 360.)

8336.—4982. *Ripening corn.* It is important, Dr. Madden observes, that the process of ripening after the seed has filled, should be as rapid as possible. "When the ear first fills, it appears composed almost entirely of a substance resembling milk; in about a fortnight after this, if we again examine the crop, we shall find the seed much more solid, the milky juice having hardened and consolidated, and the straw having begun to wither, which it always does from the ground to the ear. At this period the straw will be yellow for about a foot above the ground; in another fortnight the crop will be perfectly ripe, that is to say, the straw will be uniformly yellow up to the ear, and the chaff will be sufficiently loose to admit of the grain being rubbed out by the hands. On examining the ear, the most perceptible difference which has taken place since the last period is, that the skin has become much thicker and harder, while the flour is diminished in quantity. Now this is the important point, viz., that the last change in the seed is an increase of bran, and a relative diminution of flour, which change increases materially, according to the length of time that elapses between the ripening and the harvesting of the crop." (*Trans. H. S.*, vol. xiv. p. 628.)

8337.—4991. *Diseases of Corn.* Professor Henslow delivered a learned lecture on this subject, the essence of which will be found in the *Gard. Chron.* 1841, p. 5.

8338. *The bunt fungus (Uredo caries Dec.)*, called also smutballs and pepperbrand, may be described as a powder occupying the interior of a grain of wheat, the only corn it attacks. The effects which alkaline substances, such as potash, lime, &c., produce in destroying the smut, when seed or corn is dressed with those substances, is supposed to be owing to their forming a soapy compound with the oil of the fungi, which is then more easily detached from the surface of the corn, to which its natural greasiness makes it adhere.

8339. *The smut or dust-brand (Uredo setigera Dec.)* is a fungus which differs from the last in wanting its disgusting odour, and in escaping through the sides of the infected grain in the form of a sooty powder. It rarely attacks wheat, but is a common enemy of oats and barley. The usual palliative of this evil is steeping, as in the case of the bunt.

8340. *Rust (Uredo rubigo Dec.)* is a fungus resembling an orange powder, exuding from the inner chaff-scales, and forming yellow or brown spots and blotches on various parts of corn plants. In itself it is a pest of comparatively small importance; but Professor Henslow has made the very curious discovery that it is the young of the mildew, the *Puccinia graminum* of botanists, which is so destructive when it attacks the straw. He stated that these fungi are at first spherical, or nearly so, and then constitute the *Uredo* or rust; but by degrees the spherules lengthen, acquire a stalk, contract in the middle, and so form the head of the *Puccinia*; so that two supposed genera of botanists, *Uredo* and *Puccinia*, are undoubtedly the same species in different states of development.

8341. *Ergot* was regarded as a monstrous state of the grain of rye, produced by the external action of a minute fungus, which causes the grain to lengthen into a horn something like a cocks spur. It is so exceedingly oily that it will burn like an almond in the flame of a candle. The action of ergotised corn has been ascertained to be highly deleterious, both to man and animals; the latter, indeed, preferred starvation to feeding upon it, even when mixed with good flour. A duck which had been fed with ergot mixed with flour, in the proportion (say) of 1 in 17, died in ten days, after having had the end of its tongue rotted off, and drops of blackish blood oozing from its nostrils. A pig was poisoned in like manner in twenty-three days; the ears and the flesh of the tail having rotted away, and the legs having mortified. Fortunately we know little of this pest in England; for it is equally fatal in its horrible effects upon man, as has been amply proved in France. Draining is considered as the only known preventive of ergot.

8342. *Ear cockles* are produced by an animalcule called the *Vibrio tritici*, which may be compared to the eels in paste on a small scale. They form a cottony mass in the interior of the grain, which, when the latter is ground, will not pass through the cloth, but remain behind in the bran. Although this creature is microscopically small when young, it is a giant at its full growth, becoming a quarter of an inch long. Nevertheless, Mr. Bauer has calculated that 50,000 of the young might be contained in one grain of wheat. Scalding water was mentioned as the most obvious remedy for these creatures.

8343. *The wheat midge (Cecidomyia tritici)*, millions and millions of which infest every wheat-field, is hardly known by farmers to do them any wrong; and yet, on an average, it destroys one-twentieth of a crop, and may possibly destroy a great deal more. It appears in June, up to which time its chrysalis lies amongst the chaff of the corn. When the corn is winnowed, the pupæ of the midge are driven forward with the chaff from the winnowing machine, and fall before it within the space of about three yards. As wheat chaff is always sifted before it is given to horses, and the pupæ pass through the sieve with the dust, it occurred to Professor Henslow that if a wire gauze sieve were placed before the winnowing machine in a sloping position, so as to allow the chaff to fall upon it, and then roll from it, the pupæ would pass through, and might be taken with the dust in a tray placed below the sieve. (*Gard. Chron.* 1841, p. 5, 52, 556, 815.)

8344. *Cure for smut.* Steep in dung-hill water, to which salt and saltpetre, or coppers, have been added, so as to cause the water to bear an egg: steep the corn twelve hours, and afterwards dry it with slaked lime, or dry turf ashes, and sow it as soon as possible. (*Gard. Chron.* 1841, p. 69.)

8345. *Smut* effectually cured by scalding in boiling water for a few seconds, and then dipping in cold water and drying with lime. Great care was taken that the water was boiling, and the wheat taken out of the water as soon as completely wetted. (*J. Ellis, Esq. of Barming in Kent, at the February Meeting of the English Agricultural Society.*)

8346. *Sleeping seed wheat.* Professor Henslow found, that steeping in sulphate of copper effectually prevented disease, while it did not affect germination. (*Gard. Chron.* 1841, p. 815.)

8347.—4992. *The advantages of cutting corn crops before they are dead ripe*, that is, when the straw immediately below the ear is just beginning to turn yellow, are thus summed up by Mr. Sheriff.—An increased quantity of grain, greater security from the weather, improved quality of straw, and an extension of the harvesting season. To these may be added, greater security against the effects of wind and rain, either as affects the shedding, discoloration, or germinating of the grain. The colour of grain which was not cut till it became dead ripe is generally of an opaque whitish hue; while that which was cut before it was dead ripe is transparent, and tinged with brown. The latter description of sample bears the highest price in most British markets. (*Brit. Farm. Mag.*, vol. v. p. 23.)

8348. *The period at which corn crops ought to be reaped* is best determined by examining the upper grains of the spikes. The cereal grasses, like all monocotyledonous plants, ripen the seeds on the upper extremity of their flowers, or even in the upper part of their seed-vessels, in the case of plants with pods containing many seeds: whereas dicotyledonous plants ripen their seeds equally throughout the seed-

vessel, and in general rather ripen them first at the lower end than at the upper end. When the uppermost grain of a spike of corn has dropped out, the stalk may be considered as having stood rather too long, and the reaping point to be that when the uppermost grain is firm and plump. On the whole, the most improved practice of British farmers is in favour of reaping their crops at an earlier state of ripeness than they have hitherto been accustomed. (*Quart. Journ. Agr.*, vol. iv. p. 501.)

8349.—4995. *Cutting grain crops with a common scythe* has been generally practised in Aberdeenshire since 1818. The crops grown in this country are chiefly oats and barley. No change whatever is made in the common grass and clover scythe, for cutting heavy or lodged grain crops; but for light standing crops, a very simple addition is found of advantage. This consists of a small rod or shoot, nearly an inch in diameter, of green willow, or rowan (mountain ash), or broom, or any other flexible and tough young wood. It has its thick end twisted into the small iron rod, which aids in attaching the blade of the scythe to its handle, named provincially the grass-nail. Its small end passes over the upper side of the blade as far as the back, where it is bent upwards in an easy curve, and is brought backward, and tied with several rounds of strong twine to the handle, about fifteen inches above the blade. In cutting grain with a scythe, the swathe or cut corn is laid away from the standing corn. Every mower is attended by a gatherer; and, as the gathering is the part of the work that women can best perform, the gatherers are generally women. The grain is left by the scythe, having the stems forming an acute angle with the line of the standing corn, the root end of the stems pointing partly backwards and partly inwards towards the uncut part of the field. The gatherer places herself at the root end of the stems, so as to be able to stoop forward nearly in the line in which they are laid; and by a succession of lifts with her hands, placing the corn on the rear over that which is more forward, stepping at the same time towards the right hand herself, she gathers into one heap what she deems sufficient for a sheaf, and, having carefully separated it with her right hand from the forward part of the swathe, then makes a band, in the ordinary way, of a part of the gathered heap, and lays the heap upon it. A hinder is also attached to every mower, who is able to bind up all the sheaves cut by one scythe, and also to set them up in shocks; but there is no novelty in his operations. The gatherer and binder could generally, after a skillful mower, gather up all the corn sufficiently clean; but their labour would be greatly impeded, so as that they could not keep up with the scythe, were the cleanest gathering strictly enforced. That is, therefore, dispensed with; and a raker, generally a woman, follows the other operators, to collect the straggling ears and straws. (*Highland Soc. Trans.*, vol. x. p. 189.) The Rev. James Farquharson, speaking of this mode of reaping, says,—"In no branch of agricultural labour, not even in the substitution of the two-horse plough for the one drawn by ten oxen, or of the threshing-machine for the flail, has a more valuable advance been made, within our memory, from an old and inferior system to a new and better one, than in the adoption of scythe-reaping. It is calculated that double the work is done by the scythe, which could be performed in the same time by the sickle. It is also better performed; because the straw is cut off more closely to the ground, and consequently a better provision is made for cattle fodder during the winter, and for a larger quantity of manure. When the grain is over-ripe, much less is shaken out by the scythe than by the sickle. Another advantage, of which the magnitude can scarcely be believed, except by those who have learnt to estimate it by their own experience, is the quickness with which the mowed shock winds (dry or withers) thoroughly, and becomes fit for the stack; a matter of the utmost importance in our unsteady climate. The straws are not crushed, as they frequently are with the hand in reaping with the sickle; and the sheaf, although not more liable to break out of the band, is more elastic and open to the action of the atmosphere. It is perhaps not too much to say, that a sheaf of equal weight, cut with the scythe, becomes ready for the stack, under equal circumstances of weather, in half the time needed by one cut with the sickle. The most pleasing advantage is the total change of the character of the labour, as it affects the larger part of the workpeople. The mowers, gatherers, and rakers deem their work delightful in comparison with the labour of the sickle.

8350. *The scythe for reaping corn* (fig. 1179.) should have its blade (a) of the best steel, four feet long,

strengthened by a plate of iron along the back (b). The handle should be straight, because that gives the greatest command over the scythe. A well-seasoned young larch tree, reduced to the proper thickness, with a slight curve at the root end, for receiving the blade in a proper position, makes the best handle to a reaping-scythe. A hone, covered with fine sand, and a fine sandstone, to whet the edge of the scythe, are hooked on to the handle at c, near its upper extremity. There should be a cradle (d), consisting of three long teeth fastened to an upright stem (e), formed of ash, and as light as the strength of the wood will permit. The upper tooth should be a little more than two feet in length, and the two under ones should be the first three inches, and the second six inches, shorter. The upright stem of the cradle is driven into a socket of iron. The height of the cradle is about thirteen inches; the left-hand handle (f) is straight, and the right-hand handle (g) is crooked. For the construction of this important instrument, further details will be found in the *Quart. Journ. of Agr.*, from which our figure is taken; but the above outline will suffice for any one who can construct a common scythe.

8351. *Corn of every description may be reaped with the scythe.* Oats make the most perfect work, with the greatest ease to all the labourers. Barley, with new grass, is not difficult to cut; but the clammy juice from the barley straw lubricates the scythe with a viscid coating like varnish, which must be rubbed off frequently with the whetstone. The binders have always hard work among barley. Wheat is beautifully laid in swath when mown. The takers-up and binders have less labour among wheat than the mowers, who must be powerful men to continue a length of time at the work; but there are modes of equalising the labour, and, of course, of diminishing the fatigue. For example: when a field of wheat and a field of oats are nearly ready for reaping, it is an excellent arrangement to reap the oats in the dewy mornings, before breakfast, or as long as there is any dampness on the corn, and then to go to the wheat, or to the barley, if there be little wheat on the farm, during the dry period of the day. By this plan much valuable time can be saved in reaping the whole crop. Oats are not the worse for being reaped in a damp state. It is a remarkable fact, that oats reaped in a damp state, with the scythe, will be nearly as soon ready for the stack as when reaped dry. Not so with barley. Shocks of oats which are reaped dry, but have afterwards been soaked with rain, will be longer before they are ready for the stacks than oats that have been reaped in a damp state. It is a still more remarkable fact, that damp oats reaped with the scythe will be sooner ready for the stack than would the same oats, reaped in a dry state with the sickle. Oats reaped with the scythe will be quite ready for the stack in eight days, whereas oats reaped with the sickle require at least a fortnight. Shocks that have been reaped with the scythe will keep off much more rain than those reaped with the sickle. (*Quart. Journ.*, vol. iv. p. 366.)

8352.—5002. *Wheat* said to be indigenous in the country of the Baschkirs, where the summer temperature is as high as 97°. It is grown extensively in Egypt and Barbary, in the Caraccas, and in Cuba, in

places little elevated above the sea. Hence it may grow in the West Indies. The varieties cultivated in warm climates accommodate themselves to them. (*Gard. Chron.* 1841, p. 451.)

8353.—5003. *Cone wheat*, a variety of *Triticum turgidum*, has been found by Mr. Gorria to be but little injured by the wheat-fly, as this insect appears in the fly state much sooner than the wheat blossom bursts from the spathe. The grain of this variety is coarse; but every spike generally yields from seventy to ninety grains, which is double the number of the common wheat, *Triticum bybernum*. It ripens about a week after the red wheat, and, when standing, is from a foot to eighteen inches taller than the common wheat. (*Quart. Jour. Agr.*, vol. iii. p. 641.)

8354. *Dantzic creeping wheat* is a variety cultivated on the borders of Scotland, which possesses the property of tillering, or throwing tap-shoots from the root in the autumn, in a remarkable degree. It originally came from Dantzic. (*Quart. Jour. Agr.*, vol. iv. p. 536.)

8355.—5013. *Varieties of wheat*. The following six kinds produced per acre, as follows:—

	£	s.	d.		£	s.	d.
Whittington white, 36 bush. value	13	16	9	Brown called clover, 40 bush. value	15	13	6
Surrey white - 36 - - -	14	14	0	Essex brown - 40 - - -	16	17	0
Snowdrop white - 39 - - -	15	9	0	Burwell brown - 45 - - -	17	12	0

(*Hillyard in Journ. E. A.*)

8356.—5024. *On the climate requisite to bring wheat to perfection*. Nothing is here said of altitude, latitude, or temperature. The highest altitude on which wheat will succeed on the banks of the Tay, is 450 feet above the level of the sea, where the mean temperature for the year is 46°. Wherever the annual mean temperature is below this, wheat cannot be raised with advantage. (*A. G.*)

8357.—5031. *Throwing out the young plants of wheat*. This is known to take place in many soils in spring after frost, owing to the expansion produced in the subsoil by the freezing of the water which had lodged there. The obvious remedy is furrow draining, subsoil ploughing, and thoroughly stirring the soil by a cultivator. (*Jour. R. A. S. E.*, vol. iii. p. 125.)

8358. *Wheat*. List of fifty-four sorts by M. Vilmorin in *G. M.* 1837, p. 45.

8359. *New kinds of wheat*. Experiments with fifty-five varieties are detailed in *G. M.* 1840, p. 38.

8360.—5041. *Harvesting wheat*. The loss sustained by allowing wheat to become dead ripe before it is cut, has been frequently pointed out, and recently Mr. Hannam has shown that the practice is attended by a loss of at least 26s. per acre, as the following results of a great many experiments will prove.

	£	s.	d.
The value of an acre of wheat cut with the straw quite green, is	11	17	0
Green - - - - -	13	6	0
With the grain raw - - - - -	14	18	0
With the grain not quite so raw - - - - -	14	17	4
With the grain ripe - - - - -	13	11	8

Mr. Honoam shows that by wheat being cut raw we have a gain of 15½ per cent., compared with wheat cut ripe, of flour, upon equal measures of land; and again in the weight of straw, of 14 per cent.; advantages which afford a clear gain of 52½ lbs. of flour upon every quarter of wheat. "A gain of 7s. 4½d. in the value of every quarter of wheat. A gain of 7s. 6½d. in the value of every quarter of wheat, and the straw producing it. A gain of 1l. 6s. 4d. upon every acre producing 28 bushels, and of 1l. 8s. 2½d. upon every acre producing 30 bushels." (*Q. J. A.*, vol. xiii. p. 178.)

8361.—5075. *Rye straw* is preferred to that of any other plant for littering horses; and rye is somewhat extensively cultivated about Newmarket for the sake of obtaining the straw for the livery stables. (*J. D.*)

8362.—5081. *Naked barley* (*Hordeum distichum* var. *nudum Metz.*), strongly recommended in preference to every other variety. Weight 60 lbs. per bushel; flour whiter and sweeter than common barley flour; absorbs more water, and makes better bread; malts in seven days less time than common barley; three bushels will seed the land as well as four of other barley, with other excellent qualities. See *Kenbury*, in *G. M.* 1840, p. 313.

8363.—5121. *The Hopetoun oat* is an accidental variety brought into notice by Mr. Sheriff in 1824. It is chiefly remarkable for its long reedy straw, which, in a crop of twenty acres in East Lothian, has averaged six feet in length, while the grain is thin in the husk, and nearly as short and plump as the grains of the potato oat. (*Trans. of Highland Soc.*, vol. viii. p. 362.)

8364.—5290. *The value of crops of Swedish turnips, potatoes, and mangold wurzel as food for cattle* is not materially different, provided the crops are alike good of their kind. This is the opinion formed by an East Lothian farmer of great skill and experience, after having made a number of experiments to determine the value of these roots. (*Highland Soc. Trans.*, vol. ix. p. 273.)

8365.—5300. *The Bohem potato*, a French variety, which has been cultivated extensively both in Europe and North America for its large produce, chiefly applied for feeding cattle. Mr. Buel of Albany had nine bushels as the produce of twelve lbs. (*Gard. Mag.* 1840, p. 98.)

8366. *The pine-apple potato* keeps quite sound and well flavoured till June.

8367. *The Knepp Castle kidney potato* is large, very mealy, and superior in flavour to any other kidney. The farina is of a pure white, the eyes of the tubers are remarkably full, and hence there is very little waste in paring or peeling them. They have been grown for twenty years in the garden at Knepp Castle, near Horsham, Sussex, without degenerating in the slightest degree. (*G. M.* 1840, p. 102.)

8368. *The best early and late potatoes*. The Manly, a round white potato of moderate and equal size, is one of the best early sorts; and the bread-fruit, a rather large round white potato, a good bearer and a good keeper, is one of the best late sorts. (*G. C.* 1842, p. 97.)

8369. *Comparative merit of different varieties of potato*. Experiments with a view to determine the comparative merit of different varieties led to the conclusion that the *lumpers* and the *cups* are excellent varieties to grow for cattle, because they cover the ground well, do not curl, and produce great weights. In autumn the *white* and *blue Dons* are excellent for family use, and in spring the *old rough black* and *Irish apple*. Through summer the *ash-leaf* is the first that comes into use, and next *Dudgeon's black early*, and the *Flamingo* or *red early*. (*Trans. H. S.*, vol. xi. p. 85.)

8370.—5307. *Soil for the potato*. In the peninsula of Kintyre, the soil is calcareous clay, in which there is found gypsum, an earth said to be congenial to the potato; and there, Mr. Stewart states, that the potato crops far surpass any he had elsewhere seen, either in Scotland or Ireland. (*Brit. Farm. Mag.*, vol. vii. p. 473.)

8371.—5312. *Comparative produce of different modes of preparing the sets, and planting potatoes*. The following interesting experiments were made by the Messrs. Drummond of Stirling, with the Irish blue potato, on the same piece of ground, and under similar circumstances. The space which each experiment occupied was forty square yards, which were drilled and dunged at the rate of thirty tons the imperial acre. They were all planted on 28th May, and raised 13th October, 1832:—

8372. *The first plot* was planted on the plan recommended by Mr. Knight, Pres. Hort. Soc. The tubers were whole, weighing half a pound each, and were planted at the distance of six inches in the row, and the rows four feet apart, and lying north and south; forty square yards required nine pounds of sets, and produced 364 pounds of potatoes; being, per acre, 136 bushels of sets, and 550 bushels of produce: net increase, 414 bushels.

8373. *The second plot* was also planted with similar tubers to the last, at nine inches apart. The seed required weighed sixty pounds, the produce 326 pounds; being, per acre, ninety-one bushels of seed, and 493 bushels of crop: net increase, 402 bushels.

8374. *In both these plots* the plants were highly vigorous, and early in advance of others planted in the ordinary manner. The potatoes were not too large, but the crop contained a great proportion of small ones.

8375. *The third plot was planted* the same as the last, but the sets were cut of the common size. The seed required weighed only six pounds, the produce, 276 pounds; being, per acre, nine bushels of seed, and 417 of produce: net increase, 408 bushels. The plants in this plot grew fast in the autumn, and produced by much the largest potatoes; but they did not ripen well.

8376. *The fourth plot was planted* with sets cut of the common size. The seed required weighed twelve pounds, and the produce 376 pounds; being, per acre, eighteen bushels of seed, and 568 of produce: net increase, 550 bushels. The potatoes in the produce of this last lot were the most equal sized.

8377. *The result of these experiments* (which were conducted with great care) is entirely contrary to Mr. Knight's theory, and consequent practice. (*Quart. Jour. Agr.*, vol. iv. p. 411.) In the *Transactions of the Horticultural Society*, second series, vol. i. p. 445. to 456. (published in August, 1834), an account is given of a number of experiments made with the greatest care and accuracy, under the direction of Professor Lindley, in the garden of the Horticultural Society, the result of which is conformable to that obtained by Messrs. Drummond. It also appears in the same work that Sir George Mackenzie made experiments of the same kind in Ross-shire, and found the produce decidedly better from sets than from whole potatoes. (See *Gard. Mag.*, vol. x. p. 433, 435, and p. 499.)

8378.—5316. *The depth at which the potato should be planted.* In warm dry land 9 inches are not too deep; in cold stiff soil, 4 inches would be better; 6 inches is a good depth for average land. Certain experiments conducted in the Hort. Soc. garden, gave the following results: 3 inches deep gave 13 tons; 4 inches, 14 tons; 6 inches, 14½ tons; and 9 inches, 13 tons. At so great a depth as nine inches, sets are apt to perish, unless the soil is dry, light, and warm. The deeper, however, the sets can be safely inserted, the better, for the following reason: potatoes are formed on underground branches; the deeper the set, the more branches will be formed before the shoots emerge from the soil, and consequently the more ample will be the means possessed by the potato-plant of forming tubers. The important practice of earthing up is to effect the same end, by compelling the potato-stem to grow as much as possible under ground. (*G. C.* 1842, p. 155.)

8379.—5320. *Distance at which potatoes ought to be planted.* Experiments with regard to the cultivation of potatoes gave the best results from sets containing only one eye in each, both in early and late crops. The most eligible distance between the rows varies according to the richness of the soil and vigour of the sort planted in it. Two feet is the least distance that should be allowed for common sorts, and much less for dwarf early kinds; but two and a half feet is in general the most proper distance, as it affords sufficient space for earthing up. The distance between the sets in the rows should be about six inches. The formation of tubers depends on the elaboration of sap by the leaves; and this cannot be duly performed unless the leaves are sufficiently exposed to light. When a number of eyes are retained in each set, or when whole sets are employed, a crowded growth of small stems is the consequence; or, if one take the lead, some large tubers result from it, and a number of small imperfectly matured ones from the small stems with shaded foliage. Equality among the stems tends to produce equal sized tubers, which ought always to be a desideratum; for a crop of very large and small tubers is neither so good in quality, nor so profitable, as one of medium-sized tubers. Single eyes, planted at the above distance, will best insure this. (*G. C.* 1841, p. 185.)

8380.—5327. *Earthing up potatoes*, according to Mr. Peter Mackenzie, probably originated in wet undrained soils, in order that the roots might be raised above stagnant water. The result of an experiment proved that a very slight degree of earthing up gave fully a third more of increase of tubers, of better quality than those which had been deeply earthed up; while potatoes not earthed up at all gave a produce equal to those slightly earthed up, but rather inferior in quality, from many of the potatoes having their sides green from exposure to the light. (*Q. J. A.*, vol. xiii. p. 363.) Earthing up potatoes has no doubt to a certain extent the same bad effect as earthing up turnips, carrots, or parsneps, that of preventing the tuber from swelling so much as it would otherwise do.

8381. *The utility of earthing potatoes*, provided the soil be deeply worked, and highly pulverised, proved experimentally in the county of Carlow. Potatoes earthed up in the usual way produced 10 per cent. less than unearthed potatoes. (*Q. J. A.*, vol. v. p. 191.) A good deal depends on the variety of the potato, the stolons of some, such as the *Irish apple*, for example, having a tendency downwards, while others, such as the *rup* potato, have a tendency to rise out of the soil.

8382.—5328. *The usefulness of earthing up potatoes* has been pointed out by Mr. Hayward; and, independently of the effect of earthing up, and other operations between the rows, in destroying weeds and loosening the soil, we should think his practice the best. He says, that a farmer who simply boed the soil between the rows of potatoes in one of his fields, had a much larger crop than he had in an adjoining field, where the rows were earthed up with the greatest care. A potato placed an inch only under the surface of the soil will produce a greater number of tubers than one planted at the depth of a foot. "I have no doubt," says Mr. Hayward, "if potatoes are planted shallow, and placed wide enough apart to admit of the stems being laid down after the young potatoes are formed; and if the earth between them was then thrown over five or six inches thick, so as to form a flat surface, that it would increase the crop. But this is a very different operation from that which I object to." (*Gard. Mag.*, vol. ix. p. 323.)

8383.—5337. *Benefit resulting from the removal of potato blossoms.* By a well-conducted experiment on a field of two acres, for which the honorary silver medal of the Highland Society was given, it appears that one third part of the field, being those drills from which the blossoms were plucked in the bud, produced thirty bolls, two bushels. One third part from which the blossoms were plucked when in full flower produced twenty-seven bolls, three bushels; and one third part, being those drills on which the plants were allowed to ripen their seed, produced twenty-six bolls. The difference here, in favour of plucking off the blossoms at so early a period, instead of allowing them to remain and ripen their seed, is nearly one sixth part of the produce. (*Highland Soc. Trans.*, vol. x. p. 237.)

8384.—5342. *Potatoes should never be covered with straw* excepting on the outside of the earth, for straw soon decays, and communicates a bad flavour to the potato. Quantity of sets to an acre 24 bushels, the rows 3 ft. apart, and the sets 6 in. distant in the rows.

8385.—5348. *Produce of potatoes.* Mr. Knight raised 34 tons and Mr. Parker 52 tons per acre; a ton is 40 bushels. (*G. C.* 1841, p. 247.)

8386.—5354. *Potatoes may be preserved* by being rasped or ground to a pulp, afterwards pressed into dry cakes by Bramah's or any other powerful press, and then dried like cheeses. Potato cakes of this sort have been found to keep for years perfectly sweet; and, as a great deal of nutriment is thus put into very little bulk, it is thought by some that ships bound for long voyages might find it advantageous to lay in their stock of potatoes in this form. (*Quart. Jour. Agr.*, vol. iv. p. 483.)

8387. *Potato flour* was shown at Messrs. Drummond's exhibition at Stirling in 1832, which was thirty-eight years old. It was made from damaged potatoes, which, it seems, answer as well as sound ones, and was in the finest condition. (*Quart. Jour. Agr.*, vol. iv. p. 414.)

8388.—5360. *Potato hayum* forms a rich and excellent manure for wheat, at the rate of four acres of hays to one of wheat, ploughed in green immediately before sowing the wheat. It is found decidedly superior to stable-yard dung. The mode of preparing it is simply to pull up the stems, and to avoid burying potatoes with it, however small they may be. (*A. Gorrie, in Country Times*, October, 1831.)

8389.—5363. *Good beer can be produced from potatoes* by grating them to a pulp, mixing it well with boiling water, and then adding ground barley malt. The liquid, being drawn off, is to be hopped in the

usual way, yeast added, and fermentation induced. The liquor thus produced, after being bottled, was found greatly to resemble the Paris beer. (*Dom. Econ. in Lardner's Cyclopaedia.*)

8390. *Beer may be made from parsneps in a similar manner to that from potatoes.*

8391.—5364. *The distillation of spirit from potatoes is thus practised in France:—* The potatoes are boiled by means of a steaming apparatus; and, where the apparatus is good, will be prepared sufficiently in ten minutes. As soon as they are in a proper state, they must be bruised when at as high a degree of temperature as possible, and then thrown, for the purpose of fermentation, into a tub or other vessel containing, for every 1000 pounds of potatoes, 416½ pounds of cold water; the temperature of which, however, should not be below 14° of Reaumur (63½° of Fahrenheit). The whole must then be covered up, and allowed to remain. There will be 750 pounds of sediment contained in the quantity of potatoes which has been mentioned; and this proportion, with the 416½ pounds of water, will be quite sufficient to produce a mass, of which the consistency will be that of pap or curdled milk, and the temperature from 48° to 50° Reaum. (140° to 144° Fahr.) There are then taken 3¼ pounds of the malt of barley, which is steeped in 250 pounds of water that has been previously heated to the height of 60° Reaum. (167° of Fahr.), and the whole is allowed to remain until it shall have cooled to the temperature of 22° of Reaum. (81½° of Fahr.) There are then added 22½ pounds of yeast, which is mixed by being actively stirred, and the whole is then well covered and allowed to remain. When the mass of fermenting potatoes is cooled to the temperature of 38° of Reaum. (117° of Fahr.), the fermentation is stopped by adding 416½ pounds of cold water, and the whole is well stirred together. This mass having fallen to the temperature of 25° Reaum. (83½° Fahr.), the prepared malt, which has already begun to ferment, is added; the whole is again well stirred together, the vessel very lightly covered, and the fermentation allowed to proceed. This latter operation takes place very regularly, and terminates in from forty-eight to sixty hours. The fermented mass assumes a spirituous odour, and furnishes, on distillation, so abundant a quantity of spirit, that, for every 100 pounds of potatoes, there are obtained eight French piats of spirit, in which, according to the scale of Richter, there are thirty per cent. of alcohol. If, before carrying the fermented mass to the still, it is passed through a sieve of iron wire of close meshes, the pulp of potatoes is kept back, and the spirit is then more pure, and more pleasant to the taste and smell. This will be still more the case, if there be added to this mass half a pound of potash for every 100 pounds of potatoes, before submitting it to distillation. If it is wished to have a spirit analogous to that obtained from wine, it must be rectified accordingly. (*Mollem's Recueil Industriel, and Quart. Jour. Agr., vol. iii. p. 321.*)

8392.—5365. *Mincing potatoes, and mixing them intimately with straw cut into chaff "completely prevents the fermentation of the potatoes in the paunch from injuring the cattle. They eat up the prepared mess with relish, are soon satiated, and then lie down with ease and comfort, and of course fatten rapidly."* (*Q. J. A., vol. vii. p. 244.*)

8393.—5369. *Frozen potatoes.* When frozen potatoes are thawed, they frequently do not give a fourth part of the starch which they give before being frozen. The cause of this, it appears, is, that the starch, being contained in the cells, or vesicles which constitute the principal part of the parenchyma of the potato, is, in the case of potatoes not frozen, set free by the operation of the rasp or grater in grating them down for starch. When the potato has been frozen, however, and is afterwards thawed, the cells are no longer firmly fixed in the fibrous matter of the potato, and the grater has no longer any power to tear them to pieces. Every one knows that the most mealy part of a potato is immediately within the skin; and M. Payen has discovered that by far the greater number of cells of starch are in that part of the tuber, and that there are comparatively few towards its centre. M. Payen also found that the freezing of the outer part of the potato, and the subsequent thawing, cause that bitterness which is invariably found in frosted potatoes. Before the potato is frozen, the bitter principle, being contained in the skin, is readily removed by paring or peeling; but, when the structure of the parenchyma of the potato is deranged by freezing and thawing, the bitter matter is communicated to the adjoining parts of the potato, in consequence of their comparatively fluid state. The inhabitants of Peru dry their frozen potatoes, and thus preserve them for food for an indefinite length of time. (*G. M. 1839, p. 186.*) If gradually thawed in cold water, and cooked immediately afterwards, they are eatable, but in a few days become bitter, from the diffusion of the bitter of the skin. (*G. C. 1841, p. 116.*)

8394.—5377. *Dale's hybrid turnip* was originated, about 1828, by Mr. Robert Dale, of Libberton West, near Edinburgh. It is tankard-shaped, and resembles the Swedish or yellow turnip in colour. It is equal in size to the white globe, superior in size to most other varieties, whether of white, yellow, or Swedish turnips, and is found to produce a greater weight in a given space, and at a given expense of manure, than any other turnip hitherto introduced. It is not so hardy as the Swedish, and it runs to flower rather sooner in the spring; but, with these exceptions, it is the best of all field turnips. (*Quart. Journ. Agr., vol. lii. p. 578.*)

8395.—5410. *The most economical mode of dividing a field of turnips which is to be eaten off with sheep.* I have this year two pieces of turnips, of ten acres each, nearly square, which I intend to divide by hurdles into eight divisions each, for eating on the ground by sheep and young cattle: now it is plain that if I divide them straight across the field, from hedge to hedge, I shall have seven settings of hurdles, of 220 yards in length, in each field, making in the whole a length of 3080 yards for setting hurdles at different times.

To save labour, I therefore adopt the method explained in the annexed diagram, *fig. 1180.* Suppose the figure, *A B C D*, a square field of ten acres, then *a b* will be the first setting of hurdles, *c d* the second, *b e* the third, *c f* the fourth, *b g* the fifth, *h i* the sixth, *b k* the seventh, and *l m* the eighth; in the whole, eight; in the whole, and the turnips

will be eaten in rotation, as the plots of ground are numbered.

Length of hurdling in former way	-	-	-	-	-	3080 yards
Length of ditto in latter way	-	-	-	-	-	1760
Saving of labour	-	-	-	-	-	1320

(*Young's Annals of Agriculture*, vol. xiii. p. 346.)

8396.—5413. *The taste of turnips in milk, butter, and beef.* It is said, may be prevented by the following means:—“Never allow the cow to taste of the roots within six or eight hours of milking, but feed her immediately after each milking; and do not give her any more of the roots at a time than she will eat in two or three hours; and be careful that she does not get any more till after she is milked again. By this method cows may be fed on rutabaga or other turnips, and no person will be able to discover the taste in the butter or milk. Upon the same principle, those who wish to feed their cattle on turnips may do so without any danger of affecting the taste of the beef, provided they will omit feeding with this kind of food two or three days previous to the killing. Cases have occurred where the beef was rendered unfit to eat, on account of the animals eating a few turnip-tops or cabbage leaves before being slaughtered. The difficulty may be obviated as mentioned above.” (*Brit. F. M.*, v. s., vol. iv. p. 361.)

8397.—5420. *Storing turnips.* By experiment it was found that raising them in stacks above the surface by means of wattled stakes to prevent them from spreading out, and when the stack is as high as it will stand, thatching them is superior in every point of view to burying them in the soil in the manner of potatoes. (*Jour. A. E.*, vol. ii. p. 228.)

8398.—5432. *Fly on turnips.* The following mode of prevention has been resorted to with success at Green Hammerton, Yorkshire. A board, about eighteen inches in breadth, and sufficiently long to cover four ridges of turnips, was made to run upon wheels, high enough to allow the board to pass over the turnips without touching the tops of them. The lower side of this board was painted with white paint, which the men provided themselves with, and took into the field, and during the night (at which time the fly is more injurious and destructive than during the day) the instrument was wheeled from one end of the field to the other. The insects, on being disturbed, of course immediately fly or jump up, and stick to the paint; and at the end of every set of ridges the board was almost covered with them. (*Leeds Mercury*, and *Report Dom. Agr. Association*.)

8399.—5444. *The white or Belgian carrot*, produced on Lord Ducie's farm at Whitfield, at the rate of 26 tons 3 cwt. per acre. The soil is a deep sandy loam, belonging to the new red sandstone formation. “The seed was sown in the second week in April, on land which had been ploughed 10 inches deep. It was sown on the flat, in rows 18 inches apart, by the common Suffolk drill. The seed had been mingled with damp sand for several days previous, as well to sprout it partially, as to render it capable of being drilled, as carrot-seed clings so much together. They are thinned out when a fortnight old, to intervals of 6 inches in the row, and two horse-hoings, with a hand-hoeing whenever the weeds made their appearance, was all the cultivation they received. The result is a crop, not only much more valuable per ton than any other green crop we have, but also heavier per acre, and raised at an expense less by at least one-half than that attending the cultivation of the turnip.” (*Journ. A. E.*, vol. ii. p. 40.)

8400. *The white carrot.* The produce with Sir C. M. Burrell in Sussex was upwards of 1,300 bushels per acre, after separating the green tops. Some of the roots had penetrated as deep as 3 feet 5 inches, so that the white carrot cannot be a very scouring crop. The soil was loamy and well and deeply drained, and subsoil ploughed, but not manured. (*B. F. M.*, v. s., vol. iv. p. 466.)

8401.—5453. *Carrot seed.* Messrs. Drummond, the eminent seedsmen of Stirling, state that the carrot crop in the field may almost always be insured, other circumstances being favourable, by bringing the seed to the point of vegetating before sowing. This is done by mixing it with sand or earth, kept moist, and turned occasionally for several days. They also recommend some nourishing compost to be placed under the seed in the drills, or sown along with it. They have made an experiment to prove that carrots may be grown to great advantage in peaty soil, and that they may be even grown in old worn-out garden soil by mixing peat and dung together, and putting the compost thus formed in a gutter made by a wedge-shaped dibble, six inches wide at top, six or eight inches long, and at least a foot deep; the seed being sown immediately above the compost. (*Quart. Jour. of Agr.*, vol. iv. p. 410.)

8402.—5471. *The parsnep* is superior to all other roots for fattening hogs; but they must be given raw, for the boiling of the root renders the bacon flabby. Parsneps will fatten a hog in six weeks, more especially if sour milk is given with them. The roots are never to be washed, because it is found that washed roots are found to surfeit both hogs and cattle. (*G. C.* 1842, p. 837.)

8403.—5478. *Parsneps in Guernsey* produce from 9 to 11 tons per statute acre, which are excellent for fattening oxen or pigs, and when boiled will fatten poultry in an extraordinary manner. The produce of Altringham carrot in Guernsey, as compared to that of the parsnep, was as 261 to 840. According to Sir Humphry Davy, 1000 parts of parsnep afford 90 parts of saccharine matter and 9 of mucilage; and 1000 parts of carrot, 90 parts of sugar and 3 of mucilage. The greater proportion of mucilage in the parsnep may be the cause of its superior fattening properties. (*Jour. A. E.*, vol. i. p. 422.)

8404.—5488. *Mangold wurzel* proved to have greater fattening properties than Swedish turnip by Earl Spencer. (*Journ. A. E.*, vol. ii. p. 296.)

8405.—5516. *Symphytum aspererrimum*, Mr. Gorrie observes, is assuredly liked by horses and cattle, and will soon recommend itself to the cottager and dairyman as a powerful auxiliary to clover, in summer and autumn. (*Highland Soc. Trans.*, vol. ix. p. 249.)

8406.—5517. *Enothera biennis*, a biennial plant growing to the height of four or five feet, is said to make a very good forage plant in some parts of Germany. It is of the earliest culture, more especially in dense sandy soils. The roots are fusiform, white, sweetish, and in Germany are frequently used in cookery, like those of the skirret or scorzonera.

8407. *Lupinus polyphyllus* has been tried as a forage plant by the Earl of Mansfield, and found valuable in good sandy loams, but it is thought inferior in nutritive properties to the lucern.

8408.—5522. *Trifolium elegans* D. Don., *T. hybridum Bon Jordanicæ*, the elegant hybrid or Alsike clover, apparently a gigantic variety of the common white clover, has been cultivated in Sweden for upwards of forty years, though only lately brought into notice by M. Vilmorin. It produces trailing shoots five or six feet in length, is remarkably hardy, and prefers strong moist soil. We believe it to be the same plant which we collected in Poland in 1813, and of which we exhibited specimens at the Linnæan Society about the end of the following year. In England it is now being cultivated by Mr. W. Taylor, F.L.S., who conceives a very high opinion of its value to the agriculturist. It does not suffer, he says, from the severest frost, its growth being merely suspended, while its foliage is not injured; it may be readily propagated on a large scale by division of the root, and it flourishes in inferior soil.

8409.—5527. *Trifolium incarnatum* is considered in Italy as the earliest of clovers; as particularly calculated for dry soils, and as preferring the mountain to the plain. It is an annual, and succeeds best when sown in the autumn, after the corn crop has been removed. (*Quart. Jour. of Agr.*, vol. iii. p. 729.) *Trifolium incarnatum* is found of great value in filling up blanks in fields of common clover being sown immediately after carrying the corn crop.

8410. *Trifolium giganteum*, the Afghan clover, thrives in England during summer, but is too tender for winter. (*Gard. Chron.* 1841, p. 598.)

8411.—5550. Clover is dried in the hilly parts of Germany by resting it, immediately after being mown, against portable trellises, as corn is dried in Sweden and Norway. (*L. Agronomie*, vol. i. p. 136.)

8412.—5618. *The Prangos hay plant*, is described in *Moorcroft's Travels*, vol. i. p. 288., as singularly

productive of forage; but though many attempts have been made to bring the seeds to Europe in a live state, the attempt has not yet been attended with success. (*G. C.* 1842, p. 351.)

8413.—5629. *Gorse*, instead of being bruised as formerly before being given to horses or cattle, is now cut by machios like those in use for cutting hay and straw. It is found that both horses and cattle feed with much greater avidity upon the gorse when cleanly and regularly cut, than when reduced into a consistency nearly approaching a pulp, by bruising or crushing. In this state also it is apt to become sour in the summer season, in which state it is rejected by all animals. (*Brit. F. M.*, N. S., vol. iv. p. 359.)

8414.—5643. *Old pasture converted new*. John Boswell, Esq., of Kingcausie, a berdenshire, has long been of opinion that permanent pasture, instead of being a good thing, is a bad thing. After recapitulating his experience during several years, and strongly recommending thorough under-draining, deep ploughing, and manuring, he concludes thus:—"I maintain that, except a few favoured spots, such as banks of rivers, &c., no ground can, without loss, be left long in pasture; and that it appears to me, four or five years is, generally speaking, the longest period land should be allowed to lie in grass. If pasture be the object, at the end of that time the ground should be broken up as arable land, and then returned to grass again. I maintain, that without grass severely cropped land cannot be restored to full fertility; and without cropping, grass cannot be made to continue at the maximum point of verdure and utility. Lastly, I maintain, no land, under any circumstances, ought to be cut in hay, if intended to remain some years in pasture; and, if cut as hay, every kind of land ought to be directly ploughed, and again put through the rotation." (*Quart. Jour. Agr.*, vol. iv. p. 790.)

8415.—5647. *The great object of mixing different grass and herbage seeds together*, is to stock the surface of the soil at once so thickly with plants as to prevent weeds from rising up through them. Experience has proved that this cannot be done so effectually when only one or two species of grass or herbage seeds are employed, as when a greater number are made use of; and the reason appears to be found in the diversity of soils and situations. In general, the richer the soil the smaller will be the number of species which it will require. When the selection of grass seeds is judicious, there will be a constant succession of herbage kept up by them the whole year round, as grasses of several sorts grow at all times when the temperature is above the freezing point.

8416.—5647. *Grass seeds*. By an experiment made by Messrs. Drummond of Stirling, with a view to ascertain the proper covering for grass seeds, it appears that the common rye grass will penetrate through a deeper covering than any other agricultural grass, having risen through a layer of soil of three inches in thickness. The *Poa* and *Agrótes*, which have very small seeds, will not bear more than a quarter of an inch of cover; and from a quarter to half an inch appears the proper depth for the other sorts. Hence, instead of using the common harrow for covering grass seeds, the surface should merely be ruffled by a brush, or some implement in imitation of one, and well rolled. (*Gard. Mag.* 1841, p. 509.)

8417.—5653. *The Tussock Grass (Festuca sabellata Lamarck, F. caespitosa Rurm. et Schultes, Dactylis caespitosa Forster)*, a native of the Falkland Islands, where it is perennial and grows six feet high, with fan-shaped leaves, like those of an Iris, is expected soon to be introduced at Kew, whence some of Ward's cases have been sent out for bringing it home. Every animal is said to feed upon it with avidity, and get fat in a short time. It may be planted and cut like the Guinea grass of the West Indies, but unfortunately it will only thrive where its roots have access to salt water. There is another kind of Tussock grass in the Falkland Islands, the *Carex trifida*, which grows only 1½ feet high, and, like other *Cárices*, is of no use as a forage grass. (*G. C.* 1843, p. 131. and 190.; and the *Jour. A. E.*, vol. iv. p. 17.; and *Hooker's Notes on the Botany of the Antarctic Voyage, &c.*, 1843, p. 52.)

8418.—5655. *Italian rye grass* is found far ahead of all other grasses in early spring, and therefore it is particularly adapted for coming in after the turnip season as early green food for cattle. It should be sown in autumn along with *Trifolium incarnatum*, which keeps pace with it in early and vigorous vegetation, even in Scotland. (*Brit. Farm. Mag.*, vol. 1, 2d Series, p. 502.)

8419.—5656. *The Italian rye grass*, Mr. Lawson found to be the same variety as Stickney's rye grass. It is considered superior to any other grass in producing winter herbage, and to be more hardy than the common rye grass. (*Highland Soc. Trans.*, vol. x. p. 28.)

8420.—5663. *Poa nemoralis var. nervosa*, the Hudson's Bay meadow grass, has been brought into notice by Mr. Bishop. Its value arises from a property which it possesses, and which is common to no other grass cultivated in Scotland, viz., that of the flower stem, after being cropped, reproducing shoots from the stem as well as the root; in consequence of which it continues growing throughout the whole year, particularly in the latter part of summer and autumn. A specimen mown off cold damp land on the 14th of April, 1836, averaged from 18 inches to 20 inches in length (*G. M.* 1837, p. 283.)

8421. *Bromus pratensis* L., *B. erectus Sinclairi*, is strongly recommended by M. Vilmorin for poor soils liable to be burnt up with drought. Sheep, he says, are remarkably fond of it. (*G. M.* 1841, p. 467.) It is the only grass

8422.—5717. *Number of kinds of grasses required in laying down permanent pasture*. A judicious writer in the *Quart. Jour. of Agr.* is of opinion, that more of these grasses are brought into notice than their good properties will warrant. Independently of perennial rye grass and white clover, which must always occupy a large share of every permanent pasture, perhaps five or six of the others are all that are worth cultivation. It is true, many worthless grasses will grow up among our most carefully laid down pastures, and they no doubt assist in thickening the sward. But this is surely no adequate reason to sow them; and if it be necessary to sow a certain quantity of seed to cover the ground, that quantity should be composed of the best kinds. One reason for sowing a number of kinds is, that more plants will thrive closely together of different sorts than of the same sort. Allowing this to be the fact, there is still no necessity for incurring the trouble and expense of sowing worthless kinds, when a variety of them will grow naturally out of the soil to form a thick sward. Should the different kinds arrive successively at their greatest vigour, seeds of the best sorts can be selected on account of their coming to maturity at the different seasons when pasturage is required. It seems that 4½ bushels will just furnish as many fertile seeds, that is, seven to the square inch, as there are plants in that space in a natural pasture; but if even more are required to render the pasture better, more of the best kinds only should be sown to insure the requisite thickness of sward. (*Quart. Jour. Agr.*, vol. iv. p. 414.)

8423. *Kinds and qualities of grass seeds for laying down land*. The most valuable article which has appeared on this subject since the publication of Sinclair's *Hortus Gramineus Woburnensis*, will be found in the *Quarterly Journal of Agriculture*, vol. iv. p. 714—724. This article is by Mr. Lawson, an eminent seedsman in Edinburgh; who for a number of years has directed his attention to the subject, with a degree of success which has been acknowledged by the first agriculturists in Scotland to be pre-eminently great. After giving a short description of thirty species or varieties of proper grasses, and eleven herbage plants, of which he has seeds for sale, he enumerates six other herbage plants, all Leguminosæ, the seeds of which are not yet articles of commerce, but which he says may be advantageously introduced into cultivation, as soon as their seeds can be obtained. These are, *Lotus major*, *Vicia Cracca*, *V. sepium*, and *V. sylvatica*, *Lathyrus pratensis*, and *Trifolium medium*.

8424. *Sowing the seeds of grasses and herbage plants by weight*, instead of the general practice of sowing the grasses by measure, and the clovers by weight, is strongly recommended by Mr. Lawson. "For, although in grass seeds the greater weight of one variety is no criterion of its superiority over another variety of less weight, yet a greater weight in the same variety always denotes a superior quality. Thus, when seed is light, and consequently inferior, the greatest number of seeds is obtained by adhering to a given weight; and hence there is the chance of nearly an equal number of plants springing up as when the seeds are plump and heavy. But a given weight of measure of seeds does not indicate the relative number of plants that will spring up; because there is both a difference in the relative bulk and specific

gravity of seeds, and there is also a difference in the number of seeds that grow from a given quantity." (p. 719.)

8425. *The weight of the seeds of grasses*, per Imperial bushel, is next given by Mr. Lawson; and the differences between the seeds of different species in this respect is most remarkable. Of thirty species, the heaviest appears to be the common perennial rye grass, a bushel of which weighs from eighteen to thirty pounds; and the next heaviest appears to be the crested dog's-tail grass, which weighs twenty-six pounds. The lightest seed is that of *Avena* [*Trisetum*] *flavescens*, a bushel of which weighs only five pounds, and the next lightest is the meadow fox-tail grass, which weighs five pounds and a quarter. *Anthoxanthum odoratum* and *Alopecurus geniculatus* weigh each six pounds; *Aira flexuosa*, six pounds and a quarter; *Poa glauca*, seven pounds and a half; *Elymus arenarius* and *Festuca duriuscula*, each nine pounds and a half; and the remaining species weigh from ten to sixteen pounds. Rye weighs sixty-two pounds the bushel.

8426. *The weights of clover and other herbage plants* are much less various. Burnet weighs twenty-four pounds and a half; saintfoin weighs twenty-six pounds; *Achillea Millefolium*, twenty-eight pounds and a quarter; ribwort, fifty-one pounds and a half; *Medicago lupulina* (the nonsuch of English farmers, and the yellow clover of the Scotch) weighs sixty-three pounds and three quarters; and the different species of clover (*Trifolium*), from sixty-two to sixty-five pounds.

8427. *With reference to the culture of grasses in Britain*, Mr. Lawson observes that, wherever land produces the cereal grains and other cultivated plants, the pasture and herbage grasses will grow with vigour. Plants of this kind, he observes, are improved, by different kinds of soils, and more especially with relation to their states of dryness or moisture. As a convenient arrangement for practical purposes, he classes all soils under light, medium, and heavy; and he has composed twelve different tables, each containing the quantity of grass seeds, per Scotch acre, for these three divisions of soil. Whoever, whether in Britain or America, wishes to sow grasses on a large scale, will find it worth their while to correspond with Mr. Lawson, with reference to the subject of these tables, because every year he is adding to his experience, and in all probability improving the selection. We shall, therefore, not copy them into our pages in detail, but merely give their titles, with a few remarks, chiefly with a view of showing how much greater the number of species is which Mr. Lawson recommends than what is commonly sown, and yet how much smaller is the quantity of seed per acre.

8428. *Grass and herbage seeds for alternate husbandry*. For one year's hay, twenty-two pounds of annual rye grass, ten pounds of red and two pounds of white clover. For one year's hay and one year's pasture, eight pounds of annual and eighteen pounds of perennial rye grass; three pounds of *Phleum pratense*, five pounds of red and five pounds of white clover, and two pounds of nonsuch. For one year's hay and two years' pasture, twenty-eight pounds of perennial rye grass, two pounds of *Phleum pratense*, two pounds of red, six pounds of white, two pounds of cow clover, and two pounds of nonsuch. These proportions are for soils suited for the turnip husbandry; in heavy soils, from two to four pounds of *Phleum pratense* may be added for one year's grass.

8429. *Grasses and herbage plants for permanent pasture*. Of proper grasses, seven species are employed; of proper clovers, three species, and also the nonsuch. The proportions are given for laying down without a crop and also with a crop; and it is worthy of remark, that in the latter case the quantity required is not much above half what it is in the former. Without a crop, seventy-five pounds are required for a light soil, and eighty-two for a heavy soil; while with a crop, forty-one pounds and a half in the one case, and forty-five lbs. in the other, only are required.

8430. *Grasses, &c., for permanent pasture in ornamental parks*. Of proper grasses, fourteen species are employed, besides the clovers mentioned in the preceding paragraph. It is added, that *Achillea Millefolium* may be added in dry soils; saintfoin in dry calcareous soils; wild endive in heavy soils; and from one to two pounds of parsley per acre on lands where sheep are apt to get the rot.

8431. *Grasses and herbage plants for lawns, bowling-greens, &c., kept constantly under the scythe*. Of proper grasses, fifteen species are employed, together with the common white clover. On each soil, Pacey's perennial rye grass, more than one fourth part of the proper grasses, and the quantity of white clover per acre, varies from six to twelve pounds.

8432. *Grasses and herbage plants for grounds much shaded with trees*. Twelve species of proper grasses and white clover.

8433. *Grasses, &c., for heathy and moory lands which have been pared and burned, or scorified for the purpose of producing herbage*. The following cheap mixture is recommended:—Mixed hay seeds twenty-five pounds, and white clover, six pounds, with a crop; and forty pounds of mixed hay seeds, forty-five pounds of rye, and nine pounds of white clover, without a crop. When land of this description is situated 500 feet and upwards above the level of the sea, sheep's fescue and the two allied species, and *Poa glauca*, may be added, at the rate of two pounds each.

8434. *Grasses for improved deep peaty ground intended to lie in grass*. Perennial rye grass, ten pounds; *Phleum pratense*, eight pounds; *Agrostis stolonifera*, two pounds; *Alopecurus pratensis*, two pounds; and *Trifolium repens*, eight pounds, are recommended, when they are to be sown with a crop; when without a crop, the proportions are, eighteen, twelve, three, three, and twelve pounds.

8435. *Grasses for land in preparation for irrigation*. We shall take the liberty, in this case, of copying the table verbatim:—

	Light Soil.		Medium Soil.		Heavy Soil.	
	With a Crop.	Without a Crop.	With a Crop.	Without a Crop.	With a Crop.	Without a Crop.
Perennial rye grass	10	18	7	12	7	12
<i>Agrostis stolonifera</i>	2	4	2	4	3	6
<i>Alopecurus pratensis</i>	2	4	3	6	4	8
<i>Festuca pratensis</i>	2	4	2	4	4	8
<i>Festuca lolïacea</i>	4	7	4	7	4	7
<i>Poa trivialis</i>	2	4	2	4	3	6
<i>Poa fluitans</i>	1	2	2	4	2	4
<i>Phleum pratense</i>	4	6	6	9	7	10
	27	49	28	50	32	57

8436. *Grasses for lands which are occasionally subject to the overflowing of lakes and rivers, or which are always in a very wet state*. These are, *Poa aquatica*, six pounds; *Poa fluitans*, six pounds; *Festuca lolïacea*, four pounds; *Phleum pratense*, six pounds; *Alopecurus geniculatus*, six pounds; *Agrostis stolonifera*, four pounds.

8437. *Grasses for rabbit warrens, or light sandy soils*. These are perennial rye-grass, fourteen pounds; *Anthoxanthum odoratum*, one pound; *Festuca duriuscula*, one pound; *Festuca ovina*, one pound; *Festuca rubra*, one pound; *Cynosurus cristatus*, two pounds; *Poterium Sanguisorba*, four pounds; *Achillea Millefolium*, half a pound; *Trifolium repens*, six pounds; *Trifolium minus vel procumbens*,

two pounds; *Medicago lupulina*, two pounds. If this mixture be sown without a crop, a bushel and a half of rye grass may be sown along with it.

8438. For drifting sands, which are to be consolidated, and have a sward produced upon them by sowing. These are, *Elymus arenarius*, ten pounds, which should be mixed with clay and straw ropes cut into pieces and dibbled into the sand. After a sward has been produced, the mixture recommended for rabbit-warrens, or light sandy soils, may be sown.

8439. For dry gravelly situations, which resist a sward from all ordinary means. These soils may be sown with *Agrostis vulgaris*, two pounds; *Poa annua*, four pounds; *Briza media*, four pounds; *Aira flexuosa*, one pound; *Trifolium minus vel procumbens*. We repeat our strong recommendation of Mr. Lawson, as an agricultural seedsman, to all persons residing near Edinburgh who have lands to lay down in grass. We are not less anxious to recommend Messrs. Drummond of Stirling; Messrs. Dickson and Turnbull of Perth; Messrs. Cornack and Son, and Mr. Gibbs of London; and M. Vilmorin, of Paris, to all those similarly circumstanced in their respective localities.

8440. *Mixtures of grasses for the alternate husbandry.* From the result of an experiment made by Mr. Shireff of Mungoswells (*Quart. Jour. Agr.*, vol. ii. p. 242.), it appears decidedly preferable to use a mixture of seeds, even where a single crop of hay, to be succeeded by a year's pasturage, is to be taken. The grasses sown were cock's-foot, hard fescue, cat's-tail, rye grass, and red, white, and yellow clover. "The rye grass was conspicuous for growing early in spring as well as late in autumn, and remaining comparatively unproductive in the summer months. The cock's foot, throughout the season, put forth new leaves with rapidity, after being cut with the scythe, and produced culms to the hay crop only; the fescue planted thinly, and also grew rapidly after being cut; the cat's-tail was later in producing flower-stalks, than the other grasses used in the experiment, and, after being cut, did not put forth new leaves so rapidly as the cock's-foot and fescue; but, in every instance, it produced numerous culms, white blossomed, at the same time as the red clover; and where a part of the field was four times mown, yielded a rich crop of culms to the last. The produce, as compared with that of clover and rye grass only, sown in the same field in the same season, was about a ninth part greater, and the extra expenses of the seed about a fifteenth part. Had the clover failed to grow along with the rye grass, as it frequently does, the difference in the produce would have been much greater. The great advantage of a numerous combination of grasses is that the failure of a crop is rendered next to impossible. It is also found that a mixture of grasses is less injurious to the succeeding corn crop than rye grass only. The family of grasses, Mr. Shireff observes, forms a useful class of machinery in the manufacture of productions for the dairy, the shambles, and the manufacturer of clothing; but, in order to take advantage of the raw materials, air and moisture, so bountifully supplied by nature, the most efficient machinery, must be employed. The husbandman who clothes his fields only with rye grass and clover employs a limited machinery, the former being unproductive in summer, the latter moderately so in spring; but when he, for this purpose, uses a variety of plants, differing in their habits of growth and periods of luxuriance, a numerous and powerful machinery is kept successively in full operation.

8441. *Poa nemoralis* was found by Mr. Taunton to produce a thick sward in plantations where every other grass was killed. He says, "its rich nutritive quality, its beautiful and perpetual verdure, and, above all, its quality of flourishing under a dense cover of trees, appear to me to render it peculiarly valuable for the particular purpose of rendering ornamental, and also of turning to a profit, the site of grown-up plantations and thick groves, which are, usually, in a state of complete nakedness." (*Quart. Jour. of Agr.*, vol. iii. p. 413.)

8442.—5768. *Irrigating meadows with liquid manure* from the common sewers of Edinburgh. This has been practised to a considerable extent in the neighbourhood of Edinburgh, and according to Mr. Stephens (*Practical Irrigator and Drainer*, p. 76.), it is one of the greatest improvements ever made in agriculture. The inhabitants of Edinburgh, however, are of a different opinion, and according to a pamphlet on this subject published in 1839, entitled *Papers relating to the Noxious Effects of the Fætid Irrigation around the City of Edinburgh*, it appears that no horse or other animal will eat a particle of the produce of these meadows, either while growing, or when first cut; and the cows when first put to eat it have for some days an absolute loathing, and can hardly be got to feed upon it; but when they do, it causes an immense flow of milk, which is kept up by this grass, and what is called dreg (brewers' wash); but whenever the supply of this grass becomes short, they are found to be incapable of digesting the usual fodder of cattle, and completely diseased, and get unfit for any purpose almost. (*G. M.* 1840, p. 270.)

8443.—8920. *To destroy moss in old turf.* "It is a singular fact, but not generally known to agriculturists, that by merely lifting the turf of an old pasture field that is overrun with moss, and ploughing and loosening the subsoil, and then laying the same turf down again, the whole of the moss will disappear the first season, without applying either water or manure to the surface." (*Stephens on Irrigation and Draining*, p. 59.)

8444. *Renovating defective meadows.* The late Mr. Sinclair, of the New Cross Nursery, had perhaps more experience, as be certainly had more science and skill, in this department, than any other man. In his excellent work the *Hortus Gramineus Woburnensis*, he recommends first ascertaining that the meadow is completely under-drained; then stirring the surface, by harrowing it, in all directions; the best harrow for which is unquestionably that of Finlayson. After this he gives a thorough top-dressing of rich finely divided compost; he again harrows and cross harrows, and then sows from two to six pecks per acre of grass and clover seeds. For a meadow of low rich alluvial soil, he employs meadow fox-tail, meadow cat's-tail, meadow fescue, rough-stalk meadow grass, crested dog's-tail grass, sweet-scented vernal grass, and perennial red clover. In two years such a meadow will be thoroughly renovated, and will bear abundant crops of hay.

8445.—992. *New fibre plants.* Mr. Taylor of Holbrooke, near Ipswich, sowed five rods of ground with the seeds of *Sida Abutilon*, a malvaceous annual, and received from it at the rate of 15 cwt. of saleable fibre per acre, which he had manufactured into excellent ropes. *Málva crispa*, *M. peruviana*, and *M. mauritiana* also produce fibre which might be applied to the same purpose as that of *Sida Abutilon*; more especially *Málva crispa*, a very common annual in British gardens. (*G. M.* 1840, p. 38.)

8446.—6101. *Camelina sativa*, an annual, a native of Siberia, has been long cultivated on the Continent as an oil plant, and has lately been tried in this country by Mr. W. Taylor, F. L. S., of Holbrooke, near Ipswich, with great success. In 1839, Mr. Taylor obtained upwards of 50 bushels of seed from an acre, which produced at the rate of 12 lbs. of oil per bushel, worth 2s. 6d. per gallon, and 44 lbs. of oil-cake.

8447. *Mádia sativa*, an annual, a native of Chili, cultivated in gardens as a border flower, has also been grown on a considerable scale in 1839 by Mr. Taylor, who obtained 33 bushels of seed from an acre, which being crushed produced 250 lbs. of oil, and 410 lbs. of oil-cake. The oil alone was worth 9l. (*Gard. Mag.* 1840, p. 38.)

8448.—6111. "*Buckwheat* is ground generally into grits by means of handmills, or lever hammers, and is made either coarse or fine. The coarse sort is used for gruel, and the fine sort for cakes and biscuits. In some places they even make use of the first grinding with the bran, more or less, in addition to the finer flour, for baking household bread. It also serves to fatten hogs or poultry in a short time. The principal method to cleanse and separate the husk is, to pour boiling water on a given quantity of cleaned buckwheat, to stir the mass about with a stick, and draw the water off, then to pour cold water upon it, having first stirred it about well. In a quarter of an hour after, the buckwheat is taken out with the bands, and the water squeezed out. In the summer it is dried in the sunshine, and in winter in a warm room, and spread on the floor. As soon as it is quite dry, it is ground in a hand-mill or a stamping-

machine into grits, in which state it is very clean and tasteful. The flour obtained from the *stève* is dainty and very fit for cakes." &c. (*Com. Board Agr.*, vol. i.)

8449.—6199. *The extirpation of ferns in pastures*, where the plough cannot be used. The Highland Society having offered a premium for the best essay on this subject, two were produced and published. (*Trans. H. S.*, vol. xx. p. 371.) In both, the writers, finding that ferns grew always in dry land, propose to irrigate it for a few years. A knowledge of the functions of the leaves of plants would have suggested the cutting off of these in their incipient state, as soon as they made their appearance above the soil, and consequently before they had time to return any nutriment to the root; which will not only kill ferns, but every other plant whatever.

8450.—6218. *The varieties of the horse described by Professor Low*, are: 1. The race horse; 2. The hunter; 3. The Connemara, or Irish pony breed, of Spanish origin; 4. Classes of British horses: viz. Zetland ponies; Orkney ponies; Highland ponies; Welch, Dartmoor, Exmoor, and Hampshire horses; hack horses, and Galloways of the borders; 5. The old English black horse; 6. The Cleveland bay; 7. The Suffolk punch; 8. The Clydesdale breed. (*Low's Domestic Animals*, vol. i.)

8451.—6594. *A machine for fixing horses while being shod*, of a simple and effective description, has recently been invented by Mr. James Catcleugh, millwright in Haddington, a mechanic of very great genius; which will be found described and figured in the *Quart. Jour. Agr.*, vol. iii. p. 510.

8452.—6598. *Roadway's concave horse-shoe* is particularly applicable in the case of horses that have to pass over wood pavement; and it is also said to contribute much to the comfort of the horse in every other description of road. (*Brit. F. M. N. S.*, vol. vi. p. 426.)

8453.—6684. *The following plan of feeding horses* has been practised by Dr. Sully of Wiveliscombe, in Somersetshire, for upwards of twenty years. In Dr. Sully's stables there are no racks for holding hay; for in his opinion a horse with a well-filled rack will consume and spoil upwards of thirty pounds of hay in twenty-four hours; whereas, if the hay were cut down, and mixed with a due proportion of cut straw, and bruised or coarsely ground oats or other grain, ten pounds are sufficient. In the loft, above the horses, Dr. Sully has prepared proportionable quantities of the food with which his horses are daily supplied; and a very simple method has been devised to convey it, when mixed, to the manger of each horse. A wooden pipe is made to pass from the loft into each of the mangers, and close by the mouth of the pipe, in the loft, is placed a tub, of size enough to contain what is sufficient food for a horse for twenty-four hours. To prevent the horse, in searching for grain, from tossing out of the manger the mixed food which is dropped into it, oak crossbars, twelve inches distant, are nailed over it; between these bars ample space remains for the horse to feed. As there can be no dependence on the measured quantities of grain or other food given to the horse, from the variation at times in the respective weights of equal quantities, Dr. Sully recommends, and, indeed, regards it as necessary, that grain of all kinds, and also the cut hay and straw, should be carefully weighed. When all the ingredients are so prepared, the proportions for each horse are allotted. From the following table will be seen the different articles of food, and the quantities and weight of each, which the horses should receive:—

	1st Class.	2d Class.	3d Class.	4th Class.
	Lbs.	Lbs.	Lbs.	Lbs.
1. Farinaceous substances, consisting of bruised or ground beans, peas, wheat, barley, or oats	6	5	10	5
2. Bran, fine or coarse	-	-	-	7
3. Boiled or steamed potatoes, mashed in a tub with a wooden bruiser	5	5	-	-
4. Fresh grains (boiled barley)	6	-	-	-
5. Hay cut down into chaff	7	8	10	8
6. Straw cut down into chaff	7	10	10	8
7. Malt dust, or ground off-cake	-	2	-	2
	30	30	30	30

With two ounces of salt for each class. By this table it will be seen that each horse receives thirty pounds of food in the twenty-four hours, a quantity that will in all cases be found to be amply sufficient. The addition of two ounces of salt is necessary to assist the digestion of the food. Of the four classes into which Dr. Sully divides his ingredients for feeding, those two which contain the steamed or boiled potatoes are the most recommended. No food conduces more to the healthy working condition of horses than the steamed or boiled potatoes; and we may observe, with relation to this, as well as to other kinds of food, that, when the horse comes in weary and hungry, after a long day's work, it is necessary to fill his manger more copiously with the ingredients prepared for him. Dr. Sully and all the other persons who have devised improved methods of feeding agree in the practices of bruising or coarsely grinding the grain and beans, of cutting down the hay and straw, of giving no hay in the rack, of allowing salt, and of weighing each article separately before mixture, instead of adopting the fallacious guide of measurement. (*Quart. Jour. of Agr.*, vol. ii. p. 727.)

8454. *Road horses*, in some parts of Scotland, and more especially in the neighbourhood of Edinburgh and Glasgow, are fed on equal parts of oat-straw and hay, cut by a machine in the lengths of from one eighth to one sixteenth of an inch. The cut straw and hay so produced are intimately mixed together, and, when musty, sometimes sprinkled with a little salt and water. The drink given to the horses is water in which oats or barley have been boiled, and the grain so boiled is found to equal double its quantity of raw grain in keeping horses in condition.

8455.—6747. *Feeding horses*. As the result of an experiment tried with boiled grain, raw grain unbruised, and raw grain bruised or cut, it appears that by far the most profitable mode is to give the grain raw but previously bruised or cut. (*Trans. H. S.*)

8456.—*The ox*. "The important family of which the common ox may be regarded as typical, divides itself into three groups,—the Bisonine, the Bubaline, and the Taurine. The bison inhabit both the Old and New Continents, and are distinguished by round, smooth horns, and a musky odour which exhalates from the skin. The buffaloes are characterised by angular horns, and a fainter odour of musk, and are natives of the warmer regions of Asia and Africa. The taurine group, comprehending the common ox and its different races, forms the most important division of bovidæ." (*Low's Domestic Animals*, vol. i. p. 1.)

8457. *The varieties of the Taurine group* described by Professor Low are: 1. The wild or white forest breed. 2. The Highland breeds, the finest of which is the West Highland. 3. The Zetland. 4. The polled Angus. 5. The Galloway. 6. The Welch, the finest of which are the Pembroke. 7. The Kerry. 8. The North Devon. 9. The Sussex. 10. The Glamrganshire. 11. The Herefordshire. 12. The Alderney. 13. The Ayrshire. 14. The polled Suffolk. 15. The Falkland. 16. The polled Irish. 17. The shetted breed of Somersetshire. 18. The long-horned. 19. The Teeswater short-horned, or Durham. (*Low's Domestic Animals*, vol. i. p. 55.)

8458. *The points by which the different breeds of cattle may be judged*, are given in the *Quart. Jour. Agr.*, vol. v. p. 156; vol. vi. p. 266, 433, and 546, by Mr. James Dickson, cattle dealer, Edinburgh, in a superior manner to anything of the kind which we have before seen in print. We can only spare room to extract a few features.

1. *The short horns*. The frame exhibits a straight level back from behind the horns to the top of the

tail, full buttocks, and a projecting basket; in short, the form is rectangular and perfect in its kind. The colour is red, and the richest white, approaching to cream, or both colours are mixed. Limbs small and clean, like those of the race horse, uniting strength with firmness. Head small, lengthy, tapering, neatly set on a broad firm deep neck; mildly beaming eyes, thin large vary ears, and semi-circularly bent, white or brownish coloured short horns; in a word, a symmetrical harmony, which has never been surpassed in beauty and sweetness by any other variety of the domesticated ox.

2. *The Shetland breed* are uniformly black, light red, or black and white. "They are naturally the smallest breed of cattle in the kingdom, weighing generally from 16 stones to 20 stones the four quarters, and when extra fat, from 25 stones to 30 stones. The beef is of the very finest quality throughout, being as small in the grain as mutton; the fat well intermixed, and the flavour most delicious. In fact, in point of quality, they are, without exception, the finest cattle that are bred in the kingdom. The cows are not great milkers, but the milk is very rich."

3. *The Orkney and Caithness breeds.* Orkney cattle are much larger than those of Shetland, and less symmetrically shaped. They are slow feeders, and incapable of early maturity. The Caithness cattle resemble those of the Orkneys.

4. *The North Highland breed* are bred in the counties of Sutherland and Ross. They are large, symmetrical, and feed well.

5. *The Aberdeenshire breeds* are middle sized, symmetrical, generally black, and capable of being fattened at four years old to fifty or sixty stone.

6. *The Angus breed.* Middle size, symmetrical, generally black, quiet, and rather slow feeding.

7. *The Fife breeds* have rather a ragged outline, and are in general symmetry inferior to many of the northern breeds. The features of the face are strongly marked, and the expression of the eye dull. They have not an aptitude to fatten at an early age, but at four or five years they feed to great substance and heavy weight.

8. *The West Highland or Kyloe breed*, is the oldest in Scotland. Form symmetrical, legs short, eyes full and sparkling, colour generally black; the nearest Scotch breed in character and properties to the short horns.

9. *The Ayrshire breed* is celebrated as milkers, but the Tweed-side short horn cows are now being preferred, on the whole the most profitable; they are larger, give more milk, and take up less room, and give less trouble in proportion to the quantity of milk they give.

10. *The Galloway breed* is readily known by being without horns. The head is rather large, and looks coarse; the legs are short and strong; colour mostly black. The beef, when well and long fed, is of first-rate quality.

11. *English breeds.* The *Hereford* is preferred, because they show, when fat, symmetry and point the nearest in resemblance to those of the short horns. The cows are bad milkers, and the calf consumes all the milk. They pay the feeder better than the breeder. *The long horns* feed to great weights, but they are rather coarse in the bone. *The Sussex* cattle are large, red, deficient in symmetry, and when fat, frequently bought by the shipping butchers, while the *Herefords* are purchased by the cutting up butchers. *The Devons* have a pure rich red colour, with white horns, fair symmetry, and consequently middling quality. When fat and cut up, they want that fine mixture of fat and lean so common in Scottish cattle and short horns. *The Suffolk cattle* are all dun coloured, and the cows are great milkers. Very few oxen of the duns are fed fat, the bull calves being fed for veal, and the cows kept for making butter. *The Welsh cattle* have thick horns, thick coarse plain hides, and narrow backs, and altogether are a very inferior breed. Graziers and feeders out of Wales never think of purchasing them when they can find Scottish West Highland cattle.

12. *Irish breeds.* There are three breeds of cattle in Ireland: the *Kerry breed*, of small size, which belongs to the mountainous part of the country; a small but larger breed, to be found chiefly in the north of Ireland; and a long horned breed, to be found in the low rich plains. The cows of the Kerry breed are, like those of the Ayrshire breed, great milkers. The breed of the plains are large and good feeders, and the grain of their flesh, being coarse, stands the salt, and is therefore well adapted for the supply of the navy. The heifers of the Kerry breed are in constant demand, fetch good prices, and make good poor men's cows.

13. *The Isle of Man breed* is of a mixed character, combining various shapes and colours, so that, in short, there is properly no breed.

14. *The Alderney and Jersey breeds* are too delicate for the climates of Scotland.

15. *The French breeds* are not unlike the Guernsey breed. They are ill made, give excellent milk, get fat on the rumps, but they are always thin on the ribs, and the beef is generally of a yellow tinge. (*Quart. Jour. Agr.*, vol. vi. p. 568.)

8459.—6809. *The points or parts by which cattle are judged* have been laid down in a masterly manner also by Mr. Dickson (*Q. J. A.*, vol. v. p. 159.), and applied to the different Scotch breeds in the subsequent volume of the same journal. The first point is the purity of breed, which is ascertained by the colours of the skin being definite, and in particular by the bald skin on the nose and around the eyes being without spots. The second point is the form of carcass, which, taken longitudinally and horizontally, ought to be that of a solid parallelogram. A third point is a full, clear, and prominent eye. The next is the state of the skin, which ought to feel mellow; a feeling which can only be understood by long practice. Sheep may be judged of by merely the same rules. A refined tone in breeding can be attained in any breed by judicious care in crossing within that breed; and the true criterion of a finished breed is "like producing like."

8460. *Measuring cattle.* The weight of all solid bodies can be ascertained by external measurement; but the shape of the bodies of cattle is so very irregular, and so much of the internal part is hollow, that none of the ordinary rules of calculation are applicable to them. Nevertheless, as it is obvious that the bodies of two oxen which are the same in size will be nearly the same in weight, tables have been formed as the result of repeated experiments, and these tables are now in general use, and found to be practically correct. "It is only by continued practice that any one is enabled to guess the weight of beasts with accuracy: those persons, therefore, who have only occasionally a few fat cattle to dispose of, meet the purchaser (who is in the constant habit of buying and proving his judgment by weighing the carcass when dead) upon very unequal terms; but that great inequality will be much lessened by this aid of measurement." The measurer should be a sufficient judge of beasts to know whether they are marketably fat or not; if not, the measurer will overrate them; and also something of their proper formation, so as to be capable of forming a just opinion whether they are proportionably heavier or lighter in their fore-quarters than in their hind-quarters; and thus making such necessary allowance in computing the weight from the sliding rule, or from the tables in the third edition of *Hillyard's Practical Farming and Grazing*. The method of measuring is to put a string or tape round the beast, just behind the shoulder-blade, and take its circumference in feet and inches; that is called the girth; then with the tape or string measure from the fore part of the shoulder-blade bone, along the side of the back, over the hip to that bone under the tail which plumbs the line with the hind part of the buttock; this is the length. Opposite these figures in the book or scale is the weight of the carcass in stones of 8 lbs. and of 14 lbs., when separated from the offal. Thus:—girth 5 ft. 6 in. by 5 ft. 8 in. length, gives 57 stones 2 lbs. of 14 lbs.; 100 stones of 8 lbs.; which is equal to 10 score per quarter:—7 ft. 10 in. by 5 ft. 10 in. gives 85 stone 10 lbs. of 14 lbs.; 150 stones of 8 lbs.; equal to 15 score per quarter. The girth is easily taken; but the length requires great care to take it correctly. The beast should stand quite straight whilst measured, and the exact part of the shoulder-blade should be felt. (*Journ. A. Z.*, vol. iii. p. 338.)

8461.—6852. *Feeding horned cattle on raw, or on steamed or boiled, food.* Though boiled corn is found

to be doubly nutritious to horses, yet, from a number of experiments made by practical farmers, with a view of obtaining the premium of thirty sovereigns offered by the Highland Society of Scotland, it has been given as an opinion, that, in the case of the ruminating animals, no advantage whatever results from cooking their food. (See *High. Soc. Trans.*, vol. x. p. 253.)

8462.—6856. *On the treatment of cattle in winter.* An excellent paper on this subject will be found in the *Quarterly Journal of Agriculture*, vol. ii. p. 228—241. Some difference of opinion exists among agricultural writers as to whether young growing cattle ought to be fed, or pampered, as Dr. Coventry calls it, with rich food, or supplied with abundance of coarser food. The writer of the article referred to inclines to the former opinion, on the principle of its being the farmer's interest to treat his cattle in such a way as shall enable him to bring them soonest to market. Coarse food, he says, ought not to be found on a well-cultivated farm. Straw and water, in an agricultural sense, are not food at all. Straw given to cattle, with a view of being consumed as their only food, is just so much straw wasted, and time lost, in the forwarding of their condition. A limited supply of turnips will keep cattle alive, and may prevent them from falling off in flesh, but it will never bring them to a state of fatness, though they were to eat in that manner for any length of time; whereas a moderate quantity beyond this limited portion would constitute abundance. Scanty food renders cattle uneasy; whereas food in abundance renders them contented and able to endure every inclemency of weather. A farmer ought neither to rear nor purchase more cattle than he has food sufficient to keep in affluence; for though this might lessen the number, both on individual farms and in the country generally, yet the quantity of butchers' meat brought to market would be greater, and its quality better, than it now is. Hence, on the score of profit to the farmer, and ease and comfort to the cattle themselves, abundant nourishment ought to be given to the latter from the earliest period of their existence, until their growth is complete. Cattle may be fed in houses, and tied to stakes, or in what are provincially called "hammels," which are small open courts, with an open shed for shelter on the north side. Twenty calves, or ten yearlings, may be put into one of these hammels. A hammel with a shed seventeen feet in width and fourteen feet in depth, with a court twenty-one feet by seventeen feet, will contain three large oxen, or four smaller-sized cattle. Every hammel must be supplied with pure water at the command of the cattle. Before the cattle are put into hammels or byres, the floors ought to be well littered, so as to form a sort of drain to carry off the urine to an underground tank, whence it may be pumped up for use. Cattle fed on turnips eat very little straw; and therefore the first thing that should be given to them in the morning is turnips, the troughs for holding them having been previously cleaned out. In the byre, the first thing to be done in the morning is to draw the dung from behind the cattle into the urine canal; and while the cattle are eating their turnips, the dung can be wheeled to the dunghill. Fresh straw, for fodder, may be given about the time that the turnips are eaten up, a small quantity being placed before each beast in the byre, and in the racks under the sheds of the courts. Oat-straw is found to constitute the best fodder for cattle; potato oat-straw is, perhaps, better than that of the common oat, as the former is always cut down before it is quite ripe. Hay is, no doubt, better than any kind of straw; and those who have abundance of that desirable fodder may give it ungrudgingly to cattle, in the certainty of being soon repaid its value. Turnips should be given again about mid-day; and about three o'clock in the afternoon the mangers should be cleared out, and straw or chaff given. In the byre, after this allowance is eaten up, the mangers should be cleaned out before giving another foddering of straw. A trowel will be found a handy instrument for this purpose. At the hammels, the last foddering of straw can be given any time after the last allowance of turnips, which should be ample, as the cattle will come backward and forward to them even in the dark, and in moonlight they will feed as well as during the day. The calves should be served with turnips immediately after the feeding-beasts; and the year-olds can also get a few at this time, to complete their day's allowance. Between the allowances of turnips, litter should be sprinkled in the byres and hammels, to induce the cattle to lie down after repelation, to chew the cud, which they will invariably do. At eight o'clock at night, the byres should be looked at with a light, and the cattle supplied with the fodder necessary, and their beds made comfortable for the night, by drawing back any dung that may be on them, sprinkling some more litter, and shaking it well up with a fork. At the hammels, if it is moonlight, some more turnips should be thrown, even at this time of night, into the mangers. During the day, the water-troughs should be all kept full of fresh water, and any filth that may have been blown into them by the wind should be removed. When the frost becomes so severe as to harden the turnips, they should no longer be brought from the field, but from the store formed of them in the beginning of winter, for the purpose of supplying the cattle with fresh turnips during the continuance of frosty weather; nor should any more be taken even from the store than what can be consumed in a day. Frozen turnips may be thawed by being placed in a tub of cold water; but this is a very tedious and troublesome mode of obtaining fresh turnips in frosty weather, compared to the excellent practice of storing a considerable quantity in open weather.

8463. *In the feeding of cattle*, it is of the utmost importance that the man who has the charge of them should be very attentive to his duty; and, in particular, that he should be exact, even to a minute, in supplying them with turnips: cattle know perfectly well when the time arrives for a fresh supply, even though the mangers in the hammels may not be empty, which they should never altogether be. When they are supplied with food at irregular times, they will either be always craving it, or become careless about it; and their uneasiness, arising from frequent disappointments, will prevent them from feeding so pleasantly and speedily as when their food is placed before them at exact periods. When the man thus regulates his different works by time, he will find leisure moments during the day to perform many necessary acts; which, though they may appear of little importance in themselves, nevertheless contribute greatly to the appearance of neatness and comfort in the farm-yard and its inmates. Thus, he might spread the stable-litter along the edge of the turnip-troughs of the year-old cattle, to keep any turnips clean that may have been pulled over by the beasts; for, when cattle are first put up to feed, the freshness and tenderness of the leaves induce them to eat these first, and in the anxiety of each to obtain another fresh bite, many turnips are necessarily turned over. The man can also shovel and scrape together any mud about the causeways, and the places on which the turnips have been laid down from the field. He can frequently examine the skins of the cattle, and give immediate notice of any eruption; for cattle, after being a month or six weeks on turnips, get very itchy in the skin, the violent rubbing of which often causes ulcerated spots to break out, but which can easily enough be cured at first, by an application of a decoction of tobacco, with a little spirit of tar. He should rub those parts of the body which they cannot easily get at to lick with an old currycomb, and scrape off any dung that may adhere to the hair in the hinder and under parts of the body, with a large blunt knife: and this attention is more necessary at the beginning of the season than afterwards, as the freshness of the stems, and the juiciness of the roots of the turnips, and the greediness which all cattle evince for them at first, often cause a looseness in their bowels. He should observe the first indication of lice in their skins in the early part of the spring, when these may be easily destroyed, by applying to the affected parts a solution of mercurial ointment; but, if neglected, they will cause much uneasiness to the cattle, making their hair peel off, and exposing to view an unsightly skin; and he may handle them frequently on every part of their bodies, as they are very fond of being handled when they are rising in condition; and it is also serviceable to familiarise them with man; as cattle, when they have been accustomed to be handled, will stand better, and show themselves more satisfactorily to the buyer. There is something so winning in a gentle disposition in powerful animals, caused by good treatment, that a buyer will prefer them, when they have to be driven a distance upon the road; and the butchers in the neighbourhood will also prefer them, as they will walk peacefully to the shambles, without the risk of being raised in a frenzy. All these constitute the minutia of the business of feeding cattle on turnips in winter; and, triding as they

may appear, attention to them will be amply repaid, in the shape of prime beef and doctle cattle. The whole may be easily accomplished by any man who regulates his movements by the watch; and the man having the charge of cattle in winter, who will do this whether he is seen by his master or not, is an inestimable servant.

8464. *The quantity of turnips which feeding cattle will consume*, as stated by most writers, is about one ton every week, for an ox of from sixty to seventy stones, or about one acre of a fair crop of turnips in six months. Thirty-three double-horse cart-loads of turnips, each weighing from sixteen cwt. to eighteen cwt., are a good crop on light sharp lands.

8465. *Time of putting up to feed*. If the second growth of grass has continued fresh till the latter part of autumn, cattle may be soon enough put up to feed by the 1st of November; but if she grass fall sooner, which it will in most seasons do, the middle of October is late enough for putting them up to feed. White globe turnips are an excellent juicy food for cattle till the commencement of the new year, after which should follow the yellow or green tops, for two months longer, and then the Swedish turnips will finish the season. If the Swedish turnips have been stored up before the second growth of the stem has made its appearance in spring, they may be taken out quite fresh till the beginning of June. Since the cultivation of the potato has increased so rapidly, many people feed their cattle on it in spring either wholly or mixed with turnips. When cattle are fed on potatoes, attention ought to be paid to them after feeding, for fear of internal swelling. When observed at first, the swelling may be allayed by pouring down the throat a bottleful or less of common whale oil, which will check the fermentation, and operate as a purgative. Should any of the young cattle or the feeding beasts in the byre be choked with a piece of turnip, for those fed in hammels never or very seldom do so, the best expedient is to use the probang at once, rather than to permit the throat of the poor animal to be squeezed, and consequently inflamed, in attempting to push the piece of turnip up and down. The probang may be used with great success, by causing the animal to be forcibly held by superior strength, with its neck and mouth stretched forward, and while one is pushing the instrument gently down, another is directing the end of it down the gullet on the outside of the neck. When the piece of turnip is pushed down into the stomach, let the instrument be gently drawn out; and if, during the operation, the animal forcibly twists its head about, the instrument should instantly be let go. Feeding cattle will eat very little straw; but they ought to have abundance of litter at all times.

8466. *Comparative merits of feeding cattle in hammels and byres*. "Our decided predilection is in favour of hammels. In them the cattle are at perfect liberty to roam about, if disposed for exercise: they are exposed to all the sunshine there may be in a wioter day; and the very rain which falls on their backs titillates the skin, and causes them to lick and clean themselves; they are comfortably warm in their sheds among an abundance of straw in the coarsest night, and cattle will never suffer from cold, when they have a comfortable shelter to which they can repair at will; they can come and go to their food whenever they please, night and day, and, their meat being constantly in the open air, it will be always fresh and sweet; and their feet and hair, when they come to travel, are quite able to bear the hardness of the road and the coldness of the air. These are all advantages which no byre can confer. Nor are the hammels so expensive in their original erection as many represent them to be. We have seen a range of them consisting of five divisions, capable of feeding twenty large oxen, erected for 20*l.*; but these had no regular roof. The roofing of all buildings is the most expensive part of them. The roof of those to which we refer, consisted of trees laid across as beams, about a foot asunder, the space between them being filled up with the branches of the spruce fir and Scotch pine. Such a place was a choice one for stacking pease or beans upon. To this purpose it was often appropriated; or it was covered with straw, roped down, which was used as bedding for the cattle in the first part of the succeeding season; when fresh straw was put in its stead. In the hammels which faced the south, the cattle were well fed and comfortably lodged; and no byre could have afforded so much accommodation at the same expense." (*Quar. Journ. Agr.*, vol. ii. p. 241.)

8467. — 6978. *Milk is preserved from becoming acid* by the addition of any alkali; because, when milk ferments, it develops an acid, which the alkalies neutralise. Hence alkalies prevent the curdling of milk. Alkalies applied to curd will turn it into milk: they are not unwholesome, but in large quantities give the milk a disagreeable flavour. (*L'Agriculteur-Manufacturier*, Mai, 1831.)

8468. — 7008. *A curd-breaker for skim-milk cheeses* (figs. 1181. and 1182.) has been invented by Mr. Robert Barles, of Gilmour Place, Edinburgh. It consists of a hopper of wood (fig. 1181. a), seventeen inches and a half by fourteen inches on the top, and ten inches in depth; and a cylinder of hard wood six inches and three quarters (b) in length, and three inches and a half in diameter. The cylinder is studded with square pegs made of hard wood, each a quarter of an inch in the side, cut square at the ends, and projecting three eighths of an inch. There are eight teeth in the length, and fifteen in the circumference, of the cylinder, 120 teeth in all. It revolves on a round iron axle twelve inches long, made to fill up, in some degree, the space between the side of the hopper and the cylinder. These pieces rest on a slip of wood nailed to the lower rim of the hopper, to keep them in their place. The face of these is studded with nine teeth of hard wood, similar to those on the cylinder, at opposite sides. The stand (c) (fig. 1182.) can be made of any length, and

in length, and is moved by the crank handle (d in fig. 1182.); c e are two wedge-shaped pieces of hard wood,

to suit the breadth of the tub into which the curd is broken. The implement is used in this manner: — Place over it a tub, heap the hopper (a), with curd, and, on turning the winch (d) in either direction, the curd will fall, broken quite small, into the tub. While one hand is moving the machine, the other can press the curd gently down into the hopper. As cleanliness is a matter of the greatest importance in cheese-making, the internal parts of this machine, being loosely put together, can be easily taken to pieces to clean. The cylinder axle rests on two hard wooden blocks (f, fig. 1182.), one on each side, which slip out of their groove. They are held in their working position by the thumb-catch

(g), sunk flush with the bottom of the stand (e), one over each block. The wedge-shaped pieces (c c, fig. 1181) come out. To prevent the curd working out of the sides of

the axle, the cylinder is set a little at both ends into the sides of the hopper. The dotted lines in fig. 1182. will give an idea how the internal part of the machine is constructed. Only one tooth is represented on the cylinder by the dotted lines, to show the position of the whole. (*Quart. Jour. Agr.*, vol. iv. p. 385.)

1183

8469. *Baird's cheese press* (fig. 1183.) is one of the most convenient in use. "The form containing the curd is put on the bottom plate, a, and the top plate, b, is made to descend and press on it. There are two ways of doing this: one quick and easy, until the resistance becomes great; and the other slower, but more powerful, and used for the conclusion of the operation. On the axis c of the wheel d there is a pinion of eight teeth (not seen in the engraving) which works in the rack a. On the axis z there is another pinion of eight teeth (concealed by the other parts) which acts in the wheel d, of twenty-four teeth. This axis, z, may be turned by the winch handle w, three turns of which will make the rack descend through a space corresponding to eight of its teeth. In this way the plate b may be lowered to touch the cheese, and to commence the pressure; but when the resistance becomes considerable, the second method of acting on the rack must be resorted to. On the axis s, besides the pinion before-mentioned, there is a fixed ratchet wheel, r; the lever i, forked at the end, which embraces

F, is also placed on this axis, but turns freely round it. In the forked part of r there is a pall or click, g (better seen at g*), which, turning on the pin k, may be made to engage in the notches of the ratchet-wheel r. By means of this arrangement, when i is raised up, and g engaged in r, the axis s, and its pinion, will be turned round with great power on depressing the end i of the lever; and by alternately raising and depressing i, any degree of pressure required may be given to the cheese; after which, if it be wished to continue the pressure, and to follow the gradual shrinking of the cheese, the lever is to be raised above the horizontal position, and the weight w hung on, which will cause it to descend as the

cheese yields. By inserting the pin f, this effect may be discontinued, and the farther descent of a prevented." (*Highland Soc. Trans.*, vol. x. p. 52.)

1184

8470. *The pneumatic cheese press* (figs. 1184. and 1185.) is the invention of John Robison, Esq., Sec. R.S.E. When of full size, this press may consist of a stand about three feet high, on the top of which may be fixed a tinned copper or zinc vessel, of any required capacity (say eighteen inches diameter, and eighteen inches deep), to contain the prepared curd. This vessel should have a loose bottom of ribbed work, covered with wire-cloth, from under which a small tube, nearly twelve inches long, should communicate with a close vessel, capable of containing all the whey which may be drawn from the curd in the upper vessel. At one side of the stand there may be a small pump-barrel of about seven inches deep, from the bottom of which a suction pipe should terminate at its upper end in a valve opening upwards, and a piston, with a similar valve, should be placed in the pump-barrel, and be worked by a jointed lever, as shown in the model. The process is to be conducted as follows:—The curd being prepared, and salted in the usual way, a cloth is to be put over and into the upper vessel, and the curd put lightly into it, except round the edges, where it should be packed quite close to the sides of the vessel, so that no air may pass that way; the pump handle is then to be briskly worked for a few minutes, on which the pressure of the external air will force the whey to run down the tube into the whey-vessel; when it ceases to run, a few strokes of the pump may be repeated.

The cloth and its contents are then to be lifted bodily out of the curd-vessel, and to be put into a mould of close wirework, with a weight placed over it until it become firm enough to be banded. The mould should stand on a sparred shelf (a shelf made of laths like a bacon rack) to allow the air free access to it on all sides of the cheeses. In fig. 1184., a is a vessel containing the curd; b, a vessel for containing the whey; c, an air pump for exhausting the air in b; d, e, tube for letting off the whey from b. Fig. 1185. is a false bottom for the vessel a; g, wood frame; h, wire-cloth.

1185

the whey; c, a tube communicating from a to b; d, e, tube communicating from d to b; f, a tub for letting off the whey from b. Fig. 1185. is a false bottom for the vessel a; g, wood frame; h, wire-cloth. (*Highland Soc. Trans.*, vol. x. p. 200.)

8471. *Attwood's newly invented churn* (fig. 1186), "being made entirely of block tin, the necessary degree of temperature can be given to the cream, by placing it in a pan of cold or hot water, which ensures the butter coming in ten or twelve minutes at all seasons of the year. The simplicity of its construction, and the facility with which it may be cleaned, are no inconsiderable advantages over those now in common use. The great advantages will be found in the winter; but in the heat of summer, the placing the churn in cold water will be the means of hardening the butter." (*Johnson's Agr. Imp.* for 1843, p. 8.)

1186

8472. — 7010. *A stoneware churn*, of which fig. 1187, is a perspective view, has lately been invented, or brought into notice, by Mr. Daniel Chambers, of Carey Street, London. In form, and in the manner of using, it is in every respect the same as the patent box-churn, figured in page 1040; but the great advantage of the present invention is, that, being made of earthenware, it is much easier kept clean and sweet than when made of wood. The size of

that of which we have given a figure is the smallest that is made, and it will churn so small a quantity as half a pound of butter at a time. As this churn,

from being made of earthenware, is rather too heavy for being lifted up and emptied, there is a small hole on one side near the bottom (indicated in the figure), to let off the butter-milk; which hole is easily stepped with a common cork. The lid has a rebate, as shown at *a* in the figure, for the purpose of preventing the milk from splashing over during the operation of churning. We have much pleasure in noticing this invention, because it will net only greatly contribute to cleanliness, and to the sweetness of the butter produced, but also to lessening the labour of the dairy maid in scalding and scouring. (*Gard. Mag.* 1853, p. 144.)

1187

8473. — 7086. *New Stilton cheeses* may be made to acquire the flavour and appearance of old ones, by inoculating them with portions of the old, containing blue mould. The little scoop which is used in taking samples of cheese, affords a ready means of performing the operation, by interchanging ten or a dozen of the rolls which it extracts, and placing them so as to disseminate the germ of the blue mould all over the cheese. A new Stilton cheese treated in this way, and well covered up from the air for a few weeks, becomes thoroughly impregnated with the mould, and generally with a flavour hardly to be distinguished from the old one. (*Hightland Soc. Trans.*, vol. xi. p. 233.)

mellilot, which smells exactly like a pigsty. (*G. C.* 1842, p. 381.)

8474. — 7093. *Schabziger cheese* is flavoured with the bruised seed of *Melilotus schabziger*, or blue

8475. — 7115. *The varieties of the sheep described by Professor Low*, are: — 1. The Zetland and Orkney breeds; 2. The breed of the higher Welsh mountains; 3. The soft-wooled sheep of Wales; 4. The breed of the Wicklow mountains; 5. The Kerry; 6. The forest breeds of England; 7. The black-faced heath breed; 8. The Cheviot; 9. The old Norfolk; 10. The old Wiltshire; 11. The Dorset; 12. The Merino; 13. The Ryeland; 14. The South Down; 15. The old Lincoln; 16. The Remney Marsh; 17. The elder long-wooled breeds of the inland districts; 18. The Cotswold; 19. The new Leicester. (*Low's Domestic Animals*, vol. ii.)

8476. — 7184. *Management of the fleece in Australia*. In order to assimilate the Australian wool as much as possible with the German, in preparing it for market, the fleeces should not be broken, but merely divested of the breech and stained locks, and so assorted or arranged that each package may contain fleeces of the same character as to colour, length of staple, fineness of hair, and general quality.

8477. *If the washing* has been performed at the same time and place, and with an equal degree of care, the colour is likely to be uniform, and it will then only be necessary to attend to the separation of the fleeces as to length, fineness, and general quality; but if a large grower has flocks of different breeds, and fed on different soils, care should be taken that the fleeces be separated, first, as to colour, and then, again, as to length, fineness, &c.

8478. *Packing*. The fleeces, being assorted as already suggested, should be spread one upon another, the neck of the second fleece being laid upon the tail of the first, and so on alternately to the extent of eight to ten fleeces, according to their size and weight. When so spread, the two sides should be folded towards the middle, then rolled together, beginning at each end, and meeting in the centre; and the roller bundle, so formed, should be held together by a slight packthread.

8479. *The bagging* should be of a close, firm, and tough nature. The material hitherto most generally used has been sail canvass, which very ill resists bad weather on a long voyage, and, when received here, even in favourable condition, is so dry and crisp, that it will tear like paper. A thicker, twilled, more flexible, and tough material would be preferable. The size and form of the package may be in length about nine feet, and in width four feet, sewed up on the two long sides, and at one end; the other end being suspended with the open end upwards to receive the bundles made up as before directed, which are to be put in one at a time, one of the flat sides of the roll or bundle being put downwards, and so on in succession; and the whole being well trodden down, until sufficiently filled for the month to be closed. This is the German mode of packing, but it is doubtful whether packages of the dimensions that have been hitherto sent from the two colonies may not be more convenient for so long a voyage.

8480. *The operation of screwing* should be discontinued where it has been practised; as the pressure by the screw, and the remaining compressed during the voyage, occasions the wool to be caked and matted together in a manner that is highly prejudicial to its appearance on arrival. The practice, also, of winding up each fleece separately, and twisting a portion into a band, is productive, in a minor degree, of the same prejudicial effect; and it is to avoid this that the making German bundles of eight or ten fleeces is suggested. (*Hobart Town Courier*, Jan. 8, 1834.)

8481. — 7219. *Feeding sheep*. It is well known, from the discoveries of the first chemists, that turnips are deficient in nitrogen, and that all animals require a portion of it for their healthy nourishment. Clover and meal contain, besides other nourishing substances, a sufficiency of nitrogen for the supply of animal flesh, and their addition greatly increases the fattening qualities of turnips; much of the juice of the turnip remains undigested, and is voided without any change, when they are the only food of the sheep, which more nitrogenous food would enable the stomach to decompose; at least such is the prevailing theory; and it is very plausible. Experiments and accurate observations alone can substantiate it, or refute its truth. (*G. C.* 1843, p. 132.)

8482. *Feeding sheep in a shed*, though they consume nearly one fifth less food, made above one third greater progress. (*J. W. Childers, Esq.*, in *Journ. A. E.*, vol. i. p. 169.) Subsequent experiments exhibit still greater advantages, particularly during the winter months. By giving the sheep cake, and a

little crushed barley, they may gain from 33 lbs. to 40 lbs. a head in the course of ten weeks, at that season. Much of the success depends on having a bearded floor, which prevents the sheep from taking the foot rot. (*Ibid.*, p. 410.)

8483. *A rain-proof feeding trough for sheep* has been invented by a farmer of Fifeshire, Mr. Bell, near Cupar, and is described and figured by Mr. Hulst. It is an adaptation of the common pheasant feeding box to the sheep trough with the addition of a simple application of the bird cage watering glass. (See *Quart. Jour. of Agr.*, vol. xi. p. 115.)

8484. — 7283. *The varieties of the hog described by Professor Low*, are: — 1. The wild hog; 2. Stamese or Chinese breed; 3. The old English breed, and 4. The Berkshire breed. (*Low's Domestic Animals*, vol. ii.)

8485. — 7315. *Preparation of food for swine*. Mr. Bolton, who has fattened swine to an enormous weight, has the following observations on the subject in the *British Farmer's Magazine*, vol. vii. We consider them worthy of quotation, with a view of impressing on the mind of the reader the importance of fermenting food for this class of animals: — "I always feed my pigs on sour food, which I have invariably found to feed them faster, and to make the flesh firmer and whiter, than food given in any other state. The following is my method of preparing it: — As soon as the potatoes are steamed, I have them, while quite hot, beaten to a pulp, and mixed with bran, in the proportion of twenty-eight pounds of bran to a sack (240 pounds) of potatoes, and this mixture is put into a vat for ten or twelve days, till quite sour; this food makes the pigs fat enough for porkers or small bacons. When I require them more than commonly fat, I begin with fifty pounds of barley flour, instead of the bran, to each sack of potatoes, gradually increasing the quantity of flour till it amounts to half the weight of the potatoes: when the quantity of flour is greater than the moisture of the potatoes will absorb, I add a sufficient quantity of water to make it into a thick paste; I never give it until it has fermented."

8486. — 7315. *Pigs in Hampshire* are frequently washed and rubbed with a hard brush, which is found greatly to improve their condition, and is one of the principal causes of the bacon of that country fetching 2d. more per pound than that of any other. (*G. C.* 1842, p. 351.)

8487. *A description of Mallet's improved apparatus for cooking fodder for cattle by steam*. The simplest form of apparatus for this purpose, usually met with, consists merely of a common open boiler, over which a tub, with its bottom perforated, is placed, and the junction rendered steam-tight by what is called a water-valve or water-lute joint; that is to say, by the lower edge of the tub projecting below its bottom, into an annular space round the upper edge of the boiler, filled with water. The tub is filled with the vegetable matter to be cooked; and the steam rising through the perforation of its bottom, from the water beneath (a fire having been lighted under the boiler), prepares it. This apparatus, excellent as it appears from its simplicity, has many disadvantages. The tub requires to be lifted on and off, by means of a crane, if of large size; a separate boiler is required for each tub; there is no mode of regulating the supply of steam, but by damping the fire, or urging it; and the boiler, to be supplied with the water spent in steam, needs the tub to be previously lifted off. Added to all, the boiler must be circular, and, therefore, of the worst possible form for economy of fuel. The next form is that in which several steaming vessels are supplied from one boiler, which may be of any form. Each of these vessels consists of a tub, as before, with a perforated bottom, and close but moveable cover, which is placed on another shallow tub, with a close bottom, into which the steam from the boiler is conducted by a pipe from the boiler; the junction between the two tubs being made good, either by three or four thicknesses of felt, or by a gasket; a cock regulates the admission of steam to each lower tub, and a crane is provided, which commands the whole range, and lifts them on or off. The arrangement answers tolerably well, but has some inconveniences. But a comparatively small surface of the potatoes or other fodder is exposed to coction. The crane for lifting off the tubs, when each is capable of containing from four to six barrels of potatoes, requires to be a strong and rather costly piece of work; and the consumption of time and labour in lifting on and off, filling and emptying those tubs while hot, is very great, whereby a considerable loss in fuel accrues. All these considerations may be of small importance where the quantity of fodder cooked is small, and therefore the cost of labour and fuel slight; but where a large stock of cattle is to be fed with cooked food, and the apparatus is therefore nearly at constant work, every consideration of facility and economy becomes in the highest degree important. Accordingly, the following train of apparatus was designed for a gentleman, who is not only an extensive rearer of cattle, but one of the most distinguished agricultural improvers in Ireland.* It is conceived that it embodies most, if not all, that can be wished for the purpose. Fig. 1188. is a longitudinal section of the boiler, which is cylindrical, and

four times its diameter in length. Witty's patent gas-furnace is applied to it; *a* is the inclined plane; *b*, the fire-bars; *c*, the dead plate; *e*, the ash-plate. The flame and heated air passes under the boiler, through the bottom flue, *f*, thence through the tubular flue, *g*, right through the body of water in the

* Robert La Zouche, Esq., of Harriston.

boiler; at the extremity of which it goes off, right and left, through two lateral flues, which join at *h*, and go into the stack or chimney; *f* is the feed head, supplied either from any sufficiently elevated source, or by a pump; it is adjusted to supply the boiler at a pressure of 1½ lb. to the square inch; *k* is the safety valve, loaded to the same pressure; the steam from it blows into the flue; *l* is the man-lid; *m*, a whistle, for the purpose of giving notice when there is a deficiency of water in the boiler, should such ever take place; boilers upon this construction being much more liable to injury in this respect than those which have no internal flues; *n* is the steam-pipe and stop-valve, which is connected with the steaming vessels. *Fig. 1189.* is a cross section of the boiler: the same letters refer to both figures. The top part of the boiler, above the masonry, is covered with a wooden jacket, one inch thick, and supported by segments of angle iron, at an interval of one inch and a quarter from its external surface; and for the same reason the walls of its setting are all built hollow. *Fig. 1190.* is a side elevation of the steaming vessel for cooking potatoes, carrots, parsneps, turnips, &c., or other such things; of which *fig. 1191.* is a cross section, through the centre of its length: the same letters refer to both.

two links formed in projections from the adjacent hoop, and made steam-tight by the bees' wax and tallow; it is capable of being very readily put on or taken off.

Fig. 1191. is a cross section, through the centre of its length: the same letters refer to both. *a* is the external cylinder or outer case of the vessel, formed of oaken staves one inch and a half thick, hooped together, and having a close end, staved in at the end *b*. The other end is closed by a moveable lid (*c*) of wood, fastened by cotters driven through the adjacent hoop, and made steam-tight by a gasket, soaked in the lower segment of the cylinder, an arched wooden false bottom, *d*, is placed, stiffened by slight cross ribs of cast iron, and perforated full of holes five eighths of an inch in diameter; above, and supported by this, the matters to be cooked are placed until they quite fill the cylinder. The whole thing is hung upon two gudgeons or journals, *e e*, passing through the centre of gravity of the cylinder, when loaded; so that, by the arrangement about to be described, either end of it may be elevated or depressed. One of these journals is hollow, and immediately connected with the steam-pipe from the boiler by a stuffing-box, *f*; so that the steam enters through this journal and the curved pipe *g*, the former having still free liberty of motion. Both journals move in brasses, resting on strong diagonal framing, *h h*, bolted down to a mass of masonry. *i i* are two wrought-iron links, connected by joints with the hoops of the cylinder at top, and with the extremities of the equibrachial lever *k*; the centre of which consists of a Y shaft, *l*, supported by two or three slight frames, *m m m*, and having the long vertical lever *n* keyed on it at one end. These frames are bolted to proper timbers in the

floor of the loft above. Now it is obvious that, by means of the vertical lever *n*, either end of the cylinder may be elevated or depressed, and that the natural tendency of the whole system, when at rest, will be to remain horizontal. From the bottom or side of the cylinder at *o* proceeds a small tube, to take away the condensed steam; so made, that it shall permit the water to pass, and yet be steam-tight; and also that it shall remain vertical, whatever be the position of the cylinder. This is shown enlarged in *fig. 1195.* The upper end of the tube works in a steam-tight joint, *a*, like the pin of a common cock; but made so that there is a free passage through in all positions of the tube: the screw tail of this joint is secured into the bottom of the cylinder by a brass nut and felt washer; the joint being placed with its axis of motion at right angles to the axis of the cylinder. The lower end of the tube *b* (shown only in part) consists of an inverted siphon, the returning limb of which is of such a length that the column of water retained in it is equal in pressure to the density of the steam in the cylinder. The greatest part of this tube hangs freely in a square aperture, below the level of the floors in *figs. 1189.* and *1190.*, where it is connected with a small sewer to take away the water. It is evident that, when the cylinder is moved, the tube will rise and fall vertically in the hole or upright trunk in the floor. Now for the mode of working this steaming vessel. The steam being up in the boiler, and the lid *c* removed, the end *c* of the cylinder is elevated to an angle of about 40°, when it comes just under a large wooden shoot or hopper from the loft above, close to which is placed a slicing machine, for dividing mangold wurzel, turnips, or other large roots requiring to be steamed; from whence they drop direct through the hopper into the cylinder until it is full. Potatoes are either shot direct from a cart (if the situation permit of it) through the hopper, or from sacks from men's shoulders, into the cylinder. When it is full, the lid *c* is put on, and cotted tight, the cylinder again placed horizontally, and the steam admitted. When the steaming is complete, a low capacious truck, or a large square basket on wheels, or any other convenient receptacle, is brought under the end *c*; the lid is removed, and the end *c* is now depressed sufficiently to cause the vegetable matter to fall out; the steam being previously shut off: the operation is then complete. The false bottom is now to be withdrawn, and it, together with the inside of the vessel, scraped and washed; the former is only necessary when potatoes are cooked in it. The objects proposed in this arrangement

are, perfect ease in filling and emptying, without the necessity of handling either the heated vessel, or food; nearly a maximum capacity with a minimum cooling surface to the vessel; perfect staunchness, durability, and readiness of examination and cleansing of the interior. If there be no other elevated supply of water to the steam kitchen, a pump should be fixed in it, both to supply the boiler and to wash the vessels; potatoes, especially, leave a kind of slime upon the inside of steam tubs, which soon putrefies. It is said the cattle are sometimes choked by small potatoes, which are not sufficiently steamed; this might be prevented by the addition of a pair of rollers, into the hopper of which the cylinder might discharge its contents; and they would bruise all to a given size, and deliver into the truck before mentioned.

Fig. 1192. is a side elevation of the cylindrical vessel for steaming hay, chaff, bran, oats, clover, &c. It is of a much larger size than the cylinder for steaming more solid matters; and, therefore, is not made of wooden staves, but of iron plates riveted together like a steam boiler. *Fig. 1194.* is a cross section of the same: the letters of reference apply to both figures alike. The cylinder is supported on four vertical frames of cast iron, *a a*, properly connected by diagonal stays: one end of it is riveted in, and through it the steam-pipe *b* enters. The other end is moveable, and closed by a circular lid or cover, also of boiler plate, secured by six cotter bolts, as shown in elevation, *fig. 1193*; it is strengthened round its edge by a ring of two inches and a half angle iron riveted on, and is externally slightly convex: *c* is the convex false bottom, formed of sheet iron one eighth of an inch thick, punched full of round holes three tenths of an inch diameter, and stiffened by ribs of T iron, riveted to its lower side: *d d* are two siphon tubes for emission of condensed water, as before described: *e* is a man-lid for the purpose of filling in chaff, &c., or other such matters. The large end lid has got a counterbalance weight attached to the chain *f*. The whole of this cylinder, and all the steam-pipes, are lapped over with slight haybands, which are lapped over with thick felt or dreadnought; and this, lastly, is sewed tightly over with strong sail

canvass painted. This mode of uniting, as a coating, several bad conductors having different conducting powers, is found to resist the passage of heat much more effectually than an equal thickness of

even the worst conductor of the three. This fact, which, I believe, has not been hitherto noticed, will at once suggest to the scientific reader some curious analogies to the passage of sound through media

of different density; and which, indeed, caused the arrangement which has been described to be adopted. It will thus be seen that this second cylinder is very similar in its general construction to that first described, except that it is not moveable; which, from its magnitude, would be inconvenient, and it is unnecessary for either hay or chaff, &c. New of the mode of working it. In the left above, immediately over the man-lid *c*, is placed a chaff-cutter, and also a bean and rat bruiser, which both discharge by separate hoppers into the cylinder. The end lid having been put on and coterred up steam-tight, the vessel is thus filled with the desired material, which is spread uniformly with a fork through the man-lid. Steam is then turned on; and, when the operation is complete, the end lid is loosed and thrown up by the aid of the counterbalance above the cylinder end, and the contents drawn out by forks, or by a large but light and slender instrument like the worm of the ramrod of a gun. Before being used the first time, the inside of this vessel is given a coat of drying oil and copal varnish mixed, which prevents subsequent oxidation. The general intent of the whole of the apparatus is to save labour and fuel, which it does effectually; and that portion of it for cooking potatoes is now about being erected in the new gaol of Mayo, the largest in Ireland. In some few cases, where the extent of the

apparatus would be very great, and labour dear, it might be advisable to connect a small steam-engine with it, working from the same boiler, to pump water, slice turnips and mangold wurzel, cut chaff, and

1194

bruise oats and beans, &c. Where a high pressure steam-engine pre-exists on a farmery for other purposes, the waste steam from it may be made fully available for steam-cooking apparatus, which thus would cost nothing; it requires, however, a particular adaptation, in order that the power of the engine may not be reduced, by driving the steam through any considerable resistance. Occasionally, but rarely,

1196 (§ 8489.)

fluids may require to be boiled by steam, as stirabout for pigs, or wash for calves: for these, another form and construction of vessel altogether is necessary. (*R. Mallet.*)

8488.—7431. Warmth is strongly recommended for promoting the health of poultry. Cold, it is found, either produces inflammation of the lungs, or pulmonary consumption. Heat constantly prevents this, and alleviates the disease when it has taken place. (*Annales des Sciences Naturelles*, as quoted in *Quart. Jour. of Agr.*, vol. ii. p. 568.) Warmth, also, makes fowls lay. Every housewife knows that eggs are most abundant in warm weather; and all country housewives know that the only way to make hens lay in cold weather, when eggs are dear, is to

feed them well and keep them warm—the latter being of very nearly as much importance as the former. Some excellent observations on the subject of rearing and feeding poultry will be found in our *Ency. of Col. Arch.*, § 1325. to 1329., and § 1356.

8489.—7684. *The pheasant-feeder* (fig. 1196.). This ingenious invention is manufactured of iron by Messrs. Cottam and Halleo, and seems the best utensil of the kind that we have seen. There is one of tin, lighter and cheaper (see *Gard. Mag.*, vol. v. p. 589.), sold by Messrs. Bailey, 272. High Holborn, and by Weir in Oxford Street, but it is by no means so durable.

8490.—7631. *The mole* may be extirpated without the use of traps by digging up the mole hills in the course of the month of March, which is the breeding season. In order to give an idea where the mole's nest is to be found, reference may be had to figs. 1197. and 1198.; the first of which is an underground

1197

1198

plan, or horizontal section of a mole-hill, and the second a vertical section. In both these figures, *a* is the mole's nest; *b*, vertical tubes or runs, by which the mole ascends with the soil which it has excavated from the place forming the nest, in order to raise a hill over it to protect it from the rain; *c* *c* show the surface of the ground; *d*, a tunnel above the surface of the ground, in the soil of the artificial hill; *e*, *e*, the common run of the mole extended to an unascertained length on every side; *f*, line indicating the base of the hillock. After removing the hill, and destroying the young moles, by waiting a little without making the least noise, the parent will make her appearance and may be also destroyed. (*L'Agrologue*, vol. i. p. 220.)

8491.—7632. *A mode of catching rats* by baiting the traps with ground pale malt scented with the oil of caraway seeds, and which is said to be very effective, will be found described, at great length, in the *Quart. Jour. of Agr.*, vol. ii. p. 319.—331.

8492.—7684. *Wire worm*. The refuse lime of gas works, probably an impure sulphuret of lime, or lime combined with sulphuretted hydrogen, a gas, the most deleterious of all others to animal life, has been found by Earl Talbot to check the ravages of the wire worm. (*Proceedings of the Royal Agr. Soc. in June 1841.*)

PART IV.

STATISTICS OF BRITISH AGRICULTURE.

BOOK I.

PRESENT STATE OF AGRICULTURE IN THE BRITISH ISLES. (p. 1121.)

8493.—7711. *The evils of the bothy system of maintaining single farm servants*, are forcibly pointed out in the *Trans. High. Soc.*, vol. xiv. p. 133., and, as a remedy, the lodging the single men with the married ones recommended.

8494.—7711. *The employment of women in field labour* is very generally condemned by benevolent men, who allege that the association of numbers of persons, of both sexes, in the fields, demoralises them; and ample evidence is produced to prove that they are in many places demoralised. On the other hand, it is denied that there is anything in the nature of the congregation of both sexes in the fields morally worse than their congregation on the basement floor of a nobleman's house, in a large workshop or factory, in a drawing-room or ball-room, or in a public park or garden. "If in the drawing room or at the ball, or anywhere else, where the rich classes congregate, there is more decorum and refinement of manners; it is not because their inherent nature is different, or that the passions slumber; it is because they, the refined, have been taught, and made to feel the value of outward decorum. Whether in the servant's hall, or in the milliner's shop, or in the factory, or in the farm-field, we look for good behaviour, we shall find it; but we shall find it existing in a lesser or greater degree, according to circumstances other than the mere associating of a number of persons together. Are there not factories in England where the workers are educated and trained in moral decorum, and brought together in social parties occasionally, that they may exercise refinement of manners, and cultivate the higher sentiments of our moral nature? And are there not factories where the associated hands have the most scrupulous care paid to their physical and moral comforts, the results of which they show in all their conduct, in the shop and out of it? And is it not a notorious truth, that in the same metropolis the greater number of workshops, and those who are mistresses and masters and workers in them, are distinguished for conduct quite the reverse? And have we not an aristocracy with large establishments of domestic servants, some of which establishments might be a pattern to any school of moral instruction; while others in licentiousness are a disgrace to civilisation and the age we live in? Have we not an orderly, ay, a virtuous and well-mannered population of both sexes working in the farm-fields of Northumberland, Cumberland, Roxburghshire, Berwickshire, and the Lothians? And have we not, according to the evidence in the *Report of the Special Assistant Poor-law Commissioners on the Employment of Women and Children in Agriculture* (presented to Parliament in June, 1843), a population in Wilts and Dorset distinguished for their poverty and their vices? No, no; it is not because men and women, and girls and boys, associate in the fields promiscuously, that they are demoralised, that they become foul-tongued and ill-mannered. The association of the sexes in all conditions of life has a tendency to refine the manners and restrain licentiousness, if no other cause to the contrary be at work. The farm-labourers are no exception.

1199 (§8495.)

"We must go deeper for the causes of demoralisation than the mere assembling together of men and women in the fields. It is said by nearly all the witnesses that the women who work in the fields make neither good housewives nor good domestic servants. Now, to be neither a good housewife, nor a good household servant, is a grievous charge against outfield labour, were outfield labour chargeable with a result so much to be regretted. But the cause of the Dorset and Wilts, and Somerset and Devon women who have worked in the fields being such thriftless housewives, as they are mentioned to be in the *Reports* mentioned, is quite a different cause from that assigned. It is just as different as possibly can be, for it is that the unstable nature of all agricultural engagements in the south of England begets a precariousness of employment, with small and uncertain wages; which, by making good furniture and clothes, and family stores of provisions, unattainable, renders good housekeeping impossible."

The remedy which the admirable writer quoted suggests is, "Not the curtailment of the employment of women in the field, but an extension of it; a thorough revision of all the engagements between landlord and tenant; the complete emancipation of the teantry from political subjection; the abolition of the variable rates of wages, dependent on a man's being married or unmarried; the establishment of agricultural schools for farmers; of national schools for all children, with no religious intermeddling whatever, save through the influence that may be exercised in the pulpit and in visitation to the houses of parents; an enactment compelling cottages to be equally good with those lately built by the Duke of Wellington for his labourers at Strathfieldsaye, with gardens not less in size, to wit, each a quarter of an acre; or as good as those cottages built for their workpeople by the Messrs. Ashworth and some other Lancashire manufacturers, as described in the *Sanitary Report* of the Poor Law Commissioners, published in 1842, and *Suppl. Encyc. Cott. Arch.* p. 1154. To discourage the giving of beer to labourers as a part of their wages. To encourage the paying of workpeople by so much a day, or week, or month, or year, and not by piece-work. To give tenaot farmers full power to break up all old grass lands, and crop each his own farm, as he sees most fit; that is, if he proves himself to be trustworthy in regard of knowledge and capital. To give him security of tenure, that he may obtain capital. To take from him, at once and for ever, all delusion about protection from commercial competition, and let increased commerce give him an increased demand for his produce. To have all rents regulated by the prices of produce. To depart from the ruinous custom of an incoming tenant paying for all the work which the outgoing tenant has done in improvements, real or supposed. To let each tenant, on the contrary, come in free, and commence with his capital to improve his farm himself, giving him at least twenty years to reap the benefits, so that when he goes out he may carry the profits of his improvements with him, and not take their supposed value out of the pocket of his successor. To give the better diet to the really helpless of the poor in the workhouses, and sufficient out-door relief to the aged who may desire to remain in the home of their affections. To send all able-bodied labourers who are willing to work and cannot find employment, to the cultivation of the crown lands, or other estates that may be procured and used for the purpose of agricultural schools; but never to send them to break stones or grind bones in a workhouse, as a punishment. To put an end to all poaching and poachers, by putting an end to all game and game-laws, and giving gamekeepers a more useful employment.

These are a few of the remedies for the present condition of the farm labourers. They are hastily

thrown together. Some of them are, of necessity, remote; others I believe to be near at hand; and all of them, I believe, must be adopted and carried out before the deplorable state of agricultural England alters from what it is. (*One who has whistled at the Plough in Morn. Chron.*, June 24th, 1843.)

8495.—7784. 11. *The application of steam to machinery for raising the water from fen and low lands.* We have mentioned (§ 7786.), that steam had been employed for this purpose in Cambridgeshire; and we have since learned from the account of a trial in the newspapers (see *Times* for July, 1834), that a gas engine has also been so employed in the Cambridge fens. We are now enabled, through the kindness of Mr. C. H. Capper, engine-maker, Union Foundry, Birmingham, to figure and describe a steam-engine and lifting machine of a very superior description, which that gentleman has erected on the estate of — Drake, Esq., at Stainfield in Lincolnshire. "The great advantage," Mr. Capper observes, "of bringing fen and low lands (formerly rendered useless by floods) into cultivation, by a small outlay of capital, must be my apology for troubling you with so minute a description of the draining machine I have erected for that purpose; and, as the same may be of use to a few, I shall feel obliged if you will give it a place in your work; and at the same time add, that by the great improvements which the use of locomotive carriages has made in high-pressure engines, I am enabled to say that as effective an engine as the one described might now be completed for a much less amount; or, if the landowners whose lands are subject to floods were to subscribe, a movable draining-machine might be made, at a very small expense."

Fig. 1199. shows the elevation of a six-horse portable condensing steam-engine, working a second shaft, marked *c*, in *figs.* 1200, 1201, and 1202. On this shaft, the large water-wheel *d d* is fixed. This wheel revolves in a brick or stone casing, similar to that formed for the wheel of a common water mill, but so accurately fitted as not to allow of any water passing by either of the sides of the paddles, or by the front; because this wheel acts by its paddles lifting the water from the bottom of the wheel-race up against the breastwork, and then throwing it over the sluice *e*. This sluice is formed of movable boards, to admit of regulating the lift of water at pleasure, from 3 feet to 8 feet in height. The water, being raised and thrown over the sluice *e*, falls into the pond or receiver *f*, whence it is carried off at as high a level as it will run; in this case, at about 3 feet higher than the surface of the lands to be drained, and about 6 feet higher than the bottom of the drains. At the lower end of the trough there is a sluice, *g*, for regulating the quantity of water introduced into the lifting wheel; because, if this were too great, the power of the steam engine might be insufficient to turn the wheel, or the machinery might be injured. The wheel, as it will be seen, consists of eight iron paddles, fixed to an octagon iron casing; each paddle acts by lifting up a portion of water from the boom of the wheel-race, and raising it to the top of the

1202

sluice *e*. When the whole of the water, or nearly so, is lifted up, of course the boards composing the sluice *e* must be attended to, lest the water force its way back again upon the wheel.

Fig. 1200. is a ground plan of the boiler, engine, and water-wheel; in which *a* is the boiler; *b*, the engine; *c*, the water-wheel shaft; *d*, the paddles of the water-wheel; *e*, the upper sluice, over which the water is thrown; *f*, the pond or reservoir which receives the water; and *g*, the lower sluice, placed across the drain which conveys the water to the wheel-race.

Fig. 1201. is a section through the steam-engine and the water-wheel; in which *a* is the boiler; *b*, the engine; *c*, the shaft or axle of the water-wheel; *d*, the paddles; *o*, the tube for supplying water to the boiler; *p*, the steam pipe; *q*, the fly-wheel; *r*, the spur-wheels; and *s*, the roof.

Fig. 1202. is a longitudinal section through the water-wheel, the trough, and the two sluices; in which *c* is the axle of the water-wheel; *d*, the paddles; *e*, the upper sluice, over which the water is thrown; *f*, the pond or reservoir to receive the water before it is carried off to the nearest river; *m*, the trough or wheel-race; and *g*, the sluice to regulate the admission of the water from the land to be drained.

Fig. 1203. is a section through the boiler lengthwise; in which *a* is the boiler; *b*, the fire-place, and flue round the boiler; *i*, the ash-pit; *k*, the safety valve; *l*, the tube for supplying water to the boiler; *m*, manhole for cleaning out the boiler; and *n*, the chimney.

8496. *Action of the machine.* After these particulars, little description will be needed; for it must be evident that, when the engine is set in motion, it will, by means of the wheel and pinion *r*, turn the water-wheel *d d* about its centre *e*; and that, when set in motion, each of the arms will lift a quantity of water from the trough, or wheel-race, *m*, over the sluice *c* (see *fig. 1202.*), at a higher level to the pond or reservoir, *f*, whence it may be taken away as circumstances may require.

8497. *The expense* of the portable steam-engine, exclusive of carriage, and putting up, was about 280*l.*; that of the lifting wheel, exclusive of the masonry, about 70*l.*; and the total expense of the whole about 450*l.*

8498.—7943. *The study of chemistry by practical farmers* is strongly recommended by most writers on scientific agriculture; but this Dr. Madden considers an error. "I have noticed," he says, "with regret, that almost all the popular works hitherto written upon agricultural science have fallen into the one common error of endeavouring to make a chemist of the practical farmer; the authors all seem to think it necessary that, in order to the improvement of agriculture, every farmer must study chemistry. In this respect, however, I hold a totally different opinion. It appears to me that it would be a precisely analogous case, if writers on climate had said, that, in order to preserve health, it were absolutely necessary that every individual should study medicine. It is not an extended knowledge of chemistry that is required,—it is only a confidence in the results obtained by chemists that is absolutely necessary. If the farmer becomes acquainted with the facts as they apply to his practice, and if he has such confidence in these facts that he is willing to act in accordance to them, there is not the least necessity that he should occupy his time and burden his mind with all the abstruse processes of reasoning and experimental proof by which the chemist has been enabled to trace out their connection with the complex phenomena which they serve to illustrate." (*Trans. H. S.*, vol. xiv. p. 616.)

8499. *Improvements.* Professor Johnstone of Durham, one of our first agri-

cultural chemists, says, "Farmers are proverbially slow in adopting improvements: it is well that they are so; for if they were to adopt every thing which is new, they would most likely suffer many disappointments." The same author observes, that "prudence and economy are the soul of agriculture; and the balance of accounts at the end of the year is the criterion of the system pursued." (*G. C.*, 1843, p. 115.)

8500. *Experience and experiments.* In Professor Henslow's lectures before the Royal Agricultural Society, the connection between agricultural science and practice is clearly pointed out. Experience is the only source of scientific knowledge, and this can only be obtained by a long series of observations

and experiments, carried on, not by one person, but by many. Subsequently the Professor drew up a scheme by which the same experiment may be repeated in any number of places all over the country. See his Letters to the farmers of Suffolk (*Gard. Mag.* 1843, p. 313.), Professor Henslow's scheme for co-operation, and Professor Johnston's suggestions. (*G. C.* 1843, p. 136.) "All England," Professor Henslow observes, "might be converted into one great experimental farm, if our different agricultural societies would prepare accounts of the exact mode in which some hundred farmers might perform a set of easy comparative experiments at the same time, and send in the results of them. This is what is most needed for accelerating the present jog-trot progress of agriculture into something like a railroad pace of advancing." (*G. C.* 1843, p. 155.) "Trust not implicitly to the suggestions of the most celebrated chemists, nor adopt their notions into your practice, without previously making a set of comparative experiments for yourselves, in order to test the value of their suggestions. Secure co-operation; act together by hundreds and thousands in attending to directions and in registering results. Such decided improvements in the art of culture will then be struck out for you, that your important interests will be able to maintain that state of prosperity which is so essential to the general well-being of the country." (*G. C.* 1843, p. 171.)

8501. *Model Farms*, which for many years have been adopted in France, Germany, and even Russia, have lately begun to be formed in Britain. One is commenced on the estate of Lord Ducie in the vale of Gloucester; and one is in progress in Yorkshire, for the Yorkshire Agricultural Society, besides some in Ireland. (*Gard. Mag.* 1840, p. 564.)

8502. *The English Agricultural Society*. The idea of this society was first suggested by Lord Spencer, at the dinner after the show of the Smithfield club in the beginning of 1838, and a meeting was held for that purpose, on the 9th of May following. (*Q. J. A.* vol. ix. p. 110.)

8503. *The Royal Agricultural Improvement Society of Ireland* was established in February, 1831. An account of its progress will be found in the *Brit. Farm. Mag.*, n. s., vol. vii. p. 74.

8504. *Schools for the instruction of farmers' sons in the physical sciences* were recommended in 1834 by Mr. William Hawkins, of Hitchin, Hertfordshire. (*Q. J. A.*, vol. v. p. 39.)

8505. *A Farmers' lending Library*, proposed to be established in Liverpool. (*B. F. M.*, n. s., vol. iv. p. 284.)

8506. *Cottagers' Garden Societies*, strongly recommended by Mr. Monteath, of Clocsburn. (*Q. J. A.*, vol. iv. p. 791.)

8507. *The great obstacles to agricultural improvement of present*, are want of sufficient capital employed in cultivation; the absence of due security to any capital employed in cultivation; the absence of due security to any capital that might be applied; and the otherwise insecure and illiberal foundation on which agricultural polity rests; and the general aversion of landowners and wealthy individuals to make any outlay that would diminish their yearly revenue; and from their considering capital to consist only in ready money that is available; and from their being unable to connect it with improvements that would increase the yearly profit. A monied man buys a portion of land, and expects a certain yearly return from it in an uncultivated state; whereas if any part of the capital were expended in improving a smaller quantity of surface, a much greater annual revenue would be derived; for, in many instances, the first crop of improvement has paid rent and all expenses, and left the future return for profit and increase of the annuity. (*Donaldson's Treatise on Manures*, &c. p. 341.)

CHAP. IV. — Bibliography of British Agriculture, from 1832 to August 1843. (p. 1206.)

- 1829—32. *Anon.*
Transactions of the Agricultural and Horticultural Society of India. Vols. I. and II. Serampore and Calcutta. (*G. M.* 1831, p. 440.; 1832, p. 519.)
1829. *Douson, Mr. Robert*, late agent to the Australian Agricultural Company, New South Wales.
Statement of his Services, &c., with a Narrative of the Treatment he received, &c. Lond. Pamph. 8vo. (*G. M.* 1830, p. 86.)
1830. *Denson, John, sen.*, market gardener near Cambridge.
A Peasant's Voice to Landowners, on the best Means of benefiting Agricultural Labourers, and of reducing Poor-rates. Cambridge. Pamph. 8vo. (*G. M.* 1831, p. 80.)
