AN
ENCYCLOPÆDIA
OF
AGRICULTURE:

COMPRISING THE
THEORY AND PRACTICE
OF THE VALUATION, TRANSFER, LAYING OUT, IMPROVEMENT,
AND MANAGEMENT OF
LANDED PROPERTY,
AND OF THE CULTIVATION AND ECONOMY OF
THE ANIMAL AND VEGETABLE PRODUCTIONS
OF AGRICULTURE,

INCLUDING

All the latest Improvements;

A GENERAL HISTORY OF AGRICULTURE IN ALL COUNTRIES;
A STATISTICAL VIEW OF ITS PRESENT STATE,
WITH SUGGESTIONS FOR ITS FUTURE PROGRESS, IN THE
BRITISH ISLES;

AND

SUPPLEMENTS

BRINGING DOWN THE WORK TO THE YEAR 1844.

BY J. C. LOUDON, F. L. G. Z. & H. S. &c.

AUTHOR OF THE ENCYCLOPÆDIA OF GARDENING, ETC.

SIXTH EDITION.

ILLUSTRATED WITH

UPWARDS OF TWELVE HUNDRED ENGRAVINGS ON WOOD, BY BRANSTON.

LONDON:
LONGMANS, GREEN, AND CO.
1866.

LONDON
PRINTED BY SPOTTISWOODE AND CO.
NEW-STREET SQUARE

PREFACE.

THE subject of Agriculture admits of two grand divisions; the improvement and general management of landed property, which may be termed *Territorial Economy*; and the cultivation and treatment of its more useful animal and vegetable productions, which are called *Husbandry*, or *Agriculture* in a more limited sense of the term. Numerous as have been the publications on rural matters during the last twenty years, there are but two or three of them whose titles might lead to a supposition that they embraced both of these departments. That none of them did embrace both, however, previously to the appearance of this Encyclopædia, may be confidently affirmed.

This work, which is termed an *Encyclopædia of Agriculture*, on account of its superior comprehensiveness, though in part an original composition from the author's practical experience and observation, is yet chiefly a compilation from books. It professes to embrace every part of the subject; and, what has never hitherto been attempted, to give a general History of Agriculture in all countries; and a condensed survey of its present state in every county of the British Isles. A systematic arrangement is adopted as by far the best for instruction, and also as best admitting of compression. At the same time, a copious General Index is supplied, to render the whole work of the easiest access as a book of reference. So much information as is here given could only be compressed into one volume by the use of a very small type, and by the liberal employment of engravings. By means of the latter, much verbal description is avoided; a knowledge of implements and operations is more forcibly conveyed to the reader; and such a body of useful matter is brought together, as, by the system of detached copper-plate engravings, and ordinary letter-press, would have occupied half a dozen volumes.

Throughout this work, we have kept in view the following objects: in PART I., to depict what may be termed Universal Agriculture, by giving a historical view of that of all countries; in PART II., to exhibit the principles on which the operations and results of the Agriculture of all countries are founded; and, in PARTS III. and IV., to apply these principles to that particular Agriculture which is practised in Britain, and adapted to similar climates. In pursuing these objects, we have aimed at language sufficiently free from provincial or obscure technology to be understood by all classes of readers. In describing the Agriculture of Britain, we have held up to view that of the northern counties of Northumberland, Berwickshire, and East Lothian, as examples, in most things, to the other parts of the empire. In addressing landlords, superior agents, valuers of land, and patrons, we have pointed out the advantages of equitable and liberal conduct to their tenants and dependants: in discussing the duties of land stewards, bailiffs, and other serving agriculturists, we have recommended habits of order, vigilance, and economy: and, finally, we have submitted to all classes of readers, the advantages of enlightening the minds and ameliorating the condition of the working classes of rural society, by facilitating the attainment of instruction; by pointing out the evils of their entering too early into the marriage state; by increasing the comfort and improving the appearance of their cottages and gardens; and, especially, by repaying the labour of farm servants to a certain extent in productions calculated for their chief support. (See § 7834. 7862. and § 7953. to 7980.) For, in our opinion, the main comfort of all those engaged in agriculture as a profession, from the labourer to the gentleman farmer, will ever consist more in the *possession within themselves of the essential means of comfortable existence*, than in the power of accumulating fortunes, such as manufacturers and commercial men frequently acquire.

As much of the value of a work of this kind will depend on the knowledge it conveys of the modern improvements in implements and buildings, particular attention has been paid to these subjects. Many of the latest improvements in implements and buildings have not found their way into any books, and for them we have had recourse to the originals, and to the most eminent agricultural mechanics and manufacturers of implements. Our thanks, in this respect, are particularly due to the proprietors of Weir's Agricultural Repository, Oxford Street, London, for permitting us to take sketches from their extensive collection, and more particularly of those implements and machines which the late Mr. Weir invented or greatly improved. Our best thanks are also due to Mr. Morton, Leith Walk, Edinburgh, who is equally eminent as an agricultural mechanist in Scotland; to Messrs. Cottam and Halleo, of Winsley Street, Oxford Street, manufacturers of agricultural implements and machines in iron; and to Mr. Wilkie, of Uddistone, near Glasgow, a scientific mechanist, and an eminent manufacturer

of agricultural implements both in timber and iron. There is no implement or machine mentioned in this work which will not be found on sale, or may not be made to order, in the establishments of these gentlemen, in the best manner, and at an equitable charge.

For important assistance in the Veterinary Part of this work, our best thanks are due to an eminent professor. Through the kind assistance of this gentleman we have been enabled to bring together a body of useful information on the anatomy, physiology, pathology, breeding, rearing, and general treatment of the horse, the ox, the sheep, and other domestic animals, even to dogs and poultry, such as we can safely assert is not to be found in any other single volume on Agriculture.

It may be necessary to mention, as a key to this work, that such technical terms as are used in a more definite sense than usual, or such as practical readers in the country, or mere general readers, may be supposed not familiar with, are explained in a Glossarial Index (p. 1241.); and that the abridged titles of books are given at length in an appropriate catalogue. (p. viii.) The systematic nomenclature of plants adopted is that of our *Hortus Britannicus*, with some exceptions which are noted where they occur. In the specific names of the more common animals, we have followed Turton's edition of the *Systēma Naturæ* of Linnæus; in those of insects, we have followed modern authors: such chemical, mineralogical, and geological terms as occur, are those used by Sir H. Davy in his *Agricultural Chemistry*, and by Professor Brande in his *Geology*: the weights and measures are always according to the standard of Britain, and the temperature to that of Fahrenheit's thermometer, unless otherwise expressed. Systematic names of animals, vegetables, and minerals are accented, and their derivations indicated, in the manner adopted in the *Gardener's Magazine* and in the *Magazine of Natural History*, as explained in a separate article. (p. vii.)

The recent changes which have taken place in the market value of currency, render price a criterion of much too temporary a nature to be employed in any work which aims at general and permanent utility. For this reason we have in this Encyclopædia generally avoided money calculations, preferring to indicate the value of objects or operations by the quantity of materials and labour requisite to produce them, or by stating their cost relatively to the cost of other articles.

We have also avoided entering on the subject of state policy, as to the relative protection of agriculture and manufactures, or of the protection of the home against the foreign grower of corn. Natural prices will always be safer for the farmer than artificial ones; and with low prices the farmer has the chance of deriving a greater benefit on an extraordinary rise, and sustaining less loss on an extraordinary fall. If the prices of corn were one half lower than they are, neither farmers nor proprietors would find their comforts diminished; for the value of manufactures and importations would fall in proportion to that of agricultural produce. Price, it is true, is not always value; but they are never materially different for any length of time.

The first edition of this work was written in the autumn and winter of 1822-3, and published in June, 1825. In this second edition, commenced in January, 1828, and completed in January, 1831, will be found very considerable additions and improvements, including nearly 500 new engravings. Of these engravings nearly 200 are more useful figures, substituted for others considered less so; and the remainder, consisting of nearly 300 are entirely additional. A catalogue of all the engravings in the work arranged systematically is also given (p. xxxii.), for more convenient reference, when the purpose of the reader is a choice of implements or machines.

The principal additions to the letter-press of this edition have been made at the suggestion of our much esteemed friend Mr. Cleghorn, of Edinburgh, late editor of the *Farmer's Magazine*, formerly published in that city; and, in consequence of the assistance procured by the Proprietors, on our recommendation, from Mr. Swainson, the eminent naturalist. The former gentleman perused an interleaved copy of the Encyclopædia, and suggested on the blank pages whatever he thought wanting; indicating at the same time the books or other sources which might be consulted for the purpose of supplying these wants. Mr. Swainson most obligingly took the trouble of writing some paragraphs in the Agricultural History of South America (p. 200.), and the whole of the article on Insects (from p. 1112. to p. 1121.), with some other sentences and paragraphs in different parts of the work, not always considered of sufficient importance to be marked with his signature. Dr. Trail, of Liverpool, on our suggestion to the Proprietors, examined the chemical and geological departments of Part II. Book III., and was good enough to send us some corrections and additions, most of which are indicated by the letter T. With the exception of the additional engravings of implements before mentioned, Mr. Swainson's article on Insects is by far the most valuable addition which the Encyclopædia has received; and it is but doing justice to him to state, that he is the only gentleman among the List of Contributors (p. vi.), who took the trouble to write out his additions in such a manner as to accommodate them to the portions of the

work for which they were intended. The amalgamation of the information sent by the other contributors, and the selection and description of the engravings, are of course our own; together with what we have been able to collect ourselves, not only from books and correspondence, but also from the personal observations we made, during a tour in France and Germany undertaken in 1828-9 on purpose for this work.

In consequence of repeated invitations given on the cover of the *Gardener's Magazine*, a considerable number of corrections, additions, and suggestions, have been sent us by the anonymous and other correspondents enumerated in the list (p. vi.) before referred to. The essence of the greater part of these communications was inserted in the *Gardener's Magazine* at the time they were received, and the whole of these are either given, quoted, or referred to, in this edition of the *Encyclopædia*, in the proper places; but some which arrived too late for being used in the body of the work are given in the Supplement. (p. 1279.) Similar Supplements are intended to be published occasionally, perhaps every two years, and sold separately at the lowest possible price. To every supplementary paragraph will be prefixed the number of the paragraph in the body of the work to which the additional information belongs; and every future impression of the body of the work will contain references from the proper paragraphs to the additions to these paragraphs given in the different Supplements: the manner is exemplified in p. 1138., viz. by the star (*) placed before § 7790., which signifies that an addition to that paragraph will be found in the Supplement given in the present edition after the General Index. (p. 1279.) Where the supplementary matter contains figures, similar references will be made from the Systematic List of Engravings, as in (p. xxxii.), where the star (*) prefixed to THRESHING MACHINES indicates that the Supplement contains a figure or figures of one or more kinds of threshing machines. This improvement in the manner of rendering supplementary information available to a work already in type, and, considered in all its bearings, a very great one it is, can only be effected in consecutive editions of a stereotyped book, in the plates of which stars or other marks can at any time be easily introduced. It is calculated to save the reader much trouble that would otherwise be unavoidable in referring to numerous Supplements at random; to prevent any additional information from escaping his attention; and to render it unnecessary on the part of the Proprietors to publish, or on that of the possessors of the work to purchase, a new edition for several years to come.

We have stated above that the essence of most of the improvements contained in this edition, and many of the new engravings, have been given from time to time in the published volumes of the *Gardener's Magazine*; into which they have been introduced in conformity with that object of the work indicated in the titlepage by the expression "Register of Rural and Domestic Improvement." We think it right here to repeat, what we stated in the Prospectus and Introduction to that Periodical (see vol. i.), that though chiefly intended as a perpetual Supplement to the *Encyclopædia of Gardening*, it is also meant to be a perpetual Supplement to the *Encyclopædia of Agriculture* in all matters of vegetable culture, implements, buildings, and territorial improvements, with a view to farm bailiffs and land stewards. Temporary agriculture and statistics, and matters connected with live stock and other things which more immediately interest the commercial farmer, we leave to journals and newspapers wholly agricultural.

In order to show how much we are indebted to contributors for the improvements contained in this second edition, as well as to simplify the duty of thanking them, we have placed their names or signatures in the following alphabetical list; and we beg leave, on the part of the Proprietors and ourselves, to return them sincere thanks. We have earnestly to request that these contributors and all our readers will examine the present work with a scrutinising eye, and send us whatever they think will contribute to its farther improvement. Our ardent wish is, by means of frequent Supplements, to keep it at all times on a pace with the rapidly advancing state of agricultural knowledge and practice; and we are well aware that this can only be done by the extensive cooperation of scientific and practical men.

By referring to the Calendarial Index (p. 1233.), those parts of this work which treat of Farm and Forest Culture and Management may be consulted monthly, as the operations require to be performed; by recurring to the General Index (p. 1248.), any particular subject may be traced alphabetically, through all its ramifications of history, theory, practice, and statistics; and, by turning to the Glossarial Index (p. 1241.), the meaning of all words not familiar to general readers may be found. Thus we have here combined an Agricultural Treatise, embracing every part of the subject, a Husbandman's Calendar, a Dictionary of Rural Affairs, and a Glossary of Agricultural Terms.

J. C. L.

Bayswater, January, 1831.

LIST OF CONTRIBUTORS

TO THE SECOND EDITION OF THE ENCYCLOPÆDIA OF AGRICULTURE.

- An Amateur Naturalist, &c.; Anon.*, Coleshill, Warwickshire; a *Reader of the Gardener's Magazine* from its commencement; a *Subscriber to the Magazine of Natural History*.
Suggestions, corrections and hints.
- Anderson, John*, 49, Park Street, Grosvenor Square, London, agricultural engineer; formerly an extensive farmer in Northumberland; afterwards draughtsman and manager at E. Weir's agricultural repository, Oxford Street.
Various elaborate drawings of machines, particularly of the bone-mill, and of the very excellent machine for threshing and other purposes erected at Bagshot Park, Berkshire.
- B.*, a retired veterinary surgeon of eminence, author of various works.
The greater part of the article on the horse, p. 949, and the veterinary part of the subsequent articles on agricultural and domestic animals.
- Bell, the Rev. Patrick*, of Mid Lich, Auchter House, near Dundee, inventor of a greatly improved reaping-machine.
Drawings and an elaborate description of his excellent invention, p. 492.
- Booth and Co.*, distillers, Brentford, Middlesex.
The details of their establishment for fattening cattle, furnished to us on the spot, p. 1025.
- Burnes*, —, Farm manager to the Duke of Gloucester, at Bagshot Park.
Various hints, and permission to publish plans of his machine, &c.
- Leighorn, James*, Accountant, Edinburgh; editor of the latter volumes of the *Farmer's Magazine*, till that work was discontinued; characterised by the late Professor Coventry to us, in 1822, as the first agricultural writer in Scotland. Author of the article *Agriculture in the Supplement to the Encyc. Brit.* and of other works.
A general examination of the whole work, with numerous corrections, various suggestions for improvements, and references to works where the requisite information might be obtained.
- Cotnam and Hales*, agricultural implement manufacturers, chiefly in iron, Winsley Street, Oxford Street.
Corrections, additions, and every assistance in delineating some new implements and machines.
- Dickson, W.* formerly a farmer near Edinburgh, now of Kidbrook, in Kent.
Various details respecting his farm when inspected by us, in April, 1829.
- Dombasle, C. J. A. Mathieu de*, director of the agricultural establishment at Roville, near Nancy, in France, and author of various agricultural works.
Various information respecting the agriculture of France, and the inspection of all the details of the establishment at Roville.
- Eichthal, M. le Baron de*, an extensive proprietor in Bavaria, who has resided some time in Britain, and especially in Scotland; studied our agriculture; and introduced it on his Bavarian estates by means of Scotch farmers.
Various information respecting the agriculture and state of property in Bavaria, in London in 1826, and at Munich and Eichthal in 1828.
- Forsyth, William*, F.H.S. &c., Nottingham Place, London.
Various corrections and additions, more especially to the bibliography, p. 1206.
- F. and W.*, the latter a Scotch farmer of experience both in Fifehire and Middlesex.
Notes on the agriculture of France and Italy, from a tour made there in 1828.
- Gibbs and Co.*, Messrs., nursery and seedsmen, London.
Lists of hardy fruits suitable for a field orchard in the midland counties of England, p. 667, and information respecting the Serradilla, p. 886.
- Gibbs, M. sen.*, late nurseryman at Inverness; afterwards superintendent of a British colony attempted to be established at Caraccas.
Information respecting the agricultural capabilities of some parts of North and South America.
- Gladstone, M.*, engineer, Chester.
Drawings of several of his late father's inventions; among others, of the bean reaping-machine, p. 471., and water-furrowing plough, p. 397.
- Gorrie, Archibald*, F.H.S. &c., Annat Gardens, Errol, Perthshire.
Various corrections and additions, as to the wheat-fly and other matters.
- Gossier, M. l' Abbé de*, of Rouen, late president of the Agricultural Society there.
Information respecting the state of agriculture in Normandy.
- Graham, James*, formerly a farmer in Perthshire; afterwards in Middlesex; and latterly in the neighbourhood of Sydney, in Australia.
Some notices respecting Australia.
- Hazzi, M.*, president of the Agricultural Society of Bavaria, and the father of improved agriculture in that country; author and editor of various works.
Various corrections and additions relative to the agriculture of Bavaria.
- Headrick, the Rev. J.*, author of the *Survey of Forfarshire*, and of various chemical and agricultural works.
Various additions and corrections to the statistics.
- J. C.*, near Alnwick, Northumberland, a very extensive farmer, and an enlightened political economist.
Various corrections and additions.
- J. W. L.*
Corrections and additions to the statistical departments, and especially to Worcestershire and Warwickshire.
- Laycock, M.*, Islington.
The details of his dairy establishment, from which we drew up the account, p. 1029.
- Lindley, John*, F.R.S. L.S. &c., professor of botany in the University of London.
Botanical corrections.
- M.*, an extensive proprietor, who cultivates a part of his own estate in Suffolk.
A general examination of the whole work, and various corrections, suggestions, and additions.
- Main, James, A.L.S.*, &c., editor of the *British Farmer's Magazine*; author of the *Cottage Florist's Directory*, and other works.
General corrections and additions.
- Masclét, M. le Chevalier de*, late French consul at Edinburgh, and then a writer in the *Farmer's Magazine* and other periodicals; now residing in Paris.
Various corrections and additions relative to the agriculture of France and Flanders.
- Mcuteath, C. G.*, stuart of Closeburn, Dumfriesshire.
An account of his limekilns, waggons, and mode of improving grass lands, p. 626. *et seq.*
- Morton and Co.*, Leith Walk, Edinburgh, agricultural implement manufacturers, chiefly in wood.
Various information respecting agricultural implements, and several drawings of some new ploughs, drill-machines, &c.
- Pearson and Co.*, Messrs., nurserymen, Chilwell, near Nottingham.
Lists of hardy fruits suitable for a field orchard in the northern counties of England, p. 668.
- R. M.* of Devonshire.
Additions to the dairy department.
- Ransome and Co.*, agricultural implement makers, Ipswich.
Drawings of ploughs and other implements.
- Rhodes and Co.*, Islington.
The details of their dairy establishment, from which we drew up the account, p. 1028.
- Ronalds and Sons*, Messrs., nurserymen, Brentford.
Lists of hardy fruits suitable for a field orchard in the midland counties of England, p. 668.
- Sherriff, Patrick*, of Mungo's Wells, near Haddington.
Several important suggestions, and various corrections.
- Sinclair, George*, F.L.S., H.S., &c. of the firm of

Cormack, Sons, and Sinclair, nursery and seedmen, Newcross, London.
 Various corrections and suggestions.
Snowden and Co., agricultural implement manufacturers, Oxford Street, London.
 Drawings of the leaf-gathering machine, and other implements.
Swainson, William, F.R.S., L.S., &c., author of various important works on natural history.
 Various corrections and additions; more especially the entire article on insects injurious to agriculture, p. 119.
Taylor, R. C., F.G.S., &c.
 Geological and statistical corrections, and information from North America.
Taylor, Samuel, F.R.S., &c., late editor of the agricultural department of the Country Times newspaper.
 Various corrections and additions.
Trail, Dr., of Liverpool.
 Geological and chemical corrections.
Tredgold, Thomas, civil engineer, author of various works, who died in 1823.

Some hints as to the subject of the application of steam to agriculture.
T. W. H., agricultural pupil with a farmer near Wooler in Northumberland.
 Information and corrections.
Vilmorin, M., of the firm of Vilmorin and Co., seedsmen, Paris.
 Various corrections as to the agriculture of France, and additions to the forage plants and Cerealia.
W., proprietor of the Metropolitan Dairy establishment, in the Edgeware Road, London.
 The details of his dairy establishment, from which we drew up the account, p. 1029.
Weir and Co., Oxford Street, London, agricultural implement manufacturers, chiefly in wood.
 Corrections, additions, and every assistance in making drawings and descriptions of a great variety of new implements, machines, and utensils.
Wilkie, J., of Uddistone, near Glasgow, agricultural implement maker, both of wood and iron.
 Various drawings and descriptions; especially of his new plough, p. 392, and cultivator, p. 405.

INDICATIONS AND ACCENTUATION OF SYSTEMATIC NAMES.

THE systematic names employed in the sciences are for the greater part derived from the Greek or Latin, as being dead, and consequently fixed, languages; and partly also as being languages more or less understood by men of science throughout the world. The Greek language is preferred to the Latin, as being more copious and flexible. In general, family or generic names are composed of two or more Greek words, indicating some quality common to the family or genus; and specific or individual names, of Latin words indicative of some quality in the individual or species. A number of names, however, are formed by giving Greek or Latin terminations to aboriginal names, or by aboriginal words unchanged; not a few names, generic and specific, are given in honour of individuals; and some, more especially specific names, point to countries, towns, or other places connected with the history of the plants.

All systematic names, whether generic or specific, which Greek or Roman authors have applied to the same class of beings as the moderns, and which on this account are called classical names, are indicated by the first letter being put in Italic when the remainder of the word is in Roman, or in Roman when the remainder of the word is in Italic; as, *E'quus*, the horse; *Pinus*, the pine tree; *Mármor*, marble: or, *E'quus*, the horse; *Pinus*, the pine tree; *Mármor*, marble.

Names, whether generic or specific, formed from aboriginal words by altering the termination of the aboriginal word, or by adopting the aboriginal word without altering its termination, and names of uncertain derivation, are distinguished by all the letters being in Italic when the preceding and following words are in Roman, and in Roman when the preceding and following words are in Italic; as, *Gláma* (*Camélus Gláma*), the lama; *Tabácum* (*Nicotiána Tabácum*), tobacco; and *Táfa* (*Ceméntum Táfa*), volcanic earth: or, *Gláma* (*Camélus Gláma*), the lama; *Tabácum* (*Nicotiána Tabácum*), tobacco; and *Táfa* (*Ceméntum Táfa*), volcanic earth.

Names, generic or specific, commemorative of individuals, are indicated by putting the letters added to the name of the person, or the final letter if none are added, in Italic when the preceding and following words are in Roman, and in Roman when the preceding and following words are in Italic; as, *Cygnus Yarrélli*, *Yarréll's Swan*; *Lycium Shawi*, *Shaw's Lycium*, and *Olivinus Wernéri*, the Olive of *Werner*: or, *Cygnus Yarrélli*, *Yarréll's Swan*; *Lycium Shawi*, *Shaw's Lycium*; and *Olivinus Wernéri*, the Olive of *Werner*.

RULES FOR PRONOUNCING SYSTEMATIC NAMES.

SYLLABLES.

In classical words there are as many syllables as there are vowels; except when *u* with any other vowel follows *g*, *q*, or *s*, and when two vowels unite to form a diphthong. The diphthongs are *ae*, *ei*, *ai*, *ei*, *oi*, *ui*, *au*, *eu*, and *ou*. These seldom coalesce in final syllables. *oo*, *ee*, *ea*, and other combinations which never occur as diphthongs in classical words, follow, in commemorative names, the pronunciation of their primitives, as *Téedis*, *Wódsia*.

VOWELS.

In this work the sounds of the accented vowels are indicated by the mark placed over each; the long sound by a grave accent (̀), and the short by an acute (´), as *Máry*, *Mártha*.

In addition to the primary accent, every word of more than three syllables contains a secondary accent, which is regulated by the same rules. The secondary accent must always be at least two syllables before the primary accent, as in *Chéli'dónium*; for its place the ear is a sufficient guide, and even were it entirely omitted, still, however inharmonious, the pronunciation would not be incorrect.

CONSONANTS.

C and *g* are hard before *a*, *o*, and *u*, as *Córnus*, *Gállium*; soft before *e*, *i*, and *y*, as *Cetrària*, *Citrus*. *T*, *s*, and *c*, before *ia*, *ie*, *ii*, *io*, *iu*, and *eu*, when preceded by the accent, change their sounds, *t* and *c* into *sh*, as *Bléti'a*, *Vici'a*; and *s* into *zh*, as *Blási'a*: but, when the accent is on the first diphthongal vowel, the preceding consonant preserves its sound, as *aurantíacum*.

Ch, before a vowel, is pronounced like *k*, as *Chelidónium* (*kel*), *Cólchicum* (*kolke'tum*); but in commemorative names it follows their primitives, as *Richardsónia*, in which the *ch* is soft.

Cm, *cn*, *ct*, *gm*, *gn*, *mn*, *tm*, *ps*, *pt*, and other incombinate consonants, when they begin a word, are pronounced with the first letter mute, as *Pteris* (*teris*), *Cnclus* (*nikus*), *Gmellina* (*melina*), *Gnidia* (*nidia*); in the middle of a word they separate as in English, as *Lap-sána*, *Lém-na*.

Ph, followed by a mute, is soft sounded; but, followed by a vowel or a liquid, sounds like *f*, as *Phitum* (*Acum*).

Sch sounds like *sk*, as *Schœnus* (*skenus*); in *tl* and *zm* both letters are heard.

S, at the end of a word, has its pure hissing sound, as *Dáctylis*; except when preceded by *c*, *r*, or *n*, when it sounds like *z*, as *Ribes* (*ez*).

X, at the beginning of a word, sounds like *z*, as *Xanthium*; in any other situation it retains its own sound, as *Táxus*, *Támarix*. (*Gardener's Magazine*, vol. v. p. 232.)

N.B. Such as are in possession of some of the County Surveys above enumerated, may probably find the year of publication in the titlepage different from what is here given. The reason is, these surveys, most of which belonged to the late Board of Agriculture, were twice sold to different booksellers, on which occasions new and altered titlepages were printed. We have generally endeavoured to give the original title; and, through the kind assistance of Mr. Forsyth, we have been enabled to do so in most instances.

AGRICULTURAL WEIGHTS AND MEASURES.

As a source of reference to the readers of agricultural works, foreign as well as domestic, we have deemed it useful to bring together in this place comparative views of the land and corn measure of England, Scotland, and Ireland, and of different foreign countries. We have also given a general view of the French metrical or decimal system, as being the most perfect which has hitherto appeared, and alone worthy, in our opinion, of universal adoption. All young persons ought to make themselves masters of this system as one likely to be in general use, at least in Europe, North America, and Australia, before they become old men.

LAND MEASURE.

		Contents of a single Measure of each sort.		Number of each equal to 10 English Acres.
		English Square Yards.	French Acres.	
England	Acre	4840	40'466	10'000
Scotland	Acre	6150	51'419	7'869
Ireland	Acre	7840	65'549	6'173
France	Hectare	11960	100'000	4'046

FRENCH WEIGHTS AND MEASURES.

What is called a standard in weights and measures is merely an authority; and this in rude ages is founded on custom, or some arbitrary quantity; while, in the progress of improvement, a standard is derived from nature. Among the various natural standards, the two following may be considered the best:—

1. The length of a pendulum that vibrates seconds of mean solar time.
2. The length of an arc or portion of a meridional circle.

From the measurement of a meridional arc in France; the length of the quadrant arc was computed; and the ten-millionth part of this quadrant is the metre, which is the standard unit for all French measures.

The standard unit for all weights is the gramme, which is the weight of a cubic vessel of water of the greatest condensation and purity; the side of such cube being the hundredth part of the metre.

From these two units the other measures are derived by decimal division or multiplication, and hence this system is generally called.

THE METRICAL OR DECIMAL SYSTEM.

In order to express the decimal proportion, the following vocabulary of names has been adopted, in which the terms for multiplying are Greek, and those for dividing are Latin:—

For multipliers, the word	
<i>Deca</i> prefixed means.....	10 times.
<i>Hecto</i>	100 times.
<i>Kilo</i>	1000 times.
<i>Myria</i>	10,000 times.
On the contrary, for divisors, the word <i>Deci</i> expresses the	10th part.
<i>Centi</i>	100th part.
<i>Milli</i>	1000th part.
Thus, <i>Decametre</i> means 10 metres.	

Decimetre..... the 10th part of a metre.
Kilogramme..... 1000 grammes, &c.
 The *are* is the element of square measure, and is a square decametre, equal to 3·955 English perches.
 The *stere* is the element of cube measure, and contains 35·317 cubic feet English.
 The *litre* is the element of all measures of capacity.
 It is a cubic decimetre, and equals 2·1135 English pints. 100 litres make the hectolitre, which equals 26·419 English gallons, or 2·838 Winchester bushels.

The decimal Weights and Measures of France, compared with the Weights and Measures at present considered the National Measures of Britain.

Long Measures.	
Decimal System.	British arbitrary System.
Millimetre	0·03937 inches.
Centimetre	0·39371 inches.
Decimetre	3·93710 inches.
<i>Metre</i>	39·37100 inches.
Decametre	328·80916 feet.
Hectometre	328·09167 feet.
Kilometre	1093·6389 yards.
Myriametre	10936·38900 yards, or 6 miles, 1 furlong, 28 poles.

Decimal System.	British arbitrary System.
Hectolitre	3·5317 cubic feet, or 26·419 wine gallons, 22 Imperial gallons, or 2·839 Winchester bushels.
Kilolitre	35·3171 cubic feet, or 1 tun and 12 wine gallons.
Myrialitre	353·17146 cubic feet.

Superficial Measures.	
Centiare	1·1960 square yards.
<i>Are</i> (a square decametre) }	119·6046 square yards.
Decare	1196·0460 square yards.
Hectare	11660·4604 square yards, or 2 acres, 1 rood, 35 perches.

Solid Measures.	
Decistere	3·5317 cubic feet.
<i>Stere</i> (a cubic metre)	35·3174 cubic feet.
Decastere	353·1714 cubic feet.

Measures of Capacity.	
Millilitre	0·06103 cubic inches.
Centilitre	0·61028 cubic inches.
Decilitre	6·10280 cubic inches.
<i>Litre</i> (a cubic decimetre) }	61·02802 cubic inches, or 2·1135 wine pints.
Decalitre	610·28028 cubic inches, or 2·642 wine gallons.

Weights.	
Milligramme	0·0154 grains.
Centigramme	0·1543 grains.
Decigramme	1·5434 grains.
<i>Gramme</i>	15·4340 grains.
Decagramme	154·3402 grains, or 5·64 drams avoirdupois.
Hectogramme	3·2154 oz. troy, or 3·527 oz. avoirdupois.
Kilogramme	2 lb. 8 oz. 3 dwt. 2 gr. troy, or 2 lb. 3 oz. 4·498 drams avoirdupois.
Myriagramme	26·795 pounds troy, or 22·0485 avoirdupois.
Quintal	1 cwt. 3 qrs. 25 lb. nearly.
Millier, or Bar	9 tons 16 cwt. 3 qrs. 12 lb.

THE FRENCH SYSTÈME USUEL.

The *Système Usuel* has the metrical standards for its basis; but their divisions are binary; and instead of the new nomenclature, the names of the ancient weights and measures are used, annexing the term *usuel* to each: thus, the half kilogramme is called the *livre usuelle*, and the double metre, the *toise usuelle*, &c.

This system was legalised by an imperial decree in 1812, for the use of retail traders, and the imperial system was continued for all other kinds of business and measurement: but as the law was left optional, it led to many difficulties, inasmuch that in 1816 the *système usuel* was enforced by a royal decree, in which the use of weights or measures decimally divided is absolutely prohibited in shops or any departments of trade connected with retail business, while the decimal system is confirmed for all other purposes.

As the *système usuel* has the metre and gramme for its basis, any of its divisions may be easily computed from the foregoing tables. The following, however, are the contents of its principal units in English measure:—

- The *toise usuelle* of 2 metres equals 6 feet 6½ inches English.
- The *pied usuel* equals 1/3 of the toise, and the inch 1/12 of the foot.
- The *aune usuelle* equals 3 feet 1½ inches English, with all its divisions in proportion.
- The long measures are also divided into thirds, sixths, and twelfths, which are easily computed from the foregoing dimensions of the toise and aune.
- The *boisseau usuel* is 1/4 of the hectolitre, and equals 0·35474 English bushels, with halves, quarters, &c. in proportion.
- The *litron usuel* equals 1·074 Paris pints, with halves, quarters, &c. in proportion.

Apothecaries have adopted the *système usuel* in compounding medicines; which weight, in small quantities, scarcely differs from the poids de marc.

Diamonds are still weighed by carats of 4 grains each; but these grains differ from the foregoing: thus, 1 carat equals 3·876 grains poids de marc, or 3·798 grains usuels, and also answers to 2·01 decigrammes, or 3 1/10 English grains.

The *livre usuelle* = 500 grammes = 9413·575 grains poids de marc, or 7717 English grains; and all its divisions and multiples in proportion. Hence the common pound of France equals 1 lb. 11 oz. 10½ drams avoirdupois; and therefore the *quintal métrique* of 100 kilogrammes answers to 220·486 lb. avoirdupois, or 1 cwt. 3 qrs. 24½ lb., which is 1000 grains less than has been hitherto reckoned, on account of the undue proportion allowed to the French weight. (*Kelly's Cambist*, vol. 1. p. 140.)

The *Système Usuel* of the French, compared with the British System.

Comparison of Weight.	Troy Weight.		Avoirdupois.		Troy Weight.		Avoirdupois.	
	Grammes.	lb. oz. dwt. gr.	lb. oz. dr.	lb. oz. dr.	Grammes.	lb. oz. dwt. gr.	lb. oz. dr.

Twelfth	$0\frac{1}{6}$	0	3	$11\frac{1}{2}$

Comparison of Measures of Capacity.

Mesures usuelles.	Litres.		English bushels.	
	Litres.	Paris pint.	English pint.	
Boisseau usuel	12.5	0.35474	
With halves and quarters in proportion.				
Litron usuel	1.074	$2\frac{1}{8}$	
With halves and quarters in proportion.				

ENGLISH WEIGHTS AND MEASURES.

The following Tables show the state of English weights and measures as long established; but a new law has lately passed, which proposes the following alteration in measures of capacity, that is to say, both in liquid and dry measures, from the 1st of January, 1826. Thus, instead of the three different gallons heretofore used, viz. the wine, ale, and corn gallons, one measure only is to be adopted, called the imperial gallon, with its divisions and multiples, which are to be as heretofore for wine measure. But for corn or other dry goods not heaped, the divisions and multiples are to be as in corn measure.

The imperial gallon is to measure 277.274 cubic inches, and to weigh 10 lb. avoirdupois of water at the temperature of 62 degrees of Fahrenheit's thermometer, the barometer being at thirty inches.

The imperial bushel is to measure and weigh eight times the above, and all the other multiples and divisions of the imperial gallon are to be in proportion.

All new measures in future are to be constructed on the imperial plan; but the old measures may continue to be used, provided their contents be marked on them, that is, the proportion which they may be found to bear to imperial measure.

The following Table shows the contents of the different Gallons, both in Measure and Weight.

	Cubic Inches.	Avoirdup. Weight.		Troy Weight.	
		lb. oz. dr.	lb. oz. dwt. gr.		
Imperial gallon	277.274	10 0 0	12 1 16 16		
Corn gallon.....	268.8	9 10 12	11 9 7 12		
Wine gallon	231	8 5 6 $\frac{1}{2}$	10 1 9 22		
Ale gallon	282	10 2 11 $\frac{1}{2}$	12 4 6 8		

The above Table will be found useful in comparing different vessels where gauging cannot be relied on.

Rules for converting the Old Measures to the New, and the contrary.

1. Wine Measure multiplied by 5 and divided by 6 will give imperial measure, and the contrary.
 2. Corn Measure multiplied by 31 and divided by 32 will give imperial measure, and the contrary.
 3. Ale Measure multiplied by 59 and divided by 60 will give imperial measure, and the contrary.
- The coal measure is scarcely changed by the new law, and therefore will probably remain unaltered in practice.

Tables of English Weights and Measures, compared with those of France.

TROY WEIGHT.		French grammes.	
24 grains	1 grain	0.0648	
20 pennyweights	1 pennyweight	1.5552	
12 ounces	1 ounce	31.1027	
	1 pound	373.2330	

The grain troy is divided into 20 mites, the mite into 24 dots, the dots into 20 perlots, and the perlot into 24 blanks. These divisions are imaginary; but there are real weights of decimal divisions to the thousandth part of a grain.

APOTHECARIES' WEIGHT.		Fr. gram.	
20 grains	1 grain	0.0648	
3 scruples	1 scruple	1.295	
8 drams	1 dram	3.888	
12 ounces	1 ounce	31.102	
	1 pound	373.233	

This weight is essentially the same as troy weight, but differently divided. It is chiefly used for medical prescriptions; but drugs are mostly bought and sold by avoirdupois weight

AVOIROUPOIS WEIGHT.

		French gram.
16 drams	1 dram	1.771
16 ounces	1 ounce	28.346
28 pounds	1 pound	453.544
4 quarters	1 quarter	12.689 kilog.
20 hundred wt.	1 hundred wt.	50.796
	1 ton	1015.920

The dram is subdivided into three scruples, and each scruple into ten grains; the pound or 7680 grains avoirdupois, equals 7000 grains troy, and hence one grain troy equals 1.097 grains avoirdupois.

Hence also 144 lb. avoird. 175 lb. troy.
and 192 oz. ditto 175 oz. do.

The stone is generally 14 lb. avoirdupois, but for butcher's meat or fish it is 8 lb. Hence the hundred equals 8 stone of 14 lb. or 14 stone of 8 lb.

A stone of glass is 5 lb. A seam of glass 24 stone, or 120 lb.

Hay and straw are sold by the load of 36 trusses. The truss of hay weighs 56 lb. and of straw 36 lb. The truss of new hay is 60 lb. until the 1st of September. The hay is by that time become dry, and the same quantity weighs less.

The custom of allowing more than 16 ounces to the pound of butter is very general in several parts of the country.

Other customary Weights, &c.

CHEESE AND BUTTER.		
8 pounds	1 clove	
32 cloves	1 way in Essex.	
42 ditto	1 ditto in Suffolk	
56 pounds	1 firkin of butter.	

BEEF, MUTTON, &c.		
8 pounds	1 stone of beef, mutton, &c.	
64 pounds of soap	1 firkin.	
30 pounds of anchovies	1 barrel.	
112 pounds of gunpowder	1 ditto.	
112 pounds of raisins	1 ditto.	
120 pounds of prunes	1 ditto.	
7 $\frac{1}{2}$ pounds of oil	1 puncheon.	
8 pounds of vinegar	1 gallon.	
36 pounds of straw	1 ditto.	
60 pounds of new hay	1 truss.	
56 pounds of old hay	1 ditto.	
36 trusses of hay or straw	1 load.	
7 pounds of salt	1 gallon.	
56 pounds or 8 gallons	1 bushel.	

WOOL WEIGHT.

		Kilogram.
7 pounds	1 clove	3.1748
2 cloves	1 stone	6.3496

Wool, like all other common articles, is weighed by avoirdupois, but the divisions differ: thus

2 stone	1 tod	Kilogram.
6½ tods	1 wey	1276992
2 weys	1 sack	82543
12 sacks	1 last	165087
		1981044

LONG MEASURE.

3 barleycorns	1 inch	Fr. metres.
12 inches	1 foot	0.0254
3 feet	1 yard	0.3048
5½ yards	1 pole or rod	0.9144
40 poles	1 furlong	5.0291
8 furlongs	1 mile	2011.632
3 miles	1 league	1609.3059
60 geographical, or 69½ Eng- lish miles... } 1 degree.....		4827.9179
		11120.7442

Besides the above, there are the palm, which equals 3 inches; the hand, 4 inches; the spao, 9 inches; and the fathom, 6 feet.

SQUARE MEASURE.

144 inches	1 square foot.....	Fr. sq. metres.
9 square feet.....	1 square yard.....	0.0929
304 square yards...	1 square pole.....	0.8361
40 square poles...	1 rood.....	25.2916
4 roods.....	1 acre.....	1011.6652
		4064.6648

The inch is generally divided, on scales, into tenths, or decimal parts; but in squaring the dimensions of artificer's work, the duodecimal system is adopted; — thus, the inch is divided into 12 parts or lines, each part into 12 seconds, and each second into 12 thirds.

In land measure there are (besides the above pole of 168 feet, which is called statute measure) the woodland pole of 18 feet, the plantation pole of 21 feet, the Chesbire pole of 24 feet, and the Sherwood Forest pole of 25 feet. A rope in some kinds of measurement is reckoned 20 feet, 30 acres is called a yard of land, 100 acres a hide of land, and 640 acres a mile of land.

Land is usually measured by a chain of 4 poles, or 22 yards, which is divided into 100 links. 10 chains in length and 1 in breadth make an acre, which equals 160 square perches, or 4840 square yards.

CUBIC OR SOLID MEASURE.

1728 cubic inches	1 cubic foot.....	Fr. cubic metres.
27 cubic feet	1 cubic yard.....	0.283
40 ft. of rough timber	1 load or ton	7645
or 50 ft. hewn ditto.....		11236
42 cubic feet	1 ton of shipping	1.1892

By cubic measure marble, stone, timber, masonry, and all artificers' works of length, breadth, and thickness, are measured, and also the contents of all measures of capacity, both liquid and dry.

DRY MEASURE.

4 gills	1 pint	cu. in.	Fr. litres.
2 pints	1 quart	33.6	0.55053
2 quarts	1 pottle	67.2	1.10107
2 pottles	1 gallon	134.4	2.20214
2 gallons	1 peck	268.8	4.40428
4 pecks	1 bushel.....	537.6	8.80856
4 bushs.	1 coom.....	2150.42	35.23430
2 cooms ...	1 quarter..	4.977 feet	140.93721
5 qrs.	{ wey } or load }	9.954 ditto ...	281.87443
2 weys	1 last	49.770 ditto ...	1409.37216
		99.540 ditto ...	2818.74432

UNIFORMITY OF WEIGHTS AND MEASURES IN BRITAIN.

The act for this purpose, which came into force in 1826, contains the following clauses which more immediately concern the agriculturist:—

Standard yard defined as the measure of length.—The straight line or distance between the centres of the two points in the gold studs in the straight brass rod, now in the custody of the clerk of the House of Commons, whereon the words and figures "STANDARD YARD, 1760," are engraved, shall be the original and genuine standard of that measure of length or lineal extension called a yard; and the same straight line or distance between the centres of the said two points in the said gold studs in the said brass rod, the brass being of the temperature of sixty-two degrees by Fahrenheit's thermometer, shall be and is hereby denominated the "IMPERIAL STANDARD YARD," and shall be the unit or only standard measure of extension, wherefrom or whoroby all other measures of extension whatsoever, whether the same be lineal, superficial, or solid, shall be derived, computed, and ascertained. s. 1.

Standard pound defined weight.—The standard brass weight of one pound troy weight, made in the year 1758, now in the custody of the clerk of the House of Commons, shall be declared to be the original and genuine standard measure of weight, and such brass weight shall be denominated the imperial standard troy pound, and shall be the unit or only standard measure of weight from which all other weights shall be derived, computed, or ascertained. s. 4.

The Winchester bushel, which is the legal measure for corn and seeds, should be 18½ inches wide, and 8 inches deep. Its contents are therefore, as above, 2150.42 inches. Corn and seeds are measured in the port of London by striking the bushel from the brim, with a round piece of light wood, about 2 inches in diameter and of equal thickness from one end to the other. All other dry goods are heaped.

There are two other bushels of different shapes, but containing the same quantity; the one, called the drum bushel, generally used for the London granaries, is 13 inches in diameter, and 16.2 inches in depth; and the other, called the farmer's bushel, is chiefly used in the country, its diameter is 15.375, and depth 11.589 inches. These shapes are chosen for the convenience of working and loading; but the shallow vessel or standard, to avoid the effects of pressure in filling, which depth might cause.

The dimensions of the imperial standard bushel are as follows:—The outer diameter 19½ inches, and the inner diameter 18½. The depth is 8½, and the height of the cone, for heaped measure, is 6 inches. Hence the contents of the stricken imperial bushel are 2218.192 cubic inches, and it is to weigh 80 lb. avoirdupois of water. The contents of the imperial heaped bushel are 2815.4887 cubic inches. The subdivisions and multiples of this measure are of course in the same proportion.

In some markets corn is sold by weight, which is the fairest mode of dealing, but not the most convenient in practice. Even where measures are used, it is customary to weigh certain quantities or proportions, and to regulate the prices accordingly. The average bushel of wheat is generally reckoned at 60 lb.—of barley 49 lb.—of oats 38 lb.—peas 64, beans 63, clover 68, rye and canary 53, and rape 48 lb. In some places a load of corn, for a man, is reckoned five bushels, and a cart load 40 bushels.

COAL MEASURE.

Coals are generally sold by the chaldron, which bears a certain proportion to Winchester measure.

4 pecks	1 bushel.
3 bushels	1 sack.
3 sacks	1 vat.
4 vats	1 chaldron.
21 chaldron	1 score.

The coal bushel holds one Winchester quart more than the Winchester bushel; it therefore contains 2217.62 cubic inches. This bushel must be 19½ inches wide from outside to outside, and 8 inches deep. In measuring coals, it is to be heaped up in the form of a cone, at the height of at least 6 inches above the brim (according to a regulation passed at Guildhall in 1806). The outside of the bushel must be the extremity of the cone, and thus the bushel should contain at least 2814.9 cubic inches, which is nearly equal to the imperial heaped bushel. Hence the chaldron should measure 58.6 cubic feet.

The chaldron of coals at Newcastle is not a measure, but a weight of 53 cwt., which is found sometimes to equal two London chaldrons; but the common reckoning is, that the keel, which is 8 Newcastle chaldrons, equals 15½ London chaldrons. In such comparisons, however, there can be no certainty, as coals not only differ in their specific gravity, but even those of the same quality weigh more, measure for measure, when large, than when broken into smaller parts.—(Mortimer's Commercial Dictionary, art. *Weights and Measures.*)

Standard gallon to be the measure of capacity. — The standard measure of capacity, as well for liquids as for dry goods not measured by heaped measure, shall be THE GALLON, containing ten pounds avoirdupois of distilled water weighed in air, at the temperature of sixty-two degrees of Fahrenheit's thermometer, the barometer being at thirty inches; and a measure shall be forthwith made of brass, of such contents as aforesaid, under the directions of the commissioners of his majesty's treasury; and such brass measure shall be the imperial standard gallon, and shall be the unit and only standard measure of capacity, from which all other measures of capacity to be used, as well for wine, beer, ale, spirits, and all sorts of liquids, as for dry goods, not measured by heap measure, shall be derived, computed, and ascertained; and all measures shall be taken in parts or multiples or certain proportions of the said imperial standard gallon, and the quart shall be the fourth part of such standard gallon, and the pint shall be one eighth of such standard gallon, and two such gallons shall be a peck, and eight such gallons shall be a bushel, and eight such bushels a quarter of corn or other dry goods not measured by heaped measure. s. 6.

Standard for heaped measure. — The standard measure of capacity for coals, culm, lime, fish, potatoes, or fruit, and all other goods and things commonly sold by heaped measure, shall be the aforesaid bushel, containing eighty pounds avoirdupois of water as aforesaid, the same being made round with a plain and even bottom, and being nineteen inches and a half from outside to outside of such standard measure as aforesaid. s. 7.

In making use of such bushel, all coals and other goods and things commonly sold by heaped measure, shall be duly heaped up in such bushel, in the form of a cone, such cone to be of the height of at least six inches, and the outside of the bushel to be the extremity of the base of such cone; and that three bushels shall be a sack, and that twelve such sacks shall be a chaldron. s. 8.

Measure of weight, or heaped measure, to be used for wheat. — Provided always that any contracts, bargains, sales, and dealings, made or had for or with respect to any coals, culm, lime, fish, potatoes, or fruit, and all other goods and things commonly sold by heaped measure, sold, delivered, done, or agreed for, or to be sold, delivered, done, or agreed for by weight or measure, shall and may be either according to the said standard of weight, or the said standard for heaped measure; but all contracts, bargains, sales, and dealings, made or had for any other goods, wares, or merchandise, or other thing done or agreed for, or to be sold, delivered, done, or agreed for by weight or measure, shall be made and had according to the said standard of weight, or to the said gallon, or the parts, multiples, or proportions thereof; and in using the same the measures shall not be heaped, but shall be stricken with a round stick or roller, straight, and of the same diameter from end to end. s. 9.

Weight in Ireland. — But nothing herein shall authorise the selling in Ireland, by measure, of any articles, matters, or things, which by any law in force in Ireland are required to be sold by weight only. s. 10.

Contracts for sale, &c. by weight or measure. — All contracts, bargains, sales, and dealings, which shall be made or had within any part of the United Kingdom, for any work to be done, or for any goods, wares, merchandise, or other thing to be sold, delivered, done, or agreed for by weight or measure, where no special agreement shall be made to the contrary, shall be deemed to be made and had according to the standard weights and measures, ascertained by this act; and in all cases where any special agreement shall be made, with reference to any weight or measure established by local custom, the ratio or proportion which every such local weight or measure shall bear to any of the said standard weights or measures, shall be expressed, declared, and specified in such agreement, or otherwise such agreement shall be null and void. s. 15.

Existing weights and measures may be used, being marked. — And as it is expedient that persons should be allowed to use the several weights and measures which they may have in their possession, although such weights and measures may not be in conformity with the standard weights and measures established by this act; it is therefore enacted, that it shall be lawful for any person or persons to buy and sell goods and merchandise by any weights or measures established either by local custom, or founded on special agreement: provided that in order that the ratio or proportion which all such measures and weights shall bear to the standard weights and measures established by this act, shall be and become a matter of common notoriety, the ratio or proportion which all such customary measures and weights shall bear to the said standard weights and measures shall be painted or marked upon all such customary weights and measures respectively; but nothing herein contained shall extend to permit any maker of weights or measures, or any person or persons whomsoever, to make any weight or measure at any time after the 1st day of May, 1825, except in conformity with the standard weights and measures established under this act. s. 16.

American Weights. — The several European colonies make use of the weights of the states or kingdoms of Europe they belong to. For, as to the aroue of Peru, which weighs twenty-seven pounds, it is evidently no other than the Spanish arroba, with a little difference in the name.

African Weights. — As to the weights of Africa, there are few places that have any, except Egypt, and the countries bordering on the Mediterranean, whose weights have been already enumerated among those of the parts of the Levant. The island of Madagascar, indeed, has weights, but none that exceed the drachm, nor are they used for any thing but gold and silver.

The above information is taken from an elaborate quarto volume of Dr. Kelly, and the very useful Commercial Dictionary of Mortimer. It is impossible to turn over the leaves of such a book as Kelly's, without lamenting the time which every commercial man must lose in acquiring, and in practising, the art of overcoming the obstacles which not only impede the intercourse of nations, but open a fertile source for deception and chicanery. How easy it would be for one nation to become acquainted with another, even if they spoke different languages, provided their weights, measures, monies, and all that was done by figures, were the same! How easy for the three leading powers of the world, France, Britain, and America, to effect this! Naturalists in every part of the world use the same language, and the same names for natural objects, and they accordingly form but one family, every member of which, however remotely situated, holds ready communication with all the others. How easy for the great powers alluded to, by prospective measures, which would occasion no inconvenience to any one, not only to render one description of weights, measures, and monies, universal, but one language! The establishment in one nation after another of *Parochial Institutions*, such as those already existing in Wirttemberg and Bavaria, and obliging some one language to be taught to every one in addition to that which was the native tongue, would have the complete effect in two generations. But legislators, at least in Europe, have hitherto been too much occupied with the concerns of their own day and generation to think of futurity; and the policy has too generally been to devise measures which should isolate nations, and separate their interests, rather than unite them in one common intercourse, commercial and intellectual.

VIII. Of the Implements peculiar to Draining	712
CHAP. II.	
Embanking and otherwise protecting Lands from the Overflowing or Encroachment of Rivers or the Sea	713
I. Embanking Lands from Rivers or the Sea	713
1. General Principles of designing Embankments	714
2. Different Descriptions of Banks in general Use for excluding Waters	715
II. Guarding the Banks and otherwise improving the Courses of Rivers and Streams	719
1. Guarding River Banks	719
2. Changing the Courses of Rivers, deepening their Beds, or raising their Waters to a higher Level	721
CHAP. III.	
Irrigation, or the Improvement of Culturable Lands and Farmeries by the means of Water	722
I. Irrigation, or the Preparation of the Surface of Lands for the profitable Application of Water	723
1. Soils and Situations suitable for Watering	723
2. Implements made Use of in Watering Lands; and the Terms of Art peculiar to such Operations	723
3. Preparation of Surfaces for Irrigation	725
II. Warping, or the Improvement of Land by muddy Water	730
I. Irrigation of Arable Lands, and Subterraneous Irrigation	731
III. Artificial Means of Procuring Water for the Use of Live Stock	732
CHAP. IV.	
Improvement of Lands lying Waste, so as to fit them for Farm-Culture	741
I. Mountainous and billy Grounds and their Improvement	742
II. Rocky or Stony Surfaces	742
III. Improving Woody Wastes or Wealds	744
IV. Moors and their Improvements	745
V. Peat Mosses, Bogs, and Morasses, and their Improvement	746
VI. Marshes and their Improvement	747
VII. Downs and other Shore Lands	748
CHAP. V.	
Improvement of Lands already in a State of Culture	749
I. General Principles and Modes of Procédure, in improving Estates already more or less improved	750
II. Improvement of Farmeries and Farm Lands	750
CHAP. VI.	
Execution of Improvements	756
I. Different Modes of procuring the Execution of Improvements on Estates	756
II. General Cautions on the Subject of Executing Improvements	757
BOOK IV.	
MANAGEMENT OF LANDED PROPERTY.	
CHAP. I.	
Superintendents, or Executive Establishment of an Estate	759
1. Steward or Manager of an Estate, and his Assistants	759
II. Land Steward's Place of Business, and what belongs to it	761
CHAP. II.	
Duties of Managers of Estates	762
I. General Principles of Business considered Relatively to Land Stewardship	763
II. Management of Tenants	763
1. Proper Treatment of Tenants	763
2. Business of letting Farms	764
3. Different Species of Tenancy	764
4. Rent and Covenants of a Lease	766
5. Receiving Rents	768
III. Keeping and Auditing Accounts	769

BOOK V.

SELECTION, HIRING, AND STOCKING OF FARMS.

CHAP. I.		Page
Circumstances of a Farm necessary to be considered by a proposed Tenant	-	771
I. Climate, in respect to farming Lands	-	771
II. Soil in respect to farming Lands	-	773
III. Subsoil relatively to the Choice of a Farm	-	774
IV. Elevation of Lands relatively to Farming	-	775
V. Character of Surface in regard to farming Lands	-	775
VI. Aspect in regard to farming Lands	-	776
VII. Situation of Farm Lands in regard to Markets	-	776
VIII. Extent of Land suitable for a Farm	-	777
IX. Tenure on which Lands are held for Farming	-	777
X. Rent	-	777
XI. Taxes and other Burdens which affect the Farmer	-	779
XII. Other Particulars requiring a Farmer's Attention, with a View to the Renting of Land	-	779

CHAP. II.

Considerations respecting Himself, which a Farmer ought to keep in view in selecting and hiring a Farm	-	780
I. Personal Character and Expectations of a professional Farmer	-	780
II. Capital required by the Farmer	-	781

CHAP. III.

Choice of Stock for a Farm	-	782
I. Choice of Live Stock	-	782
1. Live Stock for the Purposes of Labour - breeding or feeding	-	783
2. Choice of Live Stock for the Purposes of breeding or feeding	-	783
II. Choice of Agricultural Implements, Seeds, and Plants	-	785
III. Choice of Servants	-	788

CHAP. IV.

General Management of a Farm	-	789
I. Keeping Accounts	-	789
II. Management of Servants	-	795
III. Arrangement of Farm Labour	-	796
IV. Domestic Management and personal Expenses	-	797

BOOK VI.

CULTURE OF FARM LANDS.

CHAP. I.

General Processes common to Farm Lands	-	798
I. Rotation of Crops suitable to different Descriptions of Soils	-	798
II. The working of Fallows	-	800
III. General Management of Manures	-	803
1. Management of Farm-yard Dung	-	804
2. Lime, and its Management as a Manure	-	805
IV. Composts and other Manures	-	807

CHAP. II.

Culture of the Cereal Grasses	-	808
I. Wheat	-	811
II. Eye	-	821
III. Barley	-	822
IV. The Oat	-	826
V. Cereal Grasses cultivated in Europe, some of which might be tried in Britain	-	828
1. Maize, or Indian Corn	-	829
2. Canary Corn	-	832
3. The Millets	-	832
4. Rice, and some other Cereal Gramina	-	834

CHAP. III.

Culture of Leguminous Field-Plants, the Seeds of which are used as Food for Man or Cattle	-	834
I. The Pea	-	835
II. The Bean	-	838
III. The Tare	-	841
IV. Various Legumes which might be cultivated in British Farming	-	843

CHAP. IV.	Page
Plants cultivated for their Roots or Leaves in a recent State as Food for Man or Cattle	844
I. The Potato	845
II. The Turnip	854
III. The Carrot	862
IV. The Parsnep	865
V. The Field Beet	866
VI. The Cabbage Tribe	867
VII. Other Plants which might be cultivated in the Fields for their Roots or Leaves, as Food for Man or Cattle, in a recent State	869
CHAP. V.	
Culture of Herbage Plants	871
I. The Clover Family	871
II. Lucern	877
III. Sainfoin	880
IV. Various Plants which are or may be cultivated as Herbage and for Hay	883
CHAP. VI.	
Cultivated Grasses	886
I. Tall-growing or Hay Grasses	887
1. Tall or Hay Grasses of temporary Duration	887
2. Tall or Hay Grasses of permanent Duration	889
II. Grasses chiefly adapted for Pasturage	893
III. General View of the Produce, Uses, Character, and Value of the principal British Grasses, according to the Result of John Duke of Bedford's Experiments at Woburn	895
CHAP. VII.	
Management of Lands permanently under Grass	901
I. Perennial Grass Lands fit for mowing, or Meadow Lands	901
II. Permanent Pastures	905
1. Rich or feeding Pastures	905
2. Hilly and Mountainous Pastures	908
III. Improvement of Grass Lands, by a temporary Conversion to Tillage	909
1. Grass Lands that ought not to be broken up by the Plough	909
2. Advantages and Disadvantages of breaking up Grass Lands	910
3. Breaking up Grass Lands, and afterwards restoring them to Grass	911
CHAP. VIII.	
Plants cultivated on a limited Scale for various Arts and Manufactures	912
I. Plants grown chiefly for the Clothing Arts	912
1. Flax	913
2. Hemp	917
3. The Fuller's Thistle, or Teasel	918
4. Madder	919
5. Woad	920
6. Weld, or Dyer's Weed	921
7. Bastard Saffron	922
8. Various Plants which have been proposed as Substitutes for the Thread and dyeing Plants grown in Britain	923
II. Plants cultivated for the Ewery and Distillery	923
1. The Hop	924
2. Culture of the Coriander and Caraway	930
3. Plants which may be substituted for Brewery and Distillery Plants	930
III. Oil Plants	931
IV. Plants used in Domestic Economy	933
1. Mustard	933
2. Buck-wheat	934
3. Tobacco	936
4. Other Plants used in Domestic Economy, which are or may be cultivated in the Fields	942
V. Plants which are or may be grown in the Fields for Medicinal Purposes	943
CHAP. IX.	
Marine Plants used in Agriculture	945
CHAP. X.	
Weeds or Plants injurious to those cultivated in Agriculture	947

BOOK VII.

THE ECONOMY OF LIVE STOCK AND THE DAIRY.

CHAP. I.	Page
The cultivated Horse	949
1. Varieties of the Horse	950
II. Organology or exterior Anatomy of the Horse	955
III. The Bony Anatomy or Osseous Structure of the Horse	962
1. Osseous Structure of the Head	962
2. Bony Anatomy of the Trunk	964
3. Bony Anatomy of the Extremities	964
4. General Functions of the Bony Skeleton	966
IV. Anatomy and Physiology of the soft Parts	966
1. Appendages to Bone, the Muscles, and Tendons	966
2. Blood-vessels of the Horse	967
3. Absorbents of the Horse	968
4. Nerves and Glands of the Horse	968
5. Integuments of the Horse's Body	968
6. The Head generally	969
7. The Ear	969
8. The Eye and its Appendages	970
9. The Nose and Sense of Smelling	971
10. The Cavity of the Mouth	972
11. The Neck	972
12. The Thorax or Chest	973
13. The Abdomen	973
14. The Pætal Colt	975
15. The Foot	976
V. Diseases of the Horse	977
1. General Remarks on the Healthy and diseased State of the Horse	977
2. Inflammatory Diseases of the Horse	978
3. Diseases of the Head	979
4. Diseases of the Neck	980
5. The Chest	980
6. Diseases of the Skin	984
7. Glanders and Farcy	985
8. Diseases of the Extremities	985
9. Diseases of the Feet	987
VI. Veterinary Operations	989
1. Treatment of Wounds	989
2. Balls and Drinks	989
3. Fomentations and Poultices	989
4. Setons and Rowels	990
5. Blistering and Firing	990
6. Clystering and Physicking	990
7. Castration, Nicking, Docking, &c.	991
8. Bleeding	991
VII. Veterinary Pharmacopœia	991
VIII. Shoeing of Horses	993
IX. Criteria of the Qualities of Horses for various Purposes	995
X. Breeding of Horses	997
XI. Rearing of Horses	999
XII. Training of Horses	1000
XIII. The Art of Horsemanship	1003
XIV. Feeding of Horses	1004
XV. Stabling and Grooming of Horses	1006
XVI. Management and Working of Horses	1007
1. Management and Working of Race Horses	1007
2. Management and Working of the Hunter	1009
3. Working and Management of Riding Horses	1009
4. Horses in Carriages and Coaches	1010
5. Working of Cart, Waggon, and Farm Horses	1010
CHAP. II.	
The Ass	1012
CHAP. III.	
The Mule and Hinny, Hybrids of the Horse and Ass	1013
CHAP. IV.	
Neat or Horned Cattle	1014
I. The Ox	1014
1. Varieties and Breeds of the Bull	1014
2. Criteria of Cattle for various Objects and Purposes	1019
3. Breeding of Horned Cattle	1020
4. Rearing of Horned Cattle	1021
5. Fattening Calves by Suckling	1023
6. Fattening Horned Cattle	1024
7. Management of Cows kept for the Dairy	1025

	Page		Page
8. Working of Horned Cattle	1029	III. Fattening of Swine	1070
9. Anatomy and Physiology of the Bull and Cow	1031	IV. Curing of Pork and Bacon	1070
10. Diseases of Horned Cattle	1032	V. Diseases of Swine	1071
II. The Buffalo	1035		
CHAP. V.			
The Dairy and its Management	1035	Of the Goat, Rabbit, Hare, Dormouse, Deer, and various other Animals, that are or may be subjected to British Agriculture	1071
I. Chemical Principles of Milk, and the Properties of the Milk of different Animals	1036		
II. The Dairy House, its Furniture and Utensils	1037	CHAP. IX.	
III. Milking and the general Management of Milk	1040	Animals of the Bird Kind employed in Agriculture	1083
IV. Making and Curing of Butter	1041	I. Poultry Houses and their Furniture and Utensils	1083
V. Process of Cheese-making	1043	II. Gallinaceous Fowls, their Kinds, Breeding, Rearing, and Management	1084
VI. Catalogue of the different Sorts of Cheeses and other Preparations made from Milk	1045	III. Anserine or Aquatic Fowls	1091
		IV. Diseases of Poultry	1095
CHAP. VI.			
The Sheep	1049	V. Birds of Luxury which are or may be cultivated by Farmers	1095
I. Varieties of Sheep	1049		
II. Criteria of Properties in Sheep	1052	CHAP. X.	
III. Breeding of Sheep	1053	Fish and Amphibious Animals subjected to Cultivation	1100
IV. Rearing and general Management of Sheep	1055		
1. Rearing and Management of Sheep on rich grass and arable Lands	1056	CHAP. XI.	
2. Rearing and general Management of Sheep on Hilly and Mountainous Districts, or what is generally termed Store Sheep Husbandry	1058	Insects and Worms which are or may be subjected to Culture	1104
V. Folding of Sheep	1061		
VI. Of Fattening Sheep and Lambs	1062	CHAP. XII.	
VII. Probable Improvement to be derived from Crosses of the Merino Breed of Sheep	1063	Animals noxious to Agriculture	1108
VIII. Anatomy and Physiology of Sheep	1064	1. Noxious Mammalia	1108
IX. Diseases of Sheep	1064	II. Birds injurious to Agriculture	1112
		1. Insects injurious to Agriculture	1112
CHAP. VII.			
The Swine	1067	1. Physiology of Insects	1112
I. Varieties of the Common Hog	1068	2. Arrangement or Classification of Insects	1113
II. Breeding and Rearing of Swine	1069	3. Insects injurious to live Stock	1114
		4. Insects injurious to Vegetables	1115
		5. Insects injurious to Food, Clothing, &c.	1118
		6. Operations for subduing Insects	1119
		IV. Worm-like Animals injurious to Agriculture	1120

PART IV.

STATISTICS OF BRITISH AGRICULTURE.

BOOK I.

OF THE PRESENT STATE OF AGRICULTURE IN THE BRITISH ISLES.

CHAP. I.	
Different Descriptions of Men engaged in the Practice or Pursuit of Agriculture	
I. Operators, or serving Agriculturists	1121
II. Commercial Agriculturists	1122
III. Agricultural Counsellors, Artists, or Professors	1123
IV. Patrons of Agriculture	1123
CHAP. II.	
Different Kinds of Farms in Britain relatively to the different Classes of Society who are the Occupiers	
	1124
CHAP. III.	
Topographical Survey of the British Isles in respect to Agriculture	
I. Agricultural Survey of England	1125
II. Agricultural Survey of Wales	1173
III. Agricultural Survey of Scotland	1178
IV. Agricultural Survey of Ireland	1198
CHAP. IV.	
Literature and Bibliography of Agriculture	
I. Bibliography of British Agriculture	1206
II. Bibliography of Agriculture in Foreign Countries	1214
1. Bibliography of French Agriculture	1214
Calendarial Index	1233
Glossarial Index	1241
General Index	1248

2. Bibliography of German Agriculture	1219
3. Bibliography of Italian Agriculture	1221
4. Bibliography of the Agriculture of other Countries of Europe	1222
5. Agricultural Bibliography of North America	1223

CHAP. V.

Professional Police and Public Laws relative to Agriculturists and Agriculture	1223
--	------

BOOK II.

OF THE FUTURE PROGRESS OF AGRICULTURE IN BRITAIN.

CHAP. I.	
Improvement of Agriculture, by refining the Taste of the Purchasers of its Products, and increasing the Knowledge of Agricultural Patrons	
	1225
CHAP. II.	
Improvement of Agriculture, by the better Education of those who are engaged in it as a Profession	
I. Degree of Knowledge which may be attained by Practical Men, and general Powers of the human Mind as to Attainments	1226
II. Professional Education of Agriculturists	1228
III. Conduct and Economy of an Agriculturist's Life	1229

LIST OF ENGRAVINGS,

ARRANGED ACCORDING TO THE SUBJECTS.

Those marked † are chiefly of historical interest; those marked * are considered the best of their kind.

No.		Page	No.		Page
	<i>Picks and Mattocks.</i>			<i>Dibbles.</i>	
2 †	Primeval pick of Egypt	5	91	The Swedish dibbling-board	112
25 †	Pick of the ancient Britons	38	224 *	The double corn-dibble	372
124 †	Picks or Pick hoes of Java	152		<i>Scythes.</i>	
460 *	The planter's foot-pick	481	21 †	Italian scythe and scythe stone of the middle ages	33
590 b *	The planting-mattock	641	25 † 26 †	Scythes of the Ancient Britons	38
590 c *	The planter's adze	651	49	The Brabant cradle scythe	69
1115 a, b	Grubbing-mattocks of Devonshire	1170	61	The great Brabant scythe	83
	<i>Spades.</i>		60 *	The Hainault scythe	83
14 †	The Roman spade	24	225 *	The improved Hainault scythe	372
155 †	The Bushman's spade	182	226 *	The improved cradle scythe	373
1136 †	The cachrom or Highland spade	1197		<i>Reaping-hooks.</i>	
210	The Flemish spade	369	6 †	The reaping-hook of Egypt	7
211 *	The turf spade	369	25 † 27 †	Ancient British reaping-hooks	38
661 *	Draining-spades	712	121 i †	The reaping-hook of Ceylon	149
673, 680 *	Irrigating-spades	725	125 a, b †	Reaping-hooks of Java	152
469 b *	The hedger's spade	485	227 *	The improved reaping-hook	373
655 a	The semicylindrical draining-spade	710		<i>Boring Instruments.</i>	
	<i>Shovels and Scoops.</i>		228 *	The stack-borer	373
459 *	The ditcher's shovel	481	238 * 239 *	Good's improved well-borers	377, 378
661 d *	The drainer's shovel	712	241 *	Busby's quicksand borer	378
680 a, b *	Irrigating shovels	725	242 *	The peat borer	378
1115 c	The Devonshire paring-shovel	1170	662	The common draining-borer	712
661 a, b, c *	Draining-scoops	712	663 *	The horizontal boring-machine	713
680 c *	The irrigator's scoop	725	708 *	The root borer for rifling roots by gunpowder	744
	<i>Forks.</i>		704—707	Stone borers, or jumpers for blasting stones	743
25, 26, 27 †	Forks of the Ancient Britons	38		<i>Hedge-bills and Pruning-axes, and ground Knives.</i>	
682 c *	The irrigator's fork	725	36 †	The pruning-hook of the middle ages	53
753 *	Forks for spreading dung	856	121 a †	The jungle-hook of Ceylon	149
548 *	The road-maker's fork	596	121 b †	The pruning-axe of Ceylon	149
	<i>Drags or Haeks, and Pronged Hoes.</i>		125 c to g †	The pruning-hooks of Java	152
752 *	A light dung drag	856	229 a *	The Berwickshire hedge-bill or hedge-scutimar	374
756 *	A turnip-hook, or pronged hoe	859	229 c *	The bill-hook	374
215 *	A three-pronged double hoe	370	229 d *	The dressing-hook	374
232 *	The pronged hoe and turnip chopper	386	229 e *	The lopping-hook	374
	<i>Rakes.</i>		229 b *	The hedge axe	374
25 †	Rake of the Ancient Britons	38	469 d *	The hedge switching-bill	485
212 *	The English corn-rake	370	469 e *	Stephens's hedge-cutting bill	485
213 *	The East Lothian corn-rake	370	469 f *	Stephens's hedge-axe	485
214 *	The daisy rake	370	661 c *	The drainer's sod knife	712
	<i>Hoes.</i>		681 *	The turf knife	725
121 c †	The hoe of Ceylon	149	682 a *	The water scythe	725
124 b, c †	The hoes of Java	152	682 b *	The water-hook	725
215 *	The double hoe, with a pronged blade	370		<i>Level Instruments.</i>	
216	Ducket's hoes	371	224 *	The common road-level	375
469 a	The common Dutch hoe	485	223 *	Parker's level	375
217 *	The improved Dutch hoe	371	225 a *	The American level	376
218 *	Knight's improved thrust-hoe	371	225 b *	The square level	376
219 *	The Spanish draw-hoe	371	225 c *	The object staff	376
513	The Dutch wheel-hoe	509	225 d to h *	The levelling staff	376
500 d *	Sang's plantation-hoe	647	549 *	Telford's road-level	596
760 *	The best turnip hand-hoe	858	677 a *	Brown's irrigator's portable level	725
	<i>Weeding Implements.</i>		678 *	The compass-level	725
220 *	Baker's thistle-extirpator	371		<i>Hand-Hummelling Implements.</i>	
221 a *	The Scotch thistle-drawers	371	405 *	The hummelling-roller	440
221 b *	The Havre weeding-pincers	371	406	The hummelling-beater	440
	<i>Rope-twisters.</i>				
222	The common twisting-crook	372			
223 *	The improved twisting-crook	372

<i>Miscellaneous Implements and Instruments.</i>		<i>Hand-drills, Dibbling and Sowing Machines.</i>	
230	* The woodman's scorer - - - 374	284	* The common hand-drill - - - 387
231	* 232 * Potato-set scoops - - - 374	287	* The hand turnip-drill - - - 388
236, 237	* Hunter's odometer - - - 376	286	* Coggins's corn-dibbler - - - 387
593	* Barking instruments - - - 659	283	* Plunket's bean or potato dibbler - - - 387
599	* Broad's callipers for measuring standing timber - - - 663	285	* The broadest sowing-machine - - - 387
703	* Callipers for raising stones - - - 745		<i>Traps for Vermin.</i>
600	* Rogers's dendrometer - - - 663	290	* Field rat-trap - - - 388
708	* The blasting screw for rending roots of trees - - - 744	291	* Improved rat-trap - - - 388
892	* Sheep crooks - - - 1057	292	* Wooden mole-traps - - - 388
870	* Syringe and enema tubes for relieving horses, cattle, sheep, and swine - - - 1034	964, 965	* Paul's rattery - - - 1110, 1111
838	* The steam for bleeding horses - - - 991		<i>Miscellaneous Hand Machines.</i>
866	* Ring for fastening cattle - - - 1030	177	† The whin-bruise of Britany - - - 207
857	* Yoke and bow for oxen - - - 1030	270-272	* The hay-binder - - - 384
	<i>Miscellaneous Utensils.</i>	273	* The rope-twister - - - 385
27	† The ancient British harvest-born - - - 38	288	* The hand turnip-roller - - - 388
1119	d Cornish dung panniers - - - 1171	289	* Doxat's mechanical power - - - 388
1119	c Cornish faggot and sheaf corn panniers - - - 1171	293	* An improved grindstone - - - 389
243	* The corn-screen - - - 378	750	* Machine for washing potatoes - - - 853
244	* The iron corn-basket - - - 378	872	* The gin-wheel potato-washer - - - 1038
245	* The seed-carrier - - - 378	767	* Cabbage-cutter for sauerkraut - - - 869
246	* Jones's corn and seed drier - - - 379	768	* Newton's cabbage-chopper - - - 869
811	* Barrel for blanching endive - - - 942	428	* A lime-pounding machine - - - 442
977	* The turnip beetle-net - - - 1120	409	* Low's machine for raising large stones - - - 442
978	* Curtis's lime-duster - - - 1120	705, 706	* Richardson's machine for raising large stones - - - 745
	<i>* Utensils for Poultry.</i>	987	* Hill and Bundy's flax-breaking machine - - - 918
926	a, b, c Poultry coops - - - 1084		<i>Ploughs of Historical Interest.</i>
926	d Portable shelter for poultry - - - 1084	2	† 3 † 4 † Primitive tillage implements of the greatest antiquity - - - 5, 6
927	* The improved poultry-feeder - - - 1084	9	† Primitive plough of Sicily - - - 10
1145	* The phasant-feeder - - - 1232	11	† Plough of the South of France - - - 23
	<i>Scientific Utensils.</i>	12	† Plough of Valencia - - - 23
203	* Vessels for examining soils - - - 318	13	a, b, c † Wheel-ploughs of the greatest antiquity - - - 23
208	* Leslie's hygrometer - - - 366	22	† A Saxon wheel-plough of the eighth century - - - 36
209	* The rain-gauge - - - 366	23	† 24 † Ancient British ploughs - - - 37
	<i>Utensils for the Dairy.</i>	38	† The modern plough of Rome - - - 55
81	† The cowherd's lure of Norway - - - 110	50	† The plough of Toulouse - - - 70
33	† The dairy caldron of Lodi - - - 49	51	† The Arabian plough - - - 70
879	* The box churn - - - 1040	74	† The plough of Tykochin, in Poland - - - 102
880	* The Derbyshire churn - - - 1040	89	† The plough of Oeterothonia - - - 112
881	* The Lancashire plough-churn - - - 1040	90	† The ancient Sammite plough - - - 112
877	* The cheese-press - - - 1039	97	† The Castilian plough - - - 119
878	* The lactometer - - - 1039	100	† The Arcadian plough - - - 121
	<i>Wheelbarrows.</i>	109	† The plough of Erzerum - - - 141
947	* The earth barrow - - - 379	113	† The plough of Yemen, in Arabia - - - 142
948	* The iron barrow for dung - - - 379	119	† Hindustanee ploughs - - - 148
949	* The corn barrow - - - 379	121	d † The plough of Ceylon - - - 149
250	* The hay and straw barrow - - - 379	131	† Chinese ploughs - - - 160
251	* The package barrow - - - 379		<i>Modern Swing Ploughs.</i>
232	* The Normandy barrow - - - 380	294	* Small's plough - - - 392
253	* The French truck - - - 380	295	* * Wilkie's iron swing plough - - - 392
254	* The common hand-barrow - - - 380	296	* Finlayson's crane-necked self-cleaning iron plough - - - 392
255	* The earth hand-barrow - - - 380	297	* Finlayson's open beam self-cleaning iron plough - - - 393
256	* The dung hand-barrow - - - 380	298	* Finlayson's skeleton self-cleaning turn-wrest plough - - - 393
257	* The improved dressing machine - - - 380	299	* Finlayson's line plough - - - 393
258	* The hand threshing-machine - - - 380	300	* Gray's turn-wrest plough - - - 394
259	* The maize sheller - - - 381	301	* Weatherley's movable stilt plough - - - 394
260	* Marriott's improved maize separator - - - 381	302	* Duckett's skim-couter plough - - - 394
1120	* The box barrow of Cornwall - - - 1172	303	* Somerville's double-furrow plough - - - 395
	<i>Handmills.</i>	304	* Clymer's iron plough - - - 396
261	* A hand flour-mill for grinding maize - - - 381	305	* Morton's trenching plough - - - 396
734	* The maize sheller - - - 831	306	* Gladstone's water-furrowing plough - - - 397
262	* A hand bolting-machine - - - 381	1130	* An addition to a plough called a ridder, used in Fifehire - - - 1188
263	* The furze bruise - - - 382		<i>Modern Wheel-Ploughs.</i>
266	* The root breaker or bruise - - - 383	308	* Improved Scotch wheel-plough - - - 398
267	* The corn bruise - - - 383	309	* The Everstone wheel-plough - - - 398
268	* The potato flour-mill - - - 383	310	* The Norfolk wheel-plough - - - 398
269	* The chaff-cutter - - - 384	311	* * Wilkie's single-horse wheel-plough - - - 399
281	* The turnip-slicer - - - 386	312	* * Wilkie's improved friction-wheel plough - - - 399
	<i>Weighting and Draught Machines.</i>	313	* The paring wheel-plough - - - 400
276	* The weighing-cage - - - 385	1158	* * Wilkie's one-wheel two-horse plough, with shifting muzzle - - - 1186
277	* Weir's cattle weighing-machine - - - 385		<i>Draining-Ploughs</i>
279	* Smith's potato-weighing machine - - - 386	314	* Clarke's draining-plough - - - 400
278	* The sack-weighing machine - - - 385	315	* Gray's draining-plough - - - 400
280	* Ruthven's farmer's steelyard - - - 386		
272	* The hay-weighing machine - - - 384		
274	* Finlayson's draught-machine - - - 385		
275	* Braby's draught-machine - - - 385		

No.	Page	No.	Page
516 * Morton's draining-plough	400		
517 * The gutter drain-plough	401		
518 Lumbert's mole-plough	401		
519 Lumbert's working power for his mole-plough	401		
320 Weir's improved working power for Lumbert's mole-plough	401		
321 * Bridgewater's draining-plough	402		
656, 657 Pearson's pipe draining-plough	710		
<i>Pronged Tillage Implements.</i>			
322 * Wilkie's parallel adjusting-brake	403		
323 Wilkie's improved prongs for brakes explained	403		
324 * Finlayson's cultivator and harrow	403		
721 * Kirkwood's grubber	803		
325 Weir's improved cultivator	404		
326 The Scotch cultivator or grubber	404		
327 Parkinson's cultivator	404		
328 Hayward's cultivator	405		
<i>Horse-hoes and Drill-Harrows.</i>			
320 * Wilkie's horse-hoe and drill-harrow	405		
331 ** Finlayson's self-cleaning horse-hoe and drill-harrow	406		
332 * Blaikie's inverted horse-hoe	406		
333 The Scotch horse-hoe	407		
334 Henry's improved scarifier	407		
335 Amos's horse-hoe and harrow	407		
336 The horse-hoe and castor wheel	407		
337 The thistle hoe, or hoe scythe	408		
882 A scuffer used in Essex	1129		
895 A drill hoe used in Worcestershire	1142		
<i>Horse Machines for sowing and planting.</i>			
338, 339 Cooke's corn-drill and horse-hoe	408, 409		
340 The Norfolk lever-drill	409		
341 * Morton's improved grain-drill	409		
342 * The improved bean-drill	410		
343 The horsebean dibbler	410		
344, 345 * The Northumberland two-row turnip drill	411		
346 * The Northumberland one-row turnip drill	411		
347 ** Weir's manuring one-row turnip drill	412		
722 ** The improved broad-cast sowing-machine	809		
<i>Watering Machines.</i>			
348 * Young's drill-waterer	413		
362 The watering-roller	416		
569 * The road water-barrow	610		
<i>Harrows.</i>			
194 † Harrow of the Singalese	152		
323, 349 Principles on which harrow prongs are formed	403, 413		
350 * The Berwickshire harrow	414		
351 The angular-sided harrow	414		
795 The grass-ground harrow	906		
352 * The grass-seed harrow	414		
353 The common brake	415		
354 * The grubber, or levelling-harrow	415		
355 * Morton's revolving brake-harrow	415		
356, 357 Gray's wet-weather harrow	416		
358 The bush harrow	416		
518 The improved single harrow	528		
565 The road-harrow	608		
990 Circular harrows	1136		
1003 * An excellent harrow used in Derbyshire	1152		
<i>Rollers, Cutters, and Scrapers.</i>			
121 <i>g, h</i> † Scrapers of Ceylon	149		
559 * The loaded roller	417		
363 The furrow roller	418		
362 The roller and water-box	418		
364, 365 * The pressing-plough	418		
360 Bartlett's cutting roller or cultivator	417		
366 Brown's furrow cross-cutter	418		
566 The road roller	608		
567, 568 * Boase's road scraper and sweeper	608, 609		
570 Biddle's road-maker	611		
709 Peat rollers	746		
<i>Levelling Machines.</i>			
59 The Mouldenaert or Flemish leveller	82		
367, 368 * The Scotch land-leveller	419		
369 The improved Flemish leveller	419		
<i>Horse-Rakes, and Hay-making Machines.</i>			
370 The Norfolk horse-rake	420		
371 * Weir's improved hay or corn rake	420		
372 * Salmon's hay tedder improved by Weir	421		
373 The hay sweeper	421		
<i>Reaping Machines.</i>			
16 † A Roman reaping machine	26		
375 Smith's reaping machine	422		
376, 377 * Bell's reaping-machine	423, 425		
378 * Gladstone's bean reaper	427		
379 The clover-pod reaper	427		
<i>Carts.</i>			
39 † The modern Roman cart	55		
48 † The gambarde, or one-horse hay and wood cart of Paris	69		
78 † Cart of Livonia	108		
103 † The cart of Albania	122		
1119 † Cornish sledges	1171		
380-383 Principles respecting wheels and axles, as applied to one-horse carts	428, 429		
386, 388, 390, 391, 392 Principles of adjusting draught and drags	430, 432, 433		
384 The Scotch one-horse cart	430		
385 The Scotch corn-cart	430		
386 The Scotch two-horse cart, with adjusting traces	430		
387 Somerville's drag cart	431		
1008, 1009 Simple carts in use in Yorkshire	1158		
<i>Waggons.</i>			
62 † The Flemish grand waggon	83		
65 † The old Danish waggon	88		
67 † The Hungarian travelling waggon	96		
68 † The Hungarian agricultural waggon	57		
75 † A Polish waggon	102		
149 † Dutch waggon of the Cape of Good Hope	180		
1118 The Cornwall harvest waggon	1171		
393, 394 Baddeley's waggon with bent axle	433		
395 * The Berkshire waggon	434		
396 Rood's waggon	434		
397, 398 Gordon's one-horse waggon	435		
<i>Threshing Machines.</i>			
17 † The Roman threshing machine	26		
32 † Threshing-rollers of modern Italy	49		
399, 400 * Meikle's two-horse threshing machine	437		
401 * Meikle's water threshing machine	438		
402 * Meikle's water and horse threshing machine	438		
984 * A threshing machine driven by water	1130		
<i>Smut and Hummelling Machines.</i>			
403 Hall's smut machine	439		
404 Mitchell's hummelling machine	440		
<i>Cider and Oil Mills impelled by Horses or Water.</i>			
602 Common cider-mill	675		
603 * Improved cider-mill	675		
604 French cider-mill	676		
994 The cider-press	1141		
95 † The olive-oil mill of Spain	1117		
128, 129 † Oil-mills of China	157, 158		
133 † Water oil-mill of China	160		
<i>Miscellaneous Horse Machines.</i>			
98 The Nora, or bucket-wheel of the Moors	119		
574 Snowden's leaf collector	421		
565 Harriott's road harrow	608		
566 Beaton's road roller or protector for common carts	608		
567 * 568 * Boase's road scraper and sweeper	608, 609		
569 The improved road-waterer	610		
570, 571 Biddle's machine for repairing roads	611		
592, 593 Steuart's machine for transplanting large trees	643		

No.	Page	No.	Page
<i>Miscellaneous Machines impelled by Water.</i>			
44 † The Neria of the Alps	64	426 * 427 * Cottages for farm-servants	455
201-206 The Persian wheel of Blair-Drummond	326	428 * A double cottage for farm-labourers	456
<i>Fixed Apparatus.</i>			
407 * A cattle food-steaming machine	441	429 * * Waistell's double cottage with cow-houses	456
597 * Boiler for distilling the spray of trees	657	430 * * Another double cottage by Waistell	456
934 * Bonnemain's apparatus for hatching eggs by hot water	1087	432 * 433 * Gothic cottages by Holland	458
<i>Portable Structures for Corn or Forage.</i>			
519 * The stack guard	532	434 * An ornamental cottage, erected by Lord Feuryn	458
520 * The stacking stage	533	435 * An economical double cottage, designed by J. C. L.	458
1136 Structures for drying hay and corn in use in Argyleshire	1197	616 * An economical double cottage	685
79 † The Russian roofed frame for drying corn in the sheaf	108	617 * A labourer's cottage with cow-house and piggery	686
<i>Farmeries or Homesteads.</i>			
123 † A Singalese farmery	150	618 * A god mechanic's cottage	686
176 † An Alpine farmery of Norway	205	619 A group of three cottages	686
55, 56 † A Flemish farmery	74, 75	620 An ornamental Gothic cottage for a labourer	686
418 * An octagon corn farmery, ground plan and isometrical views, designed and drawn by J. C. L. in 1820	449	621 An Italian cottage	686
419 * A rectangular farmery, ground plan and isometrical view, designed and drawn by J. C. L. in 1820	450	622 An entrance lodge to a farm	686
420 * Circular farmery, ground plan and isometrical view, designed and drawn by J. C. L. in 1820	450	981 A cottage for a small farmer	1129
443 * Waistell's farmery for a grazing farm in a hilly country	465	991 A cottage erected in Berkshire	1139
444 * Waistell's arable and grazing farmery	466	1002 A cottage erected in Staffordshire	1148
445 Marshal's octagon farmery	467	1122 A cottage in North Wales	1174
446 Beaton's small farmery	468	1125 A cottage in Berkshire	1181
447 * A Berwickshire farmery	468	1126 A cottage in Ayrshire	1185
448 * A proprietor's farmery with bailiff's house	469	1129 Two cottages in West Lethian	1187
449 * A very commodious farmery	470	1138 † A cabin in King's County, Ireland	1200
430 * A very complete farmery	471	<i>Buildings or other fixed Structures for Horses, Cattle, and Implements.</i>	
431, 432 * Waistell's large farmery	472	410 Trevises or partitions	444
605 * Fearn farmery with steam-power threshing machine	679	1004 * A mounted crib for hay, in use in the field in Derbyshire	1152
606 * Knolwell farmery	680	1113 A rustic shed or shelter	1165
607, 608 * A Middlesex farmery, designed by J. C. L.	681	1121 The cow or cattle feeding house in Cornwall	1172
609, 610 Farmery for a hay farm in Middlesex, designed by J. C. L.	682	421 Open cart or cattle shed	452
611, 612 * A corn and stall feeding farmery, designed by J. C. L.	683	See the details of the Farmeries.	
613 * A farmery for a meadow farm, designed by J. C. L.	684	411 * Cattle hummels	445
614, 615 * A farmery for a turnip farm	684, 685	412 Section of Harley's cow-house	446
1011 A Northumberland farmery	1161	413 * Calf-pens	446
1112 A Cheshire farmery	1154	421 Open cattle-shed for fields	452
1116, 1117 A farmery in Cornwall	1171	865, 866 Fastenings for cattle	1030
<i>Farm-houses.</i>			
35 † A farm-house in Tuscany	51	868 A shoeing-stall	1030
419 (18 to 21) * Position of the farm-house relatively to the farmery explained	450	<i>Buildings or other fixed Structures for Cows and the Dairy. See p. xxxix.</i>	
422, 423 Farm-houses of the lowest class	453	<i>Buildings or other fixed Structures for Sheep and Swine.</i>	
424 * 425 * Small farm-houses	454	416 A sheep-house and dove-cot combined	449
986, 987 An octagonal farm-house, erected by Francis, Duke of Bedford	1132	891 * Inclosure for washing sheep	1057
988 A square farm-house, erected by Francis, Duke of Bedford	1133	895-897 Rustic sheep-houses by Kraft	1063
998 * A farm-house of the Marquess of Stafford's in Shropshire	1145	1138 A rustic sheep-house	1197
1132 A farm-house combining an inn, erected by the Marquess of Stafford in Sutherland	1194	414 Harley's pigsties	447
<i>Cottages.</i>			
83 A Swedish log cottage	110	<i>Fixed or Portable Structures for Poultry, Pigeons, Rabbits, &c.</i>	
104 † A Hungarian cottage	123	110 † Pigeon-houses of Persia	141
189 † Hut of the Arabs	173	415 * Section for general poultry-house	448
84 † Circular huts of the Laplanders	111	416 A dove-cot and sheep-house combined	449
148 † Mud huts of Nubia	175	908, 909 The rabbit-hutch	1074
141 † Straw huts of Egypt	175	923, 925 A complete set of poultry-houses	1083
146 † Hired huts of the Foulahs	177	926 a A portable nest	1084
150-152 † Huts of the Hottentots	181	926 b, c Hen-coops	1084
160 † A American cottage built of logs	189	926 d Portable shelter for turkeys	1084
169 † Brazilian shelter	200	927 * An improved poultry-feeder	1084
431 An economical stair for cottages	457	1143 * A pheasant-feeder	1281
422, 423 Cottages approaching to the character of farm-houses	453	934 Bonnemain's apparatus for hatching eggs by hot water	1087
<i>Fixed or Portable Structures for Bees.</i>			
<i>Portable Structures for Cattle or Sheep.</i>			
417 The bee-house	449	940 * A decoy for wild ducks	1092
960 The chained hive	1106	946, 948 Pigeon-houses	1097
961 * The Polish hive	1106	954, 955 Bird-cages	1100
<i>Buildings or Fixed Structures for Corn or Forage.</i>			
796 Portable shelter	908	47 † Elevated hen-roost of France	69
894 A portable hay-rack	1061	<i>Buildings or Fixed Structures for Corn or Forage.</i>	
953 Wakefield's portable bridge	1130	122 † A Singalese threshing-floor	150
<i>Buildings or Fixed Structures for Corn or Forage.</i>			
436 * The common rick-stand	460	437 * The cast-iron rick-stand	460

ENCYCLOPÆDIA

OF

AGRICULTURE.

THE first want of man is food, and his first resource for it the ground. Whether herbs or fruits were resorted to, must have depended on their relative abundance in the country where man found himself; but the latter would probably be preferred, till the use of fire was discovered in the preparation of the former. The first care and labour of man would thus be bestowed on fruit trees, and hence gardening may be said to be the art of earliest invention. But man is also a carnivorous animal, and this propensity of his nature would soon induce him to attempt domesticating such beasts of the earth as be found most useful in affording milk, clothing, or food, or in performing labour. Hence the origin of pasturage, and the management of live stock. The invention of tillage would be coeval with the discovery of the use of the cereal grasses, and may be considered as the last grand step in the invention of husbandry, and the most important, as leading to the establishment of property in territorial surface.

In the earlier stages of civilisation, these branches of economy, in common with all the arts of life, would be practised by every family for itself; but the advantages of separating occupations would soon present themselves, and the result of this principle in regard to rural culture and management, the *res rustica* of the Romans and husbandry of old English authors, is, that all their operations are now classed under the two designations of agriculture and gardening.

Agriculture, the art to which we here confine ourselves, as compared to gardening, is the culture and management of certain plants and animals for the food and service of man; but, relatively to the present improved state of the art, it may be defined, the cultivation and management of territorial surface on an extended scale, by manual and animal labour, for the production of objects and materials used for the food and service of man, and for various important purposes in arts, manufactures, and civilised life.

The importance of agriculture is obvious, not only by its affording the direct supply of our greatest wants, but as the parent of manufactures and commerce. Without agriculture there can be neither civilisation nor population. Hence it is not only the most universal of arts, but that which requires the greatest number of operators: the main body of the population in every country is employed in the pursuit of agriculture; and the most powerful individuals, in almost all nations, derive their wealth and consequence from their property in land.

In the earliest ages of mankind, before tillage was invented, the surface of the earth would be common to all the inhabitants, and every family would pasture its flock, and pitch its tent, or erect its hut, where it thought fit: but when tillage came in use, it became necessary to assign to each family a portion of territory, and of this portion that family became the proprietor and cultivator, and the consumer of the product.

Hence the invention of property in land, and progressively of purchased cultivators, or slaves; of hired cultivators, or labourers; of commercial agriculturists, or farmers; and of the various laws and customs in regard to the proprietorship and occupation of landed property.

The practice of agriculture, however rude in early times or in countries still comparatively uncivilised, assumes a very different character among the most advanced nations. Not to mention the peculiarities of implements, machines, and domestic animals, and the different kinds of culture and management requisite for the different countries and climates of the world, the local variations requisite even in Britain are so considerable, that an agriculturist whose experience and observation had been confined to one district, may be comparatively unfit to exercise his profession in another. The sheep farming of the North Highlands, the dairy farming of Gloucestershire, the hop culture of Kent, the woodlands of Buckinghamshire, and the hay management of Middlesex, have given rise to commercial agriculturists of very distinct varieties from the common corn farmer. The previous preparation of land for culture, by enclosure, drainage, embanking, road-making, &c., demands considerable science; and has given rise to artist agriculturists, known as land-surveyors and land-engineers. The relative changes as to rent and occupancy which take place between land-owners and farmers, and the valuation and transfer of landed property among monied men, have produced land-valuators and land-agents; from the direction of extensive estates, and the management of small concerns and farms, have originated the serving agriculturists, known as land-stewards and bailiffs; and the operators are shepherds, herdsmen, ploughmen, carters, spadesmen, and hands of all work.

The practice of agriculture, from having been chiefly confined to men of humble station, who pursued it as a matter of business or profit, has of late years been engaged in by men of rank, and other opulent or amateur practitioners, as matter of taste and recreation. The contrast between the simple and healthy pursuits of the country, and such as require intense application, and confine men chiefly to towns and cities, gives them a peculiar charm to the industrious and active citizen, while the idle and the opulent find relief in it from the weariness of inaction or a frivolous waste of time. Some magnificent displays of the art have thus been made by great landed proprietors on their demesne or home farms; and very neat and tasteful specimens of culture, by retired citizens and other possessors of villas, farms, and *fermes ornées*. These circumstances may be said to have raised the pursuit of agriculture to a comparatively dignified state, with reference to that in which it was formerly held; while the political advantages which are enjoyed by all classes in a free and commercial country, have improved the circumstances of agriculturists of every grade, and tended to raise them in the scale of society.

The recent discoveries in chemistry and physiology, have led to the most important improvements in the culture of plants, and the breeding and rearing of animals; agriculture is, in consequence, no longer an art of labour, but of science; hence the advantage of scientific knowledge to agriculturists, and the susceptibility, in the art, of progressive advancement. "Agriculture," Marshall observes, "is a subject, which, viewed in all its branches and to their fullest extent, is not only the most important and the most difficult in rural economies, but in the circle of human arts and sciences."

For the purpose of agricultural improvement, societies have been established in every country of Europe, and in almost every county of Britain. Most of these, as well as several eminent individuals, have stimulated cultivators and breeders to exertion, by the offer of premiums, and other honorary rewards. Professorships of rural economy have also been instituted in some colleges; and other independent georgical institutions have been established for public instruction, especially on the Continent: to which we may add, the publication of numerous books on the subject of agriculture and territorial improvement.

Such are the origin, the extent, the importance, and the interest of the subject of agriculture; from which it cannot be surprising that a varied and voluminous mass of knowledge has been accumulated on the subject, and is consequently more or less necessary to every one who would practise the art with success himself, or understand when it is well practised for him by others. To combine as far as practicable the whole of this knowledge, and arrange it in a systematic form, adapted both for study and reference, are the objects of the present work. The sources from which we have selected, are the modern British authors of decided reputation and merit; sometimes we have recurred to ancient and to Continental authors, and occasionally, though rarely, to our own observation and experience: *observation* chiefly in Britain, but partly also on the Continent; and *experience* in Scotland, under the paternal roof, during our early years, — during some years' occupancy of two extensive farms in England, — and, in the engineering and surveying departments, during our practice for upwards of twenty years as a landscape-gardener.

With this purpose in view, Agriculture is here considered, in

PART	BOOK
I. As to its origin, progress, and present state,	{ 1. Among ancient and modern nations. 2. Under different geographical, physical, and political circumstances.
II. As a science founded on	{ 1. The study of the vegetable kingdom. 2. The study of the animal kingdom. 3. The study of the mineral kingdom and the atmosphere. 4. The study of the mechanical agents employed in agriculture. 5. The study of the operations of agriculture.
III. As an art comprehending	{ 1. The valuation, purchase, and transfer of landed property. 2. The laying out, or general arrangement, of landed property. 3. The improvement of cultivable lands. 4. The management of landed estates. 5. The selection, hiring, and stocking of farms. 6. The culture of farm lands. 7. The economy of live stock, and the dairy.
IV. Statistically in Britain,	{ 1. As to its present state. 2. As to its future progress.

A Calendrical Index to those parts of the work which treat of culture and management, points out the operations as they are to be performed, in the order of time and of season : and

A General Index explains the technical terms of agriculture, the abbreviations here made use of, and presents an analysis of the whole work in alphabetical, as the Table of Contents does in systematic, order.

PART I.

AGRICULTURE CONSIDERED AS TO ITS ORIGIN, PROGRESS, AND PRESENT STATE AMONG DIFFERENT NATIONS, GOVERNMENTS, AND CLIMATES.

1. *The history of agriculture* may be considered chronologically, or in connection with that of the different nations who have successively flourished in various parts of the world ; politically, as influenced by the different forms of government which have prevailed ; geographically, as affected by different climates ; and physically, as influenced by the characters of the earth's surface. The first kind of history is useful, by displaying the relative situation of different countries as to agriculture ; instructive, as enabling us to contrast our present situation with that of other nations and former times ; and curious, as discovering the route by which agriculture has passed from primitive ages and countries to our own. The political and geographical histories of the art, derive their value from pointing out causes favourable and unfavourable to improvement, and countries and climates favourable or unfavourable to particular kinds of cultivation and management.

BOOK I.

HISTORY OF AGRICULTURE AMONG ANCIENT AND MODERN NATIONS.

2. *Traditional history* traces man back to the time of the deluge. After that catastrophe, of which the greater part of the earth's surface bears evidence, man seems to have recovered himself (in our hemisphere at least) in the central parts of Asia, and to have first attained to eminence in arts and government on the alluvial plains of the Nile. Egypt colonised Greece, Carthage, and some other places on the Mediterranean sea ; and thus the Greeks received their arts from the Egyptians, afterwards the Romans from the Greeks, and finally the rest of Europe from the Romans. Such is the route by which agriculture is traced to our part of the world : how it may have reached the eastern countries of India and China is less certain ; though, from the great antiquity of their inhabitants and governments, it appears highly probable that arts and civilisation were either coeval there, or, if not, that they travelled to the east much more rapidly than they did to the west.

3. *The early history of man in America rests on very indistinct traditions: there arts and civilisation do not seem of such antiquity as in Asia; in North America they are of very recent introduction; but of the agriculture of either division of that continent, and of India and China, we shall attempt little more than some sketches of the modern history, and its present state.*

4. *The history of agriculture, among the nations of what may be called classic antiquity, is involved in impenetrable obscurity. Very few facts are recorded on the subject previously to the time of the Romans. That enterprising people considerably improved the art, and extended its practice with their conquests. After the fall of their empire, it declined throughout Europe; and, during the dark ages, was chiefly preserved on the estates of the church. With the general revival of arts and letters, which took place during the sixteenth century, agriculture also revived; first in Italy, and then in France and Germany; but it flourished most in Switzerland and Holland; and finally, in recent times, has attained its highest degree of perfection in Britain. The modern agriculture of America is copied from that of Europe; and the same may be said of the agriculture of European colonies established in different parts of the world. The agriculture of China, and the native agriculture of India, seem to have undergone no change for many ages. — Such is the outline which we now proceed to fill up by details, and we shall adopt the usual division of time, into the ages of antiquity, the middle ages, and the modern times.*

CHAP. I.

Of the History of Agriculture in the Ages of Antiquity; or from the Deluge to the Establishment of the Roman Empire, in the Century preceding the vulgar Æra.

5. *The world, as known to the ancients, consisted of not more than half of Asia, and of a small part of Africa and Europe. During the inundation of the deluge, a remnant of man, and of other animals, is related to have been saved on the top of the high mountain of Ararat, near the Caspian sea (fig. 1.), and, when the waters sub-*

sided, to have descended and multiplied in the plains of Assyria. As they increased in numbers they are related to have separated, and, after an unknown length of time, to have formed several nations and governments. Of these the principal are those of the Assyrian empire, known as Babylonians, Assyrians, Medes, and Persians, in Asia; of the Jews and the Egyptians, chiefly in Africa; and of the Grecians, chiefly in Europe. Least is known of the nations which composed the Assyrian empire; of the Jews, more is known of their gardening and domestic economy, than of their field culture; the Egyptians may be considered the parent nation of arts and civilisation, and are supposed to have excelled in agriculture; and something is known of that art among the Greeks.

6. *The authors whose writings relate to the period under consideration are few, and the relations of some of them very contradictory. The earliest is Moses, who flourished B. C. 1600; Herodotus and Diodorus Siculus, who wrote more particularly on the history and geography of Egypt, lived, the former in the fifth, and the latter in the sixth, century B. C.; and Hesiod, the ancient Greek writer on husbandry, in the tenth century preceding our æra.*

7. *Estimating the value of the writers of antiquity on these principles, they may be considered as reaching back to a period 1600 years before our æra, or nearly 3500 years from the present time; and it is truly remarkable, that, in the Eastern countries, the state of agriculture and other arts, and even of machinery, at that period, does not appear to have been materially different from what it is in the same countries at the present day.*

Property in land was recognised, the same grains cultivated, and the same domestic animals reared or employed: some led a wandering life and dwelt in tents like the Arabs; and others dwelt in towns or cities, and pursued agriculture and commerce like the fixed nations. It is reasonable indeed, and consistent with received opinions, that this should be the case; for, admitting the human race to have been nearly exterminated at the deluge, those who survived that catastrophe would possess the more useful arts, and general habits of life, of the antediluvian world. Noah, accordingly, is styled a husbandman, and is said to have cultivated the vine and to have made wine. In little more than three centuries afterwards, Abraham is stated to have had extensive flocks and herds, slaves of both sexes, silver and gold, and to have purchased a family sepulchre with a portion of territory around it. Isaac his son, during his residence in Palestine, is said to have sown and reaped a hundred fold. Corn seems to have been grown in abundance in Egypt; for Abraham, and afterwards Jacob, had recourse to that country during times of famine. Irrigation was also extensively practised there, for it is said (*Gen.*, xiii. 10.) that the plain of Jordan was watered everywhere, even as the garden of the Lord, like the land of Egypt. Such is the amount of agricultural information contained in the writings of Moses, from which the general conclusion is, that agriculture, in the East, has been practised in all or most of its branches from time immemorial. The traditions of other countries, however, as recorded by various writers, ascribe its invention to certain fabulous personages; as the Egyptians to Osiris; the Greeks to Ceres and Triptolemus; the Latins to Janus; and the Chinese to Chin-hong, successor of Fo-hi.

SECT. I. *Of the Agriculture of Egypt.*

8. *The origin of agriculture* has been sought by modern philosophers in natural circumstances. Man in his rudest state, they consider, would first live on fruits or roots, afterwards by hunting or fishing, next by the pasturage of animals, and lastly, to all of these he would add the raising of corn. Tillage, or the culture of the soil for this purpose, is supposed to have been first practised in imitation of the effects produced by the sand and mud left by the inundations of rivers. These take place more or less in every country, and their effects on the herbage which spontaneously springs up among the deposited sand and mud must at a very early period have excited the attention of the countryman. This hypothesis seems supported by the traditions and natural circumstances of Egypt, a country overflowed by a river, civilised from time immemorial, and so abundant in corn as to be called the granary of the adjoining states. Sir Isaac Newton and Stillingfleet, accordingly, considered that corn was first cultivated on the banks of the Nile. Sir Isaac fixes on Lower Egypt; but, as Herodotus and other ancient Greek writers assert that that country was once a marsh, and as Major Rennel in his work on the geography of Herodotus is of the same opinion, Stillingfleet (*Works*, vol. ii. 524.) considers it more probable that the cultivation of land was invented in Upper Egypt, and proceeded downwards according to the course of the Nile.

9. *The situation and natural phenomena of Upper Egypt*, Stillingfleet considers, rendered it fitter for the invention of cultivation than the low country; "for, while Lower Egypt was a marsh, formed by the depositions of the Nile, the principal part of Upper Egypt was a valley a few leagues broad, bounded by mountains, and on both sides declining to the river. Hence it was overflowed only for a certain time and season; the waters rapidly declined, and the ground, enriched by the mud, was soon dry, and in a state fit to receive seed. The process of cultivation in this country was also most obvious and natural; for the ground being every year covered with mud brought by the Nile, and plants springing up spontaneously after its recess, must have given the hint, that nothing more was necessary than to scatter the seeds, and they would vegetate. Secondly, the ground was prepared by nature for receiving the seed, and required only stirring sufficient to cover it. From this phenomenon the surrounding nations learned two things: first, that the ground before sowing should be prepared, and cleared from plants; and secondly, that the mixture of rich mould and sand would produce fertility. What is here stated may appear without foundation as to Upper Egypt; because at present, in the vicinity of Thebes, water is raised by art. But this objection is obviated by the testimony of Dr. Pococke, who is of opinion that formerly Upper Egypt was overflowed, in the same manner as Lower Egypt was afterwards, and is to this day." (*Stillingfleet's Life and Works*, ii. 524.)

10. *The invention of agricultural implements* must have been coeval with the invention of aration; and, accordingly, they are supposed to have originated in Egypt. Antiquarians are agreed, that the primeval implement used in cultivating the soil, must have been of the pick kind. (*fig. 2.*) A medal of the greatest antiquity, dug up at Syracuse, contained an impression of such an instrument (*Encyc. of Gard.*, *fig. 77.*): and its pro-

gress till it became a plough has been recognised in a cameo, published by Menestrier, on which a pick-like plough is drawn by two serpents (*fig. 3. a*): it may be also seen on a medal from the village of Enna, in Sicily, published by Combe (*b*); in a figure given by Spon, as found on an antique tomb (*c*); in an Etruscan plough, copied from a fragment in the Roman college at Rome, by Lasteyrie (*d*); and as we still see in the instrument depicted by Niebuhr, as used for ploughing in Egypt and Arabia at the present day (*e*). What seems to confirm these conjectures is, that the image of Osiris is sculptured with a similar plough in each hand (*fig. 4. a b c d*), and with a harrow (*e*) suspended by a cord (*f*) over the left shoulder. This plough there can be little doubt was used in war as well as in agriculture, and seems to have been of that kind with which the Israelites fought (1 *Sam.*, xiii. 19. 23.): it is thought, by some, to be the archetype of the letter alpha (the hieralpha of Kircher); and, by others, the sounds necessary to conduct the processes of culture are thought to have founded the origin of language. Thus it is that agriculture is considered by some antiquarians, as not only the parent of all other arts, but also of language and literature.

have been carried. These works are said to have been greatly increased by Sesostris, in the 17th or 18th century B. C. Many of the canals and drains have been long obliterated; but there are still reckoned eighty canals, like rivers, all excavated by manual labour, several of which are twenty, thirty, and forty leagues in length. These receive the inundations of the Nile, and circulate the waters through the country, which before was wholly overflowed by them. The large lakes of Mæris, Behire, and Mareotis, formed vast reservoirs for containing the superfluous waters, from which they were conducted by the canals over the adjacent plains. Upon the elevated ridges, and even on the sides of the hills which form the boundary to the flat alluvial grounds, the water was raised by wheels turned by oxen; and by a succession of wheels, and gradations of aqueducts, it is said, some hills, and even mountains, were watered to their summits. All the towns at some distance from the Nile were surrounded with reservoirs for the supply of the inhabitants, and for watering the gardens. For this last purpose the water was raised in a very simple manner, by a man walking on a plank with raised edges, or on a bamboo or other tube, which, it is observed in Calmet's Bible, is the machine alluded to by Moses, when he speaks of sowing the seed and watering it "with the foot." (*Deut.*, xi. 10.) They also raised water by swinging it up in baskets (*fig. 5*); a mode which, like the others, remains in use at the present day. The water is lifted in a basket lined with leather, "Two men, holding the basket between them, by a cord in each end fastened to the edge

of it, lower it into the Nile, and then swing it between them, till it acquires a velocity sufficient to enable them to throw the water over a bank into a canal. They work stark naked, or, if in summer, only with a slight blue cotton shirt or belt." (*Clarke's Travels.*)

12. *Of these immense embankments*, some of which served to keep in the river, and others to oppose the torrents of sand which occasionally were blown from the Great Desert, and which threatened to cover the country as effectually as the waters of the Nile, the ruins still remain. But, in spite of these remains, the sand is accumulating, and the limits of cultivated Egypt have been annually decreasing for the last 1200 years; the barbarous nations, to which the banks of the Nile have been subject during this period, having paid no attention to cultivation, or to the preservation of these noble works of antiquity.

13. *Landed property*, in ancient Egypt, it would appear, was the absolute right of the owners, till by the procurement of Joseph, in the eighteenth century B. C., the paramount or allodial property of the whole was transferred to the government. The king, however, made no other use of that right, than to place the former occupiers in the situation of tenants *in capite*; bound to pay a rent or land-tax of one fifth of the produce. This, Moses says, continued to be the law of Egypt down to his time; and the same thing is confirmed by the testimony of Herodotus and Strabo.

14. *The soil of Egypt* is compared by Pliny to that of the Leontines, formerly regarded as the most fertile in Sicily. There, he says, corn yields a hundred for one; but Cicero, as Gouguet observes, has proved this to be an exaggeration, and that the ordinary increase in that part of Sicily is eight for one. Granger (*Relat. du Voy. fait en Egypte*, 1730.), who paid much attention to this subject, says that the lands nearest to the Nile, which during the inundation were covered with water forty days, did not, in the most favourable seasons, yield more than ten for one; and that those lands which the water covered only five days, seldom gave more than four for one. This, however, is probably owing to their present neglected state.

15. *Of the animal or vegetable products of Egyptian agriculture* very little is known. The ox seems to have been the chief animal of labour from the earliest period; and rice at all times the principal grain in cultivation. By a painting discovered in the ancient Eleuthia (*fig. 6.*), it would appear that the operation of reaping was performed much in the same way as at present, the ears being cropped by a hook, and the principal part of the straw left as stubble. Herodotus mentions that, in his time, wheat was not cultivated, and that the bread made from it was despised, and reckoned not fit to be eaten; beans were also held in abhorrence by the ancient inhabitants: but it is highly probable, that in latter times, when they began to have commerce with other nations, they laid aside these and other prejudices, and cultivated what they found best suited to the foreign market.

16. *Agriculture was, no doubt, the chief occupation of the Egyptians*: and though they are said to have held the profession of shepherd in abhorrence, yet it appears that Pharaoh not only had considerable flocks and herds in his own possession, but was desirous of introducing any improvement which might be made in their management; for when Jacob, in answer to his questions, told him that he and his family had been brought up to the care of live stock from their youth, he expressed a wish to Joseph to have a Jewish bailiff for the superintendence of his grazing farm: "If thou knowest any men of activity among them, then make them rulers over my cattle." (*Gen.*, xlvii. 6.)

SECT. II. *Of the Agriculture of the Jews, and other Nations of Antiquity.*

17. *Of the agriculture of the nations contemporary with the Egyptians and Greeks* nothing is distinctly known; but, assuming it as most probable that agriculture was first brought into notice in Egypt, it may be concluded that most other countries, as well as Greece, would begin by imitating the practices of that country.

18. *On the agriculture of the Jews*, we find there are various incidental remarks in the books of the Old Testament. On the conquest of Canaan, it appears that the different tribes had their territory assigned them by lot; that it was equally divided among the heads of families, and by them and their posterity held by absolute right and impartial succession. Thus every family had originally the same extent of territory; but, as it became customary afterwards to borrow money on its security, and as some families became indolent and were obliged to sell, and others extinct by death without issue, landed estates soon varied in point of extent. In the time of Nebemiah a famine occurred, on which account many had "mortgaged their lands, their vineyards, and houses, that they might buy corn for their sons and daughters; and to enable them to pay the king's tribute." (*Nehem.*, v. 2.) Some were unable to redeem their lands otherwise than by selling their children as slaves, and thereby "bringing the sons and daugh-

ters of God into bondage." Boaz came into three estates by inheritance, and also a wife, after much curious ceremony. (*Ruth*, iv. 8—12.) Large estates, however, were not approved of. Isaiah pronounces a curse on those "that join house to house, that lay field to field, till there be no place, that they may be placed alone in the midst." While some portions of land near the towns were enclosed, the greater part was in common, or in alternate proprietorship and occupation, as in our common fields. This appears both from the laws and regulations laid down by Moses as to herds and flocks; and from the beautiful rural story of Ruth, who, to procure sustenance for herself and her widowed mother-in-law Naomi, "came and gleaned in the field after the reapers, and her hap was to light on a part of the field [that is, of the common field] belonging unto Boaz." (*Ruth*, ii. 3.)

19. It would appear that every proprietor cultivated his own lands, however extensive; and that agriculture was held in high esteem even by their princes. The crown-lands in King David's time, were managed by seven officers: one was over the storehouses, one over the work of the field and tillage of the ground, one over the vineyards and wine-cellar, one over the olive and oil-stores and sycamore (*Ficus Sycómorus Linn.*) plantations, one over the herds, one over the camels and asses, and one over the flocks. (*1 Chron.*, xxvii. 25.) King Uzziah "built towers in the desert, and digged many wells; for he had much cattle both in the low country and in the plains; husbandmen also and vine-dressers in the mountains, and in Carmel, for he loved husbandry." (*2 Chron.*, xxvi. 10.) Even private individuals cultivated to a great extent, and attended to the practical part of the business themselves. Elijah found Elisha in the field, with twelve yoke of oxen before him, and himself with the twelfth. Job had five hundred yoke of oxen, and five hundred she-asses, seven thousand sheep, and three thousand camels. Both asses and oxen were used in ploughing; for Moses forbade the Jews to yoke an ass with an ox, their step or progress being different, and of course their labours unequal.

20. Among the operations of agriculture are mentioned watering by machinery, ploughing, digging, reaping, threshing, &c. "Doth the ploughman plough all day to sow? doth he open and break the clods of his ground? When he hath made plain the face thereof, doth he not cast abroad the fitches, and scatter the cummin [*Cuminum Cymimum Linn.*], and cast in the principal wheat, and the appointed barley, and the rye, in their place?" (*Isaiah*, xxviii. 24, 25.) The plough was probably a clumsy instrument, requiring the most vigilant attention from the ploughman; for Luke (ch. ix. 62.) uses the figure of a man at the plough looking back, as one of utter worthlessness. Covered threshing-floors were in use; and, as appears from the case of Boaz and Ruth, it was no uncommon thing to sleep in them during the harvest. Corn was threshed in different ways. "The fitches," says Isaiah, "are not threshed with a threshing instrument, neither is a cart-wheel turned about upon the cummin; but the fitches are beaten out with a staff, and the cummin with a rod [flail]. Bread corn is bruised, because he will not ever be threshing it, nor break it with the wheel of his cart, nor bruise it with his horsemen." (*Ch.* xxviii. 27, 28.) The bread corn here mentioned was probably the *far* of the Romans (*maize*, *Zea Mays L.*), which was commonly separated by hand-mills, or hand-picking, or beating, as is still the case in Italy and other countries where this corn is grown. Corn was "winnowed with the shovel and with the fan." (*Id.*, xxx. 24.) Sieves were also in use, for Amos says, "I will sift the house of Israel, as corn is sifted in a sieve" (*Ch.* ix. 9.); and Christ is represented by St. Luke as saying, "Simon, Simon, Satan hath desired to have you, that he may sift you as wheat." Isaiah mentions (vii. 25.) the "digging of hills with the mattock:" to which implement the original pick (*fig.* 2.) would gradually arrive, first, by having the head put on at right angles, and pointed (*fig.* 7. *a*); next, by having it flattened, sharpened, and shod with iron (*b c*); and lastly, by forming the head entirely of metal, and forked (*d*), such probably as we see it in use in Judea, and the land of Canaan, at the present day.

21. Vineyards were planted on rising grounds, fenced round, the soil well prepared, and a vintage-house and watch-tower built in a central situation (*Isaiah*, v. 2.), as is still done in European Turkey and Italy. Moses gives directions to the Jews for cultivating the vine and other fruit trees; the three first years after planting, the fruit is not to be eaten; the fourth it is to be given to the Lord; and it is not till the fifth year that they are "to eat of the fruit thereof." (*Levit.*, xix. 25.) The intention of these precepts was, to prevent the trees from being exhausted by bearing, before they had acquired sufficient strength and establishment in the soil.

22. Of other agricultural operations and customs, it may be observed with Dr. Brown,

(*Antiq. of the Jews*, vol. ii. part xii. sect. 5, 6.) that they differed very little from the existing practices in the same countries, as described by modern travellers.

23. *The agricultural produce of the Jews* was the same as among the Egyptians; corn, wine, oil, fruits, milk, honey, sheep, and cattle, but not swine. The camel then, as now, was the beast of burden and long journeys (fig. 8.); and the horse, the animal of war and

luxury. The fruit of the sycamore-fig was abundant, and in general use; and grapes attained an astonishing size, both of berry and bunch; the melon and gourd tribes were common. The returns of corn were in general good; but as neither public stores, nor corn monopolisers, seem to have existed, dearths, and their attendant miseries, happened occasionally. A number of these are mentioned in Scripture, and some of extraordinary severity.

SECT. III. *Of the Agriculture of the Greeks.*

24. *The Aboriginal Greeks, or Pelasgi*, were civilised by colonies from Egypt, and received from that country their agriculture, in common with other arts and customs. Some of the ancient Greeks pretend that the culture of corn was taught them by Ceres; but Herodotus, and most of the ancients, concur in considering this divinity as the same with the Egyptian Isis. There is no particular evidence that the Greeks were much attached to, or greatly improved, agriculture; though Homer gives us a picture of old King Laertes, divested of wealth, power, and grandeur, and living happy on a little farm, the fields of which were well cultivated. (*Odyssey*, lib. xxiv.) On another occasion, he represents a king standing amongst the reapers, and giving them directions by pointing with his sceptre. (*Ibid.*, v. 550.) Xenophon highly commends the art; but the practical instances he refers to, as examples, are of Persian kings.

25. *What we know of the agriculture of Greece* is chiefly derived from the poem of Hesiod, entitled *Works and Days*. Some incidental remarks on the subject may be found in the writings of Herodotus, Xenophon, Theophrastus, and others. Varro, a Roman, writing in the century preceding the commencement of our æra, informs us, that there were more than fifty authors, who might at that time be consulted on the subject of agriculture, all of whom were ancient Greeks, except Mago the Carthaginian. Among them he includes Democritus, Xenophon, Aristotle, Theophrastus, and Hesiod. The works of the other writers he enumerates have been lost; and indeed all that remain of Democritus are only a few extracts preserved in the *Geoponika*, an agricultural treatise published at Constantinople by the Greeks of the fourth or fifth centuries of our æra. Xenophon, Aristotle, Homer, and others, touch on our subject but very slightly. Xenophon, after his banishment to Scillus, is said to have spent his time in literary pursuits, and in improving and decorating his estate; he wrote a treatise expressly on rural and domestic affairs, the third book of which is devoted to agriculture, entitled *Æconomics*, in the form of a dialogue, and he is even said to have given lessons on the subject. Of his treatise, Harte (*Essays*, p. 201.) says, "I take it to be one of the plainest and most sensible performances amongst the writings of the ancients." Theophrastus, a disciple of Aristotle, wrote on natural history, and his history of plants possesses an astonishing degree of merit, for the age in which it was written. He is justly considered the father of botany, and his work contains some curious observations on soils and manures, and on various parts of agriculture and gardening.

26. *But the writings of Hesiod are the chief resource for details as to Grecian agriculture.* This author flourished in the tenth century B. C., and was therefore contemporary with Homer. He lived at Askra, a village at the foot of Mount Helicon, in Bœotia. There he kept a flock, and cultivated a soil which he describes as "bad in winter, hard in summer, and never good," probably a stiff clay. As a poet who had written on various subjects, Hesiod was held in great veneration; and Aristotle states, that when the Thesprotians destroyed the village of Askra, and the Orchomenians received the fugitives who escaped, the oracle ordered them to send for the remains of the poet who had given celebrity to the place.

27. *The Works*, which constitute the first parts of his *Poem*, are not merely details of agricultural labours, but comprise directions for the whole business of family economy in the country. The poem sets out by describing the state of the world, past and present, for the purpose of exemplifying the condition of human nature. This condition entails on man the necessity of exertion to preserve the goods of life, and leaves him no alternative but honest industry or unjust violence; of which the good and evil

consequences are respectively illustrated. Dissension and emulation are represented as two principles actively at work ; much is said of the corruption of judges, and the evils of litigation ; contentment is apostrophised as the true secret of happiness ; virtue and industry strongly recommended. The poet now proceeds to describe the prognostics of the seasons of agricultural labour, and gives directions for providing a house, wife, slaves, and two steers ; how and when to cut down timber ; to construct carts and ploughs, and make clothes and shoes ; when to sow, reap, dress the vine, and make wine. He then treats of navigation, and gives cautions against risking every thing in one voyage : he describes the fit seasons for the coasting trade, and advises taking great care of the vessel at such time as she is not in use, and hanging up the rudder and other tackle in the smoke of the chimney. He concludes the Works with some desultory precepts of religion, personal propriety, and decorum ; and enjoins some curious superstitious observances relative to family matters. The *Days* contain a division of the lunar month into holy, auspicious, and inauspicious, mixed and intermediary days, the latter being such as are entitled to no particular observance.

28. *Property in land*, among the Greeks, seems to have been absolute in the owner, or what we would term freehold. The manner of inheritance seems to have been that of gavelkind ; the sons dividing the patrimony in equal portions. One of Solon's laws forbade that men should purchase as much land as they desired. An estate containing water, either in springs or otherwise, was highly valued, especially in Attica : and there a law existed relating to the depth of wells ; the distance they were to be dug from other men's grounds ; what was to be done when no water was found ; and other matters to prevent contentions as to water. Lands were enclosed, probably with a ring-fence, or boundary-mark ; or, most likely, the enclosed lands were such as surrounded the villages, and were in constant cultivation ; the great breadth of country being, it may be presumed, in common pasture. Solon decrees, that " he who digs a ditch, or makes a trench, nigh another's land, shall leave so much distance from his neighbour, as the ditch or trench is deep. If any one makes a hedge near his neighbour's ground, let him not pass his neighbour's landmark : if he builds a wall, he is to leave one foot between him and his neighbour ; if a house, two feet. A man building a house in his field, must place it a bowshot from his neighbour's." (*Potter's Antiq.*)

29. *The surface of Greece* was, and is, irregular and hilly, with rich vales, and some rocky places and mountains : the soil is various ; clayey in some places, but most generally light and sandy, on a calcareous subsoil.

30. *The operations of culture*, as appears by Hesiod, required to be adapted to the season : summer fallows were in use, and the ground received three ploughings, one in autumn, another in spring, and a third immediately before sowing the seed. Manures were applied : in Homer, an old king is found manuring his fields with his own hands ; and the invention of manures is ascribed by Pliny to the Grecian king Augeas. Theophrastus enumerates six different species of manures ; and adds, that a mixture of soils produces the same effects as manure. Clay, he says, should be mixed with sand, and sand with clay. The seed was sown by hand, and covered with a rake. Corn was reaped with a sickle ; bound in sheaves ; carted to a well-prepared threshing-floor, in an airy situation, where it might be threshed and fanned by the wind, as is still practised in modern Greece, Italy, and other countries of the Continent. Afterwards it was laid up in bins, chests, or granaries, and taken out as wanted by the family, to be pounded in mortars or quern-mills, into meal. Thorns and other plants for hedges were procured from the woods, as we find from a passage in Homer, in which he represents Ulysses as finding Laertes digging and preparing to plant a row of quicksets. (*Odys.*, lib. xxiv.)

31. *The implements* enumerated by Hesiod are, a plough, of which he recommends two to be provided in case of accident ; and a cart ten spans (seven feet six inches) in width, with two low wheels. The plough consisted of three parts ; the share-beam, the draught-pole, and the plough-tail. The share-beam is to be made of oak, and the other parts of elm or bay ; they are to be joined firmly with nails. Antiquarians are not agreed as to the exact form of this implement. Gouguet conjectures it may not have been unlike one still in use in the same countries, and in the south of France ; others, with greater probability, refer to the more simple plough still in use in Magna Græcia and Sicily (*fig. 9.*), originally Greek colonies. The rake, sickle, and ox-goad are mentioned ; but nothing said of their construction, or of spades or other manual implements.

32. *The beasts of labour* mentioned are oxen and mules : the former were more common ; and it would appear, from a passage in Homer (*Il.*, lib. xiii. v. 704.), were yoked by the

horns. Oxen of four years and a half old are recommended to be purchased, as most serviceable. In winter, both oxen and mules were fed under cover, on hay and straw, mast, and the leaves of vines and various trees.

33. *The most desirable age for a ploughman* is forty. He must be well fed, go naked in summer, rise and go to work very early, and have a sort of annual feast, proper rest, good food, and clothing consisting of coats of kid skins, worsted socks, and half boots of ox hides in winter. He must not let his eye wander about while at the plough, but cut a straight furrow; nor be absent in mind when sowing the seed, lest he sow the same furrow twice. The vine is to be pruned and stalked in due season; the vintage made in fine weather, and the grapes left a few days to dry, and then carried to the press.

34. *The products of Grecian agriculture* were, the grains and legumes at present in cultivation, with the vine, fig, olive, apple, date, and other fruits: the live stock consisted of sheep, goats, swine, cattle, mules, asses, and horses. It does not appear that artificial grasses or herbage plants were in use; but recourse was had, in times of scarcity, to the mistletoe and the cythus: what plant is meant by the latter designation is not agreed on; some consider it the *Medicago arborea L.*, and others the common lucerne. Hay was, in all probability, obtained from the meadows and pastures, which were used in common; flax, and probably hemp, were grown. Wood for fuel, and timber for construction, were obtained from the natural forests, which, in Solon's time, abounded with wolves. Nothing is said of the olive or fig by Hesiod; but they were cultivated in the fields for oil and food, as well as the vine for wine. One of Solon's laws directs that olive and fig trees must be planted nine feet from a neighbour's ground, on account of their spreading roots; other trees might be planted within five feet.

35. *In Hesiod's time almost every citizen was a husbandman*, and had a portion of land which he cultivated himself, with the aid of his family, and perhaps of one or two slaves; and the produce, whether for food or clothing, appears to have been manufactured at home. The progress of society would, no doubt, introduce the usual division of labour and of arts; and commercial cultivators, or such as raised produce for the purpose of exchange, would in consequence arise; but when this state of things occurred, and to what extent it was carried at the time Greece became a Roman province (B. C. 100), the ancient writers afford us no means of ascertaining.

SECT. IV. *Of the Agriculture of the Persians, Carthaginians, and other Nations of Antiquity.*

36. *Of the agriculture of the other civilised and stationary nations* of this period, scarcely any thing is known. According to Herodotus, the soil of *Babylon* was rich, well cultivated, and yielded two or three hundred for one. Xenophon, in his book of *Economics*, bestows due encomiums on a Persian king, who examined, with his own eyes, the state of agriculture throughout his dominions; and in all such excursions, as occasion required, bountifully rewarded the industrious, and severely discountenanced the slothful. In another place he observes, that when Cyrus distributed premiums with his own hand to diligent cultivators, it was his custom to say, "My friends, I have a like title with yourselves to the same honours and remuneration from the public; I give you no more than I have deserved in my own person; having made the selfsame attempts with equal diligence and success." (*Econom.*, c. iv. sect. 16.) The same author elsewhere remarks, that a truly great prince ought to hold the arts of war and agriculture in the highest esteem; for by such means he will be enabled to cultivate his territories effectually, and protect them when cultivated. (*Harte's Essays*, p. 19.)

37. *Phœnicia*, a country of Asia, at the east of the Mediterranean, has the reputation of having been cultivated at an early period, and of having colonised and introduced agriculture at Carthage, Marseilles, and other places. The Phœnicians are said to have been the original occupiers of the adjoining country of Canaan; and when driven out by the Jews, to have settled in Tyre and Sidon (now Sur and Saïda), in the fifteenth century B. C. They were naturally industrious; and their manufactures acquired such a superiority over those of other nations, that, among the ancients, whatever was elegant, great, or pleasing, either in apparel or domestic utensils, was called Sidonian; but of their agriculture it can only be conjectured that it was Egyptian, as far as local circumstances would permit.

38. *The republic of Carthage* included Spain, Sicily, and Sardinia, and flourished for upwards of seven centuries previous to the second century B. C. Agriculture was practised at an early period in Sicily; and, according to some, Greece received that art from this island. It must have been also considerably advanced in Spain, and in the Carthaginian territory, since they had books on the subject. In 147 B. C., when Carthage was destroyed by Scipio, and the contents of the libraries were given in presents to the princes, allies of the Romans, the senate only reserved the twenty-eight books on agriculture of the Carthaginian general Magon, which Decius Syllanus was directed to translate, and of which the Romans preserved, for a long time, the original and the translation. (*Encyc. Méthodique*, art. *Agriculture*.)

39. *Italy, and a part of the south of France*, would probably be partially cultivated, from the influence of the Carthaginians in Sicily and Marseilles; but the north of France, and the rest of Europe, appear to have been chiefly, if not entirely, in a wild state, and the scene of the pastoral and hunting employments of the nomadic nations, the Kelts or Celts, the Goths, and the Slaves.

40. *The Indian and Chinese nations* appear to be of equal antiquity with the Egyptians. Joseph de Guignes, an eminent French Oriental scholar, who died in the first year of the present century, has written a memoir (in 1759, 12mo), to prove that the Chinese were a colony from Egypt; and M. de Guignes, a French resident in China, who published at Paris a Chinese dictionary in 1813, is of the same opinion. The histories of the Oriental nations, however, are not yet sufficiently developed from the original sources, to enable us to avail ourselves of the information they may contain, as to the agriculture of so remote a period as that now under consideration.

41. With respect to *the American nations*, during this period, there are no facts on record to prove either their existence or their civilisation, though Bishop Huet and the Abbé Clavigero think that they also are descendants of Noah, who, while in a nomadic state, arrived in the western world, through the northern parts of the eastern continent.

CHAP. II.

History of Agriculture among the Romans, or from the Second Century B. C. to the Fifth Century of our Æra.

42. We have now arrived at a period of our history where *certainly supplies the place of conjecture*, and which may be considered as not only entertaining but instructive. The attention of the Romans to agriculture is well known. The greatest men amongst them applied themselves to the study and practice of it, not only in the first ages of the state, but after they had carried their arms into every country of Europe, and into many countries of Asia and Africa. Some of their most learned men and one of their greatest poets wrote on it; and all were attached to the things of the country. Varro, speaking of the farms of C. Tremellius Scrofa, says, "they are to many, on account of their culture, a more agreeable spectacle than the royally ornamented edifices of others." (*Var. de R. R.*, lib. i. cap. 2.) In ancient times, Pliny observes, the lands were cultivated by the hands even of generals, and the earth delighted to be ploughed with a share adorned with laurels, and by a ploughman who had been honoured with a triumph. (*Nat. Hist.*, lib. xviii. c. 3.) The Romans spread their arts with their conquests; and their agriculture became that of all Europe at an early period of our æra.

43. *The sources from which we have drawn our information* being first related, we shall review, in succession, the proprietorship, occupancy, soil, culture, and produce of Roman agriculture.

SECT. I. *Of the Roman Agricultural Writers.*

44. *The Roman authors* on agriculture, whose works have reached the present age, are Cato, Varro, Virgil, Columella, Pliny, and Palladius; there were many more, whose writings are lost. The compilation of Constantine Poligonat, or, as others consider, of Cassius Bassus, entitled *Geoponika*, already mentioned (18.), is also to be considered as a Roman production, though published in the Greek language at Constantinople, after the removal thither of the seat of government.

45. M. Porcius Cato, called the Censor, and the father of the Roman rustic writers, lived in the seventh century of the republic, and died at an extreme old age, B. C. 150. He recommended himself, at the age of seventeen, by his valour in a battle against Annihal; and afterwards rose to all the honours of the state. He particularly distinguished himself as a censor, by his impartiality and opposition to all luxury and dissipation; and was remarkably strict in his morals. He wrote several works, of which only some fragments remain, under the titles of *Origines* and *De Re Rustica*. The latter is the oldest Roman work on agriculture: it is much mutilated, and more curious for the account it contains of Roman customs and sacrifices, than valuable for its georgical information.

46. M. Terentius Varro died B. C. 28, in the 88th year of his age. He was a learned writer, a distinguished soldier both by sea and land, and a consul. He was a grammarian, a philosopher, a historian, and an astronomer; and is thought to have written five hundred volumes on different subjects, all of which are lost, except his treatise *De Re Rustica*.

This is a complete system of directions in three books, on the times proper for, and the different kinds of, rural labour; it treats also of live stock, and of the villa and offices. As Varro was for some time lieutenant-general in Spain and Africa, and afterwards retired and cultivated his own estate in Italy, his experience and observation must have been very considerable.

47. Publius Virgilius Maro, called the prince of the Latin poets, was born at a village near Mantua in Lombardy about 70 B. C., and died B. C. 19, aged 51. He cultivated his own estate till he was thirty years old, and spent the rest of his life chiefly at the court of Augustus. His works are the *Bucolics*, *Georgics*, and *Æneid*. The *Georgics* is to be considered as a poetical compendium of agriculture, taken from the Greek and Roman writers then extant, but especially from Varro.

48. Luc. Jun. Moderatus Columella was a native of Gades, now Cadiz, in Spain, but passed most of his time in Italy. The time of his birth and death are not known, but he is supposed to have lived under Claudius in the first century. His work *De Re Rustica*, in twelve books, of which the tenth is still extant, was a complete treatise on rural affairs, including field operations, timber trees, and gardens.

49. C. Plinius Secundus, surnamed the elder, was born at Verona in Lombardy, and suffocated at the destruction of Pompeii in his 56th year, A. D. 79. He was of a noble family; distinguished himself in the field and in the fleet; was governor of Spain; and was a great naturalist, and an extensive writer. Of the works which he composed none are extant but his *Natural History* in thirty-seven books; a work full of the erudition of the time, accompanied with much erroneous, useless, and frivolous matter. It treats of the stars and the heavens, of wind, rain, hail, minerals, trees, flowers, and plants; gives an account of all living animals; a geographical description of every place on the globe; and a history of commerce and navigation, and of every art and science, with their rise, progress, and several improvements. His work may be considered as a compendium of all preceding writers on these subjects, with considerable additions from his personal experience and observation.

50. Rutilius Taurus Emilianns Palladius is by some supposed to have lived under Antoninus Pius, in the second century, though others place him in the fourth. His work *De Re Rustica* is a poem in fourteen books, and is little more than a compendium of those works which preceded it on the same subject. The editor of the article Agriculture, in the *Encyclopédie Méthodique*, says it is too dull to be read as a poem, and too concise to be useful as a didactic work.

51. These works have been rendered accessible to all by translations; and a judicious and instructive treatise composed from them by Adam Dickson, a Scotch clergyman, was published in 1788, under the title of *The Husbandry of the Ancients*. To this latter work we are indebted for the greater part of what we have to submit on Roman agriculture.

52. The Roman authors, as Rozier has observed (*Dict. de l'Agr.*, art. *Hist.*), do not enable us to trace the rise and progress of agriculture, either in Italy or in any other country under their dominion. What they contain is a picture of their rural economy in its most perfect state, delivered in precepts, generally founded on experience, though sometimes on superstition; never, however, on theory or hypothesis. For, as the Rev. Adam Dickson states, "instead of schemes produced by a lively imagination, which we receive but too frequently from authors of genius unacquainted with the practice of agriculture, we have good reason to believe that they deliver, in their writings, a genuine account of the most approved practices; practices, too, the goodness of which they had themselves experienced." (*Husb. of the Anc.*, p. 16.) He adds, that if in the knowledge of the theory of agriculture, the Roman cultivators are inferior to our modern improvers; yet in attention to circumstances and exactness of execution, and in economical management, they are greatly superior.

SECT. II. Of the Proprietorship, Occupancy, and General Management of Landed Property among the Romans.

53. The Roman nation originated from a company of robbers and runaway slaves, who placed themselves under their leader Romulus. This chief having conquered a small part of Italy divided the land among his followers, and by what is called the Agrarian Law, allowed 2 jugera or $1\frac{1}{2}$ acre to every citizen. After the expulsion of the kings in the 6th century B. C., 7 yoke, or $3\frac{1}{2}$ acres were allotted. The custom of distributing the conquered lands, by giving 7 jugera to every citizen, continued to be observed in latter times; but when each soldier had received his share, the remainder was sold in lots of various sizes, even to 50 jugera; and no person was prevented from acquiring as large a landed estate as he could, till a law passed by Stolo, the second plebeian consul, B. C. 377, that no one should possess more than 500 jugera. This law appears to have remained in force during the greater period of the Roman power. Whatever might be the size of the estate, it was held by the proprietor as an absolute right, without acknowledgment to

any superior power ; and passed to his successors, agreeably to testament, if he made one ; or if not, by common law to his nearest relations.

54. *In the first ages of the commonwealth, the lands were occupied and cultivated by the proprietors themselves ; and as this state of things continued for four or five centuries, it was probably the chief cause of the agricultural eminence of the Romans.* When a person has only a small portion of land assigned to him, and the maintenance of his family depends entirely upon its productions, it is natural to suppose that the culture of it employs his whole attention. A person who has been accustomed to regular and systematic habits of action, such as those of a military life, will naturally carry those habits into whatever he undertakes. Hence, it is probable, a degree of industrious application, exactness, and order in performing operations, in a soldier-agriculturist, which would not be displayed by men who had never been trained to any regular habits of action. The observation of Pliny confirms this supposition : he asserts that the Roman citizens, in early times, "ploughed their fields with the same diligence that they pitched their camps, and sowed their corn with the same care that they formed their armies for battle." (*Nat. Hist.*, lib. xviii. c. 3.) Corn, he says, was then both abundant and cheap.

55. *Afterwards, when Rome extended her conquests, and acquired large territories, rich individuals purchased large estates ; the culture of these fell into different hands, and was carried on by bailiffs and farmers much in the same way as in modern times.* Columella informs us that it was so in his time, stating, that "the men employed in agriculture are either farmers or servants ; the last being divided into free servants and slaves." (*Col.*, lib. i. cap. 7.) It was a common practice to cultivate land by slaves during the time of the elder Pliny ; but his nephew and successor let his estates to farmers.

56. *In the time of Cato the Censor, the author of The Husbandry of the Ancients observes, though the operations of agriculture were generally performed by servants, yet the great men among the Romans continued to give particular attention to it, studied its improvement, and were very careful and exact in the management of all their country affairs.* This appears from the directions given them by this most attentive farmer. Those great men had both houses in town, and *villas* in the country ; and, as they resided frequently in town, the management of their country affairs was committed to a bailiff or overseer. Now their attention to the culture of their lands and to every other branch of husbandry, appears, from the directions given them how to behave upon their arrival from the city at their *villas*. "After the landlord," says Cato, "has come to the villa, and performed his devotions, he ought that very day, if possible, to go through his farm ; if not that day, at least the next. When he has considered in what manner his fields should be cultivated, what work should be done, and what not ; next day he ought to call the bailiff, and enquire what of the work is done, and what remains ; whether the labouring is far enough advanced for the season, and whether the things that remain might have been finished ; and what is done about the wine, corn, and all other things. When he has made himself acquainted with all these, he ought to take an account of the workmen and working days. If a sufficiency of work does not appear, the bailiff will say that he was very diligent, but that the servants were not well ; that there were violent storms ; that the slaves had run away ; and that they were employed in some public work. When he has given these and many other excuses, call him again to the account of the work and the workmen. When there have been storms, enquire for how many days, and consider what work might be done in rain ; casks ought to have been washed and mended, the villa cleaned, corn carried away, dung carried out, a dunghill made, seeds cleaned, old ropes mended, new ones made, and the servant's clothes mended. On holidays, old ditches may have been scoured, a highway repaired, briars cut, the garden digged, meadows cleared from weeds, twigs bound up, thorns pulled, far (bread-corn, maize) pounded, all things made clean. When the servants have been sick, the ordinary quantity of meat ought not to have been given them. When he is fully satisfied in all these things, and has given orders that the work that remains be finished, he should inspect the bailiff's accounts, his account of money, of corn, fodder, wine, oil, what has been sold, what exacted, what remains, what of this may be sold, whether there is good security for what is owing. He should inspect the things that remain, buy what is wanting for the year, and let out what is necessary to be employed in this manner. He should give orders concerning the works he would have executed, and the things he is inclined to let out, and leave his orders in writing. He should inspect his flocks, make a sale, sell the superfluous oil, wine, and corn ; if they are giving a proper price, sell the old oxen, the refuse of the cattle and sheep, wool, hides, the old carts, old iron tools, and old and diseased slaves. Whatever is superfluous he ought to sell ; a farmer should be a seller, not a buyer." (*Cat.*, csp. ii.)

57. *The landlord is thus supposed by Cato to be perfectly acquainted with every kind of work proper on his farm, and the seasons for performing it, and also to be a perfect judge how much work, both without and within doors, ought to be performed by any number of servants and cattle in a given time ; the knowledge of which is highly useful to a farmer, and what very few perfectly acquire.* It may be observed, likewise, that the landlord is here supposed to enquire into all circumstances, with a minuteness of which there is scarcely even an actual farmer in this age who has any conception.

58. *Varro complains that, in his time, the same attention to agriculture was not given as in former times ; that the great men resided too much within the walls of the city, and employed themselves more in the theatre and circus, than in the corn fields and vineyards.* (*Var. de R. R.*, lib. i. præf.)

59. *Columella complains that, in his time, agriculture was almost entirely neglected.* However, from the directions which he gives to the proprietors of land, it appears that there were still a few who continued to pay a regard to it ; for, after mentioning some things, which he says, by the justice and care of the landlord, contribute much to improve his estate, he adds, "But he should likewise remember, when he returns from the city, immediately after paying his devotions, if he has time, if not, next day, to view his

marches, inspect every part of his farm, and observe whether in his absence any part of discipline or watchfulness has been dispensed with; and whether any vine, any other tree, or any fruits are missing. Then likewise he ought to review the cattle and servants, all the instruments of husbandry, and the household furniture. If he continue to do all these things for some years, he will find a habit of discipline established when he is old; and at no age will he be so much impaired with years as to be despised by his servants." (*Col.*, lib. i. cap. 9.)

60. *The earliest farmers among the Romans* seem not to have been upon the same footing as in Britain. The stock on the farm belonged to the landlord, and the farmer received a certain proportion of the produce for his labour. The farmer, who possessed a farm upon these terms, was called *politor* or *polintor*, from his business, being the dresser of the land; and *partuarius*, from his being in a kind of copartnership with his landlord, and his receiving a part of the produce of the farm for his labour. Cato takes notice of this kind of farmers only, and it is probable that there were no others in his time. "The terms," says he, "upon which land ought to be let to a *politor*: in the good land of Casinum and Venafrum, he receives the eighth basket; in the second kind of land he receives the seventh; in the third kind he receives the sixth. In this last kind, when the grain is divided by the *modius*, he receives the fifth part; in the very best kind of land about Venafrum, when divided by the basket, he receives only the ninth.... If the landlord and *politor* husk the *far* in common, the *politor* receives the same proportion after as before; of barley and beans divided by the *modius*, he receives a fifth." (*Ch.* xl. xli.) The small proportion of the produce that the *politor* received, makes it evident that he was at no expense in cultivating the land, and that he received his proportion clear of all deductions.

61. *The coloni or farmers mentioned by Columella*, seem to have paid rent for their farms in the same manner as is done by the farmers in Britain. The directions given by this author to landlords, concerning the mode of treating them, are curious as well as important. A landlord, he says, "ought to treat his tenants with gentleness, should show himself not difficult to please, and be more vigorous in exacting culture than rent, because this is less severe, and upon the whole more advantageous. For, where a field is carefully cultivated, it for the most part brings profit, never loss, except when assaulted by a storm or pillagers; and therefore the farmer cannot have the assurance to ask any ease of his rent. Neither should the landlord be very tenacious of his right in every thing to which the farmer is bound, particularly as to days of payment, and demanding the wood and other small things which he is obliged to, besides paying his rent, the care of which is a greater trouble than expense to the rustics. Nor is every penalty in our power to be exacted, for our ancestors were of opinion, that the rigour of the law is the greatest oppression. On the other, the landlord ought not to be entirely negligent in this matter; because it is certainly true, what Alpheus the usurer used to say, that good debts become bad ones, by being not called for," &c. (*Col.*, lib. i. cap. 7.)

62. *These directions are valuable even with reference to the present times*; and they instruct us respecting the general management of landed property among the Romans. It appears that the landlord was considered as understanding every thing respecting the husbandry of his estate himself; and that there was no agent, or intermediate person, between him and the farmer. The farmers paid rent for the use of their farms, and were bound to a particular kind of culture, according to the conditions of their lease; but they were perfectly free and independent of their landlords; so much so, as sometimes to enter into lawsuits with them. On the whole, they seem to have been upon the same footing as the farmers of Britain in modern times.

SECT. III. *Of the Surface, Soil, Climate, and other Agricultural Circumstances of Italy, during the Time of the Romans.*

63. *The agriculture of any country must necessarily take its character from the nature of that country.* The extent and manner of cultivating the soil, and the kind of plants cultivated, or animals reared, must necessarily be regulated by the surface of the soil, the natural productions, the climate, the artificial state, and the habits of the people.

64. *The climate of Italy* is regular, dry, clear, and considerably warmer than that of Britain. At the bottoms of the mountains, it is subject to severe storms of hail in summer, and snow in winter, which often do considerable damage; but these are only accidental disadvantages; and in the champaign lands and gentle declivities, the vine, the fig, and the olive, ripened anciently, as now, in open plantations, from one extremity of Italy to the other.

65. *The surface of Italy* is very irregular. A ridge of hills, and mountains passes through its whole length, forming numerous valleys of different degrees of extent; some elevated and narrow, others low and watered by a river, a stream, or by lakes. The immense plain of the Po constitutes a capital feature towards the north-east; the sandy plain of Calabria towards the south; and the marshy plain of Terracino, and

the rocky coast of Genoa, towards the western shore. Columella and Palladius agree in stating, that the best situation for lands is, not so much on a level as to make the water stagnate, nor so steep as to make it run off with violence; nor so low as to be buried in the bottom of a valley, nor so exposed as to feel the violence of storms and heats; for in these a mediocrity is always best: but champaign lands exposed, and whose declivity affords the rain a free passage; or a hill whose sides gently decline; or a valley not too much confined, and into which the air has easy access; or a mountain defended by a higher top, and thereby secured from the winds that are most pernicious, or, if high and rugged, at the same time covered with trees and grass. (*Col.*, lib. ii. cap. 2.; *Pallad.*, lib. i. cap. 5.) The situation of lands which Cato reckons the best, is at the foot of a mountain with a south exposure. Varro and Pliny concur in this opinion, and the latter states that the best lands in Italy are so situated.

66. *The soil of Italy is as varied as the surface.* About Genoa a yellow marly clay forms a base to schistons cliffs and hilly slopes; a blue clay containing sulphur and alum on the west coast between Florence and Venice; volcanic earth about Rome and Naples; sand about Florence, and at the estuaries of most of the rivers; rich black loam in the central parts of Tuscany; and rich, deep, soft, moist earth, and mild marly clay, in Lombardy. Columella divides the soils of Italy into six kinds; fat and lean, free and stiff, wet and dry: these mixed with one another, he says, make great varieties. In common with all the other writers, he prefers a free soil.

67. *The native productions of Italy*, in an agricultural point of view, are, timber on the mountains, pastures on the hill sides, and meadow or very luxuriant grass-lands in the alluvial plains. The rich, low, and yet dry lands do not produce a close pasture, but a rough herbage, unless they are covered with trees; the sandy soils produce little of any thing; and the fens and marshes reeds and other coarse aquatics. Such were the productions of Italy antecedent to culture.

68. *The artificial state of the country*, in respect to agriculture, during the time of the Romans, seems to have differed less from its present state than will be imagined. The cultivated lands were open, and enclosures only to be seen near the villas. These were of small size, and chiefly gardens and orchards, except in the case of parks for game, formed by the wealthy, which never were very numerous. With the exception of part of Tuscany and Lombardy, this is still the case; and the landscape, as Daniel Malthus has observed (*Introd. to Girardin's Essay*), which Pliny observes as seen from his villas, does not appear to have been different two thousand years ago, from what it is at this day. But the roads, canals, markets, and artificial water-courses for the irrigation both of arable and grass-lands, are undoubtedly greatly increased since the time of the Romans: though they also practised irrigation.

69. *The habits of a people* take their rise, in a great degree, from the climate in which they live, and the native or cultivated productions with which the country abounds. As respects agriculture, it may be sufficient to mention, that the great heat of the climate, by relaxing the frame, naturally produces indolence in many, and leads to a life of plunder in some. Hence then, as now, the danger from thieves and robbers in that country; and hence, also, the custom of performing field labours early in the morning, and in the evening, and resting during the mid-day heat. The general use of oil and wine as food and drink, and also of the fig as an article of nourishment, are habits which arise immediately from the circumstance of these articles being the artificial produce of the country; but are ultimately, like most other habits, to be referred to the climate.

70. *These hints respecting the natural and agricultural geography of Italy*, during the time of the Romans, are confessedly too scanty to be of more use than to recal to the reader's recollection the information on the same subject with which his mind is already stored; and by this means to enable him to form a due estimate of the nature and merits of the agriculture which we are about to describe.

SECT. IV. *Of the Culture and Farm Management of the Romans.*

71. *The Roman authors are much more copious in describing farm culture and economy*, than in relating the state of landed property as to extent and proprietorship. Their directions, being founded on experience, are in great part applicable at the present day: they are remarkable for their minuteness; but we can only give a very brief compendium, beginning with some account of the farm and the villa, or farmery, and taking in succession the servants, heasts of labour, implements, operations, crops cultivated, animals reared, and profit produced.

SUBSECT. 1. *Of the Choice of a Farm, and of the Villa or Farmery.*

72. *In the choice of a farm*, Cato recommends a situation where there is plenty of artificers and good water; which has a fortified town in its neighbourhood; is near the sea or a navigable river, or where the roads are easy and good. (*Cat.*, cap. 1.) To these requisites Varro adds, a proper market for buying and selling, security from thieves and

robbers, and the boundaries planted with useful trees. The interior of the farm was not subdivided by enclosures, which were seldom used but for their gardens, and to form parks in the villas of the wealthy.

73. *The soil* preferred by Columella and all the Roman authors is the fat and free, as producing the greatest crops, and requiring the least culture; next, fat stiff soil; then stiff and lean soil, that can be watered; and, last of all, lean dry soil.

74. *The state of a farm* preferred by Cato and some other writers is that of pasture, meadow, and watered grass-lands, as yielding produce at least expense; and lands under vines and olives, as producing the greatest profit according to the expense. The opinions of the Roman agriculturalists, however, seem to disagree on the subject of meadows, apparently from confounding a profitable way of management, with a capacity of yielding great profit with superior management, and none without.

75. *The word Villa originally denoted a farm-house and its appurtenances.* In the first age of the commonwealth, these were very plain and small, suitable to the plain manners of the people, and adapted to the small size of their farms: but, when the Romans had extended their empire, when they had become rich and luxurious, and particular persons were possessed of large landed estates, then the villas became large and magnificent. In the time of Valerius Maximus, there were villas that covered more ground than was in the estates of some of the ancient nobles. "Now," says he, "those think themselves very much confined, whose houses are not more extensive than the fields of Cincinnatus." (*Val. Max.*, lib. iv. cap. 4. sect. 7.) In the days of Cato, it is probable that they had begun to extend their villas considerably, which makes him give a caution to the proprietors of land not to be rash in building. He recommends to them to sow and plant in their youth, but not to build till somewhat advanced in years. His words are remarkable: "A landholder," says he, "should apply himself to the planting of his fields early in his youth; but he ought to think long before he builds. He ought not to think about planting; but he ought to do it. When he is about thirty-six years of age, he may build, provided his fields are planted." (*Cat.*, cap. 3.)

76. *Men should plant in their youth, and not build till their fields are planted;* and even then ought "not to be in a hurry, but take time to consider." It is best, according to the proverb, to profit by the folly of others." (*Plin. Nat. Hist.*, lib. xviii. cap. 5.) The reason why these authors recommend greater attention to planting than building is, that the labouring oxen in Italy, in the time of the Romans, were fed, for several months in the year, with leaves and mast; and the vine, the fig, the olive, and other trees, were cultivated for their fruit.

77. *Build in such a manner that your villa may not be too small for your farm, nor your farm too small for your villa.* (*Cat.*, cap. 3.) Varro assigns proper reasons for this. "In not attending," says he, "to the measure of the farm, many have gone wrong. Some have made the villa much smaller, and others much larger than the farm required. One of these is contrary to a man's interest, and the other hurtful to the produce of his lands. For we both build and repair the larger buildings at a greater expense than is necessary; and, when the buildings are less than what the farm requires, the fruits are in danger of being destroyed." (*Var. de R. R.*, lib. i. cap. 11.) Columella expresses himself to the same purpose, and mentions two persons in particular who had fallen into each of the extremes. "I remember," says he, "that many have erred in this point, as these most excellent men did, L. Lucullus and Q. Scævola, one of whom built a villa much larger, and the other much less than the farm required." (*Col.*, lib. i. cap. 4.)

78. *Pliny, noticing the above remark of Cato's,* observes that Lucullus had thereby rendered himself liable to the chastisement of the censors, having less occasion to plough his lands than to clean his house. "In this case," says he, "to plough less than to sweep, was a foundation for the chastisement of the censors." (*Plin. Nat. Hist.*, lib. xviii. cap. 6.)

79. *Proportion the expense of the building to the rent, or the profits arising from the farm.* "An edifice should be built according to the value of the farm and fortune of the master, which, immoderately undertaken, it is commonly more difficult to support than to build. The largeness of it should be so estimated, that, if any thing shall happen to destroy it, it may be rebuilt by one, or at most by two years' rent or profits of the farm in which it is placed." (*Pal.*, lib. i. tit. 8.)

80. *The position of the villa, and the situation of its different parts,* are also noticed by some of these authors. "Some art," says Pliny, "is required in this. C. Marius, of a very mean family, seven times consul, placed a villa in the lands of Misenum, with such skill in the contrivance, that Sylla Felix said, that all others in this respect were blind, when compared to him." (*Plin. Nat. Hist.*, lib. xviii. cap. 7.) All of them advise that it shall not be placed near a marsh, nor fronting a river. Pliny cites the authority of Homer for this. Varo says, that such a situation is cold in winter and unhealthful in summer; that, in such a place, there are many small insects which, though invisible, enter the body at the mouth and nostrils, and occasion diseases. (*Var. de R. R.*, lib. i. tit. 12.) Palladius gives reasons of the same kind. (*Pal.*, lib. i. tit. 7.) Besides this, Varro

directs, that, if possible, it shall be placed at the foot of a mountain covered with woods, in such a manner as to be exposed to the most healthful winds, and to enjoy the sun in winter and the shade in summer. An east exposure, he thinks, is the best for this purpose, (*Var. de R. R.*, lib. i. cap. 12.) Palladius proposes that, for the same purpose, the villa shall front the south-east; that the *prætorium*, or master's house, shall be a little higher than the rest of the villa, both to secure the foundations, and to have a more agreeable prospect. (*Pal.*, lib. i. tit. 8.) It is probable that both these authors have Italy particularly in view. But Pliny extends his views further; for he says, that the villa in warm climates ought to front the north, in cold climates the south, and in temperate climates the east. (*Plin. Nat. Hist.*, lib. xviii. cap. 7.) Columella is more particular than any of the other authors, both in giving directions as to the situation of the villa, and giving reasons for the situation he recommends. (*Col.*, lib. i. cap. 5.)

81. *The villa is divided into three parts, the urbana, the rustica, and the fructuaria.* All the particulars of these, Columella says, ought to be properly placed with respect to each other. The *urbana* contained the apartments of the landlord; the *rustica* contained the kitchen, the houses of the labouring servants, the stables, piggeries, and poultry houses, ponds for water, dunghills, on which, says Varro, some persons place necessary conveniences for the family. (§ xii.) Adjoining the villa rustica, in the residence of opulent Romans, were placed the aviary, apiary, a place for dormice, a warren for hares and rabbits, a place for snails, and a large enclosure or park of fifty acres or more for retaining live deer and wild beasts taken in the chase. The *fructuaria* contained the oil and wine cellars, the places for the oil and wine presses, the corn-yards, barns, granaries, store-houses, repositories for roots and fruits, &c.

82. Both Columella and Palladius give directions *how all these parts should be situated and constructed*; but, though minute, they are not so explicit as to enable any one to delineate their ground plan. The same may be said as to the directions given by these author, and by Pliny (*Nat. Hist.*, lib. xviii.), respecting the laying out of the villa urbana, and the apartments for summer and winter. The subject of designing villas for the opulent belongs no doubt more to architecture than to agriculture; and therefore we shall refer, for details, to the plans given by Castel (fig. 10.) and other modern authors, who have attempted to embody the descriptions of the ancient writers.

83. *Castel's general arrangement of a grand Roman villa and its environs*, is as follows:—

- | | | |
|---|--|---------------------------|
| 1, Prætorium. | 11, Ornitlion of Varro. | 20, Mill driven by water. |
| 2, Farm-house and offices. | 12, Vivarium, or park for wild beasts. | 21, Temple of Ceres. |
| 3, Canal, parting the farm from the prætorium. | 13, Small woody islands for peacocks. | 22, Corn-fields. |
| 4, Stone-banks to the canal. | 14, Place for turkeys (11), rather swans, and their keepers: turkeys being natives of America, and consequently unknown to the Romans. | 23, Vineyards. |
| 5, Bridges. | 15, For geese and their keeper. | 24, Olive grounds. |
| 6, Museum. | 16, Cochlearium. | 25, Meadows. |
| 7, River Vinisus. | 17, Dormice. | 26, Orchard. |
| 8, Part of the island surrounded by that river. | 18, Apiary. | 27, Garden. |
| 9, The other river. | 19, Threshing floor and barn. | 28, Osier ground. |
| 10, Walk on the bank of that river. | | 29, Woods, &c. |
| | | 30, Coppices. |

84. It is remarkable that *no directions are given as to the materials* of which the villa should be built. These would, in all probability, depend on local circumstances; rammed earth, timber, brick burned or only dried in the sun, or stone, would be taken according to convenience. The remains of villas which have reached modern times, are chiefly of brick stuccoed over. Pliny mentions walls in Africa and Spain, called *formacii*, the formation of which, by cramming the earth between two boards, exactly agrees with the French mode of building mud walls, called *en pisé*. He also mentions walls of unburnt brick, of mud, of turf, and frames filled up with bricks and mud. (*Nat. Hist.*, lib. xxxv. cap. 14.)

SUBJECT. 2. *Of the Servants employed in Roman Agriculture.*

85. *The servants employed in Roman agriculture* were of two sorts, freemen and slaves. When the proprietor or farmer lived on the farm and directed its culture, these were directly under his management; in other cases there was a bailiff or overseer, to whom all the other servants were subordinate. This was the case so early as Cato's time, who is very particular in his directions respecting the care a bailiff ought to take of the servants, the cattle, the labouring utensils, and in executing his master's orders.

86. *The bailiff was generally a person who had received some education*, and could write and keep accounts; and it was expected that he should be careful, apt to learn, and capable to execute his master's orders with a proper attention to situations and circumstances. Columella, however, says that "the bailiff may do his business very well, though he is illiterate." Cornelius Celsus says that "such a bailiff will bring money to his master oftener than his book; because, being ignorant of letters, he is the less capable to contrive accounts, and is afraid to trust another, being conscious of fraud." (*Col.*, lib. i. cap. 3.) There are some other things mentioned by this author, with respect to the bailiff, that are very proper, and show particularly the attention of the Romans. "He

ought not," says he, "to trade on his own account, nor employ his master's money in purchasing cattle or any other goods; for this trading takes off his attention, and prevents

10

him from keeping square accounts with his master. But when he is required to settle them, he shows his goods in the place of money. This, above all, he should be careful of, not to think he knows any thing he does not know; and always to be ready to learn what he is ignorant of. For as it is of great advantage to do a thing well, so it is most hurtful to have it ill done. This one thing holds true in all rustic work, to do but once what the manner of culture requires; because, when imprudence or negligence in working is to be set to rights, the time for the work is already wasted; nor are the effects of the amendment such as to make up the lost labour, and balance the advantages that might have been gained by improving the season that is past." (*Col.*, lib i. cap. 8.)

87. *The qualities of the other villa servants* are represented by the same author in this manner: "The careful and industrious," says he, "should be appointed masters of the works; these qualities are more necessary for this business than stature or strength of body, for this service requires diligent care and art." Of the ploughman he says,

88. *In the ploughman*, though a degree of genius is necessary, yet it is not enough. "There should be joined to it a harshness of voice and manner, to terrify the cattle; but he should temper strength with clemency; because he ought to be more terrible than cruel, that so the oxen may obey his commands, and continue the longer at their work, not being spent, at the same time, both with the severity of labour and stripes. But what the offices of masters of works and of ploughman are, I shall mention in

their proper places. It is sufficient at present to observe, that tallness and strength are of great use in the one, and of very little in the other; for we should make, as I have said, the tallest man a ploughman, and both for the reason I have already mentioned, and because there is no rustic work by which a tall man is less fatigued than by ploughing; because, when employed in this, walking almost upright, he may lean upon the handle of the plough." Of the common labourer he says, "The common labourer may be of any size, provided he is able to endure fatigue." And of the vine-dresser, "Vineyards do not require such tall men, provided they are thick and brawny; for this constitution of body is most proper for digging, pruning, and the other culture necessary for them. In this work diligence is less necessary than in the other works of husbandry; because the vine-dresser ought to perform his work in company and un/er the eye of a director. Commonly wicked men are of a quicker genius, which this kind of work requires; and, as it requires not only a stout servant, but one of an active contrivance, vineyards are commonly cultivated by slaves in chains." (*Col.*, lib. i. cap. 9.) Thus we see, that, among the Romans, labourers were appointed to the different works of husbandry, according to their strength, size, and genius.

89. With respect to the wages of agricultural labour among the Romans, very little benefit can be derived from knowing the absolute sum of money paid for any article, unless it can be compared with the price of other commodities. The price of a slave in Cato's time, was about 50*l.*; in the time of Columella it had risen to 60*l.*; or to the price of eight acres of good land. A good vine-dresser cost 66*l.* 13*s.* 4*d.*, and a good ploughman or labourer not less than 60*l.* The interest of money at this time was 6*l.* per cent per annum; therefore, in stating the expense of farm labour, a slave must be rated at not less than 12*l.* per cent, as being a perishable commodity; so that one who cost 60*l.* would fall to be charged at the rate of 7*l.* 4*s.* per annum, besides his maintenance and clothing. This may give some idea of the wages that would be paid to a free servant who hired himself by the year; of which, however, there appears to have been no great number, their wages not being stated.

90. All the servants were maintained and clothed by the farmer or proprietor; and as may be supposed, it was the interest of the latter that this should be done in a good and sufficient manner. Columella mentions what he calls an old maxim, concerning the bailiff: "That he should not eat but in the sight of all the servants, nor of any other thing but what was given for the rest." He mentions the reason of this: "For thus," says he, "shall he take care that both the bread be well baked, and the other things prepared in a wholesome manner." (*Col.*, lib. i. cap. 8.) The same author mentions the treatment that masters ought to give their slaves: "So much the more attentive," says he, "ought the master to be in his enquiry concerning this kind of servants, that they may not be injured in their clothes and other things afforded them, inasmuch as they are subject to many, such as bailiffs, masters of works, and gaolers; and the more they are liable to receive injuries, and the more they are hurt through cruelty or avarice, the more they are to be feared. Therefore a diligent master ought to enquire, both at themselves, and likewise the free servants in whom he may put greater confidence, whether they receive the full of what is allowed them; he himself ought likewise to try, by tasting the goodness of the bread and drink, and examine their clothes, mittens, and shoes." (*Col.*, lib. i. cap. 8.) In another place, he says, "That the bailiff should have the family dressed and clothed rather usefully than nicely, and carefully fortified against the wind, cold, and rain; all which they will be secured from, by sleeved leathern coats, old centones (thick patchwork as bed-quilts) for defending their heads; or cloaks with hoods. If the labourers are clothed with these, no day is so stormy as to prevent them from working without doors: (*Col.*, lib. i. cap. 8.) Cato likewise makes particular mention of the clothes of the slaves: "The vestments of the family," says he, "a coat and a gown three feet and a half long should be given once in two years; whenever you give a coat or a gown, first receive the old one; of these make centones. Good shoes should be given once in two years." (*Col.*, cap. 59.)

91. Cato informs us what quality of bread and wine, and what other kinds of meat, were given to labourers. Of bread, he says, each labourer was allowed at the rate of three pounds avoirdupois, or of three pounds twelve ounces avoirdupois in the day, according to the severity of his labour. "During the winter," says he, "the bailiff should have four modii of wheat each month, and during the summer four modii and a half; and the housekeeper, or the bailiff's wife, and the shepherd, should have three. During the winter, the slaves should have four pounds of bread each in the day; and from the time that they begin to dig the vineyard, to the ripening of the figs, they should have five pounds each; after which they should return again to four." (*Col.*, cap. 56.) To this bread, there was a daily allowance of wine; during the three months that immediately followed the vintage, the servants drank a weak kind of wine called *torra*. The manner in which this liquor was made, is described both by Pliny and Columella; and from the description given by them, it may well be supposed to be as good as the small beer given to servants in Britain. (*Plin. Nat. Hist.*, lib. xiv. cap. 10.) It does not appear that the Roman slaves were much restricted in the quantity; Cato mentions no measure; he only says, that they have this to drink for three months after the vintage; he proceeds in this manner: "In the fourth month, each should get a hemina of wine in the day, which is at the rate of two and a half congii in the month; in the fifth, sixth, seventh, and eighth months, each a sextaria in the day, which is five coagii in the month; in the ninth, tenth, and eleventh, each three heminae in the day, which is an amphora in the month. More than this, at the *soturnalibus* and *compitiatis*, to each man was given a congius. The quantity of wine for each man in the year is eight quadrants; however, as addition must be made according to the work in which the slaves are employed, it is not too much for each of them to drink ten quadrants in the year." This allowance of wine, it must be acknowledged, was not inconsiderable, being at least seventy-four gallons in the year, or at an average 1 $\frac{62}{100}$ parts of a pint in the day.

92. Besides bread and wine, the slaves got what was called *pulmentarium*, which answers to what in some parts of the country is called kitchen dripping or fat. (*Plin. Nat. Hist.*, lib. xviii. cap. 8.) For this purpose Cato recommends the laying up as

many fallen olives as can be gathered ; afterwards the early olives from which the smallest quantity of oil is expected ; at the same time observing that these must be given sparingly, that they may last the longer. When the olives are finished, he desires salt fish and vinegar to be given, and besides, to each man a *sextarius* of oil in the month, and a *modius* of salt in the year. (*Cat.*, cap. 18.) Columella, for this purpose, directs apples, pears, and figs, to be laid up : he adds, if there is a great quantity of these, the rustics are secured in no small part of their meat during the winter, for they serve for dripping or fat. (*Col.*, lib. xii. cap. 14.)

SUBJECT. 3. *Of the Beasts of Labour used by the Romans.*

93. *The labouring cattle used by the Romans*, as well as by all the ancient nations, were chiefly the ox, the ass sometimes, the mule for burdens, and but very rarely the horse. The horse, however, was reared ; but almost exclusively for the saddle, the chase, or for war. The respect for the ox which existed among the Egyptians, Jews, and Greeks, was continued among the Romans, so much so that Varro, and after him Columella and Pliny, adduce an instance of a man having been indicted and condemned, for killing one to please a boy who longed for a dish of tripe.

94. *The breeding, breaking, feeding, and working of the ox* are very particularly treated of by the ancient authors.

95. *Bulls*, says Palladius, "should be tall, with huge members, of a middle age, rather young than old, of a stern countenance, small horns, a brawny and vast neck, and a confined belly." (*Pal.*, lib. iv. sect. 11.)

96. *The cows* Columella "most approves of, are of a tall make, long, with very large belly, very broad forehead, eyes black and open, horns graceful, smooth, and black, hairy ears, strait jaws, very large dewlap and tail, and moderate hoofs and legs." (*Col.*, lib. vi. cap. 21.)

97. *Breeders both of horses and cows*, Virgil observes, should attend principally to the make of the female. "If any one," says he, "fond of the prize at the Olympic games, breeds horses ; or if any one breeds stout bullocks for the plough, he chiefly attends to the make of the mother, who ought to be large in all her parts." (*Georg.*, iii. v. 49.) The same maxim is enforced scientifically by Cline. (*Commun. to Board of Ag.*, vol. iv.)

98. *For breaking and training cattle to the yoke*, Varro and Columella give very particular directions. "To break bullocks," says Varro, "put their necks between forked stakes ; set up one for each bullock, and give them meat from the hand ; they will become tractable in a few days : then, in order that by degrees they may become accustomed to the yoke, let an unbroken one be joined with a veteran, whom he will imitate ; then let them go upon even ground without a plough ; then yoked to a light plough in a sandy soil. That they may be trained for carriages, they should first be put to empty carts, and driven, if convenient, through a village or town ; the habit of hearing frequent noise, and seeing a variety of objects, will soon make them fit for use." (*Var.*, lib. i. cap. 20.)

99. *Training* commences with the calf state ; and "calves," says Virgil, "which you intend for country labour, should be instructed while their youthful minds are tractable, and their age manageable : first bind round their necks wide wreaths of tender twigs ; then, when their free necks have been accustomed to servitude, put real collars upon them ; join bullocks of equal strength, and make them step together ; at first let them frequently be employed in drawing along the ground wheels without any carriage upon them, so that they may print their steps only upon the top of the dust ; afterwards let the beechen axle groan under the heavy load, and the pole draw the wheels joined to the weighty carriage." (*Georg.*, iii. v. 163.)

100. *Labouring oxen were fed* with the mast or nuts of the beech or sweet chestnut, grape stones and husks after being pressed, hay, wheat and barley straw, bean vetch and lupine chaff, all parts of corn and pulse, grass, green forage, and leaves. The leaves used were those of the holm oak, ivy, elm (considered the best), the vine, the poplar, &c. The poplar leaves were mixed with the elm leaves to make them hold out, and when there were no elm leaves, then oak and fig leaves were used. (*Cat.*, cap. 54.) The food preferred before all others by Columella, is good pasturage in summer, and hay and corn in winter ; but he says the food and manner of feeding differ in different countries.

101. *Oxen were worked in pairs abreast* both with the cart and plough, and stood in the stables also in pairs, in *bulilia* or stalls formed on purpose. They were carefully matched, in order that the stronger might not wear out the weaker. They were yoked either by the horn or neck ; but the latter mode was greatly preferred.

102. *Yoking by the horns*, Columella observes, "is condemned by almost all who have written on husbandry ; because cattle can exert more strength from the neck and breast, than the horns ; as in the one way, they press with the whole weight and bulk of their bodies ; whereas in the other way, they are tormented with having their heads drawn back and turned up, and with difficulty stir the surface of the earth with a light plough." (*Col.*, lib. ii. cap. 11. 22.)

103. *Oxen, when in the plough*, were not allowed to go a great way without turning ; one hundred and twenty feet was the length fixed upon, and further than this it was thought improper for them to pull hard without stopping. The Reverend A. Dickson thinks it probable, that "the breaks or plats for the different kinds of corn and pulse

were laid out nearly of this length and breadth" (*Husb. of the Anc.*, ii. 452.); and there appear grounds for concluding that the case was the same among the Jews and Greeks. It was thought proper that oxen, in ploughing, should be allowed to stop a little at the turning, and when they stopped, that the ploughman should put the yoke a little forward, that so their necks might cool. "Unless their necks are carefully and regularly cooled," says Columella, "they will soon become inflamed, and swellings and ulcers will arise." The same author directs that "the ploughman, when he has unyoked his oxen, must rub them after they are tied up, press their backs with his hands, pull up their hides, and not suffer them to stick to their bodies; for this is a disease that is very destructive to working cattle." No food must be given them till they have ceased from sweating and high breathing, and then by degrees, in portions as eaten; and afterwards they are to be led to the water, and encouraged by whistling." (*Col.*, lib. ii. cap. 3.)

104. *In purchasing working oxen*, Varro directs to choose such as have "spacious horns, rather black than otherwise, a broad forehead, wide nostrils, a broad chest, and thick dewlap." (*Lib.* i. cap. 20.) All the Roman authors agree that the best colour of the body is red or dark brown; that the black are hardier, but not so valuable; that the hair should be short and thick, and the whole skin very soft to the touch; the body in general very long and deep, or, as Columella and Palladius express it, compact and square. The particular parts they also describe at length in terms such as would for the most part be approved by experienced breeders of cattle; making due allowance for the difference between choice for working, and choice for fattening. They all concur in recommending farmers to rear at home what oxen they want, as those brought from a distance often disagree with the change of soil and climate.

105. *The ass was the animal next in general use.* Varro says they were chiefly used for carrying burdens, or for the mill, or for ploughing where the land was light, and that they were most common in the south of Italy, especially in Campania. (*Lib.* ii. cap. 6.) He gives directions for breeding and rearing them; and states that the female should not be allowed to work when in an advanced state of pregnancy, but that the male does not improve by indulgence in labour. The foal is removed from the dam a year after being foaled, and broken for labour in the third year.

106. *Mules*, Columella says, "are very proper both for the road and the plough, provided they are not too dear, and the stiff lands do not require the strength of the ox." "Mules and hinnis," Varro observes, "are of two kinds; the first being the offspring of a mare and an ass, and the second of a horse and an ass. A hinnus is less than an ass in the body, commonly of a brighter colour; his ears, mane, and tail like those of the horse. The mule is larger than the ass, but has more of the character of that animal in its parts than the hinnus. To breed mules, a young jackass is put under a mare when he is foaled, and being reared with her is admitted to her the third year; nor does he despise the mare on account of former habits. If you admit him younger he soon gets old, and his offspring is less valuable. Persons who have not an ass which they have brought up under a mare, and who wish to have an ass for admission, choose the largest and the handsomest they can find, from a good breed." (*Varro*, lib. ii. cap. 8.) Mules are fed like the ass, on spray, leaves, herbage, hay, chaff, and corn.

107. *The horse was scarcely, if at all, used in Roman agriculture*, but was reared for the saddle and the army, by some farmers. Varro and Columella are particular in their directions as to the choice of mares, and breeding and rearing their young; but as these contain nothing very remarkable, we shall merely remark that the signs of future merit in a colt are said to be a small head, well formed limbs, and contending with other colts or horses for superiority in running, or in any other thing.

108. *The dog is a valuable animal in every unenclosed country*, and was kept by the Roman farmers for its use in assisting the shepherd, and also for watching. Varro mentions two kinds: one for hunting, which belongs to fierce and savage beasts; and one for the shepherd and the watch-box. The latter are not to be bought from hunters or butchers, because these are either lazy, or will follow a stag rather than a sheep. The best colour is white, because it is most discernible in the dark. They must be fed in the kitchen with bread and milk; or broth with bruised bones, but never with animal food, and never allowed to suffer from hunger, lest they attack the flock. That they may not be wounded by other beasts, they wear a collar made of strong leather set with nails, the inward extremities of which are covered with soft leather, that the hardness of the iron may not hurt their necks. If a wolf or any other beast is wounded by these, it makes other dogs that have not the collar remain secure. (*Varr.*, lib. ii. cap. 9.)

SUBJECT. 4. *Of the Agricultural Implements of the Romans.*

109. *The Romans used a great many instruments* in their culture and farm management; but their particular forms and uses are so imperfectly described, that very little is known concerning them.

110. *The plough*, the most important instrument in agriculture, is mentioned by Catu as

of two kinds, one for strong, and the other for light, soils. Varro mentions one with two mould boards, with which, he says, "when they plough after sowing the seed, they are said to ridge." Pliny mentions a plough with one mould board for the same purpose, and others with a coulter, of which, he says, there are many kinds. It is probable indeed, as the Rev. A. Dickson has remarked, that the ancients had many kinds of ploughs, though, perhaps, not so scientifically constructed as those of modern times. "They had ploughs," he says, "with mould boards, and without mould boards; with and without coulters; with and without wheels; with broad and narrow pointed shares; and with shares not only with sharp sides and points, but also with high-raised cutting tops." (*Husb. of the An.*, ii. 388.) But amidst all this variety of ploughs, no one has been able to depict the simplest form of that implement in use among the Romans. Professor John Martyn, in his notes to Virgil's *Georgics*, gives a figure of a modern Italian plough to illustrate Virgil's description. Rosier says the Roman plough was the same as is still used in the south of France (*fig. 11.*) Some authors have made fanciful representations

of it of the rudest construction; others have exhibited more refined pieces of mechanism, but most improbable as portraits.

111. From the different parts of the plough mentioned by the Roman authors, a figure has been imagined and described by the author of the *Husbandry of the Ancients*, which, from his practical knowledge of agriculture, and considerable classical attainments, it is to be regretted he did not live to see delineated. A plough in use from time immemorial in Valentia (*fig. 12.*), is supposed to come the nearest to the common Roman implement.

In it we have the buris or head (a); the temo, or beam (b); the stiva, or handle (c); the dentale, or share head (d); and the vomer or share (e). The other parts, the aura or mould board, and the culter or coulter, composed no part of the simplest form of Roman plough; the plough-staff, or paddle, was a detached part; and the manicura, or part which the ploughman took hold of, was a short bar fixed across, or into the handle, and the draught pole (f) was that part to which the oxen were attached.

112. The plough described by Virgil had a mould board, and was used for covering seed and ridging; but that which we have depicted, was the common form used in stirring the soil. To supply the place of our mould boards, this plough required either a sort of diverging stick (g), inserted in the share head, or to be held obliquely and sloping towards the side to which the earth was to be turned. The Romans did not plough their fields in beds, by circumvolving furrows, as we do; but the cattle returned always on the same side, as in ploughing with a turnwrest plough.

113 Wheel ploughs, Lasteyrie thinks, were invented in or not long before the time of Pliny, who attributes the invention to the inhabitants of Cisalpine Gaul. Virgil seems

to have known such ploughs, and refers to them in his *Georgics*. In the Greek monuments of antiquity are only four or five examples of these. Lasteyrie has given figures of three wheel ploughs from Caylus's *Collection of Antiquities* (fig. 13. a and b), and from a Sicilian medal (c).

114. *The urpex, or trpex*, seems to have been a plank with several teeth, used as our brake or cultivator, to break rough ground, and tear out roots and weeds.

115. *The crates* seems to have been a kind of harrow;

116. *The rastrum*, a rake used in manual labour;

117. *The sarculum*, a hand hoe, similar to our draw hoe; and

118. *The marra*, a hand hoe of smaller size.

119. *The bidens* (bi-dens) seems to have been a two-pronged hoe of large size, with a hammer at the other end used to break clods. These were used chiefly in cultivating vineyards.

120. *The ligo* seems to have been a spade (fig. 14.), and the *pala* a shovel or sort of spade, or probably a synonym. The *ligo* and *pala* were made of wood only, of oak shod with iron, or with the blade entirely of iron.

121. *The securis* seems to have been an axe, and the same term was applied to the blade of the pruning knife, which was formed like a crescent.

122. *The dolabra* was a kind of adze for cutting roots in tree culture.

123. *The reaping hook* seems to have been the same as that in modern use: some were used for cutting off the ears of far or maize, and these, it may be presumed, were not

serrated like our sickles; others for cutting wheat and barley near the ground, like our reaping hooks. In the south of Gaul, Pliny informs us, they had invented a reaping machine: from his description this machine must have borne a considerable resemblance to that used in Suffolk, for cropping the heads off clover left for seed, and not unlike other modern attempts at an engine of this description. (See fig. 16.)

124. *There were threshing implements* for manual labour, and for being drawn by horses; and some for striking off the ears of corn (fig. 15.), like what are called rippling combs, for combing off the capsules of newly pulled flax.

125. *A variety of other instruments* for cleaning corn, and for the wine and oil press, are mentioned; but too obscurely to admit of exact description.

15

14

SUBJECT. 5. *Of the Agricultural Operations of the Romans.*

126. *Of simple agricultural operations*, the most important are ploughing, sowing, and reaping; and of such are compound, or involve various simple operations, fallowing, manuring, weeding, and field-watering.

127. *Ploughing* is universally allowed to be the most important operation of agriculture. "What," says Cato, "is the best culture of land? Good ploughing. What is the second? Ploughing in the ordinary way. What is the third? Laying on manure." (Cap. lxi.) The season for ploughing was any time when land was not wet: in the performance, the furrow is directed to be kept equal in breadth throughout, one furrow equal to another; and straight furrows. The usual depth is not mentioned, but it was probably considerable, as Cato says corn land should be of good quality for two feet in depth. No *scamni* or balks (hard unmoved soil) were to be left, and to ascertain that this was properly attended to, the farmer is directed, when inspecting the work done, to push a pole into the ploughed land in a variety of places. The plough was generally drawn by one pair of oxen, which were guided by the ploughman without the aid of a driver. In breaking up stiff land he was expected to plough half an acre, in free land an acre, and in light land an acre and a half, each day. Land, as already noticed (103.), was ploughed in square plots of 120 feet to the side, two of which made a *jugerum* or acre. A similar practice seems to have existed among the Eastern nations, and is probably alluded to in the book of Samuel (chap. xiv. 5. 14.), where Jonathan and his armour-bearer are said to have slain about twenty men within half an acre, or literally "half a furrow of an acre of land."

128. *Fallowing* was a *universal practice among the Romans*. In most cases, a crop and a year's fallow succeeded each other; though, when manure could be got, two crops or more were taken in succession; and on certain rich soils, which Pliny describes as favourable for barley, a crop was taken every year. In fallowing, the lands were first ploughed after the crop was removed, generally in August; they were again cross-ploughed in spring, and at least a third time before sowing, whether spring corn or winter corn was the crop. There was, however, no limit to the number of ploughings and sarplings, and, when occasioned required, manual operations; the object being, as

Theophrastus observes, "to let the earth feel the cold of winter, and the sun of summer, to invert the soil, and render it free, light, and clear of weeds, so that it can most easily afford nourishment." (*Theo. de Caus. Plant.*, lib. iii. cap. 25.)

129. *Manuring* was held in such high esteem by the Romans, that immortality was given to Sterculius for the invention. They collected it from every source which has been thought of by the moderns, vegetable, animal, and mineral, territorial, aquatic, and marine. Animal dung was divided into three kinds, that produced by birds, that by men, and that by cattle. Pigeon-dung was preferred to all, and next human ordure and urine. Pigeon-dung was used as a top-dressing; and human dung, mixed with cleanings of the villa, and with urine, was applied to the roots of the vine and the olive. "M. Varro," says Pliny, "extols the dung of thrushes from the aviaries, as food for swine and oxen, and asserts that there is no food that fattens them more quickly." Varro prefers it also as a manure; on which Pliny observes, "we may have a good opinion of the manners of our times, if our ancestors had such large aviaries, as to procure from them dung to their fields." (*Nat. Hist.*, lib. xvii. cap. 9.) Dung-hills were directed to be placed near the villa, their bottoms hollowed out to retain the moisture, and their sides and top defended from the sun by twigs and leaves. Dung usually remained in the heap a year, and was laid on in autumn and spring, the two sowing seasons. No more was to be spread than could be ploughed in the same day. Crops that were sickly were revived by sowing over them the dust of dung, especially that of birds, that is, by what is now called a top-dressing. Frequent and moderate dungs are recommended as preferable to occasional and very abundant supplies. Green crops, especially lupines, were sown, and before they came into pod ploughed in as manures: they were also cut and buried at the roots of fruit trees for the same purpose. Trees, twigs, stubble, &c., were burned for manure. Cato says, "If you cannot sell wood and twigs, and have no stone that will burn into lime, make charcoal of the wood, and burn in the corn fields the twigs and small branches that remain." Palladius says that "lands which have been manured by ashes of trees will not require manure for five years." (Lib. i. 6.) Stubble was very generally burned, as it was also among the Jews. Lime was used as a manure, especially for vines and olives. Cato gives particular directions how to form the kiln and burn it. He prefers a truncated cone, ten feet in diameter at the bottom, twenty feet high, and three feet in diameter at the top. The grate covers the whole bottom; there is a pit below for the ashes, and two furnace-doors, one for drawing out the burnt stone, and the other for admitting air to the fire. The fuel used was wood or charcoal. (Cap. 38.)

130. *Marl* was known to the earlier Roman authors, but not used in Italy. It is mentioned by Pliny as having been "found out in Britain and Gaul. . . . It is a certain richness of earth," he says, "like the kernels in animal bodies that are increased by fatness." Marl, he says, was known to the Greeks, "for is there any thing," he adds, "that has not been tried by them? They call the marl-like white clay *leucargillon*, which they use in the lands of Megara, but only where they are moist and cold." (*Nat. Hist.*, lib. xvii. cap. 5. 8.) But though the Romans did not use marl, because they had not discovered it in Italy, they were aware, as Varro and others inform us, of its use. "When I marched an army," says Varro, "to the Rhine, in Transalpine Gaul, I passed through some countries where I saw the fields manured with white fossil clay." (Lib. i. cap. 7.) This must have been either marl or chalk.

131. *Sowing* was performed by hand from a basket, as in modern times; the hand, as Pliny observes, moving with the step, and always with the right foot. The corns and leguminous seeds were covered with the plough, and sometimes so as to rise in drills; the smaller seeds with the hoe and rake.

132. *In reaping corn*, it was a maxim, that it is "better to reap two days too soon than two days too late." Varro mentions three modes of performing the operation: cutting close to the ground with hooks, a handful at a time; cutting off their ears with a curved stick, and a saw attached; and cutting the stalks in the middle, leaving the lower part or stubble to be cut afterwards. Columella says, "Many cut the stalks by the middle, with drag-hooks, and these either beaked or toothed: many gather the ears with *mergeæ*, and others with combs. This method does very well where the crop is thin; but it is very troublesome where the corn is thick. If, in reaping with hooks, a part of the straw is cut off with the ears, it is immediately gathered into a heap, or into the nubilarium, and after being dried, by being exposed to the sun, is threshed. But if the ears only are cut off, they are carried directly to the granary, and threshed during the winter." (*Col.*, lib. ii. cap. 21.) To these modes Pliny adds that of pulling up by the roots; and remarks, generally, that, "where they cover their houses with stubble, they cut high, to preserve this of as great a length as possible; when there is a scarcity of hay, they cut low, that straw may be added to the chaff." (*Nat. Hist.*, lib. xviii. cap. 30.)

133. *A reaping machine* used in the plains of Gaul, is mentioned both by Pliny and Palladius, which is thus described by the latter:—"In the plains of Gaul, they use this quick way of reaping, and, without

reapers, cut large fields with an ox in one day. For this purpose a machine is made, carried upon two wheels; the square surface has boards erected at the side, which, sloping outwards, make a wider space above; the board on the fore part is lower than the others; upon it there are a great many small teeth, wide set in a row, answering to the height of the ears of the corn, and turned upwards at the ends; on the back part of this machine two short shafts are fixed, like the poles of a litter; to these an ox is yoked, with his head to the machine, and the yoke and traces likewise turned the contrary way: he is well trained, and does not go faster than he is driven. When this machine is pushed through the standing corn, all the ears are comprehended by the teeth, and heaped up in the hollow part of it, being cut off from the straw, which is left behind; the driver setting it higher or lower, as he finds it necessary; and thus, by a few goings and returnings, the whole field is reaped. This machine does very well in plain and smooth fields, and in places where there is no necessity for feeding with straw." (*Pal.*, lib. vii. tit. 2.) A conjectural delineation of this machine (*fig. 16.*) is given by Læteyrie, in his *Collection des Machines*, &c.

134. *The Romans did not bind their corn into sheaves, as is customary in northern climates. When cut it was in general sent directly to the area to be threshed; or, if the ears only were cropped, sent in baskets to the barn. Among the Jews, Egyptians, and Greeks, the corn was bound in sheaves; or at least some kinds were so treated, as appears from the story of Ruth "gleaning among the sheaves;" of Joseph's dream, in which his "sheaf arose;" and from the harvest represented by Homer, on one of the compartments of Achilles's shield. (Il., lib. xviii. 550.)* Reapers were set in bands on the opposite sides of the field or plot, and worked towards the centre. As the land was ploughed in the same manner from the sides to the middle, there was an open furrow left there, to which the reapers hastened in the way of competition. A reaper was expected to cut down a jugerum of wheat in a day and a half; of barley, legumes, and medica or clover, in one day; and of flax in three days.

135. *Threshing was performed in the area or threshing floor, a circular space of from 40 to 60 feet in diameter, in the open air, with a smooth hard surface. The floor was generally made of well wrought clay mixed with amurca or the lees of oil; sometimes it was paved. It was generally placed near the nubilarium or barn, in order that when a sudden shower happened, during the process of threshing, the ears might be carried in there out of the rain. Sometimes also the ears or unthreshed corn of the whole farm were first put in this barn and carried out to the area afterwards. Varro and Columella recommended that the situation of the area should be high and airy, and within sight of the farmer or bailiff's house, to prevent fraud; distant from gardens and orchards, because, though dung and straw are beneficial to the roots of vegetables, they are destructive when they fall on their leaves.*" (*Var.*, lib. i. cap. 51.)

136. *The corn being spread over the area a foot or two in thickness, was threshed or beaten out by the hoofs of cattle, or horses driven round it, or dragging a machine over it. This machine, Varro informs us, was "made of a board, rough with stones or iron, with a driver or great weight placed on it." A machine composed of rollers studded with iron knobs, and furnished with a seat for the driver (fig. 17.), was used in the Carthaginian territory. Sometimes also they threshed with rods or flails. Far, or Indian corn (Zea Mays L.), was generally hand-picked, or passed through a handmill.*

137. *Corn was cleansed or winnowed by throwing it from one part of the floor to another (in the wind when there was any), with a kind of shovel called ventilabrum; another implement, called a van, probably a kind of sieve, was used when there was no wind. After being dressed, the corn was laid in the granary, and the straw either laid aside for litter, or, what is not a little remarkable, "sprinkled with brine; then, when dried, rolled up in bundles, and so given to the oxen for hay." (Plin. Nat. Hist., lib. xviii. cap. 30.)*

138. *Hay-making among the Romans was performed much in the same way as in modern times. The meadows were mown when the flowers of the grass began to fade; "as it dries," says Varro, "it is turned with forks; it is then tied up in bundles of four pounds each, and carried home, and what is left strewed upon the meadow is raked together, and added to the crop." "A good mower," Columella informs us, "cuts a jugerum of meadow, and binds twelve hundred bundles of hay." It is probable that this quantity, which is nearly two tons, was the produce per acre of a good crop. A second crop was cut, called cordum, and was chiefly used for feeding sheep in winter. Hay*

was also made of leafy twigs for the same purpose. Cato directs the bailiff to "cut down poplar, elm, and oak spray, and put them up in time, not over dry, for fodder for the sheep." (Cap. 5.)

139. *Weeding and stirring the soil* were performed, the first by cutting with a hook, or pulling the weeds up with the hand; and the second by sarcling or hoeing. Beans were hoed three times, and corn twice: the first time they were earthed up, but not the second or third; "for," says Columella, "when the corn ceases to tiller, it rots if covered with earth." Lupines were not sarclad at all, "because so far from being infested with weeds, they destroy them." Horse-hoeing was also practised, the origin of which is thus given by Pliny:—"We must not omit," says he, "a particular method of ploughing, at this time practised in Italy beyond the Po, and introduced by the injuries of war. The Salassi, when they ravaged the lands lying under the Alps, tried likewise to destroy the panic and millet that had just come above ground. Finding that the situation of the crop prevented them from destroying it in the ordinary way, they ploughed the fields; but the crop at harvest being double what it used to be, taught the farmer to plough amongst the corn." This operation, he informs us, was performed, either when the stalk was beginning to appear, or when the plant had put forth two or three leaves. The corn being generally sown in drills, or covered with the plough, so as to come up in rows, readily admitted this practice.

140. *Pasturing and harrowing corn*, when too luxuriant, were practised. Virgil says, "What commendation shall I give to him, who, lest his corn should lodge, pastures it while young, as soon as the blade equals the furrow." (*Geor.*, i. 111.) Pliny directs to comb the corn with a harrow before it is pastured, and sarcle it afterwards.

141. *Watering* on a large scale was applied both to arable and grass lands. Virgil advises to "bring down the waters of a river upon the sown corn, and when the field is parched, and the plants dying, convey it from the brow of a hill in channels." (*Geor.*, i. 106.) Pliny mentions the practice, and observes that the water destroys the weeds, nourishes the corn, and serves in place of sarcling. Watering grass lands was practised wherever an opportunity offered. "As much as in your power," says Cato, "make watered meadows." Land that is naturally rich and in good heart, says Columella, "does not need to have water set over it, because the hay produced in a juicy soil is better than that excited by water; when the poverty of the soil requires it, however, water may be set over it." The same author likewise describes, very particularly, the position of the land most proper for water meadows. "Neither a low field," says he, "with hollows, nor a field broken with steep rising grounds, are proper. The first, because it contains too long the water collected in the hollows; the last, because it makes the water to run too quickly over it. A field, however, that has a moderate descent, may be made a meadow, whether it is rich or poor, if so situated as to be watered. But the best situation is, where the surface is smooth, and the descent so gentle, as to prevent either showers, or the rivers that overflow it, from remaining long; and, on the other hand, to allow the water that comes over it gently to glide off. Therefore, if in any part of a field intended for a meadow, a pool of water should stand, it must be let off by drains; for the loss is equal, either from too much water or too little grass." (*Col.*, lib. ii. cap. 17.)

142. *Old water meadows were renewed by breaking up and sowing them with corn* for three years; the third year they were laid down with vetches and grass seeds, and then watered again, but "not with a great force of water, till the ground had become firm and bound together with turf." (*Col.*, lib. ii. cap. 18.) Watering, Pliny informs us, was commenced immediately after the equinox, and restrained when the grass sent up flower stalks; it was recommenced in mowing grounds, after the hay season, and in pasture lands at intervals.

143. *Draining*, though an operation of an opposite nature to watering, is yet essential to its success. It was particularly attended to by the Romans, both to remove surface water, and to intercept and carry off under the surface the water of springs. Cato gives directions for opening the furrows of sown fields, and clearing them so as the water might find its way readily to the ditches: and for wet-bottomed lands he directs to make drains three feet broad at top, four feet deep, and a foot and a quarter wide at the bottom; to lay them with stones, or, if these cannot be got, with willow rods placed contrariwise, or twigs tied together. (Cap. 43.) Columella directs both open and covered drains to be made sloping at the sides, and in addition to what Cato says respecting the water-ways of covered drains, directs to make the bottom narrow, and fit a rope made of twigs to it, pressing the rope firmly down, and putting some leaves or pine branches over it before throwing in the earth. Pliny says the ropes may be made of straw, and that flint or gravel may be used to form the water-way, filling the excavation half full, or to within eighteen inches of the top.

144. *Fencing* was performed by the Romans, but only to a limited extent. Varro says "the limits of a farm should be fenced (rendered obvious) by planting trees, that families may not quarrel with their neighbours, and that the limits may not want the

decision of a judge." (Lib. i. 15.) Palladius directs to enclose meadows, and gardens, and orchards. Columella mentions folds for enclosing the cattle in the night-time; but the chief fences of his time were the enclosures called parks for preserving wild beasts, and forming agreeable prospects from the villas of the wealthy. Pliny mentions these, and says they were the invention of Fulvius Lupinus. (*Nat. Hist.*, lib. viii.) Varro describes fences raised by planting briars or thorns, and training them into a hedge; and these, he says, have the advantage of not being in danger from the burning torch of the wanton passenger; fences of stalks, interwoven with twigs, ditches with earthen dykes, and walls of stone or brick, or rammed earth and gravel. (Lib. i. cap. 14.)

145. *Trees* were pruned and felled at different times, according to the object in view. The olive was little cut; the vine had a winter dressing, and one or two summer dressings. Green branches or spray, of which the leaves were used as food for oxen and sheep, were cut at the end of summer; copse wood for fuel, in winter; and timber trees generally in that season. Cato, however, directs that trees which are to be felled for timber should be cut down at different times, according to their natures: such as ripen seeds, when the seed is ripe; such as do not produce seeds, when the leaves drop; such as produce both flowers and seeds at the same time, also when the leaves drop; but if they are evergreens, such as the cypress and pine, they may be felled at any time.

146. *Fruits* were gathered by hand. The ripest grapes were cut first; such as were selected for eating were carried home and hung up; and those for the press were put in baskets, and carried to the wine-press to be picked and then pressed. Olives were plucked by hand, and some selected for eating; the rest were laid up in lofts for future bruising, or they were immediately pressed. Such as could not be reached by ladders, Varro directs to be "struck with a reed rather than with a rod, for a deep wound requires a physician." It does not appear that green olives were pickled and used as food as in modern times.

147. *Such are the chief agricultural operations of the Romans*, of which it cannot fail to be observed as most remarkable, that they differ little from what we know of the rural operations of the Jews and Greeks on the one hand, and from the practices of modern times on the other.

SUBJECT. 6. *Of the Crops cultivated, and Animals reared by the Romans.*

148. *The cereal grasses* cultivated by the Romans were chiefly the *triticum* or wheat, the *far*, or Indian corn (*Zea*), and the *hordeum* or barley: but they sowed also the *siligo* or rye, the *holcus* or millet, the panic grass (*Panicum miliaceum*), and the *avena* or oat.

149. *Of legumes* they cultivated the *fabæ* or bean, the *pisum* or pea, the *lupinus* or lupine, the *ervum* or tare, the *lens* or flat tare (*Lathyrus Cicera*), the chickling vetch (*Lathyrus sativus*), the chick or mouse pea (*Cicer arietinum*), and the kidneybean (*Phaseolus*). The bean was used as food for the servants or slaves, the others were grown principally for food to the labouring cattle.

150. *The sesamum*, or oily grain (*Sesamum orientale* L.) (fig. 18.), was cultivated for the seeds, from which an oil was expressed, and used as a substitute for that of olives, as it still is in India and China, and as the oil of the poppy is in Holland, that of the walnut in Savoy, and that of the hemp in Russia.

151. *The herbage plants* were chiefly the *trifolium* or clover, the medic or lucern, and the *cytissus*. What the latter plant is, has not been distinctly ascertained. They cultivated also the *ocymum* and *fœnum græcum*, with several others, which from the descriptions left of them cannot now be identified. The *napus* or turnip, and *rapa* or rape, were much esteemed and carefully cultivated. Pliny says "they require a dry soil; that the rapa will grow almost any where; that it is nourished by mists, hoar-frosts, and cold; and that he has seen some of them upwards of forty pounds' weight. The *napus*," he says, "delights equally in colds, which make it both sweeter and larger, while by heat they grow to leaves." He adds, "the more diligent husbandmen plough five times for the *napus*, four times for the *rapa*, and apply dung to both." (*Nat. Hist.*, lib. xviii. cap. 13.) Palladius recommends soot and oil as a remedy against flies and snails, in the culture of the *napus* and *rapa*. While the turnips were growing, it appears, persons were not much restricted from pulling them. Columella observes that, in his time, the more religious husbandmen still observed an ancient custom, mentioned by Varro as being recorded by Demetrius, a Greek. This was, that while sowing them they prayed they might grow both for themselves and neighbours. Pliny says the sower was naked.

152. *Of crops used in the arts* may be mentioned the flax, the sesamum already mentioned, and the poppy; the two latter were grown for their seeds, which were bruised for oil.

153. *The ligneous crops* were willows, both for basketmaking, and as ties and poles for olives and vines. Cupse wood was grown in some places for fuel; but chiefly in natural woods, which were periodically cut. Timber was also procured from the natural forests, which were abundant in oak, elm, beech, pine, and larix.

154. *The fruit trees* cultivated extensively were the vine and the olive. The fig was grown in gardens and orchards, and also the pear; and in the gardens of the wealthy were found most fruits in present use, with the exception of the pineapple, the gooseberry, and perhaps the orange, though the lemon seems to have been known in Palladius's time. The vine was supported by elms or poplars (fig. 19.), or tied to different sorts of trellises (fig. 20.), as in Italy at the present day.

20

155. *Such are the principal field crops of Roman agriculture* from which, and from the list of cultivated vegetables given by Pliny, it appears that they had most plants and trees now in use, with the exception of the potato, and one or two others of less consequence.

156. *Of animals reared*, the quadrupeds were of the same kinds as at present; and to the common sorts of poultry they added thrushes, larks, peacocks, and turtle doves; they also reared snails, dormice, bees, and fish. The care of the poultry was chiefly committed to the wife of the farmer or bailiff; and it was principally near Rome and Naples that the more delicate birds were extensively reared. When Rome was at her greatest height, in the time of the Cæsars, the minor articles of farm produce bore a very high price. Varro informs us that "fat hiris, such as thrushes, blackbirds, &c., were sold at two shillings, and sometimes 5000 of them were sold in a year from one farm. (*Var.*, lib. iii. cap. 2.) Pea-fowls were sold at 1*l.* 13*s.* 4*d.*; an egg was sold at 3*s.* 4*d.* A farm produced sometimes as many of these fowls as to sell at 500*l.* (*Var.*, lib. iii. cap. 6.) A pair of fine doves were commonly of the same price with a peacock, 1*l.* 13*s.* 4*d.* If very pretty, they were much higher in the price, no less than 8*l.* 6*s.* 8*d.* L. Anius, a Roman knight, refused to sell a pair under 13*l.* 6*s.* 8*d.*" (*Var.*, lib. iii. cap. 7.) Some kinds of fishes were very highly valued among the Romans in the time of Varro. Hortensius, whom Varro used frequently to visit, would sooner have parted with a pair of his best coach-nules, than with a bearded mullet. (*Var.*, lib. iii. cap. 17.) Herrius's fishponds, on account of the quantity of fish, were sold for 33,333*l.* 6*s.* 8*d.* (*Plin. Nat. Hist.*, lib. ix. cap. 55.); Lucullus's, likewise, for the same price. (*Id.*, lib. ix. cap. 54.)

SUBJECT. 7. *Of the general Maxims of Farm Management among the Romans.*

157. *In every art which has been long practised, there are maxims of management which have been handed down from one generation to another*; and in no art are there more of these than in agriculture. Maxims of this sort were held among the Romans in the greatest estimation, and their writers have recorded a number derived from the lost Greek writers, and from their own traditionary or experimental knowledge. A few of these shall be noticed, as characteristic of Roman economy, and not without their use in modern times.

158. *To sow less and plough better* was a maxim indicating that the extent of farms ought to be kept in their proper bounds. Pliny and Virgil consider large farms as prejudicial, and Columella says, one of the seven wise men has pronounced that there should be limits and measures in all things. "You may admire a large farm, but cultivate a small one;" and the Carthaginian saying, that "the land ought to be weaker than the husbandman," were maxims to the same effect.

159. *The importance of the master's presence* in every operation of farming, was incalculated by many maxims. "Whoever would buy a field ought to sell his house, lest he delight more in the town than in the country," was a saying of Mago. "Wherever the eyes of the master most frequently approach," says Columella, "there is the greatest increase." It is justly remarked by the Rev. A. Dickson, that though "every person knows that the presence and attention of the master is of great importance in every business; yet every person does not know, that in no business are they so important as in farming." (*Husb. of the An.*, i. 206.)

160. *That more is to be gained by cultivating a small spot well than a large space indifferently*, is illustrated by many sayings and stories. "A vine-dresser had two daughters and a vineyard; when his eldest daughter was married, he gave her a third of his vineyard for a portion; notwithstanding which, he had the same quantity of fruit as formerly. When his younger daughter was married he gave her the half of what remained, and still the produce of his vineyard was not diminished." (*Col.*, lib. iv. cap. 3.) Pliny mentions a freedman, who having much larger crops than his neighbours, was accused of witchcraft

and brought to trial. He produced in the forum a stout daughter, and his excellently constructed iron spades, shears, and other tools, with his oxen, and said, "These, Romans, are my charms." He was acquitted. (*Nat. Hist.*, lib. xviii. cap. 6.)

161. *Ostentatious or profuse culture* is not less condemned than imperfect culture. "The ancients," says Pliny, "assert that nothing turns to less account than to give land a great deal of culture. To cultivate well is necessary, to cultivate in an extraordinary manner is hurtful. In what manner, then," he asks, "are lands to be cultivated to the best advantage?" To this he answers, "In the cheapest manner, if it is good;" or "by good bad things," which, he says, were the words in which the ancients used to express this maxim.

162. *Industry* is recommended by numerous maxims. "The ancients," says Pliny, "considered him a bad husbandman who buys what his farm can produce to him; a bad master of a family, who does in the day-time what he may do at night, except in the time of a storm; a worse, who does on common days what is lawful on holidays; the worst of all, who on a good day is employed more within doors than in the fields." (*Nat. Hist.*, lib. xviii. cap. 6.)

163. *Kindness and humanity to servants and slaves* is strongly recommended. "Slaves," says Varro, "must not be timid nor petulant. They who preside must have some degree of learning and education; they must be frugal, older than the workmen, for the latter are more attentive to the directions of these, than they are to those of younger men. Besides, it must be most eligible that they should preside, who are experienced in agriculture; for they ought not only to give orders, but to work, that they may imitate him, and that they may consider that he presides over them with reason, because he is superior in knowledge and experience: nor is he to be suffered to be so imperious to use coercion with stripes rather than words, if this can be done. Nor are many to be procured of the same country, for domestic animosities very often arise from this source. You must encourage them who preside, by rewarding them, and you must endeavour to let them have some privilege, and maid servants wedded to them, by whom they may have a family; for by these means they become more steady and more attached to the farm. On account of these connections, the Epirotic families are so distinguished and attached. To give the persons who preside some degree of pleasure, you must hold them in some estimation; and you must consult with some of the superior workmen concerning the work that is to be done: when you behave thus, they think that they are less despicable, and that they are held in some degree of esteem by their master. They become more eager for work by liberal treatment, by giving them victuals, or a large garment, or by granting them some recreation or favour, as the privilege of feeding something on the farm, or some such thing. In relation to them, who are commanded to do work of greater drudgery, or who are punished, let somebody restore their good will and affection to their master by affording them the benefit of consolation."

164. *Knowledge in matters relative to agriculture* is inculcated by all the rustic authors. "Whoever," says Columella, "would be perfect in this science, must be well acquainted with the qualities of soils and plants; must not be ignorant of the various climates, that so he may know what is agreeable, and what is repugnant, to each; he must know exactly the succession of the seasons, and the nature of each, lest, beginning his work when showers and wind are just at hand, his labour shall be lost. He must be capable to observe exactly the present temper of the sky and seasons; for these are not always regular, nor in every year does the summer and winter bring the same kind of weather, nor is the spring always rainy, and the autumn wet. To know these things before they happen, without a very good capacity, and the greatest care to acquire knowledge, is, in my opinion, in the power of no man." (*Col.*, lib. i. præf.) To these things mentioned by Columella, Virgil adds several others. "Before we plough a field to which we are strangers," says he, "we must be careful to attain a knowledge of the winds, from what points they blow at the particular seasons, and when and from whence they are most violent; the nature of the climate, which in different places is very different; the customs of our forefathers; the customs of the country; the qualities of the different soils; and what are the crops that each country and climate produces and rejects." (*Virg. Georg.*, i. 1.)

165. *The making of experiments* is a thing very strongly recommended to the farmer by some of our authors. "Nature," says Varro, "has pointed out to us two paths, which lead to the knowledge of agriculture, viz. experience and imitation. The ancient husbandmen, by making experiments, have established many maxims. Their posterity, for the most part, imitate them; we ought to do both, imitate others and make experiments ourselves, not directed by chance, but reason." (*Var.*, lib. i. cap. 18.)

SECT. V. *Of the Produce and Profit of Roman Agriculture.*

166. *The topics of produce and profits in agriculture, are very difficult to be discussed satisfactorily.* In manufactures the raw material is purchased for a sum certain, and the

manipulation given by the manufacturer can be accurately calculated ; but in farming, though we know the rent of the land and price of seed-corn, which may be considered the raw materials ; yet the quantity of labour required to bring forth the produce, depends so much on seasons, accidents, and other circumstances, to which agriculture is more liable than any other art, that its value or cost price cannot easily be determined. It is a common mode to estimate the profits of farming by the numerical returns of the seed sown. But this is a most fallacious ground of judgment, since the quantity of seed given to lands of different qualities, and of different conditions, is very different ; and the acre, which, being highly cultivated and sown with only a bushel of seed, returns forty for one, may yield no more profit than that which, being in a middling condition, requires four bushels of seed, and yields only ten for one.

167. *The returns of seed sown*, mentioned by the ancients, are very remarkable. We have noticed Isaac's sowing and reaping at Gerar (7.), where he received a hundred for one. In Mark's gospel, "good seed sown upon good ground, is said to bring forth in some places thirty, in others forty, in others sixty, and in others even an hundred fold." (*Mark*, iv. 8.) A hundred fold, Varro informs us, was reaped about Garada in Syria, and Byzacium in Africa. Pliny adds, that from the last place, there were sent to Augustus by his factor nearly 400 stalks, all from one grain ; and to Nero, 340 stalks. He says he has seen the soil of this field, "which when dry the stoutest oxen cannot plough ; but after rain I have seen it opened up by a share, drawn by a wretched ass on the one side, and an old woman on the other." (*Nat. Hist.*, lib. xviii. cap. 5.) The returns in Italy were much less extraordinary. Varro says, there are sown on a jugerum, four modii (pecks) of beans, five of wheat, six of barley, and ten of far (maize) ; more or less as the soil is rich or poor. The produce is in some places ten after one, but in others, as in Tuscany, fifteen after one." (*Lib. i. cap. 44.*) This, in round numbers, is at the rate of twenty-one and thirty-two bushels an English acre. On the excellent lands of Leontinum in Sicily, the produce, according to Cicero, was no more than from eight to ten for one. In Columella's time, when agriculture had declined, it was still less.

168. *The farmer's profit* cannot be correctly ascertained ; but, according to a calculation made by the Rev. A. Dickson, the surplus produce of good land in the time of Varro, was about fifteen pecks of wheat per acre ; and in the time of Columella, lands being worse cultivated, it did not exceed three and one third pecks per acre. What proportion of this went to the landlord cannot be ascertained. Corn, in Varro's time, was from 4*d.* to 5½*d.* per peck ; seventy years afterwards, in the time of Columella, it had risen to 1*s.* 9*d.* per peck. Vineyards were so neglected in the time of this author, that they did not yield more to the landlord as rent, than 1*s.* or 1*s.* 6*d.* per acre.

169. *The price of land*, in the time of Columella and Pliny, was twenty-five years' purchase. It was common, both these writers inform us, to receive 4 per cent for capital so invested. The interest of money was then 6 per cent ; but this 6 per cent was not what we would call legal interest ; money among the Romans being left to find its value, like other commodities, of course the interest was always fluctuating. — Such is the essence of what is known as to the produce, rent, and price of lands among the Romans.

SECT. VI. *Of the Roman Agriculturists, in respect to general Science, and the Advancement of the Art.*

170. *The sciences cultivated by the Greeks and Romans were chiefly of the mental and mathematical kind.* They knew nothing of chemistry or physiology, and very little of other branches of natural philosophy ; and hence their progress in the practical arts was entirely the result of observation, experience, or accident. In none of their agricultural writers is there any attempt made to give the *rationale* of the practices described : absolute directions are either given, as is frequently the case in Virgil and Columella ; or the historical relation is adopted, and the reader is informed what is done by certain persons, or in certain places, as is generally the case with Varro and Pliny.

171. *Wherever the phenomena of nature are not accounted for scientifically, recourse is had to supernatural causes ;* and the idea of this kind of agency once admitted, there is no limit that can be set to its influence over the mind. In the early and ignorant ages, good and evil spirits were supposed to take a concern in every thing ; and hence the endless and absurd superstitions of the Egyptians, some of which have been already noticed, and the equally numerous though perhaps less absurd rites and ceremonies of the Greeks, to procure their favour, or avert their evil influence. Hesiod considered it of not more importance to describe what works were to be done, than to describe the lucky and unlucky days for their performance. Homer, Aristotle, Theophrastus, and all the Greek authors, are more or less tinctured with this religion, or superstition as we are pleased to call it, of their age.

172. *As the Romans made few advances in science, consequently they made equally few in divesting themselves of the superstitions of their ancestors.* These, as most readers know, entered into every action and art of that people, and into none more than agri-

culture. In some cases it is of importance for the general reader to be aware of this, before perusing their rustic authors; as in the case of heterogeneous grafting, and the spontaneous generation and transmutation of plants, which, though stated by Virgil and Pliny, and others, as facts, are known to every physiologist to be impossible: but other relations are too gross to be entertained as truths by any one. Of these we may mention the lunar days, the impregnation of animals by particular winds, &c. It is impossible not heartily to concur with Lord Kaimes in congratulating the present age on its delivery from such "heavy fetters." It is curious to observe the religious economy of Cato. After recommending the master of the family to be regular in performing his devotions, he expressly forbids the rest of the family to perform any, either by themselves or others, telling them that they were to consider that the master performed sufficient devotions for the family. (*Cat.*, cap. 43.) This was probably intended not only to save time, but also to prevent such slaves as had naturally more susceptible imaginations than the others, from becoming religious enthusiasts.

173. *What degree of improvement agriculture received from the Romans*, is a question we have no means of answering. Agriculture appears obviously to have declined from the time of Cato and Varro to Pliny; and therefore any improvement it received must have taken place antecedently to their era. As these authors, however, generally refer to the Greeks as their masters in this art, it appears very doubtful whether they did any thing more than imitate their practice. As a more luxurious people, they introduced new fruits, and probably improved the treatment of birds, and other minor products; but these belong more to gardening and domestic economy, than to field cultivation. In the culture of corn, herbage, plants, and fruit trees, and in the breeding and rearing of cattle, Noah and his sons, the Jews, the Babylonians, Egyptians, and Greeks, may have been as far advanced as the Romans, for any thing that appears to the contrary. The great agricultural advantage which mankind have derived from the Romans, is the diffusion of the art by their almost universal conquests.

SECT. VII. *Of the Extent to which Agriculture was carried in the Roman Provinces, and of its Decline.*

174. *The art of agriculture was not only familiar to, but held in estimation by, every Roman soldier.* It was practised by him in every foreign country where he was stationary; and he taught it to the inhabitants of such as were uncultivated. In some countries, as in Carthagina, great part of Spain, and a part of the south-east of France, agriculture was as far advanced as in Italy; because at Carthage and Marseilles the Greeks had planted colonies, which flourished anterior to the Romans, or at least long before they extended their conquests to these countries: but in Helvetia, Germany, and Britain, it was in a very rude state or unknown.

175. *In Germany*, except on the borders of the Rhine, agriculture was never generally practised. The greater part of the country was covered with forests; and hunting and pasturage were the chief occupations of the people when not engaged in war. The decline of the Roman power in that country, therefore, could make very little difference as to its agriculture.

176. *In Britain*, according to Cæsar, agriculture was introduced by colonies from Belgium, which took shelter there from the encroachments of the Belgæ from Germany, about B. C. 150. These colonies began to cultivate the sea coasts; but the natives of the inland parts lived on roots, berries, flesh, and milk, and it appears from Dionysius that they never tasted fish. Pliny mentions the use of marl as being known to the Britons; and Diodorus Siculus describes their method of preserving corn, by laying it up in the ear in caves or granaries.

177. *But the general spread of agriculture in Britain* was no doubt effected by the Romans. The tribute of a certain quantity of corn, which they imposed on every part of the country, as it fell under their dominion, obliged the inhabitants to practise tillage; and from the example of the conquerors, and the richness of the soil, they soon not only produced a sufficient quantity of corn for their own use and that of the Roman troops, but afforded every year a very great surplus for exportation. The Emperor Julian, in the fourth century, built granaries to receive this corn, and on one occasion sent a fleet of eight hundred ships, "larger than common barks," to convey it to the mouth of the Rhine, where it was sent up the country for the support of the plundered inhabitants.

178. *Agriculture among the Romans themselves had begun to decline in Varro's time*, and was at a low ebb in the days of Pliny. Many of the great men in Rome, trusting to their revenues from the provinces, neglected the culture of their estates in Italy; others, in want of money to answer the demands of luxury, raised all they could upon credit or mortgage, and raised the rents of their tenants to an oppressive height to enable them to pay the interest. The farmer was in this manner deprived of his capital; his spirits were broken, and he ceased to exert himself, or became idle and rapacious like his landlord. The civil wars in the end of the second century, the tyrannic conduct of

the emperors in the third ; and the removal of the seat of empire to Constantinople in the middle of that which followed, prepared the way for the entrance of the Goths in the beginning of the fifth century, which completed the downfall of agriculture and every peaceful art. It declined at the same time in all the western provinces : in Africa and Spain, from the incursions of the Moors ; in France, from the inroads of the Germans ; in Germany and Helvetia, from the inhabitants leaving their country and preferring a predatory life in other states ; and in Britain, from the invasion of the Saxons, and the inroads of the Scots and Picts.

CHAP. III.

History of Agriculture during the Middle Ages, or from the Fifth to the Seventeenth Century.

179. *In the ages of anarchy and barbarism which succeeded the fall of the Roman power in Europe, agriculture appears to have been abandoned, or at least extremely neglected. Pasturage, in troublesome times, is always preferred to tillage, because sheep or cattle may be concealed from an enemy, or driven away on his approach ; but who would sow without a certainty of being able to reap ? Happily, the weaknesses of mankind sometimes serve to mitigate the effects of their vices. Thus, the credulity of the barbarians of those times led them to respect the religious establishments, and in these were preserved such remains of letters and of arts as had escaped from utter destruction. These institutions were at first very limited, both in their buildings and possessions, and the inhabitants frugal and virtuous in their habits ; but in a very few years, by the grants of the rich warriors, they acquired extensive possessions ; erected the most magnificent buildings, and lived in abundance and luxury. Their lands were cultivated by servants, under the direction of the priests, who would have recourse for information to the Roman agricultural writers, which, in common with such other books as then existed, were almost exclusively to be found in their libraries. We know little of the progress of agriculture under these circumstances for nearly ten centuries, when it began to revive throughout Europe among the lay proprietors. We shall notice some particulars relative to this revival, first in Italy, and next in Germany, France, and England. So little is known of the husbandry of Spain and the Netherlands during this period, that we shall defer what we have to say of those countries till we treat of their modern state.*

SECT. I. *History of Agriculture in Italy, during the Middle Ages.*

180. *Little is known of the agriculture of Italy from the time of Pliny till that of Crescenzo, a senator of Bologna, whose work In Commodum Ruralium, written in 1300, was first printed at Florence in 1478. He was soon followed by several of his countrymen, among whom Tatti, Stefano, Augustino Gallo, Sansovino, Lauro, and Torello deserve to be mentioned with honour. From some records, however, it appears that irrigation had been practised in Italy previously to 1037. The monks of Chiarevalle had formed extensive works of this kind, and had become so celebrated as to be consulted and employed as hydraulic engineers, by the Emperor Frederic I., in the thirteenth century. Silkworms were imported from Greece into Sicily by Roger, the first king of that island, in 1146 ; but they did not extend to the Continental states for many years afterwards.*

181. *In the early part of the fourteenth century, the inhabitants of the south of Italy were strangers to many of the conveniences of life ; they were ignorant of the proper cultivation of the vine, and the common people were just beginning to wear shirts. The Florentines were the only people of Italy who, at that time, traded with England and France. The work of Crescenzo is, in great part, a compilation from the Roman authors ; but an edition published at Basil in 1548, and illustrated with figures, may probably be considered as indicating the implements then in use. The plough is drawn by only one ox : but different kinds to be drawn by two and four oxen are described in the text. A driver is also mentioned, which shows that the ploughmen in those days were less expert than during the time of the Romans, who did not use drivers. A waggon is described with a wooden axle and low wooden wheels ; each wheel formed either of one piece or of four pieces joined together. Knives, scythes (fig. 21.), and grafting tools, as well as the mode of performing the operation, are figured. Sowing was then performed exactly as it was among the Romans, and is still in most parts of Europe, where a sowing machine is not employed. The various hand tools for stirring and turning the soil are described and exhibited ; and the Roman bidens shown as in use for cultivating the vine. All the agricultural and horticultural plants described by Pliny are treated of, but no others.*

182. *Towards the end of the sixteenth century*, Torcello's *Ricordo d'Agricoltura* was published. In 1584, Pope Sixtus, according to Harte (*Essay i.*), forced his subjects to work, that they might pay the heavy taxes imposed on them; and by this means rendered them happy and contented, and himself rich and powerful. He found them sunk in sloth, overrun with pride and poverty, and lost to all sense of civil duties; but he recovered them from that despicable state, first to industry, and next to plenty and regularity.

183. *Naples* being at this period a Spanish province, the wars in which Spain was engaged obliged her to put a tax upon fruit; and as fruits were not only the chief delicacies, but articles of subsistence, among the Neapolitans, this imposition is said to have rendered them industrious. But though some agricultural books were published at Naples during the sixteenth century, there is no evidence that they ever made much progress in culture. Their best lands are in Sicily; and on them a corn crop and a fallow was and is the rotation, and the produce seldom exceeded eight or ten for one, as in the time of the Romans. This is the case in Sicily at present; and it is likely that it was not different, or at least, that it was not better, from the fifth to the seventeenth centuries.

184. *The greatest agricultural improvements in Italy* which took place during the period in question, were in Tuscany and Lombardy. In the former country the culture of the vine and the olive were brought to greater perfection than any where else in Europe. The oil of Lucca and the wines of Florence became celebrated in other countries, and the commerce in these articles enriched the inhabitants, and enabled the proprietors to bestow increased attention on the cultivation of their estates. Lombardy excelled in the management of corn and cattle as well as of the vine. The butter, cheese, and beef of the country, were esteemed the best in Italy. The pastures were at that time, and still are, more productive than any in Europe, or perhaps in the world, having the three advantages of a climate so temperate in winter that the grass grows all the year, a soil naturally rich, and an abundant supply of river water for irrigation. The irrigation of Lombardy forms the chief feature of its culture. It was begun and carried to a considerable extent under the Romans, and in the period of which we speak extended and increased under the Lombard kings and wealthy religious establishments. Some idea may be formed of the comfort of the farmers in Lombardy in the thirteenth century, by the picture of a farm-house given by Crescenzo, who lived on its borders, which, as a French antiquarian (Paulinay) has observed, differs little from the best modern ones of Italy, but in being covered with thatch.

SECT. II. *History of Agriculture in France, from the Fifth to the Seventeenth Century.*

185. *The nations who conquered France in the fifth century* were the Goths, Vandals, and Franks. The two former nations claimed two thirds of the conquered lands (*Leges Burgundiorum*, tit. 54.), and must of course have very much altered both the state of property, and the management of the affairs of husbandry. The claim of the Franks is more uncertain; they were so much a warlike people, that they probably dealt more favourably with those whom they subjected to their dominion.

186. *All that is known of the agriculture of these nations and of France, till the ninth century*, is derived from a perusal of their laws. These appear to have been favourable to cultivation, especially the laws of the Franks. Horses are frequently mentioned, and a distinction made between the war horse and farm horse, which shows that this animal was at that period more common in France than in Italy. Horses, cattle, and sheep were pastured in the forests and commons, with bells about the necks of several of them, for their more ready discovery. The culture of vines and orchards was greatly encouraged by Charlemagne in the ninth century. He planted many vineyards on the crown lands which were situated in every part of the country, and left in his capitularies particular instructions for their culture. One of his injunctions prohibits an ox and an ass from being yoked together in the same plough.

187. *During great part of the ninth and tenth centuries*, France was harassed by civil wars, and agriculture declined; but to what extent, scarcely any facts are left us to ascertain. A law passed in that period, respecting a farmer's tilling the lands of his superior, enacts that, if the cattle are so weak that four could not go a whole day in the plough, he was to join these to the cattle of another and work two days instead of one. He who kept no cattle of his own was obliged to work for his superior three days as a labourer.

188. *In the eleventh and twelfth centuries*, the country enjoyed more tranquillity, and agriculture was improved. Judging from the Abbé Suger's account of the abbey lands of St. Denis, better farm-houses were built, waste lands cultivated, and rents more than doubled. The church published several canons for the security of agriculture during this period, which must have had a beneficial effect, as the greatest proportion of the best lands in every country was then in the hands of the clergy.

189. *In the thirteenth century* little alteration took place; but the number of holidays were diminished, and mills for grinding corn driven by wind introduced.

190. *In the fourteenth and fifteenth centuries*, agriculture suffered greatly by the English wars and conquests, and by political regulations relative to the export and market price of corn.

191. *About the middle of the sixteenth century*, the first agricultural work produced in France made its appearance. It was entitled, *Les Moyens de devenir riche*, and was composed by Bernard de Pallisy, a potter, who had written on various subjects. It is a very short tract, composed of economical remarks on husbandry, or rural and domestic economy. Towards the end of this century, under Henry IV., and his virtuous minister Sully, considerable enterprise was displayed. Canals were projected, and one begun, and, according to Sully, France in his time abounded with corn, grain, pulse, wine, cider, flax, hemp, salt, wool, oil, dyeing drugs, cattle great and small, and every thing else, whether necessary or convenient for life, both for home consumption and exportation. (*Mem.*, xvi. 225.; *Ranke's Hist. of France*, i. 433.)

SECT. III. *Of the Agriculture of Germany and other Northern States, from the Fifth to the Seventeenth Century.*

192. *The nations north of the Rhine and the Danube*, during the first half of these centuries, were chiefly employed in making inroads or conquests on their southern neighbours; and during the whole period they were more or less engaged in attacking one another. Under such circumstances, agriculture must either have remained in the state which we have already described (178.), or it must have declined. In some states or kingdoms it may have been less neglected than in others, or may even have improved; but, during the whole of this period, nothing was effected which demands particular attention.

193. *The earliest German author on husbandry* is Conradus Heresbachius, who was born in 1508, and died in 1576. His work, *De Re Rustica*, was published after his death. It is an avowed compilation from all the authors who had preceded him, and contains no information as to the state of agriculture around him. It is a dialogue in four books, and also includes gardening. The persons are Cono, a gentleman retired into the country; Rigo, a courtier; Metelea, wife of Cono; and Hermes, a servant. The conversation is carried on in Cono's house, and on his farm, and the different speakers are made to deliver all that has been said by all the Greek and Roman writers, from Hesiod to Pliny, by Crescenzio and other Italians, and by various writers on general subjects: they converse on the advantages of agriculture as a pursuit; on its general maxims and practices; on the culture of particular plants; and on the economy of the house and garden.

194. *No other books on agriculture, of any note, appeared in Germany during the period under review.* About the middle of the sixteenth century, the Elector of Saxony, Augustus II., is said to have encouraged agriculture, and to have planted the first vineyard in Saxony; but, from the implements with which he worked in person, which are still preserved in the arsenal of Dresden, he appears to have been more a gardener than a farmer. It is to be regretted that the histories of the arts in the northern countries during the middle ages are very few, and so little known or accessible, that we cannot derive much advantage from them.

SECT. IV. *History of Agriculture in Britain, from the Fifth to the Seventeenth Century.*

195. *Britain, on being quitted by the Romans, was invaded by the Saxons*, a ferocious and ignorant people, by whom agriculture and all other civilised arts were neglected. In the eleventh century, when the Saxons had amalgamated with the natives, and constituted the main body of the English nation, the country was again invaded by the Normans, a much more civilised race, who introduced considerable improvement. These two events form distinct periods in the history of British agriculture, and two others will bring it down to the seventeenth century.

SUBSECT. 1. *History of Agriculture in Britain during the Anglo-Saxon Dynasty, or from the Fifth to the Eleventh Century.*

196. *At the arrival of the Anglo-Saxons* this island, according to Fleury (*History*, vol. iv. p. 97.), abounded in numerous flocks and herds, which these conquerors seized, and pastured for their own use; and, after their settlement, they still continued to follow pasturage as one of the chief means of their subsistence. This is evident from the great number of laws that were made in the Anglo-Saxon times, for regulating the prices of all kinds of tame cattle, for directing the manner in which they were to be pastured, and for preserving them from thieves, robbers, and beasts of prey. (*Wilkins, Leges Saxon.*, passim.)

197. *The Welsh in this period*, from the nature of their country and other circumstances, depended still more on their flocks and herds for their support; hence their laws respecting pasturage were more numerous and minute than those of the Saxons. (*Leges*

Wallicæ, passim.) From these laws we learn, among many other particulars which need not be mentioned, that all the cattle of a village, though belonging to different owners, were pastured together in one herd, under the direction of one person (with proper assistants); whose oath, in all disputes about the cattle under his care, was decisive.

198. *By one of these laws, they were prohibited from ploughing with horses, mares, or cows, and restricted to oxen.* (*Leges Wallicæ*, p. 288.) Their ploughs seem to have been very slight and inartificial: for it was enacted that no man should undertake to guide a plough, who could not make one; and that the driver should make the ropes with which it was drawn of twisted willows. (*Ibid.*, p. 283.) Hence the names still in use of ridge-withey, wanty or womb-tye, whipping-trees, tail-withey, &c. But slight as these ploughs were, it was usual for six or eight persons to form themselves into a society for fitting out one of them, and providing it with oxen, and every thing necessary for ploughing; and many minute and curious laws were made for the regulation of such societies. This is a sufficient proof both of the poverty of the husbandmen, and of the imperfect state of agriculture among the ancient Britons in this period.

199. *Certain privileges were allowed to any person who laid dung on a field, cut down a wood, or folded his cattle on another's land for a year.* Such was the state of agriculture during this period in Wales; it was probably in a still more imperfect state among the Scots and Picts, but this we have no means of ascertaining.

200. *Our Anglo-Saxon ancestors derived their origin and manners from the ancient Germans, who were not much addicted to agriculture, but depended chiefly on their flocks and herds for their subsistence.* (*Strabo*, l. vii.; *Cæsar de Bell. Gall.*, l. vi.) These restless and haughty warriors esteemed the cultivation of their lands too ignoble and laborious an employment for themselves, and therefore committed it wholly to their women and slaves. (*Tacit. de Morib. German.*, c. 15.) They were even at pains to contrive laws to prevent their contracting a taste for agriculture, lest it should render them less fond of arms and warlike expeditions. (*Id.*, c. 26.)

201. *The division of landed estates into what are called inlands and outlands, originated with the Saxon princes and great men, who, in the division of the conquered lands, obtained the largest shares, and are said to have subdivided their territory into two parts, which were so named.* The inlands were those which lay most contiguous to the mansion-house of their owner, which he kept in his own immediate possession, and cultivated by his slaves, under the direction of a bailiff, for the purpose of raising provisions for his family. The outlands were those which lay at a greater distance from the mansion-house, and were let to the ceorls or farmers of those times at a certain rent, which was very moderate, and generally paid in kind. (*Reliquiæ Spelmanianæ*, p. 12.)

202. *The rent of lands in these times was established by law, and not by the owners of the land.* By the laws of Ina, king of the West Saxons, who flourished in the end of the seventh and beginning of the eighth century, a farm consisting of ten hides, or plough lands, was to pay the following rent, viz. ten casks of honey, three hundred loaves of bread, twelve casks of strong ale, thirty casks of small ale, two oxen, ten wethers, ten geese, twenty hens, ten cheeses, one cask of butter, five salmon, twenty pounds of forage, and one hundred eels. (*Wilkins, Leges Saxon.*, p. 25.) The greatest part of the crown lands in every county was farmed in this manner by ceorls or farmers, who in general appear to have been freemen and soldiers.

203. *Very little is known of the implements or operations of husbandry during this period.* In one of Strutt's plates of ancient dresses, entitled, *Saxon Rarities of the Eighth Century*, may be seen a picture of a plough and ploughman. (*fig. 22.*) This is sufficiently rude, though it has evidently undergone some improvement from the art of the delineator. The labourers were no doubt slaves, and the animals of draught, oxen. The lands belonging to the monasteries were by much the best cultivated; because the secular canons who possessed them spent some part of their time in cultivating their own lands. The venerable Bede, in his life of Easterwin, Abbot of Weremouth, tells us that "This abbot, being a strong man, and of an humble disposition, used to assist his monks in their rural labours, sometimes guiding the plough by its stilt or handle, sometimes winnowing corn, and sometimes forging instruments of husbandry with a hammer upon an anvil." (*Bede's Hist. Abbat. Weremath.*, p. 296.) For in those times the husbandmen were under a necessity of making many implements of husbandry with their own hands.

22

SUBJECT. 2. *Of the State of Agriculture in Britain after the Norman Conquest, or from the Eleventh to the Thirteenth Centuries.*

204. *That the conquest of England by the Normans contributed to the improvement of agriculture in Britain is undeniable.* "For by that event many thousands of husbandmen, from the fertile and well cultivated plains of Flanders, France, and Normandy, settled in this island, obtained estates or farms, and employed the same methods in the cultivation of them that they had used in their native countries. Some of the Norman barons were great improvers of their lands, and are celebrated in history for their skill in agriculture." "Richard de Rulos, lord of Brunne and Deeping," says Ingulphus, "was much addicted to agriculture, and delighted in breeding horses and cattle. Besides enclosing and draining a great extent of country, he imbanked the river Wielland, (which used every year to overflow the neighbouring fields) in a most substantial manner, building many houses and cottages upon the bank; which increased so much, that in a little time they formed a large town called *Deeping*, from its low situation. Here he planted orchards, cultivated commons, converted deep lakes and impassible quagmires into fertile fields, rich meadows, and pastures; and, in a word, rendered the whole country about it a garden of delights." (*Hist. Ingulphi*, Oxon. edit. 1684, tom. i. p. 77, 78.) From the above description, it appears that this nobleman (who was chamberlain to William the Conqueror) was not only fond of agriculture, but also that he conducted his improvements with skill and success.

205. *The Norman clergy, and particularly the monks*, were still greater improvers than the nobility; and the lands of the church, especially of the convents, were conspicuous for their superior cultivation: for the monks of every monastery retained such of their lands as lay most convenient in their own possession, which they cultivated with great care, under their own inspection, and frequently with their own hands. It was so much the custom of the monks of this period to assist in the cultivation of their lands, especially in seed-time, hay-time, and harvest, that the famous Thomas Becket, after he was Archbishop of Canterbury, used to go out to the field, with the monks of the monasteries where he happened to reside, and join with them in reaping their corn and making their hay. (*Chron. Gervas.*, col. 1400.) This is indeed mentioned by the historian as an act of uncommon condescension in a person of his high station in the church; but it is sufficient proof that the monks of those times used to work with their own hands, at some seasons, in the labours of the field: and, as many of them were men of genius and invention, they no doubt made various improvements in the art of agriculture. The twenty-sixth canon of the general council of Lateran, held A. D. 1179, affords a further proof that the protection and encouragement of all who were concerned in agriculture, were objects of attention to the church. For by that canon it is decreed, "That all presbyters, clerks, monks, converts, pilgrims, and peasants, when they are engaged in the labours of husbandry, together with the cattle in their ploughs, and the seed which they carry into the field, shall enjoy perfect security; and that all who molest or interrupt them, if they do not desist when they have been admonished, shall be excommunicated." (*Ibid.*, col. 1456.)

206. *The implements of husbandry, in this period*, were of the same kind with those that are employed at present, though all of them, no doubt, much less perfect in their construction. One sort of plough, for example, had but one stilt or handle, which the ploughman guided with one hand, having in his other hand an instrument which served both for cleaning and mending his plough, and breaking the clods. (*fig. 23.*) This implement was probably intended for breaking up strong lands; for such a purpose the wheels would contribute much to its steadiness, which would render two handles unnecessary, and thus leave the bolder with one hand at liberty to use his axe-like instrument in clearing away roots and clods, or otherwise aiding the operation of the plough. Another plough (*fig. 24.*) seems to have been without wheels, and was probably intended for light soil. (*See Strutt's Complete View of the Manners, &c. of England*, vol. ii. p. 12.) The Norman

23

24

plough had two wheels; and, in the light soil of Normandy, was commonly drawn by one ox, or two oxen; but in England a greater number, according to the nature of the soil, were often necessary. (*M. Montfaucon, Monumens de Monarchie François, tom. i. plate 47.*; *Girald. Cambrens. Descript. Cambria, c. 17.*) In Wales, the person who conducted the oxen in the plough walked backwards. (*Girald. Cambrens., c. 17.*) Their carts, harrows, scythes, sickles, and flails, from the figures of them still remaining, appear to have been nearly of the same construction with those that are now used. (*Strutt's View, vol. i. pl. 26, 32, 33, and our fig. 25.*) In Wales they did not use a sickle in reaping their corn, but an instrument like the blade of a knife, with a wooden handle at each end. (*Girald. Cam., c. 17.*) Water-mills for grinding corn were very common, but they had also a kind of mills turned by horses, which were chiefly used in their armies, and at sieges, or in places where running water was scarce. (*Gaufrid. Vinisau. Iter Hierosolymit., l. i. c. 33.*; *M. Paris, Vit. Abbot., p. 94. col. 2.*)

207. The various operations of husbandry, as manuring, ploughing, sowing, harrowing, reaping, threshing, winnowing, &c., are incidentally mentioned by the writers of this period; but it is impossible to collect from them a distinct account of the manner in which these operations were performed. Marl seems to have been the chief manure next to dung, employed by the Anglo-Normans, as it had been by the Anglo-Saxon and British husbandmen. (*M. Paris, Hist., p. 181.*; *In Vit. Abbot., p. 101. col. 1.*) Summer fallowing of lands designed for wheat, and ploughing them several times, appear to have been common practices of the English farmers of this period: for Giraldus Cambrensis, in his description of Wales, takes notice of it as a great singularity in the husbandmen of that country, "that they ploughed their lands only once a year, in March or April, in order to sow them with oats; but did not, like other farmers, plough them twice in summer, and once in winter, in order to prepare them for wheat." (*Girald. Cambrens. Descript. Cambria, c. viii. p. 887.*) On the border of one of the compartments in the famous tapestry of Bayeux, we see the figure of one man sowing with a sheet about his neck, containing the seed under his left arm, and scattering it with his right hand; and of another man harrowing with one harrow, drawn by one horse. (*Montfaucon, Monumens de Monarchie François, tom. i. plate 47.*) In two plates of Strutt's very curious and valuable work (*figs. 26, 27.*), we perceive the figures

of several persons engaged in mowing, reaping, threshing, and winnowing; in all which operations there appears to be little singular or different from modern practice. (*Strutt's Complete View of the Manners, Customs, &c., of England, vol. i. plates 11, 12.*)

208. Agriculture in Scotland seems to have been in a very imperfect state towards the end of this period. For in a parliament held at Scone, by King Alexander II., A. D.

1214, it was enacted, that such farmers as had four oxen or cows, or upwards, should labour their lands, by tilling them with a plough, and should begin to till fifteen days

before Candlemas; and that such farmers as had not so many as four oxen, though they could not labour their lands by tilling, should delve as much with hand and foot as would produce a sufficient quantity of corn to support themselves and their families. (*Regiam Majestatem*, p. 307.) But this law was probably designed for the highlands, and most uncultivated parts of the kingdom; for in the same parliament a very severe law was made against those farmers who did not extirpate a pernicious weed called *gulle* (*Chrysanthemum ségetum L.*) out of their lands, which seems to indicate a more advanced state of cultivation. (*Ibid.*, p. 335.) Their agricultural operations, as far as can be gathered from old tapestries and illuminated missals, were similar to those of England. Threshing appears to have been performed by women (fig. 28.), and reaping by the men (fig. 29.), which is the reverse of the modern practice in that and in most countries. Such is the account of Henry.

28

29

(*History of Britain*, vol. vi. p. 173.)

209. *The field culture of the vine*, which had been commenced by the monks for their own use, was more extensively spread by the Normans. William of Malmsbury, who flourished in the early part of the twelfth century, says there were a greater number of vineyards in the vale of Gloucester than any where else, and that from the grapes was produced a wine very little inferior to that of France. Orchards and cider were also abundant, and the apple trees, it is said, lined the roads in some parts of the country, as they still do in Normandy, whence in all probability the plants or at least the grafts were imported.

SUBJECT. 3. *History of Agriculture in Britain, from the Thirteenth Century to the Time of Henry VIII.*

210. *Agriculture in the thirteenth and fourteenth centuries*, it appears, was still carried on with vigour. Sir John Fortescue, in a work in praise of the English laws, mentions the progress that had been made in planting hedges and hedge-row trees before the end of the fourteenth century. Judge Fortescue wrote his *Legum Angliæ* in the fifteenth century, but it was not published till the reign of Henry VIII. In the law book called *Fleta* (supposed to have been written by some lawyers, prisoners in the Fleet, in 1340), very particular directions are given as to the most proper times and best manner of ploughing and dressing fallows. (*Fleta*, lib. ii. chap. 73. p. 163.) The farmer is there directed to plough no deeper in summer, than is necessary for destroying the weeds; nor to lay on his manure till a little before the last ploughing, which is to be with a deep and narrow furrow. Rules are also given for the changing and choosing of seed; for proportioning the quantity of different kinds of seed to be sown on an acre, according to the nature of the soil, and the degree of richness; for collecting and compounding manures, and accommodating them to the grounds on which they are to be laid; for the best seasons for sowing seeds of different kinds on all the variety of soils; and, in a word, for performing every operation in husbandry, at the best time, and in the best manner. (*Fleta*, lib. ii. chap. 72, 73. 76.) In the same work, the duties and business of the steward, bailiff, and overseer, of a manor and of all the other persons concerned in the cultivation of it, are explained at full length, and with so much good sense, that if they were well performed the manor could not be ill cultivated. (*Ibid.*, chap. 72. 88.; *Henry*, viii. 267.) This work, as well as others of the kind, is written in Latin, and even the farming accounts were in those days kept in that language, as they still are in the greater part of Hungary.

211. *During the greater part of the fifteenth century* England was engaged in civil wars, and agriculture, as well as other arts, declined. The labourers, called from the plough by royal proclamation or the mandates of their lords, perished in battle, or by accident and fatigue, in immense numbers. Labour rose in price notwithstanding various laws for its limitation, and this at last produced a memorable revolution in the state of agriculture, which made a mighty noise for many years. The prelates, barons, and other great proprietors of land, kept extensive tracts around their castles, which were called their demesne lands, in their own immediate possession, and cultivated them by their villains, and by hired servants, under the direction of their bailiffs. But these great landholders having often led their followers into the fields of war, their numbers were gradually diminished, and hired servants could not be procured on reasonable terms. This obliged the prelates, lords, and gentlemen to enclose the lands around their castles, and to convert them into pasture grounds. This practice of enclosing became very general in England about the middle of this period, and occasioned prodigious clamours from those who mistook the effect of depopulation for its cause.

212. *The habit of enclosing lands and converting them to pasture* continued after the cause had ceased, and an act was passed to stop its progress in the beginning of the reign

of Henry VII. The dearths of this period furnish another proof of the low state of agriculture. Wheat in 1437 and 1438 rose from 4s. or 4s. 6d., the ordinary price per quarter, to 1l. 6s. 8d., equivalent to 13l. 6s. 8d. of our money. *Stow observes that, in these extremities, the common people endeavoured to preserve their wretched lives, by drying the roots of herbs and converting them into a kind of bread. Land in those days was sold for ten years' purchase, so great was the insecurity of possession.

213. *Agriculture in Scotland* was at a low ebb during the thirteenth, fourteenth, and fifteenth centuries, on account of the long and ruinous wars in which the country was engaged. A law passed in 1424 enacts that every labourer of "simple estate" dig a piece of ground daily, of seven feet square; another in 1457, that farmers who had eight oxen should sow every year one firlot (bushel) of wheat, half a firlot of pease, and forty beans, under the pain of ten shillings to be paid to the baron; and if the baron did not do the same thing to the lands in his possession, he should pay the same penalty to the king.

214. *From the accession of Henry VII. in 1485, to nearly the middle of the seventeenth century*, England enjoyed peace. To remove the effects of former wars, however, required a considerable time. The high price of labour, and the conversion of so much land to tillage, gave rise to different impolitic statutes, prohibiting the exportation of corn; while a great demand was created for wool by the manufactures of the Netherlands, which tended to enhance the value of pasture lands, and depopulate the country. The flocks of individuals, in these times, sometimes exceeded twenty thousand, and an act was passed by Henry VIII., restricting them to a tenth of that number, apparently eluded from the partial exception of hereditary opulence. Had the restraints imposed on the exportation of corn been transferred to wool, the internal consumption would have soon regulated the respective prices of those articles; the proportion between arable and pasture lands would soon have been adjusted; and the declining cultivation of the country restored. An improved cultivation was reserved, however, for a future period, when persecution extirpated manufactures from the Netherlands; then, when the exportation of English wool had subsided, and its price diminished, the farmer or landholder, disappointed of his former exuberant profits, discovered the necessity of resuming the plough, and restoring his pastures to culture. (*Henry*, xii. 261.)

215. *Of the state of agriculture in Scotland during the fifteenth and sixteenth centuries* little can be stated. According to Major (*Historia Britannica*, Paris, 1526), a native of Berwick, "the peasants neither enclosed nor planted, nor endeavoured to ameliorate the sterility of the soil." According to Fynnis Moryson, the produce of the country consisted chiefly of oats and barley; but it would appear from Chalmers that wheat was cultivated in Scotland at least upon the church lands, so early as the thirteenth century. Different laws were enacted for planting groves and hedges, pruning orchards and gardens, and forming parks for deer: but it is not the barren injunctions of statutes that will excite a spirit of improvement in a country.

SUBJECT. 4. *History of Agriculture, from the Time of Henry VIII. to the Revolution in 1688.*

216. *Agriculture, soon after the beginning of the sixteenth century*, partook of the general improvement which followed the invention of the art of printing, the revival of literature, and the more settled authority of government; and, instead of the occasional notices of historians, we can now refer to regular treatises, written by men who engaged eagerly in this neglected, and hitherto degraded, occupation.

217. *The culture of hops* was either introduced or revived early in the reign of Henry VIII.; and that of flax was attempted, but without success, though enforced by law. (*Holinshead*, p. 110, 111.; 24 *Hen.* 8. c. 4.) The legislature at that time endeavoured to execute, by means of penalties, those rational improvements which have since been fostered and cherished by bounties; or, what is better, pursued from the common motive of self-interest.

218. *The breeding of horses* was now much encouraged. To the passion of the age, and the predilection of the monarch for splendid tournaments, may be attributed the attention bestowed on a breed of horses of a strength and stature adapted to the weight of the complicated panoply with which the knight and his courser were both invested. Statutes of a singular nature were enacted, allotting for deer parks a certain proportion of breeding mares, and enjoining, not the prelates and nobles only, but those whose wives wore velvet bonnets, to have stallions of a certain size for their saddle. The legal standard was fifteen hands in horses, thirteen in mares, and "unlikely tits" were, without distinction, consigned to execution. (27 *Hen.* 8. cap. 6; 36 *Hen.* 8. cap. 13. See *Barrington's Observations on the Statutes*, p. 443.) James the Fourth, of Scotland, with more propriety, imported horses from foreign countries in order to improve the degenerate breed of his own. (*Pitcottic*, p. 153.) The cultivation of grasses for their winter provender was still unknown; nor were asses propagated in

England till a subsequent period. (*Holinshead*, p. 220.; *Polydore Virgil*, p. 13.; *Henry*, xii. 268.)

219. *The first English treatise on husbandry* now appeared, written by Sir A. Fitzherbert, judge of the common pleas. It is entitled *The Book of Husbandry*, and contains directions for draining, clearing, and enclosing a farm; and for enriching and reducing the soil to tillage. Lime, marl, and fallowing are strongly recommended. The landlords are advised to grant leases to farmers who will surround their farms, and divide them by hedges into proper enclosures; by which operation, he says, "if an acre of land be worth sixpence before it is enclosed, it will be worth eightpence when it is enclosed, by reason of the compost and dunging of the cattle." Another reason is, that it will preserve the corn without the expense of a herdsman. From the time of the appearance of this work, in 1534, Harte dates the revival of husbandry in England.

220. *The Book of Surveying and Improvements*, by the author of *The Book of Husbandry*, appeared in 1539. In the former treatise we have a clear and minute description of the rural practices of that period; and from the latter may be learned a good deal of the economy of the feudal system in its decline. The author of *The Book of Husbandry* writes from his own experience of more than forty years; and, if we except his biblical allusions, and some vestiges of the superstition of the Roman writers about the influence of the moon, there is very little of his work that should be omitted, and not a great deal of subsequent science that need be added, with regard to the culture of corn, in a manual of husbandry adapted to the present time. It may surprise some of the agriculturists of the present day, an eminent agricultural writer remarks, to be told that, after the lapse of almost three centuries, Fitzherbert's practice, in some material branches, has not been improved upon; and that in several districts abuses still exist, which were as clearly pointed out by him at that early period, as by any writer of the present age. His remarks on sheep are so accurate, that one might imagine they came from a storemaster of the present day: those on horses, cattle, &c., are not less interesting; and there is a very good account of the diseases of each species, and some just observations on the advantage of mixing different kinds in the same pasture. Swine and bees conclude this branch of the work. He then points out the great advantages of enclosures; recommends "quyck-settyng, dychyng, and bedgyng;" and gives particular directions about the *settes*, and the method of training a hedge, as well as concerning the planting and management of trees. We have then a short information "for a yonge gentyllman that intendeth to thryve," and a "prologue for the wive's occupation," in some instances, rather too homely for the present time. Among other things, she is to "make her husband and herself some clothes;" and "she may have the lockes of the shepe, either to make blankettes and coverlettes, or both." This is not so much amiss; but what follows will bring our learned judge into disrepute, even with our most industrious housewives. "It is a wive's occupation to wynowe all manner of cornes, to make malte, to washe and wrynge, to make hey, shere corne, and, in time of nede, to helpe her husbunde to fyll the muckewayne or dounge carte, drive the ploughe, to loade hey, corne, and suche other. And to go or ride to the market, to sel butter, chese, mylke, egges, chekyns, capons, hennes, pygges, gese, and all manner of cornes." The rest of the book contains some useful advices about diligence and economy; and concludes, after the manner of the age, with many pious exhortations. (*Encyc. Brit.*, art. *Agr.*)

221. *The state of agriculture in England in the early part of the sixteenth century*, and probably for a long time before, is thus ascertained; for Fitzherbert no where speaks of the practices which he describes or recommends as of recent introduction. *The Book of Surveyinge* adds considerably to our knowledge of the rural economy of that age. "Four maner of commes" are described; several kinds of mills for corn, and other purposes, and also "quernes that goo with hand;" different orders of tenants, down to the "boundmen," who "in some places contynue as yet;.....and many tymes, by color thereof, there be many freemen taken as boundmen, and their lands and goods is taken from them." Lime and marl are mentioned as common manures; and the former was sometimes spread on the surface to destroy heath. Both draining and irrigation are noticed; though the latter but slightly. The work concludes with an enquiry "How to make a township that is worth XX merke a yere worth XX li. a year:" this is to be done by enclosing, by which, he says, live stock may be better kept and without herds; and the closes or fields alternately cropped with corn, and "let lye" for a time.

222. *Agriculture had attained a considerable degree of respectability during the reign of Elizabeth*. According to Tusser, who wrote in that age, and whose work will be presently noticed, agriculture was best understood in Essex and Suffolk; at least enclosures were more common in these counties than in any other, which is always a proof of advancement. A farmer, according to Harrison the geographer, "will thinke his gaines very small towards the end of his terme if he have not six or seven years rent lying by him, therewith to purchase a new lease; beside a fair garnish of pewter on his cupboard,

with as much more in odd vessels going about the house; three or four feather-beds; so many coverlets, and carpets of tapestrie; a silver salt; a bowle for wine, if not a whole neast; and a dozen of spoons to furnish owte the sute." (*Harrison's Description of England*, p. 188.)

223. *The condition of a yeoman, before or about Elizabeth's time*, is exemplified in the case of Bishop Latimer's father. "My father," says Hugh Latimer, "was a yeoman, and had no land of his own; only he had a farm of three or four pounds by the year at the utmost; and hereupon he tilled so much as kept half a dozen men. He had a walk for a hundred sheep; and my mother milked thirty kine, &c. He kept his son at school till he went to the university, and maintained him there; he married his daughters with five pounds, or twenty nobles apiece; he kept hospitality with his neighbours, and some alms he gave to the poor; and all this he did out of the said farm." (*Gilpin's Life of Latimer*.)

224. *Cattle were not plentiful in England at the beginning of Elizabeth's reign*. In 1563 it was enacted that no one should eat flesh on Wednesdays or Fridays, on forfeiture of three pounds, unless in case of sickness, or of a special license, neither of which was to extend to beef or veal. (*Stat. 5 Eliz. cap. 4.*) Great pains were taken in the act to prove that it was a political, not a religious measure.

225. *The vast number of parks in the kingdom* are complained of by Harrison. "There are not less," he says, "than an hundred in Essex alone, where almost nothing is kept but a sorte of wilde and savage beasts, cherished for pleasure and delight." And pursuing the same subject, he says, "that if the world last a while after this rate, wheate and rie will be no graine for poore men to feed on." (*Description of Britaine*, p. 168.)

226. *In Scotland the civil dissensions, and even anarchy, which prevailed until a late period in the sixteenth century*, operated as a harsh check on every improvement in agriculture, and the total expulsion of ecclesiastical landholders increased this evil; as the monks were easy landlords, and frequently not uninstructed in georgical knowledge. The tillers of the earth in Scotland had at least their full share of their country's misfortunes, when private vengeance for private wrongs superseded the regular but timid proceedings of public justice. A statute was then formed for their particular benefit, whereby (*Stat. 110. Parl. 7. Jac. 6.*) "the slayers and houchers (houghers) of horses and uther cattel," with their employers and maintainers, are declared "to have incurred the paine of death, and confiscation of alle their gudes movvabil." A second act passed in 1587 for the further protection of husbandmen, declaring all such as destroyed or maimed horses, oxen, &c., cut or destroyed ploughs or plough-geers (in time of tilling), or trees and corn, should suffer death. (*Stat. 83. Parl. 2. Jac. 6.*) Several acts of parliament were made to protect the farmers from petulant tithe-gatherers; the proper times of notice were herein pointed out, and liberty given to the tiller of the land to proceed in his work if this notice were neglected. The last (*Stat. 84. Parl. 2. Jac. 6.*) confirmed and explained the others. (*Andrew's Continuation of Henry's Hist.*, ii. 124.)

227. *Great attention was still paid to the breed of horses in England*; but, during the reign of Elizabeth, it was found necessary to lower the standard appointed by Henry VIII. for stallions, from fourteen hands to thirteen. This modification, however, was only to take place in the counties of Cambridge, Huntingdon, Northampton, Lincoln, Norfolk, and Suffolk. (*18 Eliz. cap. 8.*) No stallion of less height could be turned out on commons, forests, &c., for fear of deteriorating the breed. Harrison extols the height and strength of the English draught-horses; five or six of them, he says, will with ease draw three thousand weight of the greatest tale for a long journey.

228. *An English traveller, who visited Scotland in 1598, observed a great abundance of all kind of cattle, and many horses*; not large, but high-spirited and patient of labour. (*Moryson's Itin.*, part iii. p. 154.) Great care, indeed, was taken by the English, while the kingdoms were separate, to prevent the Scots from improving their breed by southern stallions; it was even made felony to export horses thither from England. (*1 Eliz. cap. 7.*) This unneighbourly prohibition was answered by a reciprocal restriction in 1567, as to the exportation of Scottish horses (*Stat. 22. Parl. 1. Jac. 6.*); but France, rather than England, seems to be aimed at by that statute. One circumstance, pointed out by a curious antiquary (*Paper apud Transactions of Sc. Ant. Soc.*, vol. i. p. 171.), is a convincing proof of the modern improvement in the breed: for many years past eight nails have been used to each horse's shoe in the north; six used to be the number.

229. *The proper seasons for turning horses to grass* was thought a consideration worth the attention of the Scottish government, avowedly to prevent the waste of corn. All horses were, therefore, ordered to be put to grass from May 15th to Oct. 15th, on pain of forfeiting each horse, or its value, to the king. Gentlemen of 1000 marks, yearly rent, and all upwards, are excepted. (*Stat. 122. Parl. 7. Jac. 6.*) The 1st of June was substituted in a subsequent act (*Stat. 56. Parl. 2. Jac. 6.*) for the 15th of May.

230. *The vine in England continued to be cultivated for wine*; but not generally, for the vineyards of the Lords Cobham and Williams of Thames, are pointed out by Barnaby Gooch as eminently productive. It is probable this branch of culture declined with the suppression of the monasteries, and the more general culture of barley; as farmers and others would soon find that good beer was a cheaper and better drink, than any wine that could be made in this country. Though in 1565, in this reign, the potato was introduced from Santa Fé by Capt. Hawkins, yet it did not come into general use, even in gardens, for nearly two centuries afterwards.

231. *The principal agricultural authors of Elizabeth's reign* are, Tusser, Googe, and Sir Hugh Platt. Thomas Tusser was born at Rivenhall in Essex, in 1527. Having a fine voice, he was impressed for the royal chapel, and sang in St. Paul's, under a celebrated musician. "Afterwards he was a scholar at Eton, and next a student at Cambridge. He next became, by turns, musician, farmer, grazier, and poet; but always unsuccessfully, although guilty of neither vice nor extravagance." His *Five Hundred Points of Husbandry* was published in 1562, and has been recommended by Lord Molesworth to be taught in schools. (*Some Considerations for the Promoting of Agriculture and employing the Poor*, Dublin, 1723.) It is written in hobbling verse, and contains some useful notices concerning the state of agriculture in different parts of England. Hops, which had been introduced in the early part of the sixteenth century, and on the culture of which a treatise was published in 1574, by Reynolds Scott, are mentioned as a well known crop. Buck-wheat was sown after barley. It seems to have been the practice then, in some places, to "geld fillies" as well as colts. Hemp and flax are mentioned as common crops. Enclosures must have been numerous in several counties; and there is a very good "comparison between champion (open fields) country, and severall." There is nothing to be found in Tusser about *serfs* or bondmen, as in Fitzherbert's works. (*Encyc. Brit.*, art. *Agricul.*)

232. *The next writer is Barnaby Googe, a Lincolnshire gentleman, whose Whole Art of Husbandry* was printed in 1578. It is, for the most part, made up of gleanings from all the ancient writers of Greece and Rome, whose absurdities are faithfully retained; with here and there some description of the practices of the age, in which there is little novelty or importance. Googe mentions a number of English writers who lived about the time of Fitzherbert, whose works have not been preserved.

233. *Sir Hugh Platt's Jewel Houses of Art and Nature*, was printed in 1594. It is chiefly a compilation from other writers. The author appears to have been a lawyer of Lincoln's Inn, but he had a seat in Essex, and another in Middlesex, where he spent great part of his time.—*The Rev. William Harrison*, a contemporary of Platt, and chaplain to Baron Cobham, wrote a description of Britain, and translated Boethius's *History of Scotland*. In the former work are many valuable hints on the progress of husbandry in the early part of the reign of Elizabeth. Among other curious things he asserts that the Spanish, or Merino sheep, was originally derived from England.

234. *The seventeenth century is distinguished by some important improvements in agriculture*, among which are the introduction of clovers and turnips in England; of hedges in Scotland and Ireland; and the execution of extensive embankments and drainages. Some useful writers also appeared, especially Norden, Gabriel Plattes, Sir Richard Weston, Hartlib, and Blythe, to whom may be added Evelyn.

235. *For the adoption of the clover, as an agricultural plant*, we are indebted to Sir Richard Weston, who, in 1645, gives an account of its culture in Flanders, where he says "he saw it cutting near Antwerp, on the 1st of June 1644, being then two feet long, and very thick; that he saw it cut again on the 29th of the same month, being twenty inches long; and a third time in August, being eighteen inches long." Blythe, in 1653, is copious in his directions for its cultivation; and Lisle (*Obs. on Husbandry*), in the beginning of the eighteenth century, speaks of it as commonly cultivated in Hampshire, Wiltshire, Gloucestershire, and other counties.

236. *Turnips* were probably introduced as a field crop by the same patriotic author, though they may probably have been grown in the gardens of the church establishments long before. They are cultivated, he observes, "for feeding kine in many parts of England; but there is as much difference between what groweth in Flanders and here, as is between the same thing which groweth in a garden and that which groweth wild in the fields." It is probable the English turnips he alludes to were rape, which is mentioned by Googe in 1586; but, though Gerarde, in 1597, and Parkinson, in 1629, mention the turnip as a garden vegetable, yet neither of these authors gives the least hint of their field culture: be that as it may, Ray, in 1686, informs us, that they are sown every where in fields and gardens, both in England and abroad, for the sake of their roots. Lisle also, in 1707, mentions their being common in Norfolk, Hampshire, Berkshire, and various counties. The common story, therefore, that their culture was first introduced by Charles Lord Viscount Townsend, cannot be true; but their culture was probably greatly improved by him, when he retired from public business to Rainham in Norfolk, in 1730.

237. *The first notices of sheep being fed on the ground with turnips*, is given in *Houghton's Collections on Husbandry and Trade*, a periodical work begun in 1681. In 1684, Worlidge, one of Houghton's correspondents, observes, "sheep fatten very well on turnips, which prove an excellent nourishment for them in hard winters, when fodder is scarce;

for they will not only eat the greens, but feed on the roots in the ground, and scoop them hollow even to the very skin. Ten acres," he adds, "sown with clover, turnips, &c, will feed as many sheep as one hundred acres thereof would before have done." (*Houghton's Collections*, vol. iv. p. 142—144.)

238. *Potatoes*, first introduced in 1565 (230.), were at this time beginning to attract notice. "The potato," says Houghton, "is a *bacciferous* herb, with *esculent* roots, bearing winged leaves, and a bell flower. This, I have been informed, was brought first out of Virginia by Sir *Walter Raleigh*; and he stopping at Ireland, some was planted there, where it thrived very well, and to good purpose; for in their succeeding wars, when all the corn above ground was destroyed, this supported them; for the soldiers, unless they had dug up all the ground where they grew, and almost sifted it, could not extirpate them. From thence they were brought to *Lancashire*, where they are very numerous, and now they began to spread all the kingdom over. They are a pleasant food, boiled or roasted, and eaten with butter and sugar. There is a sort brought from Spain that are of a longer form (*Convólulus Batatas*) (fig. 30.), and are more luscious than ours; they are much set by, and sold for sixpence or eightpence the pound." (*Ib.*, vol. ii. p. 468.)

239. *Embankments* were made on the eastward of England, in various places, by the Romans, when in possession of the country, and afterwards by some wealthy religious houses, and by the government. Considerable exertions were made at Boston during the reign of Henry VII., under the direction of Mayhave Hake, a Flemish engineer, and fourteen masons; but the principal effort, as far as respects gaining land for agricultural purposes, was made during the protectorate, by Col. Vermuyden, a Fleming, who served in Cromwell's army. Speaking of this engineer's exertions, Harte observes, "if my account stands right (and it comes from the best authority extant), our kingdom in the space of a few years, till the year 1651 only, had recovered, or was on the point of recovering, in Lincolnshire, Cambridgeshire, Huntingdonshire, and Kent, 425,000 acres of fens and morasses, which were advanced in general, from half a crown an acre to twenty and thirty shillings. So that, perhaps, few statesmen and generals have better deserved a statue or monument from this country than Vermuyden, the principal undertaker."

240. *The exportation of corn* was regulated by various laws, during the sixteenth century; and importation was not restrained even in plenty and cheapness. In 1663 was passed the first statute for levying tolls at turnpikes. Enclosures by consent and by act of parliament began also to be made during this century.

241. *The agriculture of Scotland during the fifteenth and sixteenth centuries* continued to languish, especially upon the estates of the barons, where the profession of a soldier was regarded as of greater importance than that of a cultivator of the ground; but the ecclesiastical lands were considerably improved, and the tenants of them were generally much more comfortably circumstanced than those upon the estates of laymen. The reformation of religion, beneficial as it was in other respects, rather checked than promoted agricultural improvement; because the change of property, which then occurred, occasioned a similar change of tenantry, and almost took husbandry out of the hands of the monks, the only class of people by whom it was practised upon correct principles. The dissolution of the monasteries and other religious houses was also attended with injurious consequences in the first instance; though latterly the greatest benefit has been derived from tithes and church lands having come into the hands of laymen. It is probable, had not these circumstances occurred, that the tithes system would have still remained in force, and Scottish husbandry have continued under a burthen, which sinks and oppresses the cultivator of England and Ireland. But tithes having got into the hands of lay titulars, or impropriators, were in general collected or farmed with such severity as to occasion the most grievous complaints, not only from the tenantry, but also from the numerous class of proprietors, who had not been so fortunate as to procure a share of the general spoil. This, added to the desire shown by the crown to resume the grants made when its power was comparatively feeble, occasioned the celebrated submission to Charles I., which ended in a settlement, that in modern times has proved highly beneficial, not only to the interest of proprietors, but likewise to general improvement. Tithes, in fact, are a burthen, which operate as a tax upon industry, though it was a long time before the beneficial consequences of withdrawing them were fully understood. (*Edin. Encyc.*, art. *Agr.*)

242. *Of the state of agriculture in Scotland during the greater part of the seventeenth century very little is known; no professed treatise on the subject appeared till after the revolution. The south-eastern counties were the earliest improved, and yet, in 1660, their condition seems to have been very wretched. Ray, who made a tour along the eastern coast in that year, says, "We observed little or no fallow grounds in Scotland; some ley ground we saw, which they manured with sea wreck. The men seemed to be very lazy, and may be frequently observed to plough in their cloaks. It is the fashion of them to wear cloaks when they go abroad, but especially on Sundays. They have neither good bread, cheese, nor drink. They cannot make them, nor will they learn. Their butter is very indifferent, and one would wonder how they could contrive to make it so bad. They use much pottage made of colewort, which they call *kail*, sometimes broth of decorticated harley. The ordinary country houses are pitiful cots, built of stone, and covered with turfs, having in them but one room, many of them no chimneys, the windows very small holes, and not glazed. The ground in the valleys and plains bears very good corn, but especially bears barley or bigge and oats, but rarely wheat and rye."* (*Select Remains of John Ray. Lond. 1760.*)

243. *It is probable that no great change had taken place in Scotland from the end of the fifteenth century, except that tenants gradually became possessed of a little stock of their own, instead of having their farms stocked by the landlord. "The minority of James V., the reign of Mary Stewart, the infancy of her son, and the civil wars of her grandson Charles I., were all periods of lasting waste. The very laws which were made during successive reigns, for protecting the tillers of the soil from spoil, are the best proofs of the deplorable state of the husbandman."* (*Chalmers's Caledonia, vol. ii. p. 732; Encyc. Brit., art. Agr.*)

244. *The accession of James VI. to the crown of England is understood to have been unfavourable to the agricultural interest of Scotland; inasmuch as the nobles and gentry, being by that event led into great expenses, raised the rents of the tenantry considerably, whilst the very circumstance which occasioned the rise, contributed to lessen the means of the tenant for fulfilling his engagements. Scotland, however, was much benefited by the soldiers of Cromwell, who were chiefly English yeomen, not only well acquainted with husbandry, but, like the Romans at a former period, studious also to improve and enlighten the nation which they had subdued. The soldiers of Cromwell's army were regularly paid at the rate of eightpence per day, a sum equal at least to the money value of two shillings of our currency; and as this army lay in Scotland for many years, there was a great circulation of money through the country. Perhaps the low country districts were at that time in a higher state of improvement than at any former period. In the counties of Lanark, Renfrew, Ayr, and Kirkcudbright, the rentals of various estates were greater in 1660, than they were seventy years afterwards; and the causes which brought about a declension in value are ascertained without difficulty. The large fines exacted from country gentlemen and tenants in these counties, during the reign of Charles II. and his brother James, were almost sufficient to impoverish both proprietors and cultivators, had they even been as wealthy as they are at the present day. In addition to those fines, the dreadful imprisonments, and other oppressive measures pursued by those in power, equally contrary to sound policy and to justice and humanity, desolated large tracts, drove the oppressed gentry and many of their wealthy tenants into foreign countries, and extinguished the spirit of industry and improvement in the breasts of those who were left behind.*

245. *Yet in the seventeenth century were those laws made which paved the way for the present improved system of agriculture in Scotland. By statute 1633, landholders were enabled to have their tithes valued, and to buy them either at nine or at six years' purchase, according to the nature of the property. The statute 1685, conferring on landlords a power to entail their estates, was indeed of a very different tendency, in regard to its effects on agriculture; but the two acts in 1695, for the division of commons, and separation of intermixed properties, have facilitated in an eminent degree the progress of improvement.* (*Encyc. Brit., art. Agr.*)

246. *The literary history of agriculture, during the seventeenth century, is of no great interest till about the middle of that period. For more than fifty years after the appearance of Googe's work, there are no systematic works on husbandry, though several treatises on particular departments of it. From these it is evident, that all the different operations of the farmer were performed with more care and correctness than formerly; that the fallows were better worked; the fields kept free of weeds; and much more attention paid to manures of every kind. A few of the writers of this period deserve to be shortly noticed.*

247. *Sir John Norden's Surveyor's Dialogue, printed in 1607, is a work of considerable merit. The first three books of it relate to the rights of the lord of the manor, and the various tenures by which landed property was then held, and the obligations which they imposed: among others, we find the singular custom, so humorously described in the *Spectator*, about the incontinent widow riding upon a ram. In the fifth book, there are a good many judicious observations on the "different natures of grounds, how*

they may be employed, how they may be bettered, reformed, and amended." The famous meadows near Salisbury are mentioned; and when cattle have fed their fill, hogs, it is pretended, "are made fat with the remnant, namely, with the knots and sappe of the grasse." So many extravagant assertions have been made about these meadows by several of our early writers, that we ought to receive their statements with some degree of scepticism, wherever they seem to approach the marvellous. "Clover grass, or the grass honeysuckle" (white clover), is directed to be sown with other hay-seeds. "Carrot-roots" were then raised in several parts of England, and sometimes by farmers." London street-dung and stable-dung were carried to a distance by water; though it appears from later writers to have been got almost for the trouble of removing. And leases of twenty-one years are recommended for persons of small capital, as better than employing it in purchasing land; an opinion that prevails very generally among our present farmers.

248. *Bees* seem to have been great favourites with these early writers; and among others, there is a treatise by Butler, a gentleman of Oxford, called the *Feminine Monarchie, or the History of Bees*, printed in 1609, full of all manner of quaintness and pedantry.

249. *Markham, Mascoll, Gabriel Plattes, Weston*, and other authors, belonged to this period. In Sir Richard Weston's *Discourse on the Husbandry of Brabant and Flanders*, published by Hartlib, in 1645, we may mark the dawn of the vast improvements which have since been effected in Britain. This gentleman was ambassador from England to the Elector Palatine and King of Bohemia, in 1619, and had the merit of being the first who introduced the *great clover*, as it was then called, into English agriculture, about 1645, and probably turnips also. In less than ten years after its introduction, that is, before 1655, the culture of clover, exactly according to the present method, seems to have been well known in England, and had made its way even to Ireland.

250. *A great many works on agriculture appeared during the time of the commonwealth*, of which Blythe's *Improver improved* and Hartlib's *Legacy* are the most valuable. The first edition of the former was published in 1649, and of the latter in 1650; and both of them were enlarged in subsequent editions. In the first edition of the *Improver improved*, no mention is made of clover, nor in the second of turnips; but, in the third, published in 1662, clover is treated of at some length; and turnips are recommended as an excellent cattle crop, the culture of which should be extended from the kitchen-garden to the field. Sir Richard Weston must have cultivated turnips before this; for Blythe says, that "Sir Richard affirmed to himself, he did feed his swine with them; they were first given boiled, but afterwards the swine came to eat them raw," and "would run after the carts and pull them forth as they gathered them;" an expression which conveys an idea of their being cultivated in the fields.

251. *Blythe's book is the first systematic work in which there are some traces of the convertible husbandry*, so beneficially established since, by interposing clover and turnip between culmiferous crops. He is a great enemy to commons and common fields; and to retaining land in old pasture, unless it be of the best quality. His description of different kinds of ploughs is interesting; and he justly recommends such as were drawn by two horses (some even by one horse), in preference to the weighty clumsy machines which required four horses or oxen, or more. Almost all the manures now used seem to have been then well known; and he brought lime himself from a distance of twenty miles. He speaks of an instrument which ploughed, sowed, and harrowed at the same time; and the *setting of corn* was then a subject of much discussion. "It was not many years," says Blythe, "since the famous city of London petitioned the parliament of England against two anasancies or offensive commodities, which were likely to come into great use and esteem; and that was Newcastle coal, in regard of their stench, &c.; and hops, in regard they would spoyle the taste of drinke, and endanger the people!"

252. *Hartlib's Legacy* is a very heterogeneous performance, containing among some very judicious directions, a great deal of rash speculation. Several of the deficiencies which the writer (R. Child) complains of in English agriculture, must be placed to the account of our climate, and never have been nor can be supplied.

253. *Houghton's valuable Collections of Husbandry* have been already mentioned. (237.)

254. *Worlidge's Systema Agriculturæ* was published in 1668; it treats of improvements in general, of enclosing meadows and pastures, and of watering and draining them, of clovers, vetches, spurry, Wiltshire long-grass (probably that of the meadows of Salisbury), hemp, flax, rape, turnips, &c. A Persian wheel was made by his direction in Wiltshire, in 1665, that carried water in good quantity above twenty feet high, for watering meadows, and another near Godalming in Surrey. Sowing clover and other seeds preserved the cattle in the fatal winter of 1673, in the southern parts of England; whereas in the western and northern, through defect of hay and pasture, the greater part of their cattle perished. Hops enough were not planted, but we imported them from the Netherlands of a quality not so good as our own. The authors he chiefly quotes are Weston, Hartlib, and Blythe.

255. *Among other writers of this century* may be mentioned Bacon, who, in his natural history, has some curious observations on agriculture; Ray, the botanist, whose works are rich in facts; and Evelyn, a great encourager of all manner of improvements, as well as a useful writer on planting.

256. *Some of the works of the sixteenth and seventeenth centuries* are now very scarce,

and most of them little known to agriculturists of the present day. In almost all of them there is much that is now useless, and not a little that is trifling and foolish; yet the labour of perusal is not altogether fruitless. He who wishes to view the condition of the great body of the people during this period, as well as the cultivator who still obstinately resists every new practice, may, each of them, be gratified and instructed, in tracing the gradual progress of improvement, both in enjoyment and useful industry. (*Encyc. Brit.*, art. *Agr.*)

SECT. V. *History of Agriculture in Ultra-European Countries during the Middle Ages.*

257. *The general history of the old Ultra-European countries*, during this period, is not known with sufficient precision and detail, to enable us to give a progressive account of their agriculture. There is no evidence of any improvement having been made in the agriculture of the Indian and Chinese nations, from the earliest period of their known history to the present time. The agriculture of Persia, of the African shores of the Mediterranean sea, and of all the countries under the Turks, seems, if any change has taken place, rather to have declined than advanced during the latter centuries of the middle ages.

258. *The history of the new Ultra-European countries of America and Australasia*, only dates its commencement (with the exception of part of America) from the latter end of the period under notice, and therefore cannot furnish sufficient materials for any useful account of their agriculture. Under these circumstances we think it better to defer an account of the origin and progress of Ultra-European agriculture till the succeeding Chapter, where it will precede some account of its present state. We have adopted the same plan with respect to the agriculture of some of the northern European nations, as Russia and Sweden, and also with regard to that of Spain and Ireland.

CHAP. IV.

Present State of Agriculture in Europe.

259. *Agriculture began to be studied, as a science*, in the principal countries of Europe, about the middle of the 16th century. The works of Crescenzo in Italy, Olivier de Serres in France, Heresbach in Germany, Herrera in Spain, and Fitzherbert in England, all published about that period, supplied the materials of study, and led to improved practices among the reading agriculturists. The art received a second impulse in the middle of the century following, after the general peace of Aix-la-Chapelle. Then, as Harte has observed (*Essays*, i. p. 62.), "almost all the European nations, by a sort of tacit consent, applied themselves to the study of agriculture, and continued to do so, more or less, even amidst the universal confusion that soon succeeded." During the 18th century, the march of agriculture has been progressive throughout Europe, with little exception; and it has attained to a very considerable degree of perfection, in some districts of Italy, in the Netherlands, and in Great Britain. In Spain it has been least improved, and it is still in a very backward state in most parts of Hungary, Poland, and Russia. We shall, in the following sections, give such notices of the agriculture of these and the other countries of Europe, as we have been enabled to glean from the very scanty materials which exist on the subject. Had these been more abundant, this part of our work would have been much more instructive. The past state of agriculture can do little more than gratify the curiosity, but its present state is calculated both to excite our curiosity and affect our interests. Independently of the political relations which may be established by a free trade in corn, there is probably no European country that does not possess some animal or vegetable production, or pursue some mode of culture or management, that might not be beneficially introduced into Britain; but, with the exception of Flanders and some parts of France and Italy, there are as yet no sufficient data for obtaining the necessary details.

SECT. I. *Of the present State of Agriculture in Italy.*

260. *Italy is the most interesting country of Europe in respect to its rural economy.* Its climate, soils, rivers, and surface are so various, as to have given rise to a greater variety of culture than is to be found throughout the rest of Europe; while the number of governments and petty states into which it is divided, has occasioned an almost equally great variety in the tenure of land, and the political circumstances which affect the cultivator. The great advantage which Italy possesses over the rest of Europe, in an agricultural point of view, is its climate; for though, as the learned Sismondi has shown (*Annals of Agric.*, vol. i.), it is, in point of health and agreeableness, one of the worst in the

world, yet the cool temperature of some of the northern districts admits of the finest pastures, while, from the warmth of others, the rocky sides of hills are as productive of grapes and olives as the plains are in corn. It is the only country in Europe, with the exception of some parts of Spain, where corn, grass, butcher's meat, cheese, butter, rice, silk, cotton, wine, oil, and fruits are produced, all in the highest degree of perfection. Only a fifth of its surface is considered sterile; while only a fifth of the surface of France is considered fertile. The population of Italy is greater in proportion to the surface, than that of either France or Britain.

261. *The writers on the rural economy of Italy* are, Arthur Young, in 1788; Sismondi, in 1801; and, Chateaubvieux, in 1812. From the works of these authors, from those of Forsyth, Wilson, and other recent tourists, and from our own observations in 1819, we shall select some of the most characteristic traits as to the agriculture of Italy, adopting the division of Chateaubvieux, of the region of irrigation, and the rotation of crops, in Lombardy; the region of vines and olives, exemplified in Tuscany; the region of insalubrious air, or the states of the church; and the region of volcanic ashes, or the Neapolitan culture.

SUBSECT. 1. *Of the Agriculture of Lombardy.*

262. *The climate of Lombardy* is less irregular than that of some other districts. It is temperate on the declivities of the mountains in Piedmont, where the richest sheep pastures are situated; subject to great vicissitudes and to severe storms at the base of the Alps; and warm and humid in the plain of the Po. In some parts the olive and the orange endure the open air throughout the year, as in the islands of the lakes; in other places, at Milan for example, they require nearly as much protection in winter as in England.

263. *The soil of the plain of the Po* has evidently been formed by the recession or deposition of water, and is a rich black mould, deep, and every where perfectly level.

264. *These lands are every where enclosed*, either with hedges and ditches, or with open water-courses for irrigation. The hedges, however, are not very well kept: they are a mixture of different plants; often of willows chiefly, occasionally of the mulberry for feeding the silkworms, and sometimes of reeds. The hedge-plants of the country are the Christ's thorn (*Paliurus australis*, fig. 31.), common hawthorn, and pomegranate.

265. *The lands are generally farmed by metayers* (from *meta*, one half, *Ital.*). The landlord pays the taxes, and repairs the buildings; the tenant provides cattle, implements, and seed; and the produce is divided. In some cases the landlord's half is delivered to him in kind; in others it is valued annually at harvest, and paid in money, or partly in money and partly in produce. There are some farmers who have leases, generally for short periods, not exceeding nine years, and pay fixed rents. The size of farms is from ten to sixty acres; but there are a few of two or three hundred acres. The latter, however, are chiefly cultivated by the proprietors. Farm-houses are of brick, sometimes stuccoed, and covered with tiles. They are not always detached; but two, three, or more, farmeries are often grouped together, and their united buildings might be mistaken for those of one large farm. One side of a square contains the houses of the farmers, the stables, and cattle-sheds; and the three others are sheds, supported by columns, and open on all sides, for implements and produce. The metayers never get rich, and are seldom totally ruined; they are not often changed; the same farm passes from father to son, like a patrimonial estate.

266. *Landed property is generally managed by a steward or factor* (*fattore*), whose business it is to inspect the cultivation of the lands, to direct repairs, pay taxes and tithes, and see that the landlord has his proper share of the produce. Tithes have been greatly lessened by the sale of a great part of the church lands at the revolution; but are still taken in kind, or commuted for, in order to support the parish clergy.

267. *The irrigation of Lombardy* is its most remarkable feature. The antiquity of the practice has been already noticed (180). In most states of Italy, the right and property of all rivers, and in some, as Venice, even of springs and rain, are considered as vested in the king or government. All canals taken from rivers are, therefore, purchased from the state, and may be carried through any person's lands, provided they do not pass through a garden, or within a certain distance of a mansion, on paying the value of the ground occupied. Such canals, indeed, are generally considered as enhancing the value of the property they pass through, by enabling them to purchase water, which is sold by the hour, half hour, or quarter, or by so many days' run, at certain fixed times, in the year. The right to water from such canals may even be purchased; and Arthur Young

mentions that the fee-simple for an hour's run per week, through a sluice of a certain dimension, near Turin, was, in 1788, 1500 livres. The water is not only used for grass-lands, which, when fully watered, are mown four, and sometimes five, times a year, and in some cases (e. g. Prato Marcita) as early as March; but is conducted between the narrow ridges of corn-lands, in the hollows between drilled crops, among vines, or to flood, a foot or more in depth, lands which are sown with rice. It is also used for *combles*, or depositing a surface of mud, in some places where the water is charged with that material; and this is done somewhat in the manner of what we call warping. The details of watering, for these and other purposes, are given in various works; and collected in those of Professor Re. In general, watered lands let at one third higher than lands unwatered.

268. *The implements and operations of agriculture in Lombardy* are very imperfect. The plough is of very rude contrivance, with a handle thirteen or fourteen feet long. It is drawn by two oxen without a driver or reins, the ploughman using a long light rod or goad. The names given to the different parts of the plough are corruptions or variations of the Roman terms already mentioned. (111.) Corn is generally beaten out by a wheel or large fluted cylinder (*fig. 32.*), which is turned in a circular track, somewhat in the manner of a bark-mill in England.

32

269. *The cattle of Piedmont* are, in some cases, fed with extraordinary care. They are tied up in stalls; then bled once or twice; cleaned and rubbed with oil; afterwards combed and brushed twice a day: their food in summer is clover, or other green herbage; in winter a mixture of elm leaves, clover-hay, and pulverised walnut-cake, over which boiling water is poured, and bran and salt added. Where grains (*ponture*) can be procured, they are also given. In a short time, the cattle cast their hair, grow smooth, round, fat, and so improved as to double their value to the butcher. (*Mem. della Soc. Agr.*, vol. i. p. 73.)

270. *The dairies on the plain of the Po*, near Lodi, produce the Parmesan cheese. The peculiar qualities of this cheese depend more on the manner of making than on any thing else. The cows are a mixed breed, between the red Hungarian or Swiss cow, and those of Lombardy. The chief peculiarity in their feeding is, that they are allowed to eat four or five hours in the twenty-four; all the rest of the time they are stalled, and get hay. Both their pasture and hay are chiefly from irrigated lands. The cheeses are made entirely of skimmed milk; half of that which has stood sixteen or seventeen hours, and half of that which has stood only six. The milk is heated and coagulated in a caldron (*fig. 33.*), placed in a very ingenious fire-place, being an inverted semi-cone in brickwork, well adapted for preserving heat and for the use of wood as fuel. Without being taken out of the caldron, the curd is broken very small by an implement, consisting of a stick with cross wires; it is again heated, or rather scalded, till the curd, now a deposition from the whey, has attained a considerable degree of firmness; it is then taken out, drained, salted, and pressed, and in forty days is fit to put in the cheese-loft. The peculiar properties of this cheese seem to depend on the mode of scalding the curd; though the dairysts pretend that it also depends on the mode of

33

feeding the cows. Where one farmer has not enough of cows to carry on the process himself, it is common for two or more to join and keep a partnership account, as in Switzerland. More minute details will be found in BOOK IV. PART VII.

271. *Sheep are not common in Lombardy*: there are flocks on the mountains, but in the plains only a few are kept, in the manner pigs are in England, to eat refuse vegetables. The Merino breed was introduced, and found not to succeed.

272. *The rotations of crops* are not so remarkable for preserving the fertility of the soil, as for an immediate return of profit. The produce however being seldom bulky, the object is defeated. As examples, we may mention, 1. maize drilled; 2, 3, and 4. wheat; 5. maize drilled; 6, 7, and 8. wheat. Another is, 1. fallow; 2, 3, and 4. rice; 5. fallow; 6. wheat and clover, &c. Hemp, flax, lupines, rape, millet, panic, rye, and sometimes oats, with other crops, enter into the rotations. Rice is reckoned the most profitable crop; the next, wheat and millet. The rice-grounds receive but one ploughing, which is given in the middle of March, and the seed is sown at the end of the same month; sometimes in water up to the seedsman's knees, but more frequently the water is not let on till the rice is come up. The water is then admitted, and left on the ground till the beginning of June, when the crop is weeded by hand, by women half naked, with their petticoats tucked to their waists, wading in the water; and they make so droll a

figure, that parties are often made at that season to go and view the rice-grounds. When the weeding is finished, the water is drawn off for eight days; it is again drawn on when the ear begins to form, but after its formation is let in again till the rice is nearly ripe, which is about the end of August or beginning of September. The produce is from ten to twenty fold.

273. Among the herbage crops cultivated, may be mentioned chicory, very common in the watered meadows, rib-grass, also very common, oat-grass, and some other grasses but not near the variety of grasses found in the English meadows and pastures; fenu greek (*Trigonélla L.*), clovers, lucerne, saintfoin, and in some places burnet and spurry

*274. Among the trees grown by the farmer, the mulberry predominates, and is pollarded once or oftener every year for the silkworm. The tree is common in the hedge-rows, and in rows along with vines parallel to broad ridges. The vine is generally cultivated trained or rather hung on mulberry, maple, or flowering ash pollards, or climbing up tall elms, or in the hedges, or against willow poles or rude espalier rails. The olive is no very common, but is planted in schistous declivities in warm situations; the apple, pear and green gage plum are common.

275. Though the agriculture of Lombardy appears to be practised more for subsistence than for the employment of capital and the acquisition of riches, yet, from the effect of irrigation in producing large crops of grass, the profits of rearing silk, and the rigid economy of the farmers, it is thought by Chateauvieux that it sends more produce to market than any district of Italy. (*Italy*, let. iv.)

SUBJECT. 2. Of the Agriculture of Tuscany.

276. The picture of the agriculture of Tuscany given by Sismondi, a distinguished literary character of Geneva, who resided five years as a cultivator in that country, is well known. Sismondi arranges the rural economy of this district into that of the plains, the slopes and the mountains; and we shall here state the most interesting or characteristic circumstances which occur in his work, or that of Chateauvieux, under these heads. According to Forsyth, one half of Tuscany consists of mountains which produce nothing but timber one sixth of olive and vine hills; and the remaining third is plain. The whole is distributed into eighty thousand fattorie, or stewardships. Each fattoria includes, on an average seven farms. This property is divided among forty thousand families or corporations. The Riccardi, the Strozzi, the Feroni, and the Benedictines rank first in the number. The clergy keep the farmers well disciplined in faith, and through the terror of bad crops they begin to extort the abolished tithes. This was in 1802: tithes are again fully established under the Austrian power.

277. The climate of Tuscany is esteemed the best in Italy, with the exception of that of its mareinme, or pestilential region on the sea-coast. The great heats commence at the end of June, and diminish in the middle of September; the rest of the year is; perpetual spring, and vegetation in the plains is only interrupted for two or three weeks in the middle of winter. On the mountains there is snow all the year; and the hill districts enjoy a temperate but irregular weather in summer, and a winter of from one to three months.

278. The soil of the plains is either sand or mud of "inexpressible fertility;" some parts were marshy, but the surface is now comparatively elevated and enriched (as was that of the Delta) by combles (colmata), or warping, a process ably described by Sismondi. (*Agr. Tuscan.*, § ii.)

279. Irrigation in the plains is practised in all the different modes as in Lombardy, but on a smaller scale, correspondent with their extent.

280. The plain is every where enclosed. The fields are parallelograms, generally one hundred feet broad, and four or five hundred feet long, surrounded by a ditch planted with Lombardy poplars and vines, with rows, lengthwise, of mulberries, maple, or the flowering or manna ash, also interspersed with vines; and often, by the way-sides, these hang in festoons, from tall elms. (fig. 34.) The poplars supply leaves for feeding heifers, rods which are sold for making espaliers for vines, and spray for fuel. Every now and then a few are cut down for timber, as at twenty years they are found to be too large for the situation. The top of the ash and maple is used for fuel; the timber for implements of husbandry. The mulberry is pollarded every other year for the leaves, which are stripped off for the silkworms, and the spray used as fuel. The produce of raw silk is one of the most important in Tuscany, and is almost the only article the farmer of the plains has to exchange for money. He has wine also, it is true, but that, though produced in abundance, is of so wretched a quality, compared with that of the hills, that it brings but little. Hedges are only planted on the road sides to keep off beggars and thieves, who are very numerous, and who steal the grapes and the ears of maize. Some-

times the grapes next the road are sprinkled with mud or lime-water to deter them ; at other times a temporary dead fence of thorns is used during the ripening season and taken down afterwards. The hedge plants are the hawthorn, sloe, bramble, briar, evergreen rose, ilex, service, myrtle, pomegranate, bay, laurel, &c.

281. *In the arable lands of the plains*, the row and mostly the raised drill culture are generally followed, or the land is ploughed into beds of three or four feet broad, between which water is introduced in the furrows. Every year a third of the farm is turned over with a spade to double the depth of the plough, so as to bring a new soil to the surface. The sort of trenching which effects this is performed differently from that of any other country ; the spade being thrust in horizontally or obliquely, and the trench formed by taking off successive layers from the top of the firm side, and turning them regularly over in the trench. In this way the surface is completely reversed.

282. *The rotation of crops in the plain* includes a period of three or five years, and five or seven crops. There are, for a three-years' course ; 1. wheat or other grain, and lupines in the autumn ; 2. corn of some sort, and turnips or clover in the autumn ; 3. maize, panic, or common millet, and Indian or black millet (*Hólcus Sorghum*). Corn is cut about the end of June close to the earth, left to dry a day or two, and then tied in bundles (*bottes*), and put in cocks for a week or two. At the end of this period the ears are cut off, and beaten out on a smooth prepared piece of ground in the farm-yard. The straw is stacked, and the corn cleaned by throwing it with shovels, &c. The corn is laid up till wanted in oval excavations in dry ground, which are covered with tiled roofs. The excavations are lined with straw ; one holds from twenty to a hundred sacks, and being covered with straw, is heaped over with earth. In this way it is kept in perfect preservation a year or longer, and untouched by insects. The lupines sown after wheat are often ploughed in for manure ; sometimes French beans are substituted, and the ripe seeds used as food ; or turnips are sown for cattle. They have few sorts of turnips that are good ; and Sismondi complains that half of them never bulb. Maize is sown in drills, and forms a superb crop in appearance, and no less important, constituting the principal food of the lower classes in every part of Italy where the chestnut does not abound.

When the male flowers of the maize begin to fade, they are cut off by degrees, so as not to injure the swelling grain ; the leaves are also cut off about that time, cattle being remarkably fond of them. In the plain of Bologna, hemp, flax, and beans enter into the rotation.

283. *Cattle in the plains* are kept constantly in close warm houses, and fed with weeds, leaves, or whatever can be got. The oxen in Tuscany are all dove-coloured ; even those which are imported from other states, are said to change their coat here. They are guided in the team by reins fixed to rings which are inserted in their nostrils ; sometimes two hooks, jointed like pincers, are used for the same purpose. In general, only one crop in four is raised for the food of cattle, so that these are not numerous ; it may thus appear that manure would be scarce, but the Tuscan farmers are as assiduous in preserving every particle both of human and animal manure as the Flemings.

284. *The farm-houses of the plain of Tuscany*, according to Lasteyrie (*Coll. de Mach.*), are constructed with more taste, solidity, and convenience, than in any other country on the Continent. They are built of stones generally, in rubble work, with good lime and sand, which become as hard as stucco, and they are covered with red pantiles. The elevation (*fig. 35.*) presents two deep recesses, the one a porch or common hall to the ground floor, or hus-

bandry part of the edifice (*a*); and the other above it to the dwelling family apartments. The ground floor consists of this porch, which is arched over (*a*), a workshop (*b*), a harness and tool-room (*c*), pigsty (*d*), poultry-house (*e*), a stove (*f*), staircase (*g*), stable (*h*), cow or ox house (*i*), and sheep-house (*k*). The dwelling floor consists of the upper gallery or open hall (*l*), which serves as a sort of kitchen, work-room, or scullery, a kitchen (*m*), a master and mistress's room (*n*), a girls' room (*o*), a boys' room (*p*), a store room (*q*), and silkworm room (*r*).

285. *The peasants, or farmers, of the plains* are for the most part metayers; their farms are from five to ten acres, each having a house and offices, like that just described, towards its centre. Some pay a fixed rent on short leases; and some hold farms on improving leases which extend to four generations. They are more than economical; never tasting butcher's meat but on Sunday. The three repasts of the other days are either of porridge of maize and a salad; porridge of bread and French beans, seasoned with olive oil; or of some sort of soup. In general the whole family remain at home, and aid their parents in performing the labours of the farm. Seldom any but the oldest son marries; and when the father dies he succeeds in his turn, and his brothers and sisters serve him as they did their father till they die off, and are replaced by their nephews and nieces. Such is the state of things which, as Chateauxvieux has observed, is the result of early civilisation and excessive population.

286. *The culture of the hills and declivities*, Chateauxvieux supposes to have been introduced from Canaan at the time of the crusades: but, though that culture, and also the irrigation system, have, no doubt, been originally copied from that country and Egypt, yet some think it more likely to have been imported by the Romans or the priests, than by the chivalric adventurers of the eleventh and twelfth centuries.

287. *The soil of the hills* is in general either schistous or calcareous, on a pliable rocky or gravelly bottom. It is cut into horizontal terraces, of different widths according to the steepness of the declivity, and each terrace is supported by a wall or sloping bank of turf or stones. Intercepting gutters are formed every sixty or seventy feet, in the direction of the slope, to carry off the waters which do not sink in the rainy season. Sismondin considers the turfed terraces of the hills of Nievole the most elegant. On the terraces of the most rapid and least favourably exposed slopes, olives are planted; on the best exposure, vines. Where the terrace is broad, two rows of mulberries, and sometimes of fig trees, are planted, and between these, where the soil is not too dry, early crops of grain or legumes are taken. The walls of turf are mown.

*288. *The olive* being an evergreen, and in a state of growth all the year, requires a more equable climate than the vine; but it will grow on any dry soil, and in an inferior exposure, because the fruit never ripens till the hoar frosts have commenced. The young plants are raised from cuttings or suckers in a nursery, and in the same manner in which it was during the time of the Romans. "An old tree is hewn down, and the ceppo, or stock (that is, the collar or neck between the root and the trunk, where in all plants the principle of life more eminently resides), is cut into pieces of nearly the size and shape of a mushroom, and which from that circumstance are called *novali*; care at the same time is taken that a small portion of bark shall belong to each *novalo*; these, after having been dipped in manure, are put into the earth, soon throw up shoots, are transplanted at the end of one year, and in three years are fit to form an olive yard." (*Blunt's Vestiges*, 216.) They are planted generally fifteen feet apart in rows, with the same distance between the rows.

289. *The olive is of very slow growth but of great duration.* Some plantations exist, which are supposed to be those mentioned by Pliny, and therefore must have existed nearly two thousand years, if not more. In one of these, which we have seen in the vale of Marmora, near Terni, the trunks of many trees have rotted at the core, and the circumference has split open and formed several distinct stems. Though in ruins, these trees still bear abundant crops. The olive requires little pruning, and is seldom otherwise manured than by sowing lupines under it, and digging them in. The fruit becomes black in November; is gathered in the course of that and the three following months; and ground in a stone trough by a stone turned by a water-wheel. The paste formed by the fruit, and its kernels, is then put in a hair cloth and pressed, and the oil drops in a tub of water somewhat warm, from which it is skimmed and put in glass bottles for sale, or glazed jars for home consumption. The paste is moistened and pressed a second and third time for oils of inferior quality. The crop of olives is very uncertain; sometimes one that yields a profit does not occur for six or eight years together, as in the culture of wine and cider: and these departments of culture on the Continent are considered as injurious to the peasant, because in the year of plenty he consumes his superfluous profits, without laying any thing aside to meet the years of loss. Hence the remark common in France and Italy, that wine and oil farming is less beneficial than that of corn.

290. *The vine on the hills* is generally raised where it is to remain, by planting cuttings; but it is also planted with roots procured by layering: in either case, it seldom bears fruit

till the fifth year after planting. It is trained on trees, poles, and trellised roofs, over paths, and different kinds of espalier rails. The poles are of barked chestnut, and the lesser rods used are generally of reeds; the latter forms a profitable article of culture on the brink of water-courses for this purpose. These reeds last from one to four years, according to their size. The ties used in binding the vine both on the hills and plains are of willow, often the yellow or golden sort. The general maxim in pruning the vine is to leave as much wood to one stool as possible, in order to prevent two shoots from proceeding from one eye, in which case both are generally barren. They give no summer pruning; but, when the fruit is nearly ripe, they cut off the extremities of the shoots for the sake of the leaves as forage, and to admit the sun and air more directly to the fruit. The pruning-hook they use (*fig. 36.*) is not unlike a hand hedge-bill. The fruit is gathered by women, and put into baskets and hampers; then carried to a tub or cistern of masonry, where it lies and ferments, being frequently stirred, but not pressed as in France and other parts of Italy. The management of the wine is not considered good; and there are but few sorts of Tuscan wine that will keep above a year.

291. *The potato*, little known in Lombardy, was introduced in the hills of Tuscany by Sismondi, but was little cultivated or esteemed. It is only known, he says, to the gardeners of Florence and Leghorn. If not taken up about the middle of July, the tubers are either burned and rotted by the heat, or they germinate at every bud. An early sort, he thinks, might be introduced both in the plain and hill culture with great advantage.

292. *The hill farmers*, like those of the plains, are generally metayers, and rent their farms, which seldom exceed seven or eight acres; and the most general conditions of their lease (bail), according to M. Sismondi, are the following:—1. The farmer engages to cultivate the lands, and find the requisite props for the vines. 2. To advance the half of the seed, and the half of the dung that is obliged to be purchased. 3. To deliver to the proprietor half the crop, or sell it for his account. 4. To divide with the proprietor the profit made on cattle, and to deliver a certain number of eggs, chickens, and capons in lieu of that on poultry. 5. To wash the whole or a part of the proprietor's linen, he finding soap. The proprietor on his part engages to advance the other half of the seed, and of the manure which must be purchased; to be at the expense of making up new grounds and other radical improvements, to effect repairs, &c., and to find the first props for newly planted vines. This contract goes on from year to year, and can only be dissolved by a year's notice; changes, however, very seldom take place. The conditions in some places are more severe for the farmer; and on oil and certain other articles he only receives a third of the profits.

293. *The culture of the mountains of Tuscany* consists of the harvesting of chestnuts, and the management of live stock and of forests. The chestnut trees, Sismondi is of opinion, have been originally planted, but they now receive no other care than that of replacing a worn out tree by a young one, and cutting out dead wood, which is done more for the sake of fuel than any thing else. The fruit is gathered in November, after it drops on the turf: it is eaten either in its natural state, or it is ground into meal and prepared as flour. Such as are to be ground, are first kilndried; next, they are put into small bags, which hold half a bushel each, and these are beat against the ground till the outer husk is removed; they are then taken out, the outer husks separated, and the chestnuts replaced, and beat as before till the inner husk comes off; they are then cleaned in the wind, and sent to a corn-mill to be ground. The flour they produce has no bran, and is mild and sweet, and keeps well. Lands covered with chestnuts are valued, not by their extent, but by the number of sacks of fruit annually produced. Chestnut flour is chiefly used in the form of porridge or pudding. In the coffee-houses of Lucca, Pescia, and Pistoja, patés, muffins, tarts, and other articles are made of it, and are considered delicate.

294. *The management of sheep in the mountains* is rude and unprofitable, and so little is mutton esteemed in Tuscany that it always sells at two or three sous a pound under every other meat. The sheep are pastured all the summer under the chestnut trees; but in October, when the fruit begins to fall, they are sent to the marennes, where they remain till the May or June following, at the cost of not more than a penny a head. A wretched cheese is made from the milk; but, bad as it is, it is better than what is made from the milk of goats or cows. The Tuscans, indeed, are so unwilling to believe that good cheese can be produced from the latter animals, that they consider the Dutch and other excellent foreign cheeses which they purchase at Leghorn, as all made from the milk of sheep.

295. *Forests of timber trees cover the highest parts of the mountains.* These form sources of profit to the peasantry, independently of the sale of timber, which is very limited, owing to the difficulty of carriage. Hogs are pastured there, left to themselves the whole year, and only sought for when wanted for the butcher. Their flesh is excellent,

and, being very abundant in the markets of most parts of Italy, is not dear. Acorns are collected in some places, and sold to the farmers of the plains, for feeding swine. The cones of the *Pinus Pinea* (fig. 37.) are collected, and the seeds taken out: these are much esteemed, and bear a high price. The same thing is, in some places, done with the cones of the wild pine, commonly but erroneously called the Scotch fir (*Pinus sylvestris* L.), whose seeds are equally good, though smaller. Strawberries, bramble-berries, gooseberries, currants, raspberries, and other wild fruits, are collected, and either sold publicly in the markets of the plains, or privately to the confectioners for flavouring ices; an article in great demand throughout all Italy. Sismondi seems to have been the first who noticed that the black mulberry was grown in the mountains for its leaves, being considered as hardier than the white. The fruit was only eaten by children. In the plains and gardens of Italy the mulberry is scarcely known as a fruit tree, though the white species is every where grown for the silkworm.

296. *The mountain farmers* are generally proprietors of their farms. They live together in villages, which are very numerous; many of them hire themselves to the farmers of the maremmes, where there is a scarcity of population, to assist in their harvests; and with the money saved in this way, and by sending fruits, collected by their wives and children, to the towns in the plains, they are generally better off than the farmers of the hills, or of the low country.

297. *The agricultural establishment of Rossore* may be mentioned as belonging to Tuscany. It is situated at the gate of Pisa, and was founded by the family of Medici, in the time of the crusades, and now belongs to government. A league square of ground, which was so poor and sandy as to be unfit for culture, was surrounded by a fence, and, having been left to itself, has now the appearance of a neglected park. A building was erected in its centre as a lodge, and the grounds were interspersed with stables and sheep houses. The park was stocked with an Arabian stallion and a few mares, and some Asiatic camels; and these were left to breed and live in a state of nature. About the beginning of the present century a flock of Merino sheep was added. The horses have formed themselves into distinct tribes or troops, each of fifteen or twenty mares governed by a stallion. These tribes never mix together, each has its quarter of pasture which they divide among themselves without the interference of shepherds. The shape of these horses is wretched, and the spare or superfluous ones are sold only to fuel-drivers (coalmen, *carbonari*) and the post. There are more than two hundred camels which associate together, and multiply at pleasure. They are worked in the plough and cart, and the spare stock supplies all the mountebanks of Europe, who buy them at the low price of six or seven louis each. The next feature of this establishment is a herd of 1800 wild bulls and cows, fierce and dangerous; the superfluous stock of these is either hunted and killed for their hides and flesh, or sold alive to the farmers to be fed or worked. The flock of Merinos are but lately introduced. Such are the chief features of this establishment, which Chateaubvieux terms a specimen of Tatar culture. It is evident it has no other art or merit than that of allowing the powers and instincts of nature to operate in their own way; and it forms a very singular contrast to the highly artificial state of rural economy in Tuscany.

SUBJECT. 3. *Of the Agriculture of the Maremmes, or the District of Pestilential Air.*

298. *The extent of this district* is from Leghorn to Terracina in length; and its widest part is in the states of the church; it includes Rome, and extends to the base of the Apennines.

*299. *The climate of the maremmes* is so mild that vegetation goes on during the whole of the winter; but so pestilential that there are scarcely any fixed inhabitants in this immense tract of country, with the exception of those of the towns or cities on its borders.

300. *The surface* is flat or gently varied; and the soil in most places deep and rich. In the maremmes of Tuscany it is in some places a blue clay abounding in sulphur and alum, and produces almost nothing but coltsfoot (*Tussilago*).

301. *The estates* are generally extensive, and let in large farms, at fixed rents, to men of capital. The maremmes of Rome, forty leagues in extent, are divided into a few hundred estates only, and let to not more than eighty farmers. These farmers grow corn, and pasture oxen of their own; and in winter they graze the wandering flocks of the mountains of Tuscany and other states at so much a head. The corn grown is chiefly wheat, which is reaped by peasants from the mountains, some of whom also stay

and assist in sowing the succeeding crop; after which the whole disappear, and the marmes remain a desert with a few men, whom Chateauxvieux designates as "half savages, who run over these solitudes like Tatars, armed with long lances, and covered with coarse woollens and untanned skins." The lance they use in hunting down the oxen when they are to be caught for the butcher, or to be broken in for labour; and the clothing alluded to has been recommended by the medical men of Rome, as the most likely to resist the attacks of the malaria (bad air), or pestilence.

302. *The agricultural implements and operations* differ little from those of other parts of Italy. The plough, or araire, of Rome (fig. 38.) is a rude implement, with a broad flat share, on the hinder end of which the ploughman stands; and thus drawn along, his weight makes a deeper furrow. Two strips of wood (the *binæ aures* of Virgil), about eighteen inches long, are often attached to the share, diverging a little from each other, and these serve to lay open the furrow like our mould-board. In the operation of propagating the vine, cuttings are planted in

38

trenches four feet deep, into which stones have been previously thrown, for the alleged purpose of encouraging moisture about the roots. The same mode was practised in Virgil's time. (*Georg.*, ii. 346.) The common Roman cart (fig. 39.) is supposed to have been originally de-

39

signed by the celebrated Michael Angelo, in his quality of engineer and wheeler. (See *Lasteyrie, Col. des Mach.*)

303. *The farm of Campo Morto* (field of death) includes the whole property of St. Peter's church in Rome, which is supported from its sole revenue. This vast estate is situated in the Pontine marshes, and the following outline of its management is taken from a letter of Chateauxvieux, written in July 1813. —

304. *The farmery*, the only building on an estate of many thousand acres, consists of a central building and two wings, the ground-floor of the central part consists of an immense kitchen and five large rooms, the latter without windows, and unfurnished. The first story consists of six rooms, used as corn-chambers, with the exception of one, which was furnished, and served to lodge the principal officers. The two wings contained large vaulted stables, with hay-lofts over. One female lived in the house, in order to cook for the officers or upper servants, whose wives and families live in the towns as do those of the shepherds. There was no garden, nor any appearance of neatness or cleanliness, and not a fence or a hedge, and scarcely a tree on the whole farm.

305. *The fattore, or steward*, was an educated man, and a citizen of Rome, where his family lived; he and all the other officers, and even shepherds, always went out mounted and armed.

306. *The reapers* were at work in a distant part of the estate, when Chateauxvieux went over it: they were an immense band, ranged as in the order of battle, and guarded by twelve chiefs or overseers on horseback, with lances in their hands. These reapers had lately arrived from the mountains; half were men and the rest women. "They were bathed in sweat; the sun was intolerable; the men were good figures, but the women were frightful. They had been some days from the mountains, and the foul air had begun to attack them. Two only had yet taken the fever; but they told me, from that time a great number would be seized every day, and that by the end of harvest the troop would be reduced at least one half. What then, I said, becomes of these unhappy creatures? They give them a morsel of bread, and send them back. But whither do they go? They take the way to the mountains; some remain on the road, some die, but others arrive, suffering under misery and inanition, to come again the following year."

307. *The corn is threshed* fifteen days after being cut; the grain is trodden out under the feet of horses, cleaned, and carried to Rome. The straw was formerly suffered to be dispersed by the wind; but it is now collected in heaps at regular distances over the country, and always on eminences: there it lies ready to be burned on the approach of "those clouds of grasshoppers which often devastate the whole of this country."

308. *The live stock of the farm* consisted of a hundred working oxen; several hundreds of wild cows and bulls, kept for maintaining the stock, and for the sale of their calves and heifers; two thousand swine, which are fattened upon nuts and acorns in the forests belonging to the estate; and a hundred horses for the use of the herdsmen. There were four thousand sheep on the low grounds, and six hundred and eighty thousand on the mountains belonging to the estate. Of the latter, eighty thousand were of the Negretti breed, whose wool it was intended to have manufactured into the dresses of all the mendicant monks in Italy, and into the great coats of the shepherds; the rest were of the Pouille breed, which produces a white wool, but only on the upper part of the body. As mutton is not good in Italy, and but little eaten, they kill most of the top-lambs as soon as they are born, and milk the ewes to make cheese. The temporary flocks had not arrived when Chateauxvieux was at Campo Morto, the fields not being then cleared of their crops.

309. *The farmer of this extensive domain* is M. Trucci, who pays a rent for it of 22,000 piastres (4950*l.*). This, said M. Trucci to Chateauxvieux, "supposes an extent of three thousand rubbi, or six thousand acres, of culturable land. I have nearly as

much that is not fit for the plough, and it is there my pigs and my cows principally feed. My three thousand rubbi are divided into nearly nine equal parts of three hundred and thirty rubbi each: one of these is in fallow, another in corn, and the seven others in pasture. On the two thousand three hundred rubbi, which remain in grass, I support four thousand sheep, four hundred horses, and two hundred oxen, and I reserve a portion for hay. In the macchie (bushy places, woody wastes) I have seven hundred cows, and sometimes nearly two thousand pigs.

310. *My expenses* "are limited to paying the rent of the farm, to purchasing bread for the workmen, and to the entire maintenance of my army of shepherds, superintendents, and the fatter; to paying for the work of the day-labourers, of the harvest-men, &c.; and, in short, to the expense of moving the flocks, and to what, in large farms, are called the extra-charges, the amount of which is always very high. There must also be deducted from the gross profits of the flock about one tenth, which belongs, in different proportions, to my chiefs and to my shepherds, because I support this tenth at my expense. We have also, in this mode of culture, to sustain great losses on our cattle, notwithstanding which I must acknowledge that our farming is profitable.

311. *Of annual profit* "I average above five thousand piastres, besides five per cent on the capital of my flocks. You see, then, that the lands in the Campagna of Rome, so despised, and in such a state of wildness, let at the rate of eighteen francs (fifteen shillings) the Paris acre: there is an immense quantity in France which does not let for so much. They would, doubtless, let for more if they were divided and peopled, but not in the proportion supposed: for the secret in large farms consists in their economy; and nothing on the subject of agricultural profit is so deceptive as the appearance they present to our view, for the profit depends solely on the amount of the economical combinations, and not on the richness of the productions displayed to the eye." (*Letters on Italy.*)

SUBJECT. 4. *Of Farming in the Neapolitan Territory, or the Land of Ashes.*

312. *The farming on the volcanic soil*, in the neighbourhood of Vesuvius, belongs to the valley farming of Tuscany; but, as it varies a little, and as the farmers are much more wretched, we shall give the following relation, as received by Chateaueux from a Neapolitan metayer:—

313. *We, poor metayers*, he said, "occupy only so much land as we can cultivate by our own families, that is to say, four or five acres. Our condition is not a good one, since we get for our trouble only a third of the produce, two thirds belonging to the owner, which we pay in kind into the hands of the steward. We have no ploughs, and the whole is cultivated by the spade. It is true that the soil, being mixed with ashes, is easily stirred; and even our children assist us in this work. At times the mountain, hence named Vesuvius, pours forth showers of ashes, which spread over our fields and fertilise them.

314. *The trees* which you see on the land, "are not without their use; they support the vine, and give us fruit; we also carefully gather their leaves: it is the last autumnal crop, and serves to feed our cattle in the winter. We cultivate, in succession, melons, between the rows of elms, which we carry to the city to sell; after which we sow wheat. When the wheat crop is taken off, we dig in the stubble, which is done by our families, to sow beans or purple clover. During six months, our children go every morning to cut a quantity of it with the sickle, to feed the cows. We prefer the females of the buffaloes, as they give most milk. We have also goats, and sometimes an ass, or a small horse, to go to the city and carry our burthens; but this advantage belongs only to the richer metayers.

315. *We plant the maize* "the following spring, after clover or beans. We manure the land at this time, because this plant is to support our families; this crop, therefore, interests us more than all the others, and the day in which it is harvested is a day of festivity in our country. All the villagers assemble together, the young women dance, and the rest of us walk slowly, being laden with our tools: arrived at our dwellings, each family goes into its own; but they are so near each other, that we can still converse together.

316. *We often gather seven ears from one stalk of maize*, "and many of them are three palms long. When the sun is high, the father of the family goes into the adjoining field to get some melons, while the children gather fruit from the surrounding fig trees. The fruit is brought under an elm tree, round which the whole family sits; after this repast the work begins again, and does not cease until the close of day. Each family then visits its neighbours, and tells of the rich crop the season has bestowed upon them.

317. *We have no sooner gotten in the maize than the earth is again dug, to be sown once more with wheat*; after this second crop, we grow in the fields only vegetables of different kinds. Our lands thus produce wine and fruit, corn and vegetables, and leaves and grass for the cattle. We have no reason to complain of their fertility: but our conditions are,

hard, little being left for our pains; and if the season is not propitious, the metayer has much to complain of." (*Letters on Italy*.)

318. *The cotton plant* (*Gossypium herbaceum*) (*fig. 40.*) is beginning to be cultivated in the neighbourhood of Vesuvius, and in Sicily. It is sown in March, in lines three feet distant, and the plants two feet apart in the lines. The earth is stirred by a one-horse plough, or by hoes, and carefully weeded. As soon as the flowering season is over, about the middle of September, the ends of the shoots are nipped off, to determine the sap to the fruit. The capsules are collected as they ripen; a tedious process, lasting two months; the cotton and the seeds are then separated; an operation still more tedious. The most extensive cotton farmers are in the vale of Sorrento. There the rotation is, 1. maize; 2. wheat, followed by beans, which ripen next March; 3. cotton; 4. wheat, followed by clover; 5. melons, followed by French or common beans. Thus, in five years, are produced eight crops. In this district, wherever water can be commanded, it is distributed, as in Tuscany and Lombardy, among every kind of crop.

319 *The tomato, or love apple* (*Solanum Lycopersicum L.*), so extensively used in Italian cookery, forms also an article of field culture near Pompeii, and especially in Sicily, whence they are sent to Naples, Rome, and several towns on the Mediterranean sea. It is treated much in the same way as the cotton plant.

320. *The orange, lemon, peach, fig,* and various other fruits, are grown in the Neapolitan territory, both for home use and exportation: but their culture we consider to belong to gardening.

321. *The Neapolitan maremmes*, near Salerno, to the evils of those of Rome, add that of a wretched soil. They are pastured by a few herds of buffaloes and oxen; the herdsmen of which have no other shelter during the night than reed huts; these desert tracts being without either houses or ruins. The plough of this ancient Greek colony is thought to be the nearest to that of Greece, and has been already adverted to (31.).

322. *The manna*, a concrete juice, forms an article of cultivation in Calabria. This substance is nothing more than the exsiccated juice of the flowering ash tree (*Ornus rotundifolia*), which grows there wild in abundance. In April or May, the peasants make one or two incisions in the trunk of the tree with a hatchet, a few inches deep; and insert a reed in each, round which the sap trickles down: after a month or two they return, and find this reed sheathed with manna. The use of manna, in medicine, is on the decline.

323. *The filberts and chestnuts* of the Calabrian Apennines are collected by the farmers, and sold in Naples for exportation or consumption.

324. *The culture of indigo and sugar* was attempted in the Neapolitan territory, under the reign of Murat. The indigo succeeded; but sufficient time had not elapsed to judge of the sugar culture when it was abandoned. The plants, however, grew vigorously, and their remains may still (1819) be seen in the fields near Terracina.

325 *Oysters have been bred and reared in the kingdom of Naples* from the time of the Romans. The subject is mentioned by Nonnius (*De Reb. Cib.*, l. iii. c. 37.); and by

41

Pliny (*Nat. Hist.*, b. xviii. c. 54.). Count Lasteyrie (*Col. des Mach.*) describes the place mentioned by the latter author, as it now exists in the Lake Facino, at Baia. This lake (*fig. 41.*) communicates with the sea by a narrow passage. On the water near its margin,

a house (c) is constructed for those who take care of the oysters, and who sell them to the dealers in Naples, or to those who come and eat them on the spot; and adjoining the house is a covered enclosure (b), where the oysters are kept till wanted. Along the margin of the lake, and in most parts of it, are placed circles of reeds (a), with their summits above the water. The spawn of the oysters attaches itself to these reeds, and grows there till of an edible size: the oysters are then removed to the reserve (b), and kept there till wanted. In removing them the reeds are pulled up one by one, examined, and the full-grown oysters removed and put in baskets, while the small-sized and spawn are suffered to remain, and the reed is replaced as it was. The baskets are then placed in the reserve, and not emptied till sold. In two years from the spawn, Lasteyrie observes, the oyster is fully grown.

SECT. II. *Of the present State of Agriculture in Switzerland.*

326. *The agriculture of Switzerland* is necessarily of a peculiar nature, and on a very confined scale. The country is strictly pastoral; little corn is produced, and the crops are scanty and precarious. Cattle, sheep, and goats constitute the chief riches and dependence of the inhabitants. Each proprietor farms his own small portion of land; or the mountainous tracts belonging to the communities are pastured in common. But, whether private or common property, it is evident that mountainous pastures are little susceptible of improvement. (*For. Quart. and Continent. Miscell.*, Jan. 1828.)

327. *Though of a very primitive kind*, this agriculture is not without interest, from the nice attention required in some parts of its operations. The surface, soil, and climate of the country, are so extraordinarily irregular and diversified, that in some places grapes ripen, and in many others corn will not arrive at maturity; on one side of a hill the inhabitants are often reaping, while they are sowing on the other; or they are obliged to feed the cattle on its summits with leaves of evergreens while they are making hay at its base. A season often happens in which rains during harvest prevent the corn from being dried, and it germinates, rots, and becomes useless; in others it is destroyed by frost. In some cases there is no corn to reap, from the effect of summer storms. In no country is so much skill required in harvesting corn and hay as Switzerland; and no better school could be found for the study of that part of Scotch and Irish farming. After noticing some leading features of the culture of the cantons which form the republic, we shall cast our eye on the mountains of Savoy.

SUBSECT. 1. *Of the Agriculture of the Swiss Cantons.*

328. *Agriculture began to attract public attention in Switzerland* about the middle of the eighteenth century. In 1759, a society for the promotion of rural economy established itself at Berne: they offered premiums, and have published some useful papers in several volumes. Long before that period, however, the Swiss farmers were considered the most exact in Europe. (*Stanyan's Account of Switzerland in 1714.*) Chateauxvieux attributes the progress which agriculture has made, near Vevey, on the Lake of Geneva, to the settlement of the protestants, who emigrated thither from France, at the end of the seventeenth century. They cut the hills into terraces, and planted vines, which has so much increased the value of the land, that what was before worth little, now sells at 10,000 francs per acre. (*Let. xxi.*) Improvement in Switzerland is not likely to be rapid; because agriculture there is limited almost entirely to procuring the means of subsistence, and not to the employment of capital for profit.

329. *Landed property in Switzerland* is minutely divided, and almost always farmed by the proprietors and their families; or it is in immense tracts of mountain belonging to the haliwicks, and pastured in common: every proprietor and burgess having a right according to the extent of his property. These men are, perhaps, the most frugal cultivators in Europe: they rear numerous families, a part of which is obliged to emigrate, because there are few manufactures; and land is excessively dear, and seldom in the market.

330. *The valleys of the Alpine regions of Switzerland* are subject to very peculiar injuries from the rivers, mountain rocks, and glaciers. As the rivers are subject to vast and sudden inundations, from the thawing of the snow on the mountains, they bring down at such times an immense quantity of stones, and spread them over the bottoms of the valleys. Many a stream, which appears in ordinary times inconsiderable, has a stony bed of half a mile in breadth, in various parts of its course; thus a portion of the finest land is rendered useless. The cultivated slopes, at the bases of the mountains, are subject to be buried under *éboulemens*, when the rocks above fall down, and sometimes cover many square miles with their ruins.

331. *Éboulement* (Fr.) denotes a falling down of a mountain or mass of rock, and consequent covering of the lower grounds with its fragments; when an immense quantity of stones are suddenly brought down from the mountains by the breaking or thawing of a glacier, it is also called an *éboulement*. (*Bakewell*, vol. i. p. 11.) Vast *éboulemens* are every year falling from the enormous precipices that overhang the valley of the Rhoue: many of these are recorded which have destroyed entire villages.

332. *One of the most extraordinary Eboulemens ever known* was that of Mont Greulier, five miles south of Chambéry. A part of this mountain fell down in the year 1248, and entirely buried five parishes, and the town and church of St. André. The ruins spread over an extent of about nine square miles, and are called *Les Abymes des Myans*. After a lapse of so many centuries, they still present a singular scene of desolation. The catastrophe must have been most awful when seen from the vicinity; for Mont Grenier is almost isolated, advancing into a narrow plain, which extends to the valley of the Isère.

333. *Mont Grenier rises very abruptly upwards of 4000 feet above the plain.* Like the mountains of Les Echelles, with which it is connected, it is capped with an immense mass of limestone strata, not less than 600 feet in thickness, which presents on every side the appearance of a wall. The strata dip gently to the side which fell into the plain. This mass of limestone rests on a foundation of softer strata, probably molasse. Under this molasse are distinctly seen thin strata, probably of limestone, alternating with soft strata. There can be little doubt that the catastrophe was caused by the gradual erosion of the soft strata which undermined the mass of limestone above, and projected it into the plain; it is also probable that the part which fell had for some time been nearly detached from the mountain by a shrinking of the southern side, as there is at present a rent at this end, upwards of two thousand feet deep, which seems to have cut off a large section from the eastern end, and that now "Hangs in doubtful ruins o'er its base," as if prepared to renew the catastrophe of 1248.

334. *Avalanches, or falls of immense masses of snow from the mountains, often occasion dreadful effects.* Villages are overwhelmed by them; and rivers, stopped in their course by them, inundate narrow valleys to a ruinous extent. In February 1820, the village of Obergestelen, with eighty-eight of its inhabitants, was overwhelmed by an avalanche.

335. *The glaciers, or ice-hills, or ice-heaps, slide down into the mountain valleys, and form dams across them, which produce large lakes; by the breaking up of the glacier, these lakes are sometimes suddenly poured into the lower valleys, and do immense mischief.* Man, in such a country, as Bakewell has observed, is in a constant state of warfare with the elements, and compelled to be incessantly on his guard against the powers that threaten his destruction. This constant exposure to superhuman dangers is supposed to have given the aged inhabitants, especially of the Vallais, an air of uncommon seriousness and melancholy.

336. *The Swiss cottages are generally formed of wood, with projecting roofs, covered with slates, tiles, or shingles.* A few small enclosures surround or are contiguous to them, some of which are watered meadows, others dry pasture; and one or more always devoted to the raising of oats, some barley, and rye or wheat, for the family consumption. In the garden, which is large in proportion to the farm, are grown hemp, flax, tobacco, potatoes, white beet to be used as spinach and asparagus, French beans, cabbages, and turnips. The whole has every appearance of neatness and comfort. There are, however, some farmers who hire lands from the corporate bodies and others at a fixed rent, or on the metayer system; and in some cases both land and stock are hired; and peasants are found who hire so many cows and their keep, during a certain number of months, either for a third or more of the produce, or for a fixed sum.

337. *The villages of Switzerland are often built in lofty situations, and some so high as 5000 feet above the level of the sea.* "In a country where land is much divided, and small proprietors cultivate their own property on the mountains, it is absolutely necessary that they should reside near it, otherwise a great part of their time and strength would be exhausted in ascending and descending, as it would take a mountaineer four hours in each day, to ascend to many of these villages and return to the valley. In building their houses on the mountains, they place them together in villages, when it can be done, and at a moderate distance from their property, to have the comforts of society, and be more secure from the attack of wolves and other wild animals. Potatoes and barley can be cultivated at the height of 4500 feet in Savoy, and these, with cheese and milk, and a little maize for porridge, form the principal part of the food of the peasantry. The harvest is over in the plains by the end of June, and in the mountains by the end of September. Several of the mountain villages, with the white spires of their churches, form pleasing objects in the landscape, but on entering them the charm vanishes, and nothing can exceed the dirtiness and want of comfort which they present, except the cabins of the Irish." (*Bakewell's Travels*, vol. i. 270.) Yet habit, and a feeling of independence, which the mountain peasant enjoys under almost every form of government, make him disregard the inconveniences of his situation and abode. Damsels and their flocks form pleasing groups at a distance; but the former, viewed near, bear no more resemblance to *les bergères des Alpes* of the poets, than a female Hottentot to the Venus de Medicis.

338. *The vine is cultivated in several of the Swiss cantons on a small scale; and either against trellises, or kept low and tied to short stakes as in France.* The grapes, which seldom ripen well, produce a very inferior wine. The best in Switzerland are grown in the Pays de Vaud round Vevay. They are white, and, Bakewell says, "as large and fine-flavoured as our best hot-house grapes." The physicians at Geneva send some of their patients here during the vintage, to take what is called a regular course of grapes; that is, to subsist for three weeks entirely on this fruit, without taking any other food or drink. In a few days a grape diet becomes agreeable, and weak persons, and also the insane, have found great relief from subsisting on it for three or four weeks. (*Bakewell's Travels*, ii. 206.)

339. *Of fruit trees, the apple, pear, cherry, plum, and walnut, surround the small field or fields of every peasant.* The walnut tree also lines the public roads in many places, and its dropping fruit is often the only food of the mendicant traveller.

340. *The management of woods and forests forms a part of Swiss culture.* The herbage is pastured with sheep and swine as in Italy; the copse wood and lop are used

for fuel, as in all countries; and when a mode of conveyance and a market can be found the timber is sold, but in many places neither is the case. A singular construction was erected for the purpose of bringing down to the Lake of Lucerne the fine pine trees which grow upon Mount Pilatus, by the engineer Rupp. The wood was purchased by a company for 3000*l.*, and 9000*l.* were expended in constructing the slide. The length of the slide is about 44,000 English feet, or about eight miles and two furlongs; and the difference of level of its two extremities is about 2600 feet. It is a wooden trough, about five feet broad and four deep. The bottom of which consists of three trees, the middle one being a little hollowed; and small rills of water are conducted into it, for the purpose of diminishing the friction. The declivity, at its commencement, is about 22½°. The large pines, with their branches and boughs cut off, are placed in the slide, and descending by their own gravity, they acquire such an impetus by their descent through the first part of the slide, that they perform their journey of eight miles and a quarter in the short space of six minutes; and, under favourable circumstances, that is, in wet weather, in three minutes. Only one tree descends at a time, but, by means of signals placed along the slide, another tree is launched as soon as its predecessor has plunged into the lake. Sometimes the moving trees spring or bolt out of the trough, and when this happens, they have been known to cut through trees in the neighbourhood, as if it had been done by an axe. When the trees reach the lake, they are formed into rafts, and floated down the Reuss into the Rhine.

341. *Timber is also floated down mountain torrents from a great height.* The trees are cut down during summer and laid in the then dry bed of the stream: with the first heavy rains in autumn they are set in motion, and go thundering down among the rocks to the valleys, where what arrives sound is laid aside for construction, and the rest is used as fuel.

342. *The chamois goats* abound in some of the forests, and are hunted for their fat and flesh, and for their skins, which are valuable as glove and breeches leather. They herd in flocks, led by a female; live on lichens, and on the young shoots and bark of pines; are remarkably fond of salt; and require great caution in hunting. (*Simond's Switzerland*, vol. i. p. 245.) The common goat is frequently domesticated for the sake of its milk, and may be seen near cottages, curiously harnessed (*fig. 42.*) to prevent its breaking through, or jumping over, fences.

42

343. *The care of pastures and mowing grounds* forms an important part of the agricultural economy of Switzerland. In places inaccessible to cattle, the peasant sometimes makes hay with cramps on his feet. Grass, not three inches high, is cut in some places three times a year; and, in the valleys, the fields are seen shaven as close as a bowling-green, and all inequalities cropped as with a pair of scissors. In Switzerland, as in Norway, and for the same reasons, the arts of mowing and hay-making seem to be carried to the highest degree of perfection. Harvesting corn is not less perfect; and the art of procuring fodder for cattle, from the trees, shrubs, and wild plants, and applying this fodder with economy, is pushed as far as it will go. In some parts, very minute attention is paid to forming and collecting manure, especially that liquid manure, which, in the German cantons, is known under the name of *jauche* or *mist-wasser*, and in the Canton de Vaud, of *sisser*. (*For. Quart. Rev. and Cont. Mis.*, Jan. 1828.)

344. *Cows, goats, and sheep* constitute the wealth of the Swiss farmers, and their principal means of support; or, to discriminate more accurately, the goats, in a great measure, support the poorer class; and the cows supply the cheese from which the richer derive their little wealth. The extent of a pasture is estimated by the number of cows it maintains: six or eight goats are deemed equal to a cow, as are four calves, four sheep, or four hogs; but a horse is reckoned equal to five or six cows, because he roots up the grass. Throughout the high Alps, they are of opinion that sheep are destructive to the pastures, in proportion to their elevation, because the herbage, which they eat down to the roots, cannot, in such a cold climate, regain its strength and luxuriance. The mountain pastures are rented at so much per cow's feed, from the 15th of May to the 18th of October; and the cows are hired from the peasants for the same period: at the end of it, both are restored to their owners. In other parts, the proprietors of the pastures hire the cows, or the proprietors of the cows rent the land. The proceeds of a cow are estimated at 3*l.* or 3*l.* 10*s.*, viz. 25*s.* in summer; and, during the time they are kept in the valleys or in the house, at 2*l.* The Grindelwald Alps feed three thousand cows, and as many sheep and goats. The cattle are attended on the mountains by herdsmen; when the weather is tempestuous they are up all night calling to them, otherwise they would take fright and run into danger. Chalets are built for the use of the herdsmen: these are log-houses of the rudest construction, without a chimney, having a pit or trench dug for the fire, the earth thrown up forming a mound around it, by way of a seat. To those chalets, the persons whose employment it is to milk the cows, and to make cheese and butter, ascend in the summer time. When they go out to milk the cows, a portable seat, with a single leg, is strapped to their backs; at the hour of milking, the cows are attracted home from the most distant pastures by a handful of salt, which the shepherd takes from a leathern pouch hanging over his shoulder. During the milking, the *Ranz des Vaches* is frequently sung. (*For. Quart. Rev. and Cont. Misc.*)

345. *The Swiss cows* yield more milk than those of Lombardy, where they are in great demand; but after the third generation their milk falls off. In some parts of Switzerland they yield, on an average,

twelve English quarts a day; and with forty cows, a cheese of forty-five pounds can be made daily. In the vicinity of Aitdorf they make, in the course of a hundred days, from the 20th of June, two cheeses daily, of twenty-five pounds each, from the milk of eighteen cows. On the high pastures of Scarla, a cow during the best season, supplies near sixty pounds of skim-milk cheese, and forty pounds of butter. Reckoning twenty pounds of milk, observes our author, equivalent to one of butter, the produce in milk will be eight hundred pounds for ninety days, or less than nine pounds a day. This small supply he ascribes to the great elevation of the pastures, and the bad keep of the cows in the winter. (*For. Quart. Rev. and Cont. Misc.*)

346. *Great variety of cheese is made in Switzerland.* The most celebrated are the Schabzieger and Gruyère; the former made by the mountaineers of the canton of Glarus, and the latter in the valley of Gruyère. The cheese of Switzerland must have been for a long period a great article of commerce; for, Myconius, of Lucerne, in the beginning of the sixteenth century, in a commentary on a poem of his friend Glaricus, expatiates on the large quantities of butter and cheese which his fellow-citizens sent into Burgundy, Suabia, and Italy: he adds, that twenty cows would bring in, annually, a net sum of 100 crowns. In 1563, a law was passed in the Upper Engadine to guard against fraud in the manufacture of cheese meant for sale. Formerly, the depots of rich cheese were principally near Lake Como; it was supposed that the exhalations, at once warm and moist, ripened the cheese, without drying it too much; at present, however, these depots are not near so numerous. In the Upper Engadine, cheese loses, by drying, a twentieth part of its weight in the first ten weeks; and skim-milk cheese the half of its weight in two years. Of the quantity of cheeses exported from Switzerland we have no information that can be relied upon; but it is computed that thirty-thousand hundred-weight of Gruyère cheese alone, fit for exportation, is annually made; and that, from the middle of July to October, three hundred horses, weekly, are employed in transporting Swiss cheese over Mount Grias. (*For. Rev. and Cont. Misc.*)

347. *The Schabzieger cheese is made by the mountaineers of the Canton of Glarus alone; and, in its greatest perfection, in the valley of Kloen.* It is readily distinguished by its marbled appearance and aromatic flavour, both produced by the bruised leaves of the melilot. The dairy is built near a stream of water; the vessels containing the milk are placed on gravel or stone in the dairy, and the water conducted into it in such a manner as to reach their brim. The milk is exposed to this temperature, about six degrees of Reaumur (forty-six degrees of Fahrenheit), for five or six days, and in that time the cream is completely formed. After this it is drained off, the caseous particles are separated, by the addition of some sour milk, and not by rennet. The curd thus obtained is pressed strongly in bags, on which stones are laid; when sufficiently pressed and dried, it is ground to powder in autumn, salted, and mixed with either the pressed flowers or the bruised seeds of the melilot trefoil (*Melilotus officinalis*). (*fig. 43.*) The practice of mixing the flowers or the seeds of plants with cheese was common among the Romans, who used those of the thyme for that purpose. The entire separation of the cream or unctuous portion of the milk is indispensable in the manufacture of Schabzieger. The unprepared curd never sells for more than three halfpence a pound; whereas, prepared as Schabzieger, it sells for sixpence or seven-pence. (*For. Rev. and Cont. Misc.*)

348. *The Gruyère cheese of Switzerland is so named after a valley, where the best of that kind is made.* Its merit depends chiefly on the herbage of the mountain pastures, and partly on the custom of mixing the flowers or bruised seeds of *Melilotus officinalis* with the curd, before it is pressed. The mountain pastures are rented at so much per cow's feed from the 15th of May to the 18th of October; and the cows are hired from the peasants, at so much, for the same period. On the precise day both land and cows return to their owners. It is estimated that 15,000 cows are so grazed, and 30,000 cwt. of cheese made fit for exportation, besides what is reserved for home use.

349. *Ewe-milk cheese of Switzerland.* One measure of ewe's milk is added to three measures of cow's milk; little rennet is used, and no acid. The best Swiss cheese of this kind is made by the Bergamuse sheep-masters, on Mount Splügen. (*For. Rev. and Cont. Misc.*)

350. *The establishment at Hofwyl, near Berne,* may be considered as in great part belonging to agriculture, and deserves to be noticed in this outline. It was projected by, and is conducted at the sole expense of, M. Fellenberg, a proprietor and agriculturist. His object was to apply a sounder system of education for the great body of the people, in order to stop the progress of misery and crime. Upwards of twelve years ago he undertook to systematise domestic education, and to show, on a large scale, how the children of the poor might be best taught, and their labour at the same time most profitably applied; in short, how the first twenty years of a poor man's life might be so employed as to provide both for his support and his education. The peasants in his neighbourhood were at first rather shy of trusting their children for a new experiment; and being thus obliged to take his pupils where he could find them, many of the earliest were the sons of vagrants, and literally picked up on the highways: this is the case with one or two of the most distinguished pupils.

351. *Their treatment is* nearly that of children under the paternal roof. They go out every morning to their work soon after sunrise, having first breakfasted, and received a lesson of about an hour: they return at noon. Dinner takes them half an hour, a lesson of one hour follows; then to work again till six in the evening. On Sunday the different lessons take six hours instead of two; and they have butcher's meat on that day only. They are divided into three classes, according to age and strength; an entry is made in a book every night of the number of hours each class has worked, specifying the sort of labour done, in order that it may be charged to the proper account, each particular crop having an account opened for it, as well as every new building, the live stock, the machines, the schools themselves, &c. &c. In winter, and whenever there is not out-

of-doors work, the boys plait straw for chairs, make baskets, saw logs with the cross-saw and split them, thrash and winnow corn, grind colours, knit stockings, or assist the wheelwright and other artificers, of whom there are many employed in the establishment. For all which different sorts of labour an adequate salary is credited to each boy's class.

352. *The boys never see a newspaper, and scarcely a book*; they are taught, *visâ voce*, a few matters of fact, and rules of practical application: the rest of their education consists chiefly in inculcating habits of industry, frugality, veracity, docility, and mutual kindness, by means of good example, rather than precepts; and, above all, by the absence of bad example. It has been said of the Bell and Lancaster schools, that the good they do is mostly negative: they take children out of the streets, employ them in a harmless sort of mental sport two or three hours in the day, exercise their understanding gently and pleasantly, and accustom them to order and rule, without compulsion. Now, what these schools undertake to do for a few hours of each week, during one or two years of a boy's life, the *School of Industry* at Hofwyl does incessantly, during the whole course of his youth; providing, at the same time, for his whole physical maintenance, at a rate which must be deemed excessively cheap for any but the very lowest of the people.

353. *The practicability of this scheme* for inculcating individual prudence and practical morality, not only in the agricultural, but in all the operative, classes of society, M. Simond considers as demonstrated; and it only remains to ascertain the extent of its application. Two only of the pupils have left Hofwyl, for a place, before the end of their time; and one, with M. de Fellenberg's leave, is become chief manager of the immense estates of Comte Abaffy, in Hungary, and has, it is said, doubled its proceeds by the improved method of husbandry he has introduced. This young man, whose name is Madorly, was originally a beggar boy, and not particularly distinguished at school. Another directs a school established near Zurich, and acquits himself to the entire satisfaction of his employers. M. Fellenberg has besides a number of pupils of the higher classes, some of whom belong to the first families of Germany, Russia, and Switzerland. They live *en famille* with their master, and are instructed by the different tutors in the theory and practice of agriculture, and in the arts and sciences on which it is founded. (See *Simond's Account of Switzerland*, vol. i.; *Ed. Rev.* 1819, No. 64.; *Des Institutes de Hofwyl de par Cte. L. de V.* Paris, 1821.)

SUBJECT. 2. *Of the Agriculture of the Duchy of Savoy.*

354. *Of the agriculture of Savoy*, which naturally belongs to Switzerland, a general view, with some interesting details, is given by Bakewell. (*Travels in the Tarantaise, &c.*, 1820-22.) Landed property there is divided into three qualities, and rated for a land-tax accordingly. There is an office for registering estates, to which a per centage is paid on each transfer or additional registering. There is also an office for registering all mortgages, with the particulars; both are found of great benefit to the landed interest and the public, by the certainty which they give to titles, and the safety both to borrowers and lenders on land.

355. *Land in Savoy* is divided into very small farms, and is occupied by the proprietors or *paysans*, who live in an exceedingly frugal manner, and cultivate the ground with the assistance of their wives and children; for in Savoy, as in many other parts of Europe, the women do nearly as much field labour as the men.

356. *The lands belonging to the monasteries* were sold during the French revolution, when Savoy was annexed to France. The gradual abolition of the monasteries had been begun by the old government of Sardinia before the revolution, for the monks were prohibited from receiving any new brethren into their establishments, in order that the estates might devolve to the crown, on the extinction of the different fraternities. This measure, though wise in the abstract, was not unattended with inconvenience, and perhaps we may add, injustice. The poor, who had been accustomed to fly to the monasteries for relief in cases of distress, were left without any support, except the casual charity of their neighbours, who had little to spare from their own absolute necessities. The situation of the poor is therefore much worse in Savoy, than before the abolition of the monasteries. The poor in England suffered in the same manner, on the abolition of the monasteries in the reigns of Henry VIII. and Elizabeth, before the poor's laws were enacted. The charity of the monks of Savoy lost much of its usefulness by the indiscriminate manner in which it was generally bestowed: certain days and hours were appointed at each monastery, for the distribution of provisions, and the indolent were thereby enabled to support themselves during the whole week, by walking to the different monasteries on the days of donation. This was offering a premium to idleness, and was the means of increasing the number of mendicants, which will, in every country, be proportionate to the facility of obtaining food without labour.

357. *The peasantry in Savoy are very poor, but they cannot be called miserable.* In the neighbourhood of towns, their situation is worse than at a distance; and not far from Chambéry may be seen a few families that might almost vie in squalid misery, rags, and filth, with the poor of Ireland; but the general appearance of the peasantry is respectable. Having learnt the price of labour in various parts of Savoy, Bakewell proposed the following question: Is it possible for a labourer, with a family, to procure a sufficient quantity of wholesome food for their consumption? One of the answers was, "*Cela est très-facile*" (it is very easy); the other was, "The labourer lives very frugally (*très-sobrement*)."
"In general he eats very coarse, but wholesome, bread, and, except in the mountains, he eats very little meat, and rarely drinks wine, but he has a great resource in potatoes."

358. *One day's labour of a farming man* will purchase about twelve pounds avoirdupois of wheat, or from four to five pounds of beef, veal, or mutton; but these are dainties which he rarely tastes; potatoes, rye-bread, chestnuts, and milk, form the principal part of the food of the poor. The day-labourer in Savoy has to deduct, from the amount of his labour, about seventy days in the year, including saint-days and Sundays, on which he receives no wages. (*Bakewell's Travels*, vol. i. § 114.)

359. *There are four modes of occupying land for cultivation in Savoy*: by the proprietors; by farmers; by grangers; and by tacheurs.

360. *Land very near to towns* is generally cultivated by the proprietors, who either keep cattle, or take them in to graze at so much per head.

361. *By farming land*, is understood, letting it at a fixed rent, to be paid according to the value of the produce, taken at an average of ten years.

362. *By grangers*, or renting land à moitié fruit, is understood, that the proprietor takes half of all the grain and fruit, half the produce or increase of the cows, half the eggs, and, in short, half of every thing which is productive.

363. *By tacheurs*, is another mode of cultivating land, in the immediate vicinity of towns. The proprietors, to avoid keeping too many servants in their own houses, place a father of a family in the house upon the farm. This man is called *le tacheur*. He takes care of the cows, for half their produce: he ploughs the ground, receiving for every pair of oxen employed, or for three horses, from seventy to eighty francs per annum: he has half the wine: the share he receives of the wheat and grain is in the proportion of two parts for every nine taken by the proprietor. The latter pays all the taxes, and keeps the accounts. The tacheur may be changed every year. When he is employed in repairing fences, &c., he is paid by the day; this is always undertaken when he enters the farm.

364. *The leases granted to the farmers and grangers* are on terms of three, six, or nine years; but when the leases are for six or nine years, a reservation is always made, that at the expiration of every three years the proprietor may revoke the lease, by giving three months' notice, if he be not satisfied with the tenant. The proprietor always supplies the farmer or granger with a sum of money without interest, called *chaptal* (capital), to aid him in buying oxen: for a farm of two oxen it is generally about twenty louis; for a farm of four oxen, forty louis; and so on. The proprietor, for this sum, has an exclusive right to seize the cattle of the farmer, should he sell them clandestinely.

365. *The mode of pasturage* in Chamouny will apply, with little variation, to all the Alpine communes in Savoy. The rich peasants in the Alps possess meadows, and even habitations, at different heights. In winter they live in the bottom of the valley, but they quit it in spring, and ascend gradually, as the heat pushes out vegetation. In autumn they descend by the same gradation. Those who are less rich have a resource in the common pastures, to which they send a number of cows, proportionate to their resources, and their means of keeping them during the winter. The poor, who have no meadows to supply fodder for the winter, cannot avail themselves of this advantage. Eight days after the cows have been driven up into the common pasture, all the owners assemble, and the quantity of milk from each cow is weighed. The same operation is repeated one day in the middle of the summer, and at the end of the season, the quantity of cheese and butter is divided, according to the quantity of milk each cow yielded on the days of trial. (*Bakewell.*)

366. *There are chalets, or public dairies*, near the mountain pastures in Savoy, as well as in Switzerland; persons reside in these chalets during the summer months, to make cheese and butter. In many situations it is the labour of a day to ascend to these chalets, and return to the valleys immediately below them. There are also public dairies in some of the villages, where the poorer peasants may bring all the milk they can spare, from the daily consumption of their families. The milk is measured, and an account kept of it; and at the end of the season the due portion of cheese is allotted to each, after a small deduction for the expense of making. (*Id.*)

367. *No large flocks of sheep* are kept in Savoy, as it is necessary to house them during the winter, at which time they are principally fed with dried leaves of trees, collected during the autumn. Many poor families keep a few sheep to supply them with wool for their domestic use. These little flocks are driven home every evening, and are almost always accompanied by a goat, a cow, or an ass, and followed by a young girl spinning with a distaff. As they wind down the lower slopes of the mountains, they form the most picturesque groups for the pencil of the painter; and, seen at a distance, carry back the imagination to the ages of pastoral simplicity, sung by Theocritus and Virgil. (*Id.*)

368. *The vineyards in Savoy* are cultivated for half the produce of the wine. The cultivator pays the whole expense, except the taxes, which are paid by the proprietor.

369. *Walnut trees*, of immense size and great beauty, enrich the scenery of Savoy, and supply sufficient oil for the consumption of the inhabitants, and for the adjoining canton of Geneva. The walnut has been called the olive of the country. The trees belong principally to the larger proprietors. They are planted by nature, being scattered over the fields, and in the woods and hedge-rows, intermixed with chestnuts and forest trees of various kinds. (*Bakewell.*)

370. *The walnut harvest* at Chateau Duing commences in September. "They are beaten off the trees with long poles; the green husks are taken off as soon as they begin to decay; the walnuts are then laid in a chamber to dry, where they remain till November, when the process of making the oil commences. The first operation is to crack the nuts, and take out the kernel. For this purpose several of the neighbouring peasants, with their wives and elder children, assembled at the chateau of an evening, after their work was done. The party generally consisted of about thirty persons, who were placed around a long table in the kitchen. One man sat at each end of the table, with a small mallet to crack the nuts by hitting them on the point: as fast as they are cracked; they are distributed to the other persons around the table, who take the kernels out of the shell, and remove the inner part; but they are not peeled. The peasants of Savoy are naturally lively and loquacious; and they enliven their labour with facetious stories, jokes, and noisy mirth. About ten o'clock the table is cleared to make room for the *gouilé*, or supper, consisting of dried fruit, vegetables, and wine; and the remainder of the evening is spent in singing and dancing, which is sometimes continued till midnight. In a favourable season, the number of walnuts from the Duing estate is so great, that the party assemble in this manner every evening for a fortnight, before all the walnuts are cracked; and the poor people look forward to these meetings, from year to year, as a kind of

festival. They do not receive any pay; the *gouté* and the amusement of the evening are their only reward." (*Bakewell*.)

371. *The walnut kernels* are laid on cloths to dry, and in about a fortnight are carried to the crushing-mill, where they are ground into a paste; this is put into cloths, and undergoes the operation of pressing to extract the oil. The best oil, which is used for salads and cooking, is pressed cold; but an inferior oil for lamps is extracted by heating the paste. Thirty people in one evening will crack as many walnuts as will produce sixty pounds of paste; this yields about fifteen wine-quarts of oil. The walnut-shells are not lost among so frugal a people as the Savoyards, but are burned for the ashes, which are used for washing. Two pounds of these ashes are equal in strength to three of wood-ashes; but the alkali is so caustic, that it frequently injures the linen. The paste, after it is pressed, is dried in cakes, called *pain amer*; this is eaten by children and poor people, and it is sold in the shops in Savoy and Geneva.

372. *The best walnut oil*, pressed cold, has but very little of the kernelly taste; but it may be easily distinguished from the best olive oil, which it resembles in colour. If the peel were taken off the walnuts, the oil would probably be quite free from any peculiar flavour; but this operation would be too tedious. (*Id.*)

373. *Tobacco*, which is much used in Savoy, was cultivated with success in the neighbourhood of Ramilly; but on the restoration of the old despotism, its culture was prohibited, and the implements of manufacture seized.

374. *The culture of artificial grasses* is spreading in Savoy, but is not yet very general. In the neighbourhood of Aix, Ramilly, and Annecy, wheat is succeeded by rye. The rye-harvest being over in June, they immediately sow the land with buck-wheat (*sarrasin*), which is cut in September; the following year the land is sown with spring corn.

375. *The grass-lands* are always mown twice, and the latter mowing is sufficiently early to allow a good pasturage in the autumn. Water-meadows are occasionally found near towns. The water is generally let down from mountain streams; but sometimes it is raised from rivers by a sort of bucket-wheel (*fig. 44.*), which is called the *Noria* of the

Alps. This wheel is raised or lowered by means of a loaded lever (*a*), which turns on a fulcrum (*b*), formed by a piece of wood with its end inserted in the river's bank.

376. *Agricultural improvement in Savoy* must be in a very low state, if the answers Bakewell received respecting the average quantity of the produce are correct. One of the answers stated the average increase of wheat to be from three to five on the quantity sown, and near the towns from five to seven. Another agriculturist stated the average increase on the best lands to be nine, and, in the neighbourhood of Annecy, thirteen, fold. One part of Savoy is, perhaps, the finest corn-land in Europe; and the very heavy crops Bakewell saw in the neighbourhood of Aix and Annecy, made him doubt the accuracy of the above statements; but, on referring to Arthur Young's account of the agriculture of France before the revolution, it appears that four and a half was regarded as the average increase in that country, which is very similar in climate to Savoy. (*Travels*, i. 328.)

377. *The salt-works of Moutiers*, in the valley of the Isere, in the Tarantaise, are particularly deserving attention, being perhaps the best conducted of any in Europe, with respect to economy. Nearly three million pounds of salt are extracted annually from a source of water which would scarcely be noticed, except for medical purposes, in any other country.

378. *The springs that supply the salt-works at Moutiers*, rise at the bottom of a nearly perpendicular rock of limestone, situated on the south side of a deep valley or gorge. The temperature of the strongest spring is ninety-nine Fahrenheit, it contains 1.83 per cent of saline matter. It may seem extraordinary that the waters at Moutiers, which have only half the strength of sea-water, should repay the expense of evaporation; but the process by which it is effected is both simple and ingenious, and might be

introduced with great advantage on many parts of our own coast, more particularly in Ireland. It is obvious that water, so weakly impregnated with salt as to contain only one pound and a half in every thirteen gallons, could not repay the expense of evaporating by fuel in any country. The water of the North Sea contains two and a quarter per cent of salt, and yet it has never been attempted to make salt from it by evaporation with coal-fires, even on the coast of Northumberland or Durham, where refuse coal, suited to the purpose, might be purchased for one shilling and sixpence per ton. In order to make salt from the saline water at Moutiers, it was necessary to concentrate it by natural evaporation; and to effect this speedily, it was required to spread the surface of the fluid over as large a space as possible, the ratio of evaporation being, *cæteris paribus*, in proportion to the extent of the surface exposed to the action of the atmosphere. The first attempt at Moutiers was made in 1550, by arranging pyramids of rye straw in open galleries, and letting the water trickle through the straw gradually and repeatedly. This was abandoned, and faggots of thorns were substituted: these faggots are suspended on frames, the water is raised to their height, and spread by channels so as to trickle through them: it passes through three separate sets or frames of thorns, and has then become so concentrated as to contain nearly 22 per cent of salt: it is then boiled in pans in the usual manner.

379. *Evaporating on vertical cords*, erected in a house open on all sides, is a third method, which succeeds even better than the mode by thorns. The water, by repeatedly passing over the cords, is found in forty-five days to deposit all its salt on them, and the saline cylinder is then broken off. The cords are renewed once in twenty or thirty years, and the faggots once in seven years. Minute details of these simple but very ingenious processes will be found in the very scientific *Travels* of Bakewell (vol. i. 230.).

SECT. III. *Of the present State of Agriculture in France.*

*380. *The first agricultural survey of France* was made in 1787, 8, and 9, by the celebrated Arthur Young. Since that period no similar account has been published either in France or England: but several French writers have given the statistics and culture of different districts, as the Baron de la Peyrouse, Sinetti, Cordier, &c.; and others have given general views of the whole kingdom, as *La Statistique Générale de la France*, by Penchet; *De l'Industrie Française*, by Chaptal; and *Les Forces Productives et Commerciales de la France*, &c., by Dupin. From these works, some recent tours of Englishmen, and our own observations in 1815, 1819, and 1828, we have drawn the following outline of the progress of French agriculture since the middle of the sixteenth century, and more especially since the time of Louis XIV.; including the general circumstances of France as to agriculture, its common culture, its culture of vines and maize, and its culture of olives and oranges.

SUBJECT. 1. *Of the Progress of French Agriculture, from the Sixteenth Century to the present Time.*

*381. *That France is the most favourable country in Europe for agriculture*, is the opinion both of its own and foreign writers on the subject. For, though the country "suffered deeply from the wars in which she was engaged, first by a hateful conspiracy of kings, and next, by the mad ambition of Bonaparte, the purifying effects of the revolution have indemnified her ten fold for all the losses she has sustained. She has come out of the contest with a debt comparatively light, with laws greatly amended, many old abuses destroyed, and with a population more industrious, moral, enlightened, and happy, than she ever had before. The fortunate change which peace has made in her situation, has filled her with a healthy activity, which is carrying her forward with rapid strides; she has the most popular, and therefore the most rational, liberal, and beneficial, system of government of any state in Europe, Britain not excepted; and, altogether, she is perhaps in a condition of more sound prosperity than any other state in the old world." (*Scotsman*, vol. xii. No. 861.)

382. *The agriculture of France at present*, as Mr. Jacob has observed (*Report*, &c., 1828), occupies one of the lowest ranks in that of the Northern States of Europe; but the fertility of the soil, the suitableness of the subsoil and of the surface for aration, and, above all, the excellence of the climate, are such as are not united to an equal extent in any other European State. When we consider these circumstances in connection with the extraordinary exertions now making for the education of the laborious classes, and the no less extraordinary progress that has been made within these few years in manufactures (*For. Rev.*, Jan. 1829, art. 1.), it is easy to see that in a few years the territorial riches of France will be augmented to an extraordinary extent.

383. *Of the agriculture of France, previous to the middle of the sixteenth century*, scarcely any thing is known. Chopin, who it appears resided in the neighbourhood of Paris, wrote a treatise on the *Privileges of Labourers*, in 1574, which, M. Grégoire remarks (*Hist. of Agr. prefixed to edit. of Olivier de Serres, pub. in 1804*), is calculated rather for the advantage of the proprietor than of the farmer. A *Code Rural*, published some time after, is characterised by the same writer as a Manual of Tyranny.

384. *French agriculture began to flourish* in the beginning of the seventeenth century, under Henry IV., and its precepts at that time were published by Olivier de Serres, and Charles Estienne. In 1621, great quantities of corn were exported to England, in consequence of a wise ordinance of Sully, passed some years before, permitting a free commerce in corn. In 1641, the draining of fens and bogs was encouraged; and, in 1756, the land-tax taken off newly broken up lands for the space of twenty years. Mazarin, during the minority of Louis XIV., prohibited the exportation of corn, and checked the progress of its culture. This circumstance, and the wars of that king, greatly

discouraged agriculture, and produced several dearths. Fleury, under Louis XV., was not favourable to agriculture; but, in 1754, an act was passed for a free corn trade, which effected its revival. The economists of this time, however mistaken in their views, inspired a taste for the art; and agricultural societies were first established in France under the patronage and at the expense of government. In 1761, there were thirteen such societies in France, and nineteen cooperating societies. Those of Paris, Lyons, Amiens, and Bourdeaux, have distinguished themselves by their published *Memoirs*. At Tours a georgical society was established and directed by the Marquis of Tourbilli, a patriot and agricultural writer. Du Hamel and Buffon gave eclat to the study of rural economy, and many other writers might be mentioned as having contributed to its improvement. M. de Trudaine introduced the Merino breed of sheep in 1776, and Comte Lasteyrie has studied that breed in Spain, and written a valuable work on the subject; as has the Baron de Mortemart on the English breeds, some of which he has introduced.

385. *The agriculture of France in 1819, as compared with what it was in 1789*, presents, Chaptal observes, astonishing improvements. Crops of every kind cover the soil; numerous and robust animals are employed in labouring it, and they also enrich it by their manure. The country population are lodged in commodious habitations, decently clothed, and abundantly nourished with wholesome food. The misery which existed in France in former times, when properties of immense extent supported little more than a single family, is banished, and its place supplied by ease and liberty. We are not to suppose, however, the same author observes, that the agriculture of France has arrived at perfection; much still remains to be done: new plans of improvement should be more generally introduced; and a greater quantity of live stock is wanted for every province of France, except two or three which abound in natural meadows. Few domains have more than half the requisite number of labouring cattle; the necessary result of which is a deficiency of labour, of manure, and of crop. The only mode of remedying these evils is to multiply the artificial pastures, and increase the cultivation of plants of forage. Abundance of forage is indeed the foundation of every good system of agriculture, as a proper succession of crops is the foundation of abundance of forage. The rich inhabitants of France have already adopted these principles; but they have not yet found their way among the lowest class of cultivators. According to M. Dupin, four fifths of the peasantry of France are proprietors of land, which they cultivate themselves; and though they are at present very ignorant, yet knowledge of every kind is rapidly advancing. The wages of labourers in France, compared with the price of corn, are calculated to be higher than the wages paid to labourers in England.

SUBJECT. 2. *Of the general Circumstances of France, in respect to Agriculture.*

386. *The surface of France* has been divided by geographers into what are called basins, or great plains, through which flow the principal rivers, and which basins are separated by original or secondary ridges of mountains. The chief basins are those of the Loire (fig. 45. *a*), of the Seine (*b*), of the Garonne (*c*), and of the Rhone and Saone (*d*). (*Journal de Physique*, tom. xxx.)

387. *The soil of France* has been divided by Arthur Young into the mountainous district of Languedoc and Provence (*e*); the loamy district of Limosin (*f*); the chalky districts of Champagne and Poitiers (*g*); the gravelly district of Bourbonnois (*h*); the stony district of Lorraine and Franche Comté (*i*); the rich loam of Picardy and Guienne (*k*); and the heathy surface on gravel, or gravelly sand, of Bretagne and Gascoigne (*l*). (*Agr. France*, chap. ii.)

388. *The climate of France* has been ingeniously divided by the same author into that of corn and common British agriculture, including Picardy, Normandy, French Flanders, Artois, Hainault, &c. (fig. 45. *l, b, k*); that of vines, mulberries, and common culture (*y, a, h, g, i*); that of vines, mulberries, maize, and common culture (*c, f, d, i*); that of olives, vines, mulberries, maize, oranges, and common culture (*o, e*). It is singular that these zones (*m m, n n*, and *o o*) do not run parallel to the degrees of latitude, but obliquely to them to such an extent that the climate for the vines leaves off at 46° on the west coast (*y m*), but extends to 49½° on the east (*g m*). The cause is to be found chiefly in the soil and surface producing a more favourable climate in one place than in another; but partly also in the wants of cultivators. The vine is cultivated in Germany in situations where it would not be cultivated in France, because wine is of more value in the former country than in the latter. The northern boundary of the vine culture has even extended in France since the revolution, from the natural wish of small proprietors to supply themselves with wine of their own growth. In Germany the vine is cultivated as far north as latitude 52°, on the warm sides of dry rocky hills.

389. *The central climate*, which admits vines without being hot enough for maize (*y, a, h, g, i*), Young considers as the finest in the world, and the most eligible part of France or of Europe as to soil. "Here," he says, "you are exempt from the extreme humidity which gives verdure to Normandy and England; and yet equally free from the

burning heats which turn verdure itself into a russet brown : no ardent rays that oppress with their fervour in summer, nor pinching tedious frosts that chill with their severity in winter, but a light, pure, elastic air, admirable for every constitution except consumptive ones." This climate, however, has its drawbacks ; and is so subject to violent storms of rain and hail, that " no year ever passes without whole parishes suffering to a degree of which we in Britain have no conception." It has been calculated, that in some provinces the damage from hail amounts, on an average of years, to one tenth of the whole produce. Spring frosts are sometimes so severe as to kill the broom : few years pass that they do not blacken the first leaves of the walnut trees ; the fig trees are protected with straw.

*390. *Of the vine and maize climate (c, f, d, i)* some account is given by M. Picot, Baron de la Peyrouse, an extensive and spirited cultivator. He kept an accurate account of the crops and seasons in his district for twenty years from 1800 ; and the result is, twelve years of fair average crops, four years most abundant, and four years attended with total loss.

*391. *In the olive climate (o, e)* insects are incredibly numerous and troublesome, and the locust is injurious to corn crops ; but both the olive and maize districts have this advantage, that two crops a year, or at least three in two years, may be obtained. The orange is cultivated in so small a proportion of the olive climate as scarcely to deserve notice. The caper (*Cápparis spinosa*) (fig. 46.) and the fig are also articles of field culture in this climate.

392. *The climate of Picardy and Normandy is the nearest to that of England,* and is rather superior. The great agricultural advantage which France possesses over Britain, in regard to climate, is, that, by means of the vine and olive, as valuable produce may be raised on rocky wastes as on rich soils ; and that in all soils whatever, root weeds may be easily and effectually destroyed without a naked fallow. (*Young's France*, ch. iii.)

393. *The lands of France are not generally enclosed and subdivided by hedges or other fences.* Some fences are to be seen near towns, and in the northern parts of the kingdom more especially : but, in general, the whole country is open ; the boundaries of estates being marked by slight ditches or ridges, with occasional stones or heaps of earth, rows of trees, or occasional trees. Depredations from passengers on the highways are prevented by *gardes champêtres*, which are established throughout all France. Farms are sometimes compact and distinct, but generally scattered, and often alternating in the common field manner of England, or run-rig of Scotland. The farm-houses of large farms are generally placed on the lands ; those of smaller ones in villages, often at some distance.

394. *The value of landed property* is in general lower than in England, being at present (1829) sold at from twenty-two to twenty-six years' purchase.

395. *The farming of lands in France*, according to Professor Thounin, naturally divides itself into three kinds: 1. The grand culture, in which from two to twelve ploughs are employed, and corn chiefly cultivated; 2. The middle culture, including the metayers, who also grow corn, but more frequently rear live stock, maintain a dairy, or produce silk, wine, cider, or oil, according to the climate in which they may be situated; and 3. The minor culture, or that which is done by manual labour, and into which live stock or corns do not enter. The middle culture is by far the most common. There are very few farms of six or eight ploughs in France, and equally few farmers who do not labour in person at all times of the year. It is acknowledged by Professor Thounin, that each of these divisions is susceptible of very great improvement.

SUBJECT. 3. *Of the common Farming of France.*

396. *The corn farming in France* is carried on in the best manner in French Flanders, Picardy, and Brie. The first may be considered as equally well cultivated with Suffolk; and the last produces three crops in two years, or five in three years. The crops of these districts are wheat, beans, turnips, maize, and buckwheat. The most frequent rotations are, two corn crops and a fallow, or an alternation of corn and green or pulse crops, without a naked fallow. In the heath district, broom enters into the rotation for fuel, and is cut the fourth year; buckwheat is also extensively sown, and rye and oats. After lands have borne crops, it is usual to let them rest a year or two, during which they produce nothing but grass and weeds, and they are afterwards broken up with a naked fallow. Potatoes enter more or less into the field culture of the greater part of France, and especially of the northern districts; but in Provence, and some parts of Languedoc, they are still little known. Irrigation, both of arable and grass lands, is adopted wherever it is practicable. It is common in the Vosges, and remarkably well conducted in the lands round Avignon, formerly for many miles the property of the church.

397. *The meadows of France* contain nearly the same herbage, plants, and grasses as those of England; but though clovers and lucerne are cultivated in many places, yet rye-grass and other grasses, either for hay crops or temporary or permanent pasture, are not generally resorted to. (*Chaptal de l'Industrie Française*, vol. i. p. 157.)

*398. *To sheep the French have paid considerable attention* from the time of Colbert; and there are now considerable flocks of short-wooled and Spanish breeds in some places, besides several national flocks. That of Rambouillet (established in 1786 by Louis XVI.) is managed by M. Tessier, a well known writer on agriculture, and when visited by Birkbeck, in 1814, was in excellent order. Sheep are housed, and kept in folds and little yards or enclosures, much more than in England. Great part of the sheep of France are black. (*Birkbeck*.) Some curious attempts have lately been made to inoculate them for the clavéau and the scab, but a definite result has not yet been ascertained, at least as to the latter disease. Birkbeck considers the practice of housing as the cause why the foot-rot is so common a disease among sheep in France. Where flocks remain out all night, the shepherd sleeps in a small thatched hut or portable watchhouse, placed on wheels. He guides the flock by walking before them, and his dog guards them from the wolves, which still abound even in Picardy. During summer, in the hottest districts, they are fed in the night, and housed in the heat of the day. Hay is the general winter food; and, in some parts of the Picardy climate, turnips. In 1811, Bonaparte monopolised the breeding of Merinos, and from that time to the passing of an act for the exportation of wool and rams in 1814 they declined; but they are now greatly on the increase. Among the most extensive flocks, are those of the celebrated M. Ternaux.

*399. *The beasts of labour* are chiefly the ox on small farms, and the horse on the larger. Both are kept under cover the greater part of the year. The breeds of oxen are very various; they are generally cream-coloured. The best oxen are in Auvergne, Poitiers, and Languedoc. Normandy furnishes the best breed of working horses; as Limosin does of those for the saddle. In the south of France the ass and mule are of frequent use in husbandry. There, as in many parts of Italy, the poor people collect the stolones of *Agróstitis*, and creeping roots of couch, and sell them in little bundles to the carriers and others who keep road horses. A royal stud of Arabians has been kept up at Aurillac in Limosin, for a century; and another has been lately formed near Nismes. Stud of English horses and mixed breeds of high blood, have been established by government in several departments.

400. *The best dairies* are in Normandy; but in this department France does not excel. In the southern districts, olive, almond, and poppy oil supply the place of butter; and goats' milk is that used in cookery.

401. *The goats of Thibet*, have been imported by M. Ternaux, who has been successful in multiplying them and in manufacturing their hair.

402. *Poultry* is an important article of French husbandry, and well understood as far as breeding and feeding. Birkbeck thinks the consumption of poultry in towns may be equal to that of mutton. The smallest cottage owns a few hens, which often roost under cover, in a neat little structure (fig. 47.), elevated so as to be secure from dogs, wolves, and foxes.

*403. *The breed of swine* is in general bad; but excellent hams are sent from Bretagne, from hogs reared on acorns, and fattened off with maize. Pigeon-houses are not uncommon.

404. *The management of fish-ponds* is well understood in France, owing to fish in all catholic countries being an article of necessity. In the internal district there are many large artificial ponds, as well as natural lakes, where the eel, carp, pike, and a few other species, are reared, separated, and fed, as in the Berkshire ponds in England.

405. *The implements and operations of the common farms of France* are in general rude. The ploughs of Normandy resemble the large wheel-ploughs of Kent. Those farther south are generally without wheels; often without coulter; and an iron mould-board is rare. In many parts of the south the ploughs have no mould-board, and turn the earth in the manner of the simplest form of Roman plough. (110.) Harrows are in general wholly of wood; and, instead of a roller, a plank is for the most part used. Large farmers, as in Normandy,

or, when stiff soils are to be worked out of season, they join together, and form a team of four or six cattle. Their carts are narrow and long, with low wheels, seldom shod in the remote parts of the country. The *guint-barde* of the Seine and Oise (fig. 48.) is a light

and useful machine. Corn is reaped with sickles, hooks, and the Brabant and cradle scythes. (fig. 49.) Threshing, in Normandy, is performed with the flail in houses, as in England; in the other climates, in the open air with flails, or by the tread of horses. There are few permanent threshing-floors; a piece of ground being smoothed in the most convenient part of the field is found sufficiently hard. Farmers, as we have already observed, perform most of their operations without extra labourers; and their wives and daughters

reap, thresh, and perform almost every part of the farm and garden work indifferently. Such farmers "prefer living in villages; society and the evening dance being nearly as indispensable to them as their daily food. If the farm be distant, the farmer and his servants of all descriptions set off early in the morning in a light waggon, carrying with them their provisions for the day." (Neill.) Hence it is, that a traveller in France may pass through ten or twenty miles of corn-fields, without seeing a single farm-house.

406. *Large farms*, which are extremely rare, have generally farmeries on the lands; and there the labour is in great part performed by labourers, who, as well as the tradesmen employed, are frequently paid in kind. (Birkbeck.)

*407. *All the plants cultivated* by the British farmer are also grown in France; the turnip not generally, and in the warm districts scarcely at all, as it does not bulb; but it is questionable, whether, if it did bulb, it would be so valuable in these districts as the lucerne, or clover, which grow all the winter; or the potato, from which flour is now made extensively; or the field beet, which may be used either as food for cattle, or for yielding sugar. Of plants not usually cultivated on British farms may be mentioned, the chicory for green food, fuller's thistle for its heads, furze and broom for green food, madder, tobacco, poppies for oil, rice in Dauphine (but now dropped as prejudicial to health), saffron about Angouleme, *Láthyru* sativus, the pois Breton or lentil of Spain, *Láthyru* setifolius, *Vicia* lathyroides and sativa, *Cicer* arretinum, *Ervum* Léns, *Melilotus* sibirica, *Coronilla* varia, *Hedýsarum* coronarium, &c. They have a hardy red wheat, called *l'épeautre* (spelt), which grows in the worst soil and climates, and is common in Alsace and Suabia. They grow the millet, the dura or douró of Egypt

(*Hólcus Sórghum* L.), in the maize district. The flower-stalks and spikes of this plant are sold at Marseilles and Leghorn, for making chamber-besoms and clothes-brushes. The hop and the common fruit trees are cultivated; and the chestnut is used as food in some places. An oil used as food, and also much esteemed by painters, is made from the walnut. The other fruits of field-culture, as the almond, fig, vine, caper, olive, and orange, belong to the farming of the southern districts.

408. *The forest culture* of France is scientifically conducted, both in the extensive national forests, and on private estates. The chief objects are fuel, charcoal, and bark; and next, timber for construction: but in some districts other products are collected, as acorns, mast, nuts, resin, &c. The French and Germans have written more on this department of rural economy than the English, and understand it better.

409. *A remarkable feature* in the agriculture of France, and of most warm countries, is the use of leaves of trees as food for cattle. Not only are mulberry, olive, poplar, vine, and other leaves gathered in autumn, when they begin to change colour, and acquire a sweetness of taste; but spray is cut green in July, dried in the sun or in the shade of trees in woods, faggoted, and stacked for winter use. During that season they are given to sheep and cattle like hay; and sometimes, boiled with grains or bran, to cows. The astringency of some sorts of leaves, as the oak, is esteemed medicinal, especially for sheep. Such are the outlines of that description of agriculture which is practised more or less throughout France, but chiefly in the northern and middle districts.

SUBJECT. 4. *Of Farming in the warmer Climates of France.*

410. *The culture peculiar to the vine, maize, olive, and orange climates*, we shall extract from the very interesting work of Baron de la Peyrouse. The estate of this gentleman is situated in the maize district at Pepils, near Toulouse. Its extent is 800 acres; and he has, since the year 1788, been engaged, and not without success, in introducing a better system of agriculture.

411. *The farm-houses and offices in the warm districts* are generally built of brick; framework filled up with a mixture of straw and clay; or, *en pisé*; and they are covered with gutter-tiles. The vineyards are enclosed by hawthorn hedges or mud walls; the boundaries of arable farms are formed by wide ditches; and those of grass lands by fixed stones or wild quince trees. Implements are wretched, operations not well performed, and labourers, and even overseers, paid in kind, and allowed to sow flax, beans, baricots, &c., for themselves. The old plough (fig. 50.) resembles that used by the Arabs, which the French antiquarian, Gouguet, (*Origine des Lois*) thinks, in all probability, the same as that used by the ancient Egyptians. They have also a light one-handed plough

for stirring fallows, called the *araire*. (fig. 51.) A plough with coulter was first employed at Pepils; and a Scotch plough, with a cast-iron mould-board, was lately sent there, and excited the wonder of the whole district. In nothing is France more deficient than in suitable agricultural implements.

412. *Fallow, wheat, and maize constitute the common rotation of crops.*

413. *The live stock* consists chiefly of oxen and mules; the latter are sold to the Spaniards. Some flocks of sheep are kept; but it is calculated that the rot destroys them once in three years. Beans are the grain of the poor, and are mixed with wheat for bread. The chick pea (*Cicer arietinum*) (fig. 52.) is a favourite dish with the Provençals, and much cultivated. Spelt is sown on newly broken up lands. Potatoes were unknown till introduced at Pepils from the Pyrenees, where they had been cultivated for fifty years. In the neighbourhood they are beginning to be cultivated. Turnips and rutabaga were tried often at Pepils, but did not succeed once in ten years. Maize is reckoned a clearing crop, and its grain is the principal food of the people.

*414. *The vine* is cultivated in France in fields, and on terraced hills, as in Italy, but managed in a different manner from what it is in that country. Here it is kept low, and treated more as a plantation of raspberries or currants

is in England. It is either planted in large plots, in rows three or four feet apart, and the plants two or three feet distant in the row; or it is planted in double or single rows alternating with ridges of arable land. In some cases, also, two close rows and a space of six or seven feet alternate, to admit a sort of horse-hoeing culture in the wide interval. Most generally, plantations are made by dibbling in cuttings of two feet in length, pressing the earth firmly to their lower end; an essential part of the operation, noticed even by Xenophon. In pruning, a stem or stool of a foot or more is left above ground, and the young shoots are every year cut down within two buds of this stool. These stools get very bulky after sixty or a hundred years, and then it is customary, in some places, to lay down branches from them, and form new stools, leaving the old for a time, which, however, soon cease to produce any but weak shoots. The winter pruning of the vine generally takes place in February: a bill is used resembling that of Italy (fig. 36.); the women faggot the branches, and their value, as fuel, is expected to pay the expense of dressing. In summer, the ground is twice or thrice hoed, and the young shoots are tied to short stakes with wheat or rye straw, or whatever else comes cheapest. The shoots are stopped, in some places, after the blossom has expanded; the tops are given to cows. In some places, also, great part of the young wood is cut off before vintage for feed for cows, and to let the sun directly to the fruit. The sorts cultivated are almost as numerous as the vineyards. Fourteen hundred sorts were collected from all parts of France, by order of the Comte Chaptal, and are now in the nursery of the Luxembourg: but little or no good will result from the collection, or from attempting to describe them; for it has been ascertained that, after a considerable time, the fruit of the vine takes a particular character from the soil in which it is planted; so that fourteen hundred sorts, planted in one soil and garden, would in time, probably in less than half a century, be reduced to two or three sorts; and, on the contrary, two or three sorts planted in fourteen hundred different vineyards, would soon become as many distinct varieties. The *pineau* of Burgogne, and the *auvernat* of Orleans, are esteemed varieties; and these, with several others grown for wine-making, have small berries and branches like our Burgundy grape. Small berries and a harsh flavour are universally preferred for wine-making, both in France and Italy. The oldest vines invariably give the best grapes, and produce the best wines. The Baron de la Peyrouse planted a vineyard twenty years ago, which, though in full bearing, he says, is still too vigorous to enable him to judge of the fineness and quality of the wine, which it may one day afford. "In the *Clos de Vougeot vineyard*, in which the most celebrated Burgundy wine is produced, new vine plants have not been set for 300 years: the vines are renewed by laying (*provigner*); but the root is never separated from the stock. This celebrated vineyard is never manured. The extent is 160 French arpents. It makes, in a good year, from 160 to 200 hogsheads, of 260 bottles each hogshead. The expense of labour and cooperage, in such a year, has arisen to 33,000 francs; and the wine sells on the spot at five francs a bottle. The vineyard is of the *pineau* grape. The soil, about three feet deep, is a limestone gravel on a limestone rock." (*Peyrouse*, 96.)

415. *The white mulberry* is very extensively cultivated in France for feeding the silkworm. It is placed in corners, rows along roads, or round fields or farms. The trees are raised from seeds in nurseries, sometimes grafted with a large-leaved sort, and sold generally at five years, when they have strong stems. They are planted, staked, and treated as pollards. Some strip the leaves from the young shoots, others cut these off twice one year, and only once the next; others pollard the tree every second year.

416. *The eggs of the silk-moth* (*Bombyx mori*) are hatched in rooms heated by means of stoves to 18° of Reaumur (72° Foh.). One ounce of eggs requires one hundred-weight of leaves, and will produce from seven to nine pounds of raw silk. The hatching commences about the end of April, and, with the feeding, is over in about a month. Second broods are procured in some places. The silk is wound off the cocoons, or little balls, by women and children. This operation is reserved for leisure days throughout the rest of the season, or given out to women in towns. The eggs are small round objects; the caterpillar attains a considerable size; the chrysalis is ovate; and the male and female are readily distinguishable.

417. *The olive*, of which the most luxuriant plantations are between Aix and Nice, is treated in France in the same way as in Italy. (288.) The fruit is picked green, or, when ripe, crushed for oil, as in the latter country.

418. *The fig* is cultivated in the olive district as a standard tree; and dried for winter use, and exportation. At Argenteuil it is cultivated in the gardening manner for eating green.

419. *The almond* is cultivated about Lyons, and in different parts in the department of the Rhone, as a standard, in the vineyards. As it blossoms early, and the fruit is liable to injury from fogs and rains, it is a very precarious article of culture, and does not yield a good crop above once in five, or, according to some, ten, years.

420. *The caper* is an article of field culture about Toulon. It has the habit of a bramble bush, and is planted in squares, ten or twelve feet plant from plant every way. Standard figs, peaches, and other fruit trees are intermixed with it.

421. The culture of the *orange* is very limited; it is conducted in large walled enclosures at Hieres and its neighbourhood. The fruit, like that of Geneva and Naples, is very inferior to the St. Michael's and Maltese oranges, as imported to Britain; but the lemons are good.

422. *The winter melon* is cultivated in different parts of Provence and Languedoc, and especially in the orange orchards of Hieres. It forms an article of exportation.

423. *Various other fruits* are cultivated by the small proprietors in all the districts of France, and sold in the adjoining markets; but this department of rural economy belongs rather to gardening than to agriculture.

SECT. IV. *Of the present State of Agriculture in Holland and the Netherlands.*

424. *The agriculture of the Low Countries*, and especially of Flanders, has been celebrated by the rest of Europe for upwards of 600 years; that of Holland for its pasturage, and that of the Netherlands for tillage. We shall notice a part of the agricultural circumstances of the two countries.

SUBSECT. 1. *Of the present State of Agriculture in Holland.*

425. *The climate of Holland* is cold and moist. The surface of the country towards the sea is low and marshy, and that of the interior sandy and naturally barren. A considerable part of Holland, indeed the chief part of the seven provinces comprising the country, is lower than the sea, and is secured from inundation by immense embankments; while the internal water is delivered over these banks into the canals and drains leading to the sea, by mills, commonly impelled by wind. In the province of Guelderland and other internal parts, the waste grounds are extensive; being overrun with broom and heath, and the soil a black sand. The marshes, morasses, and heaths, which are characteristic of the different provinces, are, however, intermixed with cities, towns, villages, groves, gardens, and meadows, to a degree only equalled in England. There are no hills, but only gentle elevations, and no extensive woods; but almost every where an intimate combination of land, water, and buildings. The soil in the low districts is a rich, deep, sandy mud; sometimes alluvial, but more frequently siliceous, and mixed with rotten shells. In a few places there are beds of decayed trees; but no where rough gravel or rocks. The soil of the inland provinces is in general a brown or black sand, naturally poor, and, wherever it is productive, indebted entirely to art.

*426. *The landed property of Holland* is in moderate or rather small divisions; and, in the richer parts, generally in farms of from twenty to one hundred and fifty or two hundred acres, often farmed by the proprietor. In the interior provinces, both estates and farms are much larger; and instances occur of farms of five hundred or seven hundred acres, partly in tillage, and partly in wood and pasture.

427. *The agriculture of Holland* is almost entirely confined to a system of pasturage and dairy management, for the production of butter and cheese; the latter well known in every part of the world. Almost the only objects of tillage are some madder, tobacco, and herbage plants and roots for stall-feeding the cattle. The pastures, and especially the lower meadows, produce a coarse grass, but in great abundance. The cows are allowed to graze at least a part of the day throughout the greater part of the year, but are generally fed in sheds, once a day or oftener, with rape cake, grains, and a great variety of other preparations. Their manure is preserved with the greatest care, and the animals themselves are kept perfectly clean. The breed is large, small-legged, generally red and white, with long slender horns; they are very well known in England as the Dutch breed. The fuel used in Amsterdam and most of the towns is peat, and the ashes are collected and sold at high prices, chiefly to the Flemings, but also to other nations. A considerable quantity has been imported to England; they are found excellent as a top dressing for clovers and other green crops, and are strongly recommended by Sir John Sinclair and other writers. Other particulars of Dutch culture and economy correspond with the practice of the Netherlands.

*428. *The field implements, buildings, and operations of Holland*, are more ingeniously contrived and better executed than those of any other country on the Continent. The best plough in the world (the Scotch) is an improvement on the Rotheram or Dutch implement. The farmeries, and especially the cow-houses and stables, are remarkable for arrangements which facilitate and economise manual labour, and insure comfort to the animals and general cleanliness. Even the fences and gates are generally found in a better state than in most other countries. They have a simple field gate (fig. 53.) constructed with few rails, and balanced so as it may be opened and shut without straining the posts or hinges, which deserves imitation. Their bridges, foot-planks, and other mechanical agents of culture, are in general indicative of more art and invention than is usual in Continental agriculture.

SUBJECT. 2. *Of the present State of Agriculture in the Netherlands.*

429. *The Netherlands and Holland*, from the tenth to the fifteenth century, were the great marts of manufactures and commerce in the west of Europe; and, at the same time; made distinguished progress in other arts. The particular causes which first contributed to the advancement of agriculture are not exactly known at this distance of time; but it is certain that even in the thirteenth century the art was in an advanced state, and, ever since, the culture of the Low Countries, both agricultural and horticultural, has been looked up to by the rest of Europe.

430. *About the beginning of the seventeenth century*, according to Harte, the Flemings dealt more in the practice of husbandry, than in publishing books upon the subject: so that, questionless, their intention was to carry on a private lucrative trade without instructing their neighbours; and hence it happened, that whoever wanted to copy their agriculture, was obliged to travel into their country, and make his own remarks; as Plattes, Hartlib, and Sir R. Weston actually did.

431. *To make a farm resemble a garden as nearly as possible* was their principal idea of husbandry. Such an excellent principle, at first setting out, led them of course to undertake the culture of small estates only, which they kept free from weeds, continually turning the ground, and manuring it plentifully and judiciously. Having thus brought the soil to a just degree of cleanliness, health, and sweetness, they ventured chiefly upon the culture of the more delicate grasses, as the surest means of acquiring wealth in husbandry, upon a small scale, without the expense of keeping many draught horses or servants. After a few years' experience, they soon found that ten acres of the best vegetables for feeding cattle, properly cultivated, would maintain a larger stock of grazing animals, than forty acres of common farm grass: and the vegetables they chiefly cultivated for this purpose were lucerne, saintfoin, trefoils of most denominations, sweet fenugreek (*Trigonélla*), buck and cow wheat (*Melampyrum pratense*) (fig. 54.), field turnips, and spurry (*Spérgula*), by them called Marian grass.

432. *The political secret of Flemish husbandry* was, the letting farms on improvement. Add to this, they discovered eight or ten new sorts of manures. They were the first among the moderns, who ploughed in living crops for the sake of fertilising the earth, and confined their sheep at night in large sheds built on purpose, whose floor was covered with sand, or earth, &c., which the shepherd carted away every morning to the compost-dunghill. Such was the chief mystery of the Flemish husbandry. (*Harte*.)

433. *The present state of agriculture in the Netherlands* corresponds entirely with the outline given by Harte, and it has probably been in this state for nearly a thousand years. The country has lately been visited with a view to its rural economy by Sir John Sinclair, and minutely examined and ably depicted by the Rev. Thomas Radcliff. To such British farmers as wish to receive a most valuable lecture on the importance of a proper frugality and economy in farming, as well as judicious modes of culture, we would recommend the latter work; all that we can do here, is to select from it the leading features of Flemish farming.

434. *The climate of Flanders* may be considered the same as that of Holland, and not materially different from that of the low parts of the opposite coast of England.

435. *The surface of the country* is every where flat, or very gently elevated, and some extensive tracts have been recovered from the sea. The soil is for the most part poor, generally sandy; but in various parts of a loamy or clayey nature. "Flanders," Radcliff observes, "was in general believed to be a soil of extreme natural richness; whereas, with the exception of some few districts, it is precisely the reverse." He found the strongest and best soil near Ostend; and between Bruges and Ghent some of the worst, being little better than a pure sand.

436. *From confounding the Dutch Netherlands with the Flemish Netherlands*, a good deal of confusion in ideas has resulted. Radcliff, on arriving in Flanders, was informed that, "with respect to culture, not only the English, but the French, confounded under the general name of Brabant or Flanders, all the provinces of the Low Countries, however different might be their modes of cultivation; but that in Flanders itself might best be seen, with what skill the farmer cultivates a bad soil (*un sol ingrat*), which he forces to return to him, with usury, a produce that the richest and strongest lands of the neighbouring provinces of Holland refuse to yield." The districts described as East and West Flanders, are bounded on the east by Brabant and Hainault; on the west by the German Ocean; on the north by the Sea of Zealand and the West Scheldt; and on the south by

French Flanders. It is about ninety miles long, and sixty broad, and abounds with towns and villages.

437. *The landed property of Flanders* is not in large estates: very few amount to 2000 acres. It is generally freehold, or the property of religious or civil corporations. When the proprietor does not cultivate his own lands, which, however, is most frequently the case, he lets it on leases; generally of seven, fourteen, or twenty-one years' endurance, at a fixed money rent, and sometimes a corn and money rent combined. The occupier is bound to live on the premises, pay taxes, effect repairs, preserve timber, not sublet without a written agreement, and to give the usual accommodations to an incoming tenant at the end of the lease. Leases of fourteen or twenty-one years are most common: there are scarcely any lands held from year to year, or on the metayer system. Estates are every where enclosed with hedges, and the fields are generally small.

438. *Farmeries* are convenient, and generally more ample in proportion to the extent of the farm than in England. On the larger farms a distillery, oil mill, and sometimes a flour mill, are added to the usual accommodations. The buildings on a farm of 150 acres of strong soil, enumerated by Radcliff, are:—1. The farm-house, with an arched cellar used as a dairy, an apartment for churning, with an adjoining one for a horse wheel to turn the churning machinery. 2. A small building for the use of extra-labourers, with a fire-place for cooking. 3. The grange or great barn, 130 feet long, by 35 feet wide. The ground floor of this structure, besides accommodating by its divisions all the horses and cows of the farm in comfortable stables, and furnishing two threshing floors for the flail, is sufficient also for a considerable depot of corn in the sheaf, in two extensive compartments to the height of twelve feet, at which elevation an open floor of joists, supported by wooden pillars, is extended over the entire area of the barn, and is repeated at every five feet in height, to the top. Each floor is braced from the pillars, and not only forms a connection of strength throughout the whole, but separates at the same time, without much loss of space, the different layers of corn, securing them from damage, by taking off the pressure of the great mass. 4. A house for farming implements, with granary over, and piggery behind. In the centre is the dunghill; the bottom of which is rendered impervious to moisture.

439. *A plan of a Flemish farmery*, is given by Sir John Sinclair, as suited to a farm of 300 acres: it is executed with great solidity and a due attention to salubrity, being vaulted and well aired. Sir John mentions that he saw, in some places, "a mode of making floors by small brick arches, from one beam to the other, instead of using deals, and then making the floor of bricks," a mode generally adopted in British manufactories, where the beams which serve as abutments are of cast-iron, tied together with transverse wrought-iron rods.

440. *The accommodations of this farmery (fig. 55.) are,*

- | | |
|---|--|
| 1, The vestibule, or entrance of the farm-house. | 24, 25, Sheds for carts. |
| 2, The hall. | 26, Barn. |
| 3, 4, 5, Closets. | 27, Area. |
| 6, Sheds destined for different purposes, but more especially for elevating or letting down grain from the granaries, by machinery. | 28, Flax barn. |
| 7, Kitchen. | 29, 30, Sheep-houses |
| 8, Washing-house. | 31, 32, Stables for the horses and foals. |
| 9, Chamber for female servants. | 33, 34, 35, 36, Places for the bogs. |
| 10, Hall. | 37 and 38, Cisterns destined to receive the urine of the cattle. |
| 11, 12, Closets. | 39, Well. |
| 13, Necessaries. | 40, Dung-pit, concave in the middle. |
| 14, Room for the gardener. | 41, Pool serving to receive the superabundant waters of the dung-pit, the weedings of the gardens, &c. |
| 15, Shed for fuel. | 42, 43, Reservoirs to receive the waters of the farm-yard. |
| 16, 16, Kitchen-garden. | 43, Entrance gateway with dovecot over. |
| 17, Hog-pen. | 44, Small trenches, or gutters. |
| 18, Foultry-yard. | 45, 45, Sheds destined for clover, cut green in summer, or dry in winter. |
| 19, 20, Stables for cows and calves. | 46, Cistern for the wash-houses. |
| 21, Necessaries for the servants, connected with the cisterns. | 47, 47, Situations of the corn stacks, in years of abundance. |
| 22, 23, Sheep-folds. | |

Four elevations (Fig. 56.) represent the four internal sides of the quadrangle; the north side (a); the barn, or west side (b); the south side (c); and the house, or east side (d).

441. *Urine cisterns* are formed in the fields, to receive purchased liquid manure; but, for that made in the farm-yard, generally in the yard, or under the stables. In the latter case, the urine is conducted from each stall to a common grating, through which it descends into the vault, whence it is taken up by a pump; in the best-regulated farmeries there is a partition in the cistern, with a valve to admit the contents of the first space into the second, to be preserved there free from the more recent additions, age rendering it considerably more efficacious. This species of manure is relied on beyond any other, upon all the light soils throughout Flanders; and, even upon the strong lands (originally so rich as to preclude the necessity of manure), it is now coming into great esteem, being considered applicable to most crops, and to all the varieties of soil.

442. *The arable lands of Flanders* include by far the greater part of the surface of the country. The crops raised are the same as those in Britain; but, from local circumstances, flax, hemp, chiccory, rape, spurry, madder, woad, tobacco, and some others, enter more generally into rotations.

443. *Fallows*, according to Sir John Sinclair, are in a great measure abolished, even on strong land; by means of which, produce is increased, and the expense of cultivation, on the crops raised in the course of a rotation, necessarily diminished; and by the great profit they derive from their flax and rape, or colsat, they can afford to sell all their crops of grain at a lower rate. The Flemish farmers, however, understand their interest too well, to abolish naked fallows on strong clayey soils in a humid climate.

444. *In regard to soil and culture*, Radcliff arranges Flanders into eleven agricultural divisions, and of the principal of these we shall notice the soil and rotations, and some other features of culture.

445. *The first division* extends along the North Sea, and includes Ostend. This district consists of the strongest and heaviest soil which Flanders possesses, and a similarity of quality prevails generally throughout, with some occasional exceptions. It may be represented as a clay loam of a greyish colour, and yields the various produce to be expected from a strong soil; rich pasture, wheat, beans, barley, and rape, considered as primary crops; and, as secondary (or such as are not so generally cultivated), oats, carrots, potatoes, flax, and tares. In this division, however, though the nature of the soil may be stated under the general description of a clay loam, yet there are of this three degrees of quality, not to be marked by regular limits, but to be found throughout the whole, in distinct situations. It becomes the more necessary to remark this, as the succession of crops depends on the quality of the soil; and as there are here three different degrees of quality, so are there three different systems of rotation.

446. *Upon the first quality of soil*, the succession is as follows: first year, barley; second, beans; third, wheat; fourth, oats; fifth, fallow. For the second quality of soil, the succession is as follows: first year, wheat; second, beans or tares; third, wheat or oats; fourth, fallow. For the third quality of soil, the succession is as follows: first year, wheat; second, fallow; third, wheat; fourth, fallow. Besides these three qualities of strong soil, another of still superior fertility prevails in this district in considerable extent, known by the denomination of Polders.

447. *The polders, or embanked lands of Flanders*, are certain areas of land reclaimed from the sea by embankment, whose surface, once secured from the influx of the tide, becomes the most productive soil, without requiring the assistance of any description of manure. They owe their origin partly to the collection of sand, in the small branches of rivers, gradually increasing, so as naturally to embank a portion of land, and convert it into an arable and fertile soil. They also have proceeded from the contraction of the river itself, which, by the effect of the tides, is diminished in one place, whilst an alluvial soil is formed in another by its overflow. Hence it is, that, within a century, entire polders in certain situations have been inundated, whilst, in others, new and fertile land has appeared, as if from the bosom of the water. These operations of nature pointed out facilities many centuries back, which excited the industry of the Low Countries, an industry

which has been rewarded by the acquisition of their richest soil. These newly-formed lands, before their embankment, are called *schorres*. They are flooded at every tide by the water of the sea, and are augmented by mire, bits of wood, rushes, sea-weeds, and other marine plants decayed and putrid, also by shells and fishy particles which the ebb always leaves behind in considerable quantity. This growing soil soon produces various plants and grasses, and improves daily. When such lands have acquired a crust or surface of black earth, three or four inches deep, they may be embanked and fallowed. Those are always the most productive which have been deepened in their soil by the augmentations of the sea; and experience proves that in the corners and hollows, where, from an obstructing boundary, the greatest quantity of mire has been deposited, the soil is doubly rich and good, and cannot be impoverished by the crops of many years. In some instances, the embankments are made on the part of government; in others, by companies or individuals, under a grant of a specific tenure (generally twenty-one years), rent free, or, according to circumstances, at some moderate annual payment.

448. *The polder of Snaerskirke*, near Ostend, contains about 1300 acres. It is of late formation, and was overflowed by a creek with its minor branches every spring tide. By constructing two banks and a flood-gate at the creek, the sea is excluded, and the space subdivided by roads, and laid out in fields of thirteen acres each, surrounded by ditches. The bank is fifteen feet in height, thirty feet in the base, and ten feet across the top: the land which has been reclaimed by it, was let for a sheep pasturage at 600 francs (25*l.*) per annum, and was thrown up by the farmer as untenable. Upon being dried by this summary improvement, the lots, of which there are one hundred of thirteen acres each, were sold by auction at an average of 7000 francs (291*l.* 13*s.* 4*d.*) a lot, and would now bring nearly double that rate. They are let to the occupying farmers at 36 guilders the *mésure*, or about 2*l.* 15*s.* the English acre, and are now producing superior crops of rape, of sucrion (winter barley), and beans, which constitute the usual rotation; this, however, is varied according to circumstances, as follows:—1. oats, or rape; 2. winter barley, or rape; 3. winter barley; 4. beans, pease, or tares.

449. *Other examples of reclaimed lands are given.* One called the *Great Moor*, recovered through the spirited exertions of M. Hyrwein, contains 2400 acres. Attempts had been made to recover it by the Spaniards, in 1610, but without success. This marsh was seven feet below the level of the surrounding land; therefore, to drain it, the following operations became necessary:—

450. *To surround the whole with a bank of eight feet in height, above the level of the enclosed ground, formed by the excavation of a fossé, fifteen feet wide and ten feet deep, which serves to conduct the water to the navigable canal.*—*To construct mills* to throw the water over the bank into the *fossé*.—*To intersect the interior* by numerous drains from eight to twelve feet wide, with a fall to the respective mills, to which they conduct all the rain water, and all the soakage water which oozes through the banks.

451. *The mills in use for raising the water, are of a simple but effectual construction, and are driven by wind.* The horizontal shaft above works an upright shaft, at the bottom of which a screw bucket, twenty-four feet in length, is put in motion by a bevil wheel, at such an angle as to give a perpendicular height of eight feet from the level of the interior drain to the point of disgorgement, whence the water is emptied with great force into the exterior canal. With full wind, each mill can discharge 150 *tonneaus* of water every minute. The height of the building from the foundation is about fifty feet, one half of it above the level of the bank. The whole is executed in brickwork, and the entire cost 36,000 francs, about 1500*l.* British. It is judiciously contrived that the drains, which conduct the water to the mills, constitute the divisions and subdivisions of the land, forming it into regular oblong fields of considerable extent, marked out by the lines of osiers which ornament their banks. Roads of thirty feet wide lead through the whole in parallel directions.

452. *The soil of this tract, which has been formed by the alluvial deposit of ages, is a clay loam, strong and rich, but not of the extraordinary fertility of some polders, which are cropped independent of manure for many years.* The first course of crops, commencing with rape, is obtained without manure, and the return for six years is abundant; the second commences and proceeds as follows:—

- | | |
|--|--------------------------|
| 1. Fallow, with manure from farm-yard. | 5. Clover. |
| 2. Sucrion (winter barley). | 6. Beans and Peas mixed. |
| 3. Beans. | 7. Oats. |
| 4. Wheat. | |

453. *The second division adjoins French Flanders, but does not extend to the sea.* The soil may be described as a good loam of a yellowish colour, mixed with some sand; but is not in its nature as strong as that of the former division. Its chief produce is wheat, barley, oats, hops, tobacco, meadow, rape-seed and flax, as primary crops; and, as secondary, buckwheat, beans, turnips, potatoes, carrots, and clover. This division, unlike the former in this respect, is richly wooded.

454. *The general course of crops in this division is as follows:—*

- | | | |
|--------------------------------------|---|---|
| 1. Wheat upon manured fallow. | 5. Flax, highly manured with urine and rape cake, | } Fallow, manured.
or } Rye.
} Wheat. |
| 2. Clover, top dressed with ashes. | 6. Wheat, | |
| 3. Oats, } same year, without manure | 7. Beans, | |
| 4. Turnips, } | 8. Beans, manured, | |

9. Wheat.
10. Oats.
11. Turnips.
12. Rye.
13. Tobacco, three times ploughed, and richly manured.

14. Wheat.
 15. Hops, with abundant manure.
- This last crop remains generally five years, and the ground is afterwards fit for any kind of produce.

455. *In another part of this division*, where hops are not grown, the following rotation is observed : —

- | | |
|---|------------------------------|
| 1. Potatoes, with manure. | 9. Wheat. |
| 2. Wheat. | 10. Oats, } same year. |
| 3. Beans, with manure. | 11. Turnips, } |
| 4. Rye. | 12. Fallow, without manure. |
| 5. Wheat, with manure. | 13. Rye. |
| 6. Clover, top-dressed with ashes. | 14. Tobacco, richly manured. |
| 7. Turnips, with manure. | 15. Wheat. |
| 8. Flax, highly manured with urine and rape cake. | |

456. *In addition to these crops* in some parts of the district, particularly in the line between Woomen and Ypres, magnificent crops of rape are cultivated, and are relied on as a sure and profitable return. Flax is also a crop upon which their best industry is bestowed, and their careful preparation of the soil is scarcely to be surpassed by that of the neatest garden.

457. *In the third division* the soil is a good sandy loam, of a light colour, and is in a superior state of cultivation ; it yields a produce similar to that of the foregoing division, with the same quality of hay ; but plantations are here more numerous. The succession is as follows : —

- | | |
|---|--|
| 1. Wheat, with dung. | 10. Clover, with ashes, seeds sometimes saved. |
| 2. Clover, with ashes, seed sometimes saved. | 11. Oats, without manure. |
| 3. Flax, with urine and rape cake. | 12. Flax, with urine and rape cake. |
| 4. Wheat, with compost of short dung and various sweepings. | 13. Wheat, with dung. |
| 5. Potatoes, with farm-yard dung or night soil. | 14. Beet root, with rape cake, or |
| 6. Rye, with urine. | Tobacco, with rape cake in great quantities. |
| 7. Rape seed, with rape cake and urine. | Turnips are also grown, but are taken as a second crop after |
| 8. Potatoes, with dung. | rape, flax, wheat, or rye. |
| 9. Wheat, with manure of divers kinds. | |

458. *Passing over the other divisions to the eighth and ninth*, we find the reporter describes them as of considerable extent, and, in the poverty of their soil and abundance of their produce, bearing ample testimony to the skill and perseverance of the Flemish farmers. The soil consists of a poor light sand, in the fifteenth century exhibiting barren gravel and heaths. The chief produce here consists of rye, flax, potatoes, oats, buckwheat, rape-seed, and wheat, in a few favourable spots ; clover, carrots, and turnips generally.

459. *On the western side of these districts*, and where the soil is capable of yielding wheat, there are two modes of rotation : one comprising a nine years' course, in which wheat is but once introduced ; and the other a ten years' course, in which they contrive to produce that crop a second time ; but in neither instance without manure, which, indeed, is never omitted in these divisions, except for buckwheat, and occasionally for rye. The first course alluded to above is as follows : —

- | | |
|--|---|
| 1. Potatoes or Carrots, with four ploughings, and twelve tons of farm-yard dung per English acre. | 5. Oats with Clover, with two ploughings, and ten tons and a half of farm-yard dung per English acre. |
| 2. Flax, with two ploughings, and 105 Winchester bushels of ashes, and 48 hogheads, beer measure, of urine per English acre. | 6. Clover, top-dressed, with 105 Winchester bushels of peat or Dutch ashes per English acre. |
| 3. Wheat, with two ploughings, and ten tons and a half of farm-yard dung per English acre. | 7. Rye, with one ploughing, and 52 hogheads, beer measure, of night soil and urine. |
| 4. Rye and Turnips, with two ploughings, and ten tons and a half of farm-yard dung per English acre. | 8. Oats, with two ploughings, and 52 hogheads, beer measure, of night soil and urine. |
| | 9. Buckwheat, with four ploughings, and without any manure. |

460. *Of the Flemish mode of cultivating some particular crops* we shall give a few examples. The drill husbandry has never been generally introduced in the Low Countries. It has been tried in the neighbourhood of Ostend, forty acres of beans against forty acres of drilled crop, and the result was considered to be in favour of the system. But the row culture, as distinguished from the raised drill manner, has been long known in the case of tobacco, cabbages, and some other crops.

461. *Wheat* is not often diseased in Flanders. Most farmers change their seed, and others in several places steep it in salt water or urine, and coppers or verdigrise. The proportion of verdigrise is half a pound to every six bushels of seed ; and the time in which the latter remains in the mixture is three hours, or one hour if cows' urine be used, because of its ammonia, which is considered injurious. The ripest and plumpest seed is always preferred.

462. *Rye* is grown both as a bread corn, and for the distillery. In Flanders frequently, and in Brabant very generally, the farmer upon the scale of from one hundred to two hundred acres of light soil is also a distiller, purely for the improvement of the land by the manure of the beasts, which he can feed upon the straw of the rye, and the grains of the distillery.

463. *Buckwheat* enters into the rotations on the poorest soils, and is sown on lands not got ready in time for other grain. The chief application of buckwheat is to the feeding of swine and poultry, for which it is preeminent ; it is also used in flour as a constituent in the liquid nourishment prepared for cattle and horses ; and bears no inconsiderable share in the diet of the peasant. Formed into a cake, without yeast, it is a very wholesome, and not a disagreeable, species of bread ; but it is necessary to use it while

fresh, as, if kept, it would turn sour sooner than bread made of barley, rye, or wheaten flour. Its blossom is considered to afford the best food for bees. If cut green, it yields good forage, and if ploughed in when in flower, it is thought one of the best vegetable manures in use. It is also said to be used in distillation; but this is not generally admitted to be the case.

464. *Rape* (*colza*, *colsat*, or *cole seed*; not the *Brássica Napus* of Linnæus, but the *B. campéstris* of Decandolle) is considered an important article of Flemish agriculture. It is sometimes sown broad-cast, but the general and improved method is by transplanting, which they allege, and apparently with great justice, to have many advantages: one is, that the seed-bed occupies but a small space, whilst the land which is to carry the general crop is bearing corn. By having the plants growing, they have time to harvest their corn, to plough and manure the stubble intended for the rape, which they put in with the dibble or the plough, from the latter end of September to the second week of November, without apprehending any miscarriage.

465. *The seed-bed* is sown in August, and even to the middle of September. In October, or sooner, the stubble is ploughed over, manured, and ploughed again. The plants are dibbled in the seams of the ploughing (each furrow slice being twelve inches broad), and are set out at twelve inches' distance in the rows. Instead of dibbing upon the second ploughing, in many cases they lay the plants at the proper distances across the furrow, and as the plough goes forward, the roots are covered, and a woman follows the frost, and again in the month of April, the intervals are weeded and hand-hoed, and the earth drawn up to the plants, which is the last operation till the harvest. It is pulled rather green, but ripens in the stack; and is threshed without any particular management: but the application of the haulm, or straw, is a matter of new and profitable discovery; it is burned for ashes, as manure, which are found to be so highly valuable beyond all other sorts which have been tried, that they bear a price as three to one above the other kinds, and it is considered that, upon clover, a dressing of one third less of these is amply sufficient.

466. *The seed is sold for crushing*; or, as is frequently the case, it is crushed by the farmer himself; an oil mill being a very common appendage to a farmery.

467. *The oilette, or poppy* (*Papáver somniferum*), is cultivated in some parts, and yields a very fine oil; in many instances, of so good a quality as to be used for salad oil. The seed requires a rich and well manured soil. The crop is generally taken after rape, for which the ground has been plentifully manured; and for the oilettes it receives a dressing not less abundant. The seed is sown at the rate of one gallon to the English acre, and is lightly covered by shovelling the furrows. The average produce is about thirty Winchester bushels to the English acre. The seed is not so productive as rape, in point of quantity, but exceeds it in price, both as grain and as oil, by at least one sixth. The measure of oil produced from rape, is as one to four of the seed; that produced from the seed of the oilettes, is as one to five.

468. *Poppy seed* is sown both in spring and autumn, but the latter is considered the best season; great attention is given to the pulverisation of the soil, by frequently harrowing, and (if the weather and state of the soil permit) sufficient rolling to reduce all the clods.

469. *The harvesting of the poppy* is performed in a particular manner, and requires a great number of hands. The labourers work in a row, and sheets are laid along the line of the standing crop, upon which, bending the plants gently forward, they shake out the seed. When it ceases to fall from the capsules, that row of the plants is pulled up, and placed upright in small sheaves, in the same, or an adjoining field, in order to ripen such as refused to yield their seed at the first operation. The sheets are then again drawn forward to the standing crop, and the same process is repeated, till all the plants are shaken, pulled up, and removed. In two or three days, if the weather has been very fine, the sheets are placed before the rows of the sheaves, which are shaken upon them, as the plants were before; if any seed remains, it is extracted in the barn by the flail; and, if the weather is unpromising, the plants are not left in the field after the first operation, but are placed at once under some cover to ripen; and yield the remainder of their seed, either by being threshed or shaken.

57

470. *The red clover* is an important and frequent article in the Flemish rotations. The quantity of seed sown does not exceed six pounds and a quarter to the English acre. The soil is ploughed deep and well prepared, and the crop kept very clear of weeds. Their great attention to prevent weeds, is marked by the perseverance practised to get rid of one, which occasionally infests the clover crop, and is indeed most difficult to be exterminated. The *Orobánche*, or broom rape (*Orobánche mājor*) (*fig. 57.*), is a parasitical plant which attaches itself to the pea tribe. In land where clover has been too frequently sown, it stations itself at its root, and, if suffered to arrive at its wonted vigour, will spread and destroy an entire crop. The farmer considers the mischief half done, if this dangerous plant is permitted to appear above the surface; and he takes the precaution to inspect his clover in the early spring. The moment the *Orobánche* establishes itself at the root, the stem and leaf of the clover, deprived of their circulating juices, fade to a sickly hue, which the farmer recognises, and, with true Flemish industry, roots up and destroys the latent enemy. If this is done in time, and with great care, the crop is saved; if not, the infected soil refuses to yield clover again for many years.

471. *The turnip* is not in general cultivated as a main crop, but usually after rye or rape, or some crop early removed. The turnip is sown broad-cast, thinned, and hoed with great care; but it affords a very scanty crop of green food, generally eat off with sheep in September or later. The Swedish turnip is unknown; and indeed the turnip husbandry, as practised in Britain, cannot be considered as known in Flanders.

472. *The potato* was introduced early in the seventeenth century, but attracted little notice till the beginning of the eighteenth. It is cultivated with great care. The ground is trenched to the depth of nearly two feet; and small square holes having been formed at about eighteen inches from each other, a set is deposited in each, the hole nearly filled with dung, and the earth thrown back over all. As the stalks rise they are earthed up from the intervals, and manured with liquid manure; and, as they continue to rise, they receive a second earthing round each distinct plant, which, with a suitable weeding, terminates the labour. Notwithstanding the distance between the plants, the whole surface is closely covered by the luxuriance of the stems, and the return is abundant. If the seed is large, it is cut; if small, it is planted whole. In some parts of the Pays de Waes they drop the potato sets in the furrow as the plough works, and cross-boe them as they rise; but the method first mentioned is the most usual, and the produce in many cases amounts to ten tons and one sixth, by the English acre.

473. *Potatoes are the chief food of the lower classes.* They are prized in Flanders, as being both wholesome and economical, and are considered there so essential to the subsistence of a dense population, that at one time it was in serious contemplation to erect a statue, or some other monument of the country's gratitude, to the person who first introduced amongst them so valuable a production. They are also very much used in feeding cattle and swine; but, for this purpose, a particular sort, much resembling our ox-noble, or cattle potato, is made use of, and the produce is in Flanders, as with us, considerably greater than that of the other kinds intended for the table.

474. *The carrot* is a much valued crop in sandy loam. The culture is as follows:— After harvest they give the land a moderate ploughing, which buries the stubble, and clearing up the furrows to drain off the waters, they let the field lie so for the winter; early in spring they give it a second ploughing very deep (from eleven to twelve inches), and shortly after they harrow the surface well, and spread on it ninety-six carts of manure to the bonnier, about twenty-one tons to the English acre. This manure is in general half from the dung-hill, and half of what is termed *merde*, or a collection from the privies, which being ploughed in, and the surface made smooth, they sow the seed in the month of April, broad-cast, and cover it with a harrow. The quantity sown is estimated at eleven pounds to the bonnier, or about three pounds to the English acre. The average produce, about one hundred and sixty bushels to the English acre.

475. *The carrot, as nutritive food both for cattle and horses,* is a crop extremely valuable. In Flanders it is generally substituted in the room of hay, and a moderate quantity of oats is also given. To each horse, in twenty-four hours, a measure is allotted, which weighs about twenty-five pounds. This appears a great quantity, but it makes hay-feeding altogether unnecessary. To each of the milch cows, a similar measure is given, including the tops, and this is relied on for good butter, both as to quantity and quality.

476. *The white beet, or mangold-würzel,* is not in use in Flanders as food for cattle, but was once cultivated very extensively for the production of sugar. At the time the French government encouraged the manufacture of sugar from this root, experiments were made on a considerable scale, and with great success, in the town of Bruges. The machinery was unexpensive, and the remaining cost was merely that of the manual labour, and a moderate consumption of fuel. The material itself came at a very low rate, about ten shillings British by the ton; and to this circumstance may be chiefly attributed the cessation of the manufacture. Instead of encouraging the cultivator, the government leaned altogether to the manufacturer, and made it imperative on every farmer to give up a certain proportion of his land to this root, without securing to him a fair remuneration. The consequence was, that the manufacturers, thus supported, and taking advantage of the constrained supply, have in many instances been known to refuse payment even of the carriage of a parcel, in other respects sent in gratuitously; and a consequence still more natural was, that the farmers, wherever they had the opportunity of shaking off so profitless a crop, converted the space it occupied to better purposes.

477. *To the manufacturer of beet root sugar* the profit was ample. An equal quantity of sugar with that of the West Indies, which at that time sold for five shillings a pound, could be produced on the spot from mangold-würzel, at less than one shilling by the pound; and to such perfection had the sugar thus made arrived, that the prefect, mayor, and some of the chief persons of Bruges, who were invited by a manufacturer to witness the result of his experiments, allowed the specimens which he produced to exceed those of the foreign sugar.

478. *The process of manufacturing beet root sugar,* as then in use, was simple. A cylindrical grater of sheet-iron was made to work in a trough, prepared at one side in the hopper form, to receive the clean-washed roots of the beet, which, by the rotation of this rough cylinder, were reduced to a pulp. This pulp, when placed in bags of linen or hair-cloth, and submitted to a pressure resembling that of a cider press, yielded its liquor in considerable quantity; which being boiled and subjected to a proportion of lime, the saccharine matter was precipitated. The liquor being then got rid of, a solution of sulphuric acid was

added to the precipitate, which being boiled again, the lime was disengaged; the saccharine matter, being then freed from the liquor, granulated, and was ready for the refiner. The pulp has been found to yield, upon distillation, a wholesome spirit, very inferior, but not very unlike, to geneva, and has been proved excellent as a manure, but not valuable as food for cattle, beyond the first or second day from the press. The foregoing process required but a fortnight to complete it.

479. *Flax* is cultivated with the utmost care. The field intended for this crop, after two or three ploughings and harrowings, is again ploughed, commencing in the centre, and ploughing round and round to the circumference, so as to leave it without any furrow. The heavy roller is drawn across the ploughing by three horses; the liquid manure is then spread equally over the entire surface, and when well harrowed in by eight or nine strokes of the harrow, the seed is sown, which is also harrowed in by a light harrow, with wooden pins of less than three inches; and the surface, to conclude the operation, is again carefully rolled. Nothing can exceed the smoothness and cultivated appearance of fields thus accurately prepared.

480. *The liquid universally used for the flax crop*, demands particular notice: it is termed liquid manure, and consists of the urine of cattle, in which rape-cake has been dissolved, and in which the *vidanges* conveyed from the privies of the adjoining towns and villages have also been blended. This manure is gradually collected in subterranean vaults of brickwork, at the verge of the farm next to the main road. Those receptacles are generally forty feet long, by fourteen wide, and seven or eight feet deep, and in some cases are contrived with the crown of the arch so much below the surface of the ground, as to admit the plough to work over it. An aperture is left in the side, through which the manure is received from the cart by means of a shoot or trough, and at one end an opening is left to bring it up again, by means of a temporary pump, which delivers it either into carts or tonneaus.

481. *The liquid is carried to the field* in sheets or barrels, according to the distance. Where the cart plies, the manure is carried in a great sheet called a *voile*, closed at the corners by running strings, and secured to the four uprights of the carts; and two men, standing one on each side of the cart, scatter it with hollow shovels upon the rolled ground. Where the tonneaus are made use of, each is carried by two men with poles, and set down at equal intervals across the field in the line of the rolling. There are two sets of vessels, which enable the men, who deposit the loaded ones, to bring back the others empty. One man to each vessel, with a scoop, or rather a kind of bowl with a long handle, spreads the manure, so as to cover a certain space; and thus, by preserving the intervals correctly, they can precisely gauge the quantity for a given extent of surface. For the flax crop they are profuse; and of this liquid mixture, in this part of the country, they usually allow at the rate of 2480 gallons, beer measure, to the English acre.

482. *Spurry* (*Spérgula arvensis*) (*fig. 58.*) is cultivated on the poorest soils. It is so quick of growth and short of duration, that it is often made to take an intermediate place between the harvest and the spring sowing, without any strict adherence to the regularity of succession. It is sown sometimes in the spring, but in general in the autumn, immediately after harvesting the corn crops. One light ploughing is sufficient; and as the grain is very small, it is but very lightly covered. About twenty-four pounds of seed to the acre is the usual quantity. Its growth is so rapid that in five or six weeks it acquires its full height, which seldom exceeds twelve or fourteen inches. The crop is of course a light one, but is considered of great value, both as supplying a certain quantum of provender at very little cost, and as being the best food for milch cows, to improve the quality of the butter. It lasts till the frost sets in, and is usually fed off by milch cows tethered on it, but is sometimes cut and carried to the stalls.

483. *Where spurry is sown in spring* the crop is occasionally made into hay; but from the watery nature of the plant, it shrinks very much in bulk, and upon the whole is much more advantageously consumed in the other manner. It is indigenous in Flanders; and, except when cultivated, is looked on as a weed, as in this country.

484. *The hop* is cultivated on good soils, and generally after wheat. The land being four times ploughed, the plants are put in, in the month of May, in rows with intervals of six feet, and six feet distant in the row. In the month of October they raise the earth round each plant, in little mounds about two feet and a half high, for the purpose of encouraging a number of shoots, and of preserving them from the frost. When all harsh weather has disappeared, about the beginning of April in the second year, they level those little heaps, and take away all superfluous shoots at the root, leaving but four or five of the strongest. They then spread over the entire surface, at the rate of twelve carts of 1500 lbs. each, by the English acre, of dung, either of cows, or of cows

and swine mixed; but they avoid the heat and fermentation of horse-dung. This dressing is given when the shoots begin to appear; at which time also, they fix in the earth, close to each hill, a pole of dry wood, about eighteen feet in length, for the vines to cling by. In the month of July, they give the surface another dressing with urine, at the rate of 1000 gallons the English acre. In the month of August, the crop has nearly arrived at its full growth, and flourishes in all its beauty.

485. *The crop is ready to gather in the month of September*, when they cut the runners at about three feet from the ground, and in November they cut them to the earth; they then heap up the soil about each plant as before, to the height of two feet and a half, and follow precisely the same course as above-mentioned each year, during five, which is the usual time they suffer the plantation to continue, and at the expiration of which the land is in the highest condition, and suited to the reception of any other crop.

486. *Madder* is sometimes cultivated, but only on land of the best quality, and with plenty of manure. At the end of April or May, accordingly as the young plants are large enough to be transplanted, the land must be ploughed in beds of two feet and two feet and a half wide; the beds are then to be harrowed and raked, and the young suckers of the roots or plants are to be put down in rows, at intervals of a foot or a foot and a half, and six or eight inches distant in the row.

487. *During the entire summer* the land should be frequently stirred, and kept free from weeds. In the month of November, when the leaves are faded, the plants are covered with two inches of earth by a plough, having the point of the coulter a little raised or rounded, so as not to injure the young plants.

488. *In the following spring*, when the young shoots are four or five inches long, they are gathered or torn off, and planted in new beds, in the same manner as has been pointed out above; and then in the month of September or October, after the faded leaves have been removed, the old roots are taken up.

489. *The madder thus taken up* should be deposited under cover, to protect it from the rain; and, after ten or twelve days, placed in an oven moderately heated. When dried sufficiently, it is gently beaten with a flail, to get rid of any clay that may adhere to the plants; and, by means of a small windmill, is ground and sifted, to separate it from any remaining earth or dirt. It is then replaced in the oven for a short time, and when taken out is spread upon a hair-cloth to cool; after which it is ground and cleaned once more. It is then carried to a bruising-mill, and reduced to a fine powder, after which it is packed in casks or barrels for market.

490. *The culture of woad*, though not general, has been practised in Flanders. It was an object with the French government to spread the cultivation of it, and a considerable quantity of seed was sent gratis into the country for that purpose.

491. *Woad thrives only on gravelly and sandy soils*, which must be well pulverised, manured, and formed into beds, as in the case of madder culture. It is sown in March or April in rows, or broad-cast, and harrowed or covered with a rake. All weeds are cleared away, and the plants thinned, if a careful culture is followed. The leaves are the part of the plant which is used by the indigo manufacturer. They should be gathered singly, like those of spinach, as soon as they begin to show signs of maturity, and the mature leaves taken off from time to time as they grow. This operation goes on from June to September in the first year, and from June to August in the second; when the plant being a biennial, shoots into flower stems. The leaves are fermented, and the dye precipitated from the liquor and dried, &c., in a manner analogous to what is practised in India with indigo; but with great improvements, made at the instance of the French government, which, in 1810, called forth the process described in a French work, and translated in the appendix to Radcliff's report. At present it is to be considered more as matter of curious historical information, or of local adoption, than of general utility; because no mode of cultivating or preparing woad could bring it into competition, either in the European or American market, with indigo.

492. *With culinary vegetables the Flemish markets are abundantly supplied.* Most of these are grown by the small farmers, and are of excellent quality. To every cottage in Flanders a garden of some description is attached; and according to the means, the leisure, and the skill of the possessor, is rendered more or less productive. The general principles of management with all are, frequent digging, careful weeding, ample manuring, and immediate succession. The rotation depends on circumstances. The chief vegetables in common use are, parsnep, carrot, turnip, scorzonera, savoy, jettechou cabbage (Brussels sprouts), onions, leeks, peas, beans, and all kinds of salading, with another vegetable called *fève haricot*, a large species of French bean, which has a place in the field or garden of almost every farmer, and being sliced down, pod and seed, is made a chief ingredient in all farm-house cookery.

493. *The treatment of asparagus* here, and generally in Flanders, differs considerably from our method. In forming their beds, they are not by any means particular as to very deep trenching, or a profusion of manure; nor, as they grow up, do they cover the beds with litter for the winter, nor fork and dress them in the spring. In the furrows they form a rich and mellow compost of earth and dung, with which, before winter sets in, they dress up the beds to the height of nearly eighteen inches from the level of the crowns; and, without any further operation (except supplying the furrows again for the ensuing year), as soon as the buds appear, they cut them nine inches under the surface, by which means, having but just reached the light, the whole of the stock is blanched.

494. *The frequent manurings given by the Flemish farmer astonish a stranger; the sources whence it is obtained in sufficient quantity form the difficulty, and this can only be resolved by referring to the practice of soiling; to the numerous towns and villages; and to the care with which every particle of vegetable or animal refuse is saved for this purpose. Manure in Flanders, as in China, is an article of trade. The selling price of each description is easily ascertained; the towns let the cleansing of the streets and public retiring places at great rents. Chaptal says there are in every town sworn brokers, expressly for the purpose of valuing night soil; and that these brokers know the exact degree of fermentation in that manure which suits every kind of vegetable, at the different periods of its growth. (Chimie appliquée à l'Agriculture, l. 137.)*

495. *Every substance that constitutes, or is convertible to, manure, is sought after with avidity, which accounts for the extreme cleanliness of the Flemish towns and pavements, hourly resorted to, with brooms and barrows, as a source of profit. Even the chips which accumulate in the formation of the wooden shoes worn by the peasantry, are made to constitute a part of the compost dung-heap; and trees are frequently cultivated in barren lands, merely to remain till their deciduous leaves shall, in course of time, have formed an artificial surface for the purpose of cultivation. The manures in general use are, —*

496. *The farm-yard dung, which is a mixture of every matter that the farm-yard produces, formed into a compost, which consists of dung and litter from the stables, chaff, sweepings, straw, sludge, and rubbish, all collected in a hollow part of the yard, so prepared as to prevent the juices from being wasted; and the value of this, by the cart-load of 1500 lbs. of Ghent, is estimated at five francs.*

497. *The dung of sheep, pigeons, or poultry, by the same cart-load, five francs and a half.*

498. *Sweepings of streets and roads, same quantity, three francs.*

499. *Ashes of peat and wood mixed, same quantity, eight francs.*

500. *Privy manure and urine, same quantity, seven francs.*

501. *Lime, same quantity, twenty-four francs.*

502. *Rape-cake, per hundred cakes, fifteen francs.*

503. *Gypsum, sea mud, and the sediment of the canals, have been all tried experimentally, and with fair results; but the two former have been merely tried; the latter is used successfully in the vicinity of Bruges.*

504. *Bone manure was altogether unknown in Flanders; but, at the suggestion of Radcliff, is now under experiment in that country.*

505. *The agricultural implements of Flanders are by no means such as the excellence of the Flemish culture would lead us to suspect. They are in general of rude workmanship, but constructed with attention to strength, durability, and cheapness.*

506. *The plough has a rude appearance, but works easily, and makes excellent work in loose friable soil; though it would not make a sharp angled furrow-slice in breaking up pastures. It is never drawn by more than two horses, and on light sands often by one, or by a single ass.*

507. *The binot, or Walloon plough, used in Brabant, described by Sir John Sinclair, is a plough with a double or scuffler share, two mould-boards, but no coulter. It is chiefly used for breaking up lands. If the soil is foul, they employ it two or three times, for the purpose of cleaning it thoroughly. The land is not turned over, as by the plough, and the weeds buried, but the soil is elevated into small ridges, by means of which the couch and other root-weeds are not only cut, but they are exposed to the frost in winter, and to the drought of spring; and when the land becomes dry, which it does quickly when thus elevated, these weeds are collected by the harrow, by a trident (or large pitchfork), by a rake, or by the hand. After the binot, the land is always ploughed for the seed furrow. This implement and its application are strongly recommended to the British farmer, by Sir J. Sinclair, as improvements; but, as the editor of the *Farmer's Magazine* observes, the implement is nothing more than a double mould-board plough, and the operation of rigging with it is the justly exploded practice of "ribbing." The late machinist Weir informed us, that he had orders for several binots from Sir J. Sinclair and others, and that he used exactly the same form, as when a double mould-board plough was ordered.*

59

508. *The mouldebaert (fig. 59.) is a curious and useful implement. It resembles a large square malt or cinder shovel, strongly prepared with iron on the cutting edge, and*

is drawn by a pair of horses with swingle-trees. It is used to lessen inequalities of surface, by removing a part of the soil from the heights to the hollows, which it does in an easy and expeditious manner. The driver, who uses long reins, by pressing moderately on the handle (a) as the horses go forward, collects and transports about five hundred weight of earth to the place where it is to be deposited; which is effected in the most summary manner by his letting go the handle: this causes the front, or edge of the machine, (b) to dip, and catch against the ground, whereby it is at once inverted and emptied of its load. The extremity of the handle, to which a rope (c) is affixed, by this inversion strikes against, and rests upon the swingle-tree bar, and in this manner the mouldebaert is drawn along towards the accumulated earth, when, by taking up the rope, the driver draws back the handle, collects his load as before, proceeds to the spot which is to receive it, and the horses are never for a moment delayed. The saving of time and labour, in filling and emptying, gives this implement a decided superiority over the cart; nor is the ground so much injured by this, as by wheels.

509. *The Hainault scythe* (fig. 60) is the general reaping instrument both in the Netherlands and in French Flanders. The handle is fourteen inches, with a shield for the hand of four and a half inches, in all eighteen and a half inches: the blade is two feet three inches in length, the point a little raised, and the entire edge bevelled upwards so as to avoid the surface of the ground, and the frequent use of the sharpening stone. The handle of the crook being of hard wood, is used as a scythe board. A farther account of the mode of using this instrument, and of a series of trials which have been made with it in Scotland, will be found in a succeeding part of this work.

510. *The great Brabant scythe* (fig. 61) differs little from the British implement, and is in general use for mowing clover.

61

511. *The kylanderie*, to which Radcliff seems to attach unmerited importance, is nothing more than a screen for freeing grain from vermin, dust, or small seeds. It resembles a gravel screen, and is used in the same manner.

512. *The trenching spade* consists of a blade of iron fifteen inches long, and a handle of two feet. The labourer standing in the last formed trench, with his left hand at the bottom of the handle, and his right near the top, by the weight of his body, and without the assistance of his foot, sinks the spade about eighteen inches, and standing sideways, throws off the soil with a peculiar sleight and turn of the wrist, so as to lodge it in an oblique position in the trench, and against the preceding line of work, retiring as he casts it from the spade, and thereby effecting some little mixture of the two strata, though the upper surface is at the same time placed below the other.

513. *The pronged hoe* has a pronged blade on one side, and a common plate on the other; it is exceedingly useful; one side may be used for cutting weeds where they prevail, and the other for stirring a surface already clean.

514. *The chariot, or great cart* (fig. 62), is the only machine of the Flemish farmer which appears to transgress the bounds of a rigid economy. This, as it is not only to be used for the transport of grain, but of the farmer and his family occasionally, to the market-town, is more ornamentally finished than any other, and is painted in showy colours, chiefly green and red; an awning also is very ingeniously contrived, as an occasional defence against the rain and sun. From the natural spring of so long a perch, the centre part of this machine

62

is by no means an uneasy conveyance; and there the farmer sits in all solemnity, whilst a well appointed boor acts as a postilion, and his fine and spirited pair of well-trained horses bring him home from market at a rapid trot.

515. *Agricultural operations* of every kind are performed with particular care in Flanders. The most remarkable feature in the operations of culture consists in the frequent ploughings given on all soils; in strong soils for the sake of pulverisation as well as cleanliness; in the lighter, chiefly for the destruction of weeds, and blending the manure with the soil. But, considering that but one pair of horses is in general allowed to about thirty acres, it is surprising how (with the execution of all the other farming work) time can be found for the number of ploughings which is universally given. Very generally, the number, for the various crops, respectively, is as follows: —

For <i>Wheat</i> ,	two ploughings, with two harrowings.	For <i>Oiletes</i> ,	two or three ploughings, with two harrowings.
<i>Rye</i> ,	two or three dit. o.	<i>Tobacco</i> ,	four ditto,
<i>Oats</i> ,	three ditto,	<i>Hemp</i> ,	four ditto,
<i>Potatoes</i> ,	four ditto,	<i>Turnip</i> ,	{ three as a first crop, ditto,
<i>Carrots</i> ,	four ditto,		{ one as a second crop, ditto,
<i>Flax</i> ,	two ditto,		{ three as a first crop, ditto,
<i>Buckwheat</i> ,	four ditto,	<i>Spurry</i> ,	{ one as a second crop, ditto,
<i>Rape</i> ,	three ditto,	<i>Beans</i> ,	two ditto,
<i>Barley</i> ,	three ditto,	<i>Fallows</i> ,	four or five ditto,

516. *Trenching* is a feature almost peculiar to Flemish farming, and that of Tuscany. This remarkable practice is confined to the lighter soils, and is not used where the strong clay prevails. In the districts in which it is adopted, the depth of the operation varies with that of the soil; but till this has arrived at nearly two feet of mellow surface, a little is added to it at each trenching, by bringing to the top a certain proportion of the under stratum; which, being exposed to the action of the atmosphere, and minutely mixed with a soil already fertilised, gradually augments the staple till the sought-for depth be required.

517. *The management of live stock in Flanders*, though good, is not so eminently exemplary as their tillage culture. The cattle are the short-horned Dutch breed; and the colour generally black, or black and white. Little attention is given to the improvement of the form by selection. The sheep are long-wooled and long-legged, and afford a coarse fleece and very indifferent mutton. They are housed at night, and, in the daytime, follow the shepherd and his dog through pathways and along the verges of the fields and roads, picking up a mere subsistence, and never enjoying the range of a sweet and wholesome pasture. In winter they are let out but once a day, and are fed in the sheep houses on rye and hay, &c. A cross with the Merino breed has been tried; but, as might have been predicted from the incongruous parentage, with no benefit. The swine are long-legged, narrow-backed, and flat-ribbed; not easily fatted, but, when well fed and long kept, making excellent pork and bacon.

518. *The horse* is the animal for which Flanders has long been noted, with regard to the excellence of its working breed; and that of England has been considerably improved by the frequent importation thence of stallions and mares, previous to the French revolution. The Suffolk punch horse comes nearest to the most prevalent variety in Flanders; the resemblance is strong, not only in colour, but in some of the essential points of form: however, though the prevailing colour is chestnut in all its shades, yet other colours are likewise to be met with; and, with very few exceptions, the Flemish horses are of superior strength, and of the true working character. The chief, indeed almost the only, defects to be observed in any are, a want of depth in the girth, and a dip behind the withers; for symmetry, perhaps the shoulder also, at the top, should be a little finer; but in all other respects they possess the best shapes.

519. *Every farmer breeds his own work-horses*, and disposes of the redundancy. Even the total absence of pasture is not suffered to prevent it; and the foals are found to thrive remarkably well in a close house. For this purpose, as well as for the general keep of the stock, a regular dietary is observed. The manger is formed of well cemented brickwork. In summer clover, and in winter carrots, are usually given; hay in very small quantities, but in all cases chopped straw mixed with corn or beans, or both, and water aired by keeping in the stable, and whitened with a pretty strong proportion of barley-meal. With every symptom of sufficient spirit, they are extremely docile; and, besides being obedient to the word, are guided in intricate cases, in a manner surprising to a stranger, by a single cord; this rein is never thick, and, in some instances, is as small as a stout whipcord, and yet in the deeper soils three powerful horses abreast (the bridles of the middle and off-side horses being connected with that upon the near-side horse, to which this rein is affixed) are guided by it at all the turnings, the ploughman holding the rein in one hand, and his single-handed plough in the other, and performing his work with the most accurate straightness and precision. Of corn to market, a pair of horses generally draw two tons; of manure to the field, one ton and half; and on the pavement in the towns, three tons, without appearing to be overloaded.

520. *The shoeing of horses in Flanders* is attended to with particular care, and in that country has long been practised the mode of preserving the bars of the hoof, and of letting the frog come in contact with the ground, recommended in England by Freeman and Professor Colman. The use of coekers, or turned heels, is, except in part, entirely abandoned. In two respects, however, the shoeing in Flanders differs from any of the methods in use with us. In one, that to prevent ripping, the hoofs of the fore-feet are pared away towards the toe, and the shoes so fitted, that the fore part shall not touch (within three fourths of an inch) the same level surface, upon which the heel and middle of the shoe shall rest.

521. *This preparation of the foot* is in general use; the horses are not thereby in any degree injured, and are particularly sure-footed. The other point of difference is, that the shoe is nailed on flat and close to the foot, which, in depriving the iron of all spring, and all unequal pressure against the nails, may be in part the cause of the durability of the shoeing.

522. *For shoeing vicious horses* every precaution is taken by the use of the forge machine, a common appendage to the smithies in Flanders. If the horse is not altogether unmanageable, his hind foot is tied to a cross bar, or his fore leg to a stilt and bracket; but if he is extremely vicious indeed, he can be raised from the ground in a minute, by means of a cradle-sling of strong girth web, hooked to the upper side-rails, which, with a slight handspike, are turned in the blocks that support them (the extremities of the sling thereby coiling round them), till the horse is elevated to the proper height, and rendered wholly powerless.

523. *The Flemish and Dutch dairies* are more remarkable for the abundance than the excellence of their products; owing to the inferiority of their pastures, and the cows

being kept the greater part of the winter in the house. In summer the principal article of food in Flanders is clover, cut and carried to the stall. On a small scale, when pasturage is to be had, they are left at liberty; when this is not the case, each cow is led by a rope, and permitted to feed round the corn fields, the grassy borders of which are left about ten feet wide for this purpose.

524. *The food for one cow in winter*, for twenty-four hours, is straw, eighteen pounds; turnips, sixty pounds. Some farmers boil the turnips for them; others give them raw, chopping them with the spade: one or other operation is necessary to obviate the risk of the animal being choked, where the turnips, which is usually the case in Flanders, are of too small a size. In lieu of turnips, potatoes, carrots, and grains are occasionally used. Bean-straw is likewise given, and uniformly a white drink, prepared both for cows and horses, consisting of water in which some oilcake has been dissolved, whitened with rye-meal, oatmeal, or the flour of buckwheat.

525. *In the dairies* the summer feed is pasturage day and night; in winter, hay, turnips, carrots, grains from the breweries, cakes of linseed, rapeseed, bean and other meals, and the white drink before mentioned. For the sake of cleanliness, the tails of the cows are tied to the roof of the cow-house with a cord during the time of milking. The cow-houses, both in Flanders and Holland, are kept remarkably clean and warm; so much so, that a gentleman "spoke (to Radcliff) of having drunk coffee with a cow-keeper, in the general stable, in winter, without the annoyance of cold, of dirt, or of any offensive smell." The Dutch are particularly averse from unfolding the secrets of their dairy management; and, notwithstanding the pointed queries of Sir John Sinclair on the subject, no satisfactory idea was given him of their mode of manufacturing butter or cheese.

526. *The woodlands of Flanders* are of considerable extent; but more remarkable for the care bestowed on them, than for the bulk of timber grown. To this purpose, indeed, the soil is inadequate; most of these woods having been planted or sown on land considered too poor for tillage.

527. *In forming artificial plantations*, the general mode is to plough the ground three or four times, and take a crop of buckwheat; afterwards the plants or seeds are inserted and hoed for a year or two, till they cover the surface. For the Scotch pine, which is sometimes sown alone on the poorest soils, the most common and the simplest mode is that of burning the surface, for which process its heathy quality gives great facility. The ashes being spread, the ground is formed into beds from six to fifteen feet wide, according to circumstances; the seed sown at the rate of six pounds to the English acre, and covered by a light shoveling from the furrows, which are sunk about two feet, not only to supply covering to the beds, but as drains to carry off the surface water.

528. *Extensive artificial woods* have been created in this manner, converting a barren soil into a state of productiveness, the least expensive, very profitable, and highly ornamental. Of six years' growth, there exist flourishing plantations (treated in this manner), from five to nine feet in height. At about ten years from its formation, they begin to thin the wood, and continue to do so annually, with such profit by the sale, as at the end of thirty years to have it clear of every charge; a specific property being thus acquired, by industry and attention merely, without the loss of any capital.

529. *Pine woods are often sown*, and with great success, without the labour of burning the surface; as at Vladsloo, in the neighbourhood of Dixmude, where a luxuriant crop, seven feet high, though of but five years' growth, had been cultivated by Madame de Cleir, by merely ploughing the heathy surface into beds of fifteen feet, harrowing, sowing at the rate of six pounds to the English acre, raking in the seed, and covering the beds lightly from the furrows, which are sunk about eighteen inches deep.

530. *Another mode of sowing*, practised by the Baron de Serret, in the vicinity of Bruges, was productive of a growth not less luxuriant, merely by sowing the seed upon sand (taken from the excavation for a building) which was spread over the heathy surface, the seed raked in, and the furrows shoveled up.

531. *The sowing of pine seed* in many cases is adopted for the purpose of bringing waste land into an arable state, which, when the timber has been disposed of, is found to yield admirable crops, from a surface soil formed by the accumulation of the leaves which have fallen for so many years. For this purpose also, the broom is frequently sown upon waste lands of a similar description, and at the end of four or five years is pulled away, leaving the soil capable of yielding crops of corn.

532. *The preservation of trees* is attended to in the strictest manner, not only by proprietors, but by the government. As an example of this, Radcliff mentions that at a certain season of the year, when the caterpillars commence their attack upon the trees, every farmer is obliged to destroy those upon his own premises, to the satisfaction of the mayor of his particular commune, or to pay the cost of having it done for him. As a proof of the strictness with which this is enforced, the governor sends round a circular letter annually, reminding the sub-intendants and mayors of the obligations and penalties for nonperformance.

533. *There are a number of royal forests* in Flanders; and, besides these, all the trees on the sides of the public roads belong to the government. In West Flanders there are five, amounting together to nearly 10,000 acres. They are superintended by eighteen persons: an inspector, resident at Bruges; a deputy inspector, resident at Ypres; two *gardes généraux*, and fourteen *particuliers*, or privates. The inspector is answerable for all: from him the *garde général* takes his instructions, and sees that they are enforced by the privates, to whom is committed the regulation of the necessary labour.

534. *The cuttings take place periodically* with respect to small trees and fire-wood, so as to secure an annual produce; but reserves are always left to become, eventually, large and valuable timber.

535. *The cutting of the tallis or coppice*, chiefly used as fire-wood, takes place every eleventh year; that of the high and grosser coppice, every twenty-fifth year; the felling of the half-grown forest trees, every sixtieth year; and that of the full-grown forest trees, once in a hundred years.

536. *In the management of coppices*, it is considered essential to preserve the roots from stagnant water; the trenches originally formed for that purpose are from time to time cleared out; and the sediment and manure from the falling leaves, which have accumulated in them, are carefully spread upon the ridge, or rounded set, which the wood occupies. A second branch of regular attention is to remove all brambles and briars; a third, to replace the old and fading stocks by new plantations; a fourth, to thin the stems with regularity and care.

537. *The sorts of trees* are birch, oak, service, ash, maple, elm, beech, poplar, aspen, wild pine, Weymouth pine, plane, lime, larch, Spanish chestnut, and alder. A variety of pine, called the *Pinus maritima*, but not the plant of that name which is known on the coast of Italy and Greece, has been tried on the sea-coast, and found to resist the sea-breeze. It is said extensive plantations have been made of this tree on the coast of France, at Bourdeaux, and that it produces excellent timber; but whether it is a distinct species, or a variety possessing any particular qualities, or merely the common wild or Scotch pine, in a favourable situation, does not appear. Most probably the last circumstance is the case. The

63

pine is liable to the attacks of the *Bóstrichus pínipérdu* (fig. 63.), on the wood of the old branches, and of the larva of a species of moth on the leading young shoots. The moth deposits its eggs among the buds at their extremities: the turpentine or resin which oozes from the buds, protects the eggs till the insect is brought out by the warmth of the atmosphere, when vegetation commences; it then inserts itself into one of the young shoots, about five or six inches below the end (fig. 64. a), and works upwards till it finds its way out at the extremity (b), which at this time begins to shoot, and lodging itself in the centre of it, perforates the young shoot up and down, till it either breaks off, or withers.

538. *The domestic circumstances of the Flemish farmer and his servants* are depicted by Radcliff in a favourable point of view. "Nothing," he says, "tends more to the uniform advancement of good farming, than a certain degree of ease and comfort in those who occupy the soil, and in the labouring classes whom they employ. Without it, an irregular, speculative, and anticipatory extraction of produce, always followed by eventual loss, is resorted to, in order to meet the emergencies and difficulties of the moment; whereas, under different circumstances, the successive returns of a well regulated course become the farmer's object, rather than the forced profit of a single year; and whilst he himself is thus intrinsically served, his landlord is secured, and his ground ameliorated."

539. *The laborious industry of the Flemish farmer* is recruited by intervals of decent and comfortable refreshment; and the farm-servants are treated with kindness and respect. They uniformly dine with the farmer and his family, at a clean tablecloth, well supplied with spoons, with four-pronged forks, and every thing necessary for their convenience. In Flanders, the gentlemen are all farmers; but the farmers do not aspire to be gentlemen, and their servants feel the benefit. They partake with them of a plentiful and orderly meal, which varies according to circumstances. One standing dish, however, is universal, a soup, composed of buttermilk, boiled and thickened with flour or rye-bread. Potatoes, salt pork, salt fish, various vegetables, and eggs are common; fresh meat and fresh fish occur occasionally, though not for daily consumption: add to these, a plentiful supply of butter, or rendered lard, which is sometimes substituted; and when it is recollected that these articles of provision are always made palatable by very tolerable cookery, it will be allowed that the farmer's table is comfortably supplied. The potatoes are always peeled, and are generally stewed in milk; a particular kind of kidneybean, as mentioned before, the *fève haricot*, sliced and stewed in milk also, is a frequent dish. No farmer is without a well cultivated garden, full of the best vegetables, which all appear at his own table; and apples are also introduced into their cookery. The great fruit and vegetable markets of the towns are supplied by gardeners who make it their means of subsistence; but the gardens of the farmers, unless in case of redundancy, are cultivated wholly for their own consumption."

540. *The farm-servants* partake of their master's fare, except in his refreshments of tea, coffee, and beer.

541. *The day-labourers* are not so well provided: they have, however, rye-bread, potatoes, buttermilk, and occasionally some salt pork. The labourer is, in general, very well able to support himself by his work: in a country where so much manual labour is required in weeding, the labourer's family is occupied pretty constantly in summer; and in winter they spin. Each day-labourer has, in most cases, a small quantity of land, from a rood to half an acre, for his own cultivation.

542. *Beggars* in common times are scarcely to be seen, except in the towns, and but few there. In the country, habits of industry are kept up till health fails; and to meet the infirmities of age, the poor possess a revenue from pious donations, regulated by the government, and vested by them in commissions, of which the mayors of the different communes are presidents, respectively, in right of their office.

543. *The clothing of the peasantry* is warm and comfortable, good shoes, stockings, and frequently gaiters of leather or strong linen, which are sold very cheap; their innate frugality leads them, however, to economise in those articles, substituting on many occasions coarse flannel socks and wooden *sabots*, both of which are supplied in all the public markets at about eightpence cost. Their comfortable supply

64

of linen is remarkable; there are few of the labouring classes without many changes. In riding with a landed proprietor through a part of the country in which his property was situated, a neat cottage presented itself: the clipped hedge which surrounded the garden, covered with linen very white, suggested an enquiry, "whether it did not belong to a washerwoman?" The answer was, "That it was occupied by a labourer and his family, and that the linen was all their own." It must, however, be observed, that universally in proportion to the supply is the postponement of the washing, which causes the greater display, and particularly at the beginning of May, which is a chosen season for this purpose. Any circumstance connected with the cleanliness, health, and comfort of the lower classes is interesting; and to this of which we have been speaking, a peculiar degree of decency is attached. If the labourer is comfortable in point of apparel, the farmer is still more so. In home-work, the farmer generally protects his clothes by a smock-frock of blue linen; and great attention to cleanliness prevails throughout his operations.

544. *With respect to the farm-house, the exterior is for the most part ornamented with creepers, or fruit trees trained against the walls; and within, the neatness which prevails is quite fascinating. Every article of furniture is polished; the service of pewter displays a peculiar brightness; and the tiled floor is purified by frequent ablutions.*

545. *The cottage of the labourer, though not so well furnished, is, however, as clean; a frequent and periodical use of water and the broom pervades every house, great and small, in the country and in towns; originating, perhaps, in the necessity of cleanliness, and the public enforcement of it, when Flanders was visited by the plague.*

*546. *The Flemish farmer seldom amasses riches, but is rarely afflicted by poverty; industry and frugality are his characteristics; he never looks beyond the enjoyment of moderate comforts; abstains from spirituous liquors, however easily to be procured; never exceeds his means; pays his rent punctually; and, in case of emergency, has always something to command, beyond his necessary disbursements.*

SECT. V. *Of the present State of Agriculture in Germany.*

547. *The agriculture of Germany is, in many respects, less different from that of Britain than is the agriculture of France or Italy. It is, however, but very imperfectly known in this country; partly from the numerous petty states into which the German empire is divided, which greatly increases the variety of political circumstances affecting agriculture; but principally from the German language being less generally cultivated by Britons, than that of France or of Italy. The outline which we submit is drawn chiefly from the published journals of recent travellers, especially Jacob, Hodgson, and Bright, and from our own observations made in 1813, 1814, and 1828. Those who desire more copious details may consult Thær's *Annals der Landwirthschaft*, Hassel's *Erdebeschreibung*, and the agricultural writings of Hazzi, Schwartz, and Krunitz.*

SUBJECT. 1. *General View of the Agricultural Circumstances of Germany.*

548. *A great variety of soil, surface, climate, and culture must necessarily exist in a country so extensive as Germany. From the south of Hungary to the north of Denmark are included upwards of twelve degrees of latitude, which alone is calculated to produce a difference of temperature of twenty degrees: and the effect of this difference of geographical position is greatly increased by the variations of surface; the immense ridges of mountains, inlets of the sea, lakes and rivers, and extensive plains. The winters in Denmark and Prussia are very severe, and last from six to eight months; the winters in the south of Hungary are from one to three months. The south and south-east of Germany, comprising part of Bohemia, Silesia, and Hungary, are the most mountainous: and the north-east, including Prussia and part of Holstein and Hanover, presents the most level surface. The richest soil is included in the interior and south-western parts; in the immense plain of the Danube, from Presburg to Belgrade, an extent of three hundred miles; and great part of Swabia, Franconia, and Westphalia. The most barren parts are the mountains and sandy plains and heaths of the north, and especially of Prussia; and that country, and part of Denmark and Holstein, abound also in swamps, marshes, and stagnant lakes.*

549. *Landed property, throughout Germany, is almost universally held on feudal tenure, and strictly entailed on the eldest son. It is generally in estates from one hundred acres upwards, which cannot be divided or increased. Most of the sovereigns have large domains, and also the religious and civil corporations.*

550. *The farmers of Germany are still in many instances metayers; but the variety of this mode of holding is much greater there than in France and Italy. In some cases the farmer does not even find stock; and in others, more particularly in Hungary, he and his family are little better off than the cultivators of Russia. In Brandenburg, Saxony, and part of Hanover, the farmers hold on the metayer tenure, or that of paying a fixed rent of corn or money, unalterable either by landlord or tenant. In Mecklenburg, Friesland, Holstein, Bavaria, &c., most of the property is free, as in Britain, and there agriculture is carried to great perfection. Tithes are almost universal in Germany; but are not felt as any great grievance. Poor-rates are unknown.*

551. *The consequence of these arrangements of landed property in Germany is a comparatively fixed state of society. The regulations which have forbid an augmentation*

of rent, or a union of farms, and which have secured to the owner the full enjoyment of the use of the land, have prevented any person, except the sovereign, from amassing an enormous quantity, and have preserved among the inhabitants a species of equality as to property. There are, comparatively, few absolutely destitute labourers. The mass of the people do not live in such affluence as Englishmen; but this is more than compensated to them by all being in some measure alike. In civilised society, it is not destitution, but the craving wants which the splendour of other persons excites, which are the true evils of poverty. The metayer regulations have hindered improvement; but they have also hindered absolute destitution and enormous accumulation. (*Hodgson.*)

552. *From the regulations concerning landed property in Germany*, it has resulted that fewer paupers are found there than in our country. Some other regulations are known, which have probably assisted in protecting Germany from the evil of pauperism to the same extent in which it exists with us. There is no legal provision for paupers. A law of the guilds, which extended to most trades, forbade, and still forbids, where guilds are not abolished, journeying mechanics from marrying; and, in most countries of Germany, people are obliged to have the permission of the civil magistrate, before it is legal for the clergyman to celebrate a marriage. The permission seems to be given or withheld, as the parties soliciting it are thought by the magistrates to be capable of maintaining a family. At least, it is to prevent the land from being overrun with paupers, that the law on this subject has been made.

553. *The agricultural produce of Germany* is for the greater part consumed there; but excellent wines are exported from Hungary and the Rhine; and also wool, flax, timber, bark, hams salted and smoked, geese, goosequills, the canary, goldfinch, and other singing birds, silk, &c.

554. *The culture of the mulberry and rearing of the silkworm, in Germany*, are carried on as far north as Berlin; that of the vine, as Dresden; and that of the peach, as a standard in the fields, as Vienna. The maize is little cultivated in Germany; but patches of it are to be found as far north as Augsburg, in Swabia. Rice is cultivated in a few places in Westphalia. The olive is not planted, because to it, even in the warmest part of Germany, the winters would prove fatal.

555. *The common cultivation* includes all the different corns, and many or most of the legumes, roots, herbage, and grasses, grown in Britain. They grow excellent hemp, flax, and oats; and rye is the bread-corn of all Germany. They also cultivate turnips, rapeseed, madder, woad, tobacco, hops, saffron, teasel, caraway; many garden vegetables, such as white beet, French beans, cabbage, carrots, parsneps, &c.; and some medicinal plants, as rhubarb, lavender, mint, &c.; independently of their garden culture of fruits, culinary vegetables, and herbs for apothecaries. The most common rotation in Germany is two corn crops and a fallow; or, in poor lands, one or two corn crops, and two or three years' rest; but in rich lands, in the south-western districts, green crops or legumes intervene with those of corn.

556. *The best pastures and meadows* are in Holstein, and along the margin of the German Ocean; and for the same reasons as in Holland and Britain, viz. the mildness and moisture of the winters. There are also good pastures and meadows on the Danube, in Hungary; but the great heats of summer stimulate the plants too much to send up flowers; and the culture there is not so perfected as to regulate this tendency by irrigation. Irrigation, however, is very scientifically conducted in some parts of Holstein, and on the Rhine and Oder.

557. *The operations and implements of German agriculture* vary exceedingly. They are wretched in Hungary, and some parts of Bohemia, where six or more oxen may be seen drawing a clumsy plough, entirely of wood, and without a mould-board. In Denmark, Hanover, and in Prussia, they use much better ploughs, some of which have iron mould-boards; and in many places they are drawn by a pair of oxen or horses. The plough, in the more improved districts, has a straight beam, two low wheels, a share, which cuts nearly horizontally, and a wooden mould-board sometimes partially shod with iron: it is drawn by two horses. In Friesland, and some parts of Holstein, the Dutch swing-plough is used. The common waggon

is a heavy clumsy machine on low wheels. (*fig. 65.*) The theoretical agriculturists are well acquainted with all the improved implements of Britain, and some of them have been introduced, especially in Holstein, Hanover, and Westphalia; but these are nothing in a general view. Horses are the most common animals of labour in the north and west of Germany, and oxen in the south. nothing can be worse than the mode of resting lands, and leaving them to be covered with weeds during two or three years in succession.

Fallows are rarely well cultivated; and nothing can be worse than the mode of resting lands, and leaving them to be covered with weeds during two or three years in succession.

558. *Of the live stock of Germany*, the best breeds of working horses and of oxen are in Holstein, and some districts between Hamburg and Hanover. The best saddle horses are reared in Hungary. There are also excellent oxen and cows reared in that country, and exported to Italy and Turkey. The best sheep are in Saxony and Prussia, where the Spanish breed has been naturalised. Swine are common; but the breed is every where very indifferent. Goats are reared in the mountains; and also asses and mules. The forests are stocked with wild deer, boars, stags, hares, and other game. Fish are carefully bred and fattened in some places, especially in Prussia; and poultry is every where attended to, and carried to a high degree of luxury at Vienna. Bees are attended to in the neighbourhood of the forests; and silkworms in the southern districts, as far as Presburg. Canary and other singing birds are reared in Westphalia, and exported to most parts of Europe.

559. *The culture of forests* is particularly attended to in Germany, for the same reasons as in France, and the details in both countries are nearly the same. The number of German books on *Forst-wissenschaft* is astonishing, and most of the writers seem to consider woodlands in that country as a more eligible source of income than any other.

560. *The common agriculture of Germany* may be considered as every where in a state of gradual improvement. Both governments and individuals have formed institutions for its promotion, by the instruction of youth in its principles and most enlightened practices; or for the union of men of talent. The Imperial Society of Vienna, the Geographical Institution of Presburg, and that of the late Professor Thaer, in Prussia, may be mentioned as recent efforts. The farmers in Germany are particularly deficient in the breeding and rearing of horses, cattle, sheep, and swine. Of the latter two, they require new breeds from judicious crosses; and the former require selection, and much more care in rearing. The implements of husbandry also require to be improved, and the importance of working fallows in a very different manner from what is now done should be inculcated. If peace continue, there can be no doubt that these, and all other ameliorations will go rapidly forward; for the spirit of agricultural improvement is at present, perhaps, more alive in Germany than in any other country of Europe.

561. *In noticing some traits of agriculture in the different states of Germany*, we shall begin with Denmark at the most northerly extremity, and proceed, in the order of geographical position, to Hungary in the south.

SUBSECT. 2. *Agriculture of the Kingdom of Denmark, including Greenland and Iceland.*

562. *The improvement of the agriculture of Denmark* may be dated from 1660, when the king became despotic, and was enabled to carry measures of national benefit into execution without the jarring interference of councils. The slaves of the crown were immediately made free, and the example followed by several wealthy proprietors. Acts were passed for uniting and consolidating landed property by equitable exchanges, and for preventing the right of free way; both which led to enclosures, draining, and irrigation. There are now better meadows, and more hedges and walls, in Denmark, than in any country of Germany of the same extent. Various institutions for instruction and reward were formed, and among others, in 1686, the first veterinary school founded in Germany. Artificial grasses and herbage plants enter into most rotations, and rye-grass is perhaps more sown in Holstein than any where, except in England. In a word, considering the disadvantages of climate, the agriculture of Denmark is in a more advanced state than that of any other kingdom of Germany.

563. *The Danish farm-houses* are described by Dr. Neale, in 1805, as "generally built upon the same plan, having externally the appearance of large barns, with folding doors at each end, and of sufficient size to admit loaded waggons; on one hand are the apartments occupied by the farmer and his family; on the other, the stable, cow-house, dairy, and piggery; in the centre, a large space, set apart for the waggons, ploughs, harrows, and other implements of husbandry; and overhead, the granary and hay-loft." As the postmasters are generally farmers, it is customary to drive in at one end; change horses, and then drive out at the other, which is the case in the north of Germany and in Poland, and more or less so in every part of the north of Europe.

564. *Of the farmer's family*, the same accomplished traveller observes, "we were often agreeably surprised at finding the living-apartments furnished with a degree of comfort and neatness bordering upon luxury; every article was substantially good in itself, and was preserved in the greatest order and cleanliness. Thus, white muslin curtains, with fringes and draperies, covered the windows; looking-glasses and chests of drawers were placed around; excellent large feather beds, and a profusion of the best well-bleached linen displayed the industry of the good housewives, while their dinner tables were equally well supplied with damask cloths, and snow-white napkins; and near the doors of the dairies were ranged quantities of large, singularly shaped, brass and copper vessels, bright as mirrors."

565. *The dimensions of some of their buildings*, he says, "is surprising; one measured 110 yards long, resembling in extent the area of Westminster Hall. On the tops of their roofs are generally displayed a set of antlers, and a weathercock; on others, two horses' heads are carved out in wood, and announce the rank of the inhabitants; the antlers, or rather bulls' horns, denoting the house of a tenant; and the horses' heads, that of a landed proprietor. This form of building (fig. 66.) seems to have been adopted from the earliest ages amongst the inhabitants of northern Germany," as similar ones are described by Joannes Lascius in the middle of the sixteenth century. (*Travels through Germany, Poland, &c.* 13.)

566. *The rural economy of Greenland and Iceland* has been given, the former by Crantz, and the latter by Sir G. Mackenzie. Only a small part of Greenland produces pasture, and a still smaller part grain. The culture of the last, however, is now given up. Cabbages and turnips grow well in the gardens, and there are some oak trees, brambles, and junipers between the 60° and 65° N. lat. Sir G. Mackenzie thinks potatoes and barley might succeed in some places. There are considerable pasture farms, a good and hardy breed of horses, and herds and flocks of cattle and sheep. Farmers have no leases, but pay rent in kind, and cannot be removed from the land unless it can be proved that they have neglected its culture; that is, they hold on the metayer system. The stock of cattle and sheep is considered as belonging to the soil of the landlord. A tenant may quit his farm whenever he chooses, but must leave the proper amount of stock to be taken by his successor.

SUBJECT. 8. *Of the Agriculture of the Kingdom of Prussia.*

*567. *The agriculture of Prussia* was considerably advanced by its second king, Frederic William, who is said to have imported 16,000 men from Saltzburg, and expended 25 millions of francs in building villages and distributing lands among them. His successor, Frederick the Great, after having procured a peace, made exertions in agriculture as extraordinary as in war and architecture. He drained and brought into cultivation the borders of the lakes of the Netz and the Wasta, and established 3500 families on what before was a marsh. He drained the marsh of Fridburg, and established on it 400 families. He made extensive drainages, enclosures, and other improvements in Brandenburg, and in Pomerania, and built the extensive embankments of Dallast, in Friesland, by which, by degrees, a large tract of land was recovered, which the sea submerged in 1724. He formed a Council of Woods and Waters for managing the national forests, and regulating rivers and lakes. He established the Royal Economical Society of Potsdam, and other societies, and cultivated a farm. He created a market for agricultural produce, by the establishment of manufactures; and, in short, he left nothing unattempted that might benefit his kingdom. The successors of the great Frederic have not distinguished themselves as encouragers of agriculture, with the exception of the present king, Frederic William I.

568. *The surface and soil of a country so extensive as Prussia* are necessarily various; but, nevertheless, there are few or no mountainous or hilly districts, or fertile plains. The prevailing soil is sand, and almost the whole of the country is in aration.

569. *The soil of the maritime provinces of Prussia* is in general so light, that it may be easily ploughed with two oxen, and those of diminished size, and no great strength. Jacobs not unfrequently saw, on the smaller portions of land, a single cow drawing the plough, and whilst the plough was guided by the owner, the cow was led by his wife. The more tenacious soils, on the banks of the streams, are commonly but of small extent. There is, indeed, a large portion of land in the delta, formed by the separation of the Nogat from the Vistula, between Derschau and Marienburg, which, under a good system of management, would be highly productive, and which requires greater strength to plough; there are some others, especially near Tilsit, of less extent; but the whole of them, if compared with the great extent of the surface of the country, are merely sufficient to form exceptions to the general classification which may be made of the soil. (*Jacob on the Trade in Corn. and on the Agriculture of Northern Europe.*)

570. *The landed estates in Prussia*, previously to the year 1807, were large, and could only be held by such as were of noble birth, or by merchants, manufacturers, or artisans, who had obtained a patent of nobility. When the French had overrun the country, in 1807, these restrictions were removed; and, by successive measures, personal services have been abolished, and the whole of the enslaved peasants have become converted into freemen and freeholders. These small and numerous freeholders are the occupiers and principal cultivators of the soil; rent-paying farmers being seldom to be met with, except in the vicinity of large towns, and on the domains of the crown. (*Ibid.*)

571. *The general course of cultivation in Prussia* is to fallow every third year, by ploughing three times when designed for rye, or five times if intended for wheat, and allowing the land to rest without any crop during the whole of the year, from one autumn to the next. Most of the land is deemed to be unfit for the growth of wheat, under any circumstances. Where it is deemed adapted to that grain, as much as can be manured, from their scanty supply of that article, is sown with wheat, and the remainder of the fallow-ground with rye. The portion which is destined for wheat, even in the best farms, is thus very small; and, as on many none is sown, the whole of the land devoted to wheat does not amount to one tenth of that on which rye is grown. (*Ibid.*)

572. *The live stock*, in proportion to the surface, is very deficient. According to a calculation by Mr. Jacob, the proportion of animals to an acre, over the whole of East Prussia, West Prussia, and Pomerania, is less than one third of what it is in England.

*573. *The implements of husbandry* are quite of as low a description as the working cattle. The ploughs are ill-constructed, with very little iron on them. The harrows are made of wood, without any iron, even for the tines or teeth. The waggons are mere planks, laid on the frame loose, and resting against upright stakes fixed into its sides. The cattle are attached to these implements by ropes, without leather in any part of the harness. The use of the roller is scarcely known, and the clods, in preparing the fallow-ground, are commonly broken to pieces by hand with wooden mallets. In sowing, the seed is carried in the apron or the skirts of the frock of the man who scatters it on the ground. (*Ibid.*)

574. *The produce of the soil*, whether in corn or cattle, is of an inferior quality, and bears a low money price. The scale of living of all classes, is influenced by this state of things. The working classes, including both those who work for daily wages, and those who cultivate their own little portions of land, live in dwellings provided with few conveniences, on the lowest and coarsest food; potatoes, rye, and buckwheat form their chief, and frequently their only, food; linen, from flax of their own growth, and cloth from wool spun by their own hands, both coarse, and both worn as long as they will hold together, furnish their dress; whilst an earthen pot that will bear fire, forms one of the most valuable articles of their furniture. (*Ibid.*)

575. *The improvement of the agriculture of Prussia* is ardently desired by the present government, and in consequence, about twenty-four years ago, the Agricultural Institution of Moegelin on the Oder, conducted by the late Von Thaer, justly celebrated in Germany as an agricultural writer, was founded. This institution was visited by Jacob in 1819; and from his *Travels* we shall give a short account of it.

576. *The Agricultural Institution of Moegelin* is situated in the country or march of Brandenburg, about forty-five miles from Berlin. The chief professor, Von Thaer, was formerly a medical practitioner at Celle, near Luneburg, in the kingdom of Hanover; and had distinguished himself by the translation of various agricultural works from the French and English, and by editing a *Magazine of Rural Economy*. About 1804, the King of Prussia invited him to settle in his dominions, and gave him the estate of Moegelin to improve and manage as a pattern farm.

577. *This estate consists of 1200 acres.* Thaer began by erecting extensive buildings for himself, three professors, a variety of tradesmen, the requisite agricultural buildings, and a distillery. The three professors are, one for mathematics, chemistry, and geology; one for veterinary knowledge; and a third for botany and the use of the different vegetable productions in the *Materia Medica*, as well as for oetomology. Besides these, an experienced agriculturist is engaged, whose office it is to point out to the pupils the mode of applying the sciences to the practical business of husbandry. The course commences in September. During the winter months, the time is occupied in mathematics, and the first six books of Euclid are studied; and in the summer, the geometrical knowledge is practically applied to the measurement of land, timber, buildings, and other objects. The first principles of chemistry are unfolded. By a good but economical apparatus, various experiments are made, both on a large and small scale. For the larger experiments, the brew-house and still-house with their respective fixtures are found highly useful.

578. *Much attention is paid to the analysis of various soils*, and the different kinds, with the relative quantity of their component parts, are arranged with great order and regularity. The classification is made with neatness, by having the specimens of soil arranged in order, and distinguished by different colours. Thus, for instance, if the basis of the soil is sandy, the glass has a cover of yellow paper; if the next predominating earth is calcareous, the glass has a white ticket on its side; if it is red clay, it has a red ticket; if blue clay, a blue one. Over these tickets, others, of a smaller size, indicate by their colour the third greatest quantity of the particular substance contained in the soil. This matter may appear to many more ingenious than useful, and savouring too much of the German habit of generalising. The classification of Von Thaer is, however, as much adopted, and as commonly used on the large estates in Germany, where exact statistical accounts are kept, as the classification of Linnæus in natural history is throughout the civilised world.

579. *There is a large botanic garden*, arranged on the system of the Swedish naturalist, kept in excellent order, with all the plants labelled, and the Latin as well as German names. A herbarium, with a good collection of dried plants which is constantly increasing, is open to the examination of the pupils, as well as skeletons of the different animals, and casts of their several parts, which must be of great use in veterinary pursuits. Models of agricultural implements, especially of ploughs, are preserved in a museum, which is stored as well with such as are common in Germany, as with those used in England, or other countries.

580. *The various implements used on the farm* are all made by smiths, wheelers, and carpenters, residing round the institution; the workshops are open to the pupils, and they are encouraged by attentive inspection, to become masters of the more minute branches of the economy of an estate.

581. *The sum paid by each pupil* is four hundred rix-dollars annually, besides which they provide their own beds and breakfasts. In this country, such an expense precludes the admission of all but youths of good fortune. Each has a separate apartment. They are very well behaved young men, and their conduct to each other, and to the professors, was polite, even to punctilio.

582. *Jacob's opinion of this institution* is, that an attempt is made to crowd too much instruction into too short a compass, for many of the pupils spend but one year in the institution; and thus only the foundation, and that a very slight one, can be laid in so short a space of time. It is, however, to be presumed, that the young men come here prepared with a considerable previous knowledge, as they are mostly between the ages of twenty and twenty-four, and some few appeared to be still older.

583. *The farm at Moegelin* was examined by Jacob in the autumn. The soil is light and sandy, and the climate cold. The wheat was put in the ground with a drill of Thaer's invention, which sows and covers nine rows at once, and is drawn by two horses. The sowing of seed Thaer considers the only circumstance which makes drilling preferable to sowing broad-cast, as far as respects wheat, rye, barley, and oats. The average produce of wheat is sixteen bushels per acre: not much is sown in Prussia, as rye is the bread corn of that country; it produces, with Thaer, twenty-two bushels and a half to the acre. The usual rotation of crops is, potatoes or peas, rye, clover, and wheat. Winter tares are killed by the frost, and the summer species come to nothing, owing to the dry soil and drought. The spurry (*Spergula*) is therefore grown for the winter food of sheep: it is sown on the stubbles immediately after harvest, and in six weeks furnishes an herbage of which the sheep are very fond, and which is said to be very nutritious. Potatoes are a favourite crop; and the small-tubered and rather glutinous ill-flavoured sort common in France and Germany is preferred, as containing more starch in proportion to bulk, than the large kinds. Thaer maintains that, beyond a certain size, the increase of the potato is only water and

not nutriment. The produce per acre is 300 bushels or five tons, which, Thær contends, contain more nutriment than twenty tons of turnips, because the proportion of starch in potatoes to that in turnips is more than four to one. The soil is excellent for turnips, but the long series of dry weather, common on the Continent in the beginning of summer, renders them one of the most uncertain of crops.

584. *A brewery and distillery* are the necessary accompaniments of every large farming establishment in Germany. The result of many experiments in the latter proved that the same quantity of alcohol is produced from 100 bushels of potatoes as from twenty-four bushels of wheat, or thirty-three of barley. As the products of grain or of potatoes are relatively greater, the distillery is regulated by that proportion. During the enforcement of the Continental system, many experiments were tried in making sugar from native plants. Von Thær found, after many trials, that the most profitable vegetable from which sugar could be made was the common garden turnip (of which variety Jacob did not ascertain), and that whilst sugar was sold at a six-dollar the pound, it was very profitable to extract it from that root. The samples of sugar made during that period from different roots, the processes, and their results, are carefully preserved in the museum, but would now be tedious to describe. They are certainly equal in strength of sweetness, and those refined, in colour and hardness, to any produced from the sugar-cane of the tropics.

585. *The improvement of the breed of sheep*, which has been an important object of this establishment, as far as the fineness of the wool is regarded, has admirably succeeded. By various crosses from select Merinos, by sedulously excluding from the flock every ewe that had coarse wool, and, still more, by keeping them in a warm house during the winter, Von Thær has brought the wool of his sheep to great fineness, far greater than any that is clipped in Spain; but the improvement of the carcass has been neglected, so that his, like all other German mutton, is very indifferent.

586. *The various kinds of wool* have been arranged by Von Thær, with the assistance of the professors of the institution, on cards; and the fineness of that produced from different races of sheep, is discriminated with geometrical exactness. The finest are some specimens from Saxony, his own are the next. The fine Spanish wool from Leon is inferior to his, in the proportion of eleven to sixteen. The wool from Botany Bay, of which he had specimens, is inferior to the Spanish. He had arranged, by a similar mode, the relative fineness of the wools produced on the different parts of the body of the sheep, so as to bring under the eye, at one view, the comparative value of the different parts of the fleeces; and he had, also, ascertained the proportionate weight of these different parts. The application of optics and geometry, by which the scales that accompany the specimens are constructed, is such as to leave no doubts on any mind of the accuracy of the results. The scales, indeed, show only the fineness, and not the length of the fibre; which is, I believe, of considerable importance in the process of spinning. The celebrity of the Moegelein sheep is so widely diffused, that the ewes and rams are sold at enormous prices to the agriculturists in East Prussia, Poland, and as far as Russia.

587. *The breeding of cows and the management of a dairy* are secondary objects, as far as the mere farming is regarded; but it is attended to with care, for the sake of the pupils, who thus have before their eyes that branch of agricultural practice, which may be beneficial on some soils though not adapted to this. The cows are in good order, of an excellent breed; and, considering that they are, like the sheep, fed only on potatoes and chopped straw, are in good condition. They yield, when in full milk, from five to six pounds of butter weekly. The custom of killing the calves, when only a fortnight or three weeks old, prevails here as well as elsewhere in Germany. There is no disputing about taste; but though veal is a favourite food in Germany at the tables of the rich, it always seems very unpleasant to an Englishman.

588. *The ploughs* at Moegelein are better constructed than in most parts of Germany. They resemble our common swing-plough, but with a broader fin at the point of the share. The mould-board is constructed on a very good principle and with great skill; the convexity of its fore-part so gradually changing into concavity at the hinder-part as to turn the soil completely upside down. The land is cleanly and straightly ploughed, to the depth of six and a half or seven inches, with a pair of oxen, whose usual work is about an acre and a quarter each day.

589. *A threshing-machine* is rarely used, and only to show the pupils the principle on which it is constructed, and the effect it produces; but having neither wind nor water machinery to work it, the flail is almost exclusively used, the threshers receive the sixteenth bushel for their labour. The rate of wages to the labourers is four groschen a day, winter and summer, besides which, they are provided with habitations and fuel. The women receive from two to three groschen, according to their strength and skill. They live on rye-bread or potatoes, thin soup, and scarcely any animal food but bacon, and a very small portion even of that; yet they look strong and healthy, and tolerably clean.

590. *The culture of the vine and the rearing of the silkworm* are carried on in the more southerly of the recent territorial acquisitions which have been made by Prussia. The culture of culinary vegetables is carried on round Erfurth, and other towns furnished with them whose neighbourhoods are less favourable for their growth. Garden seeds are also raised at Erfurth, and most of the seedsmen of Germany supplied with them. Anise, canary, coriander, mustard, and poppy seeds are grown for distillers and others, and woad, madder, teal, saffron, rhubarb, &c., for dyers and druggists.

591. *The present king of Prussia* has done much for agriculture, and is said to design more, by lessening the feudal claims of the lords; by permitting estates even of knightly tenure to be purchased by burghers and non-nobles; by simplifying the modes of conveyance and investiture; by setting an example of renouncing most of the feudal dues on his vast patrimonial estates; and by making good communications by roads, rivers, and canals, through his extensive territories. (*Jacob's Travels*, 189.)

SUBJECT. 4. *Of the Agriculture of the Kingdom of Hanover.*

592. *The agriculture of the kingdom of Hanover* has been depicted by Hodgson as it appeared in 1817. The territory attached to the free town of Hanover, previously to its elector being made king of Britain, was very trifling; but so many dukedoms and other provinces have been since added, that it now contains upwards of 11,045 square geographical miles, and 1,314,104 inhabitants.

593. *An agricultural society* was founded in Hanover in 1751, by Geo. II., and about the same time one at Celle in Luneburg. The principal business of the latter was to superintend and conduct a general enclosure of all the common lands; it was conducted by Meyer, who wrote a large work on the subject. The present Hanoverian ministry are following up the plans of Meyer, and, according to Hodgson, are "extremely solicitous to promote agriculture."

594. *The landed property of Hanover* may be thus arranged: — One sixth belongs to the sovereign, possibly three sixths to the nobles, one sixth to the corporations of towns and religious bodies, and less than one sixth to persons not noble. The crown lands are let to noblemen, or rather favoured persons, at very moderate rents, who either farm them or sublet them to farmers. There are six hundred and forty-four noble properties, but few of them with mansions, the proprietors living in towns. For a nobleman to live in

the country without being a magistrate, or without holding some office, is looked on as degrading. Hodgson met with only three instances of nobles cultivating their own estates, and then they lived in towns. The farmers of these estates are bauers or peasants, who hold from ten to eighty acres each, at old fixed rents and services long since established, which the landlord has no power to alter. "It may be from this cause that so few nobles reside in the country. They have in truth no land, but what is occupied by other people. The use of these small portions of land on certain conditions, is the property of the occupier, which he can sell, as the stipulated rent and services are the property of the landlord. The bauer has a hereditary right to the use; the landlord a hereditary right to be paid for that use."

595. *The land of religious corporations* is let in the same manner as the crown lands. That of towns is generally divided into very small lots of twelve or ten acres, and let to the townsmen as gardens, or for growing potatoes and corn for their own consumption. Almost every family of the middling and poorer classes in towns, as well as in the country, has a small portion of land. Most of the towns and villages have large commons, and the inhabitants have certain rights of grazing cows, &c.

596. *The occupiers of land* may be divided into two classes, metayers and leibeigeners. The first occupy from eighty to twenty acres, and pay a fixed corn or money rent, which the landlord cannot alter; nor can he refuse to renew the lease, on the death of the occupier. The money rent paid by such farmers varies from seven to twelve shillings per acre. The term leibeigener signifies a slave, or a person who owns his own body and no more. He also holds his land on fixed terms independently of the will of his lord. His conditions are a certain number of days' labour at the different seasons of sowing, reaping, &c., bringing home his lord's fuel, supplying coach or cart horses when wanted, and various other feudal services. The stock of the leibeigener is generally the property of the landlord, who is obliged to make good all accidents or deaths in cattle, and to supply the family with food when the crops fail. This wretched tenure the governments of Hanover, Prussia, and Bavaria are endeavouring to mitigate, or do away altogether; and so much has already been done that the condition of the peasants is said to be greatly superior to what it was a century back.

597. *The free landed property* of the kingdom of Hanover lies principally in Friesland and the marsh lands. There it is cultivated in large, middling, and small farms, as in England, and the agriculture is evidently superior to that of the other provinces.

598. *The large farmers of Hanover* have in general extensive rights of pasturage; keep large flocks of sheep, grow artificial grasses, turnips, and even flax; and have permanent pastures or meadows. Sometimes a brewery, distillery, or public house, is united with the farm.

599. *The farm of Coldingen*, within eight miles of Hanover, was visited by Hodgson. It contained two thousand six hundred acres, with extensive rights of pasturage: it belonged to the crown, and was rented by an amptman or magistrate. The soil was a free brown loam, and partly in meadow, liable to be overflowed by a river. The rotation on one part of the arable lands was, 1. drilled green crop; 2. wheat or rye; 3. clover; 4. wheat or rye; 5. barley or peas; and 6. oats or rye. On another portion, fallow, rape, beans, the cabbage turnip or *kohl-rabi*, flax, and oats were introduced. Seven pair of horses and eight pair of oxen were kept as working cattle. No cattle were fattened; but a portion of the land was sublet for feeding cows.

600. *Of sheep* there were two thousand two hundred, of a cross between the Rhenish or Saxton breed and the Merino. No attention was paid to the carcass, but only to the wool. The "shepherds were all dressed in long white linen coats, and white linen smallclothes, and wore large hats cocked up behind, and ornamented by a large steel buckle. They all looked respectable and clean. They were paid in proportion to the success of the flock, and had thus a considerable interest in watching over its improvement. They received a ninth of the profits, but also contributed on extraordinary occasions; such as buying oilcake for winter food, when it was necessary, and on buying new stock, a ninth of the expenses. The head shepherd had two ninths of the profits."

601. *Of the workmen* on this farm, some were paid in proportion to their labour. The threshers, for example, were paid with the sixteenth part of what they threshed. Other labourers were hired by the day, and they received about sevenpence. In harvest-time they may make eightpence. Some are paid by the piece, and then receive at the rate of two shillings for cutting and binding an acre of corn.

602. *The farming of the cultivators of free lands* resembles that of England, and is best exemplified on the Elbe, in the neighbourhood of Hamburg. A distinguishing characteristic is, that the farm-houses are not collected in villages; but each is built on the ground its owner cultivates. "This," Hodgson observes, "is a most reasonable plan, and marks a state of society which, in its early stages, was different from that of the rest of Germany, when all the vassals crowded round the castle of their lord. It is an emblem of security, and is of itself almost a proof of a different origin in the people, and of an origin the same as our own. So far as I am acquainted, this mode is followed only in Britain, and in Holland, on the sea-coast, from the Ems to the Elbe, to which Holstein may be added, and the vale of Arno in Italy. It is now followed in America; and we may judge that this reasonable practice is the result of men thinking for themselves, and following their individual interest." (*Travels*, vol. i. p. 247.) We may

add that it is also followed in great part of the mountainous regions of Norway, Sweden, and Switzerland. (See *Clarke's Scandinavia* and *Bakewell's Tarentaise*.)

603. *Many proprietors of free lands near Hamburg* also farm them. Speaking of these farmers, Hodgson observes, "compared with the other farmers of Germany, they live in affluence and splendour. They eat meat three or four times a day, and instead of being clad in coarse woollen, which has been made by their wives, they wear fine English clothes, and look like gentleman. Their sons go for soldier officers, and their daughters are said to study the *Journal des Modes*. The proprietors ride into town to take their coffee and play at billiards, and hear and tell the news, and at home they drink their wine out of cut glass, or tea out of china. Their houses are all surrounded by lofty trees and handsomely laid-out gardens; the floors are carpeted, and the windows of plate glass. The dwelling-apartments, the barns, and the places for the cattle, are all covered with one immense roof, and every house looks something like a palace surrounded with a little park. The proprietors direct the agriculture, without working a great deal themselves, and resemble much in their hearty manners English farmers."

604. *In Friesland* they use a swing-plough, known in England as the Dutch plough, the mediate origin of the Rotherham plough, and remotely of Small's Scotch plough. Even the cottagers who rent free lands are totally different from the bauers. Their cottages are white-washed; and they have gardens neatly enclosed, planted with fruit trees, and carefully cultivated. Such is the influence of liberty and security.

605. *The farming of the bauers*, like that of the metayers, is prescribed by the lease, and consists of two crops of corn and a fallow. "Sometimes," Hodgson observes, "they may sow a little clover, lucerne, or spergel (spurry); but they seldom have meadows, and keep no more cattle than is necessary for their work, and those the common lands can feed: sheep are only kept where there are extensive heaths; one or two long-legged swine are common; and poultry. The large farmers sometimes plough with two oxen; but the bauers, except in the sandy districts, invariably use horses. When they are very poor, and have no horses, they employ their cows. Two or more join their stock, and, with a team of four cows, they plough very well. Sometimes they work their land with the spade. The houses of the bauers in Hanover, as in most parts of Germany, are built of whatever materials are most readily come at, put together in the coarsest manner. They are seldom either painted or white-washed, and are unaccompanied by either yards, rails, gates, gardens, or other enclosures. They seem to be so much employed in providing the mere necessaries of life, that they have no time to attend to its luxuries. A savage curiously carves the head of his war spear, or the handle of his hatchet, or he cuts his own face and head into pretty devices; but no German bauer ever paints his carts or his ploughs, or ornaments his agricultural implements." (Vol. i. 246.)

606. *To improve the agriculture of Hanover*, Hodgson justly observes, "the simplest and most effectual way would be for government to sell all the domains by auction in good-sized farms, as the Prussian government has done in its newly acquired dominions." This would end in introducing the Northumberland husbandry, to which, according both to Jacobs and Hodgson, the soil and climate are well adapted, and double the present produce would be produced. To these improvements we may suggest another, that of limiting the rank of noble to the eldest son, so that the rest might without disgrace engage in agriculture or commerce. This last improvement is equally wanted for the whole of Germany.

SUBJECT. 5. *Of the present State of Agriculture in Saxony.*

607. *The husbandry and state of landed property in Saxony* have so much in common with that of Hanover and Prussia, that it will only be requisite to notice the few features in which they differ.

608. *The culture of the vine and the silkworm* are carried on in Saxony, and the latter to some extent. The vine is chiefly cultivated in the margravate, or county, of Theissen, and entirely in the French manner. (414.) The mulberry is more generally planted, and chiefly to separate properties or fields, or to fill up odd corners, or along roads, as in the southern provinces of Prussia and Hanover, and in France.

609. *The wool of Saxony* is reckoned the finest in Germany. There are three sorts, that from the native short-woolled Saxon sheep; that from the produce of a cross between this breed and the Merino; and that from the pure Merino. In 1819, Jacob inspected a flock of pure Merinos, which produced wool that he was told was surpassed by none in fineness, and the price it brought at market. It was the property of the lord of the soil, and managed by the amptman, or farmer of the manorial and other rights. Till the year 1813, it consisted of 1000 sheep; but so many were consumed in that year, first by the French, and next by the Swedes, that they have not been able to replace them further than to 650. The land over which they range is extensive and dry; not good enough to grow flax; but a course of 1. fallow, 2. potatoes, 3. rye or barley, was followed,

and the straw of the rye and barley, with the potatoes, constituted the winter food of the sheep. (*Travels*, p. 265.)

610. *The general rotation of crops in Saxony*, according to Jacob, is two corn crops, and a fallow, or two corn crops and pease. There are some exceptions; and cabbages, turnips, and *kohl-rabi* are occasionally to be seen. The plough has two wheels, and is drawn by two oxen; "and sometimes, notwithstanding the Mosaic prohibition, with a horse and a cow." There are some fine meadows on the borders of the brooks near the villages; but they are in general much neglected, and for want of draining yield but coarse and rushy grass. The houses of the farmers are in villages, the largest for the amptman, and the next for the metayers and leibeigeners. "The whole tract of land, from Meissen to within two English miles of Leipsic, is a sandy loam, admirably calculated for our Norfolk four-course system, by which it would be enabled to maintain a great quantity of live-stock, and produce double or treble the quantity of corn it now yields. In the whole distance from Wurzen, about fifteen miles, I saw but three flocks of sheep; two were small, the other, which I examined, consisting of about one thousand ewes, widders, and tags, belonged to a count, whose name I did not ascertain. As he is lord of a considerable tract of country, the flock has the range of many thousand acres in the summer, and in the winter is fed with chopped straw and potatoes. Upon our system, which might be advantageously introduced, the same quantity of laod would maintain ten times as many sheep, and still produce much more corn than it does at present." (*Ibid.* 301.)

611. *The cows near the villages, between Meissen and Leipsic*, were numerous compared with the sheep, but generally looked poor. "As I saw," continues Jacob, "no hay or corn stacks in the whole distance, I had been puzzled to conceive in what manner their cows could be supported through the winter. Upon enquiring, I learnt a mode of keeping them, which was quite new to me, but which I cannot condemn. The land is favourable to the growth of cabbages, and abundant quantities are raised, and form a material article of human sustenance; the surplus, which this year is considerable, is made into sour-kraut, with a less portion of salt than is applied when it is prepared as food for man. This is found to be very good for cows, and favourable to the increase of their milk, when no green food, nor any thing but straw can be obtained." (*Travels*, 303.)

612. *The land within two miles of Leipsic* is almost wholly in garden-culture, and is vastly productive of every kind of culinary vegetable. The fruit trees and orchards, notwithstanding many of them showed vestiges of the war, surprised Jacob by their abundance. The inhabitants subsist much less on animal food than we do, but a larger quantity of fruit and vegetables is consumed; and hence they have greater inducements to improve their quality, and to increase their quantity, than exist in those rural districts of Great Britain which are removed from the great towns.

613. *Jacob's opinion of the agriculture of Saxony* is, that it is equal to that of Prussia. In one respect he thinks it superior, as no portion of the soil is wholly without some cultivation; but that cultivation is far below what the land requires, and the produce much less than the inhabitants must need for their subsistence.

SUBJECT. 6. *Of the present State of Agriculture in the Kingdom of Bavaria.*

614. *Bavaria, till lately, was one of the most backward countries* of Germany, in regard to every kind of improvement. A bigoted and ignorant priesthood, not content with possessing a valuable portion of the lands of the country, had insisted on the expulsion of the Protestants, and on the strict observance of the endless holidays and absurd usages which impede the progress of industry among their followers. "Hence a general habit of indolence and miserable backwardness in all arts, and especially in agriculture; and in point of learning, a complete contrast to the north of Germany." During the electorate of Bavaria, one of its electors, contemporary with Joseph II. of Austria, desirous of introducing improvements, abolished monastic orders in some parts of his dominions; but the people were not ripe for such a change, notwithstanding the existence of masonic societies, ignorantly supposed to have rendered them ripe for any sort of revolution.

615. *The agricultural improvement of Bavaria* commenced at the time of the French revolution, when the church lands were seized by the government, and sold to the people, and a system of schools was established in every canton or parish, for the education of the lower classes. Soon afterwards agriculture was taught in these schools by a catechism, in the same way as the Christian religion of Scotland is taught in the schools there. In consequence of this state of things the country is rapidly improving in every respect, and will soon be equal to any other in Germany. The names of Monteglas and Hazzi should not be passed over in this brief statement; nor that of Eichthal, who spent upwards of a year in Britain, and chiefly in Scotland, to study its agriculture, which he has introduced on his estate near Munich by a Scotch manager and a Scotch rent-paying farmer.

616. *The surface of Bavaria* is mountainous towards the south; the ground rising in the direction of the Alps, and containing a number of lakes and marshes. To the northward are extensive plains and also wooded mountains; round Nuremberg is a tract of warm sandy soil, and along the Danube are occasional plains of fertile alluvion, partly in meadow and partly under corn.

617. *The crops cultivated* are the usual corns, legumes, and roots; and the produce of corn and turnips, under proper culture, is equal to what it is in the north of England, or in Haddingtonshire. In the dry warm sand around Nuremberg garden seeds are raised

to such an extent as to supply the greater part of Germany and a part of France, and they are even sent to Holland and England.

618. *The forests of Bavaria* are extensive; and, in consequence of a law of the state, all the public roads are bordered with rows of fruit trees, chiefly the cherry and the apple. These trees are raised in nurseries by the government, and sold at cost.

SUBJECT. 7. *Of the present State of Agriculture in the Empire of Austria.*

619. *Agriculture is in a very backward state throughout the whole of the Austrian dominions.* The soil, surface, and climate are almost every where favourable for busbandry; but the political circumstances of the country, and the ignorance of its inhabitants, which is greater than in most other parts of Germany, have kept it in nearly a fixed state for several centuries. Various attempts have been made during the eighteenth century to improve the condition of the peasantry, and simplify the laws relating to landed property, especially by Joseph II.; but they have produced no effect, chiefly, as it appears, because too much was attempted at once. There are agricultural societies at Vienna, Pesth, Prague, and other places; and a very complete agricultural school has been established at Keszthely in Hungary, by the patriotic Graf Festetics. A copious account of it has been given by Dr. Bright (*Travels in Hungary, in 1814, 341. et seq.*), by which it appears much more extensive than those of Hofwyl or Moegelin.

620. *The landed property of Austria* is under similar circumstances of division and occupation with that of the rest of Germany. Perhaps the number of large estates is greater in proportion to the small properties. In Hungary they are of immense extent, and cultivated almost entirely by their proprietors. "In considering a Hungarian property," Dr. Bright observes, "we must figure to ourselves a landed proprietor possessing ten, twenty, or forty estates, distributed in different parts of the kingdom, reckoning his acres by hundreds of thousands, and the peasants upon his estates by numbers almost as great; and remember that all this extent of land is cultivated, not by farmers, but by his own stewards and officers, who have not only to take care of the agricultural management of the land, but to direct, to a certain extent, the administration of justice amongst the people: and we must further bear in mind, that perhaps one third of this extensive territory consists of the deepest forests, affording a retreat and shelter, not only to beasts of prey, but to many lawless and desperate characters, who often defy, for a great length of time, the vigilance of the police. We shall then have some faint conception of the situation and duties of a Hungarian magnate."

621. *To conduct the business of such extensive domains,* a system of officers is formed, which is governed by a court of directors; and on well regulated estates, this band of managers exhibit, in their operations, all the subordination of military, and the accuracy of mercantile, concerns. For this purpose an office is established at or near the estate on which the magnate resides, in which a court of directors is held at stated periods, usually once a week. This court consists of a president or plenipotentiary, a director or solicitor, a prefect, auditor, engineer or architect, a fiscal for law affairs, the keeper of the archives, besides a secretary, clerks, &c. Its business is to review all that has taken place on the different estates, whether of an economical or judicial nature, to examine accounts, and regulate future proceedings. The steward of each separate estate has also a weekly court. It consists of the fiscal or lawyer, the bailiff, the forest master, the engineer, the treasurer, foreman and sub-foreman, police officers to guard prisoners and keep them at work, forest-keeper, rangers, and a gaoler. The estates of Prince Esterhazy, which are the largest in Europe, of Graf Festetics, and Prince Ballhyani, are examples of this mode of government and culture; of which it may be observed, that, like many German plans, it is very accurate and systematic, but very unproductive of profit.

622. *The crown has immense tracts of lands,* especially in Galicia; and, independently of these, the personal estates of the reigning family amount to upwards of 100,000 sterling a year, all of which are farmed by stewards. In the Moravian, Bobemian, and Austrian districts, however, where the estates are not so large as in Hungary, and the people in rather better circumstances as to property and knowledge, they are frequently farmed on the meyr system.

623. *The Austrian dominions,* like the rest of Germany, are unenclosed, with the usual exceptions; the farm-houses and cottages are usually built of wood, and thickly covered with thatch or with shingles. The cottages are remarkably uniform in Hungary, and village scenery there, according to Dr. Bright, must be the duller in Europe. Not less so are their cultivated plains. Speaking of a plain near Presburg, he says, "The peasants were employed in ploughing the land, and my driver (fig. 67.) cheered the way by a

67

Slavonian song. But let no one be induced, by these expressions, to figure to his imagination a scene of rural delight. The plain is unenlivened by trees, unintersected by hedges, and thinly inhabited by human beings; a waste of arable land, badly cultivated, and yielding imperfect crops to proprietors, who are scarcely conscious of the extent of territory they possess. It is for some branch of the families of Esterhazy or Palfy, known to them only by name, that the Slavonian peasants who inhabit these regions are employed. Their appearance bespeaks no fostering care from the superior, no independent respect, yielded with free satisfaction from the inferior. It is easy to perceive that all stimulus to invention, all incitement to extraordinary exertion, are wanting. No one peasant has proceeded in the arts of life and civilisation a step farther than his neighbour. When you have seen one, you have seen all. From the same little hat, covered with oil, falls the same matted long black hair, negligently plaited, or tied in knots; and over the same dirty jacket and trousers is wrapped on each a cloak of coarse woollen cloth, or sheep-skin still retaining its wool. Whether it be winter or summer, week-day or sabbath, the Slavonian of this district never lays aside his cloak, nor is seen but in heavy boots.

*624. *Their instruments of agriculture (fig. 68.) are throughout the same; and in all their habitations is observed a perfect uniformity of design.* A wide muddy road separates

two rows of cottages, which constitute a village. From amongst them, there is no possibility of selecting the best or the worst; they are absolutely uniform. In some villages the cottages present their ends, in others their sides, to the road; but there is seldom this variety in the same village. The interior of the cottage is in general divided into three small rooms on the ground floor, and a little space in the roof destined for lumber. The roof is commonly covered with a very thick thatch; the walls are whitewashed, and pierced towards the road by two small windows. The cottages are usually placed a few yards distant from each other. The intervening space, defended by a rail and gate, or a hedge of wicker-work towards the road, forms the farm-yard, which runs back some way, and contains a shed or outhouse for the cattle. Such is the outward appearance of the peasant and his habitation. The door opens in the side of the house into the middle room, or kitchen, in which is an oven, constructed of clay, well calculated for baking bread, and various implements for household purposes, which generally occupy this apartment fully. On each side of the room is a door, communicating on one hand with the family dormitory, in which are the two windows that look into the road. This chamber is usually small, but well arranged; the beds in good order, piled upon each other, to be spread out on the floor at night; and the walls covered with a multiplicity of pictures and images of our Saviour, together with dishes, plates, and vessels of coarse earthenware. The other door from the kitchen leads to the store-room, the repository of the greater part of the peasant's riches, consisting of bags of grain of various kinds, both for consumption and for seed, bladders of tallow, sausages, and other articles of provision, in quantities which it would astonish us to find in an English cottage. We must, however, keep in mind, that the harvest of the Hungarian peasant anticipates the income of the whole year; and, from the circumstances in which he is placed, he should rather be compared with our farmer than our labourer. The yards or folds between the houses are usually much neglected, and are the dirty receptacles of a thousand uncleanly objects. Light carts and ploughs (*fig. 68.*), with which the owner performs his stated labour, his meagre cattle, a loose rudely formed heap of hay, and half a dozen ragged children, stand there in mixed confusion; over which three or four noble dogs, of a peculiar breed, resembling in some degree the Newfoundland dog, keep faithful watch." (*Trav. in Hung.*, 19.)

*625. *The agricultural produce of Austria is more varied than that of any other part of Germany. Excellent wheat is cultivated in Galicia, where the soil is chiefly on limestone, and in the adjoining province of Buckowine; and, from both, immense quantities are sent down the Vistula to Dantzic. Wheat, rye, and all the other corns, are grown alike in every district, and the quantity might be greatly increased if there were a sufficient demand. Majze is cultivated in Hungary and Transylvania; millet in Hungary, Slavonia, and Carinthia; and rice in the marshy districts of Temeswar. Tobacco is extensively cultivated in Hungary, and excellent hops are produced in Moravia and Bohemia. It is*

estimated that about a sixth part of the Austrian dominions is under tillage. The most common rotation is two corn crops, and fallow or rest.

626. *The Austrian province of Moravia* is very fertile; and, with the exception of some districts of the Netherlands, scarcely any part of the Continent is so well cultivated. It bears too, a larger proportion of wheat than any other district in the east of Europe. Of the winter corn, wheat is estimated at one fourth, and rye at three fourths; whereas, in the adjoining province of Silesia, the land sown with rye is nearly ten times that sown with wheat. Moravia is defended by the Carpathian mountains from the east winds; and the harvest, the whole way from Teschen to Olmutz, and indeed to Brunn, is nearly six weeks earlier than in Silesia. This better state of things arose from the circumstance of Moravian agriculture finding domestic consumers. It is the chief manufacturing province of the Austrian empire. A greater proportion of the population can afford to live on meat, and to use wheaten flour; and hence the agriculturists find a market near home for their productions. The demand for animal food, too, being greater, a greater stock of cattle is kept, and more of the land is destined to clover and other green crops; and it may thence be inferred, that the growth of corn does not exhaust the land, so much as the cattle, by their manure, renew its prolific qualities. (*Jacob on the Trade in Corn, and on the Agriculture of northern Europe.*)

627. *The vine* is cultivated to the greatest extent in Hungary. The well known Tokay is raised on the last chain of the Carpathian hills, in the neighbourhood of the town of Tokay. The district extends over a space of about twenty English miles. "Throughout the whole of this country it is the custom to collect the grapes which have become dry and sweet, like raisins, whilst hanging on the trees. They are gathered one by one; and it is from them alone that the prime Tokay, or, as it is termed, Tokay Ausbruch, is prepared, which, in 1807, sold for 100 florins the cask of 180 halbes on the spot. They are first put together in a cask, in the bottom of which holes are bored to let that portion of the juice escape which will run from them without any pressure. This, which is called Tokay essence, is generally in very small quantity, and very highly prized. The grapes are then put into a vat, and trampled with the bare feet, no greater pressure being permitted. To the squeezed mass is next added an equal quantity of good wine, which is allowed to stand for twenty-four hours, and is then strained. This juice, without further preparation, becomes the far-famed wine of Tokay, which is difficult to be obtained, and sells in Vienna at the rate of 12*l.* sterling per dozen. The greater part of these vineyards is the property of the emperor; several, however, are in the hands of nobles." (*Bright's Travels.*)

628. *Another species of Hungarian wine*, called Méneser, is said to equal Tokay; next to that in value come the wines of Edeburg, Rusth, St. Gyorgy, and Ofen, followed by a great variety, whose names are as various as the hills which produce them. The grape which is preferred for making the Tokay and other Hungarian wines of that character, is a small black or blue grape, figured and described by Sickler in his *Garten Magazin* of 1804, as the Hungarian Blue.

629. *Plums* are cultivated, or rather planted and left to themselves; and an excellent brandy is distilled from the fermented fruit.

630. *The culture of silk* is in the least flourishing state in Hungary; but succeeds well in Austria and Moravia; that of cotton was tried, but left off chiefly on account of the unfavourableness of the autumns for ripening the capsules. The mountain rice (*Oryza nùtica*), from the north of China, was cultivated with success, but neglected during the

late wars. "The greatest advantages which it promised arose from the situations in which it would flourish, and the fact of its not requiring marshy lands, which are so destructive to the health of those who are engaged in the cultivation of common rice." The *Rhùs Còtinus* is extensively collected from the wastes, and used as a tanning plant, especially in the preparation of morocco leather. Woad is cultivated as a substitute for indigo; the *Cypèrus esculèntus* (fig. 69. a), and the *Astrágalus bœ'ticus* (b), as substitutes for coffee; the seeds of the latter, and the tubers of the former, being the parts used. The *Acer campèstre*, *platanùides*, and *Pseùdo-plátanus* have been tapped for sugar, and the *A. saccharinum* extensively cultivated for the same purpose, but without any useful result: it was found cheaper to make sugar from the grape. The culture of coffee, olives, indigo, and other exotics, has been tried, but failed.

631. *The rearing and care of bees* were much attended to during the latter part of the eighteenth century ; with a view to which a public school was opened at Vienna, and some in the provinces ; and great encouragement was given to such as kept hives. Some proprietors in Hungary possessed 300 stock hives. It is customary there to transport them from place to place, preferring sites where buckwheat or the lime tree abounds. The honey, when procured, is greatly increased in value by exposure to the open air for some weeks during winter ; it then becomes hard and as white as snow, and is sold to the manufacturers of liquors at a high price. The noted Italian liqueur, *rosoglio*, made also in Dantzic, is nothing more than this honey blanched by exposure to the frost, mixed with a spirituous liquor : though the honey used is said to be that of the lime tree, which is produced only in the forests of that tree near Kowno on the Niemen, and sells at more than three times the price of common honey.

632. *The live stock of Austria* consists of sheep, cattle, horses, pigs, and poultry. Considerable attention has lately been paid to the breeding of sheep, and the Merino

breed has been introduced on the government estates and those of the great proprietors. The original Hungarian sheep (*Ovis strepsiceros*) (fig. 70.) bears upright spiral horns, and is covered with a very coarse wool. "Improvement on this stock by crosses," Dr. Bright informs us, "is become so general, that a flock of the native race is seldom to be met with, except on the estates of religious establishments." Baron Giesler has long cultivated the Merino breed in Moravia. In Hungary, Graf Hunyadi has

paid great and successful attention to them for upwards of twenty years. His flock, when Dr. Bright saw it in 1814, amounted to 17,000, not one of which whose family he could not trace back for several generations by reference to his registers.

633. *The horned cattle of the Austrian dominions* are of various breeds, chiefly Danish and Swiss. The native Hungarian breed are of a dirty white colour, large, vigorous, and active, with horns of a prodigious length. The cow is deficient in milk ; but where dairies are established, as in some parts near Vienna, the Swiss breed is adopted.

634. *The Hungarian horses* have long been celebrated, and considerable attempts made from time to time to improve them by crosses with Arabian, English, and Spanish breeds ; and, lately, races have been established for this purpose. The imperial breeding shed, or huras, of Mezshegy, established in 1783, upon four commons, is the most extensive thing of the kind in Europe. It extends over nearly 50,000 acres ; employs 500 persons ; and contains nearly 1000 breeding mares of Bessarabian, Moldavian, Spanish, or English extraction.

635. *The breed of swine* in some parts of Hungary is excellent.

636. *Poultry* are extensively reared near Vienna, and also frogs and snails. Townson has described at length the method of treating these, and of feeding geese for their livers. (*Travels in Hungary in 1796.*)

637. *The land tortoise* likewise occurs in great numbers in various parts of Hungary, more particularly about Fuzes-Gyarmath, and the marshes of the river Theiss ; and, being deemed a delicacy for the table, is caught and kept in preserves. The preserve of Kesztheley encloses about an acre of land, intersected by trenches and ponds, in which the animals feed and enjoy themselves. In one corner was a space separated from the rest by boards two feet high, forming a pen for snails. The upper edge of the boards was spiked with nails an inch in height, and at intervals of half an inch, over which these animals never attempt to make their way. This snail (*Hélix pomatia*) (fig. 71. a) is in

71

great demand in Vienna, where sacks of them are regularly exposed to sale in the market, alternating with sacks of beans, lentils, kidneybeans, and truffles. (*fig. 71. b.*)

638. *The implements and operations* of the agriculture of Austria differ little from those of Saxony. Dr. Bright has given figures of the Hungarian plough and cart (*fig. 68.*), and blames the mode of depositing the corn in holes in the ground, lined with straw, by which it acquires a strong mouldy smell. Vineyards are carefully dug and hoed, and the shoots of the vines, in places where the winter is severe, laid down and covered with earth to protect them from the frost. Many of the great proprietors are introducing the most improved British implements on their estates, and some have taken ploughmen from this country to instruct the natives in their use. Prince Esterhazy has English gardeners, bailiffs, grooms, and other servants.

639. *The forests of the Austrian dominions* are chiefly in Hungary, and on the borders of Galicia, on the Carpathian mountains. They contain all the varieties of needle or pine-leaved, and broad-leaved trees, which are indigenous north of the Rhine. The oaks of Hungary are perhaps the finest in Europe. The forest of Belevor on the Drave was visited by Dr. Bright. It consists chiefly of different species of oak, the most luxuriant he ever beheld. Thousands measured, at several feet above the root, more than seven feet in diameter; continue almost of the same size, without throwing out a branch, to the height of thirty, forty, and fifty feet, and are still in the most flourishing and healthy condition. Timber there is of little value, except for the buildings wanted on an estate, or for hoops and wine barrels. In some cases the bark is not even taken from oak trees; but in others the leaf galls, and the knopperrn, or smaller galls, which grow on the calyx of the acorn, are collected and exported for the use of tanners.

640. *The improvement of the agriculture* of Austria seems anxiously desired both by the government and the great proprietors. Various legislative measures are accordingly adopted from time to time, societies formed, and premiums offered. These will no doubt have a certain quantum of effect; but the radical wants, in our opinion, are information and taste for comfortable living among the lower classes; and these can only be remedied by the general diffusion of village schools; and by establishing easy rates, at which every peasant might purchase his personal liberty, or freedom from the whole or a certain part of the services he is now bound to render his lord.

SECT. VI. *Of the present State of Agriculture in the Kingdom of Poland.*

641. *Poland was formerly called the granary of Europe*: but this was when its boundaries extended from the Baltic to the Black Sea; and when the Ukraine and Lithuania were included. At present its limits are so circumscribed, and its arable surface so indifferently cultivated, or naturally so infertile, that the kingdom of Poland strictly speaking, or what is called Vice-regal Poland, furnishes little more corn than supplies its own population. The immense supplies of wheat sent to Dantzic are chiefly from the republic of Cracow, the province both of the kingdom and republic of Galicia, united to Austria, and from Volhynia and Podolia, now belonging to Russia.

642. *The landed estates* are almost every where large, and either belong to the crown, to the nobles, or to religious corporations. One third of the surface of Vice-regal Poland belongs to the crown. Estates are farmed by the proprietors, by means of stewards; or let out in small portions on the metayer or *leiheigener* tenure. There are scarcely any rent-paying farmers. The nobles have generally houses on their estates, which they occupy, at least, part of the year; at other periods they are taken care of by the stewards, who are always admitted at the table of their lords, being themselves what is called of noble descent. The estates of religious houses are of great extent: they are sometimes let to nobles or others on a corn rent, who generally sublet them; and in a few cases they are farmed by the corporation. The postmasters on the different main roads invariably rent a considerable portion of land for the support of their horses. Many of these are metayers, but some pay a money rent; and there are one or two instances of nobles farming the post.

643. *The houses and offices of these noble postmasters* (*fig. 72.*) afford the only distant resemblance to a British farm-yard, that is to be met with in Poland. The farm-house and farmery of the peasant post-

master are both included in an immense shed or barn, with a small apartment at one end for the master's dwelling; the remaining space divided for live stock and implements of every description, and for the cattle, carriages, and lodging-place of travellers who may stop during night. Most of these places are sufficiently wretched as inns; but in the present state of things they answer very well for the other purposes to which they are applied, and are superior to the hovels of the farmers who are not postmasters, and who are clustered together in villages, or in the outskirts of towns. Some villages, however, in the south of Poland are almost entirely composed of Jews. There the houses are generally of a superior construction (*fig. 73.*), but still on the same general plan of a living-room at one end of a large barn, the

main area of which serves for all the purposes of a complete farmery. The buildings in Poland, except those of the principal towns, are constructed of timber and covered with shingles. The sheds and other agricultural buildings are boarded on the sides; but the cottages are formed of logs joined by moss or clay, or of frames filled up with wickerwork and clay, or in modes and of materials still more rude. The commonest kind have no chimneys or glass windows.

644. *The climate of Poland*, though severe, is much less precarious than that of the south of Germany or of France. A winter of from five to seven months, during the greater part of which time the soil is covered with snow, is succeeded by a rapid spring and warm summer; and these are followed by a short cold wet autumn. Under such a climate good meadows and pastures cannot be expected; but arable culture is singularly easy on free soils, which the frost has rendered at once clear from most sorts of weeds and soft and mouldy on the surface.

645. *The surface of the vice-regal kingdom of Poland* is almost every where level, with scarcely an ascent or descent, except where the courses of the rivers have formed channels below the general level of the country. As these rivers, though in summer they appear small streams, are swollen by the rains of autumn, and the melting of the snow on the Carpathian mountains in the spring, they form large channels, extending over both sides to a great distance; and their deposit, in many parts, enriches the land, which presents, in the summer, the aspect of verdant and luxuriant meadows. In other parts the periodical swellings of the streams have formed morasses, which, in their present state, are not applicable to any agricultural purposes. The plains, which extend from the borders of one river to another, are open fields with scarcely any perceptible division of the land, and showing scarcely any trees even around the villages. The portion of woodland on these plains is very extensive; but they are in large masses, with great intervals of arable land between them. (*Jacob's Report on the Trade in Corn, and on the Agriculture of Northern Europe, 1826, p. 25.*)

646. *The soil of Vice-regal Poland* is mostly sandy, with an occasional mixture of a sandy loam; it is very thin, resting chiefly on a bed of granite, through which the heavy rains gradually percolate. Such a soil is easily ploughed; sometimes two horses or two oxen, and not unfrequently two cows, perform this and the other operations of husbandry. (*Ibid.*)

647. *The southern part of the ancient kingdom of Poland*, now forming the republic of Cracow, presents a comparatively varied surface, and a more tenacious and fruitful soil, which produces excellent wheat, oats, and clover. The best wheat of the Dantzig market comes from this district.

648. *The province of Galicia*, a part of the ancient kingdom of Poland, but now added to the dominions of the Austrian empire, in surface, soil, and products, resembles the republic of Cracow.

649. *The landed estates of Vice-regal Poland* and the republic, belonging to the nobility of the highest rank, are of enormous extent: but, owing to the system of dividing the land among all the children, unless a special entail secures a majorat to the eldest son (which is, in some few instances, the case), much of it is possessed in allotments, which we should deem large; but which, on account of their low value, and when compared with those of a few others, are not so. Of these secondary classes of estates, 5 or 6,000 acres would be deemed small, and 30 or 40,000 acres large. There are, besides these, numerous small properties, some of a few acres, which, by frequent subdivisions, have descended to younger branches of noble families. The present owners are commonly poor, but too proud to follow any profession but that of a soldier, and prefer to labour in the fields with their own hands, rather than to engage in trade of any kind. As titles descended to every son, and are continued through all the successors, the nobility have naturally

become very numerous; but since the Emperor of Russia has gained the dominion over Poland, the use of titles has been restricted. The whole of the lands being made alienable may now be purchased by persons of any rank, and are actually held by some who are burghers or peasants; the Jews alone are prohibited from becoming proprietors of the soil, though they have very numerous mortgages upon it. When they foreclose, the lands must consequently be sold; and as these Jews, the monied capitalists, cannot become purchasers, the prices they yield are very trifling. (*Ibid.*)

650. *The cultivators are chiefly peasants.* They have a limited property in the lands which they occupy, and the cottages in which they live, under the condition of working a stipulated number of days in each week, on their lord's demesne, and paying specified quantities of produce, such as poultry, eggs, yarn, and other things, in conformity with ancient usage. The extent of these holdings varies, according to the quality of the land, and the quantity of duty-work, or of payments in kind, which are to be fulfilled. The peasantry of Poland were declared free in 1791, and this privilege was confirmed to them in 1815; and though their ignorance and poverty have hitherto prevented the practical effects of liberty from being very obvious among them, yet they are so far elevated in sentiment, at least, as to feel their superiority to the peasantry of Russia. (*Ibid.*)

651. *The arable culture of Poland* is abundantly simple: the course of crops is, in most places, 1st, wheat, barley, or rye; 2d, oats; 3d, fallow, or several years' rest to commence with fallow. In a very few places clover is sown, and also beans or peas, but only in small quantities. The *Digitaria sanguinalis* is sown as a plant of luxury in a few places, and the seeds used as rice; the buckwheat is also sown, and the seeds ground and used as meal. Almost every farmer sows linseed or hemp, to the extent required for home use, and some for sale. Rye is the bread corn of the country. Potatoes are now becoming general, and succeed well. The mangel, or white beet, was cultivated in many places in 1811 and 1812, by order of Bonaparte, in order that the natives might grow their own sugar; but that is now left off, and the peasants have not even learned its value as a garden plant, producing chard and spinach. Turnips or cabbages are rarely seen even in gardens; few of the cottagers, indeed, have any garden; those who have, cultivate chiefly potatoes, and kohl rübe. Many species of mushrooms grow wild in the woods and wastes, and most of these are carefully gathered, and cooked in a variety of ways as in Russia. The wastes or common pastures are left entirely to nature. There are some tracts of indifferent meadow on the Vistula, at Warsaw, Thorn, and Cracovie, and some on the tributary streams, which afford a tolerable hay in summer, and would be greatly improved by draining.

652. *The implements and operations* are incredibly rude. We have seen lands ploughed (after their manner) by one cow, tied by the horns to the trunk of a young fir tree, one of the roots sharpened and acting as a share, and the other serving the ploughman as a handle. In other instances we have seen a pair of oxen dragging a wretched implement (*fig. 74.*) formed by the peasant, who is in all cases his own plough and wheelwright, as well as house carpenter and builder. Their best or usual plough has no mould-board; and the crop is in many cases more indebted to the excellence of the soil, and the preceding winter's frost, than to the farmer. Horses are their general beasts of labour; their harness is very rude, often of straw ropes, and twisted willow shoots. The body of their best market carts, in which even the lesser nobles visit each other, are of wicker-work (*fig. 75.*), and the axle and wheels are made without any iron.

74

75

better shapes than might be expected from their treatment. The best-shaped are in the province of Lublin, but they are far inferior to the breed of Saxony. The cows are a small race, and generally kept in bad condition both as to food and cleanliness. Warsaw and Cracow are supplied with beef and veal, chiefly from the Ukraine. Mutton is little used.

654. *The extensive forests of Poland* are little attended to, except on the banks of the principal rivers, and where oak abounds, from which bark and wheel spokes may be

procured. These are cut over regularly at intervals, and standards left in the usual way. The wild or Scotch pine forests are the most extensive; these perpetuate themselves by semination; and the trees are often so crowded as to be of little use but as fuel. The chief proprietors of these forests are the crown and the religious corporations, who, whenever they can find purchasers, are glad to let them thin out the best trees at a certain rate, and float them, down the nearest stream, to the Vistula, Pregel, or Niemen. A good deal has been said about the importance of felling timber at particular seasons. In Poland, the operation generally takes place in summer, but not, as far as we could learn, from any regard to the effect on the timber. The trees are often notched half through a year or two before, in order to obtain rosin. The other products of forests, as fuel, charcoal, ashes, hoops, poles, &c., are obtained in the usual manner. Game is abundant in them; and bears, polecats, &c., are to be seen in some places. The woods belonging to the crown consist of upwards of two millions of acres, and are felled in portions annually, so as to cut them every fifty years.

655. *The management of bees is a material article in the forest culture of Poland. The honey is divided into three classes, namely lipiec, leszny, and stepowey prasznybird, thus described by How. (Gen. Rep. Scot. app.)*

656. *Lipiec is gathered by the bees from the lime tree alone, and is considered on the Continent most valuable, not only for the superiority of its flavour, but also for the estimation in which it is held as an arcanum in pulmonary complaints, containing very little wax, and being, consequently, less heating in its nature; it is as white as milk, and is only to be met with in the lime forests in the neighbourhood of the town of Kowno, in Lithuania. The great demand for this honey occasions it to bear a high price, inasmuch, that a small barrel, containing hardly one pound's weight, has been known to sell for two ducats on the spot. This species of the lime tree is peculiar to the province of Lithuania; and is quite different from all the rest of the genus Tilia, and is called *Kamienna lipsa*, or stone lime. The inhabitants have no regular bee-hives about Kowno; every peasant who is desirous of rearing bees, goes into the forest and district belonging to his master, without even his leave, makes a longitudinal hollow aperture or apertures in the trunk of a tree, or in the collateral branches, about three feet in length, one foot broad, and about a foot deep, where he deposits his bees, leaves them some food, but pays very little further attention to them, until late in the autumn; when, after cutting out some of their honey, and leaving some for their maintenance, he secures the aperture properly with clay and straw against the frost and inclemency of the approaching season: these tenements (if they may be so called), with their inhabitants and the produce of their labour, are then become his indisputable property; he may sell them, transfer them; in short, he may do whatever he pleases with them; and never is it heard that any depredation is committed on them (those of the bear excepted). In Poland, the laws are particularly severe against robbers or destroyers of this property, punishing the offender, when detected, by cutting out the navel and drawing out his intestines round and round the very tree which he has robbed.*

657. *When spring arrives, the proprietor goes along to the forest, examines the bees, and ascertains whether there is sufficient food left, till they are able to maintain themselves; should there not be a sufficient quantity, he deposits with them as much as he judges necessary till the spring blossom appears. If he observes that his stock has not decreased by mortality, he makes more of these apertures in the collateral branches, or in the trunk of the tree, that in case the bees should swarm in his absence, they may have a ready asylum. In the autumn he visits them again, carries the June and July work away with him, which is the lipiec, and leaves only that part for their food which was gathered by them before the commencement and after the decay of the flowering of the lime tree.*

658. *The leszny, the next class of honey, which is inferior in a great degree to the lipiec, being only for the common mead, is that of the pine forests; the inhabitants of which make apertures in the pine trees, similar to those near Kowno, and pay the same attention, in regard to the security of the bees, and their maintenance. The wax is also much inferior in quality; it requires more trouble in the bleaching, and is only made use of in the churches.*

659. *The third class of honey is the stepowey prasznybird, or the honey from meadows or places where there is an abundance of perennial plants, and hardly any wood. The province of Ukraine produces the very best, and also the very best wax. In that province the peasants pay particular attention to this branch of economy, as it is the only resource they have to enable them to defray the taxes levied by Russia; and they consider the produce of bees equal to ready money; wheat, and other species of corn, being so very fluctuating in price, some years it being of so little value that it is not worth the peasant's trouble to gather it in (this has happened in the Ukraine, four times in twelve years): but honey and wax having always a great demand all over Europe, and even Turkey, some of the peasants have from four to five hundred ular, or logs of wood in their bee-gardens, which are called *pasieka*, or bee-hives; these logs are about six feet high, commonly of birch wood (the bees prefer the birch to any other wood), hollowed out in the middle for about five feet; several lamina of thin boards are nailed before the aperture, and but a small hole left in the middle of one of them for the entrance of the bees. As the bees are often capricious at the beginning of their work, frequently commencing it at the front rather than the back, the peasants cover the aperture with a number of these thin boards, instead of one entire board, for fear of disturbing them, should they have begun their work at the front. It may appear extraordinary, but it is nevertheless true, that in some favourable seasons, this aperture of five feet in length, and a foot wide, is full before August; and the peasants are obliged to take the produce long before the usual time, with the view of giving room to the bees to continue their work, so favourable is the harvest some summers.*

660. *The process of brewing mead in Poland is very simple: the proportion is three parts of water to one of honey, and 50 lb. of mild hops to 163 gallons, which is called a *waar*, or a brewing. When the water is boiling, both the honey and hops are thrown into it, and it is kept stirring until it becomes milk-warm; it is then put into a large cask, and allowed to ferment for a few days; it is then drawn off into another cask, wherein there has been aqua-vitæ, or whisky, bunged quite close, and afterwards taken to the cellars, which in this country are excellent and cool. This mead becomes good in three years' time; and, by keeping, it improves, like many sorts of wine. The mead for immediate drink is made from malt, hops, and honey, in the same proportion, and undergoes a similar process. In Hungary, it is usual to put ginger in mead. There are other sorts of mead in Poland, as *wisniak*, *dereniak*, *maliński*; they are made of honey, wild cherries, berries of the *Cornus mascula*, and raspberries; they all undergo the same process, and are most excellent and wholesome after a few years' keeping. The lipiec is made in the same way, but it contains the honey and pure water only. The honey gathered by the bees from the *Azalea pontica*, at Oczakow, and in Potesia in Poland, is of an intoxicating nature; it produces nausea, and is used only for medical purposes, chiefly in rheumatism, scrophula, and eruption of the skin, in which complaints it has been attended with great success. In a disease among the hogs called *weugry* (a sort of plague among these animals) a decoction of the leaves and buds of *Azalea* is given with the greatest*

effect, and produces almost instantaneous relief. The disease attacks the hogs with a swelling of their throat, and terminates in large hard knots, not unlike the plague, on which the decoction acts as a digestive, abates the fever directly in the first stage, and suppurates the knots. It is used in Turkey, with the same view, in the cure of the plague.

661. *Such is the present state of agriculture in Poland*, as it appeared to us during a residence of four months in Warsaw and its neighbourhood in 1813, and the details in Mr. Jacob's *Report of 1826* (p. 25. to 37.) afford us but little reason for altering our opinion. But it must always be recollected, that the above view does not include either Lithuania or Galicia, the agriculture of which districts is of a much superior description. Since the middle of the 18th century some of the principal Polish nobles have occasionally made efforts for the improvement of the agriculture of their country; but they have not been designed and directed in the best manner, and what is much worse, not steadily pursued. Splendid wooden houses and villages have been built, and foreign farmers induced to settle and cultivate the lands. In the first heat of the business, all went on well; but the proprietors soon began to cool, to neglect their new tenants, and leave them to the mercy of their stewards, who, in Italy and Poland, are known to be the most corrupt set of men that can be met with. The oppression of these stewards, and the total disregard of their masters to their promises and agreements made to and with these strangers, have either forced the latter to return home, or reduced them to the necessity of becoming servants in the towns, or in Germany; and we know of instances where it has ruined men of some property. There are one or two exceptions; but we could produce names and dates in proof of the general truth of what we have asserted. The failure of a dairy establishment, and of a brewery, both established before the commencement of the French revolution, is attributable to this sort of conduct in the proprietors.

*662. *The efforts to introduce a better culture into Poland, since the peace of 1814*, have been more general, and conducted on more moderate and rational principles. British implements have been imported in considerable numbers, and an iron-foundery and manufactory of machinery of most kinds and agricultural implements is now established in Warsaw. Improved breeds of cattle and sheep have been procured from Prussia and Saxony; scientific managers are obtained from the German agricultural schools; and what will contribute essentially to improvement, encouragement is given to foreigners to settle, by letting or selling the crown lands at moderate rates, and not only free from all feudal services for ever, but for a certain period exempted from government taxes. Add to this, that the leibeigeners and metayers of every description may buy up the services which they now render their lords, at very easy rates established by law; and thus, according to their ambition and means, render themselves partially or wholly independent men. In short, the most judicious measures have been taken, by the new government of Poland, for the improvement of the country; and they have been followed up with considerable vigour by the proprietors. These proprietors are now a different and very superior class of men to what they were fifty or sixty years ago. They have mostly been officers in the French army, and with it traversed the greater part of Europe; better educated than many of the French, and more engaging in their manners than the Germans, they may be considered among the first gentlemen of the Continent. The Polish peasantry are naturally a much more lively and ingenious race than those of Russia, and since they have been rendered free, they have learned to feel their superiority, and they will gradually participate in the improvement of their masters.

SECT. VII. *Of the present State of Agriculture in Russia.*

663. *The rural economy of the Russian empire* was first described by Professor Pallas in his travels to explore that country, made by order of the Empress Catherine. It has also been incidentally noticed by various travellers, as Tooke, Coxe, Clarke, and several French and German authors. From these and other works, and a personal residence which occupied nearly a year in 1813 and 1814, we shall present a very concise statement of the agricultural circumstances of that semibarbarous country.

664. *The territory of Russia which may be subjected to aration* commences at the 43° and ends at the 65° of north latitude. Farther north, the summers are too short for ripening even barley, and the climate too severe for the growth of pasture or trees. It is a black waste, productive of little more than lichens, and supporting a few reindeer. The southern extremity of Asiatic Russia, on the other hand, admits the culture of Italy, and even the southern parts in Europe, that of the maize district of France.

665. *The climate of Russia* has been divided into four regions, the very cold, cold, temperate, and hot. The very cold extends from 60° to 78° of N. latitude, and includes Archangel. In many of its districts there is scarcely any summer; the spring has in general much frost, snow, and rain; and the winter is always severe. In this region there is no agriculture.

666. *The cold climate* extends from 55° to 60° N. latitude and includes Cazan Mos-

cow, Petersburg, and Riga; the summer is short, yet in many districts so warm and the days so long, that agricultural crops usually come to perfect maturity in a much shorter space of time than elsewhere. The winters are long and severe, even in the southern parts of the region. The ground round Moscow is generally covered with snow for six months in the year, and we have seen it covered to the depth of several inches in the first week of June.

667. *The moderate region* extends from 50° to 55° and includes Kioff, Saratoff, Wilna, and Smolensko. The Siberian part of this region being very mountainous, the winters are long and cold; but in the European part the winter is short and tolerably temperate, and the summer warm and agreeable. The snow, however, generally lies from one to three months, even at Kioff and Saratoff.

668. *The hot region* reaches from 43° to 50° , and includes the Taurida, Odessa, Astracan, and the greater part of Caucasus and the district of Kioff. Here the winter is short and the summer warm, hot, and very dry. The atmosphere in all the different climates is in general salubrious, both during the intense colds of the north, and the excessive heats of the southerly regions. The most remarkable circumstance is the shortness of the seasons of spring and autumn, even in the southern regions; while in the very cold and cold regions they can be hardly said to exist. About Moscow the termination of winter and the commencement of summer generally take place about the end of April. There the rivers, covered a yard in thickness with ice, break up at once and overflow their banks to a great extent; in a fortnight the snow has disappeared, the rotten-like blocks of ice dissolved, and the rivers are confined to their limits. A crackling from the bursting of buds is heard in the birch forests; in two days afterwards, they are in leaf; corn which was sown as soon as the lands were sufficiently dry to plough is now sprung up, and wheat and rye luxuriant. Reaping commences in the government of Moscow in September, and is finished by the middle of October. Heavy rains and sleet then come on, and by the beginning of November the ground is covered with snow, which accumulates generally to two or three feet in thickness before the middle of January, and remains with little addition till it dissolves in the following April and May. The climate of Russia, therefore, though severe, is not so uncertain as that of some other countries. From the middle of November till April it scarcely ever snows or rains; and if the cold is severe, it is dry, enlivening, and at least foreseen and provided for. Its greatest evils are violent summer rains, boisterous winds, and continued autumnal fogs. Late frosts are more injurious than long droughts; though there are instances of such hot and dry summers, that fields of standing corn and forests take fire and fill whole provinces with smoke. (*Tooke's View of the Russian Empire.*)

669. *The surface of Russia* is almost every where flat, like that of Poland, with the exception of certain ridges of mountains which separate Siberia from the other provinces, and which also occur in Siberian Russia. In travelling from Riga, Petersburg, Wilna, or Brody, to Odessa, the traveller scarcely meets with an inequality sufficiently great to be termed a hill; but he will meet with a greater proportion of forests, steppes or immense plains of pasture, sandy wastes, marshy surfaces, and gulleys or temporary water-courses, than in any other country of Europe.

670. *The soil of Russia* is almost every where a soft black mould of great depth, and generally on a sandy bottom. In some places it inclines to sand or gravel; in many it is peaty or boggy from not being drained: but only in Livonia and some parts of Lithuania was it inclined to clay, and no where to chalk. The most fertile provinces are those of Vladimir and Riazane, east of Moscow, and the whole country of the Ukraine on the Black Sea, and of the Cossacks on the Don. In Vladimir thirty-fold is often produced, and still more in Riazane. In many parts of the Ukraine no manure is used; the straw is burned; successive crops of wheat are taken from the same soil, and after a single ploughing each time, the stalks of which are so tall and thick that they resemble reeds, and the leaves are like those of Indian corn.

671. *Landed property in Russia* is almost every where in large tracts, and is either the property of the emperor, the religious or civil corporations, or the nobles. There are a few free natives who have purchased their liberty, and some foreigners, especially Germans, who have landed estates; but these are comparatively of no account. In the Ukraine, within the last thirty years, have been introduced on the government estates a number of foreigners from most countries of Europe, who may be considered as proprietors. These occupy the lands on leases of a hundred years or upwards, at little or no rent, on condition of peopling and cultivating them and residing there. In the country parts of Russia, there is no middle class between the nobles, including the priests, and the slaves. Estates are, therefore, either cultivated directly by the proprietors, acting as their own stewards; or indirectly, by letting them to agents or factors, as in Poland and Ireland, or by dividing them in small portions among the peasantry. In general, the proprietor is his own agent and farmer for a great part of his estate; and the rest he lets

to his slaves at certain rates of labour, corn, personal services, and sometimes a little money. These slaves, it is to be observed, are as much his property as the soil; and in seasons of scarcity, or in the event of any disaster, the lord is bound to provide for them, and indeed deeply interested in doing so, in order at least to maintain the population; and, if possible, to obtain a surplus for sale or for letting out to the towns. As in Poland, the lands are every where unenclosed.

*672. *The farmeries* attached to the houses of noblemen, and the cottages of the peasants, resemble those of Poland. They are almost every where constructed of timber; the stove and its chimney being the only part built of brick or of mud and stones. The noblemen generally reside on their estates, and their houses are surrounded by the village which contains their peasants. These villages (*fig. 76.*) are in general dull and miserable

76

assemblages of log-houses all of one size and shape, with a small wooden church. The mansions of the poorer nobles are merely cottages on a larger scale, with two apartments; one used for the purposes of the kitchen and other domestic offices, and the other for all the purposes of the family living-rooms: the more wealthy have wooden or brick houses stuccoed, or mudded, and whitewashed. One nobleman in the neighbourhood of Moscow has a British steward, who has drained, enclosed, and greatly improved his estate, and has built some farmeries (*fig. 77.*) which might be mistaken for those of another country.

77

673. *The agricultural products* of Russia may be known from its climates. The vegetables of the most northerly region are limited to lichens, some coarse grass, and some birch, abele, and wild pine forests. The animals there are the reindeer, bear, fox, and other beasts of the chase, or in esteem for their furs or skins. Some cows and sheep are also pastured in the northern parts of that region during the summer months.

674. *The farming crops* of the more southern regions are the same as in similar climates and countries. Winter and summer rye and oats are cultivated in every part of the empire south of latitude 60° ; winter wheat only in Russia as far as the Kama; summer wheat both in Russia and Siberia; barley and spelt plentifully in Russia. Peas, vetches, and beans are not cultivated in great quantities: but buckwheat is extensively grown, and there is a large variety, called the Tartarian millet; *Panicum germanicum* and maize are grown in Taurida. Rice is cultivated in some parts of Taurida, and what is called manna (*Festuca fluviatans*) grows wild in most places that are occasionally overflowed with water, particularly in the governments of Novogorod, Twer, Polotsk, and Smolensk. But the grain the most universally cultivated in Russia is rye, which is the bread corn of the country; next oats, which furnish the spirit in common use: and then wheat and barley.

675. *The culture of herbage plants*, of grasses, clover, turnips, &c., is rare in Russia. Hay is made from the banks of rivers or lakes; and pasture obtained from the steppes, forests, grass lands in common, or arable lands at rest.

676. *For clothing and other economical purposes the plants in cultivation are flax, which is cultivated to a great extent on the Volga; and hemp, which is indigenous, and is cultivated both for its fibre and its seed. From the latter an oil is expressed much used as food during the time of the fasts. Woad is abundantly grown, madder and cotton have been tried in Astracan and Taurida. Hops grow wild in abundance in some parts of Siberia, and are cultivated in some European districts. Tobacco is planted in great abundance, and the produce in the Ukraine is of excellent quality. The potato is not yet in general cultivation, but has been introduced in different districts. Water melons, cabbages, turnips, and a variety of garden vegetables, are cultivated in the Ukraine and Taurida. Asparagus is extensively cultivated in the government of Moscow for the Petersburg market, and also turnips, onions, and carrots. Mushrooms are found in great plenty in the steppes and forests. About thirty species are eaten by the peasants, exclusive of our garden mushroom, which is neglected. Their names and habitats are given by Dr. Lyall. (History of Moscow, 1824.) The common and Siberian nettle are found wild on the Ural mountains, and their fibres are prepared and woven into linen by the Baschkirs and Tatars. The rearing of silkworms has been tried in the Ukraine, and found to answer, as has the culture of the caper and various other plants.*

677. *Hemp and flax are extensively cultivated, and form the principal article of exportation. There is nothing very peculiar in their culture; the soil of the Ukraine is in general too rich for hemp, until reduced by a series of corn crops. Wheat, rye, barley, and oats are succeeded by one or two crops of hemp, and that by a crop of flax; the whole without any manure. The time of sowing is from the 25th of May to the 10th of June, and that of reaping from the end of August to the end of September. In general the flax is three, and the hemp about four, months in a state of vegetation. The pulling, watering, drying, and other processes, are the same as in Britain.*

678. *Of fruits grown on a large scale, or plentiful in a wild state in Russia, may be mentioned the raspberry, currant, strawberry, and bilberry. The hazel is so plentiful in Kazan, that an oil used as food is made from the nuts. Sugar, musk, and water melons thrive in the open air, as far north as lat. 52°. Pears are wild almost every where, and cherries found in most forests. On the Oka and Volga are extensive orchards, principally of these fruits and apples. The apricot, almond, and peach succeed as standards in Taurida and Caucasus, and other southern districts. The quince is wild in forests on the Terek. Chestnuts are found singly in Taurida and districts adjacent. The walnut abounds in most southern districts. Figs and orange trees grow singly in Kitzliar and in Taurida, planted no doubt by the Tatars before they were driven out of that country. Lemons, oranges, and olives, according to Pallas, would bear the winter in Taurida, and have been tried by Stevens, the director of a government nursery at Nikitka, in that country. The vine is cultivated in the governments of Caucasus, Taurida, Ekatorinoslaf, and other places; and it is calculated that nearly one fourth part of the empire is fit for the culture of this fruit for wine. An account of the products of the Crimea is given by Mary Holderness (Notes, 1821), from which it appears that all the fruits of France may be grown in the open air there, and that many of our culinary vegetables are found in a wild state. The Tatar inhabitants, who were driven out by the ambitious wars of Catherine, had formed gardens and orchards round their villages, which still exist, and present a singular combination of beauty, luxuriance, and ruin. The gardens of the village of Karagoss form a wilderness of upwards of three hundred and sixty English acres, full of scenes of the greatest beauty, and through which, she says, it requires a little experience to be able to find one's way. (Notes, 125—136.)*

679. *The live stock of the Russian farmer consists of the reindeer, horse, ox, ass, mule, and camel, as beasts of labour; the ox, sheep, and swine, and in some places the goat and rabbit, as beasts of clothing and nourishment. Poultry are common, and housed with the family to promote early laying, in order to have eggs by Easter, a great object with a view to certain ceremonies in the Russian religion. Bees are much attended to in the Ural, in some parts of Lithuania, and in the southern provinces. The Russian working horses are remarkably strong and hardy, rather small, with large heads, long flabby ears, not handsome, but not without spirit: the best saddle horses are those of the Cossacks and Tatars in the Crimea. The horned cattle of the native breeds are small and brisk; the cows give but little milk, which is poor and thin: a Dutch breed was introduced by Peter the Great, near Archangel, and do not degenerate. Oxen are much less used than horses, as beasts of labour. The original Russian sheep is distinguished by a short tail about seven inches in length: the Merinos, and other breeds from Germany, have been introduced in a few places, and promise success. The great graziers and breeders of horses, cattle, and sheep, in Russia, are the Cossacks of the Don, the Kalmucks, and other nomadic tribes. These supply the greater part of the towns both of Russia and Poland with butcher's meat; and with the hides and tallow that form so material an article of export. In the northern districts of Russia and Siberia, the chase is pursued as an occupation for a livelihood or gain. The chief object is to*

entrap by dogs and snares those animals whose skins are used as furs, and especially the sable. Next to the latter animal, the grey squirrel is the most valuable; but foxes, martins, fish, otters, bears, wolves, lynxes, gluttons, ferrets, polecats, and a variety of others, are taken for their skins by the hunters, who pay a rent or tribute to government in sable skins, or in other furs regulated by the value of those.

680. *The forests of Russia* are least abundant in the southern districts; but the cold region may, like Poland, be described as one entire forest with extensive glades. Forests of pine-leaved trees (or needle-leaved trees, as the German expression is) are chiefly indigenous in the very cold and cold regions. These include the spruce fir, the wild, and black pine, and the Siberian cedar or stone pine (*Pinus Cembra*). The larch grows on most of the Siberian mountains. Among the leafy trees, the birch is the most common, next the trembling poplar, willow, lime, and ash. The oak is not indigenous in Siberia; the beech, elm, maple, and poplar, are found chiefly in the southern districts. Timber for construction, fuel, charcoal, bark, potashes, barilla, rosin, tar, pitch, &c., are obtained from these forests, which can hardly be said to have any sort of culture applied to them.

681. *Tar* is extracted from the roots of the wild pine. These are cut into short pieces, then split, and put into an iron boiler which is closely covered. Fire being applied below, the tar oozes out of the roots, and collecting in the bottom of the boiler, runs off by a pipe into a cask, which when closed is fit for exportation. When pitch is wanted, the tar is returned to the boiler, and boiled a second time.

682. *Ashes* for the purposes of lixiviation are obtained by burning every sort of timber indiscriminately. After being lixiviated they are barrelled up and sold for exportation.

683. *The implements and operations of Russian husbandry* are the most simple and artless that can well be imagined. Pallas has given figures of ploughs and other articles; the former mere crooked sticks pointed, and drawn by horses attached by ropes of bark or straw. Speaking of the operations, he says, "the cultivator sows his oats, his rye, or his millet, in wastes which have never been dunged; he throws down the seed as if he meant it for the birds to pick up; he then takes a plough and scratches the earth, and a second horse following with a harrow terminates the work; the bounty of nature supplies the want of skill, and an abundant crop is produced." This applies to the greater part of ancient Russia and Siberia; but in Livonia and other Baltic provinces, and also in some parts of the Polish provinces of the Ukraine, the culture is performed in a superior manner, with implements equal to the best of those used in Germany. The most improved form of their carts (*fig 78.*), in use round Petersburg, is evidently copied from those of the Dutch, and was, probably, introduced by Peter the Great. In the Ukraine they thresh out their own corn by dragging boards studded with flints over it, and preserve it in pits in dry soil. In the northern provinces it is often dried on roofed frames of different sorts (*fig 79.*), as in Sweden; and about Riga and Mittau it is even kiln-dried in the sheaf before it can be stacked or threshed. The manner of performing the operation of kiln-drying in the sheaf, as it may sometimes be applicable in North Britain or Ireland in very late and wet seasons, we shall afterwards describe. (Part III. Book VI. Ch. II.)

78

79

684. *In no part of Europe are the field operations performed with such facility as in Russia*, not only from the light nature of the soil, but from the severity and long continuance of the winters, which both pulverises the surface and destroys weeds. The same reasons prevent grass lands, or lands neglected or left to rest, from ever acquiring a close sward or tough rooty surface, so that even these are broken up with a very rude plough and very little labour. In short, there is no country in Europe where corn crops may be raised at so little expense of labour as in Russia; and as no more than one corn crop can be got in the year in almost any country, so Russia may be said to be, and actually is, even with her imperfect cultivation, better able to raise immense quantities of corn than any part of the world, except, perhaps, similar parts of North America.

685. *The improvement of Russian agriculture* was commenced by Peter the Great, and continued by Catherine, and the late and present emperor. The peasants, on many of the government estates, were made free; some of these estates were let or sold to freemen, and foreign agriculturists encouraged to settle on them. Rewards and premiums were given, and professorships of rural economy established in different parts of the empire. Some of the principal nobles have also made great efforts for the improvement of agriculture. Count Romansow, about the end of the last century, procured a British farmer (Rogers), and established him on his estate near Moscow, where he has intro-

duced the improved Scotch husbandry, drained extensively, established a dairy, and introduced the potato there and on other estates belonging to his master. Others have made similar efforts, and several British farm bailiffs are now settled in Russia. The foreigners, merchants in Petersburg, or Riga, or in the employ of government, have also contributed to the improvement of agriculture. Many of these, intending to establish their families in Russia, purchase estates, and some receive presents in land from the emperor. On these they in general introduce the culture of their native country, which, if only in the superiority of the live stock and implements, is certain of being better than that of the natives. In short, from these circumstances, and from the comparatively rational views of the present government, there can be no doubt of the rapid increase of agriculture and population in Russia.

SECT. VIII. *Of the present State of Agriculture in Sweden and Norway.*

686. *Sweden and Norway are not agricultural countries*; but still great attention has been paid to perfect such culture as they admit of, both by the government and individuals. From the time of Charles XI., in the end of the seventeenth century, various laws for the encouragement of agriculture have been passed, professorships founded, rewards distributed, and the state of the kingdom, in respect to its agricultural resources, examined by Linnæus and other eminent men. Norway, till lately under the dominion of Denmark, is chiefly a pastoral country; but its live stock and arable culture have been much improved during the end of the last, and beginning of the present, century, by the exertions of the Patriotic Society established in that country, which gives premiums for the best improvements and instructions in every part of farming. Our notices of the rural economy of these countries are drawn from Clarke, Thomson, James, and our own memoranda, made there in 1813.

687. *The climate of Sweden and Norway* is similar to that of the cold and very cold regions of Russia, but rather milder in its southern districts, on account of the numerous inlets of the sea. The lands on the sea-coast of Norway are not, on this account, so cold as their latitude would lead us to expect; still the winters are long, cold, and dreary; and the summers short and hot, owing to the length of the day and the reflection of the mountains. So great is the difference of temperature, that at Sideborg, in the latitude of Upsal, in June or July, it is frequently eighty or eighty-eight degrees, and in January at forty or fifty below the freezing point. The transition from sterility to luxuriant vegetation is in this, as it is in similar climates, sudden and rapid. In the climate of Upsal, the snow disappears in the open fields from the 6th to the 10th of May; barley is sown from the 13th to the 15th of that month, and reaped about the middle of August. In some parts of Norway corn is sown and cut within the short period of six or seven weeks. According to a statement published in the *Amœn. Acad.* vol. iv., a Lapland summer, including also what in other countries are called spring and autumn, consists of fifty-six days, as follows:—

June 23. snow melts.
 July 1. snow gone.
 9. fields quite green.
 17. plants at full growth.
 25. plants in full blow.

Aug. 2. fruits ripe.
 10. plants shed their seeds.
 18. snow.
 From this time to June 23. the ground is every where covered with snow, and the waters with ice.

In such a climate no department of agriculture can be expected to flourish. The culture of corn is only prevalent in two districts, east Gothland, and the eastern shores of the Gulf of Bothnia, now belonging to Russia.

*688. *The surface of Sweden* every body knows to be exceedingly rocky and hilly, and to abound in fir and pine forests, and in narrow green valleys, often containing lakes or streams. "Sweden," Dr. Clarke observes, "is a hilly, but not a mountainous country, excepting in its boundary from the Norwegian provinces. It has been remarked, that in all countries, the abutment of the broken strata, which constitute the earth's surface every where, causes a gradual elevation to take place towards the north-west; hence, in all countries, the more level districts will be found upon the eastern, and the mountainous or metalliferous region upon the western side; either placed as a natural boundary against the territory occurring next in succession; or terminating in rocks of primary formation opposed as cliffs towards the sea." (*Clarke's Scandinavia.*) This is precisely the case with Sweden: the south-eastern provinces are level and cultivated; a ridge of mountains on the west separates it from Norway; and the intermediate space, from Gothenberg to Tornea, may be considered as one continued forest, varied by bills, rocks, lakes, streams, glades of pasture, and spots of corn culture. Norway may be considered as a continuation of the central country of Sweden, terminated by cliffs opposed to the ocean. "The tops and sloping sides of the mountains," Dr. Clarke observes, "are covered with verdure; farms are stationed on a series of tabular eminences, and grazing around them the herds of cattle all the way from the top to the bottom,

and sometimes in places so steep, that we

80

(fig. 81.), resounding from the woods. The lure is a long trumpet made of splinters of wood, bound together by withy."

689. *Of Finland*, which we have included with Sweden and Norway, a considerable part is under corn culture; the forests cleared, the lands enclosed, and population increased. The whole country appears decked with farm-houses, and village churches, rising to the view or falling from it, over an undulating district, amidst woods and water, and rocks, and large loose masses of granite: it may be called Norway in miniature. Farther up the country, towards the north, there are scenes which were described to Dr. Clarke as unrivalled in the world. Every charm which the effect of cultivation can give to the aspect of a region where Nature's wildest features — headlong cataracts, lakes, majestic rivers, and forests — are combined, may there be seen. (*Scandinavia*, sect. ii. p. 459.)

690. *The soil of the valleys is*, in general, good friable loam, but so mixed with stones as to render it very troublesome to plough or harrow; and in many places so much so, that where the valleys are cultivated it is chiefly with the spade. The only exception to these remarks is a considerable tract of comparatively even surface in South and East Gothland, where the soil inclines to clay and is well cultivated, and is as prolific in corn crops as any in Europe.

82

ways built of timber and thatched, on account of the warmth of these materials, though stone is abundant in most places. There are a few small enclosures near the farm-yard; but to enclose generally could be of no use in a country where the snow, during six or eight months in the year, renders them nugatory either as shelters or fences. The fence in universal use is made of splinters of deal, set up in a sloping position, and fastened by withies to upright poles. (fig. 82.) This is the only fence used in Sweden, Norway, Lapland, and Finland; and it is very common in Poland, Russia, and the northern parts of Germany.

692. *The Swedish cottages* are built of logs, like those of Poland (fig. 83.), but they are roofed in a different manner. Above the usual covering of boards is laid birch bark in the manner of tiles, and on that a layer of turf, so thick that the grass grows as vigorously as on a natural meadow. The walls are often painted red. They are very small, and generally very close and dirty

wonder how they could find a footing. In some places the elevation of these farms is so extraordinary, that the houses and flocks appear above the clouds, and bordering on perpetual snow, and the actual site of them is hardly to be credited. Every hanging-meadow is pastured by cows and goats; the latter often browsing upon jutties, so fearfully placed, that their destruction seems to be inevitable; below is seen the village church with its spire, the whole built of plank (fig. 80.); the cheerful bleatings of the sheep, mingled at intervals with the deep tones of the cow-herds' lures

81

691. *The landed property of Sweden* is generally in estates of a moderate size; in many cases their extent in acres is unknown, their value being estimated by the number of stock grazed in summer. The proprietors almost constantly farm their own estates, or let them out at fixed rents, in money or grain, to cottagers or farmers. The largest arable farms not occupied by the proprietors are in Gothland; but few of these exceed two hundred acres. The farm-buildings and cottages are there almost all

83

within, at least in winter. There are various exceptions, however as to cleanliness, especially among the post-masters, who are all farmers. The post-house at Yfre, north of Stockholm, was found by Dr. Clarke and his party so "neat and comfortable, and every thing belonging to it in such order," that they resolved to dine there. "The women were spinning wool, weaving, heating the oven, and teaching children to read, all at the same time. The dairy was so clean and cool, that we preferred having our dinner there rather than in the parlour. For our fare they readily set before us a service consisting of bacon, eggs, cream, curd, and milk, sugar, bread, butter, &c.; and our bill of fare for the whole amounted only to twenty pence; receiving which they were very thankful. Cleanliness in this farmer's family was quite as conspicuous as in any part of Switzerland. The tables, chairs, and the tubs in which they kept their provisions, were as white as washing could make them; and the most extraordinary industry had been exerted in clearing the land, and in rendering it productive. They were at this time employed in removing rocks, and in burning them for levigation, to lay the earth again upon the soil." (*Scandinavia*, sect. i. p. 179.)

693. The cottages in Norway are formed as in Sweden, covered with birch, bark, and turf. On some of the roofs, after the hay was taken, Dr. Clarke found lambs pasturing; and on one house he found an excellent crop of turnips. The galleries about their houses remind the traveller of Switzerland.

694. The cottages of the Laplanders are round huts of the rudest description. (fig. 84)

695. The agricultural produce of Sweden are the common corns. Wheat and rye are chiefly grown in South and East Gothland; oats are the bread corn of the country; and big, or Scotch barley, is the chief corn of Lapland and the north of Norway. The bean and pea are grown in Gothland, and potatoes, flax, and enough of tobacco for home consumption, by every farmer and cottager. Only a few districts grow sufficient corn for their own consumption, and annual importations are regular.

696. The *Cenomyce rangiferina*, or reindeer moss (fig. 85.), is not only used by the reindeer, but also as fodder for cows and other horned cattle. It adds a superior richness to the milk and butter. It is sometimes eaten by the inhabitants; and Dr. Clarke, having tasted it, found it crisp and agreeable.

697. *Roccella tinctoria* (fig. 86.), which abounds near Gottenburg and in other parts of Sweden, was in considerable demand in the early part of last war as a scarlet dye.

698. The *Lycopodium complanatum* (fig. 86.) is employed in dyeing their woollen. Even the leaves, as they fall from the trees, are carefully raked together and preserved, to increase the stock of fodder. (*Scandinavia*, chap. xviii.)

699. Tar, in Sweden, is chiefly extracted from the roots of the spruce fir, and the more marshy the forest the more the roots are said to yield. Roots or billets of any kind are packed close in a kiln, made like our limekilns, in the face of a bank. They are covered with turf and earth, as in burning charcoal. At the bottom of the kiln is an iron pan, into which the tar runs during the smothered combustion of the wood. A spout from the iron pan conveys the tar at once into the barrels in which it arrives in this country.

700. *The native trees and plants* afford important products for the farmer. "The industry of the Norwegians," Dr. Clarke observes, "induces them to appropriate almost every thing to some useful purpose. Their *summum bonum* seems to consist in the produce of the fir (*i. e.* the wild pine, not the spruce fir). This tree affords materials for building their houses, churches, and bridges; for every article of their household furniture; for constructing sledges, carts, and boats; besides fuel for their hearths. With its leaves (here the spruce fir is alluded to) they strew their floors, and afterwards burn them and collect the ashes for manure. The birch affords, in its leaves and tender twigs, a grateful fodder for their cattle, and bark for covering their houses. The bark of the elm, in powder, is boiled up with other food, to fatten hogs; sometimes, but rarely, it is mixed in the composition of their bread. The flowers of the hæg-ber (*Cornus mascula*) flavour their distilled spirits. The moss, as a substitute for mortar, is used in calking the interstices between their under walls. The turf covers their roofs.

701. *The berries of the Cloud-berry* (*Rubus Chamædrus*) (fig. 88.) are used in Lapland and the north of Sweden and Norway like the strawberry, and are esteemed as wholesome as they are agreeable. Dr. Clarke was cured of a bilious fever chiefly from eating freely of this fruit. They are used as a sauce to meat, and put into soup even, in Stockholm.

702. *The live stock* of the Swedish farmer consists chiefly of cows. These are treated in the same manner as in Switzerland. About the middle of May they are turned into meadows; towards the middle of June driven to the heights, or to the forests, where they continue till autumn. They are usually attended by a woman, who inhabits a small hut, milks them twice a day, and makes butter and cheese on the spot. On their return, the cattle are again pastured in the meadows, until the snow sets in about the middle of October, when they are removed to the cow-houses, and fed during winter with four fifths of straw and one of hay. In some places, portions of salted fish are given with the straw. The horses are the chief animals of labour; they are a small, hardy, spirited race, fed with hay and oat-straw the greater part of the year, and not littered, which is thought to preserve them from diseases. Sheep are not numerous, requiring to be kept under cover so great a portion of the year. Pigs and poultry are common.

703. *The implements and operations* of Swedish agriculture are simple, and in many places of an improved description. The swing plough, with an iron mould-board, is general throughout Gothland, and is drawn by two horses. The plough of Osterbóthnia (fig. 89) is drawn by a single horse, and sometimes by a peasant, and

90

They have a very convenient cradle-scythe for mowing oats and barley, which we shall afterwards describe; a smaller scythe, not unlike that of Hainault, for cutting grass and clovers; and, among other planting instruments, a frame of dibblers (fig. 91.) for planting beans and peas at equal distances.

*704. *Farming operations* are, in general, as neatly performed as any where in Britain. The humidity of the climate has given

87

88

89

called to Dr. Clarke's mind "the old Samnite plough, as it is still used in the neighbourhood of Beneventum, in Italy; where a peasant, by means of a cord passed over his shoulder, draws the plough, which his companion guides. It only differs from the most ancient plough of Egypt, as we see it represented upon images of Osiris (fig. 90.), in having a double instead of a single coulter." (*Scandinavia*, ch. xiii.)

91

rise to various tedious but ingenious processes for making hay and drying corn. The latter often remains in the fields in shocks or in small ricks, after the ground is covered with snow, till the clear frosts set in, when it becomes dry, and may be taken home. Besides the common mode of placing the sheaves astride with the ears downwards on horizontal fir poles (*fig. 92.*), there are various others. In some places young fir trees, with the stumps of the branches left on, are fixed in the ground, and the sheaves hung on them, like flowers on a maypole, the topmost sheaf serving as a cap or finish to all the rest. Sometimes covered rails or racks are resorted to (*fig. 79.*): at other times skeleton roofs or racks are formed, and the sheaves distributed over them. (*fig. 93.*) Often in Norway the corn is obliged to be cut green, from the sudden arrival of winter. Dr. Clarke found it in this state in October; and near Christiania it was suspended on poles and racks to dry, above fields covered with ice and snow. Corn is threshed in the north of Sweden by passing over it a threshing-

carriage, which is sometimes made of cast-iron, and has twenty wheels, and sometimes more. The sheaves are spread on a floor of boards, and a week's labour of one carriage, horse, and man will not thresh more than a ton of corn, because the crop being always cut before it is fully ripened, its texture is exceedingly tough. The hay is sometimes dried in the same manner.

After all, they are in some seasons obliged to dry both, especially the corn, in sheds or barns heated by stoves, as in Russia. (683.) In mowing hay in Lapland the scythe, the blade of which is not larger than a sickle, is swung by the mower to the right and left, turning it in his hands with great dexterity.

705. *The forests of Sweden* are chiefly of the wild pine and spruce fir; the latter supplies the spars, and the former the masts and building timber so extensively exported. The roads in Norway, as in some parts of Russia, are formed of young trees laid across and covered with earth, or left bare. Turpentine is extracted from the pine: the outer bark of the beech is used for covering houses, and the inner for tanning. The birch is tapped for wine; and the spray of this tree, and of the elm, alder, and willow is dried with the leaves on in summer, and fagoted and stacked for winter fodder. The young wood and inner bark of the pine, fir, and elm, are powdered and mixed with meal for feeding swine.

706. *The chase* is pursued as a profitable occupation in the northern parts of Sweden, and for the same animals as in Russia.

707. If any one, says Dr. Clarke, wishes to see *what English farmers once were*, and how they fared, he should visit Norway. Immense families, all sitting down together at one table, from the highest to the lowest. If but a bit of butter be called for in one of these houses, a mass is brought forth weighing six or eight pounds; and so highly ornamented, being turned out of moulds, with the shape of cathedrals, set off with Gothic spires and various other devices, that, according to the language of our English farmers' wives, we should deem it "almost a pity to cut." (*Scandinavia*, ch. xvi.) They do not live in villages, as in most other countries, but every one on his farm, however small. They have in consequence little intercourse with strangers, except during winter, when they attend fairs at immense distances, for the purpose of disposing of produce, and purchasing articles of dress. "What would be thought in England," Dr. Clarke asks, "of a labouring peasant, or the occupier of a small farm, making a journey of nearly 700 miles to a fair, for the articles of their home consumption?" Yet he found Finns at the fair at Abo, who had come from Torneo, a distance of 679 miles, for this purpose.

708. *With respect to improvement* the agriculture of Sweden is, perhaps, susceptible of less than that of any of the countries we have hitherto examined; but what it wants will be duly and steadily applied, by the intelligence and industry of all ranks in that country. It must not be forgotten, however, that it is a country of forests and mines, and not of agriculture.

SECT. IX. *Of the present State of Agriculture in Spain and Portugal.*

709. *Spain, when a Roman province*, was undoubtedly as far advanced in agriculture as any part of the empire. It was overrun by the Vandals and Visigoths in the beginning of the fifth century, under whom it continued till conquered by the Moors in the beginning of the eighth century. The Moors continued the chief possessors of Spain

until the middle of the thirteenth century. They are said to have materially improved agriculture during this period; to have introduced various new plants from Africa, and also bucket-wheels for irrigation. Professor Thouin mentions an ancient work by Ebn-al-Awam of Seville, of which a translation into Spanish was made by Banquieri of Madrid, in 1802, which contains some curious particulars of the culture of the Moors in Spain. The Moors and Arabs were always celebrated for their knowledge of plants; and, according to Harte, one fourth of the names of the useful plants of Spain are of Arabian extraction.

710. *Agriculture formed the principal and most honourable occupation among the Moors, and more especially in Granada.* So great was their attention to manure, that it was preserved in pits, walled round with rammed earth to retain moisture: irrigation was employed in every practicable situation. The Moorish or Mohammedan religion forbade them to sell their superfluous corn to the surrounding nations; but in years of plenty it was deposited in the caverns of rocks and in other excavations, some of which, as Jacob informs us (*Travels*, let. xiii.), are still to be seen on the hills of Granada. These excavations were lined with straw, and are said (erroneously, we believe) to have preserved the corn for such a length of time, that, when a child was born, a cavern was filled with corn which was destined to be his portion when arrived at maturity. The Moors were particularly attentive to the culture of fruits, of which they introduced all the best kinds now found in Spain, besides the sugar and cotton. Though wine was forbidden, vines were cultivated to a great extent; for forbidden pleasures form a main source of enjoyment in every country. An Arabian author, who wrote on agriculture about the year 1140, and who quotes another author of his nation, who wrote in 1073, gives the following directions for the cultivation of the sugar-cane:—

711. *The canes* “should be planted in the month of March, in a plain, sheltered from the east wind, and near to water; they should be well manured with cow-dung, and watered every fourth day, till the shoots are one palm in height, when they should be dug round, manured with the dung of sheep, and watered every night and day till the month of October. In January, when the canes are ripe, they should be cut into short pieces and crushed in the mill. The juice should be boiled in iron caldrons, and left to cool till it becomes clarified; it should then be boiled again, till the fourth part only remains, when it should be put into vases of clay, of a conical form, and placed in the shade to thicken; afterwards the sugar must be drawn from the canes and left to cool. The canes, after the juice is expressed, are preserved for the horses, who eat them greedily, and become fat by feeding on them. (*Ebn-al-Awam*, by Banquieri. Madrid, 1801, fol.) From the above extract it is evident sugar has been cultivated in Spain upwards of 700 years, and probably two or three centuries before.

712. *About the end of the fifteenth century* the Moors were driven out of Spain, and the kingdom united under one monarchy. Under Charles V., in the first half of the sixteenth century, South America was discovered; and the prospect of making fortunes, by working the mines of that country, is said to have depressed the agriculture of Spain to a degree that it has never been able to surmount. (*Heylün's Cosmographia*. Lond. 1657.) Albyterio, a Spanish author of the seventeenth century, observes, “that the people who sailed to America, in order to return laden with wealth, would have done their country much better service to have staid at home and guided the plough; for more persons were employed in opening mines and bringing home money, than the money in effect proved worth:” this author thinking with Montesquieu, that those riches were of a bad kind which depend on accidental circumstances, and not on industry and application.

713. *The earliest Spanish work on agriculture generally* appeared in 1569, by Herrera: it is a treatise in many books, and, like other works of its age, is made up of extracts from the Roman authors. Herrera, however, had not only studied the ancients, but visited Germany, Italy, and part of France: his work has been translated into several languages; and the later editions contain some essays and memoirs by Augustin, author of *Secrets de l'Agriculture*, Gonzalo de las Casaz on the silkworm, and Mendez and others on bees.

714. *The agriculture of Spain in the middle of the eighteenth century* was in a very neglected state. According to Harte, “the inhabitants of Spain were then too lazy and proud to work. Such pride and indolence are death to agriculture in every country. Want of good roads and navigable rivers (or, to speak more properly, the want of making rivers navigable) has helped to ruin the Spanish husbandry. To which we may add another discouraging circumstance, namely, ‘that the sale of an estate vacates the lease: *Venta deshaze renta.*’ Nor can corn be transported from one province to another. The Spaniards plant no timber, and make few or no enclosures. With abundance of excellent cows, they are strangers to butter, and deal so little in cows’ milk, that, at Madrid, those who drink milk with their chocolate, can only purchase goats’ milk. What would Columella say (having written so largely on the Andalusian dairies), if it were possible for him to revisit this country? For certain it is that every branch of rural economics, in the time of him and his uncle, was carried to as high perfection in Spain as in any part of the Roman empire. Though they have no idea of destroying weeds, and scratch the ground instead of ploughing it, yet nature has been so bounti-

ful to them, that they raise the brightest and firmest wheat of any in Christendom." (*Essays*, i.)

715. *A general spirit for improvement* seems to have sprung up in Spain with the nineteenth century, though checked for a while by the wars against Bonaparte; subsequently retarded by internal discords; and again by the cruel interference of the French in 1823. In the midst of these troubles, economical societies have been established at Madrid, Valencia, and Saragossa. That of the latter place is connected with a charitable bank in favour of distressed farmers. Money is advanced to defray the expenses of harvest, and two years allowed for returning it. It commenced its operations in June 1801, and then distributed 458*l.* 2*s.* to one hundred and ten husbandmen. In the August following it had furnished sixty-two horses to as many indigent farmers. The Patriotic Society of Madrid distinguished itself by a memoir on the advancement of agriculture, and on agrarian laws, addressed to the supreme council of Castile, in 1812. It was drawn up by a distinguished member, Don G. M. Jovellanos, who recommends the enclosure of lands, the enactment of laws favourable to agriculturists, the prevention of the accumulation of landed property in mortmain tenure; exposes the noxious state of the estates of the clergy, of various taxes on agricultural productions, and of restrictions on trade and the export of corn. His whole work breathes the most liberal, enlightened, and benevolent spirit, and was in consequence so offensive to the clergy, that they procured his condemnation by the inquisition. (*Ed. Rev.*; *Jacob's Travels*)

716. *The climate of Spain* is considered by many as superior to that of any country in Europe. It is every where dry, and though the heat in some provinces is very great in the day, it is tempered during the night by breezes from the sea, or from the ridges of high mountains which intersect the country in various directions. In some provinces the heat has been considered insalubrious, but this is owing to the undrained marshes, from which malignant effluvia are exhaled. The mean temperature of the elevated plains of Spain is 59°; that of the coasts, from 41° to 36° of latitude, is between 63½° and 68°, and is therefore suitable for the sugar-cane, coffee, banana, and all plants of the West India agriculture, not even excepting the pine-apple. The latter is cultivated in the open air in some gardens in Valencia and at Malaga.

717. *The surface of Spain* is more irregular and varied by mountains, than that either of France or Germany. These intersect the country at various distances from east to west, and are separated by valleys or plains. The strata of the mountains are chiefly granitic or calcareous; but many are argillaceous, some silicious, and Montserrat, near Cordova, is a mass of rock salt. A remarkable feature in the surface of Spain is the height of some of its plains above the level of the sea. According to Humboldt, the plain of Madrid is the highest plain in Europe that occupies any extent of country. It is 309½ fathoms above the level of the ocean, which is fifteen times higher than Paris. This circumstance both affects the climate of that part of the country, and its susceptibility of being improved by canal or river navigation. The rivers and streams of Spain are numerous, and the marshes not very common. Forests, or rather forest-wastes, downs, and Merino sheep-walks are numerous, and, with other uncultivated tracts and heaths, are said to amount to two-thirds of the surface of the country. Some tracts are well cultivated in the vine districts, as about Malaga; and others in the corn countries, as about Oviedo. The resemblance between the Asturias and many parts of England is very striking. The same is the aspect of the country, as to verdure, enclosures, live hedges, hedge-rows, and woods; the same mixture of woodlands, arable, and rich pasture; the same kind of trees and crops, and fruit, and cattle. Both suffer by humidity in winter, yet, from the same source, find an ample recompense in summer; and both enjoy a temperate climate, yet, with this difference, that as to humidity and heat, the scale preponderates on the side of the Asturias. In sheltered spots, and not far distant from the sea, they have olives, vines, and oranges. (*Townsend's Spain*, i. 318.)

718. *The soil of Spain* is in general light, and either sandy or calcareous, reposing on beds of gypsum or granite. The poorest soil is a ferruginous sand on sandstone rock, only to be rendered of any value by irrigation. The marshes, and also the best meadow soils, are along the rivers.

719. *The landed property* of Spain till the late revolution was similarly circumstanced to that of France and Germany; that is, in the possession of the crown, great nobles, and religious and civil corporations. Tithes were more rigidly exacted by the clergy of Spain, than by those of any other country of Europe (*Jacob's Travels*, 99.), and a composition in lieu of tithes was unknown in most provinces. Great part of the lands of the religious corporations are now sold, and a new class of proprietors are originating, as in France. Some of these estates are of immense extent. The monks of Saint Hieronymo told Jacob that they could travel twenty-four miles from Seville on their own property, which is rich in corn, oil, and wine. Such was the corruption of this convent, that, notwithstanding all their riches, they were deeply in debt. Lands

were and are cultivated in great part by their proprietors; and even the monasteries held large tracts in hand before their dissolution. What is farmed, is let out in small portions of arable land, with large tracts of pasture or waste, and a fixed rent is generally paid, chiefly in kind. The lands are open every where, except immediately round towns and villages. Many persons in Granada are so remote from the farmeries, that during harvest the farmers and their labourers live in tents on the spot, both when they are sowing the corn, and when cutting and threshing it. The hedges about Cadiz are formed of the soccotrine aloe and prickly pear; the latter producing at the same time an agreeable fruit, and supporting the cochineal insect. Farm-houses and cottages are generally built of stone or brick, and often of rammed earth, and are covered with tiles or thatch.

720. *A bad feature in the policy of the old government*, considered highly injurious to agriculture and the improvement of landed property, deserves to be mentioned. This is, the right which the corporation of the mesta or merino proprietors possess, to drive their sheep over all the estates which lie in their route, from their summer pasture in the north, to their winter pasture in the south, of the kingdom. This practice, which we shall afterwards describe at length, must of course prevent or retard enclosing and aration. The *emfiteutic contract* is another bad feature. It prevails in Catalonia, and is found in various other parts of the kingdom. By the *emfiteutic contract* the great proprietor, inheriting more land than he can cultivate to profit, has power to grant any given quantity for a term of years; either absolute or conditional; either for lives or in perpetuity; always reserving a quit rent, like our copyhold, with a relief on every succession, a fine on the alienation of the land, and other seigniorial rights dependent on the custom of the district; such as tithes, mills, public-houses, the obligation to plough his land, to furnish him with teams, and to pay hearth-money, with other contributions, by way of commutation for ancient stipulated services. One species of grant for uncultivated land, to be planted with vines, admitted formerly of much dispute. The tenant, holding his land as long as the first planted vines should continue to bear fruit, in order to prolong this term, was accustomed to train layers from the original stocks, and, by metaphysical distinctions between identity and diversity, to plead that the first planted vines were not exhausted, claiming thus the inheritance in perpetuity. After various litigations and inconsistent decisions of the judges, it was finally determined, that this species of grant should convey a right to the possession for fifty years, unless the plantation itself should previously fail.

721. *The agricultural products of Spain* include all those of the rest of Europe, and most of those of the West Indies; besides all the grains, for the production of which some provinces are more celebrated than others, and most of them are known to produce the best wheat in Europe. Boswell of Balmuto, a Scottish landholder, when at Xeres de la Fronteira, in the winter of 1809, was shown, on the estate of Mr. Gordon, a very beautiful crop of turnips, with drills drawn in the most masterly style. The drills were by a ploughman of East Lothian, and therefore their accuracy was not to be wondered at; but the turnips showed what the soil and climate were capable of producing under judicious management. Other products are flax, hemp, esparto, palmetto (*Chamærops humilis*), madder, saffron, aloe, cork tree (*Quercus Suber*); the kermes grana, a species of coccus, whose body in the grub state yields a beautiful scarlet colour, and which forms its nidus on the shrub *Quercus coccifera*; soda from the *Salicornia* and other plants of the salt marshes; honey from the forests; dates (*Phoenix dactylifera*), coffee, almonds, filberts, figs, olives, grapes, peaches, prickly pears, carob beans (the locust trees of scripture, *Ceratonia siliqua*), oranges, lemons, pomegranates, and other fruits.

722. *The esparto rush* (*Stipa tenacissima* L.) grows wild on the plains, and is made into a variety of articles for common use. It is employed for making ropes and cables, and is particularly calculated for the latter purpose, as it swims on the water, and the cables formed of it are, consequently, not so liable to rub against the rocks as those which are made of hemp. It is also woven into floorcloths and carpets, and made into baskets or panniers, for carrying produce to market, or manure to the fields. In Pliny's time this plant was used by the poor for beds, by the shepherds for garments, and by the fishermen for nets; but it is now superseded for these and various other ends by the hemp and flax.

723. *The pita, or aloe* (*Aloe soccotrina*, fig. 94.), is an important plant in the hus-

bandry of Spain. It grows by the leaf, which it is only necessary to slip off, and lay on the ground with the broad end inserted a little way in the soil: it makes excellent fences; and the fibres, separated from the mucilage, have been twisted into ropes, and woven into cloth. Bowles, the best Spanish writer on natural history, says, the mucilage might easily be made into brandy. The same plant is used as the boundary fence for villages in the East Indies, and is found a powerful obstacle to cavalry.

724. *The hina*, or Indian fig (*Cactus Opuntia*, fig. 94. b), is cultivated in the plains of Seville for its fruit, and also for raising the cochineal insect. It is either grown on rocky places or as hedges.

725. *The palmetto*, or fan palm (*Chamærops humilis*), is grown near Seville. From the foot-stalks of the leaves, brushes and brooms of various kinds are formed both for home use and exportation.

726. *The potato* is grown, but not in large quantities; nor so good as in England. The Irish merchants of the sea-ports import them for themselves and friends. The batatas, or sweet potato (*Convolvulus Batatas*), turnips, carrots, cabbages, broccoli, celery, onions, garlic, melons, pumpkins, cucumbers, &c., are grown in large quantities.

95

727. *Though the olive* is grown to greater perfection in Spain than in Italy, yet the oil is the worst in Europe; because the growers are thirled, that is obliged to grind their fruit at certain mills. To such mills (fig. 95.) all the olives of a district are obliged to be carried; and, as they cannot all be ground alone, they are put into heaps to wait their turn: these heaps heat and spoil, and when crushed, produce only an acrid rancid oil.

728. *The vine* is cultivated in every province of Spain, and chiefly in those of the east and south. The old sherry wine, *Xeres seco*, the sherry sack of Shakspeare, is produced in Valencia and Granada, and especially near Malaga. On the hills surrounding this city are upwards of seven thousand vineyards, cultivated by the proprietors, or by petty tenants who pay their rent monthly when in money, or during harvest when in kind. The first gathering of grapes commences in the month of June, and these are dried in the sun, and form what are known in Europe as Malaga raisins. A second crop is gathered in September, and a wine made from it resembling sherry; and a third in October and November, which furnishes the wine known on the Continent as Malaga, and in England as mountain. In Valencia the grapes for raisins are steeped in boiling water, sharpened with a ley made from vine stems, and then exposed in the air, and suspended in the sun till they are sufficiently dry.

729. *The sugar-cane* (*Saccharum officinarum*) is cultivated to a considerable extent in Malaga and other places, and the ground is irrigated with the greatest care. The sugar produced resembles that of Cuba, and comes somewhat cheaper than it can be procured from the West India Islands. Sugar has been cultivated in Spain upwards of seven hundred years; and Jacob is of opinion that capital only is wanted to push this branch of culture to a considerable extent.

730. *The white mulberry* is extensively grown for rearing the silkworm, especially in Murcia, Valencia, and Granada. The silk is manufactured into stuffs and ribands in Malaga.

731. *Of other fruits cultivated* may be mentioned the fig, which is grown in most parts of Spain, and the fruit used as food, and dried for exportation. The gum cistus (*Cistus ladaniferus*, fig. 96.) grows wild, and the gum which exudes from it is eaten by the common people. The caper shrub grows wild, and is cultivated in some places. The orange and lemon are abundant, and also the pomegranate.

732. *Other productions*, such as coffee, cotton, cocoa, indigo, pimento, pepper, banana, plantain, &c., were cultivated in Granada for many ages before the West Indies or America was discovered, and might be carried to such an extent as to supply the whole or greater part of Europe.

733. *The rotations of common crops* vary according to the soil and climate. In some parts of the fertile plains of Malaga, wheat and barley are grown alternately without either fallow or manure. The common course of crops about Barcelona, according to Townsend, is, 1. wheat, which, being ripe in June. is immediately succeeded by 2. Indian corn, hemp, millet, cabbage, kidneybeans, or

96

lettuce. In the second year the same crops are repeated; and in the third, the place of wheat is supplied by barley, beans, or vetches. In this way six valuable crops are obtained in three years. Wheat produces tenfold; in rainy seasons fifteen, and in some places as much as fifty, for one. Near Carthage the course is wheat, barley, and fallow. For wheat they plough thrice, and sow from the middle of November to the beginning of December; and in July they reap from ten to one hundred for one, as the season happens to be dry or humid. The Huerta, or rich vale of Alicant, yields a perpetual succession of crops. Barley is sown in September, and reaped in April; succeeded by maize, reaped in September; and that by a mixed crop of esculents. Wheat is sown in November, and reaped in June; flax sown in September is pulled in May. In the vale of Valencia, wheat yields from twenty to forty fold; barley from eighteen to twenty-four fold; oats from twenty to thirty fold; maize, one hundred fold; rice, forty fold.

734. *The live stock of the Spanish agriculturist* consists of oxen, asses, and mules, as beasts of labour; sometimes, also, horses are used on the farm, but these are chiefly reared for the saddle and the army. During the reign of Philip II. an act was passed forbidding their use even in coaches. The horses of Andalusia are celebrated: they are deep-chested, somewhat short-backed; rather heavy about the legs, but with a good shoulder. In general their appearance is magnificent when accoutred for the field. But for the last half century their numbers have been diminishing. The mules and asses are large, and carry heavy loads. The Spanish cows are an esteemed breed, resembling those of Devonshire. They are used chiefly for breeding, there being little use made of cow's milk in most parts of Spain; they are sometimes also put to the plough and cart. Goats are common about most towns, and furnish the milk used in cookery.

735. *The sheep of Spain* have long been celebrated. Pliny relates, that in his time Spanish clothes were of an excellent texture, and much used in Rome. For many centuries the wool has been transported to Flanders, for the supply of the Flemish manufactories, and afterwards to England, since the same manufacture was introduced there. By far the greater part of Spanish sheep are migratory, and belong to what is called the mesta or merino corporation; but there are also stationary flocks belonging to private individuals in Andalusia, whose wool is of equal fineness and value. The carcass of the sheep in Spain is held in no estimation, and only used by the shepherds and poor.

736. The term *mesta* (equivalent to *mestlin*, Eng.) in general signifies a mixture of grain; but in a restricted sense a union of flocks. This collection is formed by an association of proprietors of lands, and originated in the time of the plague in 1350. The few persons who survived that destructive calamity, took possession of the lands which had been vacated by the death of their former occupiers; united them with their own; converted nearly the whole to pasturage; and confined their attention principally to the care and increase of their flocks. Hence, the immense pastures of Estremadura, Leon, and other provinces; and the prodigious quantity of uncultivated lands throughout the kingdom. Hence, also, the singular circumstance of many proprietors possessing extensive estates without any titles to them.

737. *The flocks which form the mesta* usually consist of about 10,000 sheep each. Every flock is under the care of a directing officer, fifty shepherds, and fifty dogs. The whole flocks, composing the mesta, consist of about five millions of sheep, and employ about 45 or 50,000 persons, and nearly as many dogs. The flocks are put in motion in the latter end of April, or beginning of May, leaving the plains of Estremadura, Andalusia, Leon, and Old and New Castile, where they usually winter, and they repair to the mountains of the two latter provinces, and those of Biscay, Navarre, and Arragon. The sheep, while feeding on the mountains, have occasionally administered to them small quantities of salt. It is laid upon flat stones, to which the flocks are driven, and permitted to eat what quantity they please. During the days the salt is administered the sheep are not allowed to depasture on a calcareous soil, but are moved to argillaceous lands, where they feed voraciously. (*Townsend.*)

738. *At the end of July* the ewes are put to the rams, after separation has been made of those already with lamb. Six or seven rams are considered sufficient for one hundred ewes.

739. *In September* the sheep are ochred, their backs and loins being rubbed with red ochre, or ruddle, dissolved in water. This practice is founded upon an ancient custom, the reason of which is not clearly ascertained. Some suppose that the ochre, uniting with the oleaginous matter of the fleece, forms a kind of varnish, which defends the animal from the inclemency of the weather; others think the ponderosity of this earth prevents the wool growing too thick and long in the staple: but the more eligible opinion is, that the earth absorbs the superabundant perspiration, which would otherwise render the wool both harsh and coarse.

740. *Towards the end of September* the flocks recommence their march. Descending from the mountains, they travel towards the warmer parts of the country, and again repair to the plains of Leon, Estremadura, and Andalusia. The sheep are generally conducted to the same pastures they had grazed the preceding year, and where most of them had been yeaned: there they are kept during the winter.

741. *Sheepshearing* commences in the beginning of May, and is performed while the sheep are on their summer journey, in large buildings called *esquileos*. Those, which are placed upon the road, are capable of containing forty, fifty, and some sixty thousand sheep.

They are erected in various places ; but the principal are in the environs of Segovia, and the most celebrated is that of Iturviaca. The shearing is preceded by a pompous preparation, conducted in due form, and the interval is considered a time of feasting and recreation. One hundred and twenty-five men are usually employed for shearing a thousand ewes, and two hundred for a thousand wethers. Each sheep affords four kinds of wool, more or less fine according to the parts of the animal whence it is taken. The ewes produce the finest fleeces, and the wethers the heaviest : three wether fleeces ordinarily weigh on the average twenty-five pounds ; but it will take five ewe fleeces to amount to the same weight.

742. *The journey which the flocks make in their peregrination is regulated by particular laws, and immemorial customs.* The sheep pass unmolested over the pastures belonging to the villages and the commons which lie in their road, and have a right to feed on them. They are not, however, allowed to pass over cultivated lands ; but the proprietors of such lands are obliged to leave for them a path ninety varas, or about forty toises (eighty-four yards), in breadth. When they traverse the commonable pastures, they seldom travel more than two leagues, or five and a half miles, a day ; but when they walk in close order over the cultivated fields, often more than six varas, or nearly seventeen miles. The whole of their journey is usually an extent of one hundred and twenty, thirty, or forty leagues, which they perform in thirty or thirty-five days. The price paid for depasturing the lands where they winter is equally regulated by usage, and is very low ; but it is not in the power of the landed proprietors to make the smallest advance.

743. *The mesta has its particular laws, and a tribunal before which are cited all persons who have any suit or difference with the proprietors.* The public opinion in Spain has long been against the mesta, on account of the number of people it employs, the extent of land it keeps uncultivated, the injury done to the pasture and cultivated lands of individuals, and the tyranny of the directors and shepherds. These have been grievances from time immemorial. Government, yielding to the pressing solicitations of the people, instituted a committee to enquire into them about the middle of the eighteenth century ; but it did no good, and it was not till the revolution of 1810, that the powers and privileges of the mesta were greatly reduced.

744. *The implements of Spanish agriculture are very simple.* The common plough of Castile and most of the provinces (*fig. 97.*) is supposed to be as old as the time of the Romans. It is thus described by Townsend : "The beam is about three feet long, curved, and tapered at one end, to receive an additional beam of about five feet, fastened to it by three iron collars ; the other end of the three-foot beam touches the ground, and has a mortise to receive the share, the handle, and a wedge." From this description it is evident that the beam itself supplies the place of the sheath ; the share has no fin, and instead of a mould-board, there are two wooden pins fastened near the heel of the share. As in this plough the share, from the point to its insertion in the beam, is two feet six inches long, it is strengthened by a retch. That used near Malaga is described by Jacob as "a cross, with the end of the perpendicular part shod with iron. It penetrates about six inches into the soil, and is drawn by two oxen with ropes fastened to the horns. The plough of Valencia, on the eastern coast, we have already given (*fig. 12.*) as coming the nearest to that described by Virgil. There are many wheels and other contrivances used for raising water ; the most general, as well as the most primitive, is the noria (*fig. 98*), or bucket wheel, introduced by the Moors, from which our chain pump is evidently derived. A vertical wheel

over a well has a series of earthen jars, fastened together by cords of esparto, which descend into the water and fill themselves ; by the motion of the wheel they

rise to the surface, and then by the same motion empty themselves into a trough, from which the water is conveyed by trenches into the different parts of the garden or field. The vertical wheel is put in motion by a horizontal one, which is turned by a cow." (*Jacob's Travels*, 152.) The construction of dung-pits has already been mentioned, (710.) as introduced by the Moors, and the practice of preserving the dung in that manner is still continued in Granada and Valencia. Threshing-floors are made in the fields, and paved with pebbles or other stones.

745. Few of the operations of Spanish agriculture afford any thing characteristic. No hay is made in Spain (*Townsend*); and so dry and brittle is the straw of the corn crops, that in the process of treading out, which is generally done by mares and colts, it is broken to pieces. The grain being separated, the straw is put in stacks, and preserved for litter, or mixed with barley as food for cattle. Irrigation is carefully performed, and is the only effectual mode of insuring a crop of grain, or any sort of herbaceous vegetable. On some farms on the Vega in Malaga, scarcely any attention is paid to stirring the soil, but by the very complete irrigation which can be there given, the land yields fifty bushels per acre. Where the soil is naturally light, situated in a warm climate, and not irrigated, it is remarkably free from weeds; because from the latter end of May, or the beginning of June, when the crop is harvested, till October or November, they have no rain; and the heat of the sun during that period destroys every plant, and leaves the soil like a fallow which only requires the seed furrow. In effect it gets no more; and thus, under such circumstances, one crop a year, after only one ploughing, may be raised for an endless period.—In the Asturias, after the women milk the sheep, they carry the milk home in leather bags, shaking it all the way, till by the time of their arrival butter is formed. (*Townsend's Travels*, i. 273.)

746. The labouring man of Spain adopts a custom which might be useful to the reapers and haymakers of Britain, in many situations. The labour and heat of hay time and harvest excite great perspiration and consequent thirst, which it is often necessary to quench with sun-warmed water. To cool such water, the Spanish reaper puts it in a porous earthen pitcher (*alcarraza*), the surface of which being constantly moist with the transudation of the fluid, its evaporation cools the water within. The frequent application of wet cloths to a bottle or earthen vessel, and exposure to the sun and wind, effects the same object, but with more trouble.

747. The culture of forests is very little attended to in Spain. The best charcoal is made from heath, chiefly the *Erica mediterranea*, which grows to the size of a small tree, and of which there are immense tracts like forests. The cork tree (*Quercus Sûber*, *fig.* 99.) affords the most valuable products. The bark is taken off for the first time when the tree is about fifteen years old; it soon grows again, and may be rebarked three times, the bark improving every time, till the tree attains the age of thirty years. It is taken off in sheets or tables, much in the same way as oak or larch bark is taken from the standing trees in this country. After being detached, it is flattened by presenting the convex side to heat, or by pressure. In either case it is charred on both surfaces to close the transverse pores previously to its being sold. This charring may be seen in bungs and taps; but not in corks, which, being cut in the long way of the wood, the charring is taken off in the rounding.

748. The exertions that have been made for the improvement of the agriculture of Spain we have already noticed, and need only add, that if the late government had maintained its power, and continued in the same spirit, perhaps every thing would have been effected that could be desired. Time, indeed, would have been requisite; but improvement once heartily commenced, the ratio of its increase is astonishing. But the French invasion of Spain, first under Bonaparte, and again under the Bourbons, has spoiled every thing, and for the present almost annihilated hope.

749. The agricultural circumstances of Portugal have so much in common with those of Spain, that they do not require separate consideration. The two countries differ in the latter having a more limited cultivation, the sugar-cane, and most of the West India plants grown in Spain, requiring a warmer climate than that of Portugal. The vine and orange are cultivated to great perfection; but common agriculture is neglected. The breed of horses is inferior, and there are few cows or sheep. Swine form the most abundant live stock, and fatten, in a half wild state, on the acorns of the numerous oak forests which cover the mountains.

SECT. X. *Present State of Agriculture in European Turkey.*

750. *The Turkish empire includes a variety of climates and countries, of most of which so little is correctly known, that we can give no satisfactory account of their agriculture. Asiatic Turkey is nearly three times the extent of the European part; but the latter is better cultivated and more populous. "European Turkey," Thornton observes, "depends upon no foreign country for its subsistence. The labour of its inhabitants produces, in an abundance unequalled in the other countries of Europe, all the alimentary productions, animal and vegetable, whether for use or enjoyment. The corn countries, in spite of the impolitic restrictions of the government, besides pouring plenty over the empire, secretly export their superfluities to foreign countries. Their agriculture, therefore, though neglected and discouraged, is still above their wants."* (*Present State of Turkey*, vol. i. p. 66.)

751. *The climate and seasons of European Turkey vary with the latitude and local circumstances of the different provinces, from the Morea, in lat. 37° and surrounded by the Mediterranean sea, to Moldavia, between Hungary and Russia, in lat. 48°. The surface is generally mountainous, with plains and vales; some rivers, as the Danube in Wallachia, and numerous gulfs, bays, estuaries, and inlets of the Adriatic, the Archipelago, the Mediterranean, and the Black Seas. The soil is in general fertile, alluvial in some of the richest plains of Greece, as Thessaly; and calcareous in many parts of Wallachia and Moldavia. These provinces produce excellent wheat and rich pasture; while those of the south produce maize, wheat, and rice. The vine is cultivated in most provinces; and there are extensive forests, especially in the north. The live stock consists of the horse, ox, camel, sheep, and swine.* (*Thornton.*)

752. *Some traits of the agriculture of the Morea, the southernmost province of European Turkey, have been given by Dr. Pouqueville. The climate holds the exact medium between the scorching heat of Egypt and the cold of more northern countries. The winter is short, but stormy; and the summer is hot, but tempered by breezes from the mountains or the sea. The soil of the mountains is argillaceous; in some places inclining to marl, and in others to peat or vegetable earth: the richest parts are Arcadia and Argos. The plough consists of a share, a beam, and a handle (fig. 100.); the share is shaped somewhat like the claw of an anchor, and the edges armed with iron. In some cases it has two wheels. It is drawn by one horse, by two asses, or by oxen or buffaloes, according to the nature of the soil. The corn grown is of excellent quality, though no attention is paid to selecting the seed. The rice of Argolis is held at Constantinople the next in excellence to that of Damietta. The vine is successfully cultivated; but at Corinth, "situated in a most unwholesome atmosphere," the culture of that sort which produces the raisins of Corinth is less attended to than formerly. The olive trees (*O'lea europæa*, g. 101.) are the finest in the world; the oil of Maina is the best, and held in esteem at all the principal markets of Europe. The white mulberry is extensively cultivated for the support of the silkworm. Elis yields the best silk. The cotton is cultivated in fields, which are commonly divided by hedges of Nepal or Indian fig, which is eaten, but is here more rapid than in Egypt.*

100

101

753. *The figs of the Morea "are perhaps the most exquisite that can be eaten." The tree is cultivated with particular care, and the practice of caprifigation adopted. They collect the little figs which have fallen from the trees while very young, and which contain numbers of the eggs of the gnat insect (Cynips). Of these they make chaplets, which are suspended to the branches of the trees. The gnats are soon hatched, and spread themselves over the whole tree. The females, in order to provide a nidus for their eggs, pierce the fruit with their sting, and then deposit them. From this puncture a gummy liquor oozes; and after this the figs are not only not liable to fall, but grow larger and finer than if they had not undergone this operation. It is doubted by some modern physiologists whether this process is of any real use, it being now neglected in most fig countries where it was formerly performed. Some allege that it is merely useful as fecundating the blossoms, which most people are aware are situated inside of the fruit; others that it promotes precocity, which the puncture of an insect will do in any fruit, and which any one may have observed in the gooseberry, apple, or pear.*

754. *The almond tree* is very productive. The orange tribe abounds; and the pomegranates, peaches, apricots, grapes, &c., are of the finest flavour. The banana is cultivated in the gardens, as are melons, dates, and many other fruits. Carobs (*Ceratonia*), quinces, medlars, cherries, &c. are wild in abundance. Bees are found in the hollows of trees; and their excellent white honey is exported.

755. *The oxen of the Morea* are low, and have long white hair. The most fleshy do not weigh more than from 300 to 400 pounds. The cows give little milk, and are much injured by the jackals, who tear away their teats; and by large serpents, which are said to suck the milk. The sheep are small, and have large horns; their wool is considered of the second quality of the wool of the East. Cheese is made from their milk, and that of goats. The horses of the Morea are of a breed between the Moravian and Thracian: their form is not admired; but they are full of fire and courage; and so vigorous, that they run with a firm and rapid step over the mountains without ever stumbling. The asses are miserable.

756. *The forests of the Morea* produce the cork-tree; the kermes oak; the *Quercus E'sculus*, or *Velonia* oak, the acorns of which are eaten, and their cups used as oak-galls, in preparing black dye; the azarole, plane, larch, wild olive, sweet chestnut, manna ash; grains d'Avignon (*Rhamnus infectorius L.*), from the grains or seeds of which a fine yellow dye is prepared; *Lawsonia inermis*, which furnishes a fine aurora colour, with which the women of the East dye their nails; the turpentine tree, barren date trees, silk tree (*Mimosa Julibrissin*) with its beautiful tufts, pine fir, and a variety of others. Chestnuts were at one period the temporary food of nearly the whole country: on Mount Pholoe, where the peasants are half savages, they form the principal food for the whole year. A variety of plants used in the arts and in pharmacy grow wild in the wastes, and there are venison and game in the woods, and fishes in the rivers, lakes, and the surrounding ocean. The Morea, Dr. Pouqueville concludes, is "a fine country;" and though one does not find the golden age here renewed, yet, "under a better order of things, it will produce abundantly every thing necessary to supply the wants of man." (*Travels, transl. by A. Plumtree, p. 206.*)

757. *Some notices of the agriculture of Thessaly and Albania* have been given by Dr.

Holland. The plain of Thessaly (*fig. 102.*) is an immense tract of level country, with a fine alluvial soil, which tradition and external appearance concur in testifying, was once covered with water. "The capabilities," Dr. Holland observes, "are great throughout the whole of this fine province;

and it would not be easy to fix a limit to the amount and variety of produce which might be raised from its surface. In their present state, the plains of Thessaly form one of the most productive districts of the Grecian peninsula, and their annual produce, in grain of different kinds, cotton, silk, wool, rice, and tobacco, allows a very large amount of regular export from the provinces." The cultivation is not deficient in skill or neatness. Their plough is of a primitive form; and their carts are small cars, some of them, as Dr. Clarke observes, simple enough (*fig. 103.*); both are drawn by oxen or buffaloes. The wool of the sheep is moderately fine; the mulberry is grown in dwarf pollards; and the cotton in drills, well hoed. The men are a stern-looking race, and the women well made, and not unlike the antique. "The circumstances by which the amount of produce might be increased, are chiefly, perhaps, of a more general nature, — a better form of government; greater security to private property; a

more uniform distribution of the inhabitants; and the prevention of those monopolies in the export of grain, which have hitherto been exercised by the Turkish rulers of the country. (*Travels, 2d. edit. p. 281.*)

758. *The agriculture of Albania* differs in no essential particular from that of Thessaly. The common tenure on which land is let, is that of paying to the landlord half the produce. The vale of Deropuli is the most fertile and populous in Albania. The tillage, generally speaking, is remarkable for its neatness. The products are chiefly wheat, maize, tobacco, and rice. The returns afford a considerable surplus for exportation; and the tobacco is esteemed the best in Albania. Large flocks of sheep feed on the declivity of the mountains, and afford much coarse wool for the manufactures of the country.

759. *The agriculture of Moldavia and Wallachia*, two the most northerly provinces of European Turkey, has been given by various authors, as Carra, Baner, and Thornton. The climate of those provinces is very severe in winter. Spring begins in April; summer in June; and in July and August the days are excessively hot, and the nights cold. Heavy rains begin in September, and snows in November. The surface is generally mountainous: but the valleys are dry and rich. The usual grains are cultivated, and also

maize. They plough deep with six oxen, and never employ manure. They take a crop, and leave the land to rest, alternately. The corn is trodden out by horses, and then laid up in pits. Flax and hemp are sown for local manufacture. Newly broken up lands are planted with cabbages, which grow to a great size. The vine is cultivated on the southern declivities of hills, and the wine is said to equal that of Hungary. The mulberry is cultivated for the silkworm; and forests are extensive on the mountains. The common fruit trees are abundant, and an excellent variety of apple, called the *doiniasca*, grows wild. The olive and fig are too delicate for the climate.

760. *But the pasture lands* are the most valuable parts of these provinces. The oxen are large and fleshy, and so numerous that they form a principal article of export to Russia, Poland, and Germany. The buffalo thrives better here than in most parts of Europe; and is valued for its strength and milk. The sheep winter on the Danube, and pass the summer on the Carpathian mountains; their mutton is excellent, and the annual exportation of the wool into Germany is very considerable. There are various breeds of horses; they are brought up in great numbers, for the Austrian and Prussian cavalry. They are well formed, spirited, docile, and remarkable for the soundness of their hoofs. The carriage and draught horses are small but active, and capable of resisting fatigue. They live in the open air in all seasons, though in winter they are often attacked by wolves. Domestic fowls and game abound, especially hares. The honey and wine are of the finest quality. One author (*Carra*) mentions a kind of green wax, which, being made into tapers, diffuses an excellent perfume when lighted. Many of the cottages partake of the Swiss character, and are more picturesque than those of Hungary or Russia. (fig. 104.)

761. *The poorest agriculture in European Turkey* is that of Romelia, including the country round Constantinople. The surface is hilly, and the soil dry and stony, chiefly in pasture or waste. "The capital of the empire," Thornton observes, "as the soil in its immediate vicinity is barren and ungrateful, receives from the neighbouring villages, and from the surrounding coasts of both the seas which it commands, all the culinary herbs and fruits of excellent flavour, which the most fastidious appetites can require; and from the Asiatic coasts of the Black Sea, all materials necessary for fuel, or for the construction of ships and houses."

CHAP. V.

Modern History and present State of Agriculture in the British Isles.

762. Having, in the preceding chapter, brought down the history of British agriculture to the revolution, we shall resume it at that period, and continue our view to the present time. As this period may be considered the most interesting of the whole series, we shall, for the sake of distinctness, arrange the matter under the separate sections of the political, professional, and literary history of agriculture in Britain, and submit a separate view of the progress and present state of agriculture in Ireland.

SECT. I. *Political History of Agriculture in Britain, from the Revolution in 1668 to the present Time.*

763. *That the agriculture and general prosperity of this country were greatly benefited by the revolution* is an undisputed point. That prosperity, as far as respects agriculture, has been ascribed to the corn-laws then promulgated. "In 1670," a masterly writer on the subject remarks, "exportation was permitted, whatever the price might be; and importation was virtually prohibited, by a duty of 16s. per quarter, when wheat did not exceed 53s. 4d.; of 8s. when above that, and not exceeding 80s.; and when above 80s. the duty of 5s. 4d., imposed by the act of 1663, continued to be payable. Still, however, as there was a duty payable on exportation; and as importation, from some defect

in the law respecting the mode of ascertaining the prices at which the different duties were exigible, still continued at the low duty, the system by which exportation was encouraged, and importation in ordinary cases prohibited, was not completely established till 1688 and 1700. In the former of these years, a bounty of 5s. a quarter was given on exportation, when the price of wheat did not exceed 48s., and in the latter the duties on exportation were wholly repealed. Under these laws, not only was the excess of exports very considerable, but the prices of grain, down to 1765, were much lower than during an equal number of years preceding 1688. This is not the place to enquire how far these laws had an influence in producing this phenomenon; but the facts themselves are indisputable. Yet the mere circumstance of large exportations of grain does by no means prove the prosperity of agriculture; far less is its cheapness in the home markets any evidence of the comfortable subsistence of the lower orders. Corn seems to have been raised in such abundance, not merely because the market was extended by means of the bounty, but because there was little demand for other products of the soil, which have, since that time, withdrawn a large portion of the best arable land from the growth of corn. And the price was low, because neither the number nor wealth of the consumers had increased in a proportion corresponding to the supply. Before the accession of his present majesty, the number of acts for enclosure was only two hundred and forty-four; a clear proof that agricultural improvements proceeded much more slowly than they have done since. And it cannot be disputed, that, owing to the imperfect culture of that period, when ameliorating crops did not enter largely into the courses of management, any given extent of land did not produce so much corn as under the improved rotations of modern husbandry."

764. *The exportation of wool* was prohibited in 1647, in 1660, and in 1668; and the prohibition strictly enforced by subsequent statutes. The effect of this on its price, and the state of the wool trade, from the earliest period to the middle of last century, are distinctly exhibited by the learned and laborious author of *Memoirs on Wool*, printed in 1747.

765. *In 1765 the corn-laws established in the end of the seventeenth century began to be repealed*, and exportation was prohibited, and importation permitted without payment of duties, by annual acts, during the seven subsequent years. "A new system was established in 1773, allowing importation when the price of wheat was at or above 48s. per quarter, at the low duty of 6d. Exportation was prohibited when the price was 44s.; and below that the former bounty of 5s. per quarter continued to be payable."

766. *By an act passed in 1791*, the bounty on exportation, when the price was under 44s. per quarter, remained unaltered; but "exportation was permitted till the price was 46s. Importation was virtually prohibited by high duties when the price was below 50s.; and permitted, on payment of a duty of 6d., when at or above 54s."

767. *In 1804*, "the corn-laws were altered for the third time, and the bounty on exportation was paid till the price of wheat was 48s. per quarter; and at 54s. exportation was prohibited. The high duty of 24s. 3d. was payable on importation till the price was 63s.; above 63s. and under 66s. a duty of 2s. 6d.; and above 66s. the low duty of 6d. By an act in 1805, importation into any part of Britain is to be regulated by the aggregate average price of the twelve maritime districts of England. Importation was never stopped under the law of 1804, till February 1815.

768. *During the twenty-two years preceding 1821*, about sixty millions of pounds sterling have been paid for foreign grain. "In bad seasons the prices have been enhanced to a most alarming degree, notwithstanding large bounties have been paid on importation. The average price of every successive period of ten years, from 1765 to 1814, has risen considerably; and since 1795, the price has been seldom less than double the average of the first sixty years of the last century."

769. *The corn-laws since 1814* have undergone a change in almost every session of parliament. According to the corn act of 1828, foreign corn is admitted at 52s. per imperial quarter for a duty of 34s. 8d. per quarter, and from 52s. to 73s. at a graduated scale of duties, being admitted at the latter price at 1s. per quarter. Barley at 24s. is admitted on a duty of 25s. 10d. per quarter, and from 24s. to 41s. on a graduated scale of duties; so that at the latter price it is admitted at 1s. per quarter. Oats are admitted at 18s. per quarter, at a duty of 19s. 9d. per quarter, and from 18s. to 31s. on a graduated scale of duties; so that at the latter price the duty is 1s. per quarter. In like manner rye, peas, and beans, when at 29s. are admitted at 25s. 9d. per quarter, and when at 46s. at 1s. (*Quar. Jour. of Agriculture*, vol. i. p. 228.)

770. *Agriculture in Scotland* was at low ebb at the period of the revolution. "The calamity of that evil had so oppressed the tenantry of Scotland, that many farms remained unoccupied. Proprietors were then as eager in searching after tenants who were able to stock and cultivate the ground, as farmers were assiduous in seeking after farms previously to the late general peace. Improvements began to be made soon after the union, especially by some gentlemen of East Lothian, and by the efforts of the Agricultural Society of Scotland, established in 1723. It was now found beneficial to grant long leases, which were found greatly to increase the skill and industry of the tenants, by rendering them secure of enjoying the benefit of their improvements. A great stimulus was also given to farmers by the money circulated during the rebellion of 1745, which raised prices, and increased the tenants' capital stock."

771. *A desire to improve the roads of Scotland* now began to manifest itself among the proprietors. The first act of parliament for collecting tolls on the highways in Scotland, was passed in 1750, for repairing the road from Dunglass bridge to Haddington. In

ten years after, several acts followed for the counties of Edinburgh and Lanark, and for making the roads between Edinburgh and Glasgow. The benefit which agriculture has derived from good roads it would not be easy to estimate. The want of them was one great cause of the slow progress of the art in former times. At present, all the improvements introduced by M'Adam in the construction and preservation of the roads of England, are spreading with equal rapidity and good effect in Scotland.

772. *The relaxing of the rigour of entails, and abrogating the feudal system, greatly benefited the agriculture of Scotland.* The first was effected by an act in 1770, which relaxed the rigour of strict entails, and extended the powers of proprietors, in so far as regards the improvement of their estates, and the granting of leases.

773. *But the general progress of agriculture in Britain, from the revolution to the middle of the eighteenth century, was by no means so considerable as from the great exportation of corn we should be led to imagine.* "The gradual advance in the price of land produce, soon after the year 1760, occasioned by the increase of population, and of wealth derived from manufactures and commerce, has given a more powerful stimulus to rural industry, augmented agricultural capital in a greater degree, and called forth a more skilful and enterprising race of cultivators, than all the laws for regulating the corn trade could ever have effected. Most of the inventions for increasing produce and economising labour have either been introduced, or improved and greatly extended, since that time; and by means of both, the free surplus has been vastly increased for the supply of the general consumption. The passing of more than three thousand bills of enclosure, in the late reign, is a proof how much more rapidly the cultivation of new land has proceeded than in the former period: and the garden-like appearance of the country, as well as the striking improvement in the condition of all classes of the rural population, display, in the most decided manner, the skill and the success with which this great branch of national industry is now followed throughout the greater part of Britain."

774. *Since the conclusion of the American war in 1782, "improvement has proceeded with singular rapidity in every district; and while the rental rolls of proprietors have been doubled, tripled, and quadrupled, the condition of the tenantry, and of the lower ranks, has been ameliorated almost in a proportional degree."* (*Ed. Ency. art. Agr.*)

775. *Since the period of 1815, agriculture has sustained a severe shock from the fall of prices, occasioned by the lessened circulation of currency, the necessary preliminary to a return to a currency of the precious metals.* In this shock many hundreds of farmers lost all their capital, and were obliged to become operatives to others; while some, more fortunate, contrived to retain as much of the wreck of their property as enabled them to emigrate to other countries. Cleghorn, whose pamphlet on the depressed state of agriculture was honoured with the prize of the Highland Society of Scotland, thinks this loss cannot have been less than one year's rental of the whole island. "The replies sent to the circular letter of the Board of Agriculture, regarding the agricultural state of the kingdom, in February, March, and April, 1816, furnish a body of evidence which cannot be controverted, and exhibit a picture of widely spread ruin among the agricultural classes, and of distress among all that immediately depend upon them, to which there is probably no parallel." (See *Cleghorn on the Depressed State of Agriculture, 1822.*) After upwards of fourteen years' severe suffering, both by landlords and tenants, things have now assumed a more stationary condition. Rents have been greatly lowered every where in proportion to the fall of prices and the rise of parochial burdens, and both farmers and landlords are beginning gradually to recover themselves.

SECT. II. *Professional History of Agriculture, from the Revolution to the present Time.*

776. *In England, from the restoration to the middle of the eighteenth century, very little improvement took place, either in the cultivation of the soil, or in the management of live stock.* Even clover and turnips (the great support of the present improved system of agriculture) were confined to a few districts, and at the close of this period were scarcely cultivated at all by common farmers in the northern parts of the island. From the *Whole Art of Husbandry*, published by Mortimer in 1706, a work of considerable merit, it does not appear that any improvement was made on his practices till near the end of last century. In those districts where clover and rye-grass were cultivated, they were cut green, and used for soiling as at present. Turnips were sown broadcast, hand-hoed, and used for feeding sheep and cattle, as they were used in Houghton's time, and are still in most districts of England.

777. *In the beginning of the eighteenth century, a considerable improvement in the process of culture was introduced by Jethro Tull, a cultivator of Berkshire, who began to drill wheat and other crops about the year 1701, and whose *Horse-hoeing Husbandry* was published in 1731.* "In giving a short account of the innovations of this eccentric writer, it is

not meant to enter into any discussion of their merits. It will not detract much from his reputation to admit, that, like most other men who leave the beaten path, he was sometimes misled by inexperience, and sometimes deceived by a too sanguine imagination. Had Tull confined his recommendation of drill husbandry to leguminous and bulbous-rooted plants generally, and to the cereal gramina only in particular circumstances; and had he, without puzzling himself about the food of plants, been contented with pointing out the great advantage of pulverising the soil in most cases, and extirpating weeds in every case, he would certainly have deserved a high rank among the benefactors of his country. A knowledge of his doctrines and practice, however, will serve as a necessary introduction to the present approved modes of culture."

778. *Tull's theory* is promulgated with great confidence; and in the controversy which he thought proper to maintain in support of it, he scrupled not to employ ridicule as well as reasoning. Besides the Roman writers *de Re Rustica*, Virgil in particular, whom he treats with high disdain; he is almost equally severe on Dr. Woodward, Bradley, and other writers of his own time.

779. *Tull begins by showing that the roots of plants extended much farther than is commonly believed; and then proceeds to enquire into the nature of their food.* After examining several hypotheses, he decides this to be fine particles of earth. The chief, and almost the only use of dung, he thinks, is to divide the earth; to dissolve the "terrestrial matter which affords nutriment to the mouths of vegetable roots;" and this can be done more completely by tillage. It is therefore necessary, not only to pulverise the soil by repeated ploughings before it be seeded; but, as it becomes gradually more and more compressed afterwards, recourse must be had to tillage or *horse-hoeing*, while the plants are growing; which also destroys the weeds that would deprive the plants of their nourishment.

780. *The leading feature of Tull's husbandry, is his practice of laying the land into narrow ridges of five or six feet, and upon the middle of these drilling one, two, or three rows; distant from one another about seven inches, when there were three; and ten inches, when only two.* The distance of the plants on one ridge from those on the contiguous one, he called an *interval*; the distance between the rows on the same ridge a *space*, or partition; the former was stirred repeatedly by the horse-hoe, and the latter by the hand-hoe.

781. *The extraordinary attention Tull gave to his mode of culture is, perhaps, without a parallel.* "I formerly was at much pains," he says, "and at some charge, in improving my drills, for planting the rows at very near distances; and had brought them to such perfection, that one horse would draw a drill with eleven shares, making the rows at three inches and a half distant from one another; and at the same time, sow in them three very different sorts of seeds, which did not mix; and these too at different depths. As the barley rows were seven inches asunder, the barley lay four inches deep. A little more than three inches above that, in the same channels, was clover; betwixt every two of these rows, was a row of saintfoin, covered half an inch deep. I had a good crop of barley the first year; the next year two crops of broad clover, where that was sown; and where hop clover was sown, a mixed crop of that and saintfoin; but I am since, by experience, so fully convinced of the folly of these, or any other mixed crops, and more especially of narrow spaces, that I have demolished these instruments (in their full perfection) as a vain curiosity, the drift and use of them being contrary to the true principles and practice of horse-hoeing." (*Horse-hoeing Husbandry*, p. 62. London, 1762.)

782. *In the culture of wheat* he began with ridges six feet broad, or eleven on a breadth of sixty-six feet; but on this he afterwards had fourteen ridges. After trying different numbers of rows on a ridge, he at last preferred two, with an intervening space of about ten inches. He allowed only three pecks of seed for an acre. The first hoeing was performed by turning a furrow from the row, as soon as the plant had put forth four or five leaves; so that it was done before, or at the beginning of, winter. The next hoeing was in spring, by which the earth was returned to the plants. The subsequent operations depended upon the circumstances and condition of the land, and the state of the weather. The next year's crop of wheat was sown upon the intervals which had been unoccupied the former year; but this he does not seem to think was a matter of much consequence. "My field," he observes, "whereon is now the thirteenth crop of wheat, has shown that the rows may successfully stand upon any part of the ground. The ridges of this field were, for the twelfth crop, changed from six feet to four feet six inches. In order for this alteration, the ridges were ploughed down, and then the next ridges were laid out the same way as the former, but one foot six inches narrower, and the double rows drilled on their tops; whereby, of consequence, there must be some rows standing on every part of the ground, both on the former partitions, and on every part of the intervals. Notwithstanding this, there was no manner of difference in the goodness of the rows; and the whole field was in every part of it equal, and the best, I believe, that ever grew on it. It is now the thirteenth crop, likely to be good, though the land was not ploughed cross ways." (*Ibid.*, p. 424.)

783. *According to Tull, a rotation of crops of different species was altogether unnecessary; and he labours hard to prove, against Dr. Woodward, that the advantages of such a change, under his plan of tillage, were quite chimerical; though he seems to admit the benefit of a change of the seed itself.* But the best method of determining the question would have been, to have stated the amount of his crops per acre, and the quality of the grain, instead of resting the superiority of his management on the alleged saving of expense, when compared with the common broadcast husbandry.

784. *On the culture of the turnip*, both his principles and his practice are much more correct. The ridges were of the same breadth as for wheat; but only one row was drilled on each. His management, while the crop was growing, differs very little from the present practice. When drilled on the level, it is impossible, he observes, to hoe-plough them so well as when they are planted upon ridges. But the seed was deposited at different depths, the half about four inches deep, and the other half exactly over that, at the depth of half an inch. "Thus planted, let the weather be never so dry, the deepest seed will come up; but if it raineth immediately after planting, the shallow will come up first. We also make it come up at four times, by mixing our seed, half new and half old, the new coming up a day quicker than the old. These four comings up give it so many chances for escaping the fly; it being often seen that the seed sown over night will be destroyed by the fly, when that sown the next morning will escape, and *vice versa*: or you may hoe-plough them when the fly is like to devour them; which will bury the greatest part of those enemies; or else you may drill in another row without new ploughing the land."

785. *Drilling, and horse and hand hoeing*, seem to have been in use before the publication of Tull's book. "Hoeing," he says, "may be divided into deep, which is our horse-hoeing; and shallow, which is the English hand-hoeing; and also the shallow horse-hoeing used in some places betwixt rows, where the intervals are very narrow, as

sixteen or eighteen inches. This is but an imitation of the hand-hoe, or a succedaneum to it, and can neither supply the use of dung, nor of fallow, and may be properly called scratch-hoeing." But in his mode of forming ridges, his practice seems to have been original; his implements display much ingenuity; and his claim to the title of father of the present horse-hoeing husbandry of Great Britain seems indisputable. A translation of Tull's book was undertaken at one and the same time in France, by three different persons of consideration, without the privity of each other. Two of them afterwards put their papers into the hands of the third, *M. Du Hamel du Monceau*, of the Royal Academy of Sciences, at Paris, who published a treatise on husbandry, on the principles of Tull, a few years after. But Tull seems to have had very few followers in England for more than thirty years. The present method of drilling and horse-hoeing turnips was not introduced into Northumberland till about the year 1780 (*Northum. Survey*, p. 100.); and it was then borrowed from Scotland, the farmers of which had the merit of first adopting Tull's management in the culture of this root, and improving on it, about 1760, and from them it has since made its way, but slowly, in the southern part of the island. Tull was born in Oxfordshire, was bred a barrister, and made the tour of Europe. He commenced his experiments on his own estate, but being unsuccessful, was obliged to sell it. He afterwards took a farm in Berkshire, where he renewed his operations. He published his book in 1731, and died in 1740, leaving a son, an officer in the army, who ruined himself by projects, and died in the Fleet prison in London in 1764.

786. *In the live stock of British agriculture, very little improvement had been made previously to the middle of the eighteenth century, or later.* About this time, the best breed of cattle and sheep were about Doncaster, in Yorkshire, and in Leicestershire, and the first grand and successful effort to improve them was made by Robert Bakewell, of Dishley, in the latter county. Bakewell was born about 1725 or 26; and soon after arriving at the years of maturity, took an interest in improving the breed of sheep. His father was a farmer, and died in 1760; but the son had taken an active management of the farm for many years before that time, having begun, about the year 1755, that course of experiments which terminated in the important improvements for which his name is celebrated. (*Hunt's Agricultural Memoirs*, p. 35; *Fleming's Farmer's Journal*, August, 1828, p. 319.)

787. *By Bakewell's skilful selection at first, and constant care afterwards, to breed from the best animals, without any regard to their consanguinity, he at last obtained a variety of sheep, which, for early maturity, and the property of returning a great produce of mutton for the food they consume, as well as for the small proportion which the weight of the offal bears to that of the four quarters, are altogether unequalled either in this or any other country.* The Dishley or New Leicester sheep, and their crosses, are now spread over the principal corn districts of Britain; and from their quiet domesticated habits, are probably still the most profitable of all the varieties of sheep, on farms where the rearing and fattening of live stock are combined with the best courses of tillage crops.

788. *The practice of Bakewell and his followers furnishes an instance of the benefits of a division of labour, in a department of business where it was little to be expected.* Their male stock was let out every year to breeders from all parts of England; and thus, by judiciously crossing the old races, all the valuable properties of the Dishley variety descended, after three or four generations, to their posterity. By no other means could this new breed have spread so rapidly, nor have been made to accommodate itself so easily to a change of climate and pasture. Another recommendation of this plan was, that the ram-hirer had a choice among a number of males, of somewhat different properties, and in a more or less advanced stage of improvement; from which it was his business to select such as suited his particular object. These were reared by experienced men, who gave their principal attention to this branch alone; and having the best females as well as males, they were able to furnish the necessary supply of young males in the greatest variety, to those farmers whose time was occupied with other pursuits. The prices at which Bakewell's rams were hired appear enormous. In 1789, he received twelve hundred guineas for the hire of three brought at one birth; two thousand for seven; and, for his whole letting, at least three thousand guineas. (*Encyc. Brit. art. Agr.*)

789. *Messrs. Matthew and George Culley carried the improvements of Bakewell into Durham and Northumberland, and perpetuated them in the north of England and south of Scotland.* Messrs. Culley were pupils of Mr. Bakewell in 1762 and 1763, and Mr. George Culley soon became Mr. Bakewell's confidential friend, and was always considered his favourite disciple. After practising their improvements for a number of years in the county of Durham, they removed, in 1767, to Fenton farm, near Wooler, in Northumberland, containing upwards of 1100 acres. At this time, the sheep flocks that were kept on the arable and grazing districts of Northumberland were a large, slow-feeding, long-woolled kind; and a mixed breed, between those long-woolled sheep and the Cheviot. These breeds were rarely got fattened before three years old; but the improved Leicesters (which were introduced by Messrs. Culley) were sold fat at little more than a year old; and though they met with much opposition at their first introduction, there is now scarcely a flock to be found that has not been improved by them. Their breed of short-horned, or Teeswater, cattle, was also a great acquisition to the district; and the breed of draught horses was considerably improved by their introducing a stallion of Mr. Bakewell's. They were

always amongst the first to adopt and make experiments of any new mode of culture, new implements of husbandry, or new varieties of grain; and they practised draining, irrigation, fencing, and other improvements, on the most correct principles. Their great attention to minutiae, unremitting industry, and superior cultivation, not only raised a spirit of exertion and emulation in the surrounding neighbourhood, but gained them such celebrity as first-rate breeders and agriculturists, that they had pupils from various parts of the island, with whom they received considerable premiums, besides being amply paid for their board and instruction. To all those acquirements, they added strict economy; the consequence of which was a great accumulation of wealth, which they applied (as occasions offered) to increasing their farming concerns; and this to such an extent, that for several years they occupied farms to the amount of about 8000*l.* a year. The large capital which such extensive concerns required, applied with so much attention and judgment, could not fail of producing the most lucrative effects. The result is, that, from a small original capital, their respective families are now enjoying landed property to the amount of nearly 4000*l.* a year each (besides a very large sum invested in farming), the well merited reward of unremitting industry and extensive agricultural knowledge. In 1786, Mr. George Culley published his *Observations on Live Stock*, which was the first treatise on the subject that attempted to describe the domesticated animals of Britain, and the principles by which they may be improved. The great merits of this work are evinced by the number of editions it has gone through. In 1793, Mr. G. Culley, in conjunction with Mr. Bailey of Chillingham, drew up the *Agricultural Reports for Durham and Northumberland*, and in 1813 he died at Fowberry Tower, the seat of his son, in the 79th year of his age. (*Farmer's Mag.* vol. xiv. p. 274.)

790. *Merino sheep* were first brought into England in 1788, when His Majesty procured a small flock by way of Portugal. In 1791, another flock was imported from Spain. In 1804, when His Majesty's annual sales commenced, this race began to attract much notice. Dr. Parry, of Bath, has crossed the Ryeland, or Herefordshire sheep, with the merinos, and brought the wool of the fourth generation to a degree of fineness not excelled by that of the pure merino itself; while the carcass, in which is the great defect of the merinos, has been much improved. Lord Somerville, and many other gentlemen, have done themselves much honour by their attention to this race; but it does not appear that the climate of Britain, the rent of land, and the love of good mutton, admit of substituting it for others of native origin. (*Encyc. Brit.* art. *Agr.*)

791. *The agriculture of Scotland*, as we have seen, was in a very depressed state at the revolution, from political circumstances. It was not less so in point of professional knowledge. Lord Kaimes, that excellent judge of mankind and sound agriculturist, declares, in strong terms, that the tenantry of Scotland, at the end of the seventeenth and beginning of the eighteenth century, were so benumbed with oppression or poverty, that the most able instructor in husbandry would have made nothing of them. Fletcher of Saltoun, who lived in the best part of Scotland, and in the end of the seventeenth century, describes their situation as truly deplorable.

792. *John Cockburn, of Ormiston, East Lothian, a spirited individual*, who rose at this time, and to whom the agriculture of Scotland is much indebted, deserves to be mentioned. He was born in 1685, and succeeded to the family estate of Ormiston in 1714. He saw that internal improvement could only be effected by forming and extending a middle rank of society, and increasing their prosperity. In fact, as an able writer, Brown, the founder of the *Farmer's Magazine*, has remarked, "the middling ranks are the strength and support of every nation." In former times, what we now call middling classes were not known, or at least little known in Scotland, where the feudal system reigned longer than in England. After trade was introduced, and agriculture improved, the feudal system was necessarily overturned; and proprietors, like other men, began to be estimated according to their respective merits, without receiving support from the adventitious circumstances under which they were placed.

793. In 1723, a number of landholders, at the instigation of Mr. Cockburn, formed themselves into a *Society of Improvers in the Knowledge of Agriculture in Scotland*. The Earl of Stair, one of their most active members, is said to have been the first who cultivated turnips in that country. This society exerted itself in a very laudable manner, and apparently with considerable success, in introducing cultivated herbage and turnips, as well as in improving on the former methods of culture: but there is reason to believe, that the influence of the example of its members did not extend to the common tenantry, who are always unwilling to adopt the practices of those who are placed in a higher rank, and supposed to cultivate land for pleasure, rather than profit. Though this society, the earliest in the united kingdom, soon counted upwards of three hundred members, it existed little more than twenty years. Maxwell delivered lectures on agriculture for one or two sessions at Edinburgh, which, from the specimens he has left, ought to have been encouraged.

794. *Draining, enclosing, summer-fallowing; sowing flax, hemp, rape, turnip, and grass seeds; planting cabbages after and potatoes with the plough, in fields of great extent*, are practices which were already introduced: and, according to the general opinion, more corn was now grown where it was never known to grow before, than, perhaps, a sixth of all that the kingdom used to produce at any former period. It is singular that though the practice of summer-fallowing seems to have prevailed in England since the time of the Romans, yet it was neglected in Scotland till about the beginning of the eighteenth century, when it was first practised by John Walker, tenant at Beanston, in East Lothian. The late Lord Milton considered this improvement of so much importance, that he was

“eager to procure the erection of a pillar to the memory of Mr. Walker.” (*Farm. Mag.*, vol. i. p. 164.)

795. *The first notice of a threshing machine* is given by Maxwell, in his *Transactions of the Society of Improvers, &c.*; it was invented by Michael Menzies, advocate, who obtained a patent for it. Upon a representation made to the society, that it was to be seen at work in several places, they appointed two of their number to inspect it; and in their report they say that one man would be sufficient to manage a machine which would do the work of six. One of the machines was “moved by a great water wheel and treddles;” and another, “by a little wheel of three feet in diameter, moved by a small quantity of water.” This machine the society recommended to all gentlemen and farmers. (*Encyc. Brit. and Ed. Encyc. art. Agr.; Brown’s Treatise on Rural Affairs, Introduction, &c.*)

796. *Dawson, of Frogden, in Rosburghshire*, is a man to whom Scottish agriculture is perhaps more indebted than to any other. Findlater, the author of the *Survey of Peeblesshire*, one of the best judges, terms him the “father of the improved system of husbandry in Scotland.” Dawson was born at Harperton, in Berwickshire, a farm of which his father was tenant, in 1734. At the age of 16 he was sent to a farm in the neighbourhood of Sheffield, and thence into Essex, where he directed his attention chiefly to grazing. He afterwards travelled through several other counties of England, “accurately examining the best courses of husbandry, and storing up for his own use whatever seemed likely to be introduced with advantage into his own country.” On his return to Scotland he tried, with the consent of his father, the culture of turnips on the farm of Harperton, but he did not commence the culture of this root upon a large scale until he entered on the farm of Frogden on his own account in 1759. Great exertions were required in enclosing, draining, liming, and manuring the arable part of this farm; but the soil being sandy, the expense was ultimately more than repaid. It was here that Mr. Dawson perfected the drill-system of cultivating turnips, but not before he had grown them for several years in the broadcast manner. The first drills were drawn in the year 1763, and the extent of turnip crop was about 100 acres annually. In a few years the success which attended Mr. Dawson’s management enabled him first to rent two contiguous farms, and afterwards to purchase and improve, in that county, the estate of Gracoe, a property of considerable extent, adjoining Frogden. On these lands he introduced and exemplified, for the first time in Scotland, what has been called the convertible husbandry; i. e. the growth of clover and sown grasses for three or more years in succession, alternately with corn crops and turnips.

797. *Mr. Dawson was the first to introduce to Scotland the practice of ploughing with two horses abreast without the aid of a driver.* The first ploughman who effected this was James McDougal, who, after being 14 years overseer to Mr. Dawson, in 1778 took a farm of his own at West Linton, in Peeblesshire, where he died in 1822, aged 82 years. It was the desire of Mr. Dawson that justice should be done to the memory of this able and worthy man, whose example, as the Rev. Charles Findlater observes, has had more effect in diffusing the improved system of husbandry than all the premiums ever given by landlords. (*Douglas’s Surv. of Roxb.; Farm. Mag.*, vol. xiii. p. 512.) Mr. Dawson spent the last years of his life in Edinburgh, where he died in January, 1815, in his 81st year, leaving a numerous family in prosperous circumstances.

798. *The character of Dawson* is thus given by his biographer in the *Farmer’s Magazine*, and may well be quoted here as a model for imitation. “He was exceedingly regular in his habits, and most correct and systematical in all his agricultural operations, which were not only well conducted, but always executed at the proper season. His plans were the result of an enlightened and sober calculation; and were persisted in, in spite of every difficulty and discouragement, till they were reduced to practice. Every one who knows the obstacles that are thrown in the way of all innovations in agriculture, by the sneers of prejudice and the obstinacy of ignorance, and not unfrequently by the evil offices of jealousy and malevolence, must be aware, that none but men of very strong minds, and of unceasing activity, are able to surmount them. Such a man was Mr. Dawson; and to this single individual may be justly ascribed the merit of producing a most favourable change in the sentiments, in regard to the trial of new experiments, as well as in the practice, of the farmers of Scotland. The labouring classes were not less indebted to this eminent person for opening up a source of employment, which has given bread to the young and feeble in almost the only branches of labour of which they are capable in merely rural districts. Most of his servants continued with him for many years; and such as had benefited by his instructions and advice were eagerly engaged to introduce their master’s improvements in other places. This benevolence, which often sought for objects at a distance that were not personally known to him, was displayed, not only in pecuniary donations, while the giver frequently remained unknown, but was strikingly evinced in the attention which he paid to the education of the children of his labourers, for whom he maintained teachers at his own expense. If fame were always the reward of great and useful talents, there are few men of any age or country that would live longer in the grateful remembrance of posterity than the subject of this memoir.” (*Farm. Mag.*, vol. xvi. p. 168.)

799. *As the leading features of practical agricultural improvement in Britain during the eighteenth century*, and to the present time, we may enumerate the following:—The gradual introduction of a better system of rotation since the publication of Tull’s *Horse-hoeing Husbandry*, and other agricultural works, from 1700 to 1750; the improvement of live stock by Bakewell, about 1760; the raised drill system of growing turnips, the use of lime in agriculture, and the convertible husbandry, by Pringle, and more especially by Dawson, about 1765; the improved swing plough, by Small, about 1790; and the improved threshing machine, by Meikle, about 1795. As improvements of comparatively limited application might be mentioned, the art of tapping springs, or what has been called Elkington’s mode of draining, which seems to have been discovered by Dr. Anderson, from principle, and Mr. Elkington, by accident, about 1760, or later; and the revival of the art of irrigation, by Boswell, about 1780. The field culture of the potato, shortly after 1750; the introduction of the Swedish turnip, about 1790; of spring wheat, about 1795; of summer wheat, about 1800; and of mangold wurtzel more recently, have, with the introduction of other improved field plants, and improved breeds of animals, contributed to increase the products of agriculture; as the enclosing of common field lands and wastes, and the improvements of mosses and marshes, have contributed to increase the produce and salubrity of the general surface of the country.

*800. *The progress of the taste for agriculture in Britain* is shown by the great number of societies that have been lately formed; one or more in almost every county, for the diffusion of knowledge, and the encouragement of correct operations and beneficial discoveries. Among these, the *Bath and West of England Society*, established in 1777, and the *Highland Society of Scotland*, in 1784, hold the first rank. The establishment of the Board of Agriculture, in 1793, ought to have formed a new era in the history of the agriculture and rural economy of Britain; but it effected little beyond the publication of the County Agricultural Surveys, and, to a certain extent, rendering the art fashionable among the higher classes.

SECT. III. *Of the Literature of British Agriculture from the Revolution to the present Time.*

*801. *The literature of English agriculture from the revolution* is rich in excellent works. We have already, in detailing the professional improvements, noticed the writings of Morimer and Tull. To these we now add the numerous works of Bradley, which appeared from 1717 to his death in 1732. They are all compilations, but have been of very considerable service in spreading a knowledge of culture, and a taste for rural improvement. Stephen Switzer, a seedsman in London, in 1729; Dr. Blackwell, in 1741; and Hiitt, a few years afterwards, published tracts recommending the burning of clay as manure, in the manner recently done by Governor Beatson, of Suffolk; Craig, of Cally in Kircudbrightshire, and some others. Lisle's useful *Observations on Husbandry* were published in 1757; Stillingfleet's *Tracts*, in which he shows the importance of a selection of grasses for laying down lands, in 1759; and the excellent *Essays* of Harte, canon of Windsor, in 1764. The celebrated Arthur Young's first publication on agriculture, entitled, *The Farmer's Letters to the People of England, &c.*, appeared in 1767; and was followed by a great variety of excellent works, including the *Tour in France*, and the *Annals of Agriculture*, till his pamphlet on the utility of the Board of Agriculture, in 1810. Marshall's numerous and most superior agricultural works commenced with his *Minutes of Agriculture*, published in 1787, and ended with his *Review of the Agricultural Reports*, in 1816. Dr. R. W. Dickson's *Practical Agriculture* appeared in two quarto volumes, in 1806, and may be considered as giving a complete view of the present state of agriculture at the time. The last general work we shall mention is the *Code of Agriculture*, by Sir John Sinclair, which may be considered as a comprehensive epitome of the art of farming. It has already been translated into several foreign languages, and passed through more than one edition in this country. In this sketch a great number of useful and ingenious authors are necessarily omitted; but they will all be found in their places in the *Literature of British Agriculture*, given in the Fourth Part of this work.

802. *The Scottish writers on agriculture* confirm our view of the low state of the art in that country in the beginning of the eighteenth century. The first work, written by James Donaldson, was printed in 1697, under the title of *Husbandry Anatomised; or, an Enquiry into the present Manner of Teiling and Manuring the Ground in Scotland*. It appears from this treatise that the state of the art was not more advanced at that time in North Britain, than it had been in England in the time of Fitzherbert. Farms were divided into *infield* and *outfield*; corn crops followed one another, without the intervention of fallow, cultivated herbage, or turnips, though something is said about fallowing the outfield; enclosures were very rare; the tenantry had not begun to emerge from a state of great poverty and depression; and the wages of labour, compared with the price of corn, were much lower than at present; though that price, at least in ordinary years, must appear extremely moderate in our times. Leases for a term of years, however, were not uncommon; but the want of capital rendered it impossible for the tenantry to attempt any spirited improvements.

803. *The Countryman's Rudiments; or, an Advice to the Farmers in East Lothian how to labour and improve their Grounds*, said to have been written by Lord Bellhaven, about the time of the union, and reprinted in 1723, is the next work on the husbandry of Scotland. In this we have a deplorable picture of the state of agriculture, in what is now the most highly improved county in Scotland. His Lordship begins with a very high encomium on his own performance. "I dare be bold to say, there never was such a good, easy method of husbandry as this, so succinct, extensive, and methodical in all its parts, published before." And he bespeaks the favour of those to whom he addresses himself, by adding, "neither shall I afflict you with hedging, ditching, marling, chalking, paring and burning, draining, watering, and such like, which are all very good improvements indeed, and very agreeable with the soil and situation of East Lothian; but I know ye cannot bear as yet such a crowd of improvements, this being only intended to initiate you in the true method and principles of husbandry." The farm lands in East Lothian, as in other districts, were divided into infield and outfield, the former of which got all the dung. "The infield, where wheat is sown, is generally divided by the tenant into four divisions or breaks, as they call them, viz. one of wheat, one of barley, one of peas, and one of oats; so that the wheat is sowed after the peas, the barley after the wheat, and the oats after the barley. The outfield land is ordinarily made use of promiscuously for feeding their cows, horses, sheep, and oxen: it is also dunged by their sheep, who lay in earthen folds; and sometimes, when they have much of it, they fanch or fallow part of it yearly." Under this management, the produce seems to have been three times the seed; "and yet," says His Lordship, "if in East Lothian they did not leave a higher stubble than in other places of the kingdom, their grounds would be in a much worse condition than at present they are, though bad enough. A good crop of corn makes a good stubble, and a good stubble is the equallest

mucking that is." Among the advantages of enclosures, he observes, "you will gain much more labour from your servants, a great part of whose time was taken up in gathering thistles, and other garbage, for their horses to feed upon in their stables; and thereby the great trampling and pulling up, and other destruction of the corns, while they are yet tender, will be prevented." Potatoes and turnips are recommended to be sown in the yard (kitchen-garden). Clover does not seem to have been known. Rents were paid in corn; and, for the largest farm, which he thinks should employ no more than two ploughs, the rent was "about six chalders of victual, when the ground is very good, and four in that which is not so good. But I am most fully convinced they should take long leases or tacks, that they may not be straitened with time in the improvement of their rooms (farms); and this is profitable both for master and tenant."

804. Maxwell's *Select Transactions of the Society of Improvers of the Knowledge of Agriculture in Scotland* was published in 1743 (see 793.), and his *Practical Husbandman*, in 1757, including an *Essay on the Husbandry of Scotland*. In the latter he lays it down as a rule, that it is bad husbandry to take two crops of grain successively, which marks a considerable progress in the knowledge of modern culture; though he adds that, in Scotland, the best husbandmen after a fallow take a crop of wheat; after the wheat, peas, then barley, and then oats; and after that they fallow again. The want of enclosures was still a matter of complaint. The ground continued to be cropped so long as it produced two seeds for one; the best farmers were contented with four seeds for one, which was more than the general produce. In 1765, *A Treatise on Agriculture* was published by the Rev. Adam Dickson, minister of Dunse, in Berwickshire, which was decidedly the best work on tillage which had then appeared in the English language, and is still held in esteem among the practical farmers of Scotland. In 1777, Lord Kames published *The Gentleman Farmer*, being an attempt to improve agriculture by subjecting it to the test of rational principles. His Lordship was a native of Berwickshire; and had been accustomed to farm in that country for several years, and afterwards at Blair Drummond, near Stirling. This work was in part a compilation, and in part the result of his observation; and was of essential service to the cause of agriculture in Scotland. In 1778, appeared Wight's *Present State of Husbandry in Scotland*. This is a valuable work; but the volumes not appearing but at intervals of some years, it was of less benefit than might have been expected. In 1783, Dr. Anderson published his *Essays relating to Agriculture and rural Affairs*: a work of science and ingenuity, which did much good both in Scotland and England. In 1810, appeared *The Husbandry of Scotland*, and, in 1815, *The General Report of the Agricultural State and Political Circumstances of Scotland*, both by Sir John Sinclair, and excellent works. *The Code of Agriculture*, by the same patriotic and indefatigable character, has been noticed as belonging to English publications on agriculture. (801.)

805. *Agricultural Periodicals*. — *The Farmer's Magazine*; a quarterly work, exclusively devoted to agriculture and rural affairs, was commenced in 1800, and has done more to enlighten both the proprietors and tenantry of Scotland than any other book which has appeared. It was at first conducted jointly by Robert Brown, farmer of Markle; and Robert Somerville, M. D. of Haddington. Afterwards, on Dr. Somerville's death, by Brown alone; and subsequently, on the latter gentleman's declining it, by James Cleghorn, one of the most scientific agriculturists of Scotland. The frequent recurrence that will be made to *The Farmer's Magazine* in the course of this work, will show the high value which we set on it. In November 1825, this work terminated with the 26th volume, and has since been succeeded by *The Farmer's Register and Monthly Magazine*, and *The Quarterly Journal of Agriculture*, in Scotland; and by *The British Farmer's Magazine* in England. *The Farmer's Journal* is the first agricultural newspaper which appeared in Britain; it was commenced in 1808, and is still continued. *The Irish Farmer's Journal* was commenced in 1812, but discontinued for want of patronage in 1827. The names and writings of all the British agricultural authors, with abridged biographies of all such as could be procured, will be found in chronological order in Chap. IV. of Book I. of Part IV. of this work. (See *Contents or Index*.)

806. *A professorship of agriculture* was established in the university of Edinburgh, in 1790, and the professor, Dr. Andrew Coventry, is well known as a man of superior qualifications for fulfilling its duties. Professorships of agriculture, and even of horticulture, or rather of culture in general, are said to be partly provided for, and partly in contemplation, both in Oxford and Cambridge. The professor of botany in the London University, John Lindley, in the Prospectus of his Lectures, announces "the application of the laws of Vegetable Physiology to the arts of Agriculture and Horticulture."

SECT. IV. *Of the Rise, Progress, and present State of Agriculture in Ireland.*

807. *Of the agriculture of Ireland* very little is known up to a recent period. With a soil singularly prolific in pasture, and rather humid for the easy management of grain, it is probable that sheep and cattle would be the chief rural products for many centuries. In the twelfth century and earlier, various religious establishments were founded, and then it is most probable tillage on something like the Roman mode of culture would be introduced. The monks, says O'Connor, fixed their habitations in deserts, which they cultivated with their own hands, and rendered them the most delightful spots in the kingdom.

808. *During the thirteenth, fourteenth, and fifteenth centuries*, the English were obliged to suppress the numerous rebellions of their Irish subjects by war, and the forfeited estates of the rebels would in part be divided among the troops. This might end in introducing some agricultural improvements; but there is no evidence that such was effected before the time of Elizabeth, when the enormous demesnes of the Earl of Desmond were forfeited, and divided amongst a number of English undertakers, as they were called, who entered into a stipulation to plant a certain number of English families

on their estates, in proportion to the number of acres. Among others who received portions were, Sir Walter Raleigh, and Spenser, the poet. The former is said to have then introduced the potato.

809. *The reign of James I.* was one of comparative tranquillity for Ireland: the power of the judges, and of the English government, was extensively fixed; the Irish laws and customs were abolished, and the English laws were established in all cases without exception, through the whole island. Numerous colonies were also sent from England and Scotland, especially the latter, to occupy the forfeited estates; and seven northern counties were wholly allotted to undertakers. This was called the "plantation of Ulster," and was attended by the introduction of an improved agriculture, and by the linen manufacture, which is still carried on by the descendants of the first colonists in the same counties.

810. *The city of London participated in this distribution of land.* The corporation having accepted of large grants in the county of Derry, they engaged to expend 20,000*l.* on the plantation; to build the cities of Derry and Colerain, and at the same time stipulated for such privileges as might make their settlement convenient and respectable. Under a pretence of protecting this infant settlement, or perhaps with a view of raising money, the king instituted the order of Irish baronets, or knights of Ulster; from each of whom, as was done in Scotland with respect to the knights of Nova Scotia, he exacted a certain sum, as the price of the dignity conferred. (*Wakefield.*)

811. *Of the husbandry of Londonderry* a curious account was published about a century ago, by the archbishop of Dublin. He states that there was little wheat grown, and that of very inferior quality; the soil being considered as unsuitable to its production. Potatoes remained three or four years in the ground, reproducing a crop, which at the best was a very deficient one. Lime was procured by burning sea shells. The application of them in an unburnt state arose from accident. A poor curate, destitute of the means for burning the sea shells which he had collected, more with a view to remove an evidence of his poverty, than in any hope of benefit, spread them on his ground. The success which attended the experiment occasioned surprise, and insured a rapid and general adoption of the practice. (*Wakefield.*) The improvements made since the period of which the archbishop treats, Curwen remarks, are undoubtedly very considerable: and whilst we smile at the very subordinate state of agriculture at that time, may we not on reasonable ground expect that equal progress will at least be made in this century as in the last? (*Letters on Ireland*, vol. ii. p. 246.)

812. *A considerable impulse was given to the agriculture of Ireland after the rebellion of 1641*, which was quelled by Cromwell, as commander of the parliamentary army in 1652. Most of the officers of this army were yeomen, or the sons of English country gentlemen; and they took pleasure in instructing the natives in the agricultural practices to which they were accustomed at home. Afterwards, when Cromwell assumed the protectorship, he made numerous grants to his soldiers, many of whom settled in Ireland; and their descendants have become men of consideration in the country. Happily these grants were confirmed at the restoration. Some account of the state of culture in that country at this time, and of the improvements which it was deemed desirable to introduce, will be found in *Hartlib's Legacy*.

813. *The establishment of the Dublin Society in 1749* gave the next stimulus to agriculture and general industry in Ireland. The origin of the Dublin Society may be dated from 1731, when a number of gentlemen, at the head of whom was Prior of Rathdowney, Queen's county, associated themselves together for the purpose of improving the agriculture and husbandry of their country. In 1749, Prior, through the interest of the then lord-lieutenant, procured a grant of 10,000*l.* per annum, for the better promotion of its views. Miss Plumtree considers this the first association ever formed in the British dominions expressly for such purposes; but the Edinburgh Agricultural Society, as we have seen (793.), was founded in 1723.

814. *Arthur Young's Tour in Ireland* was published in 1780, and probably did more good than even the Dublin Society. In this work he pointed out the folly of the bounty on the inland carriage of corn. His recommendation on this subject was adopted; and, according to *Wakefield*, "from that hour may be dated the commencement of extended tillage in Ireland." (*Wakefield's Statistical Account; Curwen's Letters.*)

815. *The state of agriculture of Ireland, in the beginning of the present century*, is given with great clearness and ability in the supplement to the *Encyclopædia Britannica*; and from that source we have selected the following condensed account:—

816. *The climate of Ireland* is considerably more mild than that of England, and the southern and western part of the island greatly more so than the northern. The difference in this respect, indeed, is greater than can be explained by the difference of latitude; and is probably owing to the immediate vicinity of the western ocean. On the mountains of Kerry, and in Bantry Bay, the arbutus and some other shrubs grow in great luxuriance, which are not to be met with again till the traveller reaches the Alps of Italy. The

snow in these parts of the island seldom lies for any time, and frost hardly ever continues beyond a few days, and while it lasts it is by no means intense. The mildness and humidity of the atmosphere produce a luxuriance and rapidity of growth in vegetation, to which no other part of the empire can afford any parallel; and this appears in the most remarkable manner in the ivy, and other evergreens, with which the kingdom abounds. These are not only much more plentiful, but far more luxuriant, and of much quicker growth, than in the most favoured parts of Great Britain. To those who are accustomed to the dry weather of this island, the continued rains of the south and west of Ireland are extremely disagreeable; but it is to this peculiarity in their climate, that the Irish have to attribute the richness of their pasturage, an advantage which, coupled with the remarkable dryness and friability of the soil, points, in an unequivocal manner, to a rotation of crops, in which grazing should occupy a principal place.

817. *The territorial surface of Ireland* affords a pleasing variety, consisting in some parts of rich and fertile plains, in others of little hills and acclivities, which succeed one another in frequent succession. The most elevated ground is to be found in the bog of Allan. Its height above the sea does not exceed 270 feet, yet, from this ridge, the waters of the rivers run to the different seas. This elevated ground is connected with the principal mountains of Ireland, diverging in the north from the hills of Tyrone, and leading in the south to those of Sleeve Bloom and the Galtees. The chains of mountains are neither numerous nor considerable; the most remarkable are, the Kerry mountains, those of Wicklow, the Sleeve Bloom chain between the King's and Queen's county, and the mountains of Mourne, in the south of the province of Ulster.

818. *The soil of Ireland* is, generally speaking, a fertile loam, with a rocky substratum; although there are many exceptions to this description, and many varieties. Generally speaking, it is rather shallow; to which cause the frequent appearance of rocks near the surface, or at no considerable depth, is to be attributed. It possesses a much greater proportion of fertile land, in proportion to its extent, than either England or Scotland. Not only is the island blessed with this extent of cultivable ground, but it is almost all of such a quality as to yield luxuriant crops, with little or no cultivation. Sand does not exist except on the sea shore. Tenacious clay is unknown, at least near the surface. Great part of the land of Ireland throws up a luxuriant herbage, without any depth of soil, or any skill on the part of the husbandman. The county of Meath, in particular, is distinguished by the richness and fertility of its soil; and, in Limerick and Tipperary, there is a dark, friable, sandy loam, which, if preserved in a clean state, will yield crops of corn several years in succession. It is equally well adapted for grazing as for arable crops, and seldom experiences either a winter too wet, or a summer too dry. The vales in many of the bleakest parts of the kingdom, as Donegal and Tyrone, are remarkable for their richness of soil and luxuriance of vegetation, which may be often accounted for by the deposition of the calcareous soil, washed down by the rains of winter, which spreads the richest manure over the soil below, without subjecting the farmer to any labour. (*Wakefield*, i. 79, 80.)

819. *The bogs, or peat mosses, of Ireland*, form a remarkable feature of the country, and have been proved by the parliamentary commissioners to be of great extent. They estimate the whole bogs of the kingdom at 2,330,000 acres, English. These bogs, for the most part, lie together. In form, they resemble a great broad belt, drawn across the centre of Ireland, with its narrowest end nearest to the capital, and gradually extending in breadth as it approaches the western ocean. The bog of Allan is not one contiguous morass, but this name is indiscriminately applied to a great number of bogs, detached from each other, and often divided by ridges of dry country. These bogs are not, in general, level, but most commonly of an uneven surface, swelling into hills, and divided by valleys, which afford the greatest facility to their being drained and improved. In many places, particularly in the district of Allan, the rivulets which these inequalities of surface produce have worn their channels through the substance of the bog, down to the clay or limestone gravel beneath; dividing the bog into distinct masses, and presenting, in themselves, the most proper situations for the main drains, for which purpose, with the assistance of art, they may be rendered effectual.

820. *The commissioners employed by government to report on the bogs of Ireland* found three distinct growths of timber immersed below three distinct strata of bog. The timber was perfectly sound, though deprived of its bark, which has communicated its antiputrescent quality to the water, and of course has preserved every thing embedded in the mass; though, as Miss Plumtree remarks, without "any thing like a process of tanning ever taking place." The bogs of Ireland are never on low ground, and have therefore evidently originated from the decay of woody tracts. (*Plumtree's Residence in Ireland*.)

821. *Landed property in Ireland* is more generally in large estates of some thousands of acres, than in small ones; but in its occupation it is subdivided in a degree far beyond any thing which occurs in any other part of the empire. In some counties, as Mayo for example, there are upwards of 15,000 freeholders on properties of not more than 40s.

value, and who are perhaps not worth 10*l.* each. These are, for the most part, tenants of the great proprietors, possessing a life interest in their little farm.

822. *In Ireland there are no manorial rights* separable from the right to the soil, as in England, nor legal poor rates, which are circumstances materially in favour of the former country. (*Wakefield*, i. 242.)

823. *Leases are generally of long endurance*; and three lives, or thirty-one years, is a common rate. The price of land varies in different parts of Ireland. In the neighbourhood of Belfast, and thence to Armagh, it brings thirty years' purchase; in the greatest part of the island it does not exceed twenty; and, in the richest districts, it may often be bought for sixteen or eighteen. The exposure of landed estates to public sale takes place very seldom, which is, perhaps, one cause of their not bringing so high a price as they would otherwise do. (*Wakefield*.)

824. *Farming in Ireland* is, generally speaking, in a very backward state. With a few exceptions, such as the county of Meath, and some other well cultivated districts, the farmers are destitute of capital, and labour small crofts, which they hold of middlemen interposed between them and the landlord. The fact that in Ireland the landlord never lays out any thing upon repairs or buildings, coupled with the general inability of the farmer to do either in a substantial manner, is very significant as to the state of agriculture. (*Tighe's Survey of Kilkenny*, 412.; *Wakefield*, i. 244.) But the worst features of the rural economy of this island are the entire want of capital in the farmers, and the complete indifference of the landlord to the character, wealth, or industry of his tenant. "Capital," says Wakefield, "is considered of so little importance in Ireland, that advertisements constantly appear in the newspapers, in which it is stated, that the preference will certainly be given to the highest bidder. Bargains are constantly made with a beggar, as a new tenant, who, offering more rent, invariably turns out the old one, however industrious."

825. *The rent of land in Ireland* from these causes, coupled with the excessive competition of the peasantry for small farms, as their only means of subsistence, has risen to a great height. (*Townsend's Cork*, 218.; *Wakefield*, i. 582.)

826. *Ireland is divided, by Wakefield, into nine agricultural districts*, in each of which the mode of culture is somewhat different from what it is in the others.

827. *The first district* comprehends the flat parts of Antrim; the eastern side of Tyrone, Down, Armagh, Monaghan, and Cavan. Throughout this district, the farms are extremely small, and the land is generally dug with a spade. Potatoes, flax, and oats are the crops usually cultivated, and these are grown till the land is exhausted, and suffered to "lie at rest," as they term it, till its strength is recruited by the cow, the goat, two or three sheep, and the poultry lying upon it for some years. The ploughs used in this district are of the rudest structure, and perform their work in the most slovenly manner. Three or four neighbours unite their strength to each plough, every one bringing his horse, his bullock, or his cow. All the other operations of agriculture are performed in an equally slovenly manner. The little wheat that is raised is "lashed," as they call it; that is, the grain is knocked out by striking the sheaf across a beam placed above a cloth; it is, however, afterwards threshed with a flail. The operation of threshing usually takes place in the highway, and it is dressed by letting it fall from a kind of sieve, which, during a pretty strong wind, is held breast-high by a woman. Many cottiers in this district have a cabin with no land attached to it. They hire an acre or two, for grass or potato land, from some cottier in their vicinity. The custom of hiring labourers is unknown. The neighbours all assist each other in their more considerable occupations, such as sowing and reaping. The dwellings here are miserably small; in fact too small to contain the numerous families that issue from their doors. Land is every where divided into the most minute portions. (*Wakefield*, i. 363.; *Dubourdieu's Down*, 39.)

828. *Under the second district* may be comprised the northern part of Antrim, Londonderry, the north and west of Tyrone, and the whole of Donegal. Agriculture here is in a worse state than in the preceding district. There is no clover, and hardly any wheat.

829. *The third district* comprehends the northern parts of Fermanagh. Here the farms are much larger than in the former, and the agricultural system pursued far superior. They plant potatoes on a lea, twice reversing the lands; and flax, oats, and weeds constitute the course. Some wheat is grown, but oats still form the prevalent crop. In the neighbourhood of Enniskillen, the farmers are so rich as to be able to eat butcher's meat daily, and drink smuggled wine. (*Wakefield*, i. 373.)

830. *The fourth district* comprehends Sligo, Mayo, Galway, Clare, and parts of Roscommon, and Longford. In some parts of this district the spade culture is pursued; but, in general, the land is cultivated by a plough drawn by four horses abreast. In Roscommon, the old custom of yoking the horses by the tail is still continued; although, as early as 1634, an act of parliament was passed against this absurd practice. (*Life of the Duke of Ormond*, i. 79.) Oats are chiefly raised in this district, and, along the coast, barley is cultivated. A large portion of the rent depends on the illegal distilleries, and much of the district is let on lease to several persons jointly, according to the village system. (*Ibid.*, i. 381.)

831. *In the fifth district*, which comprehends Limerick, Kerry, the south side and northern part of Cork, and the county of Waterford, cultivation is in a very rude state; little corn is grown here, with the exception of the southern part of Cork. Land is extremely divided, and the farms very small. The greater part is a grazing country. (*Ibid.*, i. 387.)

832. *The sixth district* includes the southern parts of Cork. The spade culture is here almost universal, and the farms unusually small. Hogs constitute the main support of the poor. (*Townsend's Cork*, 194.)

833. *The seventh district* includes part of Tipperary, with Queen's county and King's county. The best farming in Ireland is observable in this district; a systematic course of husbandry being pursued, by which the land is kept in good heart. Oxen and horses are used in the plough, and hedgerows and good wheat fallows are to be seen. Near Roscrea the cultivation of turnips is followed, and they succeed well. Ninety acres are considered a large farm. Leases are generally for three lives. (*Wakefield*, i. 398.)

834. *The eighth district* comprises Wexford and a part of Wicklow. Beans are here sometimes introduced into cultivation, but they are sown broadcast, and never hoed. The mode of ploughing is very awkward; one man holds the plough, another leads the horse, and a third sits on it to keep it down. Notwithstanding this rude culture, however, the rents are enormous, owing to the demand for land created by an excessive population, who, if they had not a portion of land to grow potatoes (getting no employment), could not live. (*Ibid.*, i. 407.)

835. *The north district* comprehends the northern part of Kilkenny, Kildare, the cultivated parts of Westmeath, Meath, and Louth. Wheat here enters into the system of culture, but the preparatory fallows are very bad. Clover has been introduced into the district, but under the bad system of sowing it upon land exhausted, and covered by weeds. Farms are large, and the mode of culture similar to what is pursued in England, though the details are executed in a slovenly manner. (*Ibid.*, i. 413.)

836. *The agricultural implements and operations* used in Ireland are all of the rudest construction. The plough, the spade, the flail, the car, all equally partake of imperfections and defects. The fallows are not well attended to; three ploughings are usually deemed sufficient, and, from the imperfection of the plough, the ground at the end is generally full of weeds. Trenching land is very general; they form it into beds, and shovel out a deep trench between them, throwing up the earth. The expense of this operation is about eight shillings an acre. Wheat, as will be seen from the preceding details, is not by any means generally cultivated. It is unknown in Monaghan, Tyrone, Derry, Donegal, Sligo, Mayo, Leitrim, and Cavan, though it is grown to a considerable extent in Kilkenny, Carlow, Dublin, Meath, Louth, and parts of Limerick, Tipperary, Clare, and Cork. It is generally sown after potatoes or fallow. The Irish wheat is, for the most part, coarse and of inferior quality, and does not yield so much saccharine matter by twenty per cent, as the English. (*Ibid.*, i. 429. 442.)

837. *Barley is more generally cultivated in Ireland than wheat*, and it is generally sown after potatoes. Oats, however, constitute the species of grain most extensively raised; it is calculated that, throughout the whole kingdom, there are ten acres of oats sown for one of any other species of corn. The Irish oats, however, are decidedly inferior to the English.

838. *The potatoes of Ireland* have long been celebrated, both on account of their quantity and excellent qualities: they are cultivated on every species of soil, either in drills or lazy beds. Potato land lets from six pounds six shillings to ten pounds ten shillings per acre; and the expense of culture, including rent, varies from thirteen pounds to sixteen pounds per acre. The produce is from eight hundred stone to one thousand stone the acre, at twenty-one pounds to the stone; that is, from sixteen thousand eight hundred to twenty-one thousand pounds. (*Ibid.*, i. 450.)

839. *The indigenous grasses of Ireland* are not of any peculiar excellence. Notwithstanding all that has been said of the florin grass, its excellence and utility may be called in question. Their hay is seldom from sown grasses, generally consisting of the spontaneous produce of the soil. Clover is almost unknown. Newenham calculates that there are not five thousand acres under this crop in the whole island. (*Newenham*, 314.; *Wakefield*, i. 467.)

840. *There are few live hedges in Ireland*; in the level stone districts, stone walls, and in other places turf banks, are the usual fences.

841. *The dairy is the most extensive and the best managed part of Irish husbandry.* Kerry, Cork, Waterford, Carlow, Meath, Westmeath, Longford, and Fermanagh, as well as the mountains of Leitrim and Sligo, are principally occupied by dairy farms. Butter is the chief produce. The average number of cows on a dairy farm amounts to thirty or forty; three acres of land, of middling quality, are deemed necessary for the subsistence of each cow. A cow produces on an average eight quarts in twenty-four hours in summer, and five in winter; four good milkers will yield a quarter of a cwt. of butter in a week. The best butter is made in Carlow; the worst in Limerick and Meath. Generally speaking, the Irish are very cleanly in making this article; and it is exported to England, the East and West Indies, and Portugal. (*Wakefield*, i. 325. et seq.) The art of salting butter, Chaptal observes, is better known in Ireland than in any other country. (*Chimie appliquée à l'Agriculture.*) The grazing of Ireland is not, as in England, a part of the regular rotation of crops, but is carried on in a country exclusively devoted to the breeding of cattle, like the highlands of Scotland. Great tracts of the country also are devoted to the grazing of sheep. Roscommon, Galway, Clare, Limerick, and Tipperary are the chief breeding counties for sheep; and Galway, Clare, Roscommon, Tipperary, and Meath are the places where they are fattened. The sheep are of the long-wooled kind, and very large: they are never kept in sheepfolds, and hardly ever fed on turnips; which is chiefly owing to the very limited demand for mutton among the labouring people. (*Ibid.*, i. 341.)

842. *The depressed state of the agriculture of Ireland* is considered as proceeding from the depressed state of the people. The main cause of their sufferings is traced by most writers (Young, Dewar, Newenham, Wakefield, Curwen, &c.) to the redundancy of population. In 1791, the population of the whole kingdom amounted to 4,200,000 persons, and it increases at the rate of one forty-sixth part per annum; or, in other words, it doubles itself every forty-six years. As might be expected in a country where the increase in the number of mankind has so far outstripped the progress of its wealth, and the increase of its industry, the condition of the people is in every department marked by extreme indigence. (*Dewar*, 91.; *Young*, ii. 123.) The houses in which they dwell, the furniture in their interior, their clothing, food, and general way of life, all equally

indicate the poverty of the country. The dress of the people is so wretched, that, to a person who has not visited the country, it is almost inconceivable. The Irish poor, indeed, have no conception of the comforts of life; and, if they felt their full value, they could not afford them, for though necessaries are cheap, conveniences of all sorts are very dear.

843. *But while the Irish poor are in general destitute of all the accommodations, they hardly ever, except in years of extraordinary distress, know what it is to want the absolute necessaries, of life.* The unsparing meal of potatoes, at which the beggar, the pig, the dog, the poultry, and the children seem equally welcome, seldom fails the Irish labourer.

844. *Hence the laziness of the lower Irish.* Limited as their wants are to the mere support of animal life, they do not engage in labour with that persevering industry which artificial desires inspire; and the mode in which they are often paid, that is, giving them a piece of potato land by the year, at once furnishes the means of subsistence, and takes away every stimulus to farther exertion. The farm-servants of the English or Scotch farmers, who carry on agriculture upon the improved system, are constantly employed in some species of labour; but, after the potatoes of the Irish cottier are planted, there is hardly any thing to be done about his little croft till the season of digging arrives. During a great portion of the year he is doomed to idleness, and the habits he acquires during the long periods of almost total inaction, are too strong to be overcome when he is transferred to a more regular occupation. Such is the condition of the labouring classes.

845. *Ireland exhibits an assemblage of the most contradictory circumstances.* It is a country in which, under the most distressing circumstances, population has advanced with the most rapid pace, in which cultivation has advanced without wealth, and education without diffusing knowledge; where the peasantry are more depressed, and yet can obtain subsistence with greater facility, than in any other country of Europe. Their miserable condition will not appear surprising, when the numerous oppressions to which they are subject are taken into consideration.

846. *In the foremost rank of their many grievances, the general prevalence of middlemen must be placed.* It is difficult to estimate the extent of the misery which the system of letting and subletting land has brought upon the Irish cultivators. Middlemen have, in every country, been the inseparable attendants of absent proprietors: and in such a country as Ireland, where there are numbers of disaffected persons in every quarter, the vigilant eye of a superior inspector is more particularly required.

847. *The system of under-letting lands often proves a great evil in Ireland.* By the law of England, the landlord is entitled to distrain for payment of rent, not only the stock which belongs to his immediate tenant, but the crop or stock of a subtenant; on the principle that whatever grows on the soil ought to be a security to the landlord for his rent: and in Scotland the same rule holds where the landlord has not authorised the subtenant; but if he has, the subtenant is free when he has paid to the principal tenant. There is little hardship in such a rule in England, where the practice of subletting is, generally speaking, rare; but when applied to Ireland, where middlemen are universal, it becomes the source of infinite injustice; for the cultivator being liable to have his crop and stock distrained on account of the tenant from whom he holds, and there being often many tenants interposed between him and the landlord, he is thus perpetually liable to be distrained for arrears not his own. The tenant, in a word, can never be secure, though he has faithfully paid his rent to his immediate superior; because he is still liable to have every thing which he has in the world swept off by an execution for arrears due by any of the many leaseholders, who may be interposed between him and the landlord. It is obvious that such a system must prevent the growth of agricultural capital: this, joined to the exactions of the middlemen, has been the true cause of the universal prevalence of the cottage system, and the minute subdivision of farms.

848. *The tithes in Ireland have long been collected with a severity of which hardly any European state furnishes an example.* This has arisen from the wealth and influence of the clergy, joined to the destitute situation of their parishioners. They fall, by the law of that country, only on the tillage land; the greater part of which is held by cottier tenants; and thus the rich are exempted from bearing their share of the burden.

849. *Another grievance, though not so extensive, is the fine imposed upon a township, for having had the misfortune to have a seizure for illicit distillation made within its bounds.*

850. *These evils have been attended with the usual depressing effects of oppression.* They have prevented the growth of any artificial wants, or any desire of bettering their condition, among the mass of the people. Despised by their superiors, and oppressed by all to whom they might naturally have looked for protection, the Irish have felt only the natural instincts of their being. Among the Presbyterians of the north, and the peasantry in the vicinity of manufacturing towns, who are to a certain extent educated, higher notions of comfort may have imposed some restraint on the principle of population; but the humiliated poor of other parts, enjoying no respectability or consideration

in society, have sought only the means of subsistence; and finding, without difficulty, potatoes, milk, and a hovel, have overspread the land with a wretched offspring.

851. *To these causes of a redundant population, of which the government of the country is, directly or indirectly, the source, are to be added others of a different kind.*

852. *The first is the influence of the parish priests, who encourage marriage, in order to increase their own emoluments, and the superstition of the people, who regard it as a religious duty.*

853. *The second cause is, the general ignorance of the people.*

854. *On the influence of education, in restraining the tendency to early and imprudent marriage, it would be superfluous in this place to enlarge.*

855. *Various other circumstances have combined to multiply to a great degree the facilities of population, and to expand, in this country, beyond almost any other, the means of subsistence.*

856. *The fertility of the country may be mentioned as one of the most obvious of these circumstances. The soil of Ireland is in general so rich, that it will yield an alternate crop of wheat and potatoes for ever, without any very great labour, and with little manure. The introduction of the potato, and its singular adaptation to the soil and climate of Ireland, are other concurring causes. An acre of potatoes, according to Newenham, will yield four times as much nourishment as one of wheat. By thus expanding the means of human subsistence, the potato has greatly promoted the population of Ireland; but as the able writer, from whom we have selected the above remarks, observes, "unless the people are predisposed, from other causes, to press upon the means of subsistence, it has no tendency to augment their redundancy. Under the government and political institutions of the Irish, the population of the country would have been equally redundant, though much smaller than it now is, if they had lived on oats or wheaten bread. The introduction of the potato may be the cause why the population is now six in place of three millions: but it is not the cause why, during the whole period of this increase, the numbers of the people have been greater than, under existing circumstances, could be comfortably maintained." (*Sup. Encyc. Brit.*, art. *Ireland*.)*

857. *That agriculture has made considerable progress in Ireland since the above was written, nearly twenty years ago, is obvious from the increased exports of wheat and other grain from her ports; but it may be questioned whether during this period any advance has taken place in the comforts of the general mass of her population. It is a remarkable fact, that in the year 1823, when great numbers of the labouring class in Ireland were starving from a failure in the potato crop, and when large subscriptions were raising in England, and even on the Continent, for their relief, the exportation of grain was going on from Cork and other Irish ports, as if nothing had happened. Before much improvement can take place in the condition of the mass of Irish population, it is necessary that they should possess such a taste for the comforts of life as will restrain the principle of population, by lessening the number of early marriages, or inducing that degree of restraint rendered expedient by a prudent foresight. At present nothing more is necessary for the happiness of an Irish country labourer and his family than straw and potatoes: if these fail him he is lost, because he can fall no lower; if any thing is superadded to his means, it only increases the desire for these necessaries, produces a greater number of children, and creates an additional demand for straw and potatoes. It is gratifying, however, to be able to state that the time seems arrived for the introduction of domestic improvement among the peasantry of Ireland. At no former period has the British government manifested so much anxiety to discover the real causes of the miseries which afflict that country; and in every session of parliament some enactments are made for its amelioration. The enlightened principles of political economy which are now acted on by ministers, and the knowledge of this science which within these few years has spread among all classes, cannot fail to bring Ireland rapidly forward in civilisation and refinement; and we wish it may be to such a degree, as in a very few years to render the account which we have above given mere matter of history. No one can desire this result more ardently than we do.*

CHAP. VI.

Of the present State of Agriculture in Ultra-European Countries.

858. *In this department of our history the reader will not expect more than a very slight outline; not only from our limited space and the comparative scarcity of materials, but because the subject is less interesting to general readers. We shall notice in succession the principal countries of Asia, Africa, Australia, and America.*

SECT. I. *Of the present State of Agriculture in Asia.*

859. *The agriculture of Asia* is of a very different character from that of Europe, owing chiefly to the great difference of climate, and partly to the difference of civilisation. The culture of this division of the globe is chiefly of two kinds, water culture and pasturage. Very little can be done without artificial watering, except in the northern and mountainous parts, where the climate resembles that of Europe. Even the palm and other fruit trees are watered in some parts of Persia and Arabia, and several fruit trees are regularly irrigated in India. The grand bread corn of Asia is rice, a watered grain; and the most valuable fruits, those of the palm family; the most useful agricultural labourer is the ox, and his species are also the most valuable as pasturage animals.

SUBSECT. 1. *Of the present State of Agriculture in Asiatic Turkey.*

860. *Asiatic Turkey* extends from the Archipelago 1050 miles to Ararat in Persia on the east, and from the Euphrates 1100 miles to the Caucasian mountains on the north. It contains a number of provinces differing materially from each other in natural circumstances, and artificial culture; but, unfortunately for us, very little is known of their agriculture. In general, the Asiatic Turks are to be considered as a wandering and pastoral people, cultivating no more corn than what is sufficient for their own maintenance; and scarcely half civilised.

*861. *The climate of Asia Minor* has been always considered excellent. The heat of the summer is tempered by numerous chains of high mountains, some of which are covered constantly with snow. The aspect of Asiatic Turkey is mountainous, intermingled with spacious and beautiful plains, which afford pasture to the numerous flocks and herds of the Turkomans. The soil is varied; but the chief agricultural products are wheat, barley, and doura (millet). It abounds also with grapes, olives, and dates. In Syria, the agriculture is deplorable, and the peasants are in a wretched condition, being sold, as in Poland, with the soil, and their constant fare being barley bread, onions, and water.

862. *The numerous mountains of Asiatic Turkey* are frequently clothed with immense forests of pines, oaks, beeches, elms, and other trees; and the southern shores of the Black Sea present many gloomy forests of great extent. The inhabitants are hence supplied with abundance of fuel, in defect of pit-coal, which has not been explored in any part of

Asiatic Turkey. Sudden conflagrations arise from the heedless waste of the caravans, which, instead of cutting off a few branches, often set fire to a standing tree. The extensive provinces of Natioia, Syria, and Mesopotamia have been little accessible to European curiosity, since their reduction under the Turkish yoke. In Pinkerton's *Geography* we have a catalogue of those plants and trees that have been found wild in the Asiatic part of the Ottoman territory. Several dyeing drugs and articles of the materia medica are imported from the Levant, among which are madder, and a variety called alizan, which grows about Smyrna, and affords a much finer red dye than the European kind; jalap, scammony, sebesten, the ricinus (*Ricinus communis*, fig. 105.) yielding by expression castor oil, squirting cucumber, colocintida, opium poppy, and spikenard. The best horses in Asiatic Turkey are of Arabian extraction; but mules and asses are more generally used. The beef is scarce and bad, the mutton superior, and the kid a favourite repast. Other animals are the bear, tiger, hyæna, wild boar, jackal, and dogs in great abundance.

On the summits of Caucasus is found the ibex, or rock-goat; at Angora, singular goats and cats; the gazel, deer, and hares in great abundance, are found in Asia Minor. The partridges are generally of the red-legged kind, larger than the European; fish is plentiful and excellent.

SUBSECT. 2. *Of the present State of Agriculture in Persia.*

863. *The climate of Persia* is various in different parts; depending less on difference of latitude than on the nature and elevation of the country, so that it is said to be the country of three climates. The northern provinces on the Caspian are comparatively cold and moist: in the centre of the kingdom, as Chardin observes, the winter begins in November and continues till March, commonly severe, with ice and snow, the latter falling chiefly on the mountains, and remaining on those three days' journey west of Ispahan for eight months in the year. From March to May high winds are frequent; but from May to September the air is serene, refreshed by breezes in the night. The heat,

however, is during this period excessive in the low countries bordering on the Indian Ocean and Persian Gulf, in Chusistan, the deserts of Kerman, and also in some parts of the interior, particularly at Tehraun, the capital. From September to November the winds again prevail. In the centre and south the air is generally dry; thunder and lightning are uncommon, and a rainbow is seldom seen; earthquakes are almost unknown; but heat is often destructive in the spring. Near the Persian Gulf the hot wind, called "samiel," sometimes suffocates the unwary traveller. The summers are, in general, very mild, after ascending the mountains. To the north of Shiraz the winters are severe, inasmuch that, in the vicinity of Tehraun and Tabreez, all communication is cut off for several successive weeks between these cities and the adjoining villages. The climate, notwithstanding this sudden transition from heat to cold, is singularly healthy, with the exception of the provinces of Ghilan, and Mazanderam. The air is dry; the dews not insalubrious. The atmosphere is always clear, and at night the planets shine with a degree of lustre unknown in Europe; and as it seldom rains, here are none of those damps or pestiferous exhalations so common in the woody parts of Hindustan.

*864. *The surface of Persia* is distinguished by a deficiency of rivers and a multitude of mountains; its plains, where they occur, are generally desert. So that Persia may be divided into two parts by deserts and mountains; and this division, it is said, has generally influenced its history and destinies in all ages. It is every where open, and no where presents a thriving populous appearance. Even the cities and their environs have something of desolation and decay in their aspect, and many of them are actually ruined or neglected, of which Buschire and its territory (fig. 106.) is an example. The most fertile and thriving provinces are those on the north.

106

865. *The soil* may be regarded as infertile, and, according to Chardin, not more than one tenth part was cultivated in his time. The mountains of this country, which are for the most part rocky, without wood or plants, are interspersed with valleys, some of which are stony and sandy, and some consisting of a hard dry clay, which requires continual watering; and hence the Persian cultivator is much employed in irrigation. In general the soil of Persia is light and sandy in the south and east; hard and gravelly in the west, and rich and loamy on the borders of the Caspian Sea.

866. *The landed property of Persia*, like that of other despotic countries, is considered as wholly the property of the sovereign; and held by the proprietors and occupiers on certain conditions of military service, and supplies of men and provisions in time of war.

867. *The agricultural products of Persia* are as various as the climate and soils. The wheat is excellent, and is the common grain used in bread-making. Rice, which is in more universal use, is produced in great perfection in the northern provinces, which are well watered. Barley and millet are sown, but oats are little cultivated; in Armenia there is some rye. The vine is generally cultivated; but in the north-west countries they are obliged to bury the shoots to protect them from the frost. The silkworm is cultivated in most parts of the country; cotton and indigo are also grown; and no country in the world equals Persia in the number and excellence of its fruits.

868. *The date tree* is grown in plantations in the proportion of fifty females to two males. The natives begin to impregnate the females with the blossoms of the male in March and April, alleging that their proximity is not sufficient to insure the produce of fruit: this practice has been carried on among them from the earliest ages. (*Scot Waring's Persia*, chap. xxix.)

869. *The most esteemed of the cultivated fruits of Europe are indigenous in Persia*, and have probably been hence diffused over the western world. These are the fig, the pomegranate, the mulberry, the almond, peach, and apricot. Orange trees of an enormous size are found in the sheltered recesses of the mountains, and the deep warm sand on the shore of the Caspian is peculiarly favourable to the culture of the citron and the leguminous fruits. Apples, pears, cherries, walnuts, melons, besides the fruits already mentioned, are every where to be procur'd at very low prices; the quinces of Ispahan are

the finest in the East; and no grape is more delicious than that of Shiraz. In the provinces bordering on the Caspian Sea and Mount Caucasus, the air is perfumed with roses and other sweet-scented flowers. Among the vegetable productions we may enumerate cabbages, cucumbers, turnips, carrots, peas, and beans; and the potato, which has been lately introduced, thrives remarkably well. Poppies, from which an excellent opium is extracted, senna, rhubarb, saffron, and assafetida are produced in many parts of the kingdom. The vine grows here luxuriantly, and further to the south cotton and sugar are articles of common cultivation. Poplars, large and beautiful, and the weeping willow, border the courses of the streams, and the marshy tracts abound with the kind of rush that serves for the Persian matting. Ornamental shrubs or herbaceous plants are little known; but the jasmine and the blue and scarlet anemone in the thickets, and the tulip and ranunculus in the pastures, are abundant and beautiful, and give an air of elegance to the country.

870. *The saline deserts of Persia* are for the most part destitute of trees, and support hardly any plants except such as are also found on the sea-shore. On the high mountains they are much the same as those observed on the alps of Switzerland and Italy. The plants on the hills and plains adjoining the Caspian are better known.

871. *The live stock of Persia* is the same as in European countries with some additions. According to Chardin, the Persian horses are the most beautiful in the East; but they yield in speed, and, as some say, in beauty also, to the Arabian; however, they are larger, more powerful, and, all things considered, better calculated for cavalry than those of Arabia. There are several breeds of horses, but the most valuable is that called the Turkoram; these are so hardy that they have been known to travel nine hundred miles in eleven successive days. The Arabian blood has been introduced into this country. Their usual food is chopped straw and barley; their bed is made of dung, dried and pulverised, and every morning regularly exposed to the sun. They are clothed with the greatest attention, according to the climate and season of the year; and during the warm weather are kept in the stable all day, and taken out at night.

872. *Mules* are also here in considerable request, and the ass resembles the European; but a breed of this animal has been brought from Arabia, of an excellent kind, the hair being smooth, the head high, and the motion spirited and agile. Although the mules are small, they are fairly proportioned, carry a great weight, and those that are intended for the saddle are taught a fine amble, which carries the rider at the rate of five or six miles an hour. The camel (*fig. 107.*) is also common; and the animals which

are exported from Persia to Turkey have, as Chardin says, only one hunch, while those of India and Arabia have two. The Persian cattle in general resemble the European. Swine are scarce, except in the north-west provinces.

The flocks of sheep, among which are those with large tails, are most numerous in the northern provinces of Erivan, or the Persian part of Armenia and Balk. The few forests abound with deer and antelopes; and the mountains supply wild goats, and probably the ibex, or rock goat. Hares are common. The ferocious animals are chiefly concealed in the forests, such as the bear and boar, the lion in the western parts, the leopard, and, as some say, the small or common tiger. Seals occur on the rocks of the Caspian. The hyæna and jackal belong to the southern provinces. The seas abound with fish of various descriptions; the Caspian affords sturgeon and delicious carp. The most common river fish is the barbel. The same sorts of wild and tame fowl are common in Persia and in Europe, with the exception of the turkey, whose nature does not seem to be congenial to this climate. Pigeons are numerous, and partridges are large and excellent. The bul-bul, or Oriental nightingale, enlivens the spring with his varied song. The Persians have been long accustomed to tame beasts of prey and even to hunt with lions, tigers, leopards, panthers, and onces.

873. *The Persians hunt the quail in a curious manner.* (*fig. 108.*) They stick two poles in their gridle, upon which they place either their outer coat, or a pair of trowsers, and these at a distance are intended to look like the horns of an animal; they then with a hand-net prowl about the fields, and the quail, seeing a form more like a beast than a man, permits it to

107

approach so near as to allow the hunter to throw his net over it. In this manner they catch these birds with astonishing rapidity.

874. *Of the implements and operations of Persian agriculture little is known with precision. The plough is said to be small, and drawn by lean cattle, so that it merely scratches the ground. The plough of Erzerum (fig. 109.) is a clumsy implement, on the share of which the driver stands, both for the sake of being carried along and of pressing down the wedge. After the plough and harrow the spade is used for forming the ground into squares, with ledges or little banks to retain the water. The dung used is chiefly human, and that of pigeons, mingled with earth and preserved for two years to diminish its heat.*

by conical spiracles through which the pigeons descend. Their interior resembles a honeycomb, forming thousands of holes for nests; and the outsides are painted and ornamented. The dung is applied almost entirely to the rearing of melons, a fruit indispensable to the natives of warm countries during the great heats of summer, and also the most rapidly raised in seasons of scarcity; and hence the reason that during the famine of Samaria a cab of dove's dung was sold for five pieces of silver. (*2 Kings*, vi. 25.) In Persia are grown the finest melons in Asia. The nobles pride themselves in excelling in this fruit, and some are said to keep pigeons to the extent of 10,000, and upwards, solely for their dung, as a manure for this fruit, the pigeon not being eaten by Persians. (*Morier's Second Journey*, 141.)

876. *No arable culture is carried on in Persia without artificial watering; and various modes are adopted for raising the element from wells and rivers for this purpose. The Persian wheel is well known. The deficiency of rivers in Persia has obliged the natives to turn all their ingenuity to the discovery of springs, and to the bringing of their streams to the surface of the earth. To effect this, when a spring has been discovered, they dig a well until they meet with the water; and if they find that its quantity is sufficient to repay them for proceeding with the work, they dig a second well, so distant from the other as to allow a subterranean communication between both. They then ascertain the nearest line of communication with the level of the plain upon which the water is to be brought into use, and dig a succession of wells, with subterranean communications between the whole suite of them, until the water at length comes to the surface, when it is conducted by banked-up channels into the fields to be irrigated. The extent of country through which such streams are sometimes conducted is quite extraordinary. In making the wells (fig. 111.) a shaft is first dug, then a wooden handle is placed over it, from which is suspended a leathern bucket, which is filled with the excavated matter by a man below, and wound up by another above. Where the soil is against the mouth of the wells, they are secured by masonry. This mode of procuring water is common to the whole of Persia, and has the great defect of being easily destroyed by an enemy. (*Morier's Second Journey*, 164.)*

877. *The forests of Persia are few, and chiefly in the mountains of Mazanderam and Ghilan, and those towards Kurdistan. The trees are several kinds of pines, the cedar and cypress, limes, oaks, acacias, and chestnuts; the sumach is abundant, and used for tanning; manna is procured from the *Fraxinus Ornus*. Very little fuel is consumed in Persia, and timber is seldom used; in the castles and principal houses, arches are employed instead of timber floors.*

SUBJECT. 3. *Of the present State of Agriculture in Independent Tatory.*

878. *The extent of Independent Tatory* can hardly be considered as well defined; but Pinkerton measures it from the Caspian Sea on the west to the mountains of Belus on the east, a space of 870 miles; and from the mountains of Gaur to the Russian boundaries on the north of the desert of Issim, a distance of 1500 miles. It is occupied by the Bucharian, Tungusian, Kirgusian, and other Tatar hordes; and is a celebrated and interesting country, as being the probable seat of the most ancient Persian kingdoms, and as having given birth to Zoroaster and other men eminent in Oriental literature. Modern travellers represent the more civilised of this nation as indolent, but good-natured. They are easily recognised among other varieties of man.

879. *The climate* of this extensive country appears to be excellent, the heat even of the southern provinces being tempered by the high mountains capped with perpetual snow; and though situated in the parallel of Spain, Greece, and Asiatic Turkey, the proximity of the Siberian deserts and the lofty alps render the summer more temperate.

880. *The surface* of the country presents a great variety; and there are numerous rivers, hills, and mountains.

881. *The soil* near the rivers is very productive, so that the grass exceeds the height of a man. In any other hands but those of the Tatars, this country might rival any European region.

882. *All that is known of the tillage of the Tatars* is, that rice and other grains are cultivated near the towns, but that the great dependence of the people is upon their flocks and herds. Bucharina is the richest country, both in corn and cattle. There they have horses, camels, oxen, sheep, and goats, which some individuals reckon by thousands, and make large sales, especially of horses, to the Persians and Turks. They have also dromedaries, which furnish a considerable quantity of woolly hair, which they clip off periodically and sell to the Russians. The lambskins are celebrated, being damasked, as it were, by clothing the little animal in coarse linen; but the wool of the sheep is coarse, and only used in domestic consumption for felts and thick cloths. The steppes, which are of immense extent, supply them with objects of the chase, wolves, foxes, badgers, antelopes, ermines, weasels, marmots, &c. In the southern and eastern mountains are found wild sheep (*Ovis Mûsimon*), the ox of Thibet (*Bôs grûnniens*, *fig.* 112.) which seems to delight in snowy alps, chamois, tigers, and wild asses. There seems throughout the whole of Tatory a deficiency of wood; and the botany of this immense region is as little known as its agriculture.

SUBJECT. 4. *Of the present State of Agriculture in Arabia.*

883. *The extent of Arabia* is somewhat greater than that of Independent Tatory. The climate is hot, but there is a regular rainy season, from the middle of June to the end of September, in some mountainous districts, and from November till February in others. The remaining months are perfectly dry; so that the year in Arabia consists only of two seasons, the dry and the rainy. In the plains, rain is sometimes unknown for a whole year. It sometimes freezes in the mountains, while the thermometer is at 86° in the plains, and hence at a small distance are found fruits and animals which might indicate remote countries.

884. *The general surface* presents a central desert of great extent, with a few fertile oases or isles, and some ridges of mountains, chiefly barren and unwooded. The flourishing provinces are those situated on the shores of the Red and Persian Seas, the interior of the country being sterile for want of rivers, lakes, and perennial streams. The soil is in general sandy, and in the deserts is blown about by the winds.

885. *The agricultural products* are wheat, maize, doura or millet, barley, beans, lentils, and rape, with the sugar-cane, tobacco, and cotton. Rice seems unknown in Yemen, and oats throughout Arabia; the horses being fed with barley, and the asses with beans. They also cultivate "uars," a plant which dyes yellow, and is exported in great quantities from Mocha to Oman; and "fua," used in dyeing red; likewise indigo. The wheat, in the environs of Maskat, yields little more than ten for one; and in the best cultivated districts of Yemen, fifty for one; but the doura sometimes much exceeds this ratio, yielding in the highlands 140, and in the Tehama, or plain, from 200 to 400. By their mode of sowing and watering this grain, the inhabitants of Tehama reap three successive crops from the same field in the same year. The plough (*fig.* 113.) is simple, and the pick is used instead of the spade.

886. *The indigenous, or partially cultivated, plants and trees of Arabia are numerous, and several of them furnish important articles of commerce. The vegetables of the dry barren districts, exposed to the vertical sun, and refreshed merely by nightly dews, belong for the most part to the genera of Aloe, Mesembryanthemum, Euphorbia, Stapelia, and Salsola. On the western side of the Arabian desert, numerous rivulets, descending into the Red Sea, diffuse verdure; and on the mountains from which they run vegetation is more abundant. Hither many Indian and Persian plants, distinguished for their beauty or use, have been transported in former ages, and are now found in a truly indigenous state: such is the case probably with the tamarind, the cotton tree (inferior to the Indian), the pomegranate, the banyan tree or Indian fig, the sugar-cane, and many species of melons and gourds. Arabia Felix may peculiarly boast of two valuable trees, namely, the coffee (Coffea arabica), found both cultivated and wild; and the Amyris Opobalsamum, which yields the balm of Mecca. Of the palms, Arabia possesses the date, the cocoa-nut, and the great fan-palm. It has also the sycamore fig, the plantain, the almond, the apricot, the peach, the papaw, the head tree, the Mimosa nilotica and sensitiva, and the orange. Among its shrubs and herbaceous plants may be enumerated the ricinus, the liquorice, and the senna, used in medicine; and the balsam, the globe amaranth, the white lily, and the greater pancratium, distinguished for their beauty and fragrance.*

887. *The live stock of Arabia is what constitutes its principal riches, and the most valuable are those species of animals that require only succulent herbs for their nourishment. The cow here yields but little milk; and the flesh of the ox is insipid and juiceless. The wool and mutton of the sheep are coarse. The bezoar goat is found in the mountains. The buffalo is unknown; but the camel and dromedary (fig. 114.) are both in use as beasts of burden. The civet cat, musk rat, and other mountain animals, are valuable in commerce. Pheasants, partridges, and common poultry abound in Yemen; and there are numerous ferocious animals, birds of prey, and pestiferous insects.*

114

888. *But the horse is of all the animals of Arabia the most valuable. This animal is said to be found wild in the extensive deserts on the north of Hadramant: this might have been the case in ancient times, unless it should be thought more probable, that the wild horse of Tataria has passed through Persia, and has been only perfected in Arabia. The horses here are distributed into two classes, viz. the kadischi, or common kind, whose genealogy has not been preserved, and the kochlani, or noble horses, whose breed has been ascertained for 2000 years, proceeding, as their fables assert, from the stud of Solomon. They are reared by the Bedouins, in the northern deserts between Bassora, Merdin, and the frontiers of Syria; and though they are neither large nor beautiful, their race and hereditary qualities being the only objects of estimation, the preservation of their breed is carefully and authentically witnessed, and the offspring of a kochlani stallion with an ignoble race is reputed kadischi. These will bear the greatest fatigues, and pass whole days without food, living, according to the Arabian metaphor, on air. They are said to rush on a foe with impetuosity; and it is asserted that some of them, when wounded in battle, will withdraw to a spot where their master may be secure; and if he fall, they will neigh for assistance; accordingly, their value is derived from their singular agility, extreme docility, and uncommon attachment to their master. The Arabian steeds are sometimes bought at excessive rates by the English at Mocha. The Duke of Newcastle asserts that the ordinary price of an Arabian horse is 1000*l.*, 2000*l.*, or even 3000*l.*; and that the Arabs are as careful in preserving the genealogy of their horses, as princes in recording that of their families. The grooms are very exact in registering the names of the sires and dams of these animals; and some of these pedigrees are of very ancient date. It is affirmed that Arabian colts are brought up with camels' milk.*

889. *Of the agricultural implements and operations of Arabia almost nothing is known. Their plough, as we have seen, is a poor implement, and instead of a spade they use the pick. The principal exertion of the husbandman's industry is to water the lands from the rivulets and wells, or by conducting the rains. Barley is reaped near Sana in the middle of July; but the season depends on the situation. At Maskat, wheat and barley are sown in December, and reaped in March; but doura (the great millet) is sown in August, and reaped in the end of November. The Arabians pull up their ripe corn by the roots; but the green corn and grass, as forage for their cattle, are cut with the sickle. In threshing their corn, they lay the sheaves down in a certain order, and then lead over them two oxen dragging a large stone.*

SUBJECT. 5. *Of the present State of Agriculture in Hindustan.*

890. *The climate and seasons* of this extensive region are considerably diversified by difference of latitude and local situation; nevertheless, throughout the wide regions of Hindustan there is some similarity of climate. Although in Thibet the winter nearly corresponds with that of Switzerland and other parts of Europe, in the whole extent of Hindustan, except in Cashmere, there can hardly be said to be a vestige of winter, except the thick fogs similar to those of our November; and excessive rains, or excessive heats, form the chief varieties of the year.

891. *The surface of the country* is much diversified; but there are no mountains of any very great height; the ghauts not being estimated at above three thousand feet. The vast extent of Hindustan consists chiefly of large plains, fertilised by numerous rivers and streams, and interspersed with a few ranges of hills. The periodical rains and intense heats produce a luxuriance of vegetation almost unknown to any other country on the globe; and the variety and richness of the vegetable creation delight the eye of every spectator. Bengal is a low, flat country, like Lower Egypt, watered and fertilised by the Ganges, as the latter country is by the Nile; and, like the Nile, the Ganges forms an immense delta before it falls into the sea. The interior of the country is so flat, that the water runs only at the rate of three miles an hour; and the ground rises from the sea towards the interior, at not more than four inches in a mile.

892. *The soil varies*, but is in most places light and rich: that of Bengal is a stratum of black vegetable mould, rich and loamy, extending to the depth of six feet, and in some places fourteen, and even twenty feet; lying on a deep sand, and interspersed with shells and rotten wood, which indicate the land to have been overflowed, and to have been formed of materials deposited by the rivers. It is easily cultivated without manure, and bad harvests seldom occur. In this country they have two harvests; one in April, called the "little harvest," which consists of the smaller grains, as millet; and the second, called the "grand harvest," is only of rice.

*893. *Landed property* in Hindustan, as in all the countries of Asia, is held to be the absolute right of the king. The Hindû laws declare the king to be the lord and proprietor of the soil. All proprietors, therefore, paid a quitrent or military services to the king or rajah, except some few, to whom it would appear absolute grants were made. In general, the tenure was military; but some lands were appropriated to the church and to charitable purposes, and in many places commons were attached to villages as in Europe. Lands in Hindustan, and in Bengal more especially, are very much divided, and cultivated in small portions by the ryots, or peasants, who pay rent to subordinate proprietors, who hold of others who hold of the rajah. The actual cultivators have hardly any secure leases; they are allowed a certain portion of the crop for the maintenance of their families and their cattle; but they are not entrusted with the seed, which is furnished by the proprietor or superior holder. The ryot, or cultivator, is universally poor; his house, clothing, and implements of every kind, do not amount to the value of a pound sterling; and he is considered as a sort of appendage to the land, and sold along with it, like his cattle. So little attention is paid to any agreement made with him, that in a good season, Dr. Tennant informs us, the zemindar, or superior holder, raises his demands to a fourth more than the rent agreed on. Custom has rendered this evil so common, that the miserable ryot has no more idea of obtaining redress from it than from the ravages of the elements. Since Bengal was conquered by the British, the government is, properly speaking, the proprietor of all the lands; and Tennant accordingly observes, that "nine tenths of all the rent of Bengal and the provinces constitute the revenue of the company, who are, in room of the Mogul emperor, the true proprietors of the soil." (*Recr.* ii. 184.)

894. *The agricultural products* of Hindustan are very various. Rice, wheat, and maize are the common grains; but barley, peas, a species of tare or cytus called dohl, and millet, are also cultivated. Next to them the cotton plant and the sugar-cane are most extensively grown. To these may be added, indigo, silk, hemp, poppy for opium, palma Christi, sesamum, mustard; the cocoa-nut, which supplies a manufacture of cordage, and also a liquor called toddy; guavas, plantains, bananas, pompelos, limes, oranges, and a great variety of other fruits, besides what are cultivated in gardens, where the settlers have all the vegetables of European horticulture. The potato has been introduced, and though it does not attain the same size as in Europe, is yet of good quality. It is not disliked by the natives, but cannot be brought to market at so low a price as rice.

895. *The sugar-cane* (*Sácharum officinárum*) (*fig.* 115.) is cultivated in low grounds that may be flooded. The ground being cleaned and pulverised by one or two years'

fallow is planted with cuttings of two or three buds, in rows four feet apart and eighteen inches wide in the row; as they grow, each stool, consisting of three shoots or more, is tied to a bamboo reed eight or ten feet long, the lower leaves of each cane being first carefully wrapt round it, so as to cover every part, and prevent the sun from cracking it, or side shoots from breaking out. Watering and flooding in the dry season, and keeping open the surface drains during the periodical rains, are carefully attended to. Nine months from the time of planting, the canes are ten feet high, and ready to cut. The process of sugar-making, like all others in this country, is exceedingly simple. A stone mortar and wooden pestle turned by two small bullocks express the juice, which is boiled in pots of earthenware sunk in the ground, and heated by a fire which passes beneath and around them, and by which no heat is lost.

896. *The indigo (Indigofera tinctoria, fig. 116.)* is one of the most profitable articles of culture in Hindustan; because an immense extent of land is required to produce but a moderate bulk of the dye; because labour and land here are cheaper than any where else; and because the raising of the plant and its manufacture may be carried on without even the aid of a house. The first step in the culture of the plant is to render the ground, which should be friable and rich, perfectly free from weeds and dry, if naturally moist. The seeds are then sown in shallow drills about a foot apart. The rainy season must be chosen for sowing, otherwise, if the seed is deposited in dry soil, it heats, corrupts, and is lost. The crop being kept clear of weeds is fit for cutting in two or three months, and this may be repeated in rainy seasons every six weeks. The plants must not be allowed to come into flower, as the leaves in that case become dry and hard, and the indigo produced is of less value; nor must they be cut in dry weather, as they would not spring again. A crop generally lasts two years. Being cut, the herb is first steeped in a vat till it has become macerated, and has parted with its colouring matter; then the liquor is let off into another, in which it undergoes the peculiar process of beating, to cause the fecula to separate from the water. This fecula is let off into a third vat, where it remains some time, and is then strained through cloth bags, and evaporated in shallow wooden boxes placed in the shade. Before it is perfectly dry it is cut in small pieces of an inch square; it is then packed in barrels, or sowed up in sacks, for sale. Indigo was not extensively cultivated in India before the British settlements were formed there; its profits were at first so considerable, that, as in similar cases, its culture was carried too far, and the market glutted with the commodity. The indigo is one of the most precarious of Oriental crops; being liable to be destroyed by hail storms, which do comparatively little injury to the sugar-cane and other plants.

897. *The mulberry* is cultivated in a different manner from what it is in Europe. It is raised from cuttings, eight or ten of which are planted together in one pit, and the pits are distributed over the field at the distance of two or three feet every way. These cuttings being well firm ed at the lower ends soon form stools about the height of a raspberry bush, and from these the leaves are gathered. The stools are cut over once a year to encourage the production of vigorous shoots from the roots.

898. *The poppy (Papaver somniferum)* is cultivated on the best soil, well manured. The land sometimes receives as many as fifteen stirrings, and the seed is then dropped into shallow drills about two feet apart. During the growth of the plants the soil is stirred, well watered, and sometimes top-dressed. In two months from the time of sowing, the capsules are ready for incision, which process goes on for two or three weeks; several horizontal cuts being made in the capsule on one day, on the next the milky juice which had oozed out, being coagulated, is scraped off. This operation is generally repeated three times on each capsule, and then the capsules are collected for their seed. The raw juice is kneaded with water, evaporated in the sun, mixed with a little poppy oil, and, lastly, formed into cakes, which are covered with leaves of poppy, and packed in chests with poppy husks and leaves.

899. *Tobacco* in Hindustan is cultivated in the same manner as in Europe. The soil must be rich and well pulverised, the plants transplanted, and the earth stirred during their growth; the main stems are broken off, and the leaves are dried by being suspended on beds of withered grass by means of ropes, and shaded from the sun and protected from nightly dews. The leaves afford a much weaker odour than those of the tobacco of Europe or America.

900. *The mustard, Sesamum orientale, flax, palma Christi,* and some other plants, are grown for their seeds, which are crushed for oil. The use of the flax, as a clothing plant, is not understood in India, hemp supplying its place. The mustard and sesamum are sown on the sand left by the overflowings of the rivers, without any other preparation or culture than that of drawing a bush over the seeds to cover them. The palma Christi is sown in patches three or four feet apart, grows to the size of a little tree, and is cut down with an axe when the seeds are to be gathered. The mill for bruising the seeds of these plants is simply a thick trunk of a tree hollowed into a mortar, in which is placed the pestle, turned by oxen.

901. *Palm trees* of several species are in general cultivation in Hindustan. The most useful is the cocoa-nut tree (*Cocos nucifera, fig. 117.*), which grows almost perfectly straight to the height of forty or fifty feet, and is nearly one foot in diameter. It has no branches, but about a dozen leaves spring immediately from the top: these are about ten feet long, and nearly a yard in breadth towards the bottom. The leaves are employed to cover the houses of the natives; and to make mats either for sitting or

lying upon. The leaf when reduced to fine fibres is the material of which a beautiful and costly carpeting is fabricated for these in the higher ranks; the coarser fibres are made into brooms. After these useful materials are taken from the leaf, the stalk still remains, which is about the thickness of the ancle, and furnishes firewood.

902. *The wood of this palm, when fresh cut, is spongy; but becomes hard, after being seasoned, and assumes a dark-brown colour. On the top of the tree a large shoot is produced, which when boiled resembles broccoli, but is said to be of a more delicate taste; and, though much liked, is seldom used by the natives; because on cutting it off the pith is exposed, and the tree dies. Between this cabbage-like shoot and the leaves spring several buds, from which, on making an incision, distils a juice differing little from water, either in colour or consistence. It is the employment of a certain class of men to climb to the tops of the trees in the evening, with earthen pots tied to their waists, these they fix at the top to receive the juice, which is regularly carried away before the sun has any influence upon it. This liquor is sold at the bazaars by the natives, under the name of toddy. It is used for yeast, and forms an excellent substitute. In this state it is drank with avidity, both by the low Europeans and the natives; and it is reckoned a cooling and agreeable beverage. After being kept a few hours, it begins to ferment, acquires a sharp taste, and a slightly intoxicating quality. By boiling it, a coarse kind of sugar is obtained; and by distillation it yields a strong ardent spirit, which being every where sold, and at a low price, constitutes one of the most destructive beverages to our soldiers. The name given to this pernicious drink by Europeans is pariah arrack, from the supposition that it is only drank by the pariahs, or outcasts that have no rank.*

903. *The trees from which the toddy is drawn do not bear any fruit, on account of the destruction of the buds; but if the buds be left entire, they produce clusters of the cocoa-nut. This nut, in the husk, is as large as a man's head; and when ripe falls with the least wind. If gathered fresh, it is green on the outside; and the husk and the shell are tender. The shell, when divested of the husk, may be about the size of an ostrich's egg, and is lined with a white pulpy substance, which contains about a pint and a half of liquor like water; and, though the taste be sweet and agreeable, it is different from that of the toddy.*

904. *In proportion as the fruit grows old, the shell hardens, and the liquor diminishes, till it is at last entirely absorbed by the white milky substance; which gradually acquires the hardness of the kernel of the almond, and is almost as easily detached from the shell. The natives use this nut in their victuals; and from it they also express a considerable quantity of the purest and best lamp oil. The substance which remains after this operation supplies an excellent food for poultry and hogs. Cups and a variety of excellent utensils are made of the shell.*

905. *The husk of the cocoa-nut is nearly an inch thick, and is, perhaps, the most valuable part of the tree; for it consists of a number of strong fibres, easily separable, which furnish the material for the greatest part of the Indian cordage; but is by no means the only substitute which the country affords for hemp. This the natives work up with much skill.*

906. *The palmyra, a species of Corypha, is taller than the cocoa tree; and affords still greater supplies of toddy; because its fruit is in little request, from the smallness of its size; the produce of the tree is therefore generally drawn off in the liquid state. This tree, like the cocoa, has no branches; and, like it too, sends forth from the top a number of large leaves, which are employed in thatching houses, and in the manufacture of mats and umbrellas. The timber of the tree is much used in building.*

907. *The date tree (Phoenix dactylifera), being smaller, does not make so conspicuous a figure in the Indian forest as the two last described. Its fruit never arrives at maturity in India, owing to the heat: toddy is drawn from it, but not in such quantity, nor of so good a quality, as that which is produced by the other species of the same genus.*

908. *The bamboo (Bambusa arundinacea) is, perhaps, one of the most universally useful trees in the world; at all events it is so in the tropical regions. There are above fifty varieties, all of which are of the most rapid growth, rising from fifty to eighty feet the first year, and the second perfecting its timber in hardness and elasticity. It grows in stools, which are cut over every two years, and thus the quantity of timber furnished by an acre of bamboos is immense. Its uses are almost without end. In building it forms entire houses for the lower orders, and enters both into the construction and furniture of those of the higher classes. Bridges, boats, masts, rigging, agricultural and other implements, and machinery, carts, baskets, ropes, nets, sailcloth, cups, pitchers, troughs, pipes for conveying water, pumps, fences for gardens and fields, &c., are made of it. Macerated in water it forms paper; the leaves are generally put round the tea sent to Europe; the thick inspissated juice is a favourite medicine, is said to be indestructible by fire, to resist acids, and by fusion with alkali to form a transparent permanent glass.*

909. *The fruits of Hindustan may be said to include all those in cultivation; since the hardier fruits of Europe, as the strawberry, gooseberry, apple, &c., are not only grown by the European settlers in cool situations, but even by the native shahs. The indigenous sorts include the mango, the mangostan, and the durion, the noblest of known fruits next to the pine-apple.*

910. *The natural pastures of Hindustan are every where bad, thin, and coarse, and there is no such thing as artificial herbage plants. In Bengal, where the soil is loamy to the depth of nine and ten feet, a coarse bent, or species of Juncus, springs up both in*

the pasture and arable lands, which greatly deteriorates the former as food for cattle, and unfits the latter for being ploughed. This *Juncus*, Tennant observes, pushes up a single seed stem, which is as hard as a reed, and is never touched by cattle so long as any other vegetable can be had. Other grasses of a better quality are sometimes intermixed with this unpalatable food; but, during the rain, their growth is so rapid that their juices must be ill fitted for nutrition. In Upper Hindustan, during the dry season, and more particularly during the prevalence of the hot winds, every thing like verdure disappears; so that on examining a herd of cattle, and their pasture, you are not so much surprised at their leanness as that they are alive. The grass-cutters, a class of servants kept by Europeans for procuring food for their horses, will bring provender from a field where grass is hardly visible. They use a sharp instrument, like a trowel, with which they cut the roots below the surface. These roots, when cleared of earth by washing, afford the only green food which it is here possible to procure.

911. *The live stock* of Hindustan consists chiefly of beasts of labour, as the natives are by their religion prohibited the use of animal food. The horses are chiefly of Persian or Arabian extraction. The Bengal native horse is thin and ill-shaped, and never equals the Welch or Highland pony, either in figure or usefulness. The buffalo is common, both tame and wild, and generally jet black, with semicircular horns laid backwards upon the neck. They are preferred to the ox for carrying goods, and kept in herds for the sake of their milk, from which ghee, a universal article of Hindoo diet, is made.

912. *The common ox* of Hindustan is white, and distinguished by a protuberance on the shoulder, on which the yoke rests. Those kept for travelling-coaches are capable of performing long journeys nearly in the same time as horses; those kept by the poor ryots work patiently in the yoke, beneath the vertical sun, for many hours, and upon the most wretched food, chaff or dried straw. Cow's milk is used pretty generally in India; but buffalo's milk, or goat's milk, is reckoned sweeter and finer than cow's milk, and preferred at the breakfast table even by the English. Goat's milk is decidedly the best for tea.

913. *The sheep* is small, lank, and thin; and the wool chiefly black or dark grey. The fleece is harsh, thin, and hairy, and only used for a kind of coarse wrappers or blanketing. A somewhat better breed is found in the province of Bengal. The mutton of India is generally good; at Poona, and in the Mahratta country, and in Bengal, it is as fine as any in the world.

914. *The goat* is kept for its milk, which is commonly used at the breakfast table; and also for the flesh of the kids, which is by some preferred to the mutton.

915. *Swine* are pretty common except among Mohammedans. They might be reared in abundance; but only Europeans and the low Hindoos eat pork. Wild hogs are abundant, and do so much injury to the rice fields that it is a material part of the ryot's business to watch them, which he does night and day, on a raised platform of bamboos.

916. *The elephant* is used as a beast of burden, but is also kept by a few European gentlemen, for hunting or show. He is taken by stratagem, and by feeding and gentle usage soon becomes tame, docile, and even attached to his keeper; but does not breed freely in a domesticated state. The leaves and smaller branches of trees, and an allowance of grain, constitute his food. It is a singular deviation from general nature, that an old elephant is easier tamed than one taken young.

917. *The camel* is used chiefly as a beast of burden, and is valued for his uncommon power of abstinence from drink. He is also patient of fatigue, hunger, and watching, to an incredible degree. These qualities have recommended the camel, as an auxiliary to British officers for carrying their baggage; and from time immemorial, he has been used by merchants for conveying goods over extensive tracts of country.

918. *The predatory animals* are numerous. Of these the jackal (*fig.* 118.) is the most remarkable. He enters at night every farmyard, village, and town, and traverses even the whole of Calcutta. His voracity is indiscriminate, and he acts as a scavenger in the towns; but, in the farmyards he is destructive to poultry, if he can get at their roosts; and in the fields the hare and the wild pig sometimes become his prey. The numerous village dogs, which in general are mangy, are almost as troublesome as the jackal. Apes of different kinds haunt houses, and pilfer food and fruits. The crow, kite, mino, and sparrow hop about the dwellings of man with a familiarity unknown in Europe, and pilfer from the dishes of meat, even as they are carried from the kitchen to the eating-room. The stork is common; and toads, serpents, lizards, and other reptiles and insects, are greatly kept under by him and other birds.

919. *The implements and operations of Hindustanee agriculture are as simple as can well be imagined. The plough, of which General Beatson has given several forms (fig. 119.), is little better than a pointed stick, and is carried to the field on the shoulder like the spade. It scratches the sandy uplands, or the mud left by the rivers, in a tolerable manner; but the strong lands of Bengal, that send up the Juncus already mentioned, appear as green after one ploughing as before; "only a few scratches are perceptible here and there, more resembling the digging of a mole than the work of the plough." To accomplish the work of pulverisation, the ploughman repeats the operation from five to fifteen times, and at last succeeds in raising mould enough to cover the seed: one plough and pair is allowed to five acres. From this mode of repeatedly going over the same surface and effecting a little each time, General Beatson has drawn some ingenious arguments in favour of the use of the cultivator in this country, which will be afterwards noticed.*

920. *The cart, or hackery, has two wheels, and is drawn by two bullocks. The wheels are under three feet in diameter, and the body of the carriage consists of two bamboos, united by a few cross-bars, also of bamboo, and approaching each other the whole length of the machine, till they meet at a point between the necks of the cattle, where they are supported by a bar projecting sideways over the shoulders of both. By this the oxen or buffaloes are often galled in a shocking manner, and the supuration which takes place in consequence is, perhaps, not perfectly cured during the whole life of the animal; the evil being aggravated by the crows, which set upon him as soon as he is relieved from the yoke.*

921. *As no department of aration can be carried on without artificial watering, that operation becomes very expensive and troublesome in elevated districts. In the Mongheer district of Bengal, a deep well is dug in the highest part of the field. The fields, after being ploughed, are divided into little square plots, resembling the checkers of a backgammon table. Each square is surrounded with a shelving border, about four inches high, capable of containing water. Between the square checkers thus constructed small dykes are formed for conveying a rivulet over the whole field. As soon as the water has stood a sufficient time in one square for that portion to imbibe moisture, it is let off into the adjoining one, by opening a small outlet through the surrounding dyke. Thus one square after another is saturated, till the whole field, of whatever extent, is gone over.*

922. *The water is raised in large leathern bags, pulled up by two bullocks yoked to a rope. The cattle are not driven in a gin as ours, but retire away from the well, and return to its mouth, accordingly as the bag is meant to be raised or to descend. When raising the filled skin they walk down hill away from the well, and they ascend backwards as the emptied skin redescends into the water. The earth is artificially raised to suit this process. The rope is kept perpendicular in the pit, by a pulley, over which it runs. From the mouth of the well thus placed, the rivulets are formed to every part of a field*

923. *In the district of Patna the wells are not so deep. Here the leathern bags are raised by long bamboo levers, as buckets are in several parts of this country. In a few places rice is transplanted, which is done with pointed sticks, and the crop is found to be better than what is sown broadcast.*

924. *In the hilly districts they neither plough nor sow; what grain they raise is introduced into small holes, made with a peg and mallet, in a soil untouched by the plough. The only preparation given to it is the turning away of the jungle. In the vicinity of RajamahI there are many tribes of peasants, who subsist partly by digging roots, and by killing birds and noisome reptiles. In these savage districts ninety villages have been taxed for two hundred rupees; and yet this paltry sum could only be made up by fruits peculiar to the situation. The wretched state of these peasants, Dr. Tennant observes, outdoes every thing which a European can imagine.*

925. *Harvests are gathered in at different seasons of the year; and as often as a particular crop is collected, the ryot sends for the brahmin, or parish priest, who burns ghee and says prayers over the collected heap, and receives one measure of grain for his trouble.*

926. *The selections we have now submitted will give some idea of the aboriginal agri-*

culture of Hindustan; not in its details, but as to its peculiar features. It is evidently wretched, and calculated for little more than the bare sustenance of an extensive population: for though the revenue of the state is in fact the land rent, that revenue, notwithstanding the immense tract of country from which it is collected, is known to be very small. The state of agriculture, however, both politically and professionally, is capable of great improvement; and it is believed that the present government has already effected material benefits, both for the natives and for itself. Wherever the British influence is preeminent, there Europeans settle and introduce improvements; and even the more industrious Asiatics find themselves in greater security. The Chinese are known to be a remarkably industrious people, and many of them have established themselves in British-Indian seaports. Wathen (*Voyage, &c.*, 1814) mentions a corn-mill, combining a bake-house, both on a large scale and driven by a powerful stream of water, as having been established at Penang, in the island of that name, by Amee, a Chinese miller. The building is in the Chinese taste, and forms a very picturesque group in a romantic spot. (fig. 120.) About sixty people are employed; though great part of the labour is done by machinery, and among other things the kneading of the dough. The shipping is the chief source of consumption.

SUBJECT. 6. *Of the Agriculture of the Island of Ceylon.*

927. *The agriculture of Ceylon* is noticed at some length by Dr. Davy, who says the art is much respected by the Singalese. The climate of that country is without seasons, and differs little throughout the year in any thing but in the direction of the wind, or the presence or absence of rain. Sowing and reaping go on in every month.

928. *The soil of Ceylon* is generally silicious, seldom with more than from one to three per cent of vegetable matter. Dr. Davy (*Account, &c.*) found the cinnamon tree in a state of successful culture in quartz sand, as white as snow on the surface, somewhat grey below; containing one part in one hundred of vegetable matter, five tenths of water, and the remainder silicious sand. He supposes the growth of the trees may be owing in a considerable degree to the situation being low and moist.

929. *The cultivation in the interior of Ceylon* is almost exclusively of two kinds; the dry and wet. The former consists of grubbing up woods on the sides of hills, and sowing a particular variety of rice and Indian corn; the latter is carried on in low flat surfaces, which may be flooded with water. Rice is the only grain sown. The ground is flooded previously to commencing the operation of ploughing, and is kept under water

while two furrows are given; the water is then let off, and the rice, being previously steeped in water till it begins to germinate, is sown broadcast. When the seed has taken

root, and before the mud has had time to dry, the water is re-admitted: when the plants are two or three inches high, the ground is weeded, and any thin parts made good by transplanting from such as are too thick. The water remains on the field till the rice begins to ripen, which is commonly in seven months: it is then let off and the crop cut down with reaping hooks, and carried to the threshing floor, where it is trod out by buffaloes.

930. *The agricultural implements of the Singalese are few and simple; they consist of jungle hooks (fig. 121. a), for cutting down trees and underwood; an axe (b); a sort of French spade or béche (c); a plough of the lightest kind (d), which the ploughman holds with one hand, the beam being attached to a pair of buffaloes, by a yoke (e), and with the other, he carries a long goad (f), with which, and his voice, he directs and stimulates the animals. A sort of level (g) is used for levelling the ground after ploughing, which, like the plough, is drawn by a pair of buffaloes, the driver sitting on it to give it momentum. For smoothing the surface of the mud preparatory to sowing, a sort of light scraper (h) is employed. The reaping hook (i) is similar to ours; their winnow (k) is composed of strong matting, and a frame of rough twigs. The threshing floor is made of beaten clay; and previously to commencing the operation of treading out, a charm (fig. 122. l) is drawn on the middle of the floor. A forked stick (m) is used to gather and stir up the straw under the buffaloes' feet. (Davy's Ceylon, 278.)*

931. *A Singalese farmyard bears some resemblance to one of this country (fig. 123.); but fewer buildings are required, and no barn.*

123

932. *An embankment, or retaining mound, by which an artificial lake of three or four miles in circumference is dammed up, is described by Dr. Davy. It is nearly a straight line across the valley, twenty feet high, and 150 or 200 feet wide; the side next the water forming an angle of 45°, and faced with large stones, in the manner of steps. This must have been a work of great labour to so rude and simple a people.*

SUBJECT. 7. *Of the present State of Agriculture in the Birman Empire, in Java, Malacca, Siam, Cochín-China, Tonquin, Japan, &c.*

933. *The agriculture of these countries, and of others of minor note adjoining them, differs little, as far as it is known, from that of Hindustan. In all of them the sovereign is the lord of the soil; the operative occupier is wretchedly poor and oppressed. The chief product is rice; the chief animal of labour the buffalo or ox; the chief manure, water; and the chief material for buildings and implements, the bamboo.*

934. *The Birman empire is distinguished for the salubrity of its climate, and the health and vigour of the natives. In this respect they possess a decided preeminence over the enervated natives of the East; nor are the inhabitants of any country capable of greater bodily exertions than the Birmans.*

935. *The seasons of this country are regular, and the extremes of heat and cold are seldom experienced; at least, the duration of that intense heat, which immediately precedes the commencement of the rainy season, is so short that its inconvenience is very little felt. The forests, however, like some other woody and uncultivated parts of India, are extremely pestiferous; and an inhabitant of the campaign country considers a journey thither as inevitable destruction. The wood-cutters, who are a particular class of men, born and bred in the hills, are said to be unhealthy, and seldom attain longevity.*

936. *The soil of the southern provinces of the Birman empire is remarkably fertile, and produces as luxuriant crops of rice as are to be found in the finest parts of Bengal. Towards the north, the face of the country is irregular and mountainous, with headlong torrents and rivers in yawning chasms, crossed by astonishing bridges: but the plains and valleys are exceedingly fruitful; they yield good wheat and various kinds of small grain which grow in Hindustan, together with most of the esculent legumes and vegetables of India. Sugar-canes, tobacco of a superior quality, indigo, cotton, and the different tropical fruits in perfection, are all indigenous products of this country. Besides the teak tree (*Tectona grandis*), which grows in many parts of the Birman empire, as well to the north of Ummerapoora, as in the southern country, there is almost every description of timber that is known in India.*

937. *The cattle used in some parts of the country for tillage and draught are remarkably good; they put only a pair of them to the plough, which is little different from the plough of India, and turns up the soil very superficially. In their large carts they yoke four stout oxen, which proceed with the speed of a hand gallop, and are driven by a country girl, standing up in her vehicle, who manages the reins and a long whip with ease and dexterity. Many of the rising grounds are planted with indigo; but the natives suffer the hills for the most part to remain uncultivated, and only plough the rich levels. They every where burn the rank grass once a year to improve the pasture. The Birmans will not take much pains; they leave half the work to nature, which has been very bountiful to them. In the neighbourhood of Loenghe many fields are planted with cotton, which thrives well; sesamum is also cultivated in this soil, and is found to answer better than rice, which is most productive in low and moist grounds. In the suburbs of Pagalm, there are at least two hundred mills employed in expressing oil from the sesamum seed. In this operation the grain is put into a deep wooden trough, and pressed by an upright timber fixed in a frame; the force is increased by a long lever, on the extremity of which a man sits and guides a bullock that moves in a circle; thus turning and pressing the seed at the same time. The machine is simple, and yet effectually answers the purpose.*

938. *Among the vegetable productions of this country, we may enumerate the white sandal-tree, and the Aloéxylon verum, producing the true jet-black ebony wood; the sycamore fig, Indian fig, and banyan tree; the Bignonia indica, Nauclea orientalis; Córpyha rotundifolia, one of the loftiest of the palm trees; and Excæcaria cochinchinensis, remarkable for the crimson under-surface of its leaves. To the class of plants used in medicine and the arts, we may refer the ginger and cardamom, found wild on the sides of rivers, and cultivated in great abundance; the turmeric, used by the natives of the coast to tinge and flavour their rice and other food; the betel pepper, Fagðra Piperita, and three or four kinds of Capsicum; the Justicia tinctoria, yielding a beautiful green tinge; Morinda umbellata, gamboge, and Carthamus, furnishing yellow dyes; the red wood of the Lawsonia spinosa and Cæsálpinia Sáppan; and the indigo. The bark of the Nerium antidysenterica called codagapala, and that of the Laurus Culitaban; the fruit of the Strychnos núx vomica, the Cassia fistula, the tamarind, and the Cræton Tigilium; the inspissated juice of the aloe, the resin of the camphor tree, and the oil of the Ricinus, are occasionally imported from this country for the European dispensaries. The cinnamon laurel, sometimes accompanied by the nutmeg, sugar cane, bamboe, and spikenard, is found throughout the whole country; the last on dry hills, and the bamboe and sugar cane in rich swamps. The sweet potato, Ipomœa tuberosa, mad apple and love-apple Solánum Melóngena and Lycopersicon, Nymphaea, Nelúmbium, gourds, melons, water melons, and various other esculent plants, enrich this country by cultivation; and the plantain, cocca-nut, and sago palm, are produced spontaneously. The vine grows wild in the forests, but its fruit is inferior, from want of cultivation and through excess of heat, to that of the south of Europe; but this country is amply supplied with the mango, pine-apple, Sapindus edulis, mangostan plum, Averrhoa Carambóla, custard-apple, papaw-fig, orange, lemon, lime, and many other exquisite fruits.*

939. *The animals of the Birman empire correspond to those of Hindustan. The wild elephants of Pegu are very numerous; and, allured by the early crops of rice, commit great devastation among the plantations that are exposed to their ravages. The king is the proprietor of these animals; and one of his Birman majesty's titles is "lord of the white elephants and of all the elephants in the world." The forests abound with tigers. The horses are small, but handsome and spirited, hardy and active; and are frequently exported in timber-ships bound for Madras and other parts of the coast, where they are disposed of to considerable advantage. Their cows are diminutive, resembling the breed on the coast of Coromandel; but their buffaloes are noble animals, much superior to those of India, and are used for draught and agriculture: some of them are of a light cream colour, and are almost as fierce as tigers, who dare not molest them. The ichneumon, or rat of Pharaoh, called by the natives ounbaui, is found in this country; but there is no such animal as the jackal in the Ava dominions, though they are very*

numerous in the adjoining country. Among the birds, which are the same with those of other parts of India, is one called the *henza*, the symbol of the Birman nation, as the eagle was of the Roman empire. It is a species of wild fowl, called in India the Bramin goose; but the natives of Ava do not deify this bird.

940. *The agriculture of Java* has been noticed by Thunberg, and more fully described by Sir Stamford Raffles. *The climate*, like that of other countries situated within about ten degrees of the equator, presents a perpetual spring, summer, and harvest. The distinction of weather is into wet and dry, never hot and cold, and rain depends on the winds. *The surface of the country* is low towards the coast, but hilly in the interior; unhealthy about Batavia, but in most other parts as salubrious as any other tropical country. *The soil* is for the most part rich, and remarkable for its depth; probably, as Governor Raffles conjectures, owing to its volcanic origin.

941. *Landed property* in Java is almost exclusively vested in the king, between whom and the cultivator there are no intermediate holders; and the cultivator is without lease or right beyond the will of the sovereign. The manner in which the king draws his income from the whole surface of the country is by burdening certain "villages or estates with the salaries of particular officers, allotting others for the support of his relatives or favourites, or granting them for the use of particular charitable institutions; in the same manner as before the consolidation act in Britain, the interest of particular loans was paid upon the produce of specific imports." Tradesmen, government officers, priests, and the government, are all alike paid in kind.

942. *The crops raised by the farmer for home consumption* are chiefly rice and maize, some wheat is also grown; but the staple article is rice, of which one pound and a half per day are considered sufficient nourishment for an adult.

943. *The crops raised by the colonists* are coffee, sugar, cotton, tobacco, and a variety of other productions of the East. One of the principal articles is coffee. The coffee plants are first raised in seed-beds, then transplanted under an open shed for the sake of shade, and then in about eighteen months removed into the garden or plantation, where they are destined to yield their fruit. A plantation is laid out in squares, the distance of plant from plant being commonly about six feet, and in the centre of each four trees is placed a *dadap tree*, for the purpose of affording shade, which in Java seems necessary to the health of the plants. They are never pruned, grow to the height of sixteen feet, and will bear for twenty years; but a plantation in Java is seldom continued more than ten years. In general three crops of berries are produced in a season.

944. *The live stock* of the Java farmer consists of the ox and buffalo, used in ploughing, and the horse for burden: they have a few sheep, and goats and poultry.

945. *The implements* are the plough, of which they have a common or rice ground sort, a dry-soil plough, and a garden or plantation plough, all of which are yoked to a pair of buffaloes, or oxen, in the same manner. The harrow (*fig. 124. a*), on which the

driver sits, is a sort of rake; and they have a sort of strong hoe, which they use as a substitute for a spade (*b*), and a lighter one, used as a draw hoe (*c*). Their knives for weeding, pruning, and reaping (*fig. 125. a to f*), are very curious; one of them (*g*) is used both as an axe and bill, and another (*h*) as a thrust hoe and pruning hook. It is observed by Governor Raffles, that in reaping they crop off "each separate ear along with a few inches of the straw;" an "operose process," which he was informed had its origin in some religious notions. Crops are generally dibbled or

transplanted; no manure is even required or given in Java except water. In ploughing for rice, the land is converted into a semifluid mire, in which the plants are inserted. A curious mode is made use of to scare the birds from ripening crops. An elevated shed is raised in the middle of the plantation or field, within which a child on the watch touches from time to time a series of cords, extending from the shed to the extremities of the field like the radii of a circle, and thus prevents the ravages of birds. The native cart of Java is a clumsy conjunction of boards, running on two solid wheels from five to six feet in diameter, and only from one inch to two inches broad, on a revolving axle. It is drawn by two buffaloes.

946. *The upas, or poison tree (Antiaris toxicaria)*, has been said to be a native of, and peculiar to, Java; but Dr. Horsfield and other botanists have ascertained that there is no tree in the island answering its description: there are two trees used for poisoning warlike instruments, but neither is so powerful as to be used alone; and, indeed, they are in no way remarkable either as poison plants or trees. The *Rafflesiæ Arnóldi*, the most extraordinary parasitic plant known to botanists, is believed to be a native of this island as well as of Sumatra, where it was originally found.

947. *The roads of Java*, Sir Stamford Raffles observes, are of a greater extent and of a better description than in most countries. A high road, passable for carriages at all seasons of the year, runs from the western to the eastern extremity of the island, a distance of not less than eight hundred English miles, with post stations and relays of horses every five miles. The greater part of it is so level that a canal might be cut along its side. There is another high road which crosses the island from north to south, and many intersecting cross roads. The main roads were chiefly formed by the Dutch as military roads, and "so far," Governor Raffles continues, "from contributing to the assistance of the agriculture or trade of Java, their construction has, on the contrary, in many instances been destructive to whole districts. The peasant who completed them by his own labour, or the sacrifice of the lives of his cattle, was debarred from their use, and not permitted to drive his cattle along them, while he saw the advantages they were capable of yielding reserved for his European masters, who thus became enabled to hold a more secure possession of his country." (*History of Java*, i. 198.)

948. *Of the peninsula of Malacca* very little is known. Agriculture is carried on in the marginal districts of the country; but the central parts are covered with unexplored forests, which swarm with lemurs, monkeys, tigers, wild boars, elephants, and other animals. The chief grain cultivated is rice; and the chief exports are, pepper, ginger, gum, and other spices, raisins, and woods. Game and fruits abound. "The lands," Le Pouvre observes, "are of a superior quality; and covered with odoriferous woods; but the culture of the soil abandoned to slaves is fallen into contempt. These wretched labourers, dragged incessantly from their rustic employments by their restless masters who delight in war and maritime enterprises, have rarely time, and never resolution, to give the necessary attention to the labouring of their grounds."

949. *The kingdom of Siam* may be described as a wide vale between two high ridges of mountains; but compared with the Birman empire, the cultivated land is not above half the extent either in breadth or length.

950. *The agriculture of the Siamese* does not extend far from the banks of the river or its branches; so that towards the mountains there are vast aboriginal forests filled with wild animals, whence they obtain the skins which are exported. The rocky and variegated shores of the noble Gulf of Siam, and the size and inundations of the Meinam, conspire with the rich and picturesque vegetation of the forests, illumined at night by crowds of brilliant fire-flies, to impress strangers with admiration and delight.

951. *The soil* towards the mountains is parched and infertile; but, on the shores of the river, consists, like that of Egypt, of a very rich and pure mould, in which a pebble can scarcely be found; and the country would be a terrestrial paradise if its government were not so despotic as to be justly reckoned far inferior to that of their neighbours the Birmans. Rice of excellent quality is the chief product of their agriculture; wheat is not unknown; peas and other vegetables abound; and maize is confined to their gardens. The fertility of Siam depends in a great degree, like that of Egypt on the Nile, on its grand river Meinam and its tributary streams.

952. *The kingdom of Laos* borders on China, and is surrounded by forests and deserts, so as to be of difficult access to strangers. The climate is so temperate, and the air so pure, that men are said to retain their health and vigour, in some instances, to the age of one hundred years. The flat part of the country resembles Siam. The soil on the east bank of the river is more fertile than that on the west. The rice is preferred to that of other Oriental countries. Excellent wax and honey are produced in abundance, and the poppy, ginger, pepper, and other useful plants are cultivated, and their products exchanged with the Chinese for cloths.

953. *Cambodia*, like Siam, is enclosed by mountains on the east and west; and fertilised by an overflowing river. The climate is so hot that the inhabitants are under

the necessity of residing on the banks of the rivers and lakes, where they are tormented by mosquitos. The soil is fertile, and produces abundance of corn, rice, excellent legumes, sugar, indigo, opium, camphor and various medicinal drugs. The most peculiar product is the gamboge gum (*Stalagmitis cambogioides*), which yields a fine yellow tint. Ivory, also, and silk are very plentiful, and of little value. Cattle, particularly of the cow kind, are numerous and cheap. Elephants, lions, tigers, and almost all the animals of the deserts of Africa are found in Cambodia. It has several precious woods, among which are the sandal and eagle wood, and a particular tree, in the juice of which they dip their arrows; and it is said, that though a wound from one of the arrows proves fatal, the juice itself may be drank without danger. The country, though fertile, is very thinly peopled.

954. *Cochin-China* presents an extensive range of coast, but few marks of tillage. Besides rice and other grains, sugar, silk, cotton, tobacco, yams, sweet potatoes, pumpkins, melons, and other culinary vegetables, are cultivated; and cinnamon, pepper, ginger, cardamom, silk, cotton, sugar, aulac wood, Japan wood, Columbo, and other woods and spice plants, abound in the forests and copses. The horses are small but active; and they have the ox, buffalo, mules, asses, sheep, swine, and goats. Tigers, elephants, and monkeys abound in the forests, and on the shores are found the edible swallows' nests, esteemed a luxury in the East and especially in China. These nests, according to some, are formed of the *Fucus lichenoides*; according to others, of the spawn of fish. A good account of them will be found in the *Farmer's Magazine* (vol. xx.), written by a gentleman who had resided some years on Prince of Wales's Island. Almost every kind of domestic animal, except sheep, appears to be very plentiful. In *Cochin-China* they have bullocks, goats, swine, buffaloes, elephants, camels, and horses. In the woods are found the wild boar, tiger, rhinoceros, and plenty of deer. They account the flesh of the elephant a great dainty, and their poultry is excellent. They pay little attention to the breeding of bullocks, as the tillage is performed by buffaloes, and bullock's flesh is not esteemed as food. The sea, as well as the land, is a never-failing source of sustenance to those who dwell on the coast. Most of the marine worms distinguished by the name of *Mollusca*, are used as articles of food by the *Cochin-Chinese*. All the gelatinous substances derived from the sea, whether animal or vegetable, are considered by them the most nutritious of all aliments; and on this principle various kinds of sea-weeds, particularly the *Fuci* and *Algæ*, are included in their list of edible plants. They likewise collect many of the small succulent, or fleshy, plants, which are usually produced on salt and sandy marshes; these they either boil in their soups, or eat in a raw state, to give sapidity to their rice, which with them is the grand support of existence. In *Cochin-China* they are almost certain of two plentiful crops of rice every year, one of which is reaped in April, the other in October. Fruits of various kinds, as oranges, bananas, figs, pine-apples, pomegranates, and others of inferior note, are abundantly produced in all parts of the country. They have very fine yams, and plenty of sweet potatoes. Their small breed of cattle does not appear to furnish them with much milk; but of this article they make a sparing use, even with regard to their young children.

955. *Tonquin*, in regard to surface, may be divided into two portions, the mountainous and the plain. The mountains are neither rocky nor precipitous, and are partly covered with forests. The plain is flat like Holland, being intersected by canals and dykes, and varied by lakes and rivers. The chief agricultural product is rice, of which there are two harvests annually in the low country, but in the high lands only one. Wheat and wine are unknown. The mulberry tree is common; and the sugar cane is indigenous; but the art of refining the juice is unknown. The live stock are chiefly oxen, buffaloes, and horses; swine abound, and there are a few goats, but asses and sheep are unknown. Dogs, cats, and rats are eaten. Poultry, ducks, and geese abound, and are found wild in the forests. The eggs of ducks are heated in ovens, and produce young, which swarm in the canals and ponds. The forests contain deer, boars, peacocks, a peculiar kind of partridge, and quails. The tigers are large and destructive; one of them is said to have entered a town, and to have destroyed eighty-five people. The wild elephants are also very dangerous. Apes are found in these forests, and some of them of large size: these and the parrots are not a little destructive to the rice and fruits. The *Tonquin* plough consists of three pieces of wood, a pole, a handle, and a third piece, almost at right angles with the last, for opening the ground; and they are simply fixed with straps of leather: this plough is drawn by oxen or buffaloes.

956. *The agriculture of Japan* is superior to that of most Eastern countries. The climate is variable. In summer the heat is violent; and, if it were not moderated by sea breezes, would be intolerable. The cold in winter is severe. The falls of rain commence at midsummer, and to these Japan owes its fertility, and also its high state of population. Thunder is not unfrequent: tempests, hurricanes, and earthquakes are very common. From *Thunberg's* thermometrical observations it appears that the greatest

degree of heat at Negasaki was 98° in August, and the severest cold in January, 35°. The face of the country presents some extensive plains, but more generally mountains, hills, and valleys; the coast being mostly rocky and precipitous, and invested with a turbulent sea. It is also diversified with rivers and rivulets, and many species of vegetables.

957. *The soil of Japan*, though barren, is rendered productive by fertilising showers, by manure, and by the operation of agricultural industry.

958. *Agriculture, Thunberg informs us, is here well understood*, and the whole country, even to the tops of the hills, is cultivated. Free from all feudal and ecclesiastical impediments, the farmer applies himself to the culture of the soil with diligence and vigour. Here are no commons; and it is a singular circumstance, that, if any portion be left uncultivated, it may be seized by a more industrious neighbour. The Japanese mode of manuring is to form a mixture of all kinds of excrements with kitchen refuse, which is carried in pails into the field, and poured with a ladle upon the plants, when they have attained the height of about six inches; so that they thus instantly receive the whole benefit. They are also very attentive to weeding. The sides of the hills are cultivated by means of stone walls, supporting broad plots, sown with rice or esculent roots. Rice is the chief grain; buckwheat, rye, barley, and wheat being little used. A kind of root, used as the potato (*Convolvulus edulis*), is abundant, with several sorts of beans, peas, turnips, cabbages, &c. From the seed of a kind of cabbage, lamp oil is expressed; and several plants are cultivated for dyeing, with the cotton shrubs, and mulberry trees for the food of silkworms. The varnish and camphire trees, the vine, the cedar, the tea tree, and the bamboo reed, not only grow wild but are planted for numerous uses.

959. *In respect to live stock*, there are neither sheep nor goats in the whole empire of Japan; and, in general, there are but few quadrupeds. The food of the Japanese consists almost entirely of fish and fowl with vegetables. Some few dogs are kept from motives of superstition; and cats are favourites with the ladies. Hens and common ducks are domesticated for the sake of their eggs.

SUBJECT. 8. *Of the present State of Agriculture in the Chinese Empire.*

960. *Agricultural improvement in China* has, in all ages, been encouraged and honoured. The husbandman is considered an honourable, as well as a useful, member of society; he ranks next to men of letters or officers of state, of whom he is frequently the progenitor. The soldier, in China, cultivates the ground. The priests also are agriculturists, whenever their convents are endowed with land. Notwithstanding all these advantages, however, the Chinese empire is by no means so generally cultivated as Du Halde and other early travellers asserted. Some districts are almost entirely under cultivation; but in many there are extensive wastes.

961. *Dr. Abel is of opinion* that in that part of China passed through by Lord Amherst's embassy, the land "very feebly productive in food for man fully equalled that which afforded it in abundant quantity." He never found extensive tracts of land in general cultivation, but often great industry and ingenuity on small spots; and concludes that "as horticulturists the Chinese may perhaps be allowed a considerable share of merit; but, on the great scale of agriculture, they are not to be mentioned with any European nation." (*Narrative*, 127.)

962. *Livingstone*, an intelligent resident in China, observes, "The statement in the *Encyclopædia Britannica*, that 'Chinese agriculture is distinguished and encouraged by the court beyond all other sciences,' is incorrect, since it is unquestionably subordinate to literature; and it may be well doubted whether it ought to be considered as holding among the Chinese the rank of a science; for, independently of that routine which has been followed, with little variation, from a very high antiquity, they seem to be entirely ignorant of all the principles by which it could have been placed on a scientific foundation." (*Hort. Trans.*, v. 49.)

963. *The climate of China* is in general reckoned moderate, though it extends from the 50th to the 21st degree of south latitude, and includes three climates. The northern parts are liable to all the rigours of a European winter. Even at Peking, at that season, the average of the thermometer is under 20° during the night, and in the day considerably below the freezing point. The heat of those parts which lie under the tropics is moderated by the winds from the mountains of Tatory. In the southern parts there is neither frost nor snow, but storms are very frequent, especially about the time of the equinoxes; all the rest of the year the sky is serene, and the earth covered with verdure.

964. *The surface of the country*, though in general flat, is much diversified by chains of granite mountains, hills, rivers, canals, and savage and uncultivated districts, towns innumerable, villages, and cottages covered with thatch, reed, or palm leaves, and in some places with their gardens, or fore-courts, fenced with rude pales, as in England.

(fig. 126.) China, Dr. Abel observes, from the great extent of latitude contained in its boundaries, and from its extensive plains and lofty mountains, partakes of the advantages and defects of many climates, and displays a country of features infinitely varied by nature. Every thing artificial, however, has nearly the same characters in every province.

126

965. *The soil varies exceedingly*: it is in many parts not naturally fertile; but has almost every where been rendered so by the application of culture and manure for successive ages.

966. *The landed property of China* is considered as the absolute right of the emperor: but the sub-proprietor, or first holder, is never turned out of possession as long as he continues to pay about the tenth part of what his farm is supposed capable of yielding; and, though the holder of lands is only considered as a tenant at will, it is his own fault if he is dispossessed. If any one happens to hold more than his family can conveniently cultivate, he lets it to another, on condition of receiving half the produce, out of which he pays the whole of the emperor's taxes. The greater part of the poor peasantry cultivate land on these terms. In China there are no immense estates, no fisheries are let out to farm. Every subject is equally entitled to the free and uninterrupted enjoyment of the sea, of the coasts, of the estuaries, of the lakes and rivers. There are no manor lords with exclusive privileges, nor any game laws.

967. *The agricultural products of China* extend to every useful vegetable. There is scarcely a grain, a fruit, a tree, or a culinary vegetable of Europe, or the rest of the world, that they do not cultivate; and they have a number peculiar to themselves. Fowl and fish are not extensively reared, as the chief articles of diet are vegetables. Rice is the common grain of the country; a species of cabbage, the universal culinary vegetable; swine, the most abundant live stock; and tea, the chief plant of export.

968. *The tea districts of China* extend from the 27th to the 31st degree of latitude. According to the missionaries, it thrives in the more northern provinces; and from Kæmpfer it appears to be cultivated in Japan as far north as lat. 45°. It seems, according to Dr. Abel's observation, to succeed best on the sides of mountains, where there can be but little accumulation of vegetable mould. The soils from which he collected the best specimens consisted chiefly of sandstone, schistus, or granite. The land forming the Cape of Good Hope consisting of the same rocks, and its geographical position corresponding to that of the tea districts of China, Dr. Abel considers it might be grown there, if desirable, to such an extent as to supersede the necessity of procuring it from China. It grows well in St. Helena and Rio Janeiro, and will grow any where in a meagre soil and moderate temperature.

969. *The culture of the tea plant* in China has been given by various authors. It is raised from seeds sown where the plants are to remain. Three or more are dropped into a hole four or five inches deep; these come up without further trouble, and require little culture, except that of removing weeds, till the plants are three years old. The more careful stir the soil, and some manure it; but the latter practice is seldom adopted. The third year the leaves are gathered, at three successive gatherings, in February, April, and June, and so on till the bushes become stunted or tardy in their growth, which generally happens in from six to ten years. They are then *cut-in* to encourage the production of fresh shoots.

970. *The gathering of the leaves* is performed with care and selection. The leaves are plucked off one by one: at the first gathering only the unexpanded and tender are taken; at the second, those that are full grown; and at the third, the coarsest. The first forms what is called in Europe imperial tea; but of this and other names by which tea is designated, the Chinese know nothing; and the compounds and names are supposed to be made and given by the merchants at Canton, who, from the great number of varieties brought to them, have an ample opportunity of doing so. These varieties, though numerous, and some of them very different, are yet not more so than the different varieties of the grape; they are now generally considered as belonging to one species; the *Thèa Bohèa*, now *Camèllia Bohèa* (fig. 127. a), of botanists. Formerly it was thought that green tea was gathered exclusively from *Camèllia viridis*; but that is now doubtful, though it is certain there is what is called the green tea district, and the black tea district; and the varieties grown in the one district differ from those grown in the other. Dr. Abel could not satisfy himself as to there being two species or one; but thinks there are two species. He was told by competent persons that either of the two plants will afford the black or green tea of the shops, but that the broad thin-leaved plant (*C. viridis*) is preferred for making the green tea.

971. *The tea leaves* being gathered are cured in houses which contain from five to ten or twenty small furnaces, about three feet high, each having at the top a large flat iron pan. There is also a long low table covered with mats, on which the leaves are laid, and rolled by workmen, who sit round it: the iron pan being heated to a certain degree by a little fire made in the furnace underneath, a few pounds of the fresh-gathered leaves are put upon the pan; the fresh and juicy leaves crack when they touch the pan, and it is the business of the operator to shift them as quickly as possible with his bare hands, till they become too hot to be easily endured. At this instant he takes off the leaves with a kind of shovel resembling a fan, and pours them on the mats before the rollers, who, taking small quantities at a time, roll them in the palms of their hands in one direction, while others are fanning them, that they may cool the more speedily and retain their curl the longer. This process is repeated two or three times or oftener, before the tea is put into the stores, in order that all the moisture of the leaves may be thoroughly dissipated, and their curl more completely preserved. On every repetition the pan is less heated, and the operation performed more slowly and cautiously. The tea is then separated into the different kinds, and deposited in the store for domestic use or exportation.

972. *The different sorts of black and green* are not merely from soil, situation, and age of the leaf: but, after winnowing the tea, the leaves are taken up in succession as they fall; those nearest the machine, being the heaviest, form the gunpowder tea; the light dust the worst, being chiefly used by the lower classes. That which is brought down to Canton undergoes there a second roasting, winnowing, packing, &c., and many hundred women are employed for these purposes.

973. *As more select sorts of tea*, the blossoms of the *Camèllia Sasánqua* (fig. 127. b) appear to be collected; since they are brought over land to Russia, and sold by Chinese and Armenians in Moscow at a great price. The buds also appear to be gathered in some cases. By far the strongest tea which Dr. Abel tasted in China, was that called Yu-tien, used on occasions of ceremony. It scarcely coloured the water, and on examination was found to consist of the half-expanded leaves of the plant.

974. *As substitutes for tea*, used by the Chinese, may be mentioned a species of moss common to the mountains of Shan-tung; an infusion of ferns of different sorts, and, Dr. Abel thinks, the leaves of the common camellia and oil camellia may be added. Du Halde observes that all the plants called tea by the Chinese are not to be considered as the true tea plant; and Kämpfer asserts that in Japan a species of *Camèllia*, as well as the *O'lea frágans*, is used to give it a high flavour.

975. *The oil-bearing tea plant* (*Camèllia oleífera*) is cultivated for its seeds, from which an oil is expressed, in very general use in the domestic economy of China. It grows best in a red sandy soil; attaining the height of six or eight feet, and producing a profusion of white blossoms and seeds. These seeds are reduced to a coarse powder, either in a mortar by a pestle acted on by the cogs of a water-wheel (fig. 128.), or by a horizontal wheel, having small perpendicular wheels, shod with iron, fixed to its circumference, and acting in a groove lined with the same metal. The seeds, when ground, are stewed or boiled in bags, and then pressed, when the oil is yielded. The press is a hollow cylinder, with a piston pressed

against one end, by driving wedges at the side; it is very simple and yet powerful. (*Dr. Abel's Nar.*, 176.) An oil used as a varnish is extracted from another variety of the *Camélia*, or tea plant (the *Dryandra cordata* of Thunb.), which is used as a varnish for their boats, and coarser articles of furniture.

976. *The tallow tree* (*Craton sebiferum*) resembles the oak in the height of its stem and the spread of its branches, and its foliage has the green and lustre of the laurel; its flowers are small and yellow, and its seeds white. The latter are crushed either as the camellia seeds, or in a hollow trunk of a tree, lined with iron, by means of a wheel laden with a heavy weight (*fig. 129.*), and suspended from a beam. The bruised matter next undergoes nearly the same process as the camellia seeds, and the oily matter is found to have all the properties of animal tallow. It is mixed with vegetable oil and wax, to give it consistence, and then made into candles, which burn with great flame, emit much smoke, and quickly consume.

977. *The wax tree, or Pe-la*, is a term which is not applicable to any one species of tree, but to such as are attacked by a small worm, which runs up, and fastens to their leaves, covering them with combs. When these worms are once used to the trees of any district, they never leave them, unless something extraordinary drives them away. The wax produced is hard, shining, and considerably dearer than that of bees.

978. *The Sesamum orientale* and the *Ricinus communis*, or castor-oil plant, are cultivated for the essential oils extracted from their seeds. They appear to have some method of depriving the castor oil of its purgative qualities, but Dr. Abel thinks not completely.

979. *The camphire tree* (*Laurus Camphora*) grows to the size of our elms or oaks. The camphire is procured by boiling the fresh-gathered branches of the tree, and stirring the whole with a stick, till the gum begins to adhere to it in the form of a white jelly. The fluid is then poured off into a glazed vessel, and left to congeal. The crude camphire is then purified in the following manner. A quantity of the finely powdered materials of some old wall, built of earth, is put as a first layer at the bottom of a copper basin; on this is placed a layer of camphire, and then another of earth, and so on till the vessel is nearly filled; the series being terminated with a layer of earth; over this is laid a covering of the leaves of the plant *Poa*, perhaps a species of *Mntha*. A second basin is now inverted over the first, and luted on. The whole thus prepared is put over a regulated fire, and submitted to its action for a certain length of time; it is then removed and suffered to cool. The camphire is found to have sublimed, and to be attached to the upper basin, and is further refined by repetitions of the same process." (*Narrative*, &c., 179.)

980. *The oak* is as much prized in China as in other countries, and is styled the tree of inheritance. There are several species in general use for building, dyeing, and fuel; and the acorns are ground into a paste, which mixed with the flour of corn is made into cakes.

981. *The maidenhair tree* (*Salisbiana adiantifolia*) is grown for its fruit, which Dr. Abel saw exposed in quantities; but whether as a table fruit, a culinary vegetable, or a medicine, he could not ascertain. Kämpfer says, the fruit assists digestion.

982. *The cordage plant* (*Sida tiliaefolia*) is extensively cultivated for the manufacture of cordage from its fibres. The common hemp is used for the same purpose, but the *Sida* is preferred. A species of *Misa* is also grown in some places, and its fibres used for rope and other purposes.

983. *The common cotton*, and also a variety bearing a yellow down, from which, without any dyeing process, the nankeen cloths are formed, are grown in different places. The mulberry is grown in a dwarf state, as in Hindustan.

984. *The ground nut* (*Arachis hypogæa*), the eatable arum (*Arum esculentum*), the *Trapa bicornis*, the *Scirpus tuberosus*, and *Netumbium*, all producing edible tubers, are cultivated in lakes, tanks, or marshy places.

985. *The Nelumbium*, Dr. Abel observes, with its pink and yellow blossoms, and broad green leaves, gives a charm and productiveness to marshes, otherwise unsightly and barren. The leaves of the plant are watered in the summer, and cut down close to the roots on the approach of winter. The seeds, which are in size and form like a small acorn without its cup, are eaten green, or dried as nuts, and are often preserved in sweetmeats; they have a nut-like flavour. Its roots are sometimes as thick as the arm, of a pale green without, and whitish within; in a raw state they are eaten as fruit, being juicy and of a sweetish and refreshing flavour; and when boiled are served as vegetables.

986. *The Scirpus tuberosus*, or water chestnut (*fig. 130.*), is a stoloniferous rush, almost without leaves, and the tubers are produced on the stolones. It grows in tanks, which are manured for its reception about the end of March. A tank being drained of its water, small pits are dug in its bottom; they are filled with human manure, and exposed to the sun for a fortnight; their contents are next intimately blended with the slimy bottom of the tank, and slips of the plant inserted. The water is now returned to the tank, and the first crop of tubers comes to perfection in six months. (*Box. Coromandel.*)

987. *The millet* (*Hôteus*) is grown on the banks of rivers, and attains the height of sixteen feet. It is sown in rows, and after it comes up *Panicum* is sown between, which comes to perfection after the other is cut down.

988. Among the many esculent vegetables cultivated in China, the petsai, a species of white cabbage, is in most general use. The

129

130

quantity consumed of it over the whole empire is, according to all authors, immense; and, Dr. Abel thinks, it may be considered to the Chinese what the potato is to the Irish. It is cultivated with great care, and requires abundant manuring, like its congeners of the *Brássica* tribe. Boiled, it has the flavour of asparagus; and raw, it eats like lettuce and is not inferior. It often weighs from fifteen to twenty pounds, and reaches the height of two or three feet. It is preserved fresh during winter by burying in the earth; and it is pickled with salt and vinegar.

989. *Almost every vegetable of use, as food, in the arts, or as medicine, known to the rest of the world, is cultivated in China, with, perhaps, a very few exceptions of equatorial plants.* The bamboo and cocoa-nut tree, as in Hindustan, are in universal use: indigo is extensively cultivated; sugar also in the southern provinces, but it is rather a luxury than an article of common consumption. It is used mostly in a coarse granulated form; but for exportation, and for the upper classes, it is reduced to its crystallised state. Tobacco is every where cultivated, and in universal use, by all ages, and both sexes. Fruits of every kind abound, but they are mostly bad, except the orange and the *lee-tchee* (*Dimocarpus Lüchi*), both of which are probably indigenous. The art of grafting is well known, having been introduced by the missionaries; but they do not appear to have taken advantage of this knowledge for the improvement of their fruits. They have also an art which enables them to take off bearing branches of fruit, particularly of the orange and peach, and transfer them, in a growing state, to pots, for their artificial rocks and grottos, and summer-houses. It is simply by removing a ring of the bark, plastering round it a ball of earth, and suspending a vessel of water to drop upon it, until the upper edge of the incision has thrown out roots into the earth.

990. *The live stock of Chinese agriculture is neither abundant nor various.* The greater part of their culture being on a small scale, and performed by manual operations, does not require many beasts of labour: their canals and boats supply the place of beasts of burden: and their general abstemiousness renders animals for the butcher less necessary. They rear, however, though in comparatively small number, all the domestic animals of Europe; the horse, the ass, the ox, the buffalo, the dog, the cat, the pig; but their horses are small and ill-formed. The camels of China are often no larger than our horses; the other breeds are good, and particularly that of pigs. The kind of dog most common in the south, from Canton to Tong-chin-tcheu, is the spaniel with straight ears. More to the north, as far as Peking, the dogs have generally hanging ears and slender tails.

991. *The Chinese are exceedingly sparing in the use of animal food.* The broad-tailed sheep are kept in the hilly parts of the country, and brought down to the plains; but the two animals most esteemed, because they contribute most to their own subsistence and are kept at the cheapest rate, are the hog and the duck. Whole swarms of the latter are bred in large barges, surrounded with projecting stages covered with coops for the reception of these birds, which are taught, by the sound of the whistle, to jump into the rivers and canals in search of food, and by another call to return to their lodgings. They are usually hatched by placing their eggs, as the ancient Egyptians were wont to do, in small ovens, or sandbaths, in order that the same female may continue to lay eggs throughout the year, which would not be the case if she had a young brood to attend. The ducks, when killed, are usually split open, salted, and dried in the sun; in which state they afford an excellent relish to rice or other vegetables.

992. *The wild animals are numerous.* Elephants are common in the south of China, and extend as far as the thirtieth degree of north latitude in the province of Kiangnan and of Yun-nan. The unicorn rhinoceros lives on the sides of the marshes in the provinces of Yun-nan and Quan-si. The lion, according to Du Halde and Trigault, is a stranger to China; but the animal figured by Neuhoff, under the name of the tiger, seems to be the maneless lion known to the ancients, described by Oppian, and seen by M. Olivier on the Euphrates. Marco Polo saw lions in Fo-kien: there were some at the court of Kublai Khan. The true tiger probably shows himself in the most southerly provinces, where there are also various kinds of monkeys; the long-armed gibbon or *Símia longimànus*; the *Símia influens*, or ugly baboon; and the *Símia Sylvànus*, which mimics the gestures and even the laughter of men. The musk animal, which seems peculiar to the central plateau of Asia, sometimes goes down into the western provinces of China. The deer, the boar, the fox, and other animals, some of which are little known, are found in the forests.

993. *Several of the birds of the country are distinguished for beauty of form and brilliancy of colour; such as the gold and silver pheasants, which we see often painted on the Chinese papers, and which have been brought to this country to adorn our aviaries; also the Chinese teal, remarkable for its two beautiful orange crests. The insects and butterflies are equally distinguished for their uncommon beauty. Silkworms are common, and seem to be indigenous in the country. From drawings made in China, it appears to possess almost all the common fishes of Europe; and M. Bloch, and M. de Lacepede have made us acquainted with several species peculiar to it. The Chinese gold-fish*

(*Cyprinus auratus*), which, in that country, as with us, is kept in basins as an ornament, is a native of a lake at the foot of the high mountain of Tein-king, near the city of Tchang-hoo, in the province of Tché-kiang. From that place it has been taken to all the other provinces of the empire and to Japan. It was in 1611 that it was first brought to England.

994. *The fisheries of China*, as already noticed, are free to all; there are no restrictions on any of the great lakes, the rivers, or canals. The subject is not once mentioned in the *Leu-lee*; but the heavy duties on salt render the use of salt-fish in China almost unknown. Besides the net, the line, and the spear, the Chinese have several ingenious methods of catching fish. In the middle parts of the empire, the fishing corvator (*Pelicanus piscator*) is almost universally in use; in other parts they catch them by torch-light; and a very common practice is, to place a board painted white along the edge of the boat, which, reflecting the moon's rays into the water, induces the fish to spring towards it, supposing it to be a moving sheet of water, when they fall into the boat.

995. *The implements of Chinese agriculture* are few and simple. The plough has one handle, but no coulter; there are different forms: some may be drawn by women, (*fig. 131. a*), others are for stirring the soil under water (*b*), and the largest is drawn by a single buffalo or ox (*c*). Horses are never employed for that purpose. The carts are

low, narrow, and the wheels so diminutive as often to be made without spokes. A large cylinder is sometimes used to separate the grain from the ear, and they have a winnowing machine similar to that which was invented in Europe about a century ago. The most ingenious machines are those for raising water for the purposes of irrigation. A very ingenious wheel for this purpose has been figured by Sir George Staunton: but the most universally used engine is the chain-pump, worked in various ways by oxen, by walking in a wheel, or by the hand; and next to it buckets worked by long levers (*fig. 132.*), as in the gardens

round London, Paris, Constantinople, and most large cities of Europe. For pounding oleiferous seeds they have also very simple and economical machines, in which pestles on the ends of levers are worked by a horizontal shaft put in motion by a water-wheel. (*fig. 133.*) The chief thing to admire in the implements and machines of India and China is their simplicity, and the ease and little expense with which they may be constructed.

996. *The operations of Chinese agriculture* are numerous, and some of them curious. Two great objects to be procured are water and manure. The former is raised from rivers or wells by the machines already mentioned, and distributed over the cultivated surface in the usual manner, and the latter is obtained from every conceivable source.

997. *The object of their tillage*, Livingstone observes, "appears to be, in the first instance, to expose the soil as extensively as possible; and this is best effected by throwing it up in large masses, in which state it is allowed to remain till it is finally prepared for planting. When sufficient rain has fallen to allow the husbandman

to flood his fields, they are laid under water, in which state they are commonly ploughed again, in the same manner as for fallow, and then a rake, or rather a sort of harrow, about three feet deep and four

feet wide, with a single row of teeth, is drawn, by the same animal that draws their plough, perpendicularly through the soil, to break the lumps, and to convert it into a kind of ooze; and as the teeth of this rake or harrow are not set more than from two to three inches apart, it serves, at the same time, very effectually to remove roots and otherwise to clean the ground. For some purposes, the ground thus prepared is allowed to dry; it is then formed into beds or trenches; the beds are made of a convenient size for watering and laying on manure. The intermediate trenches are commonly about nine inches deep, and of the necessary breadth to give to the beds the required elevation; but when the trenches are wanted for the cultivation of water plants, some part of the soil is removed, so that a trench may be formed of the proper dimensions.

998. For these operations they use a hoe, commonly ten inches deep, and five inches broad, made of iron, or of wood with an iron border, and for some purposes it is divided into four or five prongs. By constant practice the Chinese have acquired such dexterous use of this simple instrument, that they form their beds and trenches with astonishing neatness and regularity. With it they raise the ground which has not been ploughed, from the beds and trenches, by only changing it from a vertical to a horizontal direction, or employing its edge. It is also used for digging, planting, and in general for every purpose which a Chinese husbandman has to accomplish.

999. The collection of manure is an object of so much attention with the Chinese, that a prodigious number of old men, women, and children, incapable of much other labour, are constantly employed about the streets, public roads, and banks of canals and rivers, with baskets tied before them, and holding in their hands small wooden rakes, to pick up the dung of animals, and offals of any kind that may answer the purpose of manure: this is mixed sparingly with a portion of stiff loamy earth, and formed into cakes, dried afterwards in the sun. It sometimes becomes an object of commerce, and is sold to farmers, who never employ it in a compact state. Their first care is to construct very large cisterns, for containing, besides those cakes and dug of every kind, all sorts of vegetable matter, as leaves, roots, or stems of plants, with mud from the canals, and offals of animals, even to the shavings collected by barbers. With all these they mix as much animal water as can be procured, or common water sufficient to dilute the whole; and, in this state, generally in the act of putrid fermentation, they apply it to the ploughed earth. In various parts of a farm, and near the paths and roads, large earthen vessels are buried to the edge in the ground, for the accommodation of the labourer or passenger who may have occasion to use them. In small retiring-houses, built also upon the brink of the roads, and in the neighbourhood of villages, reservoirs are constructed of compact materials, to prevent the absorption of whatever they receive, and straw is carefully thrown over the surface from time to time, to prevent evaporation. Such a value is set upon the principal ingredient, called *ta-feu*, for manure, that the oldest and most helpless persons are not deemed wholly useless to the family by which they are supported. The quantity of manure collected by every means is still inadequate to the demand.

1000. Vegetable or wood ashes, according to Livingstone, are esteemed the very best manure by the Chinese. The weeds which were separated from the land by the harrow, with what they otherwise are able to collect, are carefully burnt, and the ashes spread. The part of the field where this has been done is easily perceived by the most careless observer. Indeed the vigour of the productions of those parts of their land where the ashes have been applied is evident, as long as the crop continues on the ground. The ashes of burnt vegetables are also mixed with a great variety of other matters in forming the compositions which are spread on the fields, or applied to individual plants.

1001. The plaster of old kitchens is much esteemed as a manure; so that a farmer will replaster a cook-house for the old plaster, that he may employ it to fertilise his fields.

1002. Of *night-soil* (*ta-feu*), the Chinese have a high notion: and its collection and formation into cakes, by means of a little clay, clay and lime, or similar substances, give employment to a great number of individuals. They transport these cakes to a great distance. This manure in its recent state is applied to the roots of cauliflowers, cabbages, and similar plants, with the greatest advantage.

1003. The dung and urine of all animals are collected with great care; they are used both mixed and separately. The mixture is less valuable than the dung, and this for general purposes is the better the older it is. Horns and bones reduced to powder, the cakes left after expressing several oils, such as of the ground-nut, hemp-seed, and the like, rank also as manures. Small crabs, the feathers of fowls and ducks, soot, the sweepings of streets, and the stagnant contents of common sewers, are often thought sufficiently valuable to be taken to a great distance, especially when water carriage can be obtained.

1004. Lime is employed chiefly for the purpose of destroying insects; but the Chinese are also aware of its fertilising properties.

1005. The Chinese often manure the plant rather than the soil. The nature of the climate in the southern part of the empire seems to justify fully this very laborious but economical practice. Rain commonly falls in such quantities and with such force as to wash away all the soluble part of the soil, and the manure on which its fertility is supposed to depend; and this often appears to be so effectually done, that nothing meets the eye but sand and small stones. It is therefore proper that the Chinese husbandman should reserve the necessary nourishment of the plant to be applied at the proper time. For this purpose reservoirs of the requisite dimensions are constructed at the corner of every field, or other convenient places.

1006. With the seed or young plant its proper manure is invariably applied. It is then carefully watered in dry weather night and morning, very often with the black stagnant contents of the common sewer; as the plants advance in growth the manure is changed, in some instances more than once, till their advance towards maturity makes any further application unnecessary.

1007. The public retiring-houses are described by Dr. Abel, as rather constructed for exposure than concealment, being merely open sheds with a rail or spar laid over the reservoir.

1008. The mixture of soils is said to be a common practice as a substitute for manure: "they are constantly changing earth from one piece of ground to another; mixing sand with that which appears to be too adhesive, and loam where the soil appears to be too loose," &c.

1009. The terrace cultivation is mentioned by Du Halde and others, as carried to great perfection in China: but the observations of subsequent travellers seem to render this doubtful. Lord Amherst's embassy passed through a hilly and mountainous country for many weeks together: but Dr. Abel, who looked eagerly for examples of that system of cultivation, saw none that answered to the description given by authors. Du Halde's description, he says, may apply to some particular cases: but the instances which he

observed lead him to conclude that terrace cultivation is in a great measure confined to their ravines, undulations, and gentlest declivities.

1010. *Rows, or drills, are almost always adopted* in planting or sowing; and for this purpose the lands are laid flat, and not raised into ridges with intervening furrows. They are said to be particular in having the direction of their rows from north to south, which, other circumstances being suitable, is certainly a desirable practice. Before sowing, seeds are generally kept in liquid manure till they germinate. Barrow frequently saw in the province of Keang—see a woman drawing a light plough with a single handle (*fig. 131. a*), through ground previously prepared; while a man held the plough with one hand, and with the other cast the seed into the drills.

1011. *Forests of immense extent* exist on the mountains of the western districts of China, and abound in almost every species of tree known in Europe, and many others unknown. Besides timber and fuel, these forests supply many valuable products, as barks, gums, oils, and resins, used in the arts. Rose wood, ebony, sandal wood, iron wood, and a great variety of others are sent to Europe for cabinet work. The Chinese aloe has the height and figure of an olive tree. It contains within the bark three sorts of wood; the first, black, compact, and heavy, is called eagle-wood; it is scarce; the second, called calambooc, is light like rotten wood; the third, near the centre, is called calamba wood, and sells in India for its weight in gold; its smell is exquisite, and it is an excellent cordial in cases of fainting or of palsy.

1012. *The national agricultural fête* of the Chinese deserves to be noticed. Every year on the fifteenth day of the first moon, which generally corresponds to some day in the beginning of our March, the emperor in person goes through the ceremony of opening the ground; he repairs in great state to the field appointed for this ceremony. The princes of the imperial family, the presidents of the five great tribunals, and an immense number of mandarins attend him. Two sides of the field are lined with the officers of the emperor's house, the third is occupied by different mandarins; the fourth is reserved for all the labourers of the province, who repair thither to see their art honoured and practised by the head of the empire. The emperor enters the field alone, prostrates himself, and touches the ground nine times with his head in adoration of *Tien*, the God of heaven. He pronounces with a loud voice a prayer prepared by the court of ceremonies, in which he invokes the blessing of the Great Being on his labour, and on that of his whole people. Then, in the capacity of chief priest of the empire, he sacrifices an ox, in homage to heaven as the fountain of all good. While the victim is offered on the altar, a plough is brought to the emperor, to which is yoked a pair of oxen, ornamented in a most magnificent style. The prince lays aside his imperial robes, lays hold of the handle of the plough with the right hand, and opens several furrows in the direction of north and south; then gives the plough into the hands of the chief mandarins, who, labouring in succession, display their comparative dexterity. The ceremony concludes with a distribution of money and pieces of cloth, as presents among the labourers; the ablest of whom execute the rest of the work in presence of the emperor. After the field has received all the necessary work and manure, the emperor returns to commence the sowing with similar ceremony, and in presence of the labourers. These ceremonies are performed on the same day by the viceroys of all the provinces.

SUBSECT. 9. *Of the present State of Agriculture in Chinese Tatar, Thibet, and Bootan.*

1013. *Chinese Tatar* is an extensive region, diversified with all the grand features of nature, and remarkable for its vast elevated plain, supported like a table by the mountains of Thibet in the south, and Allusian chain in the north. This prodigious plain is little known; its climate is supposed to be colder than that of France; its deserts to consist chiefly of a black sand; and its agriculture to be very limited and imperfect. Wheat, however, is said to be grown among the southern Mandshurs.

1014. *Thibet or Tibet* is an immense tract of country little known. It consists of two divisions, *Thibet* and *Bootan*. The climate of Thibet is extremely cold and bleak towards the south, for though on the confines of the torrid zone it vies in this respect with that of the Alps of Italy. That of Bootan is more temperate; and the seasons of both divisions are severe compared to those of Bengal.

1015. *With respect to surface*, Bootan and Thibet exhibit a very remarkable contrast. Bootan presents to the view nothing but the most misshapen irregularities; mountains covered with eternal verdure, and rich with abundant forests of large and lofty trees. Almost every favourable aspect of them, coated with the smallest quantity of soil, is cleared and adapted to cultivation, by being shelved into horizontal beds: not a slope or narrow slip of land between the ridges lies unimproved. There is scarcely a mountain whose base is not washed by some rapid torrent, and many of the loftiest bear populous villages, amidst orchards and other plantations, on their summits and on their sides. It combines in its extent the most extravagant traits of rude nature and laborious art.

1016. *Thibet*, on the other hand, strikes a traveller, at first sight, as one of the least favoured countries under heaven, and appears to be in a great measure incapable of culture. It exhibits only low rocky hills, without any visible vegetation, or extensive arid plains, both of the most stern and stubborn aspect, promising full as little as they produce.

1017. *The agriculture of Thibet* has many obstacles to contend with. Its common products are wheat, peas, and barley. Rice grows only in the southern parts. Turnips, pumpkins, and cucumbers are abundant. The greater part of the plants which travellers have noticed are such as are met with also in Europe and in Bengal. At the foot of the mountains are forests of bamboos, bananas, aspens, birches, cypresses, and yew trees. The ash (*Ornus floribunda*) is remarkably large and beautiful, but the firs small and stunted. On the snow-clad mountains grows the *Rhèum undulatum*, which the natives use for medicinal purposes. The country contains, both in a wild and cultivated state, peaches and apricots, apples, pears, oranges, and pomegranates. The *Cacàlia saracénica* serves for the manufacture of *chong*, a spirituous and slightly acid liquor.

1018. *Thibet abounds in animals*, partly in herds and flocks; but chiefly in a wild state. The tame horses are small, but full of spirit and restive. The cattle are only of middling height. There are numerous flocks of sheep, generally of small breed; their head and legs are black, their wool fine and soft, and their mutton excellent; it is eaten in a raw state, after having been dried in the cold air, and seasoned with garlic and spices. The goats are numerous, and celebrated for their fine hair, which is used in the manufacture of shawls; this grows under the coarser hair. The yak, or grunting ox, furnished with long and thick hair, and a tail singular for its silky lustre and undulating form, furnishes an article of luxury common in all the countries of the East. The musk ox, the ounce, a species of tiger, the wild horse, and the lion, are among the animals of the country.

1019. *That elegant specimens of civil architecture*, both in the construction of mansions (fig. 134.), or palaces, and in bridges and other public works, should be found in such a country is rather singular. In Turner's journey through this mountainous region, he found bridges of various descriptions generally of timber. Over broad streams, a triple or quadruple depth of stretching timbers project one over the other, their ends inserted into the rock. Piers are almost totally excluded, on account of the extreme rapidity of the rivers. The widest river has an iron bridge, consisting of a number of iron chains which support a matted platform, and two chains are stretched above parallel with the sides, to allow of a matted border for the safety of the passenger. Horses are permitted to go over this bridge, one at a time. There is another bridge of a more simple construction, formed of two parallel chains, round which creepers are loosely twisted, sinking very much in the middle, where suitable planks are placed for a path. Another mode of passing rivers is by two ropes of rattan or stout osier, stretched from one mountain to another, and encircled by a hoop of the same. The passenger places himself between them, sitting in the hoop, and seizing a rope in each hand, slides himself along with facility and speed over an abyss tremendous to behold. Chain and wire bridges, constructed like those of Thibet, are now becoming common in Britain; and it is singular, that one is described in Hutchinson's *Durham* (Newcast. 1785) as having been erected over the Tees.

SUBJECT. 10. *Of the present State of Agriculture in the Asiatic Islands.*

1020. *The islands of Asia* form a considerable part of our globe; and seem well adapted by nature for the support of civilised man, though at present they are mostly peopled by savages. We shall notice these islands in the order of Sumatra, Borneo, the Manillas, the Celebes, the Loochoo Isles, and the Moluccas.

1021. *Sumatra* is an island of great extent, with a climate more temperate than that of Bengal, a surface of mountains and plains, one third of which is covered with impervious forests, and a soil consisting of a stratum of red clay, covered with a layer of black mould. The most important agricultural product is rice, which is grown both for home consumption and export. Next may be mentioned the cocoa-nut, the areca palm, or betel nut tree, and the pepper. Cotton and coffee are also cultivated; and the native trees afford the resin benzoin, cassia or wild cinnamon, rattans or small canes (*Arúndo Ròtang*), canes for walkingsticks, turpentine, and gums; besides ebony, pine, sandal, teak, manchineel, iron wood, banyan, aloe, and other woods.

1022. *The pepper plant (Piper nigrum, fig.*

is cut off. Two pepper-vines are usually planted to one chinkareen, round which the vines twist for support; and after being suffered to grow three years (by which time they acquire eight or twelve feet in height), they are cut off about three feet from the ground, and being loosened from the prop, are bent into the earth in such a manner that the upper end is returned to the root. This operation gives fresh vigour to the plants, and they bear fruit plentifully the ensuing season. The fruit, which is produced in long spikes, is four or five months in coming to maturity: the berries are at first green, turn to a bright red when ripe and in perfection, and soon fall off if not gathered in proper time. As the whole cluster does not ripen at the same time, part of the berries would be lost in waiting for the latter ones; the Sumatrans, therefore, pluck the bunches as soon as any of the berries ripen, and spread them to dry upon mats, or upon the ground; by drying they become black, and more or less shrivelled, according to their degree of maturity. These are imported here under the name of *black pepper*.

1023. *White pepper* consists of the ripe and perfect berries of the same species stripped of their outer coats. For this purpose the berries are steeped for about a fortnight in water, till, by swelling, their outer coverings burst; after which they are easily separated, and the pepper is carefully dried by exposure to the sun; or the berries are freed from their outer coats by means of a preparation of lime and mustard-oil, called "chinam," applied before it is dried. Pepper, which has fallen to the ground over-ripe, loses its outer coat, and is sold as an inferior sort of white pepper.

1024. *The betel leaf (Piper Bètle, fig. 135. b)* is also cultivated to a considerable extent. It is a slender-stemmed climbing or trailing plant, like the black pepper, with smooth pointed leaves. These leaves serve to enclose a few slices of the nut of the areca palm erroneously called the *betel nut*. The areca being wrapped up in the leaf, the whole is covered with a little chunam or shell-lime to retain the flavour. The preparation has the name of betel, and is chewed by the better sort of southern Asiatics to sweeten the breath and strengthen the stomach; and by the lower classes for the same reasons as ours do tobacco. The consumption is very extensive.

1025. *The areca palm (Arèca Câtechu)* grows to the height of forty or fifty feet with a straight trunk, and is cultivated in the margins of fields for its nut or fruit, which is sold to be prepared as betel.

1026. *Three sorts of cotton are cultivated*, including the silk cotton (*Bómbax Cèba*), a handsome tree, which has been compared by some to a dumb waiter, from the regularity of its branches.

1027. *The live stock of Sumatra* consists of horses, cows, buffaloes, sheep, and swine. They are all diminutive. The horse is chiefly used for the saddle, and the buffalo for labour. The wild animals are numerous, and include the civet cat, monkey, argus pheasant, the jungle or wild fowl, and the small breed of poultry found also at Bantam on the west of Java, and well known in Britain by that name.

1028. *Borneo* is the largest island in the world next to New Holland. It is low and marshy towards the shore, and in this respect and in its climate, is similar to Java. The soil is naturally fertile; but agriculture is neglected, the inhabitants occupying themselves in searching for gold, which they exchange with the Japanese for the necessaries of life.

1029. *The ava, or intoxicating pepper (Piper methysticum)*, is cultivated here. It is a shrub with a forked stem and oblong leaves, bearing a spike of berries, and having thick roots. The root of this plant, bruised or chewed in the mouth, and mixed with the saliva, yields that nauseous, hot, intoxicating juice, which is so acceptable to the natives of the South Sea islands, and which is spoken of with so much just detestation by voyagers. A similar drink is made in Peru from the meal of the maize. They pour the liquor of the cocoa-nut, or a little water, on the bruised or masticated matter, and then a small quantity

produces intoxication and sleep. After the use of it for some time, it produces inflammation, leprons ulcers, and consumption. It is cultivated in all the South Sea islands, except the New Hebrides and New Caledonia. (*Syrie's Travels.*)

1030. *The Manillas, or Philippine Islands*, are a numerous group, generally fruitful in rice, cotton, the sugar cane, and cocoa. The bread-fruit also begins to be cultivated here.

1031. *The Celebesian Islands* are little known. They are said to abound in poisonous plants; and the inhabitants cultivate great quantities of rice.

1032. *The agriculture of the Loochoo Isles*, as far as it is known, resembles that of China. The climate and soil of the principal island seem to be among the most favourable for man on the face of the globe. The sea breezes, which, from its situation in the midst of an immense ocean, blow continually over it, preserve it from the extremes of heat and cold; while its configuration, rising in the centre into considerable eminences, supplies it with rivers and streamlets of excellent water. The verdant lawns and romantic scenery of Tinian and Juan Fernandez are displayed here in higher perfection; cultivation being added to the beauties of nature. The fruits and vegetable productions are excellent, and those of distant regions are found flourishing together. The orange and the lime, the banyan of India and the Norwegian fir, all thrive in Loochoo. The chief object of cultivation is rice, the fields of which are kept extremely neat, and the furrows regularly arranged by a plough of a simple construction: irrigation is practised. They have also a very nourishing variety of sweet potato. The animal creation is generally of diminutive size, their bullocks seldom weighing more than 350 lbs., though plump and well conditioned, and the beef excellent; their goats and hogs are also diminutive, but the poultry large and excellent. The bull is chiefly used in agriculture. These islands are not infested by any wild animals. The inhabitants seem to be gifted with a natural politeness, good-breeding, and kindness, analogous to their climate and the productions of their country. (*Hall in Edin. Gaz.*, vol. iv.)

1033. *The Moluccas, or Spice Islands*, are small, but fertile in agricultural products. In some the bread-fruit is cultivated, also the sago palm, with cloves and nutmegs. The nutmeg-tree (*Myristica moschata*) grows to the size of a pear tree, with laurel-like leaves; it bears fruit from the age of ten to one hundred years. The fruit is about the size of an apricot, and when ripe nearly of a similar colour. It opens and discovers the mace of a deep red, growing over, and in part covering, the thin shell of the nutmeg, which is black. The tree yields three crops annually; the first in April, which is the best; the second, in August; and the third, in December; yet the fruit requires nine months to ripen it. When it is gathered, the outer coriaceous covering is first stripped off, and then the inner carefully separated and dried in the sun. The nutmegs in the shell are exposed to heat and smoke for three months, then broken, and the kernels thrown into a strong mixture of lime and water, which is supposed to be necessary for their preservation, after which they are cleaned and packed up; and with the same intention the mace is sprinkled with salt water.

SECT. II. *Of the present State of Agriculture in the Australian Isles.*

1034. *The Islands of Australia* form a most extensive part of the territorial surface of our globe, and the more interesting to Britons as they are likely one day to be over-spread by their descendants and language. The important colonies of New Holland and Van Diemen's Land are increasing in a ratio which, if it continue, will at no very distant period spread civilisation over the whole of the islands composing this large division of the earth. The immense population, territorial riches and beauty, commerce, naval power, intellect and refinement, which may then exist in these scarcely known regions are too vast and various for the grasp of the imagination. Their rapid progress to this state, however, is unquestionable; being founded on those grand requisites, temperate climate, culturable soil, ample water intercommunication; and, to take advantage of all these, an advanced state of civilisation in the settlers.

1035. *The principal Australian Isles* are New Holland, Van Diemen's Land, New Guinea, New Britain, and New Zealand.

1036. *New Holland and Van Diemen's Land* are not rich in mines, sugar canes, cochineal, or cottons; but they are blessed with a climate which, though different in different places, is yet, on the whole, favourable to the health, comfort, and industry of Europeans; they exhibit an almost endless extent of surface, various as to aspect and capability, but, taken together, suited in an extraordinary degree to the numerous purposes of rural economy, the plough and spade, the dairy and sheep-walk. The emigrant has not to wage hopeless and ruinous war with interminable forests and impregnable jungle, as he finds extensive plains prepared by the hand of nature, ready for the ploughshare, and capable of repaying manifold in the first season. He is not poisoned by pestiferous swamps, nor frightened from his purpose by beasts of prey and loathsome reptiles; he is not chilled by hyperborean cold, nor scorched and enfeebled by

tropical heat; and he is not separated from his kind, nor hardened in his heart, by the debasing influence of open or concealed slavery. It is true, that he is surrounded by those who have the brand of crime and punishment upon them, and who are, therefore, to a certain extent infamous; but he has the satisfaction of knowing that it is his duty and interest to improve, not contribute to the farther degradation of, these fallen beings. (*Widowson's Present State of Van Diemen's Land.* 1829.)

*1037. *New Holland, Notasia*, or what may be called the continent of Australia, is of a size nearly equal to the whole of Europe. So extended a surface naturally presents different characters of climate, elevation, and soil. But the climate is said to be every where temperate and salubrious; to the north it may be considered semitropical, to the south not materially different from that of England. The whole country being south of the equator, the seasons are like those of the southern parts of Africa and America, and consequently the reverse of those of Europe. The surface of the country is in general low and level; far northward it is hilly, and a chain of mountains is said to run north and south, very lofty and irregular. Hills and mountains, however, form but a small part of this extensive country. Lakes and rivers are not very frequent; but in the interior there are extensive marshes and savannas, covered with luxuriant grasses. In some places the country is highly beautiful. Mr. Evans, who made a journey of 300 miles into the interior, in 1818, states that "the farther he advanced the more beautiful the scenery became; both hill and dale were clothed with fine grass, the whole appearing at a little distance as if laid out into fields divided by hedge rows. Through every valley meandered trickling streams of fine water. Many of the hills are capped with forest trees, chiefly of the eucalyptus; and clumps of these, mixed with mimosas and the cassuarina, were interspersed along the declivities of the hills, and in the valleys, so as to wear the appearance of a succession of gentlemen's parks."

*1038. *The mineral productions* include coal, limestone, slate, granite, quartz, sandstone, freestone, and iron, the last in great abundance. The coal is of the best quality, often found in hills, and worked from the side like a stone quarry without expensive drainage.

1039. *The soil* towards the south is frequently sandy, and many of the lawns or savannas are rocky and barren. In general the soil towards the sea coast is naturally more fertile than in the interior; but almost every where it may be brought into cultivation with little labour and abundant success. The colony of New South Wales possesses every variety of soil, from the sandy heath and the cold hungry clay, to the fertile loam, and the deep vegetable mould. The prevailing soil hitherto subjected to agriculture is a thin black earth resting on a stratum of yellow clay, which is again supported by a deep bed of schistus.

*1040. *The productions of nature* in New Holland present a remarkable sameness among themselves, and a no less remarkable difference from those of the rest of the world. This applies more particularly to the animal and vegetable kingdoms. The rocks, mountains, and earths, resemble nearly the inorganic substances which are met with in other parts of the world; but the animals and plants are decidedly peculiar. The natives are copper-coloured savages of the very lowest description. The quadrupeds are all of the kangaroo or opossum tribe, or resemble these, with one or two exceptions, among which is the *Ornithorhynchus paradoxus*, a quadruped with the beak of a bird. The fish are for the most part like sharks. Among the birds are black swans and white eagles, and the emu, supposed to be the tallest and loftiest bird that exists; many of them standing full seven feet high. Every one acquainted in the slightest degree with the plants in our green-houses is aware of the very peculiar appearance of those of Australia, and there is scarcely a gardener who cannot tell their native country at first sight. Mr. Brown, who is better acquainted with these plants than any other botanist, observes that the *Acacia* and *Eucalyptus*, of each of which genera there are upwards of one hundred species, when taken together, and considered with respect to the mass of vegetable matter which they contain, calculated from the size as well as from the number of individuals, are, perhaps, nearly equal to all the other plants of that country. (*App. to Flinders's Voyage.*)

*1041. *There is no indigenous agriculture in any part of New Holland*; but the colony of New South Wales, which was established in 1788, has appropriated extensive tracts of country in that quarter of the island, and subjected them to the field and garden cultivation of Europe. Every thing that can be cultivated in the open air in England can be cultivated in New South Wales; the fruits of Italy and Spain come to greater perfection there than here, with the single exception of the orange, which requires a slight protection in winter. Pine-apples will grow under glass without artificial heat; the apple and the gooseberry are the only fruits which are found somewhat inferior to those produced in Britain. But the great advantage of this colony to the agriculturist is, that it is particularly suited to maize and sheep: maize, it is well known, produces a greater return in proportion to the seed and labour than any other bread-corn; and the wool of

the sheep of New South Wales is equal to the best of that produced in Saxony, and can be sent to the British market for about the same expense of transport. This wool forms the grand article of agricultural export from New Holland. According to a calculation made by Mr. Kingdom in 1820 (*British Colonies*, p. 282.), "making the most liberal allowance for all kind of expenses, casualties, and deteriorations, money sunk in the rearing of sheep in this colony will, in the course of three years, double itself besides paying an interest of 75 per cent."

*1042. *As a country for an agriculturist to emigrate to*, New South Wales is perhaps one of the best in the world, and its advantages are yearly increasing by the great number of independent settlers who arrive there from Britain. Settlers, on arrival at New South Wales and Van Diemen's Land, have a grant of land allotted to them proportionate to their powers of making proper use of it, with a certain number of convicts as labourers, who with their families are victualled from the public stores for six months. (*Kingdom*, p. 311.) The country seems fully adequate to support itself with every necessary, and almost every luxury, requisite to the present state of human refinement; in this respect it has the advantage over France, in being able to bring to perfection the cotton plant. "As a criterion of the luxuries enjoyed by the inhabitants in fruit, one garden, belonging to a gentleman a few miles from Sydney, contains the following extensive variety: — viz. oranges, citrons, lemons, pomegranates, loquatts, guavas, the olive, grapes of every variety, pine-apples, peaches, nectarines, apricots, apples, pears, plums, figs; English, Cape, and China mulberries; walnuts, Spanish chestnuts, almonds, medlars, raspberries, strawberries, melons, quinces and the caper, with others of minor value; and such is the abundance of peaches, that the swine of the settlers are fed with them." (*Kingdom*, p. 308.) In the *Gardener's Magazine*, vol. v. p. 280., Mr. Fraser, the Colonial botanist, has given a catalogue of upwards of 100 species and varieties of fruit under his care in the open garden at Sydney, including the pine-apple, the date, the plantain, the cocoa, and the mango.

1043. *An Australian Agricultural Society* was established, in the year 1823, for "the promotion both of field and garden cultivation;" and, besides newspapers, there is a quarterly publication entitled the *Australasian Magazine of Agricultural and Commercial Information*. In June 1824, an Act of Parliament was passed creating an "Australian Agricultural Company, for the Cultivation and Improvement of waste Land, in the Colony of New South Wales." This company have an establishment in London, for the purpose of raising a capital of one million of pounds sterling, in shares of 100l. each.

*1044. *Van Diemen's Island* is about as large as Ireland, and it enjoys a temperate climate resembling that of England, but less subject to violent changes. According to Evans, the deputy surveyor of the colony, the climate is more congenial to the European constitution than any other on the globe. That of New Holland has been commended for its salubrity, but the north-west winds which prevail there are unknown at Van Diemen's Land. Neither the summers nor winters are subject to any great extremes of heat or cold; for though the summits of the mountains are covered during the greater part of the year with snow, yet in the valleys it never remains on the ground more than a few hours. The mean difference of temperature between Van Diemen's Land and New South Wales is ten degrees, the mean temperature of the whole island may be reckoned at about 60°, and the extremes at from 36° to 80°. The spring commences early in September; the summer in December; the autumn in April; and the winter, the severity of which continues about seven weeks, in June.

1045. *The surface of the country* is richly variegated, diversified by ranges of moderate hills and broad valleys, and towards the western part of the island there is a range of mountains, in height 3500 feet; on their summit is a large lake, the source of several rivers. But though there are hills in various other parts of the island, there are not above three or four of them that can be considered mountains. The hills, the ridges or sky outlines of which form irregular curves, are for the greater part wooded; and from their summits are to be seen levels of good pasture land, thinly interspersed with trees, below which is a luxuriant grassy surface. These beautiful plains are generally of the extent of 8000 or 10,000 acres, and, Evans observes, are common throughout the whole island.

1046. *The soil*, as in New Holland, is greatly diversified; but in proportion to the surface of the two countries, this one contains comparatively much less of an indifferent quality. Many fine tracts of land are found upon the very borders of the sea; and the plains and valleys in the interior are composed of rich loamy clay and vegetable mould.

1047. *The animal and vegetable kingdoms* are the same as those of New Holland. The native dog, the agriculturist's great enemy in that country, is unknown here; but there is an animal of the panther family in its stead, which commits as great havoc among the flocks, as the wolf did formerly in Britain. It is very cowardly, and by no means formidable to man. The native savages are, if possible, more uncivilised than those of New Holland; they subsist entirely by hunting, and though the country has the finest rivers, they have no knowledge whatever of the art of fishing. They bear great animosity

to the colonists, having been fired upon by them soon after their first settlement, by which numbers were killed. Fortunately, however, the natives seldom act on the offensive, and two persons with muskets may traverse the island from one end to the other in perfect safety.

1048. *The agricultural facilities of Van Diemen's Land* are still greater than those of New South Wales. Large tracts of land, perfectly free from timber or underwood, and covered with the most luxuriant herbage, are to be found in all directions, but more particularly in the environs of Port Dalrymple. These tracts of land are invariably of the very best description, and millions of acres, which are capable of being instantly converted to all the purposes of husbandry, still remain unappropriated. Here the colonist has no expense to incur in clearing his farm: he is not compelled to a great preliminary outlay of capital, before he can expect a considerable return. He has only to set fire to the grass to prepare his land for the immediate reception of the ploughshare; insomuch that, if he but possesses a good team of horses or oxen, with a set of harness and a couple of substantial ploughs, he has the main requisites for commencing an agricultural establishment, and for insuring a comfortable subsistence for himself and family.

1049. *To this great superiority* which these southern settlements may claim over the parent colony, may be superadded two advantages, which are perhaps of equal magnitude and importance. In the first place, the rivers here have a sufficient fall to prevent any excessive accumulation of water from violent or continued rains, and are, consequently, free from those awful and destructive inundations to which the rivers of New South Wales are perpetually subject. Here, therefore, the industrious colonist may settle on the bank of a navigable river, and enjoy all the advantages of sending his produce to market by water, without running the constant hazard of having the fruits of his labour, the golden promise of the year, swept away in an hour by a capricious and domineering element. Secondly, the seasons are more regular and defined, and those great droughts, which have been so frequent in Port Jackson, are altogether unknown. In the years 1813, 1814, and 1815, when the whole face of the country was there literally burnt up, and vegetation completely at a stand still from the want of rain, an abundant supply of it fell here, and the harvests, in consequence, were never more productive. Indeed, since these settlements were first established, the crops have never sustained any serious detriment from an insufficiency of rain; whereas, in the parent colony, there have been, since its foundation, I may venture to say, half a dozen dearths occasioned by droughts, and at least as many arising from floods.

1050. *The system of farming in Van Diemen's Land* consists principally of growing one crop year after year. There are a few enterprising individuals who grow the various descriptions of grain; but wheat is what the old settler grew first, and from that he cannot depart. It is not many years since, when the plough might be said to be unknown in the island, the ground was then broken up with a hoe, similar to those used in the West Indies, and the corn brushed in with thorns. This rude system is now abolished, a pair of bullocks and a plough being within the reach of the smallest landholder. New and old land are generally broken up at the same season of the year. Once ploughed, it is sown and harrowed, and never again interfered with until the crop is cut down. Wheat, barley, and oats may be sown at the same season, namely, about the beginning of August, although wheat is sometimes sown late in November, and a good crop reaped in the early part of March. There is no fear of injuring the grain by sowing early; I have seen seed sown in the beginning of winter, and flourish surprisingly. From ten to fifteen crops of wheat have been taken in succession, until the land has been completely exhausted. It is then abandoned, and a new piece broken up. The exhausted land generally becomes covered with young mimosas (acacias). (*Widowson.*)

1051. *As a country to emigrate to*, the circumstance of Van Diemen's Land being exempt from those calamitous consequences which are so frequent in New Holland, from a superabundance of rain on the one hand, and a deficiency of it on the other, is a most important point of consideration for all such as hesitate in their choice between the two countries. In the system of agriculture pursued in the two colonies there is not any difference, save that the Indian corn, or maize, is not cultivated here, because the climate is too cold to bring that grain to maturity. Barley and oats, however, arrive at much greater perfection, and afford the inhabitants a substitute, although by no means an equivalent, for this highly valuable product. The wheat, also, which is raised here is of a much superior description to the wheat grown in any of the districts of Port Jackson, and will always command, in the Sydney market, a difference of price sufficiently great to pay for the additional cost of transport. The average produce, also, of the land is greater, although it does not exceed, nor perhaps equal, that of the rich flooded lands on the banks of the Hawkesbury and Nepean. The produce of both colonies, it is stated, would be double what it is, if the operations of agriculture were as well performed as in Britain. At present, however, this can only be the case when a settler is so fortunate as to get what are called country convicts, that is, Irishmen who have been employed as

agricultural labourers at home. The system of rearing and fattening cattle is perfectly analogous to that which is pursued at Port Jackson. The natural grasses afford an abundance of pasturage at all seasons of the year, and no provision of winter provender, in the shape either of hay or artificial food, is made by the settler for his cattle; yet, notwithstanding this palpable omission, and the greater length and severity of the winters, all descriptions of stock attain here a much larger size than at Port Jackson. Wool has every promise of becoming a staple commodity of Van Diemen's Land. It was at first thought that the climate was more favourable for the production of carcass than of fleece; but it has been found since the introduction of merinos, that wool can be produced in every respect as good as that of New South Wales. In 1822, upwards of 300,000 lbs. of wool were consigned to London, which sold there at prices equal to those given for the wool of New South Wales and Saxony. Those who are desirous of more ample information respecting this colony, which certainly ranks as the first in the world for a British emigrant, may consult *Kingdom's British Colonies*, 1820; *Evans's Van Diemen's Land*, 1824; *Godwin's Emigrant's Guide to Van Diemen's Land*, 1823; *Widowson's Van Diemen's Land*, 1829.

1052. *New Britain, New Ireland, the Solomon Isles, New Caledonia, and the New Hebrides*, are little known. They are mountainous and woody, with fertile vales and beautiful streams. The nutmeg, cocoa, yam, ginger, pepper, plantains (fig. 136.), sugar canes, and other fruit and spice trees, abound.

1053. *Papua, or New Guinea*, partakes of the opulence of the Moluccas (1033.), and their singular varieties of plants and animals. The coasts are lofty, and abound with cocoa trees. In the interior, mountain rises above mountain, richly clothed with woods of great variety of species, and abounding in wild swine. Birds of paradise and elegant parrots abound; they are shot with blunt arrows, or caught with birdlime or nooses. The bowels and breast being extracted, they are dried with smoke and sulphur, and sold for nails or bits of iron to such navigators as touch at the island.

*1054. *New Zealand* has scarcely any agriculture, except plantations of yam, cocoa, and sweet potato. There is only one shrub or tree in this country which produces fruit, and that is a kind of a berry almost tasteless; but they have a plant (*Phormium ténax*) which answers all the uses of hemp and flax. There are two kinds of this plant, the leaves of one of which are yellow, those of the other deep red, and both resembling the leaves of flags. Of these leaves they make lines and cordage much stronger than any thing of the kind in Europe; they likewise split them into breadths, and tying the slips together form their fishing-nets. Their common apparel, by a simple process, is made from these leaves; and their finer, by another preparation, is made from the fibres. This plant is found both on high and low ground, in dry mould and deep bogs; but as it grows largest in the latter, that seems to be its proper soil. It has lately been found to prosper in the south of Ireland, but not to such an extent as to determine its value.

SECT. III. *Of the present State of Agriculture in Polynesia.*

1055. *This sixth great division of the earth's surface* consists of a number of islands in the northern and southern hemispheres, which, though at present chiefly inhabited by savages, are yet, from their climate and other circumstances, singularly adapted for culture and civilisation. The principal are the *Pellew Isles*, the *Ladrone Isles*, the *Sandwich Isles*, in the northern hemisphere; and the *Friendly Isles*, the *Navigator's Isles*, the *Society Isles*, the *Georgian Isles*, and the *Marquesas*, in the southern hemisphere.

1056. *The Pellew Isles* are covered with wood, and encircled by a coral reef. None of these islands has any sort of grain or quadruped; but they are rich in the most valuable fruit and spice trees, including the cabbage tree (*Arca oleracea*) (fig. 137.), cocoa, plantain, and orange; and abound with wild cocks and hens, and many other birds. The culture of the natives only extends to yams and cocoa-nuts.

1057. *The Ladrones* are a numerous collection of rocky fragments, little adapted to agriculture. The isles of *Guam* and *Tinian* are exceptions. The latter abounds in cattle and fruits, the bread-fruit, and orange, but is without agriculture.

1058. *The Marquesas* are in general rocky and mountainous, and include very few spots fit for cultivation. The inhabitants are savages, but rudely cultivate the yam in some places. They have, however, the *ava*, or intoxicating pepper (1029.); and procure also a strong liquor from the root of ginger, for the same general purpose of accumulating enjoyment, forgetting care, and sinking into profound sleep.

1059. *The Sandwich Isles* resemble those of the West Indies in climate, and the rest of the South Sea islands in vegetable productions. The bread-fruit tree attains

great perfection. Sugar canes grow to an unusual size, one being brought to Captain Cook eleven inches and a quarter in circumference, and having fourteen feet catable. Dogs, hogs, and rats are the only native quadrupeds of these islands, in common with all others that have been discovered in the South Sea. The king of these islands visited England in the time of Geo. II., and again in 1824.

1060. *The Friendly Islands* are in most respects similar to Otaheite (1061.). Tongataboo appears to be a flat country, with a fine climate, and universally cultivated. The whole of this island is said to consist of enclosures, with reed fences about six feet high, intersected with innumerable roads. The articles cultivated are bread-fruit, plantains, cocoa-nuts, and yams. In the other islands, plantains and yams engage most of their attention; the cocoa-nut and bread-fruit trees are dispersed about in less order than the former, and seem to give them no trouble. Their implements of culture consist of pointed sticks of different lengths and degrees of strength.

1061. *The island of Otaheite* is the principal of the Georgian Islands. It is surrounded by a reef of coral rocks. The surface of the country, except that part of it which borders upon the sea, is very uneven; it rises in ridges that run up into the middle of the island, and there form mountains which may be seen at the distance of sixty miles. Between the foot of these ridges and the sea is a border of low land, surrounding the whole island, except in a few places where the ridges rise directly from the sea. This border is of different breadths in different parts, but no where more than a mile and a half.

1062. *The soil of Otaheite*, except on the very tops of the ridges, is extremely rich and fertile, watered by a great number of rivulets of excellent water, and covered with fruit trees of various kinds. The low land that lies between the foot of the ridges and the sea, and some of the valleys, are the only parts of the island that are inhabited, and here it is populous: the houses do not form villages or towns, but are ranged along the whole border, at the distance of about fifty yards from each other, with little plantations of plantains, the tree which furnishes them with cloth.

1063. *The produce of Otaheite* is the bread-fruit (*Artocarpus integrifolia*), cocoa-nuts, bananas of thirteen sorts, plantains; a fruit not unlike an apple, which, when ripe, is very pleasant; sweet potatoes, yams, cocoas (*Arum Colocasia*, and *Caladium esculentum*, both propagated by the leaves); a fruit known here by the name of jambu, and reckoned most delicious; sugar cane, which the inhabitants eat raw; a root of the saloop kind, which the inhabitants call pea; a plant called ethee, of which the root only is eaten; a fruit that grows in a pod, like that of a large kidneybean, which, when it is roasted, eats very much like a chestnut, by the natives called whee; a tree here called wharra, but in the East Indies pandanus, which produces fruit something like the pine-apple; a shrub called nono; the morinda, which also produces fruit; a species of fern, of which the root is eaten, and sometimes the leaves; and a plant called theve, of which the root also is eaten: but the fruits of the nono, the fern, and the theve, are eaten only by the inferior people, and in times of scarcity. All these, which serve the inhabitants for food, the earth produces spontaneously, or with little culture. They had no European fruit, garden stuff, pulse, or legumes, nor grain of any kind, till some seeds of melons and other vegetables were given them by Captain Cook.

1064. *Of tame animals*, the Otaheitans have only hogs, dogs, and poultry; neither is there a wild animal on the island, except ducks, pigeons, parrots, with a few other birds, and rats, there being no other quadruped, nor any serpent. But the sea supplies them with great variety of most excellent fish, to eat which is their chief luxury, and to catch it their principal labour.

1065. *The remaining Polynesian Islands of the southern hemisphere* are, for the most part, inhabited by savages, and are without agriculture.

SECT. IV. *Of the present State of Agriculture in Africa.*

1066. *The continent of Africa*, in point of agricultural as of political and ethical estimation, is the meanest of the great divisions of the earth; though in one corner of it (Egypt) agriculture is supposed to have originated. The climate is every where hot, and intensely so in the northern parts. The central parts, as far as known, consist of ridges of mountains and immense deserts of red sand. There are very few rivers, inland lakes, or seas, and indeed fully one half of this continent may be considered as either desert or unknown. Some of the African islands are fertile and important, especially Madagascar, Bourbon, Mauritius, &c. We shall take the countries of Africa in the order of Abyssinia, Egypt, Mohanmedan states of the north, western coast, Cape of Good Hope, eastern coast, Madagascar and other isles.

SUBSECT. 1. *Of the present State of Agriculture in Abyssinia.*

1067. *The climate of Abyssinia*, though exceedingly various in different parts, is in general temperate and healthy. The surface of the country is generally rugged and mountainous; it abounds with forests and morasses; and it is also interspersed with many fertile valleys and plains adapted both to pasture and tillage. The rivers are numerous and large, and contribute much to general fertility. The soil is not naturally good, being in general thin and sandy; but it is rendered fertile and productive by irrigation and the periodical rains.

1068. *The agricultural products* are wheat, barley, millet, and other grains. They cultivate the vine, peach, pomegranate, sugar cane, almonds, lemons, citrons, and oranges; and they have many roots and herbs which grow spontaneously, and their soil, if properly managed, would produce many more. However, they make little wine, but content themselves with the liquor which they draw from the sugar cane, and their honey, which is excellent and abundant. They have the coffee tree, and a plant called ensete, which produces an eatable nourishing fruit. The country also produces many other plants and fruits adapted both for domestic and medicinal uses. Here is plenty of cotton, which grows on shrubs like that of India. The forests abound with trees of various descriptions, particularly the rock, baobob, cedar, sycamore, &c.

1069. *The live stock* of Abyssinia includes horses, some of which are of a very fine breed, mules, asses, camels, dromedaries, oxen of different kinds (*fig. 138.*), cows, sheep, and goats; and these constitute the principal wealth of the inhabitants. Amongst the wild animals, we may reckon the antelope, the buffalo, the wild boar, the jackal, the elephant, the rhinoceros, the lion, the leopard, the hyæna, the lynx; the ape and baboon which, as well as the common rat, are very destructive to the fields of millet; the zecora, or wild mule, and the wild ass; the jerboa, the fennic, ashkoko, hare, &c. The hare, as well as the wild boar, is deemed unclean, and not used as food. Bruce saw no sparrows, magpies, nor bats; nor many water-fowl, nor any geese, except the golden goose, or goose of the Nile, which is common in every part of Africa; but there are snipes in the marshes. The locusts of this country are very destructive; they have also species of ants that are injurious; but from their bees they derive a rich supply.

1070. *The agriculture of Abyssinia* is of far less use to the inhabitants than it might be, for want of application and exertion. There are two, and often three, harvests in the year; and where they have a supply of water, they may sow in all seasons; many of their trees and plants retain their verdure, and yield fruit or flowers throughout the year; the west side of the tree blossoms first and bears fruit, then the south side, next the north side, and last of all the east side goes through the same process towards the beginning of the rainy seasons. Their pastures are covered with flocks and herds. They have grass in abundance, but they neglect to make hay of it; and therefore they are obliged to supply this defect by feeding their cattle with barley, or some other grain. Notwithstanding the plenty and frequent return of their crops, they are sometimes reduced almost to famine, either by the devastations of the locusts or grasshoppers which infest the country, or by the more destructive ravages of their own armies, and those of their enemies.

SUBJECT. 2. *Of the present State of Agriculture in Egypt.*

1071. *The climate of Egypt* has a peculiar character from the circumstance of rain being very uncommon. The heat is also extreme, particularly from March to November; while the cool season, or a kind of spring, extends through the other months.

1072. *The surface of the country* is varied in some regions, but is otherwise flat and uniform. Far the greater part presents a narrow fertile vale, pervaded by the Nile, and bounded on either side by barren rocks and mountains. The soil of Egypt has been variously described by different travellers, some representing it as barren sand, only rendered fertile by watering, and others as "a pure black mould, free from stones, of a very tenacious and unctuous nature, and so rich as to require no manure." The latter appears to prevail only in the Delta.

1073. *The fertility of Egypt* has been generally ascribed to the inundations of the Nile, but this is applicable in a strict sense only to parts of the Delta; whereas, in other districts there are canals, and the adjacent lands are generally watered by machines. Gray's description of Egypt, as immersed under the influx of the Nile, though exquisitely poetical, is far from being just. In Upper Egypt the river is confined by high banks, which prevent any inundation into the adjacent country. This is also the case in Lower Egypt, except at the extremities of the Delta, where the Nile is never more than a few feet below the surface of the ground, and where of course inundation takes place. But the country, as we may imagine, is without habitations. The fertility of Egypt, according to Browne, an intelligent traveller, arises from human art. The lands near the river are watered by machines; and if they extend to any width, canals have been cut. The soil in general is so rich as to require no manure; it is a pure black mould, free from stones, and of a very tenacious unctuous nature. When left uncultivated, fissures have been observed, arising from extreme heat, of such depth that a spear of six feet could not reach the bottom.

1074. *The limits of cultivated Egypt* are encroached upon annually, and barren sand is accumulating from all parts. In 1517, the era of the Turkish conquest, Lake Mareotis was at no distance from the walls of Alexandria, and the canal which conveyed the waters into the city was still navigable. At this day, the lake has disappeared, and the lands watered by it, which, according to historians, produced abundance of corn, wine, and various fruits, are changed into deserts, in which are found neither shrub, nor plant, nor verdure. The canal itself, the work of Alexander, necessary to the subsistence of the inhabitants of the city which he built, is nearly choked up, and preserves the waters only when the inundation is at its greatest height, and for a short time. About half a century ago, part of the mud deposited by the river was cleared out of it, and it retained the water three months longer. Schemes have lately been adopted for opening and perfecting this canal. The Pelusiac branch, which discharges itself into the eastern part of the Lake of Tanais, or Menzalé, is utterly destroyed. With it perished the beautiful province which it fertilised, and the famous canal begun by Necos, and finished by Ptolemy Philadelphus. The famous works, executed by kings who sought their glory and happiness in the prosperity of the people, have not been able to resist the ravages of conquerors, and that despotism which destroys every thing, till it buries itself under the wreck of the kingdoms whose foundations it has sapped. The last of the great works of Egypt, the canal of Amrou, which formed a communication between Fostat and Colzoum, reaches at present no farther than about four leagues beyond Cairo, and loses itself in the Lake of Pilgrims. Upon the whole, it may be confidently affirmed that upwards of one third of the lands formerly in cultivation is metamorphosed into dreary deserts.

1075. *Landed property in Egypt* is for the most part to be considered as divided between the government and the religious bodies who perform the service of the mosques, and have obtained possession of what they hold by the munificence of princes and rich men, or by the measures taken by individuals for the benefit of their posterity. Hence, a large proportion of the tenants and cultivators hold either of the government or the procurators of the mosques. But there is one circumstance common to both, viz. that their lands, when they become unoccupied, are never let but upon terms ruinous to the tenants. Besides the property and influence of the beys, of the Mamelukes, and of the professors of the law, are so extensive, and so absolute, as to enable them to engross into their own hands a very considerable part: the number of the other proprietors is extremely small, and their property liable to a thousand impositions. Every moment some contribution is to be paid, or some damage repaired; there is no right of succession or inheritance for real property, except for that called "wakf," which is the property of the mosques; every thing returns to government, from which every thing must be repurchased. According to Volney, the peasants are hired labourers, to whom no more is left than what is barely sufficient to

sustain life; but Browne says, that these terms can be properly applied to very few of them.

1076. *The occupier of the land*, assisted by his family, is the cultivator; and in the operations of husbandry scarcely requires any other aid. He commonly holds no more than he and they can cultivate, and gather the produce of. When, indeed, the Nile rises, those who are employed to water the fields are commonly hired labourers. The rice and corn they gather are carried to their masters, and nothing is reserved for them but dourra, or Indian millet, of which they make a coarse and tasteless bread without leaven; this, with water and raw onions, is their only food throughout the year; and they think themselves happy if they can sometimes procure a little honey, cheese, sour milk, and dates. Their whole clothing consists of a shirt of coarse blue linen and a black cloak. Their head-dress is a sort of cloth bonnet, over which they roll a long handkerchief of red woollen. Their arms, legs, and breasts are naked, and some of them do not even wear drawers. Their habitations (*fig. 139.*) are mud-walled huts, in which they are suffocated with heat and smoke, and in which, besides the experience of other inconveniences, they are perpetually distressed with the dread of the robberies of the Arabs, and the extortions of the Mamelukes, family feuds, and all the calamities of a perpetual civil war.

*1077. *The agricultural products of Egypt* consist of grain of most sorts, and particularly rice. Barley is grown for the horses, but no oats are seen. In the Delta a crop of rice and a crop of barley are obtained within the year on the same ground. Sometimes, instead of barley, a fine variety of clover (*Trifolium alexandrinum Forskahl*) is sown without ploughing or harrowing. The seed sinks to a sufficient depth in the moist soil, and produces three cuttings before the time for again sowing the rice.

1078. *Rice* is sown from the month of March to that of May; and is generally six months in coming to maturity. In reaping, it is most commonly pulled up by the roots. As the use of the flail is unknown in Egypt, the rice plants are spread in thick layers on floors formed of earth and pigeon's dung, which are well beaten and very clean; and then, in order to separate the grain from the straw, they make use of a sort of carts, constructed like our sledges with two pieces of wood joined together by two cross bars. Between the longer sides of this sledge are fixed, transversely, three rows of small wheels, made of solid iron, and narrowed off towards their circumference; and on the fore part is fixed a high seat, on which a man sits, for the purpose of driving two oxen that are harnessed to the machine, thus moving it in a circular direction over every part of the heap of rice, till the grain is completely separated from the straw; the grain is then spread in the air to be dried. The dried rice is carried to the mill, where it is stripped of its chaff or husk. This mill consists of a wheel turned by oxen, which sets several levers in motion; and at their extremity is an iron cylinder, about a foot long, and hollow underneath; these cylinders turn in troughs which contain the grain; and at the side of each trough there stands a man, whose business it is to place the rice under the cylinders. The next operation is to sift the rice in the open air, by filling a small sieve, which a man lifts over his head, and thus lets fall, with his face turned to the wind, which blows away the small chaff or dust. This cleaned rice is put a second time into the mill, in order to bleach it; it is afterwards mixed up in troughs with some salt, which contributes very much to its whiteness and also to its preservation, and in this state it is sold. Rice is furnished in great quantities in the Delta; and that which is grown in the environs of Rosetta is more esteemed, on account of its preparation, than that which is produced in the vicinity of Damietta. The produce of the one and the other is equally wonderful. In a good season, that is, when the rise of the Nile occasions a great expansion of its waters, the profit of the proprietors of rice fields is estimated at fifty per cent, clear of all expenses. Savary says that it produces eighty bushels for one.

1079. *Wheat* is sown as soon as the waters of the Nile have retired from the lands appropriated to it; the seed time varies with the latitude, and also the harvest, which is earlier in Upper than in Lower Egypt. Near to Syene they sow the barley and the corn in October, and reap it in January. Towards Girge they cut in February; and in the month of March, in the vicinity of Cairo. This is the usual progress of the harvest in the Said. There is also a number of partial harvests, as the lands are nearer to, or at a greater distance from, the river, lower or more elevated. In Lower Egypt they are sowing and reaping all the year. Where the waters of the river can be procured the earth is never idle, and furnishes three crops annually. In descending from the cataracts in January, the corn is seen almost ripe; in lower down it is in ear; and, advancing further, the plains are covered with verdure. The cultivator, in general, merely casts the seed upon the moistened earth; the corn soon springs up from the mud; its vegetation is rapid, and four months after it is sown it is fit to be reaped. In performing this operation, the sickle not being used, the stalks are pulled up by the roots, and carried to large floors, like those which are used for treading out rice; and by a similar operation the corn is separated from the ear. Unripe ears of corn are dried and slacked baked in an oven; and being afterwards bruised and boiled with meat, form a common dish in Lower Egypt, called "ferik."

1080. *Flax* has been cultivated in Egypt from the most remote period, and is still grown in considerable quantities. Indigo is also grown for dyeing it, the colour of the shirt in this country being universally blue.

1081. *From the hemp*, which is abundantly cultivated in this country, the inhabitants prepare intoxicating liquors; and also by pounding the fruit into a paste, which when fermented answers a similar purpose; and they mix the capsules with tobacco for smoking.

1082. *The sugar cane* is also one of the valuable productions of Egypt. The common people do not wait for the extraction of the sugar, but cut the canes green, which are sold in bundles in all the towns. They begin to ripen in October, but are not, in general, fit to be cut till November or December. The skill of the sugar-refiners is in a very imperfect state.

1083. *Fruit trees of various species* abound in this country. Among these we may reckon the olive tree, fig trees which yield figs of an exquisite flavour, and the date tree which is to be found every where in the Thebais and in the Delta, in the sands as well as in the cultivated districts, requiring little or no culture, and yielding a very considerable profit, on account of the immense consumption of its fruit. The species of palm tree that furnishes dates produces also a bark which, together with its leaves and the rind of its fruit, affords filaments from which are manufactured ropes and sails for boats. The leaves are also used for making baskets and other articles. The very long rib of the branches is employed, on account of its lightness and solidity, by the Mamelukes, in their military exercises, as javelins, which they throw at each other from their horses when at full speed. A species of Cypèrus, which produces a fruit resembling the earth-nut, but of a much more agreeable flavour, is cultivated in the environs of Rosetta; and the small tubercles are sent to Constantinople and other towns of the Levant, where they are much valued. The Egyptians express from them a milky juice, which they deem pectoral and emollient; and give them to nurses, in order to increase the quantity of their milk. The banana trees, though not natives of the soil of Egypt, are nevertheless cultivated in the northern parts of that country. The papaw, or custard-apple tree (*Anóna*), is also transplanted into the gardens of Egypt, and yields a fruit equally gratifying to the taste and smell. In the shade of the orchards are cultivated various plants, the roots of which are refreshed by the water that is conveyed to them by little trenches; each enclosure having its well or reservoir, from which the water is distributed by a wheel turned by oxen. The mallow (*Málva rotundifolia*) grows here in abundance: it is dressed with meat, and is one of those herbs that are most generally consumed in the kitchens of Lower Egypt. Two other plants used as food, are the garden Jew's mallow, and the esculent *Hibiscus*. Another tree, which appears to be indigenuous in this country, is the "atle," a species of larger tamarisk (*Támarix orientális Forskahl*). The wood of this tree serves for various purposes; and, among others, for charcoal. It is the only wood that is common in Egypt, either for fuel or for manufactures. Fenu-greek is cultivated for fodder, though for this use a plant called barsim is preferred. The plant called "helbe" is cried about for sale, in November, in the streets of the towns: and it is purchased and eaten with incredible avidity, without any kind of seasoning. It is pretended that it is an excellent stomachic, a specific against worms and the dysentery, and, in short, a preservative against a great number of disorders. Lentils form a considerable article of food to the inhabitants of Upper Egypt, who rarely enjoy the luxury of rice. The Egyptian onions are remarkably mild, more so than the Spanish, but not so large. They are of the purest white, and the laminae are of a softer and looser contexture than those of any other species. They deteriorate by transplantation; so that much must depend on the soil and climate. They remain a favourite article of food with all classes; and it is usual to put a layer or two of them, and of meat, on a spit or skewer, and thus roast them over a charcoal fire. We need not wonder at the desire of the Israelites for the onions of Egypt. Leeks are also cultivated and eaten in this country; and almost all the species of European vegetables abound in the gardens of Rosetta. Millet and Turkey corn, the vine, the henné or Egyptian privet, and the water-melon are cultivated in Egypt; and the country furnishes a variety of medicinal plants, as *Cárthamus tinctorius* (fig. 140.), senna, colocintida, &c. Of late years the cotton has been grown on an extensive scale under the care of European and American cultivators, and the raw produce in part manufactured by machinery sent from Britain, and in part exported to Europe.

1084. *The live stock* of Egyptian agriculture principally consists of the ox, buffalo, horse, ass, mule, and camel. The oxen of Egypt are employed in tillage, and in giving motion to a variety of hydraulic machines; and as they are harnessed so as to draw from the pitch of the shoulder, their withers are higher than those of our country; and, indeed, they have naturally some resemblance to the bison (*Bós ferus*), or hunched ox. It has been said that the cows of Egypt bring forth two calves at a time; an instance of fecundity which sometimes happens, but is not reckoned very common. Their calves are reared to maturity, veal, which is forbidden by the law of the Mohammedans, and from which the Copts also abstain, not being eaten in Egypt.

1085. *The buffalo* is more abundant than the ox, and is equally domestic. It is easily distinguishable by the constantly uniform colour of the hair, and still more by a remnant of ferocity and intractability of disposition, and a wild lowering aspect, the characteristics of all half-tamed animals. The females are reared for the sake of the milk, and the males to be slaughtered and eaten. The flesh is somewhat red, hard, and dry; and has also a musky smell, which is rather unpleasant.

1086. *The horses of Egypt* rank next to those of the Arabians, and are remarkable for their valuable qualities. Here, as in most countries of the East, they are not castrated either for domestic use or for the cavalry.

1087. *The asses* of Egypt have no less a claim to distinction than the horses; and these, as well as those of Arabia, are esteemed for vigour and beauty the finest in the world. They are sometimes sold for a higher price than even the horses, as they are more hardy, less difficult as to the quality and quantity of their food, and therefore preferred in traversing the deserts. The handsomest asses seen at Cairo are brought from Upper Egypt and Nubia. On ascending the Nile, the influence of climate is perceptible in these animals, which are most beautiful in the Said, but are in every respect inferior towards the Delta. With the most distinguished race of horses and asses, Egypt possesses also the finest mules; some of which, at Cairo, exceed in price the most beautiful horses.

1088. *The camel and dromedary*, as every body knows, are the beasts of burden in Egypt, and not only answer all the purposes of our waggons and public conveyances, but bear the vehicles (fig. 141.) in which the females of the higher classes pay their visits on extraordinary occasions.

1089. *The agricultural implements of Egypt are simple; but some of them, particularly the contrivances for raising water, very ingenious. The plough is of the rudest kind, as are the cart and spade.*

1090. *The operations of threshing and sowing have been already described (1078, 1079.); that of irrigation is performed as in other countries. At present there are eighty canals in use for this purpose, some of them twenty, thirty, and forty leagues in length. The lands near the river, as the Delta, are watered directly from it: the water is raised by wheels in the dry season; and, when the inundation takes place, it is retained on the*

fields for a certain time by small embankments made round them.

1091. *Nubia, the Ethiopia of the ancients, is a miserable country or desert, thinly inhabited by a wretched people, who live chiefly on millet, and dwell in groups of mud huts. (fig. 142.)*

SUBJECT. 3. Present State of Agriculture in the Mohammedan States of the North of Africa.

1092. *These are Tripoli, Tunis, Algiers, and Morocco, territories chiefly on the southern shore of the Mediterranean; rich and celebrated in the ages of antiquity, but at present depressed by the barbarism and fanaticism of their rulers, who are in general tributary to the Porte.*

1093. *Tripoli is generally distinguished into maritime and inland. In neither is there much agriculture; for the inhabitants of countries on the coast live chiefly by commerce and piracy, and those of the inland parts on plunder and robbery. There are a few fields of grain, chiefly rice, round the capital, date palms, olives, and what is called the lotus tree (*Zizyphus Lötus*), whose fruit is reckoned superior to the date, and makes excellent wine.*

1094. *The kingdom of Tunis was formerly the chief seat of Carthaginian power. The soil is in general impregnated with marine salt and nitre, and springs of fresh water are more rare than those of salt. But the Tunisians are much more agriculturists than their neighbours either of Tripoli or Algiers. The southern parts of the country are sandy, barren, and parched by a burning sun: the northern parts enjoy a better soil and temperature, and are more under cultivation: near the sea, the country is rich in olive trees: the western part abounds in mountains and hills, and is watered by numerous rivulets; it is extremely fertile, and produces the finest and most abundant crops. The first rains commonly fall in September, and then the farmers break up the ground, sow their grain, and plant beans, lentils, and garvancos. By May following harvest commences; and we may judge of its productiveness by what the Carthaginians experienced of old. The ox and the buffalo are the principal beasts of labour, and next the ass, mule, and horse. The zebu, or humped ox (fig. 143.), considered by many naturalists as a distinct species, is common both in this and other kingdoms of northern Africa.*

1095. *The territory of Algiers, in an agricultural point of view, is chiefly distinguished by the fertile plain of Mettjah, a vast country which stretches fifty miles in length, and twenty in breadth, to the foot of one of the branches of Mount Atlas. This plain is watered by several streams, the soil is light and fertile, and it is better cultivated than any other district of the*

143

kingdom. The country-seats and masharcas, as the call the farms of the principal inhabitants of Algiers, are found in this plain; and it is chiefly from it that the metropolis is supplied with provisions. Flax, alhenna, roots, potherbs, rice, fruit, and grain of all kinds are produced here to such perfection, that the Mettijiah may be justly reckoned the garden of the whole kingdom.

1096. *In the inland provinces* are immense tracts of country wholly uninhabited and uncultivated. There are also extensive tracts of brushwood, and some timber forests. The fertility of the soil decreases in approaching Sahara or the Desert, although in its borders, and even in the desert itself there are some districts which are capable of cultivation, and which produce corn, figs, and dates. These regions are inhabited by nomadical tribes, who, valuing themselves on their independence, endure with fortitude and resignation the inconveniences attending their condition, and scarcely regret the want of those advantages and comforts that pertain to a civilised state of society.

1097. *The seed-time* here, as in Tunis, is during the months of October and November, when wheat, barley, rice, Indian corn, millet, and various kinds of pulse, are sown. In six months the crops are harvested, trodden out by oxen or horses, winnowed by throwing with a shovel against the wind, and then lodged in subterraneous magazines.

1098. *The empire of Morocco* is an extensive territory of mountains and plains, and chiefly an agricultural country. The mountains consist of limestone or clay, or a mixture of both, and no vestiges appear of granite, on which they are supposed to rest. The climate is temperate and salubrious, and not so hot as the situation would lead us to suppose. The rains are regular in November, though the atmosphere is not loaded with clouds: January is summer; and in March barley harvest commences. The soil consists either of pure sand often passing into quicksand, or of pure clay; and is often so abundantly mixed with iron ochre, that agricultural productions, such as wax, gum, wool, &c., are distinguished by a reddish tint, which, in the wool, cannot be removed by washing or bleaching. Cultivation, in this country, requires little labour, and, in general, no manure; all weeds and herbaceous plants, not irrigated, are, at a certain season, burnt up by the sun, as in some parts of Spain (745.); the ground, being then perfectly clean and dry, is rendered friable and easily pulverised by the rains; and one rude stirring suffices both for preparing the soil and covering the seed. The produce in wheat, rice, millet, maize, barley, and chick-peas (*Cicer arietinum*), is often sixty fold; thirty fold is held to be an indifferent harvest.

1099. *In general* they make use of no manure except that which is left on the fields by their flocks and herds. But the people who inhabit places near forests and woods avail themselves of another method to render the soil productive. A month or two before the rains commence, the farmer sets fire to the underwood, and by this conflagration clears as much land as he intends to cultivate. The soil, immediately after this treatment, if carefully ploughed, acquires considerable fertility, but is liable soon to become barren, unless annually assisted by proper manure. This system of burning down the woods for the sake of obtaining arable land, though not generally permitted in states differently regulated from this, is allowable in a country, the population of which bears so small a proportion to the fertility of the soil, and in which the most beautiful tracts are suffered to remain unproductive from want of hands to cultivate them. In this manner the nomadic Arab proceeds in his conflagrations, till the whole neighbourhood around him is exhausted; he then packs up his tents and travels in search of another fertile place where to fix his abode, till hunger again obliges him to continue his migration. Thus it is computed, that at one and the same time no more than a third part of the whole country is in a state of cultivation.

1100. *The live stock of Morocco* consists of numerous flocks and herds. Oxen of a small breed are plentiful, and also camels; the latter animal being used in agriculture, for travelling, and for food. The horses are formed for fleetness and activity, and taught to endure fatigue, heat, cold, hunger, and thirst. Mules are much used, and the breed is encouraged. Poultry is abundant in Morocco; pigeons are excellent; partridges are plentiful; woodcocks are scarce, but snipes are numerous in the season; the ostrich is hunted both for sport and for profit, as its feathers are a considerable article of traffic; hares are good, but rabbits are confined to the northern part of the empire, from Saracha to Tetuan. Fallow deer, the roebuck, the antelope, foxes, and other animals of Europe, are not very abundant in Morocco; lions and tigers are not uncommon in some parts of the empire; of all the species of ferocious animals found in this empire, the wild boar is the most common: the sow has several litters in the year, and her young, which are numerous, serve as food for the lion.

1101. *The nomadic agriculturists* form themselves into encampments, called douhars (fig. 144.), composed of numerous tents, which form a circle or crescent, and their flocks and herds returning from pasture occupy the centre. Each douhar has a chief, who is invested with authority for superintending and governing a number of these encampments; and many of the lesser subdivisions are again reunited under the govern-

ment of a bashaw; some of whom have 1000 douhars under their command. Their tents, of a conical form, about eight or ten feet high in the centre, and from twenty to twenty-five in length, are made of twine composed of goats' hair, camels' wool, and the leaves of the wild palm, so that they keep out water; but, being black, their appearance at a distance is not agreeable. In camp the Moors live in the utmost simplicity, and present a faithful picture of the earth's inhabitants in the first ages. In the milk and wool of their flocks, they find every thing necessary for their food and clothing. It is their custom to have several wives, who are employed in all domestic affairs. Beneath their ill-secured tents they milk their cows and make butter; they sort and sift their wheat and barley; prepare vegetables; and grind flour with a mill composed of two round stones, eighteen inches in diameter, in the upper one of which is fixed a handle by which it is made to turn upon an axle. They daily make bread, which they bake between two earthen plates, and very often on the ground heated by fire.

1102. *No alteration in the agriculture of Morocco* seems to have taken place for several centuries, owing to the insecurity of its government; every thing being despotic; and property in land, as well as the person and life, being subject to the caprice of the sovereign, and to the laws of the moment.

SUBJECT. 4. *Of the present State of Agriculture on the Western Coast of Africa.*

1103. *Of the innumerable tribes which occupy the western coast of Africa*, the principal are the Jalefs and Foulahs, and of the former little is known. The remaining part of the country consists of the territories of Benin, Loango, and Congo.

1104. *The soil of the Foulah country* is fertile. The inhabitants are said to be diligent as farmers and graziers, and to raise millet, rice, tobacco, cotton, peas, carob beans (*Ceratonia siliqua*) (fig. 145.), roots, and fruits in abundance. Their live stock, however, constitutes their chief wealth, and, accordingly, pursuing a kind of wandering life, they roam, from field to field and from country to country, with large droves of cows, sheep, goats, and horses; removing, as the wet and dry seasons require, from the low to the high lands, and continue no longer in one place than the pasture for their cattle will allow. The inconvenience and labour of this roving life are augmented by the defence they are obliged to provide against the depredations of the fierce animals with which the country abounds; as they are molested by lions, tigers, and elephants, from the land, and crocodiles from the rivers. At night they collect their herds and flocks within a circle of huts and tents in which they live, and where they light fires in order to deter these animals from approaching them. During the day they often place their children on elevated platforms of reeds (fig. 146.) for security from wild beasts, while they are hunting or pursuing other labours. The elephants are so numerous, that they appear in droves of 200 together, plucking up the small trees, and destroying whole fields of corn; so that they have recourse to hunting, not merely as a pastime, but as the means of self-preservation.

145

146

1105. *The English settlement of Sierra Leone* is situated to the west of the country of the Foulahs, on the river Senegal. It was formed in 1787, for the benevolent purpose of promoting African civilisation. A tract of land was purchased from the prince of the country, and a plantation established, in which are cultivated rice, cotton, sugar, pepper, tobacco, and other products. Gum arabic (*Mimosa nilotica*) (fig. 147.) and other valuable articles are procured from the native woods. In these woods the pine-apple grows wild in the greatest abundance and luxuriance. The fruit is large and highly flavoured, and, when in season, may be purchased by strangers at less than a halfpenny each. A meal in common use by the natives is made from

the pounded roots of the manioc (*Játropha Mánihot*). This meal, after being first ground from the root, is made into a pulp and pressed to get rid of a poisonous juice. It is then redried and constitutes a wholesome farina, which forms almost the entire food of the slaves.

1106. *Benin* is an extensive country, very productive of fruits, trees, and plants, including the orange, cocoa, cotton, &c.; and abounding in animals, among which are enumerated civet cats, and a sort of hairy sheep. Agriculture, however, is little attended to, the chief object being the commerce of slaves.

1107. *The inhabitants of Loango*, instead of cultivating the land, content themselves with bread and fish, and such fruits, greens, and pulse, as the soil naturally produces. Coconuts, oranges, or lemons are not much cultivated; but sugar-canes, cassia, and tobacco, as well as the palm, banana, cotton, and pimento trees, grow here plentifully. They have also a great variety of roots, herbs, fruits, grain, and other vegetables, of which they make bread, or which they use for food. They have few quadrupeds for domestic use, except goats and hogs; but poultry and various sorts of game are abundant. Among the wild beasts they have the zebra, and a great number of elephants, whose teeth they exchange with the Europeans for iron.

1108. *Congo* is an extensive and very fertile country; but the inhabitants are indolent, and neglect its culture. The operations of digging, sowing, reaping, cutting wool, grinding corn, and fetching water, they leave to their wives and slaves. Under their management, several sorts of grain and pulse are cultivated, especially maize, of which they have two crops in a year: but such is the heat of the climate, that wheat will not produce plump seeds; it shoots rapidly up into the straw and ear, the former high enough to hide a man on horseback, and the latter unfilled. Grass grows to a great height, and affords sheltering places for a number of wild animals and noisome reptiles and insects. The Portuguese have introduced a variety of palm and other fruit trees, which are adapted for producing human food in such a climate.

1109. *The baobab (Adansonia digitata)* is a native of Congo. This tree, discovered by the celebrated French botanist, Adanson, is considered the largest in the world: several, measured by this gentleman, were from sixty-five to seventy-eight feet in circumference, but not extraordinarily high. The trunks, at the height of from twelve to fifteen feet, divided into many horizontal branches, which touched the ground at their extremities; these were from forty-five to fifty-five feet long, and were so large that each branch was equal to a monstrous tree; and where the water of a neighbouring river had washed away the earth so as to leave the roots of one of these trees bare and open to the sight, they measured one hundred and ten feet long, without including those parts of the roots which remained covered. It yields a fruit which resembles a gourd, and which serves for vessels of various uses; the bark furnishes them with a coarse thread which they form into ropes, and into a cloth with which the natives cover their middle from the girdle to the knees; and the small leaves supply them with food in a time of scarcity, while the large ones are used for covering their houses, or are by burning manufactured into good soap. At Sierra Leone, this tree does not grow larger than an orchard apple-tree.

1110. *Of the bark of the infanda tree*, and also of the mulemba, resembling in many respects our laurel, they form a kind of stuff or cloth, which is fine, and used for cloaks and girdles by persons of the highest rank. The butter tree (*fig. 148*) affords an excellent substitute for that European luxury. With the moss that grows about the trunk, the rich commonly stuff their pillows; and the *Giagas* apply it to their wounds with good effect: with the leaves the Moors cover their houses, and they draw from these trees, by incision, a pleasant liquor like wine, which, however, turns sour in five or six days.

1111. *Among other fruits and roots*, they have the vine, which was brought thither from Candia, and yields grapes twice a year.

1112. *The live stock* common to other agricultural countries are here much neglected; but the Portuguese settlers have directed their attention to cows, sheep, and goats, chiefly on account of their milk. Like most parts of Africa, this country swarms with wild animals. Among these, the zebra, buffalo, and wild ass are hunted, and made useful as food or in commerce. The dante, a kind of ox, the skin of which is sent into Germany to be tanned and made into targets called dantes, abounds, and also the cameleon, a great variety of monkeys, and all the sorts of domestic poultry and game.

SUBJECT. 5. *Of the present State of Agriculture at the Cape of Good Hope.*

1113. *The Dutch colonised the Cape of Good Hope* in 1660, and the English obtained possession of it in 1795.

1114. *The climate of this Cape* is not unfriendly to vegetation; but it is so situated, within the influence of periodical winds, that the rains are very unequal, descending in torrents during the cold season, though hardly a shower falls to refresh the earth in the hot summer months, when the dry south-east winds prevail. These winds blast the foliage, blossom, and fruit, of all those trees that are not well sheltered; nor is the human constitution secure against their injurious influence. As a protection from these winds, the colonists who inhabit the nearest side of the first chain of mountains, beyond which their effect does not very sensibly extend, divide that portion of their ground which is appropriated to fruit groves, vineyards, and gardens, by oak screens; but they leave their corn lands altogether open. The temperature of the climate at the Cape is remarkably affected by local circumstances. In summer the thermometer is generally

between 70° and 80°, and sometimes between 80° and 90°, but scarcely ever exceeds 95°.

1115. *The surface of the country* consists of some mountains and extensive barren-looking plains. The upper regions of all the chains of mountains are naked masses of sand-stone; the valleys beneath them are clothed with grass, with thickets, and in some cases with impenetrable forests. The inferior hills or knolls, whose surfaces are generally composed of loose fragments of sandstone, as well as the wide sandy plains that connect them, are thinly strewn over with heaths and other shrubby plants, exhibiting to the eye a uniform and dreary appearance. In the lowest part of these plains, where the waters subside, and, filtering through the sand, break out in springs upon the surface, vegetation is somewhat more luxuriant. In such situations the farm-houses are generally placed; and the patches of cultivated ground contiguous to them, like the oases in the sandy deserts, may be considered as so many verdant islands in the midst of a boundless waste.

1116. *Soils*, in this tract of country, are generally either a stiff clay, impenetrable by the plough till they are soaked by much rain; or light and sandy, tinged with red, and abounding with small round quartzose pebbles. A black vegetable mould seldom appears, except in patches of garden-ground, vineyards, and orchards, that surround the habitations, where, by long culture, manure, and the fertilising influence of springs or rills of water, the soil is so far mellowed as to admit the spade at all seasons of the year. The extensive plains, known in the colony by the Hottentot name of karroo, which are interspersed between the great chains of mountains, exhibit a more dismal appearance than the lower plains, which are chequered with patches of cultivated ground; and their hard surfaces of clay, glistening with small crystals of quartz, and condemned to perpetual drought and aridity, are ill adapted to vegetation. The hills that break these barren plains are chiefly composed of fragments of blue slate, or masses of felspar, and argillaceous limestone. However, in those karroo plains that are tinged with iron, and are capable of being watered, the soil is extremely productive. In such situations, more especially in the vicinity of the Cape, they have the best grapes, and the best fruit of every sort. The great scarcity of water in summer is much more unfavourable to an extended cultivation than either the soil or the climate.

1117. *Landed property* was held by the original Dutch from the government of the Cape on four different tenures. The first tenure was that of a yearly lease renewable for ever, on condition of payment of a certain rent, not in general exceeding eight tenths of a farthing per acre; the second tenure, a sort of perpetual holding subject to a small rent; the third, a holding on fifteen years' leases at a quit-rent, renewable; and the last was that of real estate or freehold, the settler having purchased his farm at once for a certain sum. The second tenure is the most common in the colony. The lands were originally measured out and allotted in the following manner: a stake was stuck as near the centre of the future estate as could be guessed, and a man, starting thence, walked for half an hour in a straight line, to each of the four points of the compass; giving thus the radii of a circle that comprised a space of about 6000 acres.

1118. *Of these extensive farms*, the greater part is, of course, mere sheep and cattle walks. They break up for tillage, patches here and there, where the plough can be directed with the least difficulty, or the soil is most inviting for the purpose. A slight scattering of manure is sometimes used, but more frequently none at all; and it is astonishing to see the crops this soil, and even the lightest sands, will produce with so little artificial stimulus. Seventeen successive crops of wheat without any manure have been taken. When the land is somewhat exhausted by a succession of crops, they break up fresh ground, and the old is suffered to lie fallow, as they term it, for many years; that is, it is permitted to throw up plentiful crops of huge bushes and heath till its turn comes round again, which may be in about seven years, when there is the trouble of breaking it up anew. The sheep and cattle are permitted to stray at pleasure, or are, perhaps, intrusted to the care of a Hottentot.

1119. *The agricultural products* of the Cape farmers are chiefly wheat and other grains, pulse, wine, and brandy, wool, hides, and skins, dried fruits, aloes, and tobacco. The returns of grain and pulse are from ten to seventy, according to the nature of the soil and the supply of water. Barley, i. e. here or bigg, is very productive, and is used only for feeding horses. Rye and oats run much to straw, and are chiefly used as green fodder. Indian corn thrives well, and is very productive; and various kinds of millet, kidneybeans, and other pulse, are extensively cultivated. The wheat is generally heavier, and yields a finer flour, than that of England. It is all spring wheat, being sown from the month of April to June. The returns are very various in the different soils; some farmers declare that they have reaped sixty and eighty for one; the average may be from twenty to thirty; but it is impossible to come to a true estimate upon this point, as no farmers can tell you the exact quantity sown upon a given quantity of acres. The crops seem to be remarkably precarious, failing sometimes for three or four years in succession.

1120. *The vine*, however, is the most profitable, and what may be considered the staple article of culture. Better grapes are not produced in any part of the world; but the art of making wine and brandy from them admits of much improvement. Ten or twelve different kinds of wine are at present manufactured, having a distinct flavour and quality, according to the farms on which they are produced.

1121. *The celebrated Constantia wine* is made on two farms of that name, close under the mountains between Table Bay and False Bay. The white wine of that name is made on the farm called Little Constantia, and the other produces the red. The grape is the muscadell, and the rich quality of the wine is owing partly to the situation and soil of the vineyards, and partly to the care taken in manufacturing the wine. No stalks, nor any berries but such as are fully ripe, are suffered to go under the press; precautions rarely taken by the other farmers of the Cape. The muscadell grape grows on every farm; and on some farms in Drakenstein the wine pressed from it is as good as the Constantia, if not superior to it, though sold, on account of the name of the latter, at one sixth part of the price. When they find that the wine is to be sent abroad, they adulterate it with some other wine: for, according to their own returns, the quantity exported and consumed in Cape Town, as in the case of Madeira wine, greatly exceeds the quantity manufactured.

1122. *The almond* is a very productive tree at the Cape; the tree thrives in the driest and worst soil, and the fruit, though small, is of excellent quality. Dried peaches, apricots, pears, and apples, are not only plentiful, but good of their kind; dried grapes, or raisins, are not so well managed. Potash is procured from a species of *Salsola* which grows on the deserts; and with this and the fat of sheep's tails the farmers make their soap. The berries of the candleberry myrtle (*Myrica cerifera*) supply a vegetable wax sold at Cape Town in large green cakes, from which odoriferous candles are made.

1123. *The Aloe socotrina and perfoliata* cover large tracts of ground, and these afford the inspissated juice or resin of the apothecaries. The leaves of the plant are cut off one by one, and, as they are cut, thrown into tubs. In a day or two after they are thrown in, the juice will have run out of itself, when the leaves are taken out and used as manure. The juice is then either clarified in the sun or by boiling, and when dry, cut into cakes and packed up for sale.

1124. *The tobacco* grown at the Cape is said to be as good as that of Virginia. Enough is grown for home consumption, which is considerable, but none for exportation.

1125. *The live stock* of the Cape farmers chiefly consists of oxen, horses, sheep, swine, and poultry. There are only some districts adapted to grazing; and the farmers who follow this department are in a much less civilised state than the others. The flocks and herds wander over immense tracts, for the use of which a rent or tax according to the number of beasts is paid. At night they are brought home to folds or kraals, which are close to the huts of the farmers, and are represented as places of intolerable filth and stench.

1126. *The native cattle of the Cape* are hardy, long-legged, hony animals, more in the coach-horse line than fitted for the shambles. They are bad milkers, probably from the bad quality and scanty supplies of forage.

1127. *The sheep* are wretched beasts, more resembling goats, with wool that might be taken for frizzly hair, and is in fact only used for stuffing chairs, or for like purposes; the other parts of the body seem drained to supply the accumulation of fat upon the tail which weighs from six to twelve pounds.

1128. *The Merinos*, of which there are a few flocks, do very well: they are much degenerated for want of changing, and a proper selection of rams.

1129. *The Ryeland, or Southdown sheep*, would be a great acquisition here; for the Cape mutton forms a detestable food.

1130. *The Cape horse*, which is not indigenous, but was introduced originally from Java, is a small, active, spirited animal; a mixture of the Spanish and Arabian, capable of undergoing great fatigue; and, as a saddle-horse, excellently adapted to the country. As a draught-horse for the farmer he is too small; and the introduction of a few of the Suffolk punch breed would be a real benefit to the colony, as well as a source of profit to the importer.

1131. *Pigs* are scarce in the colony amongst the farmers; it is difficult to say why, except that there is more trouble in feeding them, and they cannot be turned to graze like sheep. Poultry is, for the same reason, neglected. Indeed, bad mutton may be said to be the only food of the colonists.

1132. *The agricultural implements and operations* of the Cape farmers are said to be performed in the rudest manner, and their crops are thought to depend principally on the goodness of the soil and climate. The plough of the Dutch farmers is a couple of heavy boards nailed together, and armed with a clumsy share, which it requires a dozen oxen to work. Their harrow, if they use any at all, is composed of a few brambles. Their waggons (which will carry about thirty Winchester bushels, or a ton-weight, and are generally drawn by sixteen and sometimes twenty oxen) are well constructed to go tilting up and down the precipitous passes of the kloofs with safety; but they have no variety for the different roads. Burchell has given a portrait of one of these imposing machines. (fig. 149.) Their method of beating out the corn is well known; the sheaves

are spread on a circular floor, surrounded by a low wall, with which every farm is supplied. The farmer's whole stock of brood mares and colts are then turned in, and a black man, standing in the centre, with a long whip to enforce his authority, the whole herd are compelled to frisk and canter round till the corn is trampled out of

the ear. This is termed tramping out. The winnowing is performed by tossing the trampled grain and dung in the air with shovels, or by exposing it to the wind in a sieve.

*1133. *The agriculture of the Cape* appears capable of much improvement, were the farmers less indolent, and more ambitious of enjoying the comforts and luxuries of existence. Barrow is of opinion that there might be produced an abundance of corn, cattle, and wine, for exportation; but that, to effect this, "it will be necessary to procure a new race of inhabitants, or to change the nature of the old ones." At the suggestion of this writer, an attempt was recently made by government to settle a number of British families in the district of the Albany, an immense plain 60 or 70 miles long, by about 90 broad; but after remaining there a year, the greater number of them were obliged to leave that district on account of its unsuitableness for arable culture. A considerable part returned to England, others remained and became servants in the colony, and a few who had some property left, took land in more favourable situations. Pringle, who has given an account of this settlement (1824), describes the deplorable situation of the greater number of 5000 individuals who had fixed themselves there, and ascribes their calamities more to the nature of their situation than to any other cause. Other districts, he contends, might have been chosen much better adapted for the plough and the spade, while the low and fertile region of Albany might have been usefully occupied as a sheep pasture. With all the deficiencies of the country and climate, he says, if things are properly managed, the Cape is not a worse land to live in than any other English colony. Comparing his own account, however, with the description of other colonies, especially Van Diemen's Land and New South Wales, we should be disposed to differ from him in opinion, and to prefer the latter settlements. (*Pringle's Present State of Albany, South Africa*, 12mo, 1824.)

1134. *In the interior of the country* are many tribes of whom little or nothing is known; but some of which are every now and then brought into notice by modern travellers. Some have been visited, for the first time, by the missionary Campbell; and the account he gives of their agriculture, manufactures, and customs is often very curious. It is astonishing how ingenious he found some tribes in cutlery and pottery; and the neatness and regularity of the houses of others are equally remarkable. In one place the houses were even tasteful; they were conical, and enclosed by large circular fences (*fig. 150.*); and he found them threshing out the corn on raised circular threshing-floors (*a*), with flails, much in the same manner as we do.

1135. *The unimproved Hottentots* form their huts (*fig. 151.*) of mats bound on a skeleton of poles or strong hoops. (*fig. 152.*) Their form is hemispherical; they are entered by a low door, which has a mat shutter, and they are surrounded by a reed or mat fence to exclude wild animals and retain fuel and cattle. Attempts to introduce European forms of cottages have been made by the missionaries, which, with a knowledge of the more useful arts, The missionary Kuishe conducted

will no doubt in time humanise and refine them. Burchell along the valley of Genadendal, to exhibit the progress which the Hottentots, under his instruction, had made in horticulture and domestic order. The valley is a continued maze of gardens and fruit trees. "The huts (*fig. 153.*), unlike those of Hottentot construction, are a rude imitation of the quadrangular buildings of the colonist. They are generally from ten to fifteen feet long, and from eight to ten wide, having an earthen floor and walls white-washed on their inside, composed of rough unhewn poles, filled up

between with reeds and rushes plastered with mud, and the whole covered with a

roof of thatch. The eaves being in general not higher from the ground than four or six feet, the doors could not be entered without stooping. A small unglazed window admitted light, but there was nei-

ther chimney nor any other opening in the roof by which the smoke might escape.

(*Burchell's Travels*, i. 112.)

1196. *The cattle of all the Hottentot and other tribes* are kept in circular folds during night; and it is remarkable that these folds are the only burial places known to be in use among that people. "Corn is preserved in what may be termed large jars, of various dimensions, but most commonly between four and five feet high and three wide. The shape of these corn jars is nearly that of an egg shell, having its upper end cut off: sometimes their mouth is contracted in a manner which gives them a great resemblance to a European oil-jar. They are formed with stakes and branches fixed into the ground and interwoven with twigs; this frame-work being afterwards plastered within and without with loam and cow-dung. Frequently, the bottoms of these jars are raised about six inches or a foot above the ground; and the lower part of the stakes, being then uncovered, gives them the appearance of standing on short legs. Their contents are usually protected by a covering of skin or straw." This mode of keeping their corn and beans, Burchell observes, shows a degree of ingenuity equal to that which is displayed in the construction of their houses, and is to be admired for its simplicity and perfect adequateness to the purpose. In the dwellings of the richer inhabitants, the back part of the houses is completely filled with jars of this kind. (*Travels*, ii. 520.)

1137. *The natives of the South of Africa* live much on bulbous roots, of which their country is naturally more productive than any other. Burchell has enumerated a considerable number which he saw them use. One of the most remarkable grows on the mountains of Grafreynet, and is called Hottentot's bread (*Tamus elephántipes Herit.*, *Testudinária elephántipes Burch.*).

(*fig. 154.*) Its bulb stands entirely above ground, and grows to an enormous size, frequently three feet in height and diameter. It is closely studded with angular ligneous protuberances, which give it some resemblance to the shell of a tortoise. The inside is a fleshy substance, which may be compared to a turnip, both in substance and colour. From the top of this bulb arise several annual stems, the branches of which have a disposition to twine round any shrub within reach. The taste of this bulb is thought to resemble that of the yam of the East Indies, the plant being closely allied to the genus *Dioscœrea*. (*Burchell's Travels*, ii. 147.)

1138. *The Bachapins* are a people of the interior of South Africa, who were visited by Burchell.

Their agriculture, he says, is extremely simple and artless. It is performed entirely

155

by women. To prepare the ground for sowing, they pick it up to the depth of about four inches, with a kind of hoe or mattock, which differs in nothing from a carpenter's adze but in being twice or thrice as large. The corn they sow is the Caffre corn or Guinea corn, a variety of millet (*Hólcus Sorghum Caffròrum*). They cultivate also a kind of kidneybean, and eat the ripe seeds; they likewise raise water-melons, pumpkins, and the calabash gourd for the use of its shell as a domestic vessel for drinking and other purposes. They are inordinate smokers of tobacco, but they do not cultivate the plant. Burchell gave them some potatoes and peach stones to cultivate, which pleased them exceedingly, and for which they were very thankful. (*Travels*, ii. 518.)

1139. *The Bushman spade* (*fig. 155.*) is a pointed stick about three feet long, to which there is affixed, about the middle, a stone to increase its power in digging up bulbous roots. This stone is about five inches in diameter, and is cut or ground very regularly to a round form, and perforated with a hole large enough to receive the stick and a wedge by which it is fixed to its place. (*Burchell's Travels*, ii. 50.)

SUBJECT. 6. *Of the present State of Agriculture on the Eastern Coast of Africa, and in the African Islands.*

1140. *Of the various countries on the eastern coast of Africa* the chief is Mocaranga, the agriculture of which may be considered as a specimen of that of the savage tribes of the other states. The climate is temperate, though the mountains called Supata, or the spine of the world, forming a great chain from north to south, are perpetually covered with snow; the air clear and salubrious; and the soil fertile and well watered, so that its pastures feed a great number of cattle, more valued by the inhabitants than their gold. The inland parts of the country, however, are sandy, dry, and barren. The products of the country on the coast, are rice, millet, and maize, but no wheat; sugar canes and cotton are found both wild and cultivated. They are without the ox and horse, but elephants, ostriches, and a great variety of wild animals abound in the forests. According to the doubtful accounts of this country, the king, on days of ceremony, wears a little spade hanging by his side as an emblem of cultivation.

1141. *The Island of Madagascar* is celebrated for its fertility, and the variety of its productions. Its climate is mild and agreeable; and the surface of the country is divided into the eastern and western provinces by a range of mountains. The summits of these mountains are crowned with lofty trees of long duration, and the low grounds are watered by torrents, rivers, and rivulets, which flow from them. The agricultural products are rice, cotton, indigo, sugar, pulse, the yam, banana, cocoa, pepper, ginger, turmeric, and a variety of other fruits and spices. There are a great number of rare fruits and esculent plants, and many curious woods. Oxen and flocks of sheep abound; but there are no horses, elephants, lions, or tigers. The culture is very imperfect, the soil and the excellence of the seasons supplying the place of labour and skill.

1142. *The Mauritius, or Isle of France*, is a productive island, chiefly indebted to the industry of the French, who have introduced there most of the grains, roots, and fruits of other parts of the world, all of which seem to thrive. The climate is excellent, and similar to that of the Bourbon and Canary Islands. The surface is mountainous towards the sea coast, but within land there are many spots both level and fertile. The soil is, generally speaking, red and stony. The agricultural products are numerous. A crop of maize, succeeded by one of wheat, is procured in one season from the same field. The rice of Cochin China is extensively cultivated; the manioc, or cassava (*Játropha Mánihot*) of Brazil; sugar, which is the chief product for export; cinnamon, clove, and nutmeg trees, &c. Oranges, citrons, and guavas abound; and pine-apples are said to grow spontaneously. Many valuable kinds of woods are found in the forests; and on the banks of the rivers are fed the flocks and herds of the country.

1143. *The Isle of Bourbon* differs little in its natural and agricultural circumstances from that of the Mauritius.

1144. *St. Helena* is a rugged, but beautiful island, occupied by a few farmers, chiefly English. Their chief productions are cattle, hogs, and poultry; and when the India ships arrive every house becomes a tavern.

1145. *The Cape Verd Islands* are, in general, hot and unhealthy as to climate, and stony and barren as to soil. Some, however, produce rice, maize, bananas, oranges, cotton, and sugar-canes, with abundance of poultry.

1146. *The Canary Islands* having been subject to Spain for many centuries, the agriculture of the parent country prevails throughout. The climate is temperate, and the soil generally rich. The stock of the farm belongs to the proprietor of the soil, who lends it to the cultivator, on condition of getting half of the produce. The products are, wheat, barley, rice, oats, flax, anise seeds, coriander, the mulberry, grape, cotton, sugar-cane, dragon's-blood tree (*Dracæna*), and a variety of esculent plants and fruits. The celebrated Canary wine is made chiefly in the islands of Teneriffe and Canary. Potatoes have been introduced within the last fifty years, and now constitute the chief food of the inhabitants. The archil (*Roccella tinctoria*) (fig. 156. a), a moss used in dyeing, grows wild on all the rocks; and kali (*Salsòla Kàli*) (fig. 156. b), from which soda is extracted, is found wild on the sea-shore. The roots of the male fern (*Ptêris aquilina*) are, in times of scarcity, ground into flour, and used as food. The live stock of the Canaries consists of cattle, sheep, horses, and asses; and the well-known Canary birds, with a great variety of others, abound in the woods.

1147. *The Island of Madeira* is chiefly celebrated for its wine. It is the boast of the islanders, that their country produces the best wheat, the purest sugar, and the finest

wines in the world, besides being blest with the clearest water, the most salubrious air, and a freedom from all noxious reptiles. The first view of the island is particularly magnificent; the country rising in lofty hills from every part of the coast, so steep as to bring very distant objects into the foreground. The sides of these hills are clothed with vines as high as the temperature will admit; above this they are clothed with woods or verdure to their summits, as high as the sight can distinguish; except those columnar peaks, the soil of which has been washed away by the violent rains to which those latitudes, and especially such elevated parts, are liable. Deep ravines or valleys descend from the hills to the sea, and in the hollow of most of them flows a small river, which in general is rapid and shallow. The soil is clay on the surface; and large masses of it, as hard as brick, are found underneath. The island, it is said, when discovered by the Portuguese, was covered with wood; and the first step taken by the new settlers was to set fire to the wood. This conflagration is said to have lasted seven years, and to have been the chief cause of the fertility of the soil; but whatever may have been the effect at first, this fertility could not have lasted for three centuries.

1148. *The lands of Madeira are cultivated on the metayer system*; in entailed estates leases cannot be granted for a longer period than nine years; but in no case can the tenant be dismissed till he is paid the full value of his improvements.

1149. *The vine is cultivated chiefly in the French, but partly in the Italian, manner.* In the low grounds it is suffered to grow to a considerable height, and tied to trees, poles, or trellises; on the sides of the hills the terrace culture is adopted, and there the plants are kept lower, and tied to single stakes or low trellises. The variety of grape cultivated is what in France is called the Rhetish, a sort of small black cluster; but its character is greatly altered since its transplantation to Madeira. The grape from which the Malmsey Madeira wine is made is the Ciotat of the French, or parsley-leaved muscadine with a white berry. The quantity of genuine malmsey produced annually is very small; and of that a good deal is supposed to be manufactured with refined sugar. The quality of the wine here, as every where else, depends more on the aspect and soil than on the kind of grape. The best is grown on the south side of the island, on the lower declivities which point towards the south-east; the west being always cooled by the sea breeze.

1150. *Wheat is grown on lands previously prepared by the culture of common broom.* This is cut for fuel, and, after a time, grubbed up and burnt on the soil. By these means, a crop of wheat is insured for a succession of years, more or less, according to the soil; after which the same process is again resorted to. For this purpose, the seeds of the broom are collected, and generally bear the same price by measure as wheat.

1151. *The live stock are not numerous.* Animals of all sorts, as in most mountainous countries, are small. The beef and mutton appear to a Briton lean and tasteless; common poultry are small; but ducks and turkeys equal those of England. Pork is rare, but excellent when well fed.

1152. *The tropical fruits are not readily produced here.* In the villages are found guavas, bananas, oranges, and shaddock. Pine-apples are reared with great difficulty; but neither the granadilla nor the alligator pear, though they grow vigorously, produces fruit.

SECT. V. *Of the present State of Agriculture in North America.*

*1153. *The climate of this region, which extends from the vicinity of the equator to the arctic circle, is necessarily extremely various.* In general, the heat of summer and the cold of winter are more intense than in most parts of the ancient continent. The middle provinces are remarkable for the unsteadiness of the weather. Snow falls plentifully in Virginia, but seldom lies above a day or two. Carolina and Florida are subject to insufferable heat, furious whirlwinds, hurricanes, tremendous thunder, and fatal lightnings. The climate of the western parts is least known; that of California seems to be in general moderate and pleasant.

1154. *The surface of North America is nobly diversified with rivers, lakes, mountains, and extensive plains, covered in many places with forests.* Its shores are, in general, low, irregular, with many bays and creeks; and the central parts seem to present a vast fertile plain, watered by the Missouri and its auxiliary streams. New Mexico in surface is an alpine country, resembling Norway and Greenland; Labrador, and the countries round the Hudson Sea, present irregular masses of mountain covered with eternal snow. In general, all the natural features of America are on a larger scale than those of the old world. (*Darby's View of the United States, 1826.*)

1155. *The agriculture of North America is chiefly that of the north of Europe: but in the provinces near the equator the culture of the southern parts of Europe prevails; and in the West India Islands that of the warmest climates is followed; there being no production of any part of the world which may not be there brought to perfection.*—After this general outline of the agricultural circumstances of North America, we shall select some notices of the agriculture of the United States, the Spanish dominions in North America, British possessions, unconquered countries, and North American Islands or West Indies.

SUBJECT. 1. *Of the present State of Agriculture in the United States.*

1156. *The climate of the United States must necessarily vary in its different parts.* In the north-east the winters are very cold and the summers hot, changing as you proceed

southward. In the south-east, and along the Gulf of Mexico, the summers are very hot, and the winters mild and pleasant. Among the mountains it is cold towards the north, and temperate in the south. Beyond the mountains, in the rich valleys of Ohio, Mississippi, and Missouri, the climate is temperate and delightful, till we approach the Rocky Mountains, when it is subject to extremes, the winters being very cold. The climate must be chilled among mountains constantly covered with snow. West of these mountains, the climate changes, until we reach the shores of the Pacific Ocean, where it resembles that of the western parts of Europe. The prevailing winds are from the west, and, as they pass over a wide expanse of water, they cool the air in summer, and in winter deluge the country with frequent rain.

1157. *The seasons* generally correspond with those in Europe, but not with the equality to be expected on a continent, as even during the summer heats single days will occur which require the warmth of a fire. The latitude of Labrador corresponds with that of Stockholm, and that of Canada with France, but the climates of those places are widely different. It would appear from Humboldt, that the difference of temperature between the old and new continents, in the same latitude, is between 4° and 5° in favour of the former.

1158. *The surface* of the country in the United States presents every variety. The north-eastern part of the coast is broken and hilly; and is remarkably indented with numerous bays and inlets. Towards the south, and along the Gulf of Mexico, the land is level and sandy, interspersed with many swamps and numerous islands and inlets. At the outlets of many of the rivers, there is a large portion of alluvial land, which is particularly the case along the Mississippi. Beyond the head of tide-waters, there is a tolerably rich and agreeably uneven country, which extends to the mountains. The mountainous district, on the Atlantic side of the country, is about 150 miles in breadth, and 1200 miles in length. It extends in large ridges, from north-east to south-west, and is known as the Alleghany Mountains. Beyond these the great valley of the Mississippi presents a surface of the finest land in the world. To the westward of this valley are the mountains of Louisiana, and beyond these the bold shores of the Pacific Ocean.

*1159. *The soil of the United States*, though of various descriptions, is generally fertile; often, on the east of the Blue Mountains, in Virginia, a rich, brown, loamy earth; sometimes a yellowish clay, which becomes more and more sandy towards the sea. There are considerable marshes and salt-meadows, sandy barrens producing only a few pines, and sometimes entirely destitute of wood. On the west of the Apalachian Mountains the soil is also generally excellent; and in Kentucky some spots are deemed too rich for wheat, but the product may amount to sixty bushels per acre. About six feet below the surface there is commonly a bed of limestone.

1160. *The landed property of the United States* is almost universally freehold, having been purchased or conquered by the different states, or by the general government, from the native savages; and either lotted out to the conquering army, or reserved and sold afterwards according to the demand.

1161. *The mode of dividing and selling lands in the United States* is thus described by Birkbeck. "The tract of country which is to be disposed of is surveyed, and laid out in sections of a mile square, containing six hundred and forty acres, and these are subdivided into quarters, and, in particular situations, half quarters. The country is also laid out in counties of about twenty miles square, and townships of six miles square in some instances, and in others of eight. The townships are numbered in ranges, from north to south, and the ranges are numbered from west to east; and, lastly, the sections in each township are marked numerically. All these lines are well defined in the woods, by marks on the trees. This done, at a period of which public notice is given, the lands in question are put up to auction, except the sixteenth section, which is near the centre, in every township, which is reserved for the support of schools, and for the maintenance of the poor. There are also sundry reserves of entire townships, as funds for the support of seminaries on a more extensive scale, and sometimes for other purposes of general interest. No government lands are sold under two dollars per acre; and I believe they are put up at this price in quarter sections at the auction, and if there is no bidding they pass on. The best lands and most favourable situations are sometimes run up to ten or twelve dollars, and in some late instances much higher. The lots which remain unsold are from that time open to the public, at the price of two dollars per acre; one fourth to be paid down, and the remaining three fourths to be paid by instalments in five years; at which time, if the payments are not completed, the lands revert to the state, and the prior advances are forfeited. When a purchaser has made his election of one, or any number, of the vacant quarters, he repairs to the land-office, pays eighty dollars, or as many times that sum as he purchases quarters, and receives a certificate, which is the basis of the complete title, which will be given him when he pays all; this he may do immediately, and receive eight per cent interest for prompt payment. The sections thus sold are marked immediately on the general plan, which is always open at the land-office to public inspection, with the letters A. P., i. e. advance paid. There is a receiver and a register at each land-office, who are checks on each other, and are remunerated by a per centage on the receipts."

1162. *The price of land*, though low when not cleared, rises rapidly in value after a very slight occupation and improvement. Instances are frequent of a rise of 1000 per cent, in about ten years. Cobbett, who resided in 1817 in Long Island, which may be considered the middle climate of the United States, gives the price of a cultivated farm in that part of the country. "A farm, on this island," he says, "any where not nearer than thirty miles off, and not more distant than sixty miles from New York, with a good farm-house, barn, stables, sheds, and sties; the land fenced into fields with posts and rails, the wood-land being in the proportion of one to ten of the arable land, and there

being on the farm a pretty good orchard ; such a farm, if the land be in a good state, and of an average quality, is worth *sixty dollars an acre, or thirteen pounds sterling* ; of course, a farm of a hundred acres would cost 1300*l*. The rich lands on the necks and *bays*, where there are *meadows* and surprisingly productive orchards, and where there is *water carriage*, are worth, in some cases, three times this price. But what I have said will be sufficient to enable the reader to form a pretty correct judgment on the subject. In New Jersey, in Pennsylvania, every where the price differs with the circumstances of water-carriage, quality of land, and distance from market. — When I say a good farm-house, I mean a house a great deal better than the general run of farm-houses in England ; more neatly furnished on the inside ; more in a parlour sort of style ; though round about the house, things do not look so neat and tight as in England.”

1163. *The agriculture of the United States* may be considered as entirely European, and chiefly British. Not only is the climate better adapted for the British agriculture, but the great majority of the inhabitants are of British origin. To enter into details of the products and processes of North American agriculture would therefore be superfluous in a work principally devoted to British agriculture. All we shall attempt is, to notice some of the leading peculiarities of North American agriculture, as resulting from national, political and civil circumstances.

1164. *The natural circumstances of lands not under culture* chiefly affect the commencement of farming operations. In general, the lands purchased by settlers are underwood, which must be felled or burned, and the roots grubbed up ; a laborious operation, which, however, leaves the soil in so rich a state, that it will bear heavy crops of grain, potatoes, and tobacco, with very little culture and no manure, for several years. Sometimes they are under grass, or partially covered with brushwood, in which the operation of clearing is easier. In either case, the occupier has to drain where necessary ; to enclose with a ring fence, if he wishes to be compact ; to lay out and make the farm

157

road ; and to build a house and farmery. The latter he constructs of timber, sometimes plastered with neatness and taste, as in England (*fig. 157.*), but generally with logs and mud, as in Poland and Russia (*fig. 158.*). With timber he generally forms also his fences, though thorn and other live hedges are planted in some of the earlier-cultivated districts.

158

1165. *The usual practice of settlers with capital* may be very well exemplified in the case of Birkbeck. This gentleman having purchased an estate of 1440 acres, in the Illinois, and fixed on that part of it which he intended as his future residence and farm, “the first act was building a cabin, about two hundred yards from the spot where the house was to stand. This cabin is built of round straight logs, about a foot in diameter, lying upon each other, and notched in at the corners, forming a room eighteen feet long, by sixteen ; the intervals between the logs ‘chinked,’ that is, filled in with slips of wood ; and ‘mudded,’ that is, daubed with a plaster with four hundred clap boards of cleft oak, very much like the pales used in England for fencing parks. A hole is cut through the side, called, very properly, the ‘door (the through),’ for which there is a ‘shutter,’ made also of cleft oak, and hung on wooden hinges. All this has been executed by contract, and well executed, for twenty dollars. I have since added ten dollars to the cost, for the luxury of a floor and ceiling of sawn boards, and it is now a comfortable habitation.”

1166. *An example of a settler who began with capital only sufficient to pay the first instalment* of eighty dollars of the price of 160 acres of land is given by the same author, who had the information from the settler himself. Fourteen years ago, he “unloaded his family under a tree,” on his present estate ; where he has now two hundred acres of excellent land, cleared and in good cultivation, capable of producing from eighty to one hundred bushels of Indian corn per acre. The poor emigrant, having collected the eighty dollars, repaired to the land-office, and entered his quarter section, then worked his way, without another cent in his pocket, to the solitary spot which was to be his future abode, in a two-horse wagon, containing his family and his little all, consisting of a few blankets, a skillet, his rifle, and his axe. Arrived in the spring, after putting up a little log cabin, he proceeded to clear, with intense labour, a plot of ground for Indian corn, which was to be their next year’s support ; but for the present, being without means of obtaining a supply of flour, he depended on his gun for subsistence. In pursuit of the game, he

was compelled, after his day's work, to wade through the evening dews, up to the waist in long grass or bushes; and, returning, found nothing to lie on but a bear's skin on the cold ground, exposed to every blast through the sides, and every shower through the open roof of his wretched dwelling, which he did not even attempt to close, till the approach of winter, and often not then. Under such distresses of extreme toil and exposure, debarred from every comfort, many valuable lives have sunk, which have been charged to the climate. The individual whose case is here included had to carry the little grain he could procure twelve miles to be ground, and remembers once seeing at the mill a man who had brought his corn sixty miles, and was compelled to wait three days for his turn. Such are the difficulties which these pioneers have to encounter; but they diminish as settlements approach each other, and are only heard of by their successors.

1167. *The political circumstances of the United States* affect the agriculturist both as to the cost of production and the value of produce. It is evident that the want of population must render the price of labour high, and the produce of land low. In this Parkinson, Birkbeck, Cobbett, and all who have written on the agriculture of America, agree. "The simple produce of the soil," Birkbeck observes, "that is to say, grain, is cheap in America; but every other article of necessity and convenience is dear in comparison. Every service performed for one man by another must be purchased at a high rate, much higher than in England." The cheapness of land affords the possession of independence and comfort at so easy a rate, that strong inducements of profit are required to detain men in the condition of servitude. Hence the high price of all commodities, not simply agricultural; of the labour of mechanics of every description; and hence also the want of local markets for grain, because where three fourths of the population raise their own grain (which is the calculation), the remaining fourth will use but a moderate proportion of the spare produce. The low rate of land and taxes and this want of home markets form the reason why the American farmer, notwithstanding the price of labour, affords his grain so cheap for exportation. Although the rate of produce is low, the profits of the American farmers are high, on account of the small capital required. With 2000*l.* Birkbeck calculates that a farm of 640 acres, in the Illinois, may be purchased, stocked, and cultivated, so as to return, after deducting all expenses, twenty-two per cent, besides the value of the improvements made on the land, that is, its increased value, which, as has already been stated (1164.), is incredible, in a very short time.

1168. *The agricultural products of the United States* include all those of Britain and France. The British grains, herbage, plants, and fruits are grown in every district. What appears at first sight very remarkable is, that in America the native pastures (except on the banks of the rivers) consist entirely of annuals; and that is the reason why the country is generally bare and black in winter; but perennial grasses, when sown in the uplands, are found to thrive in many situations. The greatest quantity of wheat is grown in Pennsylvania and New England. Maize ripens in all the districts, except some of the most northerly. Rice is cultivated in Virginia, and on the Ohio; and the vine is indigenous in these and other provinces, though its culture has not yet been much attempted. Some French cultivators are of opinion that the American soil and climate are unfavourable; this, however, is not likely to be the case, it being a native of the country. The government have established a Swiss colony for its culture, at Vevay, in Indiana; and another in Louisiana, for the culture of the olive. The mulberry, the cotton, and the sugar-cane are cultivated in Virginia, but not extensively. Sugar is procured plentifully in the woody districts, by tapping different species of *Acer*, especially the *saccharinum*, in spring; boiling the juice till it thickens; and then granulating it by letting it stand and drain in a tub, the bottom of which is pierced with small holes. The sugar obtained does little more than pay for the labour.

1169. *Of the live stock of the United States*, the breed of horses of English extraction is, in general, good, as are the cows and hogs. In many cases there is no limit to the number of these that may be grazed in the unoccupied woods: all that the farmer has to do is, to protect them from bears and wolves at particular seasons, and to keep them tame, as in Russia and Switzerland, by giving them salt. Sheep are totally unfit for the climate and state of the country, though a number of proprietors have been at great pains in attempting to introduce the merinos. Mutton, Birkbeck observes, is almost as abhorrent from an American palate or fancy, as the flesh of swine from an Israelite; and the state of the manufactures does not give great encouragement to the growth of wool of any kind, of merino wool less, perhaps, than any other. Mutton is sold in the markets of Philadelphia at about half the price of beef; and the Kentuckian, who would have given a thousand dollars for a merino ram, would dine upon dry bread rather than taste his own mutton. A few sheep on every farm, to supply coarse wool for domestic manufacture, seems to be all that ought at present to be attempted in any part of America that I have yet seen. Deep woods are not the proper abodes of sheep. When America shall have cleared away her forests, and opened her uplands to the breezes, they will soon be covered with fine turf, and flocks will be seen ranging over them here, as in other parts of the world.

1170. *Agricultural operations in America* are skilfully performed by the farmers of

capital, who have all the best implements of Europe; by the poorest settlers this is not the case, from want of stock; and by the native American farmers, from indolence, which, according to all accounts, is their general defect. An American labourer is most expert at the use of the axe and the scythe; the spade he handles in a very awkward manner, and has no idea of banking, hedging, clipping or cutting hedges, and many other operations known to every labourer in a highly cultivated and enclosed country like Britain. But the versatility of talent of an American labourer amply compensates for his inexperience in these operations, and is more useful in his circumstances. In handling the saw, the hammer, and even the trowel, the British labourer has no chance with him. Most of them can build a house, mend a plough or waggon and even the harness, and kill and dress sheep and pigs.

1171. *Field labours in America* require to be performed with much greater expedition than in England. The winter is long and severe, and the transition to spring is sudden; this season in many provinces only lasts a few weeks, when summer commences, and the ground becomes too hard and dry for the operations of tillage. The operations of seed-time must therefore be performed with the greatest rapidity. The climate of New York may be reckoned one of the best in North America. There the ground is covered with snow, or rendered black by frost, in the beginning of December, and continues without a speck of green till May. Ploughing generally begins in the last week of April; oats are sown in that month; and maize and potatoes about the middle of May. By the end of May the wheat and rye which has stood the winter, the spring-sown corn, the grass, and the fruit trees appear as forward as they are at the same period in England. There is very little rain during June, July, and August. Cherries ripen in the last week of June; by the middle of July the harvest of wheat, rye, oats, and barley, is half over; pears ripen in the beginning of August; maize (*fig. 159.*), rye, and wheat are sown during the whole of October; corn is cut in the first week of September; peaches and apples are ripe by the end of the month; the general crop of potatoes is dug up in the beginning of November; and also turnips and other roots taken up and housed; a good deal of rain falls in September, October, and November, and severe frosts commence in the first week of December, and, as above stated, continue till the last week of April. Such is the agricultural year in the country of New York. Live stock require particular attention during the long winter; and unless a good stock of Swedish turnip, carrot, or other roots, has been laid up for them, they will generally be found in a very wretched state in April and May.

1172. *The civil circumstances* of the United States are unfavourable to the domestic enjoyments of a British farmer emigrating thither. Many privations must be suffered at first, and some, probably, for one or two generations to come. The want of society seems an obvious drawback; but this Birkbeck has shown not to be so great as might be imagined. When an emigrant settles among American farmers, he will generally find them a lazy ignorant people, priding themselves in their freedom, and making little use of their privileges; but, when he settles among other emigrants, he meets at least with people who have seen a good deal of the world and of life; and who display often great energy of character. These cannot be considered as uninteresting, whatever may be their circumstances as to fortune; and, when there is something like a parity in this respect and in intellectual circumstances, the social bond will be complete. It must be considered that one powerfully operating circumstance must exist, whatever be the difference of circumstances or intellect; and that is, an agreement in politics both as to the country left and that adopted. For the rest, the want of society may be, to a certain degree, supplied by the press; there being a regular post in every part of the United States, and numerous American and European newspapers and periodical works circulated there. Birkbeck mentions that the *Edinburgh and Quarterly Reviews*, the *Monthly* and other *Magazines*, and the *London newspapers* are as regularly read by him at the prairie in Illinois, as they were at his farm of Wanborough in Suffolk; and that all the difference is, that they arrive at the prairie three months later than they did at his British residence. We have seen sketches of the houses erected by this gentleman, and by some others who have settled around him, and we consider them as by no means deficient either in apparent commodiousness or effect. They remind us of some of the best houses of Switzerland and Norway. (*fig. 160.*) Birkbeck and part of his family were drowned in crossing the Wabash in 1825, an event which must be deeply

lamented by all who knew any thing of this intelligent, enterprising, and benevolent character.

1173. *The want of domestic servants* is a considerable drawback in most parts of the United States; but especially in the new settlements. Families who remove into Western America, Birkbeck observes, should bring with them the power and the inclination to dispense, in a great degree, with servants. To be easy and comfortable there, a man should know how to wait upon himself, and practise it. In other respects, this gentleman and his friends hope to live on their estates at the prairie, "much as they were accustomed to live in England." An interesting account of the house, garden, and domestic economy of Mr. Hall of Wanborough, a neighbour of Mr. Birkbeck's, will be found in the *Gardener's Magazine*, vol. i. p. 327. and vol. iv. p. 155.

1174. *As a country for a British farmer to emigrate to*, we consider the United States as superior to every other, in two respects: — first, on account of its form of government; by which property is secure, and personal liberty greater than any where else, consistently with public safety, and both maintained at less expense than under any government in the world: secondly, on account of the stock of people being generally British, and speaking the English language. The only objection we have to America is the climate — the long and severe winter, and the rapid and hot spring and summer. Land equally good, and nearly as cheap, may be had in the south of Russia and in Poland; but who that knows any thing of the governments of these countries, would voluntarily put himself in their power while the United States were accessible?

SUBSECT. 2. *Of the present State of Agriculture in Mexico.*

1175. *The climate of this extensive and recently revolutionised country* is singularly diversified, between the tropical seasons and rains, and the temperature of the southern and even middle countries of Europe. The maritime districts of Mexico are hot and unhealthy, so as to occasion much perspiration even in January; the inland mountains, on the other hand, present snow and ice in the dog-days. In other inland regions, however, the climate is mild and benign, with some snow of short duration in winter; but no artificial warmth is necessary, and animals sleep all the year under the open sky. From April to September there are plentiful rains, generally after noon; hail storms are not unknown; thunder is frequent; and earthquakes and volcanoes occasionally occur. The climate of the capital, in lat. 19° 25', differs much from that of the parts of Asia and Africa under the same parallel; which difference seems to arise chiefly from the superior height of the ground. Humboldt found that the vale of Mexico is about 6960 feet above the level of the sea, and that even the inland plains are generally as high as Mount Vesuvius, or about 3600 feet. This superior elevation tempers the climate with a greater degree of cold; upon the whole, therefore, it cannot be regarded as unhealthy.

1176. *The surface of the country* is diversified by grand ridges of mountains, numerous volcanoes some of which are covered with perpetual snow, cataracts worthy of the pencil of Rosa, delicious vales, fertile plains, picturesque lakes and rivers, romantic cities and villages, and a union of the trees and vegetables of Europe and America.

1177. *The soil* is often deep clay, surprisingly fertile and requiring no stimulus except irrigation. In some places it is boggy or composed of a soft black earth, and there are barren sands and stony soils in the elevated regions.

1178. *Of the agriculture of Mexico* some account is given by the Abbé Clavigero and the Baron de Humboldt. According to the first author, agriculture was from time immemorial exercised by the Mexicans, and almost all the people of Anahuac. The Toltecan nation employed themselves diligently in it, and taught it to the Thechemecan hunters. With respect to the Mexicans, during the whole of their peregrination, from their native country Atzlan, unto the lake where they founded Mexico, they are said to have cultivated the earth in all the places where they made any considerable stop, and to have lived upon the produce of their labour. When they were brought under subjection to the Colhuau and Tepanecan nations, and confined to the miserable little islands on the lake, they ceased for some years to cultivate the land, because they had none, until necessity and industry together taught them to form movable fields and gardens, which floated on the waters of the lake.

160

1179. *The method of forming floating fields*, which they still practise, is extremely simple. They plant and twist together willows and roots of marsh plants, or other materials which are light, but capable of supporting the earth: of the field firmly united. Upon this foundation they lay the light bushes which float on the lake, and, over all, the mud and dirt which they draw up from the bottom of the same lake. Their regular figure is quadrangular; their length and breadth various; but in general, they are about eight perches long, and not more than three in breadth, and have less than a foot of elevation above the surface of the water. There were the first fields which the Mexicans owned after the foundation of Mexico; there they first cultivated the maize, great pepper, and other plants, necessary for their support. In progress of time as those fields grew numerous from the industry of those people, there were among them gardens of flowers and odoriferous plants, which were employed in the worship of their gods, and served for the recreation of the nobles. At present they cultivate flowers, and every sort of garden herbs upon them. Every day of the year, at sun-rise, innumerable vessels loaded with various kinds of flowers and herbs, which are cultivated in those fields and gardens, are seen arriving by the canal, at the great market-place of that capital. All plants thrive there surprisingly; the mud of the lake is an extremely fertile soil, and requires no water from the clouds. In the largest islands there is commonly a little tree, and even a little hut to shelter the cultivator, and defend him from rain or the sun. When the owner of an island, or the *chinampa*, as he is usually called, wishes to change his situation, to remove from a disagreeable neighbour, or to come nearer to his own family, he gets into his little vessel, and by his own strength alone, if the garden is small, or with the assistance of others, if it is large, he tows it after him, and conducts it wherever he pleases with the little tree and hut upon it. That part of the lake where those floating fields are is a place of infinite recreation, where the senses receive the highest possible gratification. These floating fields, Humboldt informs us, still exist; they are of two sorts: the one mobile and blown here and there by the winds, and the others fixed and united to the shore. The former alone merit the appellation of floating, and they are diminishing day by day. He assigns to them the same origin as the Abbé Clavigero; but thinks it probable that nature also may have suggested the first idea, and gives instances of small pieces of the surface, netted with roots and covered with plants, being detached from the marshy shores of other American lakes, and floating about in the water. The bean, pea, apple, artichoke, cauliflower, and a great variety of other culinary plants, are cultivated on them.

1180. *A floating island, in a small lake in Haverhill*, in New England, is mentioned by Dr. Dwight. It has, he was informed, immemorially floated from one shore to another, whenever it was impelled by a violent wind. Lately it has adhered for a considerable time to a single spot; and may perhaps be so firmly fixed on the shelving bottom, as to move no more hereafter. Several trees and shrubs grow on its surface, and it is covered by a fresh verdure. (*Travels*, vol. i. p. 371.)

1181. *Having neither ploughs nor oars*, nor any other animals proper to be employed in the culture of the earth, the Mexicans, when they had shaken off the Tepanecan yoke, supplied the want of them by labour, and other more simple instruments. To hoe and dig the ground they made use of the *coatl*, or *coa*, which is an instrument made of copper, with a wooden handle, but different from a spade or mattock. They made use of an axe to cut trees, which was also made of copper, and was of the same form with those of modern times, except that we put the handle in the eye of the axe, whereas they put the axe into an eye in the handle. They had several other instruments of agriculture; but the negligence of ancient writers on this subject has not left in our power to attempt their description.

1182. *They irrigated their fields* with the water of rivers and small torrents which came from the mountains, raising dams to collect them, and forming canals to conduct them. Lands which were high, or on the declivity of mountains, were not sown every year, but allowed to lie fallow until they were over-run with bushes, which they burned, to repair by their ashes the salt which rains had washed away. They surrounded their fields with stone enclosures, or hedges made of the penguin, which makes an excellent fence; and in the month Panquetzalitzli, which began on the third of December, they were repaired if necessary.

1183. *In the sowing of maize*, the method they observed, and which they still practise in some places, is this: the sower makes a small hole in the earth with a stick, or drill probably, the point of which is hardened by fire; into this hole he drops one or two of the grains of maize from a basket which hangs from his shoulder, and covers them with a little earth by means of his foot; he then passes forward to a certain distance, which is greater or less according to the quality of the soil, opens another hole, and continues so in a straight line to the end of the field; thence he returns, forming another line parallel to the first. The rows of plants by these means are as straight as if a line were made use of, and at equal distances from each other as if the spaces between were measured. This method of sowing, which is now used by a few of the Indians only, though more slow, is, however, of some advantage, as they can more exactly proportion the quantity of seed to the strength of the soil; besides that there is almost none of the seed lost which is sown: in consequence of this, the crops of the fields which are thus cultivated are usually more plentiful. When the maize springs up to a certain height, they cover the foot of the plant round with earth, that it may be better nourished, and more able to withstand sudden gusts of wind.

1184. *In the labours of the field men were assisted by the women*. It was the business of the men to dig and hoe the ground, to sow, to heap the earth about the plants, and to reap; to the women it belonged to strip off the leaves from the ears, and to clear the grain; to weed and to shell it formed the employment of both.

1185. *They had places like farm-yards*, where they stripped off the leaves and shelled the ears, and granaries to preserve the grain. Their granaries were built in a square form, and generally of wood. They made use of the *ojameth* for this purpose, which is a very lofty tree, with but a few and slender branches, and a thin smooth bark; the wood is extremely pliant, difficult to break and slow to rot. These granaries were formed by placing the round and equal trunks of the *ojameth* in a square, one upon the other, without any labour except that of making a small notch towards their extremities, to adjust and unite them so perfectly as not to allow any passage to the light. When the structure was raised to a sufficient height, they covered it with another set of cross-beams, and over these the roof was laid to defend the grain from rains. These granaries had no other door or outlet than two windows; one below, which was small, and another above somewhat wider. Some of them were so large as to contain five or six thousand, or sometimes more, fanegas of maize. There are some of this sort of granaries to be met with in a few places at a distance from the capital, and amongst them some so very ancient, that they appear to have been built before the conquest; and, according to information had from persons of intelligence, they preserve the grain better than those which are constructed by the Europeans.

1186. *A little tower of wood*, branches, and mats, they commonly erected close to fields which were sown, in which a man, defended from the sun and rain, kept watch, and drove away the birds which came in flocks to consume the young grain. These little towers are still made use of, even in the fields of the Spaniards, on account of the excessive number of birds.

1187. *The woods* which supplied them with fuel to burn, timber to build, and game for the diversion of the king, were carefully preserved. The woods of King Timotezuma were extensive, and the laws of King Nezahualcojotl concerning the cutting of them particular and severe in their penalties. It would be of advantage to that kingdom, says Clavigero, that those laws were still in force, or at least that there was not so much liberty granted in cutting without an obligation to plant a certain number of trees; as many people, preferring their private interest and convenience to the public welfare, destroy the wood in order to enlarge their possessions.

1188. *The breeding of animals* was not neglected by the Mexicans: though there were no sheep, they bred up innumerable species of animals unknown in Europe. Bullock (*Travels*, 1824) informs us, that they are very curious in rearing and feeding swine; and that an essential requisite in a Mexican swineherd is an agreeable voice; in order that he may sing or charm the animals into peace when they quarrel and fight, and lull them to sleep at proper times to promote their fattening. Wind and sounds of every kind have been long known to have a powerful effect on this genus of animals. Private persons brought up *techichis* (quadrupeds similar to little dogs), turkeys, quails, geese, ducks, and other kinds of fowl; in the territories of the lords were bred fish, deer, rabbits, and a variety of birds; and at the royal residences, almost all the species of quadrupeds and winged animals of those countries, and a prodigious number of water animals and reptiles. We may say that in this kind of magnificence Montezuma II. surpassed all the kings of the world, and that there never has been a nation equal in skill to the Mexicans in the care of so many different species of animals, which had so much knowledge of their dispositions, of the food which was most proper for each, and of all the means necessary for their preservation and increase.

1189. *The Mexican cochineal*, so greatly valued in Europe on account of its dyes of scarlet and crimson, demands a great deal more care from the breeder than is necessary for the silkworm. Rain, cold, and strong winds destroy it; birds, mice, and worms persecute it furiously, and devour it; hence it is necessary to keep the rows of Opúntia, or nopal, where those insects are bred, always clean; to attend constantly to drive away the birds, which are destructive to them; to make nests of hay for them among the Opúntia, by the juice of which they are nourished; and when the season of rain approaches, to raise them with a part of the plants, and guard them in houses. Before the females are delivered they cast their skin, to obtain which spoil, the breeders make use of the tail of the rabbit, brushing most gently with it that they may not detach the insects from the plants, or do them any hurt. On every lobe they make three nests, and in every nest they lay about fifteen cochineals. Every year they make three gatherings, reserving, however, each time, a certain number for the future generation; but the last gathering is least valued, the cochineals being smaller then, and mixed with the prickles of the Opúntia. They kill the cochineal most commonly with hot water. On the manner of drying it afterwards the quality of the colour which is obtained from it chiefly depends. The best is that which is dried in the sun. Some dry it in the *comalli*, or pao, in which they bake their bread of maize; and others in the *temazcalli*, a sort of oven. (*Clavigero*, vol. I. p. 357. to 381.)

1190. *The fruits of Mexico* are very numerous. The banana and granadilla are very common; in the bread-fruit and cocoa are extensively cultivated; and a number of sorts of anona, or custard apple, and especially the cherimoyer (*A. Cherimólia*), which is much esteemed. In short, all the fruits of Europe, and most of those of both Indies, are to be found in the gardens of the nobles and the priests.

SUBJECT 3. *Present State of Agriculture in the British Possessions of North America.*

1191. *The principal British provinces in America* are Canada, New Brunswick, Nova Scotia, Cape Breton, and the adjacent islands of Newfoundland and the Bermudas.

*1192. *Canada* is an extensive country, and the only British province in which agriculture is generally pursued. The climate of this country is extremely irregular; in July and August, the heat is often 96°, while in winter the mercury freezes. The ground is covered with snow from November till May, when it thaws suddenly, and vegetation is instantaneous. The surface of the country is generally mountainous and woody; but there are savannas and plains of great beauty towards Upper Canada.

1193. *The soil* consists principally of a loose dark-coloured earth, ten or twelve inches deep, lying on a bed of cold clay. This thin mould, however, is very fertile, and yields plentiful crops, although it is worked every year by the French Canadians, without being ever manured. The manures chiefly used, since the practice of manuring has been introduced, by those who are the best farmers, are marl and gypsum, the former is found in great quantities in many places along the shores of the river St. Lawrence.

1194. *With respect to the products of Canada*, the low country is peculiarly adapted to the growth of small grain. Tobacco also thrives well in it, but the culture is neglected, except for private use; and more than half of what is used is imported. The snuff produced from the Canadian tobacco is held in great estimation. Culinary vegetables arrive at great perfection in Canada, which is also the case with most of the European fruits. The currants, gooseberries, and raspberries are very fine; the latter are indigenous, and are found very abundantly in the woods. A kind of vine is also indigenous; but the grapes produced by it in its uncultivated state are very poor and sour, and not much larger than fine currants. In the forest there is a great variety of trees; such as beech, oak, elm, ash, pine, sycamore, chestnut, and walnut; and the sugar-maple tree is found in almost every part of the country. Of this tree there are two kinds: the one called the swamp maple, being generally found on low lands; and the other, the mountain or curled maple, from its growing upon high dry ground, and from the grain of its wood being beautifully variegated with little stripes and curls. The former yields more sap than the latter, but its sap affords less sugar. A pound of sugar is frequently procured from two or three gallons of the sap of the curled maple, whereas no more than the same quantity can be had from six or seven gallons of that of the swamp tree. The maple

sugar is the only sort of raw sugar used in the country parts of Canada, and it is also very generally used in the towns.

*1195. *New Brunswick and Nova Scotia* are intensely cold countries, and only partially civilised. The vale of St. John's river is the principal scene of cultivation in New Brunswick. The upland parts of the country are chiefly covered with forests of pines, hemlock and spruce fir, beech, birch, maple, and some oak. The pines of St. John's river are the largest in British America, and afford a considerable supply of masts for the royal navy. Nova Scotia produces little grain; supplies being sent from England. The soil is thin and barren, except on the banks of the river, where it produces grass, hemp, and flax. A great improvement, however, in the agriculture of Nova Scotia is said to have taken place, in consequence of certain letters written on the subject, which first appeared under the name of Agricola, in the *Acadian Recorder*, a Halifax newspaper. These letters are by John Young, secretary to the provincial agricultural board, and have since been collected and published in a separate volume. Some account of them, accompanied by extracts, will be found in the *Farmer's Magazine*, vol. xxiv. p. 81.

1196. In the island of *Cape Breton* the soil is mere moss, and has been found unfit for agriculture. Newfoundland seems to be rather hilly than mountainous, with woods of birch, pine, and fir, numerous ponds and morasses, and some dry barrens. The chief produce of these islands, as well as of the other British possessions in America, consists of furs and skins; and the same remark will apply to the Bermudas and the unconquered countries, which need not be further noticed.

SUBJECT. 4. *Of the present State of Agriculture in the West India Islands.*

*1197. *The principal West India Islands* are Cuba, St. Domingo, Jamaica, and Porto Rico; and, next, the Windward Islands, Trinidad, the Leeward Islands of the Spanish, and the Bahamas.

1198. *Cuba* is an extensive and naturally fertile island; but, from the indolence of the Spaniards, not above a hundredth part of it is cleared and cultivated. Like most islands in the West Indies it is subject to storms, but the climate is, upon the whole, healthy, and even temperate; for, though in this latitude there is no winter, the air is refreshed with rains and cooling breezes. The rainy months are July and August; the rest of the year is hot. A chain of mountains extends the whole length of the island from east to west, and divides it into two parts; but the land near the sea is in general level, and flooded in the rainy season. The soil is equal in fertility to any in America, producing ginger, long pepper, and other spices; aloes, mastich, cassia fistula, manioc, maize, cocoa, &c. Tobacco is one of its principal productions, and it is supposed to have the most delicate flavour of any produced in the new world. The cultivation of sugar has lately been introduced; but the indolence of the inhabitants renders it in every respect much less productive than it otherwise might be. The quantity of coffee is inconsiderable; the chief plantations are in the plains, and are cultivated by about 25,000 slaves. Among the trees are oaks, firs, palms, cotton trees, ebony, and mahogany (*Swietenia Mahágoni*). (fig. 161.) In 1763 bees were introduced by some emigrants from Florida, and they multiplied so much in the hollows of old trees, that they soon obtained honey enough for their annual consumption. In 1777 they exported honey to the amount of 715,000 pounds. The island abounds with mules, horses, sheep, wild boars, hogs, and fine black cattle. The horned cattle have increased so much that the forests are filled with droves of them, which run wild, and are hunted and killed for their hides and tallow. The chief birds are paroquets, turtle doves, and partridges; water-fowl are numerous; and on the coast turtles are abundant; mullets and shads are the principal fish.

1199. *Jamaica* has been in possession of the English since the middle of the seventeenth century. The climate is extremely hot throughout the year, though mitigated by various causes. The surface of the country is very irregular: a ridge of mountains from east to west divides it into two parts. At a small distance from the shore it rises into hills with gentle acclivity, which are separated from each other by spacious vales and romantic inequalities. On the southern side of the island there are precipices and inaccessible cliffs, amidst which are vast plains covered with extensive cane fields. To the inequalities of surface that distinguish this island it is owing, that, although the soil in many parts of the island is deep and very fertile, yet the productive land is but of small extent in proportion to the whole. That which is actually cultivated is of a middling quality, and requires labour and manure to make it yield liberally.

1200. *Landed property in Jamaica* is in general freehold without manorial rights, and is chiefly in the enjoyment of individuals, though there is some government and corporation territory. Estates are generally small, few exceeding 1000 acres: formerly they were managed by resident proprietors; but at present, and for some time past, by far the greater number have been managed by agents or attorneys, who are represented by Roughley as a selfish, grasping, unprincipled set of men, "too ignorant to be planters, and too ostentatious, proud, and supine, to contribute to the good of their constituents." (*Planter's Guide*, p. 8.) They often contrive, by getting estates in debt and mortgaging them, ultimately to become the proprietors themselves. Some proprietors are so over-careful as to have what is called a planting attorney, and a mercantile attorney, the latter for the sale of produce, and the purchase of imported stores for the slaves. Besides these, there are travelling agents who visit different estates, and make annual or biennial voyages to Europe to the proprietors; an overseer for each estate, who has both free white men and slaves under him; a head driver, a slave; the head cattle and mule man; the head boiler or manufacturer of sugar; head carpenters, coopers, masons, coppersmiths, and watchmen; a hot-house or hospital doctor or doctress midwife; the great gang of able men and women; the second gang of rather weakly habits; and the third, or weeding gang, composed of children; cattle and mule boys, watchmen, invalids, and superannuated, and young children and infants. The qualifications, duties, and treatment of all these classes are discussed at length by Roughley, who gives a picture of culture and management very different from any thing belonging to the management of landed property, or the culture of farm lands, in Britain.

1201. *The overseer*, who is generally known by his hat and pipe (fig. 162.), should be a man of intelligence, tempered with experience, naturally humane, steadfast in well-defined pursuits, of settled sober habits, not given to keeping indiscriminate company, or suffering his subordinate white people to do so, thereby vitiating their manners; presenting a gentleman-like appearance; keeping a regular, well-supplied, comfortable table, without profusion, not only for himself and the white people under him, but for the benefit of such sick and convalescent slaves as require salutary and restoring nourishment. His business hours will be fully occupied by the concerns of the estate, his leisure ones in the innocent enjoyment of some domestic amusement. He must be kind and courteous to the young men under him, but giving or allowing them no opportunity to treat him with disrespect; attentive and hospitable to respectable strangers; cautious and wary how he suffers strollers to tempt his benevolence. He must not capriciously or suddenly discharge his white people (as is very often the case), taking care that no envious or jealous sentiment or idea arises in his mind, if his young men have merit on their side, or are creased by their superiors. He must keep the slaves strictly to their work, yet not imposing on them unusual hours, or inflicting punishment for every trifling offence; but, when punishment for crimes is necessary, tempering it with prudent mercy. He must be attentive to their real wants, not suffering them to tease him with their trifling complaints, or tamper with him by their arts, but promptly satisfying them, by enquiries into their serious grievances. Above all things, he must not encourage the spirit of Obea in them (which is horrible), nor dishearten them by cohabiting with their wives, annulling thereby their domestic felicities. He must not suffer their provision-grounds to be neglected, trespassed on, or ruined, nor their houses to be out of repair or uncomfortable; for it very often happens, that well-disposed slaves, by such freedoms taken with their wives, their well-established grounds ruined by thieves or cattle, their domestic quiet and comfort intruded upon, or their houses rendered uninhabitable by storm or other casualty, become runaways. Their conduct influences others, till at last the strength of the estate vanishes, the evil becomes notorious, and the plantation, of course, becomes neglected. The magistrates are then obliged to take this growing evil into serious consideration. Hunting parties are sent out (perhaps with little success) to bring in the fugitives; martial law is at last proclaimed throughout the diseased district; all sorts of people are harassed; public trials are instituted; some of the runaways are never caught; others who are brought in undergo trial, and are convicted and sentenced to death or transportation for life. (*Roughley*, 40. 43.)

1202. *The head driver* is seen carrying with him the emblems of his rank and dignity, a polished staff or wand, with prongy hooks on it to lean on, and a short-handled flexible whip; his office combining within itself a power, derived principally from the overseer, of directing all conditions of slaves, relative to the precise work he wishes each gang or mechanic to undergo or execute. The great gang is comprised of the most powerful field negroes, and is always under his charge. These form the strength with which principally to carry into effect the main work in the field, and to manufacture the sugar and rum. There are so many points to turn to, so many occasions for his skill, vigilance, steadiness, and trust-worthiness, that the selection of a man, fit for such a place, requires circumspection, and an intimate knowledge of his talents and capacity. A bad or indifferent head driver sets almost every thing at variance; injures the negroes, and the culture of the land. He is like a cruel blast that pervades every thing, and spares nothing; but when he is well-disposed, intelligent, clever, and active, he is the life and soul of an estate. He very often is an elderly or middle-aged negro, who has long been so employed. If it should be so ordered, that a new head driver is requisite to be put in commission, I must beg leave to lay before my readers my opinion of the proper choice of one. I may err, but I hope not irretrievably. He should, in my judgment, be an athletic man; sound and hardy in constitution; of well-earned and reputed good character; of an age, and, if possible, an appearance, to carry respect; perhaps about thirty-five years old; clean in his person and apparel; if possible, a native or creole of the island, long used to field work, and marked for his sobriety, readiness, and putting his work well out of his hands. His civility should be predominant, his patience apparent, his mode of inflicting punishment mild. He should be respectful to white people, suffering no freedoms from those under him, by conversation or trifling puerile conduct. It is rare, indeed, to find this mass of perfection in a negro; but you may obtain a combination of most of these virtues; and, as to petty vices, always inherent in some measure in human nature, they must be looked over, when not too full of evil. The junior drivers likewise, if possible, should be men of this description; but having a good master over them in the head driver, they will be induced to behave tolerably. (*Ib.*, 79. 82.)

1203. *The labourers on a Jamaica sugar estate* consist almost entirely of slaves, creoles, natives, or Africans, with some free blacks and men of colour or mixed progeny. The overseers are almost always whites, and sometimes also the head drivers.

1204. *The buildings required for a sugar plantation* are numerous and extensive. In a central situation, by a stream or other supply of water, an extensive set of works, including an overseer's house, hospital or hot-house, mill-house, large mill-yard, mule stable, trash or fuel house, cooper and carpenter's shops, boiling and curing houses, a distilling house, tanks, cisterns, &c., should be built, and so arranged as all to be seen from the overseer's house.

1205. *The overseer's house*, it would appear, must be both a comfortable and elegant building. It should be built compact and convenient, not over roomy; and raised sufficiently high from the foundation, with good masonry work, to admit of suitable stores underneath, to keep all the plantation stores and supplies in. It should be so placed that all the works can be seen from it, and not far from the boiling-house. The rooms should be all on the same floor, and closely boarded with seasoned stuff. Each white man should have a small bed-room to himself, with a glazed sash window on hinges, and a shutter to it. The bed-rooms should be eleven feet by nine each, of which five should be in every overseer's house on a sugar estate, leaving the overseer's room somewhat larger than the book-keeper's. A large well-covered

piazza, with comfortable glazed windows (to rise and fall occasionally), will answer all the purposes of a dining and breakfast hall, and for walking in. Large centre halls in such houses are of very little use, take up a great deal of room, are very expensive, and make the house large, without any real convenience. A small back piazza, made comfortable by moving blinds with stops, would be proper for the servants. I think every dwelling-house on a plantation should have a small fire-place in it, with a well-raised chimney, for fire to be made in occasionally in damp weather; it will be wholesome and preservative. The fire-place should be in an extreme angle of the dining piazza, and the overseer's cooking-room, washing-room, &c., should be apart from the house, though not far off, conveniently fitted up, and of moderate size. The little appendages of a hog-sty, fowl-house, &c., to raise small stock in, are easily built at a small expense. (*Roughley*, 184, 185.)

1206. *A lime-kiln* is an essential building for a sugar estate, a considerable quantity of lime being wanted to neutralise the acid of the expressed juice of the cane. A fixed kiln at the works is best, as what lime is wanted can then be burnt at any time; but it often happens that temporary kilns, composed of layers of stones and wood, with a funnel in the centre, are made in the woods, lighted and burnt, and the produce carried home. Such a kiln, twenty feet in diameter, and ten or twelve feet high, will produce lime enough to make sixteen hogsheads of sugar. (*Ib.*, 314.)

1207. *The houses of the slaves* are grouped together on some estates, and scattered in different places in others, generally on the outskirts of the estate. They are low cottages of one or two apartments, with open sheds, and pieces of garden ground of from one eighth to one quarter of an acre attached to each, and some of them are kept neat, and have a clean, not uncomfortable, appearance; they are generally built with stone, and covered with shingles.

1208. *Every building composing the works of a sugar estate* should be formed of the most substantial materials, durable, hard, well-seasoned timber, well put together, and supported by the best mason work. They should be shingled instead of being thatched, and kept free from the hungry destructive ant, who by his mighty though diminutive efforts, will level a substantial building to the ground in a short time. Poisoning by arsenic is the most expedient mode of getting rid of them, as the living will feed on the dead, so that the whole nest (by devouring one another) are thus killed. (*Ib.*, 194.)

1209. *The live stock of a sugar estate* consists chiefly of oxen, spayed heifers, and mules, as beasts of labour; the overseer generally keeps a riding horse, as does the resident agent or proprietor, if there are such; and there are pigs and poultry, with some sheep for consumption. The cattle and mules are kept on the savannas or open waste pastures, and on Guinea grass (*Panicum*) and Scotch grass (*Panicum hirtellum*) (*fig.* 162. *a*), on which they are folded, tethered, or soiled. Mares and Spanish or Maltese jackasses are kept for breeding the mules; and the cattle are in general reared on the estate. A jack should be from ten to twelve hands high, and either stabled or put into a close pasture, with high firm walls and gates to it. He should be regularly corned once a day at least; should have pure water to drink, and should not be suffered to cover more than one mare daily. The mares should be put to him in season, and attended by an experienced groom. A proper covering pit should be made for the mare to stand in, with a surmounting stage for the jack to stand on. They should be daily led out to exercise, kept well cleaned, and by no means allowed to stay out in bad weather, but be comfortably stabled, foddered, and littered. (*Ib.*, 141, 142.)

1210. *The agricultural operations of Jamaica* are for the most part performed by the manual labour of indigenous slaves; but there are also free servants, and the period, it is to be hoped, is rapidly approaching when the whole population will be emancipated. The soil is seldom either ploughed or dug, but generally worked with the hoe-pick. The spade the negroes are awkward at using; and they are not more expert at the plough. White ploughmen have been imported by some cultivators; but the prejudices of the overseers, the awkwardness of the oxen and negro drivers, and the effects of the climate in wearing out the spirits of the ploughman, are said to have discouraged its use. Long, in 1774, Dr. Stokes (*Young's Annals of Agr.*, xviii. 148.), and others, have tried the plough, and strongly recommend it, as doing the work better and lessening the necessity of having so many slaves. Roughley, however, who was "nearly twenty years a sugar planter in Jamaica" (*Jamaica Planter's Guide*, 1823), is decidedly against it, whether drawn by negroes or cattle; both because it does not do the work so well as the hoe, and because of the difficulty of getting ploughmen and properly trained beasts. It is probable, however, that necessity may ultimately lead to the use of the plough drawn by oxen, and that the operative man in the West India Islands will in time assume the same attitude as in Europe.

1211. *The agricultural productions of Jamaica* of the greatest importance are sugar, indigo, coffee, and cotton. The several species of grain cultivated in this island are maize, or Guinea corn, yielding from thirty to sixty bushels an acre; various kinds of calavances, a species of pea; and rice, but in no great quantity. The island abounds also with different kinds of grass of excellent quality: the artificial grass, called "Scots grass" (*Panicum hirtellum*) (*fig.* 163. *a*), grows spontaneously in most of the swamps and morasses of the West Indies; and it is so productive, that a single acre of it will maintain five horses for a whole year. The "Guinea-grass" (*P. polygamum*) (*fig.* 163. *b*) is next in importance to the sugar-cane, as the grazing and breeding farms are chiefly supported

163

by it. Hence arises the plenty of horned cattle, both for the butcher and planter; which is such, that few markets in Europe furnish beef of better quality, and at a cheaper rate, than that of Jamaica. Mutton also is cheap and good. The seeds of the Guinea grass were brought from the coast of Guinea, as food for some birds which were presented to Ellis, chief justice of the islands. The several kinds of kitchen-garden productions, that are known in Europe, thrive in the mountains of this island; and the markets of Kingston and Spanish Town are supplied with cabbages, lettuces, carrots, turnips, parsneps, artichokes, kidneybeans, green peas, asparagus, and various sorts of European herbs, in the greatest abundance. Other indigenous productions, that may be classed among the esculent vegetables, are plantains, bananas, yams of several varieties, collaloo (a species of *Arum* used as spinach), eddoes (*Arum* and *Caladium*), cassavi, and sweet potatoes. Among the more elegant fruits of the island we may reckon the ananas, or pine-apple, tamarind, papaw, guava, sweet sop, cashew apple, custard apple, Akee tree, cocoa nut, star apple, grenadilla, avocado pear, hog plum, naesberry, mamme sapota, Spanish gooseberry, prickly pear, anchovy pear, and some others, for which Jamaica is probably indebted to the bounty of nature. For the orange, the lemon, lime, shaddock, vine, melon, fig, and pomogranate, the West India Islands are perhaps obliged to their Spanish invaders. The cinnamon has been lately introduced, and the mango is become almost as common as the orange. The mountains are generally covered with extensive woods, containing excellent timber; such as the lignum vitæ, logwood, iron wood, pigeon wood, green-heart brazilletto, and bully trees; all of which are to a great degree heavy, as well as compact and impene- trable. Of softer kinds, for boards and shingles, the species are innumerable; and there are many beautiful varieties for cabinet-work; and among these we may enumerate the bread nut, the wild lemon, and the well-known mahogany.

1212. *The culture of the sugar-cane in Jamaica* in some respects resembles that of the hop in this country. The ground being cleared and worked a foot or more in depth, the sets or cuttings of cane, which are the tops of the shoots cut off about a foot long, are planted in rows, generally five feet distant, and from two to five feet apart in the row, according to the quality of the soil; more plants being allowed for poor soil than rich. The ground is kept clear of weeds, frequently stirred, and some earth drawn up to the plants. From each hill a number of shoots are produced: in six months or more these will generally be from seven to ten feet high; the skin smooth, dry, and brittle, heavy with a grey or brown pith, and sweet glutinous juice. In this state the canes are cut, tied in bundles or sheaves, and taken to the mill to be divested of their leaves and decayed parts, and then passed through rollers to express their juice, &c. Cane plantations are made either in May and June, or in December and January, these being the rainy seasons. The first cutting of the canes often does not take place till a year after planting; but an established plantation is cut over every six months. In good soil the plants will last twenty years; in inferior soils not more than half the time. (*Letter to a Young Planter*, London, 1785; *Martin's Essay on Plantership*, in *Young's Annals*, xviii. p. 236; *Roughley's Jamaica Planter's Guide*, 1823.)

1213. *The cotton plant cultivated in Jamaica* is a different species from that grown in Italy, Malta, and the Levant. It is the *Gossypium barbadense Linn.*, a suffruticose biennial, growing from six to fifteen feet in height, with lobed leaves and yellow flowers. It is propagated by the seed, which is set in rows, about five feet asunder, at the end of September or beginning of October; at first but slightly covered, but, after it is grown up, the root is well moulded. The seed is subject to decay, when it is set too deep, especially in wet weather. The soil should not be stiff nor shallow, as this plant has a tap-root. The ground is hoed frequently, and kept very clean about the young plants, until they rise to a moderate height; otherwise they are apt to be destroyed by caterpillars. It grows from four to six feet high, and produces two crops annually; the first in eight months from the time of sowing the seed; the second within four months after the first; and the produce of each plant is reckoned about one pound's weight. The branches are pruned and trimmed after the first gathering; and if the growth is over-luxuriant, this should be done sooner. When great part of the pods are expanded, the wool is picked, and afterwards cleared from the seeds by a machine called a gin, composed of two or three smooth wooden rollers of about one inch in diameter, ranged horizontally, close and parallel to each other, in a frame; at each extremity they are toothed or channelled longitudinally, corresponding one with the other; and the central roller, being moved with a treadle or foot-lathe, resembling that of a knife-grinder, makes the two others revolve in contrary directions. The cotton is laid, in small quantities at a time, upon these rollers, whilst they are in motion, and, readily passing between them, drops into a sack placed underneath to receive it, leaving the seeds, which are too large to pass with it, behind. The cotton thus discharged from the seeds, is afterwards hand-picked, and cleansed thoroughly from any little particles of the pods or other substances which may be adhering to it. It is then stowed in large bags, in which it is well trod down, that it may lie close and compact; and the better to answer this purpose, some water is every now and then sprinkled upon the outside of the bag, the marketable weight of which is usually three hundred pounds. An acre may be expected to produce from two hundred and forty pounds to that quantity, or two hundred and seventy pounds on an average. (*Long's Jam.*, vol. iii. p. 686, et seq.; and *Browne*.)

1214. *The indigo cultivated in the West Indies* is the same species as that grown in the East Indies and other places (*Indigófera tinctoria*), though there are various species and varieties which afford a similar dye. Indigo thrives best in a free rich soil, and a warm situation, frequently refreshed with moisture. Having first chosen a proper piece of ground, and cleared it, hoe it into little trenches, not above two inches, or two inches and a half, in depth, nor more than fourteen or fifteen inches asunder. In the bottom of these, at any season of the year, strew the seeds pretty thick, and immediately cover them. As the plants shoot, they should be frequently weeded, and kept constantly clean, until they spread sufficiently to cover the ground. Those who cultivate great quantities, only strew the seeds pretty thick in little shallow pits, hoed up irregularly, but generally within four, five, or six inches of one another, and covered as before. Plants raised in this manner are observed to answer as well as the others, or rather better; but they require more care in the weeding. They grow to full perfection in two or three months, and are observed to answer best when cut in full blossom. The plants are cut with reaping hooks, a few inches above the root, tied in loads, carried to the works, and laid by strata in the steeper. Seventeen negroes are sufficient to manage twenty acres of indigo; and one acre of rich land, well planted, will, with good seasons and proper management, yield five hundred pounds of indigo in twelve months; for the plant ratoons (stools, stoles, or tillers, i. e. it sends out stolones, or new growths), and gives four or five crops a year, but must be replanted afterwards. (*Browne*.)

1215. *The coffee tree* (fig. 164.) is less cultivated in Jamaica than in Barbadoes, Domingo, and some other islands: the richness of the soil is found to lessen the flavour of the berry, when compared with those produced in the sandy, dry, hot soil, and arid climate of Arabia. In a rich soil and cool situation in Jamaica, Browne informs us that it produces so great a quantity of fruit, that the branches can hardly sustain the weight; the fruit large and succulent, and the berries lax and clammy. Some affirm, that by keeping these, and other West India berries, for ten or fourteen years, they will become equal to the best now brought from Turkey. Small-grained coffee, or that which is produced in a dry soil and warm situation, will in about three years be as good as that in general use in London.

1216. *In cultivating the coffee*, the berries are sown immediately after being gathered, as they are found to retain their vegetative quality only a few weeks. In three months they are fit to transplant, either to a nursery or to a final plantation. In the low lands they are planted five feet apart, and in the mountains ten feet or more. In three years the plants will produce a crop, and continue bearing for a number of years. The berries are gathered when they are just about to drop; and are immediately carried to sheds, where they are dried upon cloths or mats, till the husk shrivels. They are then passed through between wooden rollers turned by a mule, which separates the husk, after which they are winnowed, sifted, cleaned, exposed to the sun for a few days, and then barrelled up for sale. The produce of a good tree is from one pound and a half to two pounds' weight. (*Browne's Hist. of Jam.*, p. 161.)

1217. *The cocoa-root or eddoe* (*Ayam esculentum*) and also a species of *Caladium* produce a root something like the Indian yam (*Dioscorea sativa*) (fig. 165.), but differ from them in lasting for several years. Both the cocoa-root, and yam are cultivated much in the same way as our potato. They have what they call Bourbon cocoas and country cocoas, and Negro and white yams; the yams have a stake driven in at each hill for the vines to twine on after the manner of hops.

1218. *The plantain* (*Musa paradisiaca*) is cultivated in rows ten feet apart, and the plants seven feet asunder in the row. The following account of the manner of planting and managing will give some idea of the mode in which agricultural operations are carried on by a slave population, and how they are described by a writer who has been "nearly twenty years" at the business. "The ground being all cleared from grass, bushes, and weeds, and lined out and pegged every seven feet, the great gang should be put in with hoes to dig the plantain holes at every peg, a Negro to each row. The holes should be dug deep, two feet long by sixteen inches broad, to give room for the large ponderous plantain sucker to be placed in them. The mould must be heaped up to the edge of the hole, and broken if too large. The plantain suckers being ready and trimmed, each negro should take some, and place one good sucker at every hole in the piece, and begin to plant them, by taking a sucker, and placing it with the but, or rooty end, in the bottom of the hole; make the sucker lie in a leaning, reclining, or half-horizontal position in the hole, with the small, or sucker, end of the plant a little above the ground; and when thus placed, draw the mould from the bank, and cover the plant well with it, leaving a little of the plant above the ground. In this manner the plantain walk should be formed. In a few weeks (if the weather is favourable) the young plantain shoot will be seen rearing its perpendicular head, perhaps three or four growing from the same stock. They should then be carefully moulded, and cleared of grass and weeds when they are a few inches high. No cavities, or water-logging holes, should be near them. The banks must be levelled about them, the holes filled and properly closed up, and some fine mould given them to encourage their growth. There will be no occasion to give them more than two mouldings till they are established; but they must be carefully kept clear from weeds or grass; and when any dry trash happens to be hanging about them, it should be gently cut off with a knife, and placed about their roots, to keep them free from either too much sun or chill. A plantain walk well taken care of will be in bearing in twelve months after it is planted, amply repaying for the labour and trouble of planting it, and giving an almost inexhaustible supply of fine provisions, if the vicissitudes of hurricanes or storms (which this climate is unhappily subject to) do not destroy it, which no human foresight or care can prevent. When a plantain walk is made, there may be a row of cocoas (1217.) in the middle of the ten feet spaces, which will yield a crop by the time the plantain walk bears fruit, but they must then be pulled up. A few bananas (*Musa sapientum*) suckers can be planted in the plantain row, instead of plantain suckers; sometimes they are much in request, as a luscious wholesome fruit, and for the strong flavoured vinegar which is produced from them. After this piece of ground is thus planted, the whole of it may be sown with corn (maize), which will not injure the plantain suckers or trees, if it be not too close or thick." (*Roughley*, p. 413, 416.)

1219. *The Indian arrow-root* (*Marranta arundinacea*) is cultivated, and yields an annual supply of roots, which, being washed, bruised, and compressed, yield a starch esteemed as a very light wholesome food for invalids.

1220. *Other plants*, in great variety, are cultivated both for culinary and medicinal purposes, and in the gardens of the overseers and agents almost every fruit in the world may be raised.

1221. *The pinguin* (*Bromelia Pinguin*) is grown on the tops of ditches, and forms an impenetrable fence.

1222. *Maize* is grown among the canes, and in fields by itself in rows four feet and a half apart, and the corn dibbled or set in patches of four seeds in a space of six inches square.

1223. *Guinea grass* (*Panicum poligamum*) (fig. 163. b) and Scotch grass (fig. 163. a) are the clovers or artificial herbage plants of Jamaica. They are perennial, and grow in small enclosures, which are either eaten down or mown. Cane tops, the leaves of maize, millet, and a variety of other herbage, are given to the mules and cattle.

1224. *Rats, ants, and other vermin*, greatly injure the canes; ticks (*Acarus*) of different kinds and flies very much annoy the cattle; and a great variety of evil propensities and diseases assail the negroes and their children, among others *Obea*, and what Roughley calls "eating dirt," which he thus characterises: — "Too much tenderness gives the child a fretful longing for the mother, and her scanty milk engendering disease, and, what is worse than all, often (though secretly) giving it a growing liking for the hateful

164

165

fatal habit of eating dirt, than which nothing is more horribly disgusting, nothing more to be dreaded; nothing exhibiting a more heart-rending ghastly spectacle, than a negro child possessed of this malady. Such is the craving appetite for this abominable custom, that few, either children or adults, can be broken of it, when once they begin to taste and swallow its insidious slow poison. For, if by incessant care, watchfulness, or keeping them about the dwelling-house, giving them abundance of the best nourishing food, stomachic medicines, and kind treatment, it is possible to counteract the effects and habit of it for some time, the creature will be found wistfully and irresistibly to steal an opportunity of procuring and swallowing the deadly substance. The symptoms arising from it are a shortness of breathing, almost perpetual languor, irregular throbbing, weak pulse, a horrid cadaverous aspect, the lips and whites of the eyes a deadly pale (the sure signs of malady in the Negro), the tongue thickly covered with scurf, violent palpitation of the heart, inordinately swelled belly, the legs and arms reduced in size and muscle, the whole appearance of the body becoming a dirty yellow, the flesh a quivering pellucid jelly. The creature sinks into total indifference, insensible to every thing around him, till death at last declares his victory in his dissolution. This is no exaggerated account of the effects and termination of this vile propensity. (*Ib.*, 118. 120.)

1225. *The agriculture of the other West India Islands* may be considered as similar to that of Jamaica. So many different kinds of East India fruits have not yet been introduced in them; but the great articles of sugar, coffee, cotton, indigo, pepper, &c., are every where cultivated. One of the richest of these islands is St. Domingo, now independent, and known by its original name of Hayti.

SECT. VI. *Of the present State of Agriculture in South America.*

1226. *The climate of South America* combines the most opposite extremes. The southern parts are subject to all the horrors of the antarctic frosts; Terra del Fuego being subject to the almost perpetual winter of Greenland. Even under the torrid zone the cold is extreme on the Andes, and the heat and moisture equally extraordinary in the plains. The surface of the country is remarkably irregular: there are immense chains of mountains which stretch along the western coast from the one extremity of the country to the other. Many parts of the interior are still obscure; wide regions on the great river Maragnon being covered with impenetrable forests, and others flooded by the inundations. In the south there are vast saline plains, and small sandy deserts and savannas. This country being, or having been, almost entirely under the Spaniards and Portuguese, the cultivated parts display a slovenly agriculture, something like that of Spain; the varied and abundant products of the soil depending more on nature than on man. Indeed minerals have always been more the objects of European nations in South America than vegetables. — After this general outline we shall, without regard to the recent political changes, offer such slight notices of South American agriculture as we have been able to collect, under the divisions of Terra Firma, Peru, Chile, Paraguay, Brazil, Cayenne, Colombia, Surinam, Amazonia, and Patagonia.

1227. *The climate of Terra Firma* is extremely hot throughout the year. From the month of May to the end of November, the season called winter by the inhabitants, is almost a continual succession of thunder, rain, and tempests; the clouds precipitating the rain with such impetuosity, that the low lands exhibit the appearance of an ocean. Great part of the country is in consequence almost continually flooded; and this, together with the excessive heat, so impregnates the air with vapours, that in many of the provinces, particularly about Papayan and Portobello, it is extremely unwholesome. The soil of this country is very different, the inland parts being exceedingly rich and fertile, while the coasts are sandy and barren. It is impossible to view, without admiration, the perpetual verdure of the woods, the luxuriance of the plains, and the towering height of the mountains. This country produces corn, sugar, tobacco, and fruits of all kinds: the most remarkable is that of the manzanillo tree; it bears a fruit resembling an apple, but which, under this appearance, contains a most subtle poison. The bean of Carthagena is about the bigness of a common bean, and is an excellent remedy for the bite of the most venomous serpents, which are very frequent all over this country.

1228. *In Peru* the soil is dry and has no rain, vegetation being supported by immense dews. The only spots capable of cultivation are the banks of the rivers, and other places susceptible of being artificially irrigated. The improvement of the mines is, or ought to be, the first object of attention in this singular country.

1229. *Chile* is an extensive, rich, and fertile country. The climate is the most delicious in the new world, and is hardly equalled by that of any region on the face of the earth. Though bordering on the torrid zone, it never feels extreme heat, being screened on the east by the Andes, and refreshed on the west by cooling sea-breezes. The temperature of the air is so mild and equable, that the Spaniards give it the preference to that of the southern provinces of their native country. The fertility of the soil corresponds with the benignity of the climate, and it is wonderfully accommodated to European

productions. The most valuable of these, corn, wine, and oil, abound in Chile, as it tillage had been native to the country. The soil, even that part of it which has been long in tillage, is so little degenerated by producing successive crops, that no manure is necessary. The grain, as some say, yields from 100 to 150; but by a more moderate and just estimate, as it is stated both by Molina and in Peyrouse's *Voyage*, from 60 to 70 in the midland country, and in the maritime 40 or 50.

1230. *Many of the plants of Chile are the same with those of Europe, and almost all the potherbs and fruits of our Continent flourish there.* The northern provinces produce the sugar-cane, the sweet potato, and other tropical plants. Maize is common and abundant; the magu is a kind of rice, and the tuca a species of barley, both of which were cultivated before the arrival of the Spaniards. Peas and potatoes were also well known to the Chilese. Of the latter they have thirty different kinds: and it is even conjectured that this valuable root was first brought into Europe from this country. The large white strawberry of Chile is well known in English gardens. Many of its plants are valuable as dyes, and others as medicinal. The *vira-vira* expels the ague; the *payco* is excellent for indigestion. Wild tobacco abounds in Chilo, and also the *annotto* (*Bixa Orellana*). (fig. 166.) The beautiful flowers and shrubs are infinite. Incense, not inferior to that of Arabia, is produced by a shrub, distilling tears of a whitish yellow, and of a bitter aromatic taste. The trunk of the *puyi* supplies excellent cork; the *Salobla Káli* is plentiful on the shores; and Chile produces seven kinds of beautiful myrtles, one of which yields an excellent stomachic wine, preferred by strangers to any muscatel. The *crelon* furnishes a tea, which is known as a vermifuge. An *acacia* of Quillota yields a balsam, which is used in the cure of wounds; and the *palqui* is esteemed, as a febrifuge, superior to the Peruvian bark. The *Cassia Senna* grows on the banks of the rivers Mayo and Salvia. Of ninety-seven kinds of trees that diversify the beautiful forests of Chile, only thirteen lose their leaves in winter. Cypresses, pines, and red and white cedars grow in the valleys of the Andes; the red cedars, particularly in the Isle of Chiloe, are of an enormous size, so that from 700 to 800 planks, twenty feet long, may be cut from one tree. The cinnamon tree, which yields what is called Winter's bark, is regarded as sacred by the Araucans, who present it as a token of peace. Beautiful woods of various colours are supplied by the Chilese forests. Vines, though none appear to be natives, flourish admirably well: they are found in the forests, arising from seeds deposited by the birds: on the confines of the river Mauli they are three or four feet high, and supported by stakes; but further to the south they are left loose on the sides of the hills. The best wine is that which is obtained from the banks of the river Itati, and is commonly called wine of Conception; it is red, generous, of an excellent flavour, and equal to the best in Europe. Muscatel wines are also excellent. The vintage is in April and May. All the other European fruits attain the greatest perfection. Most of the European animals have improved in this delicious climate and fertile country. The celebrated Spanish sheep have not lost any of their distinguished qualities: the horned cattle are larger than those of Spain; and the breed of horses surpasses both in beauty and spirit the famous Andalusian race from which they spring.

1231. *Paraguay is a fertile province, and singularly prolific in native vegetables.* The climate is extremely hot: the surface of the country consists generally of extensive plains; but some tracts are very mountainous. The soil is every where rich and deep; and the native pastures so excellent, that the immense herds of wild oxen which feed on them are only valued for their skins; the flesh being left to be consumed by ravenous beasts and birds. Among the agricultural products may be mentioned the potato, of which they have several sorts of a large size; red, white, and yellow cotton; maize, wheat, and the vine. The last is greatly injured by the ants; but where that insect is kept under, the wine of Paraguay is excellent. The bean, pea, melon, cucumber, lettuce, turnip, mustard, cress, leek, onion, asparagus, and other European vegetables, are found wild in the plains. The forests abound in the most valuable trees, among which is the *Cinchona*, or Jesuits' bark, so called because the Society of Jesus settled there had originally the monopoly of this medicine; the *sarsaparilla*, *sassafras*, *guaiaacum*, dragon's blood, *nux vomica*, *vanilla*; *Theobroma*, or chocolate plant (fig. 167.); and several species of the *Ceratonia*, the seeds of which are ground and made into bread. Palms, figs, peaches, pomegranates, lemons, and oranges are cultivated; and the jujube, mulberry, granadilla, banana, pine-apple, and a great variety of other fruits, are found in a wild state. Of the live stock, the

most abundant are the ox and the camel; but there are horses, asses, sheep, many wild swine (fig. 168.), and poultry. The bear, elk, deer, ostrich, and others, are in a wild state.

1232. *Brazil is the most extensive empire in South America, rivalling Europe in size, while its provinces may be compared to the territories of European sovereigns.* It enjoys a climate but little inferior in salubrity to that of Chile, but less variable, as the interior is not traversed by chains of lofty mountains. The climate of the *Sertoens* (a general name for the inland country) is colder in winter, and warmer in summer, than that of the maritime parts. The first of these peculiarities is caused by its greater elevation; and the second, by its sandy arid nature, and by the air not being cooled by

the delicious sea breezes of the coast. During the rainy season (which is the tropical winter) the nights are sometimes chilly; and, although the thermometer is seldom lower than 68° or 65° , the warmth of a fire is found desirable. This coldness is principally felt in Minas Geraes (the most mountainous part in Brazil), and in the other provinces beyond Rio de Janeiro. In comparison of the extent of the country, the rivers are very few; and nearly throughout the interior there is a general deficiency of water, even for the purposes of life. During the dry or summer season the heat is excessive, yet it is neither unhealthy nor very oppressive, being mitigated by the sea breeze, which usually sets in about half past seven or eight o'clock in the morning, and continues until sunset.

1233. *The vegetable productions of Brazil* are numerous and important. The extensive cultivation of the sugar-cane and cotton plant has, of late years, given an importance to its commerce far greater than that of any other neighbouring state. The sugar plantations are confined to a short distance from the coast, on account of the superior quality of the soil (a red clayey loam), and the difficulty of conveyance in a country where regular carriage roads do not exist. Cotton thrives best on those poor, sandy, and dry lands, which are met with at a distance from the sea; it is, therefore, cultivated only in the interior, and is brought to the coast on the backs of mules and horses, frequently from a distance of 150 miles. Coffee has not yet been cultivated very extensively, although it thrives remarkably well, particularly near Rio de Janeiro; wheat is only produced in the milder provinces of the South, and even there but sparingly. Indeed, the "staff of life," throughout the greatest part of Brazil is the mandioca, known in the West Indies by the name of cassava; the root, being divested of its poisonous juices by pressure, is rasped or ground so as to resemble sago; and, being boiled, forms the principal sustenance of the great mass of the people. The cultivation of the plant is easy; it will thrive both in the richest and poorest soil, and vast quantities are grown in the sandy (or tabulara) tracts of Paraiba, Maranhão, and Pernambuco. As we approach the southern provinces, the mandioca in some measure gives place to the maize or Indian corn, which, although less nutritious, is much esteemed both by man and beast: its culture however is more confined, as it requires a good soil and frequent moisture. Rice is grown but sparingly, and not in sufficient quantities to make it an article of commerce. Besides these esculent vegetables, there are many others, either indigenous, or introduced by the Portuguese from their African possessions; among these may be reckoned the ochro, the different species of *Cápsicum*, yams, and love apples. I believe the potato is unknown in Brazil; several attempts were made in 1817 by the English residents of Pernambuco and Bahia, to cultivate this root from the English stock; but they were completely unsuccessful. The tobacco of Brazil is well known: very extensive tracts in the vicinity of Bahia are entirely covered with this plant, which flourishes best in a light sandy soil; although great attention is paid to its cultivation, the leaves are dried in a careless way, and the subsequent operations conducted in a most slovenly manner. The fruits are in great variety: besides those common to the West India Islands, and other parts of tropical America, as the cocoa nut, pine-apple, plantain, banana, mango, jack, custard apple, orange, and citron, there are several others peculiar to this country, and only known by Indian names. Those above enumerated are only to be met with near the coast; but the cashew tree, so valuable for the astringent qualities of its fruit, covers extensive tracts in the interior of Pernambuco and Paraiba, where the soil is loose, sandy, and arid. In similar situations are also to be seen many kinds of guava. While the fruit of the larger species of passion flower (*Passiflora*) is much esteemed for the coolness and delicacy of its pulp, the European fruits, which thrive so well on the table land of Mexico, and on the sides of the Cordilleras of Chile, wither and die beneath the fervour of a Brazilian sun. The vine, indeed, is sometimes seen in the gardens of the rich; and there is no doubt but that it might be cultivated with complete success in the southern provinces; but this has been hitherto prevented by that short-sighted policy of the mother country, which prohibited both the vine and the olive from being planted in any of the colonies. Agriculture and gardening, in short, are here in their infancy. There is, indeed, a botanical garden both at Rio de Janeiro and Pernambuco; but the first is neglected, and the last, existing (in 1816) only in name, is a wilderness. The private gardens of the higher classes usually consist of orange, citron, and lime trees, planted in rows, intermixed with a few heavy earthen pots of China-asters, pinks, and other common plants of Europe, here esteemed because they are exotic; while, as in other countries, the most lovely creepers and flowering shrubs grow in the thicket and fences, totally disregarded. The woods and forests abound with innumerable medicinal plants, as the castor, two species of *contrayerva* (*Dorstenia rotundifolia* and *pernambucana* of Arruda), the pinaõ, the angelim (*Skolemira pernambucensis* Arru.), and many others, the names and qualities of which, the Brazilians, from some unaccountable fancy, studiously conceal from Europeans, although they willingly administer them as prepared medicaments when applied to. The most valuable dyeing wood is that bearing the

name of the country: the monopoly which the crown assumed, of cutting and exporting it, was so arbitrary and vexatious, that it has been used as fire-wood by many of the planters, to conceal from the revenue officers that it was found on their lands. Its produce has long been gradually diminishing, and unless some judicious measures are adopted, this valuable wood will be totally lost in a few years. There are many other beautiful woods fit for ornamental furniture, but none are so well known as the rose wood (said to be a species of *Jacaranda*), which of late years has become so fashionable in this country. Numerous species of laurel and myrtle abound in the forests; the *Mimosa sensitiva*, or sensitive plant, will sometimes form impenetrable thickets on the sides of the ponds and rivers; while the various species of *Amarýllis*, as also the crimson passion flower, are more particularly natives of the southern provinces.

1234. *The botanists of Europe have long been unacquainted with the plant which produces the true Ipecacuana; and even those who have recently travelled in Brazil appear to have fallen into some mistakes on this subject. In fact, there are two plants essentially very different, but which, from possessing the same medicinal qualities, have long passed under the same name, even in Brazil. The opinion of the accurate Arruda, whose name as a botanist may rank with the first in Europe, but who lived and died in Brazil, may be considered, on this question, as decisive. He considers the true Ipecacuana, or Ipecacuanha preta of the natives, as belonging to a new genus. This plant he calls Ipecacuana officinalis (Cent. Plant.); it grows in the southern provinces, and requires shade. The other, called by the Brazilians the white sort (I. Branca), is the Fombilla Ipecacuana of Vandel: this is found in considerable abundance in the sandy tracts of Pernambuco and Paraiba, and its root, when dried and pounded, is much used in these provinces as a gentle purgative; it likewise promotes perspiration, and possesses stimulant qualities. (Swainson's MSS.)*

1235. *The nut tree (Lycythis olivaria) is one of the greatest ornaments of the woods; its immense stem is above a hundred feet high, and spreads into a majestic and vaulted crown, which is extremely beautiful in the spring when the rose-coloured leaves shoot out, and in the flowering season from the large white blossoms. The nuts, which have a thick shell, are of the size of a child's head, with a lid which is loose all round, and which at length, when the weight of the fruit turns it downwards, separates, and lets the seed fall out. In a high wind it is dangerous to remain in the woods on account of these heavy nuts falling from so great a height. The seeds are collected in great quantities by the Indians, who are extremely fond of them, and either eat them raw, or preserve them roasted and pounded, in pots, and the shells themselves are used as drinking cups. (Spix, vol. ii. p. 222.)*

1236. *Dr. Arruda has described several of the most valuable of those indigenous plants whose fibres are adapted for economic purposes. The most important of these are,—1. The caroa (Bromelia variegata Ar.), found in great abundance in the Sertoens of Paraiba and of the northern provinces: the fibres of the leaves are of two kinds; from one, a very strong cordage is made, while the other is manufactured by the fishermen into nets, and sometimes into a coarse cloth, when care is taken in preparing the thread. 2. The Craua de Rede (Bromelia sagenaria Ar.) is confined to the maritime parts of Pernambuco and Paraiba; the leaves are from six to nine feet long, and the fibres so strong, and at the same time so fine, that cables made from them are much superior in strength to those of Europe, while they are equally well adapted for sail-cloth or stockings. The most delicate fibres, however, are those procured from the leaves of the ananas (Bromelia Ananas), as they are capable of being manufactured into cloth of a superior quality. Other plants possess the same qualities, though in an inferior degree. The Brazilian government has hitherto paid little attention to these matters. (Swainson's MSS.)*

1237. *Brazil likewise produces a species of croton, the leaves of which are sometimes used as a substitute for the tea of China. Some years ago, the government evinced a great desire to introduce and cultivate the genuine tea plant, and actually induced several Chinese to settle near Rio de Janeiro, for the purpose of superintending its culture: the plan, however, from some jealousy or mismanagement, was abandoned before it had received a fair trial. A similar project was formed for introducing the cochineal insect, but which, from similar causes, proved equally abortive. There is every reason to believe, however, that both would have succeeded under proper management. (Swainson's MSS.)*

1238. *The live stock of Brazil chiefly consists of horned cattle, which are pastured in great numbers in the interior of the southern provinces. The hides are sent to Europe: and the flesh, after being cut into long stripes and dried in the sun, becomes an article of considerable internal commerce. Paraiba and Rio Grande are particularly celebrated for this traffic. Fresh meat, even in maritime towns, cannot always be had, and is at all times dear. Swine are good, but sheep and goats are almost unknown.*

1239. *Cavies of different species, porcupines, armadillos, and other wild animals, abound in some of the interior of the forests; most, if not all, are eaten by the native Indians and the Brazilians: the former do not even reject the monkeys. In some parts of the interior are small ounces, but they seldom show themselves by day. Hammocks made of network are universally preferred to beds; and from being of little value, they are generally possessed by the poorest natives, who suspend them between beams in the house, or trees in the open air. (fig. 169.) (Ib.)*

169

1240. *Cayenne or French Guiana, is a fertile country, and has been long well cultivated by the colonists. The climate is salubrious; the surface of the country is not mountainous, but abounds in hills and forests; the soil is in general uncommonly fertile, and the productions it yields are of excellent quality. The Cayenne pepper (Capsicum annum, and other species) is a noted produce of this country, and, with sugar, cocoa, coffee, indigo, maize, cassia, and vanilla, forms the chief article of its*

commerce. The interior parts, though much neglected, and remaining obstructed by thick forests and underwood, feed, nevertheless, a great number of horses, sheep, goats, and cattle, which roam at pleasure: the beef and mutton are reckoned excellent. (*Maison Rustique de Cayenne*, Paris, 1763.)

1241. *Colombia* is a fertile tract of country, with an irregular surface and warm climate. An association was formed in London some years ago to send emigrants thither. A million of acres were granted to it, besides several important exemptions, by the Colombian government. A hundred and ninety-one persons left Scotland to settle there in 1825; but, according to the superintendent, they were such a set of people, with a very few exceptions, as could not have been procured in any country. They had every advantage, but acted as if resolved to avail themselves of none. Yet, by the surgeon's report, the most sickly months in the year were passed over by a population of drunken adults, and a large proportion of children, with a mortality of about one fifth less than that of the most healthy parts of Europe. Mr. Powles is perfectly justified in his declaration, that the defaulters in this transaction are the settlers themselves. They are the parties who have not performed their agreement; and who, by their own misconduct, have brought a very heavy loss upon the association; and what is more to be regretted, have greatly retarded the progress of an undertaking calculated to produce the most extensive advantages both to Colombia and Great Britain. We trust the success of this wise and benevolent experiment is retarded only. The million of acres granted to this company present a very different prospect and security from those golden bubbles which the Reports of Messrs. Head, Andrews, and Beaumont have by this time blown away. (*Ed. Rev.*, Jan. 1828.)

1242. *Surinam* is a low moist country, which has been in part studded with wooden houses (fig. 170.), and well cultivated by the Dutch. The climate is hot, and is the most unhealthy and pestilential in South America, although the heat in some measure is tempered by the sea breeze. The surface of the country is little varied by inequalities. The uncultivated parts are covered with immense forests, rocks, and mountains, some of the latter enriched with a great variety of mineral substances; and the whole country is intersected by very deep marshes or swamps, and by extensive heaths or savannas. The soil is, in general, very fertile; and its fertility may be ascribed, not only to the rains and warmth of this climate, but also to the low and marshy situation of the country, which prevents the intense heats from destroying vegetation, and to the extreme richness of the soil, particularly in those parts that are cultivated by European industry.

1243. *The principal products of Surinam* are tobacco, sugar, coffee, cocoa, cotton, and indigo. The quassia tree, or bitter drug, used by the porter brewers, grows wild in the woods, and was first exposed for sale by a native called Quassi, after whom the tree is named. The cabbage tree is abundant; and under the rind of the palms is found the *Curculio palmærum* Lin. (fig. 171. a), the larva of which (b) is eaten by the natives as a luxury. A very interesting account of this colony is given by Captain Stedman (*Journal*, 2 vols. 4to, 1794), who filled an important military situation there for several years. This gentleman, in the midst of the most arduous duties, contrived to make himself tolerably comfortable. He built a country house there (fig. 172.); kept a wife, pigs, bees, sheep, and cattle, and had children and slaves. He lived by turns with his family in a house, and with strange women in the woods, where he slept in hammocks (fig. 173.) and adopted many of the practices of the natives. He made many sketches, and kept a journal; and after many years full of interesting adventures with the rebellious natives, and of endearing scenes with Joanna his local wife, he came home and wrote a very entertaining account of what he had seen and done. (*See Stedman's Surinam*, 2 vols. 4to, 1794.)

1244. *Amazonia* is an extensive, unconquered, or at least uncivilised, country. In so far as it is known, its climate is more temperate than might be expected from its geographical position. The surface of the country is clothed, in most places, by inter-

minable forests, and its immense river is well known. The soil of a small settlement formed by the Portuguese is very fertile, and produces corn, grain; and all kinds of tropical fruits; besides a variety of timber, as cedar, brazil wood, oak, ebony, iron wood, logwood, and other dyeing woods; and also cocoa, tobacco,

sugar-canes, cotton, cassava root, potatoes, yams, sarsaparilla, gums, raisins, balsams of various sorts, pine-apples, guavas, bananas, &c. The forests abound with wild honey,

173

and also with tigers, wild boars, buffaloes, and cavies; while the true Amazonian parrot, with a green plumage and pale yellow front (*fig. 174.*), is found in vast flocks, and annually exported to all parts of Europe. The rivers and lakes afford an ample supply of fish, manattas, and mud-tortoises; but the alligators and water serpents render fishing a dangerous employment. The trees, fields, and plants are verdant throughout the year.

1245. *Patagonia* consists mostly of open deserts and savannas, with a few willows on the rivers. It seems to enjoy a temperate but rather cool climate; but, separated in the middle by the vast mountains of the Andes, one part of it differs widely from the other. Northward of La Plata, this part of South America is covered with wood, and stored with an inexhaustible fund of large timber: but, southward of that river, there is scarcely a tree or shrub fit for any mechanical purpose; yet even this seemingly barren country has some good pastures. There are numerous droves of wild horned cattle, and abundance of horses, both originally introduced by the Spaniards.

1246. *Of the South American islands*, that of Juan Fernandes abounds in pasture, cattle, and woods; and Terra del Fuego, amidst its horrible snows, exhibits a variety of plants. The Falkland Islands contain number of fowls and plants, somewhat resembling those of Canada. Georgia is a field of ice, in which, or in any of the other islands, there is no cultivation whatever.

BOOK II.

AGRICULTURE AS INFLUENCED BY GEOGRAPHICAL, PHYSICAL, CIVIL, AND POLITICAL CIRCUMSTANCES.

1247. *Agriculture, considered with regard to climate, territorial surface, and society*, presents some features which it may be instructive to contemplate. Whoever has perused with attention the outline which we have now concluded of the field culture of the different nations of the world, must have a general and enlarged view of that art; and must necessarily have observed that there are different species of territorial culture, founded on difference of geographical position or climate, difference of physical circumstances or surface, and difference of civilisation or human wants. The object of the present Book is to characterise these different species, and to refer to them the proper districts throughout the world.

CHAP. I.

Agriculture as influenced by Geographical Circumstances.

1248. *The influence of climate* extends not only to the kind of plants and animals to be reared, but also to the mode of rearing. A few useful plants are universal, and but a few. Of those belonging to agriculture, we may enumerate most of the annual pasture or hay grasses, and, of the cereal grasses, the wheat, rye, and barley. The oat, the pea, bean, turnip, potato, and the perennial pasture grasses, will neither thrive in very hot nor in very cold climates; the maize, millet, and rice can only be grown in warm countries, and the oat in temperate regions. The roots and fruits of what are denominated hot climates, as the yam, plantain, bread-fruit, &c., are limited to them; and equally so the timber trees of temperate and torrid regions, as the oak and pine, the mahogany and teak tree.

1249. *Animals as well as plants* are affected by climate. Some animals are universal, as the ox and swine, which are found in every latitude; others are limited in their range, as the rein-deer, camel, elephant, and, considered as a domesticated animal, the sheep. The horse and ass are nearly universal, but cannot be substituted for the rein-deer. The sheep will exist in India and also in Greenland, but loses its useful character in both countries; in Greenland it requires protection during nine months of the year, and in India the wool is changed to hair, and the carcass is too lean for the butcher.

1250. *The management* required for both plants and animals depends materially on climate. It is not easy for a person who has never been out of Britain to conceive a just idea of the aquatic culture even of Italy or Spain. In these countries though most crops, whether of grain or roots, require watering, yet some in the rainy season may be obtained in the usual way, as melons in Italy and onions in Spain. But in Arabia, Persia, and India no culture can be undertaken without water, except in the upper regions of mountains. The fundamental process of culture in these countries is to prepare the surface for the reception of water, and its circulation in trenches and gutters, and to procure the water by raising it from wells or rivers by machinery. Wherever the surface cannot be irrigated, no regular culture need be attempted nor corn crop expected. Nature in such situations produces periodical crops of annual succulents or bulbous-rooted plants; and man might, perhaps, to a certain extent, turn this circumstance of climate to account, by changing the sorts of annual bulbs, &c., from such as are useless, to such as are useful. The onion or edible crocus or cyperus might, perhaps, be substituted for the ixia of the Cape; the sesamum, or some rapid annual, furnishing useful seeds or herbage, for numerous annual weeds; and the cochineal cactus for the showy but useless mesembryanthemums and stapelias of the African wastes. These, however, are only suggestions.

1251. *Culture in the north of Europe* depends for the most part more on draining lands of their superfluous water, than on artificial supplies of that element. When irrigation is applied it is limited entirely to grass lands; and that not for the purpose of supplying such lands with moisture, but for stimulating by manure held in solution by the water, and for increasing or maintaining heat. The greatest care is requisite to prevent this mode of watering from proving more injurious than useful; but little danger results from the application of water in hot countries, and there it is valuable by moderating rather than increasing the temperature of the soil. Water in the north of Europe is generally supplied in more than sufficient quantity by the atmosphere; and, therefore, one great object of the cultivator is to keep the soil thoroughly drained by surface gutters and subterraneous conductors; to keep it pulverised for the moisture to pass through, and for the roots to extend themselves; well stocked with manure to supply nourishment; freed from weeds, to prevent any of this nourishment from being wasted; and to admit the light, air, and weather to the useful plants. In the hot countries keeping the soil free from weeds is generally a duty easily performed, and often rendered unnecessary; for whenever water is withheld, even in the south of Spain (745.), every living plant is burned up with drought. It is remarkable that in the most northerly parts of Europe and America the same effect, especially as to fibrous-rooted perennials, is produced by cold; and in Russia and New England, where there is scarcely any spring, the agriculturist has only to plough once, and sow in the same way as in the hot valleys of the south of Spain, and in South America, where vegetation is as rapid from the accession of moisture, as it is in the cold plains of Russia from the influence of the sun during the long days of a northern summer. In hot countries, putrescent manures are not altogether neglected, but they are much less necessary than in cold countries, and can be done without where there is abundance of water; there, water,

intense heat, and light, a consequently moist atmosphere, and a soil well pulverised by art, supply every thing necessary for luxuriant vegetation.

1252. Hence it is that agriculture considered geographically admits of two grand divisions : that of the cold climates, which may be called agriculture by draining and manures ; and that of the hot climates, which may be called agriculture by irrigation. To the former belong the greater part of Europe, the north of Asia, the north of America, and part of the Australian isles ; to the latter, Egypt, Persia, India, China, Africa, great part of the south of America, and part of Australia. As intermediate between agriculture by watering, and agriculture by draining, may be mentioned that mixed culture by watering and manuring which prevails in the south of France, Spain, and Italy ; and as opposed to the aquatic culture of the torrid zone, may be placed the rural economy of the arctic circle, which, from the prevalence of cold and ice, precludes all culture of the soil, admits little else than the growth of mosses and lichens, and is therefore limited to fishery and the chase.

1253. These leading divisions of culture are by no means so absolute as to be determinable by degrees of latitude, so much depending on physical circumstances, as elevation, soil, aspect, island or continent, &c. ; but as an approximation which may impress some general ideas on the mind of the practical agriculturist, we submit the following : —

1254. The agriculture of irrigation may be considered as extending thirty-five degrees on each side of the equator.

1255. The agriculture of manures and irrigation from the thirty-fifth to the forty-fifth degree north and south of the equator.

1256. The agriculture of draining and manures from the forty-fifth degree, north and south of the equator, to the sixty-seventh degree or polar circle.

1257. The arts of fishing and hunting, as the only means of subsistence, from the sixty-seventh degree, or polar circle, to the pole.

CHAP. II.

Agriculture as influenced by Physical Circumstances.

1258. The physical circumstances which principally affect agriculture are temperature, light, elevation, moisture, and soil.

1259. Temperature and light have the most powerful influence both on the culture of plants and rearing of animals. Elevation, when not considerable, admits of being rendered subservient to the processes of culture, and to the habits of different plants and animals ; moisture may be moderated or increased, soil improved, but temperature and light are in a great measure beyond human control. Hence it is that the plants and animals under the management of the husbandman do not altogether depend on his skill or choice, but on his local situation. Not only the maize, rice and millet, which are such valuable crops in Asia and Africa, are incapable of cultivation in the north of Europe ; but even within the extent of the British isles, some kinds of grain, pulse, and roots cannot be grown to such perfection in certain districts as in others. Thus the Angus variety of oat will not come to the same perfection, south of London, that it does north of York ; and, of different varieties, the Dutch, Polish, and potato oat will succeed better in a warm climate, than the Angus, black, or moorland oat, which answer best for cold, moist, and elevated districts. The turnip arrives at a greater size in Lancashire, Berwickshire, and Ayrshire, than it does in Kent, Surrey, or Sussex, even admitting the best possible management in both districts. The pea requires a dry soil and climate, and more heat than the bean, and consequently thrives much better in the south of England, in Kent, and Hampshire, than in Scotland or Ireland. Hops cannot be cultivated advantageously in Scotland, nor clover seeds, except, perhaps, in a few very favourable situations. Even wheat does not come to maturity in many parts of that country in ordinary seasons. It is certain that the perennial grasses thrive best where the temperature and light are moderate throughout the year, as on the sea-coast in various countries, where mildness is obtained from the influence of the sea, and light from the absence of a covering of snow ; and also in the south of England, where the snow seldom lies, and where the temperature is moderate, and the nights not so long as they are farther north. It is equally certain that in America and Russia, where the cold is intense during winter, and the plants on the surface of the ground are deprived of light for six or seven months together by a covering of snow, all herbaceous vegetation is destroyed. Contrasted with these facts may be mentioned, as equally well ascertained, that annual plants in general attain a greater size, and a higher degree of perfection, where the winters are long, and the summers hot

and light; the reason of which seems to be that the alternate action of heat and cold, rain and ice, meliorates the soil and prepares it better for the nourishment of annuals than it can well be in countries where the soil is not only harder naturally (for all countries that have long winters have soft soils), but more or less occupied by perennial weeds, insects, and vermin. In cold countries the insects are generally of that kind whose eggs go through the processes of the larva and chrysalis state under water, and land reptiles are generally rare.

1260. *Elevation*, when considerable, has an absolute influence on agriculture. The most obvious effect is that of obliging the agriculturist to isolate his dwelling from those of other cultivators or villagers in the plains, and to reside on his farm. This is well exemplified in Switzerland and Norway. We have already noticed the judicious reflections of Bakewell on the subject as referable to the former country (337.), and have also referred to those of Dr. Clarke respecting Norway (602.). The latter author has depicted these alpine farms, both with his elegant pen and skilful pencil (fig. 175).

The farmeries are generally built with fir planks, and covered with birch bark and turf. The inhabitants chiefly live by the dairy, and seldom see their neighbours or any human being beyond their own fire-side, except on the Sunday mornings when they go to church, and on the Sunday afternoons in summer when they meet to dance (fig. 176.) and amuse themselves.

1261. *As elevation is known to lessen temperature* in regular gradation according to the altitude above the sea, its influence on plants and animals must correspond. Three hundred feet in height are considered nearly equal to half a degree of latitude, and occasion a difference of temperature of nearly twelve degrees of Fahrenheit. Hence it is that the agriculture of the temperate, may sometimes be adopted in the torrid, zone; and that some of the mountains of Jamaica will produce, between their base and summit, almost all the plants of the world. Hence, also, that even in the limited extent of the island of Britain, a given elevation on mountains in Devonshire will be adapted for an agriculture different from that required by the same elevation on the Cheviot, Grampian, or Sutherland mountains; and while wheat ripens at six hundred feet above the level of the sea in Cornwall, oats will hardly ripen at that height in the Western Isles.

1262. *Elevation exposes plants and animals to the powerful operation of wind*, and in this respect must influence the disposition of the fields, fences, plantations, and buildings of the agriculturist, as well as the plants and animals on the farm. It has some influence also on the density of the air and the supplies of water and vapour, and even in these respects must affect the character of the agriculture. In Switzerland and Norway the upper mountain-farms are completely above the more dense strata of clouds, and their

occupiers are often for weeks together without getting a view of the plains or valleys below.

1263. *That soil* must influence the agriculture of a country appears at first sight very obvious; though, if climate is favourable, time and art will render the soil fit for any species of culture. Naturally, however, soil has a powerful influence; and the period, under ordinary management, will be considerable, before strong deep clays on a flat surface can be rendered equally fit for the turnip or potato, with friable loams, or more gravelly or sandy soils.

1264. *The influence of moisture* on the state of lands is naturally very considerable; and though draining or irrigation can effectually remove excesses or supply deficiency, yet fen lands and chalk hills, such as we find in Huntingdonshire, Surrey, and other counties, will ever have a peculiar character of agriculture; the marsh perennial bay grasses will be the characteristic plants of the former, and saintfoin of the latter.

1265. *As the general result* of this outline of the influence of physical circumstances on agriculture, we may form a classification of that of any particular country to whichever of the four universal divisions (1254. to 1257.) it belongs. We submit the following:—

1266. *The agriculture of water-fed lands*, including fens, marshes, and marsh meadows.

1267. *The agriculture of sun-burnt lands*, including chalk, gravel, and sandy hills, where vegetation is annually more or less burned up during two or more of the summer months.

1268. *The agriculture of mountains*, in which the farmery is placed on the farm, as distinguished from those cases in which the whole or a part of the mountain lands is appended to lands on the plain.

1269. *Common agriculture*, or that of the plains, valleys, and hills of a country, in which all the crops and all the animals suitable to the climate may be profitably cultivated and reared.

CHAP. III.

Agriculture as affected by Civil, Political, and Religious Circumstances.

1270. *The influence of the state of society and government on agriculture* must, as well as the climate and situation, obviously be very considerable; for it will signify little what a country is capable of producing, if the inhabitants are too barbarous to desire, too ignorant to know, or too much oppressed to attain, these products. Some of the finest lands in the world, capable of producing wheat, maize, rice, and the grape, are inhabited by savages, who live on game, wild fruits, or native roots; or by half-civilised tribes who cultivate maize and yams, or some other local root. Even in Ireland, where the soil is better than in Britain, and with very moderate culture will produce excellent wheat and other corns, with beef, mutton, and wool, the greater part of the inhabitants, from ignorance, oppression, and in part, as we have seen (852.), religious slavery, content themselves with roots and rags, the latter often the cast off refuse of other countries.

1271. *The state of civilisation and refinement of a people* not only influences agriculture by the nature of the products such a state requires, but also by the means of production it affords; by the superior ease with which information on every subject may be attained; and by the existing state of knowledge, for example, in mechanics, chemistry, and physiology, by which the implements and machines are improved, the operations of soils and manures regulated, the influence of water, the atmosphere, and the functions of plants and animals understood. The difference in the means taken to effect the same end in a poor but yet ingenious country, and in one rich and enlightened, is exemplified in China and India, as compared with Britain. Wealth and ignorance, as contrasted with poverty and ingenuity, may also be exemplified in comparing the farmer of Hindustan with the English farmer. The latter, to stir the soil, employs an unwieldy implement drawn by several oxen or horses; the former uses a small light implement drawn by one ox or buffalo, but effects his object by repeating the operation many times. The Englishman effects it at once, often in spite of the worst means, by main force. The processes of Chinese manufacture are exceedingly curious and ingenious, and form a remarkable contrast to the rapid and scientific processes of Britain. There are many curious practices in France and Germany, the result of poverty and ingenuity. In Brittany the whin is used as horse provender: to bruise the spines one man operates on a simple but ingenious machine (*fig. 177.*), and effects his purpose completely. Here the same thing is done by a couple of iron rollers turned by a horse or by water: but the farmer of Brittany, who would purchase a pair of whin-bruising rollers, must first sell the greater part of his stock and crop.

1272. *The political state of a country will powerfully affect its agriculture.* Where security, the greatest object of government, is procured at too high a rate, the taxes will depress the cultivator, and not only consume his profits, but infringe on his capital; where security, either relatively to external circumstances or internal laws, is incomplete, there the farmer who has capital will be unwilling to risk it: in either case, few who have capital will engage in that profession; and if any find it profitable, the fear of exposing himself to exactions from government or from his landlord, will prevent him from making a proper use of his profits either in the way of employment or of consumption. Many instances of this state of things are to be found in the foregoing history. Wherever the metayer system or that of short leases prevails, whatever may be the nature or practice of the government, these remarks will apply. Security and liberty at a moderate price are essential to the prosperity of agriculture, even more so than to that of manufactures or commerce.

1273. *Religion may be thought to have very little influence on agriculture:* but in a Catholic or Mohammedan country, where the religion enjoins a frequent abstinence from animal food, and long periodical fasts from even the produce of the cow, surely the rearing and feeding of stock for the shambles or the dairy cannot prosper to the same extent as in a country less enslaved by prejudice, or whose religious opinions do not interfere with their cookery. The number of holidays is also a great grievance.

1274. *The natural character of a people may even have some influence on their agriculture, independently of all the other circumstances mentioned.* The essential character of a people is formed by the climate and country in which they live, and their factitious or accidental character by their government and religion for the time being. The latter may alter, but the original or native character remains. Thus the French appear to be the same gay people that they were in the time of Julius Cæsar; and, as far as history enables us to judge, the Greeks and Romans have only lost their accidental character.

1275. *The agriculture of the world, in regard to the state of society, may perhaps admit of the following divisions:—*

1276. *The agriculture of science, or modern farming, in which the cultivator is secure in his property or possession, both with relation to the government and to the landlord he lives under, as generally in Britain and North America.*

1277. *The agriculture of habit, or feudal culture, in which the cultivator is a metayer, or a tenant at will, or on a short lease, or has covenanted to pursue a certain fixed system of culture.*

1278. *Barbarian agriculture, or that of a semi-barbarous people who cultivate at random, and on land to which they have no defined right of possession, roots or grain, without regard to rotation, order, or permanent advantage.*

1279. *The economy of savages, such as hunting, fishing, gathering fruits, or digging up roots.*

CHAP. IV.

Of the Agriculture of Britain.

1280. To which of these *geographical, physical, and social divisions of agriculture* that of the British isles may be referred, is the next object to be determined, and we submit the following as its classification:—

1281. *Geographically* it is the agriculture of draining and manures.

1282. *Physically*, those of water-fed and sun-burnt lands, mountains, and variable plains.

1283. *Socially* considered, it is the agriculture of science.

1284. *The following PARTS of this work, therefore, are to be considered as treating of a kind of agriculture so characterised; that is, of the agriculture of our own country.* Whoever has paid a due attention to what has preceded, can scarcely fail to have formed an idea of the agriculture of every other part of the world.

PART II.

AGRICULTURE CONSIDERED AS A SCIENCE.

*1285. *All knowledge is founded on experience* ; in the infancy of any art, experience is confined and knowledge limited to a few particulars ; but as arts are improved and extended, a great number of facts become known, and the generalisation of these, or the arrangement of them according to some leading principle, constitutes the theory, science, or law of an art.

1286. *Agriculture, in common with other arts.* may be practised without any knowledge of its theory ; that is, established practices may be imitated : but in this case it must ever remain stationary. The mere routine practitioner cannot advance beyond the limits of his own particular experience, and can neither derive instruction from such accidents as are favourable to his object, nor guard against the recurrence of such as are unfavourable. He can have no resource for unforeseen events but ordinary expedients ; while the man of science resorts to general principles, refers events to their true causes, and adapts his measures to meet every case.

1287. *The object of the art of agriculture* is to increase the quantity and improve the quality of such vegetable and animal productions of the earth as are used by civilised man ; and the object of the agriculturist is to do this with the least expenditure of means, or, in other words, with profit. The result of the experience of mankind as to other objects may be conveyed to an enquiring mind in two ways : he may be instructed in the practical operations of the art, and their theory, or the reasons on which they are founded, laid down and explained to him as he goes along ; or he may be first instructed in general principles, and then in the practices which flow from them. The former mode is the natural and actual mode in which every art is acquired (in so far as acquirement is made) by such as have no recourse to books, and may be compared to the natural mode of acquiring a language without the study of its grammar. The latter mode is by much the more correct and effectual, and is calculated to enable an instructed agriculturist to proceed with the same kind of confidence and satisfaction in his practice, that a grammarian does in the use of language.

1288. In adopting what we consider as the *preferable mode of agricultural instruction*, we shall, as its grammar or science, endeavour to convey a general idea of the nature of vegetables, animals, minerals, mixed bodies, and the atmosphere, as connected with agriculture ; of agricultural implements and other mechanical agents ; and of agricultural operations and processes.

1289. *The study of the science of agriculture* may be considered as implying a regular education in the student, who ought to be well acquainted with arithmetic and mensuration ; and to have acquired the art of sketching objects, whether animals, vegetables, or general scenery, of taking off and laying down geometrical plans : but especially he ought to have studied chemistry, hydraulics, and something of carpentry, smithery, and the other building arts ; and, as Professor Von Thaer observes, he ought to have some knowledge of all those manufactures to which his art furnishes the raw materials.

 BOOK I.

OF THE STUDY OF THE VEGETABLE KINGDOM WITH A VIEW TO AGRICULTURE.

1290. *The various objects with which we are surrounded* are either organised, having several constituent parts which united form a whole capable of increase by nourishment ; or they are unorganised, and only increased by additions to their external parts. To the first division belong the animal and vegetable kingdoms, and their study is founded chiefly on observation : to the second belongs the mineral kingdom, the study of which in masses, or geology and mineralogy, is also founded chiefly on observation ; and, with regard to composition and elements, on experiment or chemistry.

1291. *Vegetables are distinguished from animals* in not being endowed with sentiment, or a consciousness of existence. Their study has employed the attention of mankind from a very early period ; and has been carried to a high degree of perfection within the last

century; more especially by the exertions of Linnæus, and those of Jussieu, Mirbel, and some other French philosophers. This study comprehends systematic botany, vegetable anatomy, vegetable chemistry, physiology, pathology, the distribution of vegetables, and vegetable culture. The study of these branches is of the utmost importance to the agriculturist, especially that of vegetable physiology; and though the limits of this work do not permit us to enter into the subject at great length; yet we shall direct his attention to the leading points, and refer him to the best books.

CHAP. I.

Of the Study of Systematic Botany.

1292. *Glossology*, or the study of the names of the parts of plants, is the first step in this department.

1293. *All the arts and sciences require to express with brevity and perspicuity a crowd of ideas unused in common language*, and unknown to the greater part of men: whence that multitude of terms, or technical turns, given to ordinary words, which the public often turn into ridicule, because they do not feel the use of them; but which all are obliged to make use of, who apply themselves to any study whatever. Botany having to describe an immense number of beings, and each of these beings having a great variety of organs, requires a great variety of terms. Nearly all botanists are agreed as to these terms, and in order that they may be universally understood and remain unchanged in meaning, they are taken from a dead or fixed language.

1294. *A plant in flower, surveyed externally*, may be perceived to be composed of a variety of obvious parts, such as the root, the stem, the branch, the leaf, the flower, the fruit, and perhaps the seed; and other parts less obvious, as buds, prickles, tendrils, hairs, glands, &c. These, with their modifications, and all the relative circumstances which enter into the botanical description of a plant, constitute the subject of glossology, or the study of the language of botany. The reader may consult Smith's *Introduction to Botany*, or almost any recent work on the elements of botanical science.

1295. *Phytography, or the naming and describing of plants*, is the next part of the subject to be considered. Before botany became a regular science, plants were named as individual beings, without regard to any relation which they had to one another. But from the great number of names to be retained on the memory, and the obvious affinities existing among certain individuals or natural families, some method was soon found necessary, and it was then deemed requisite to give such composite names as might recall to mind something of the individuals to which they were applied. Thus we had *Anagallis flore cæruleo*, *Méspilus aculeata pyriformis*, &c. In the end, however, the length of these phrases became inconvenient, and Linnæus, struck with this inconvenience, proposed that the names of plants should henceforth consist of two words only, the one the generic or family name, and the other the specific or individual name.

1296. *The names of classes and orders* were originally primitive or without meaning, as the *Grasses* of Tragus, *Poppies* of Bauhin, &c.; and afterwards so compounded as to be long and complex, as the *Pollopostemonopétale*, *Eleutheromacrostémone*, &c., of Wachendorf. Linnæus decided that the names of classes and orders should consist of a single word, and that word not simple or primitive, but expressive of a certain character or characters found in all the plants which compose it.

1297. *In applying names to plants, three rules are laid down by botanists*: 1st, That the languages chosen should be fixed and universal, as the Greek and Latin. 2d, That these languages should be used according to the general laws of grammar, and compound words always composed from the same language, and not of entire words, &c. 3d, That the first who discovers a being, and enregisters it in the catalogue of nature, has the right of giving it a name; and that that name ought to be received and admitted by naturalists, unless it belongs to a being already existing, or transgresses the rules of nomenclature. Every one who discovers a new plant may not be able to enregister it according to these laws, and in that case has no right to give it a name; but the botanist who enregisters it, and who is in truth the discoverer, may give it the name proposed by the finder, if he chooses.

1298. *The whole vegetable kingdom is divided into classes, orders, genera, species, and varieties*. A class is distinguished by some character which is common to many plants; an order is distinguished by leaving some character limited to a few plants belonging to a class; a still more limited coincidence constitutes a genus; and each individual of a genus, which continues unchanged when raised from seed, is called a species. A variety is formed by an accidental deviation from the specific character, and easily returns by seed to the particular species from which it arose.

1299. *For the purposes of recording and communicating botanical knowledge* plants are described; and this is done either by the use of language alone, or by language and figures, models, or dried plants, conjoined. The description of plants may be either abridged or complete. The shortest mode of abridgement is that employed in botanical catalogues, as in those of Donn or of Sweet. The most exact descriptions are deficient without figures or a herbarium. Hence the advantage of being able to see plants at pleasure, by forming dried collections of them. Most plants dry with facility between the leaves of books, or between sheets of paper, the smoother the better. If there is plenty of paper, they often dry best without shifting; but if the specimens are crowded, they must be taken out frequently, and the paper dried before they are replaced.

1300. *The language of botany* may be acquired by two methods, analogous to those by which common languages are acquired. The first is the natural method, which begins with the great and obvious classes of vegetables, and distinguishes trees, grasses, &c., next individuals among these, and afterwards their parts or organs: this knowledge is acquired insensibly, as we acquire our native tongue. The second is the artificial method, and begins with the parts of plants, as the leaves, roots, &c., ascending to nomenclature and classification, and is acquired by particular study, aided by books or instructors, as one acquires a dead or foreign language. This method is the fittest for such as wish to attain a thorough knowledge of plants, so as to be able to describe them; the other mode is easier, and the best suited for cultivators, whose object does not go beyond that of understanding their descriptions, and studying their physiology, history, and application. A very good method, for a person at a distance from botanists, is to form a collection of dried specimens of all the plants of which he wishes to know the names, and to send them to the curator of the nearest botanic garden, requesting him to write the name below each specimen, and to refer to some work easily procured, such as Lindley's *Vasculars*, or Withering or Gray's *Arrangement of British Plants*, in which are given its description, uses, history, &c. We know of no work in which an attempt has been made to comprehend so much, both of theoretical and practical botany, as is comprised in our *Encyclopædia of Plants*; and to those therefore who cannot afford to have many books, and especially to gardeners, for whose convenience it is more especially intended, it may be confidently recommended.

1301. *Taxonomy, or the classification of plants*, is the last part of the study of technological botany. It is very evident, that, without some arrangement, the mind of man would be unequal to the task of acquiring even an imperfect knowledge of the various objects of nature. Accordingly, in every science, attempts have been made to classify the different objects that it embraces, and these attempts have been founded on various principles: some have adopted artificial characters; others have endeavoured to detect the natural relations of the beings to be arranged, and thus to ascertain a connection by which the whole may be associated. In the progress of zoology and botany, the fundamental organs on which to found a systematic arrangement have been finally agreed on. In both, those which are essential, and which discover the greatest variety, form the basis of classification. Animals are found to differ most from each other in the organs of nutrition, plants in the organs of reproduction.

1302. *Two methods of arranging vegetables* have been distinguished by botanists, the natural and the artificial. A natural method is that which, in its distribution, retains all the natural classes; that is, groups into which no plants enter which are not connected by numerous relations, or which can be disjoined without doing a manifest violence to nature. An artificial method is that whose classes are not natural, because they collect together several genera of plants which are not connected by numerous relations, although they agree in the characteristic mark or marks assigned to that particular class or assemblage to which they belong. An artificial method is easier than the natural, as in the latter it is nature, in the former the writer, who prescribes to plants the rules and order to be observed in their distribution. Hence, likewise, as nature is ever uniform, there can be only one natural method; whereas artificial methods may be multiplied almost *ad infinitum*, according to the different relations under which bodies are viewed.

1303. *The object of the natural method* is to promote our knowledge of the vegetable kingdom by generalising facts and ideas; the object of the artificial method is to facilitate the knowledge of plants as individual objects. The merits of the former method consist in that which plants are grouped together in natural families or orders, and these families grouped among themselves; the merits of the latter consist in the perfection with which they are arranged according to certain marks by which their names may be discovered. Plants arranged according to the natural method may be compared to words arranged according to their roots or derivations; arranged according to an artificial method they may be compared to words in a dictionary. The success attending attempts at botanical arrangement, both natural and artificial, has been singularly striking. Linnæus has given the most beautiful artificial system that has ever been bestowed by genius on mankind; and Jussieu has, with unrivalled ability, exhibited the natural affinities of the vegetable kingdom. For the study of this department we refer to the works of Smith, Lindley, Decandolle, and Gray, but especially to the *Encyclopædia of Plants*.

CHAP. II.

Vegetable Anatomy, or the Structure and Organisation of Plants.

1304. *Vegetables may be classed for the study of their anatomy and physiology*, accordingly as they are distinguished by a structure or organisation more complicated or more simple. The former will constitute what may be denominated perfect plants, and will form a class comprehending the principal mass of the vegetable kingdom; the latter will constitute what may be denominated imperfect plants, and will form a class comprehending all such vegetables as are not included in the foregoing class. We shall first consider their external, and next their internal, organisation.

SECT. I. *Of the External Structure of Perfect Plants.*

1305. *The parts of perfect plants* may be distributed into conservative and reproductive, as corresponding to their respective functions in the economy of vegetation.

1306. *The conservative organs* are such as are absolutely necessary to the growth and preservation of the plant, and include the root, trunk, branch, leaf, and frond.

1307. *The root* is that part of the plant by which it attaches itself to the soil in which it grows, or to the substance on which it feeds, and is the principal organ of nutrition.

1308. *The trunk* is that part of the plant which, springing immediately from the root, ascends in a vertical position above the surface of the soil, and constitutes the principal bulk of the individual.

1309. *The branches* are the divisions of the trunk, originating generally in the upper extremity, but often also along the sides.

1310. *The leaf*, which is a temporary part of the plant, is a thin and flat substance of a green colour, issuing generally from numerous points towards the extremities of the branches, but sometimes also immediately from the stem or root, and distinguishable by the sight or touch into an upper and under surface, a base and apex, with a midrib and lateral veins or nerves.

1311. *The frond*, which is to be regarded as a compound of several of the parts already described, consists of a union or incorporation of the leaf, leaf-stalk, and branch or stem, forming, as it were, but one organ, of which the constituent parts do not separate spontaneously from one another by means of the fracture of any natural joint, as in the case of plants in general, but adhere together even in their decay. It is found in palms and ferns.

1312. *The conservative appendages* are such accessory or supernumerary parts as are found to accompany the conservative organs occasionally, but not invariably. They are permanent in whatever species they are found to exist, some being peculiar to one species, and some to another; but they are never found to be all united in the same species, and are not necessarily included in the general idea of the plant. They are denominated gems, glands, tendrils, stipulæ, ramenta, armature, pubescence, and anomalies.

1313. *Gems or bulbs* are organised substances issuing from the surface of the plant, and containing the rudiments of new and additional parts which they protrude; or the rudiments of new individuals, which they constitute by detaching themselves ultimately from the parent plant, and fixing themselves in the soil.

1314. *Glands* are small and minute substances of various forms, found chiefly on the surface of the leaf and petiole, but often also on the other parts of the plant, and supposed to be the organs of secretion.

1315. *The tendril* is a thread-shaped and generally spiral process issuing from the stem, branch, or petiole, and sometimes even from the expansion of the leaf itself, being an organ by which plants of weak and climbing stems attach themselves to other plants or other substances for support; for which purpose it seems to be well fitted by nature, the tendril being much stronger than a branch of the same size.

1316. *The stipule* are small foliaceous appendages accompanying the real leaves, and assuming the appearance of leaves in miniature.

1317. *Ramenta* are thin, oblong, and strap-shaped appendages, of a brownish colour, issuing from the surface of the plant, and somewhat resembling the stipule, but not necessarily accompanying the leaves.

1318. *The armature* consists of such accessory and auxiliary parts as seem to have been intended by nature to defend the plant against the attacks of animals.

1319. *The pubescence* is a general term, including under it all sorts of vegetable down or hairiness, with which the surface of the plant may be covered, finer or less formidable than the armature.

1320. *Anomalies.* There are several other appendages proper to conservative organs, which are so totally different from all the foregoing, that they cannot be classed with any of them; and so very circumscribed in their occurrence, that they do not yet seem to have been designated by any peculiar appellation.

The first anomaly, affecting the conservative appendages, occurs in *Dianæa muscipula*. Venus's fly-trap (fig. 178. a). A second is that which occurs in *Sarracenia purpurea* or purple side-saddle-flower (b). A third, which is still more singular, occurs in *Nepenthes distillatoria* (c). The last anomaly is a small globular and membranaceous organ, attached as an appendage to the roots and leaves of some of the aquatics. It is confined to a few genera, but it is to be seen in great abundance on the roots or leaves of the several species of *Utricularia* inhabiting the ponds and ditches of this country; and on the leaves of *Aldrovanda vesiculosa*, an inhabitant of the marshes of Italy. In *Utricularia vulgaris* this appendage is pear-shaped, compressed, with an open border at the small end, furnished with several slender fibres originating in the margin, and containing a transparent and watery fluid and a small bubble of air, by means of which it seems to acquire a buoyancy that suspends it in the water.

1321. *The reproductive organs* are such parts of the plant as are essential to its propagation, whose object is the reproduction of the species, terminating the old individual, and beginning the new. It includes the flower, with its immediate accompaniments or peculiarities, the flower-stalk, receptacle, and inflorescence, together with the ovary or fruit.

1322. *The flower*, like the leaf, is a temporary part of the plant, issuing generally from the extremity of the branches, but sometimes also from the root, stem, and even leaf, being the apparatus destined by nature for the production of the fruit, and being also distinguishable, for the most part, by the brilliancy of its colouring or the sweetness of its smell.

1323. *The flower-stalk* is a partial trunk or stem, supporting one or more flowers, if the flowers are not sessile, and issuing from the root, stem, branch, or petiole, and sometimes even from the leaf.

1324. *The receptacle* is the seat of the flower, and point of union between the different parts of the flower, or between the flower and the plant, whether immediate and sessile, or mediate and supported upon a flower-stalk.

1325. *The inflorescence*, mode of flowering, is the peculiar mode of aggregation in which flowers are arranged or distributed upon the plant.

1326. *The fruit* is the ripened ovary, or seed-vessel which succeeds the flower. In popular language the term is confined chiefly to such fruits as are esculent, as the apple, the peach, and the cherry; but with the botanist the matured ovary of every flower, with the parts contained, constitutes the fruit.

1327. *Appendages.* The reproductive organs, like the conservative organs, are often found to be furnished with various additional and supernumerary parts, not at all essential to their constitution, because not always present, and hence denominated appendages. Many of them are precisely of the same character with that of the conservative appendages, except that they are of a finer and more delicate texture; such are the glands, down, pubescence, hairs, thorns, or prickles, with one or other of which the parts of the fructification are occasionally furnished: but others are altogether peculiar to the reproductive organs, and are to be regarded as constituting, in the strict acceptation of the term, true reproductive appendages. Some of them are found to be proper to the flower, as the involucre, spathe, bractea, &c.; and others to the fruit, as the persisting calyx, exemplified in the pomegranate.

SECT. II. *Of the External Structure of Imperfect Plants.*

1328. *Plants apparently defective* in one or other of the more conspicuous parts or organs, whether conservative or reproductive, are denominated imperfect. The most

generally adopted division of imperfect plants is that by which they are distributed into *Filices*, *Equisetaceæ*, *Lycopodiaceæ*, *Músci*, *Hepaticæ*, *Algæ*, *Lichènes*, and *Fúngi*.

1329. *The Filices, Equisetaceæ, and Lycopodiaceæ are for the most part herbaceous, and die down to the ground in the winter; but they are furnished with a perennial root, from which there annually issues a frond bearing the fructification. The favourite habitations of many of them are heaths and uncultivated grounds, where they are found intermixed with furze and brambles; but the habitations of such as are the most luxuriant in their growth are moist and fertile spots, in shady and retired situations, as on mossy dripping rocks, or by fountains and rills of water. Some of them will thrive even on the dry and barren rock, or in the chinks and fissures of walls; and others only in wet and marshy situations where they are half immersed in water.*

1330. *The Músci (fig. 179. a b) form a tribe of imperfect plants of a diminutive size, often consisting merely of a root, surmounted with a tuft of minute leaves, from the centre of which the fructification springs; but furnished for the most part with a stem and branches, on which the leaves are closely imbricated, and the fructification terminal or lateral. They are perennials and herbaceous, approaching to shrubby; or annuals, though rarely so, and wholly herbaceous, the perennials being also evergreens.*

1331. *The Hepaticæ (fig. 179. c) form a tribe of small herbaceous plants resembling the mosses, but chiefly with frondose herbage, and producing their fruit in a capsule that splits into longitudinal valves. In their habitations, they affect for the most part the same sort of situations as the mosses, being found chiefly in wet and shady spots, by the sides of springs and ditches, on the shelving brinks of rivulets, or on the trunks of trees. Like the mosses, they thrive best also in cold and damp weather, and recover their verdure though dried, if moistened again with water.*

1332. *The Algæ, or sea-weeds, include not merely marine and many other submersed plants, but also a great variety of plants that are not even aquatic. All the Algæ agree in the common character of having their herbage frondose, or but rarely admitting of the distinction of root, stem, and leaf.*

1333. *The utility of the Algæ is obviously very considerable, whether we regard them as furnishing an article of animal food, or as applicable to medicine and the arts. The Laminária saccharina (fig. 180 a), Halménia palmáta (b) and edúlís (c), and several other Fúci, are eaten, and much relished by many people, whether raw or dressed; and it is likely that some of them are fed upon by various species of fish. The Fucus lichenoides (Turner, c. 118.) is now believed to be the chief material of the edible nests of the East India swallows, which are so much esteemed for soups, that they sell in China for their weight in silver. (Far. Mag., vol. xx.) When disengaged from their place of growth and thrown upon the sea-shore, the European Algæ are often collected by the farmer and used as manure. They are also often employed in the preparation of dyes, as well as in the lucrative manufacture of kelp, a commodity of the most indispensable utility in the important arts of making soap and glass.*

1334. *The utility of the Lichènes is also worthy of notice. The Lichen rangiferinus forms the principal nourishment of the reindeer during the cold months of winter, when all other herbage fails. The Lichen islándicus is eaten by the Icelanders instead of bread, or used in the preparation of broths; and, like the Lichen pulmonarius, has been lately found to be beneficial in consumptive affections. Many of them are also employed in the preparation of some of our finest dyes or pigments; and it is from the Lecanora parélla that the chemical analyst obtains his litmus. The lichens and the mosses seem instituted by nature to provide for the universal diffusion of vegetable life over the whole surface of the terrestrial globe. The powdery and tuberculous lichens attach themselves even to the bare and solid rock. Having reached the maturity of their species, they die and are converted into a fine earth, which forms a soil for the leathery lichens. These again decay and moulder into dust in their turn; and the depth of soil, which is thus augmented, is now capable of nourishing and supporting other tribes of vegetables. The seeds of the mosses lodge in it, and spring up into plants, augmenting also by their decay the quantity of soil, and preparing it for the support of plants of a more luxuriant growth,*

so that, in the revolution of ages, even the surface of the barren rock is covered with a soil capable of supporting the loftiest trees.

1335. *The Fungi form a tribe of plants whose herbage is a frond of a fleshy or pulpy texture, quick in its growth and fugacious in its duration, and bearing seeds or gems in an appropriate and exposed membrane, or containing them interspersed throughout its mass. This assemblage of plants may be regarded as the lowest in the vegetable scale, exhibiting a considerable resemblance to the tribe of zoophytes, and thus forming the connecting link between the vegetable and animal kingdoms. The habitations they affect are very various, many of them vegetating on the surface of the earth (fig. 181. a), and some of them even buried under it; others on stumps and trunks of rotten trees (b); others on decayed fruit; others on damp and wet walls; and others on animal ordure.*

1336. *Uses of the Fungi.* The powder of the lycoperdons is said to be an excellent styptic; and is remarkable also for its property of strongly repelling moisture. If a basin be filled with water, and a little of the powder strewed upon the surface so as to cover it only, the hand may be plunged into it and thrust down to the bottom without being wetted with a single drop of water. Several of the boleti, when dried, afford a very useful tinder; and several of the agarics and tubers are used as articles of food, or as ingredients in the preparation of seasoning. The truffle is much esteemed for the rich and delicate flavour which it imparts to soups and sauces; and the mushroom and morel for their esculent property, and their utility in the preparation of catsup.

SECT. III. *Of the Internal Structure of Plants.*

1337. *The organs of plants discoverable by external examination are themselves reducible into component organs, which are again resolvable into constituent and primary organs. These are called the decomposite, the composite, and the elementary.*

SUBSECT. 1. *Decomposite Organs.*

1338. *The decomposite organs are distinguishable on external examination, and constitute the vegetable individual; to the dissection of which we will now proceed, in the order of the seed, pericarp, flower, leaf, gem, and caudex, with their decomposite appendages.*

1339. *The seed.* The mass of the seed consists of two principal parts, distinguishable without much difficulty; namely, the integuments and nucleus, or embryo and its envelops.

1340. *The integuments proper to the seed are two in number, an exterior integument and an interior integument.*

1341. *The exterior integument, or testa, is the original cuticle of the nucleus, not detachable in the early stages of its growth, but detachable at the period of the maturity of the fruit, when it is generally of a membranaceous or leathery texture; though sometimes soft and fleshy, and sometimes crustaceous and bony. It may be very easily distinguished in the transverse or longitudinal section of the garden bean or any other large seed.*

1342. *The interior integument, or membrana, lines the exterior integument, or testa, and immediately envelopes the nucleus. Like the testa, to which indeed it adheres, it may be easily distinguished in the garden bean (fig. 182.), or in a ripe walnut; in which latter it is a fine transparent and netlike membrane.*

1343. *The nucleus is that part of the seed which is contained within the proper integuments, consisting of the albumen with the vitellus, when present, and embryo.*

1344. *The albumen is an organ resembling in its consistence the white of an egg, and forming, in most cases, the exterior portion of the nucleus, but always separable from the interior or remaining portion.*

1345. *The vitellus is an organ of a fleshy but firm contexture, situated, when present, between the albumen and embryo; to the former of which it is attached only by adhesion, but to the latter by incorporation of substance, so as to be inseparable from it, except by force.*

1346. *The embryo, which is the last and most essential part of the seed, and the final object of the fructification, is a small and often very minute organ, enclosed within the albumen and occupying the centre of the seed.*

1347. *The cotyledon, or seed-lobe (b), is that portion of the embryo that encloses and protects the plantlet, and springs up during the process of germination into what is usually denominated the seminal leaf, if the lobe is solitary; or seminal leaves, if there are more lobes than one. In the former case the seed is said to be monocotyledonous; in the latter case, it is said to be dicotyledonous. Dicotyledonous seeds, which constitute by far the majority, are well exemplified in the garden bean. As there are some seeds whose cotyledon consists of one lobe only, falling short of the general number, so there are also a few whose cotyledon is divisible into several lobes, exceeding the general number. These have been denominated polycotyledonous seeds, and are exemplified in the case of *Leptidium sativum* or common garden cress, in which the lobes are six in number; as in that also of the different species of the genus *Pinus*, in which they vary from three to twelve.*

1348. *The plumule (a)*, the future plant in miniature, is the interior and essential portion of the embryo, and seat of vegetable life. In some seeds it is so minute as to be scarcely perceptible; while in others it is so large as to be divisible into distinct parts, as in the garden bean.

1349. *The pericarp*, which in different species of fruit assumes so many varieties of contecture, acquires its several aspects, not so much from a diversity of substance as of modification.

1350. *The valves of the capsule*, but particularly the partitions by which it is divided into cells, are composed of a thin and skinny membrane, or of an epidermis covering a pulp more or less indurated, and interspersed with longitudinal fibres. The capsule of the mosses is composed of a double and netlike membrane, enclosed within a fine epidermis.

1351. *The pome* is composed of a fine but double epidermis, or, according to Knight, of two skins, enclosing a soft and fleshy pulp, with bundles of longitudinal fibres passing through it, contiguous to, and in the direction of, its longitudinal axis.

1352. *The valves of the legume* are composed of an epidermis enclosing a firm but fleshy pulp lined for the most part with a skinny membrane, and of bundles of longitudinal fibres forming the seam.

1353. *The nutshell*, whether hard and bony, or flexible and leathery, is composed of a pulp more or less highly indurated, interspersed with longitudinal fibres, and covered with an epidermis.

1354. *The drupe* is composed of an epidermis enclosing a fleshy pulp, which is sometimes so interwoven with a multiplicity of longitudinal fibres as to seem to consist wholly of threads, as in the cocoa-nut.

1355. *The berry* is composed of a very fine epidermis enclosing a soft and juicy pulp.

1356. *The scales of the strobile* are composed of a tough and leathery epidermis, enclosing a spongy but often highly indurated pulp interspersed with longitudinal fibres that pervade also the axis.

1357. *The flower-stalk*, or peduncle supporting the flower, which is a prolongation of the stem or branch, or rather a partial stem attached to it, if carefully dissected with the assistance of a good glass, will be found to consist of the following parts:—1st, An epidermis, or external envelope; 2dly, A parenchyma, or soft and pulpy mass; 3dly, Bundles of longitudinal threads or fibres, originating in the stem or branch, and passing throughout the whole extent of the parenchyma. The several organs of the flower are merely prolongations of the component parts of the flower-stalk, though each organ does not always contain the whole of such component parts, or at least not under the same modifications. The epidermis, however, and parenchyma are common to them all; but the longitudinal threads or fibres are seldom, if ever, to be found, except in the calyx or corolla.

1358. *The leaf-stalk*, or petiole supporting the leaf, which is a prolongation of the branch or stem, or rather a partial stem attached to it, exhibits upon dissection the same sort of structure as the peduncle, namely, an epidermis, a pulp or parenchyma, and bundles of longitudinal threads or fibres.

1359. *Gems*. There exist among the different tribes of vegetables four distinct species of gems, two peculiar to perfect plants, the bud and bulb, and two peculiar to imperfect plants, the propago and gongylus; the latter being denominated simple gems, because furnished with a single envelope only; and the former being denominated compound gems, because furnished with more than a single envelope.

1360. *Buds* are composed externally of a number of spoon-shaped scales, overlapping one another and converging towards a point in the apex, and often cemented together by means of a glutinous or mucilaginous substance exuding from their surface. If these scales are stripped off and dissected under the microscope, they will be found to consist, like the leaves or divisions of the calyx, of an epidermis enclosing a pulp interspersed with a network of fibres, but unaccompanied with longitudinal threads. If the scales of a leaf-bud are taken and stripped off, and the remaining part carefully opened up, it will be found to consist of the rudiments of a young branch terminated by a bunch of incipient leaves embedded in a white and cottony down, being minute but complete in all their parts and proportions, and folded or rolled up in the bud in a peculiar and determinate manner.

1364. *The caudex* includes the whole mass or body both of the trunk and root; its internal structure, like its external aspect or habit, is materially different in different tribes of plants.

1365. *The first general mode of the internal structure of the caudex* is that in which an epidermis encloses merely a homogeneous mass of pulp or slender fibre. This is the simplest mode of internal structure existing among vegetables; it is exemplified in the lower orders of imperfect plants, particularly the *Algae* and *Fungi*.

1366. *The second general mode of internal structure of the caudex* is that in which an epidermis encloses two or more substances, or assemblages of substances, totally heterogeneous in their character. A very common variety of this mode is that in which an epidermis or bark encloses a soft and pulpy mass, interspersed with a number of longitudinal nerves or fibres, or bundles of fibres, extending from the base to the apex, and disposed in a peculiarity of

184

1361. *Bulbs*, which are either radical or caulinary, exhibit in their external structure, or in a part of their internal structure that is easily detected, several distinct varieties, some being solid, some coated, and some scaly; but all protruding in the process of vegetation the stem, leaf, and flower, peculiar to their species.

1362. *The propago*, which is a simple gem, peculiar to some genera of imperfect plants, and exemplified by Gertner in the lichens, consists of a small and pulpy mass forming a granule of no regular shape, sometimes naked, and sometimes covered with an envelope, which is a fine epidermis.

1363. *The gongylus*, which is also a simple gem peculiar to some genera of imperfect plants, and exemplified by Gertner in the fungi, consists of a slightly indurated pulp moulded into a small and globular granule of a firm and solid contecture, and invested with an epidermis.

183

manner characteristic of a tribe or genus. This mode prevails chiefly in herbaceous and annual or biennial plants. (Fig. 183.) A second variety of this mode is that in which a strong and often thick bark encloses a circular layer of longitudinal fibres, or several such circular and concentric layers, interwoven with thin transverse and divergent layers of pulp, so as to form a firm and compact cylinder, in the centre of which is lodged a pulp or pith. This mode is best exemplified in trees and shrubs (fig. 184), though it is also applicable to many plants whose texture is chiefly or almost wholly herbaceous, forming as it were the connecting link between such plants as are purely herbaceous on the one hand, and such as are purely woody on the other. In the latter case the wood is perfect; in the former case it is imperfect. The wood being imperfect in the root of the beet, the common bramble, and burdock; and perfect in the oak or alder.

1367. *The appendages* of the plant, whether conservative or reproductive, exhibit nothing in their internal structure that is at all essentially different from that of the organs that have been already described.

SUBSECT. 2. Composite Organs.

1368. *The composite organs* are the epidermis, pulp, pith, cortical layers, ligneous layers, and vegetable fibre, which may be further analysed, as being still compound, with a view to reach the ultimate and elementary organs of the vegetable subject.

1369. *Structure of the vegetable epidermis*. The epidermis of the vegetable, which, from its resemblance to that of the animal, has been designated by the same name, is the external envelope or integument of the plant, extending over the whole surface, and covering the root, stem, branches, leaves, flower, and fruit, with their appendages; the summit of the pistil only excepted. But although it is extended over the whole surface of the plant, it is not of equal consistence throughout. In the root and trunk it is a

tough and leathery membrane, or it is a crust of considerable thickness, forming a notable portion of the bark, and assuming some peculiar shade of colour; while in the leaves, flowers, and tender shoots, it is a fine, colourless, and transparent film, when detached; and when adherent, it is always tinged with some peculiar shade, which it borrows from the parts immediately beneath it.

1370. *The pulp* is a soft and juicy substance, constituting the principal mass of succulent plants, and a notable proportion of many parts even of woody plants. It constitutes the principal mass of many of the *Fungi* and *Fuci*, and of herbaceous plants in general. Mirbel compares it to clusters of small hexagonal cells or bladders, containing for the most part a coloured juice, and formed apparently of the foldings and doublings of a fine and delicate membrane, in which no traces of organisation are to be distinguished.

1371. *The pith* is a soft and spongy, but often succulent, substance, occupying the centre of the root, stem, and branches, and extending in the direction of their longitudinal axis, in which it is enclosed as in a tube. The structure of the pith is precisely similar to that of the pulp, being composed of an assemblage of hexagonal cells containing a watery and colourless juice, or of cellular tissue and a parenchyma.

1372. *The cortical layers*, or interior and concentric layers, constituting the mass of the bark, are situated immediately under the cellular integument, where such integument exists, and where not, immediately under the epidermis; or they are themselves external. They are distinguishable chiefly in the bark of woody plants, but particularly in that of the lime tree. They are composed of two elementary parts; bundles of longitudinal fibres constituting a network (fig. 185), and a mass of pulp more or less indurated filling up the meshes. The innermost of the layers is denominated the liber, and was used by the ancients to write on before the invention of paper. It is the finest and most delicate of them all, and often most beautifully reticulated (fig. 186 a) and varied by bundles of longitudinal fibre (b). But the liber of *Daphne Lagetto* is remarkable

186

beyond that of all other plants for the beauty and delicacy of its network, which is not inferior to that of the finest lace, and at the same time so very soft and flexible that, in countries of which the tree is a native, the lace of the liber is often made to supply the place of a neckcloth. If the cortical layers are injured or destroyed by accident, the part destroyed is again regenerated, and the wound healed up without a scar; but if the wound penetrates beyond the liber, the part destroyed is no longer regenerated. Or if a tree is bent so as to break part of the cortical fibres, and then propped up in its former position, the fractured fibres will again unite. Or if a portion of the stem is entirely decorticated and covered with a piece of bark, even from another tree, the two different barks will unite. Hence the practicability of ascertaining how far the liber extends; and hence also the origin of grafting, which is always effected by a union of the liber of the graft and etock.

1373. *The ligneous layers*, or layers constituting the wood, occupy the intermediate portion of the stem between the bark and pith; and are distinguishable into two sorts, concentric layers and divergent layers. (fig. 185.)

1374. *The concentric layers*, which constitute by far the greater part of the mass of the wood, are sufficiently conspicuous for the purpose of exemplification on the surface of a horizontal section of most trunks or branches, as on that of the oak and elm. But though they are generally described as being concentric, they are not always strictly so. For they are often found to extend more on the one side of the axis of the stem or branch, than on the other. Some authors say the excess is on the north side, but others say it is on the south side. The former account for it by telling us it is because the north side is sheltered from the sun; and the latter by telling us it is because the south side is sheltered from the cold; and thus from the operation of contrary causes alleging the same effect, which has been also thought to be sufficiently striking and uniform to serve as a sort of compass, by which the bewildered traveller might safely steer his course, even in the recesses of the most extensive forest. But Du Hamel has exposed the futility of this notion, by showing that the excess is sometimes on the one side of the axis, and sometimes on the other, according to the accidental situation of the great roots and branches; a thick root or branch producing a proportionably thick layer of wood on the side of the stem from which it issues. The layers are indeed sometimes more in number on the one side than on the other, as well as thicker; but this is the exception, and not the rule. They are thickest, however, on the side on which they are fewest, though not of the same thickness throughout. Du Hamel, after counting twenty layers on the one side of the transverse section of the trunk of an oak, found only fourteen on the other; but the fourteen exceeded the twenty in thickness by one fourth part. But the layers thus discoverable on the horizontal section of the trunk are not at all of an equal consistence throughout, there being an evident diminution in their degree of solidity from the centre, where they are hardest, to the circumference, where they are softest. The outermost layer, which is the softest of all, is denominated the albumen, perhaps from its being of a brighter white than any of the other layers, either of wood or bark; by which character, as well as by its softer texture, it is also easily distinguished. It does not acquire its utmost degree of solidity till after a number of years; but if a tree is barked a year before it is cut down, then the albumen is converted into wood in the course of that year.

1375. *The divergent layers*, which intersect the concentric layers in a transverse direction, constitute also a considerable proportion of the wood, as may be seen in a horizontal section of the fir or birch, or of almost any woody plant, on the surface of which they present an appearance like that of the radii of a circle.

1376. *The structure of the concentric layers* will be found to consist of several smaller and component layers, which are themselves composed of layers smaller still, till at last they are incapable of further division. The concentric layers are composed of longitudinal fibres, generally forming a network; and the divergent layers, of parallel threads or fibres of cellular tissue, extending in a transverse direction, and filling up the interstices of the network.

1377. *The structure of the stem, in plants that are purely herbaceous*, and in the herbaceous parts of woody plants, is distinguished by a number of notable and often insulated fibres passing longitudinally throughout its whole extent, as in the stipe of *Aspidium Flix-más* or in the leaf-stalk of the alder. These fibres, when viewed superficially, appear to be merely individuals, but when inspected minutely, and under the microscope, they prove to be groups or bundles of fibres smaller and minuter still, firmly cemented together, and forming in the aggregate a strong and elastic thread, but capable of being split into a number of component fibres, till at last you can divide them no longer. If the fibres of the bark are separated by the destruction of a part, the part is again regenerated, and the fibres are again united, without leaving behind them any traces of a wound; but, if the fibres of the wood are separated by the destruction of a part, the part is never regenerated, and the fibres are never united.

SUBSECT. 3. Elementary, or Vascular, Organs.

1378. *Fibre, cellular tissue with or without parenchyma, and reticulated membrane* are the ultimate and elementary organs of which the whole mass of the plant is composed.

If it be asked of what are the elementary organs themselves composed, the reply is, they are composed, as it appears from the same analysis, of a fine, colourless, and transparent membrane, in which the eye, aided by the assistance even of the best glasses, can discover no traces whatever of organisation; which membrane we must also regard as constituting the ultimate and fundamental fabric of the elementary organs themselves, and, by consequence, of the whole of the vegetable body. It has been asked by some phytologists whether or not plants are furnished with vessels analogous to the blood-vessels of the animal system. But if it be admitted that plants contain fluids in motion, which cannot possibly be denied, it will follow, as an unavoidable consequence, that they are furnished with vessels conducting or containing such fluids. If the stem of a plant of marigold is divided by means of a transverse section, the divided extremities of the longitudinal fibres, arranged in a circular row immediately within the bark, will be distinctly perceived, and their tubular structure demonstrated by means of the orifices which they present, particularly when the stem has begun to wither. Regarding it, therefore, as certain, that plants are furnished with longitudinal tubes, as well as with cells or utricles for the purpose of conveying or containing their alimentary juices, we proceed to the specific illustration of both, together with their peculiarities and appendages.

1379. *The utricles* are the fine and membranous vessels constituting the cellular tissue of the pith and pulp already described, whether of the plant, flower, or fruit. Individually they resemble oblong bladders inflated in the middle, as in the case of some plants; or circular or hexagonal cells, as in the case of others. Collectively they have been compared to an assemblage of threads of contiguous bladders, or vesicles, or to the bubbles that are found on the surface of liquor in a state of fermentation.

1380. *The tubes* are the vessels formed by the cavities of the longitudinal fibres, whether as occurring in the stem of herbaceous plants, or in the foot-stalk of the leaf and flower, or in the composition of the cortical and ligneous layers, or by longitudinal openings pervading the pulp itself, as in the case of the vine.

1381. *The large tubes* are tubes distinguishable by the superior width of the diameter which they present on the horizontal section of the several parts of the plant.

1382. *Simple tubes* (fig. 187.) are the largest of all large tubes, and are formed of a thin and entire membrane, without any perceptible disruption of continuity. They are found chiefly in the bark, though not confined to it, as they are to be met with also in the albumum and matured wood, as well as in the fibres of herbaceous plants.

1383. *Porous tubes* resemble the simple tubes in their general aspect; but differ from them in being pierced with small holes or pores, which are often distributed in regular and parallel rows. They are found in most abundance in woody plants, and particularly in wood that is firm and compact, like that of the oak; but they do not, like the simple tubes, seem destined to contain any oily or resinous juice.

1384. *Spiral tubes* are fine, transparent, and thread-like substances occasionally interspersed with the other tubes of the plant, but distinguished from them

by being twisted from right to left, or from left to right, in the form of a corkscrew. They occur in most abundance in herbaceous plants, particularly in aquatic.

1385. *False spiral tubes* are tubes apparently spiral on a slight inspection, but which, upon minute examination, are found to derive their appearance merely from their being cut transversely by parallel fissures.

1386. *Mixed tubes* are tubes combining in one individual two or more of the foregoing varieties. Mirbel exemplifies them in the case of the *Butomus unbellatus*, in which the porous tubes, spiral tubes, and false spiral tubes, are often to be met with united in one.

1387. *The small tubes* are tubes composed of a succession of elongated cells united, like those of the cellular tissue. Individually they may be compared to the stem of the grasses, which is formed of several internodia, separated by transverse diaphragms; and collectively to a united assemblage of parallel and collateral reeds.

1388. *Pores* are small and minute openings of various shapes and dimensions, that seem to be destined to the absorption, transmission, or exaltation of fluids. They are distinguishable into perceptible pores and imperceptible pores.

1389. *Gaps*, according to Mirbel, are empty, but often regular and symmetrical, spaces formed in the interior of the plant by means of a partial disruption of the membrane constituting the tubes or utricles. In the leaves of herbaceous plants the gaps are often interrupted by transverse diaphragms formed of a portion of the cellular tissue which still remains entire, as may be seen in the transparent structure of the leaves of *Typha* and many other plants. Transverse gaps are said to be observable also in the bark of some plants, though very rarely.

1390. *There are various appendages* connected with the elementary organs, such as internal glands, internal pubescence, &c.; the latter occurs in dissecting the leaf or flower-stalk of *Nūphar lūta*.

CHAP. III.

Vegetable Chemistry, or Primary Principles of Plants.

1391. *As plants are not merely organised beings, but beings endowed with a species of life*, absorbing nourishment from the soil in which they grow, and assimilating it to their own substance by means of the functions and operations of their different organs, it is plain that no progress can be made in the explication of the phenomena of vegetable life, and no distinct conception formed of the rationale of vegetation, without some specific knowledge of the primary principles of vegetables, and of their mutual action upon one another. The latter requisite presupposes a competent acquaintance with the elements of chemistry; and the former points out the necessity of a strict and scrupulous analysis of the several compound ingredients constituting the fabric of the plant, or contained within it. If the object of the experimenter is merely that of extracting such compound ingredients as may be known to exist in the plant, the necessary apparatus is simple, and the process easy: but if it be that of ascertaining the primary and radical principles of which the compound ingredients are themselves composed, the apparatus is then complicated, and the process extremely difficult, requiring much time and labour, and

much previous practice in analytical research. But whatever may be the object of analysis, or the particular view of the experimenter, the processes which he employs are either mechanical or chemical.

1392. *The mechanical processes* are such as are effected by the agency of mechanical powers, and are often indeed the operation of natural causes; hence the origin of gums and other spontaneous exudations. But the substances thus obtained do not always flow sufficiently fast to satisfy the wants or necessities of man; and men have consequently contrived to accelerate the operations of nature by means of artificial aid in the application of the wimble or axe, widening the passages which the extravasated fluid has forced, or opening up new ones. It more frequently happens, however, that the process employed is wholly artificial, and altogether effected without the operation of natural causes. When the juices are enclosed in vesicles lodged in parts that are isolated or may easily be isolated, the vesicles may be opened by means of rasps or graters, and the juices expressed by the hand, or by some other fit instrument. Thus the volatile oil may be obtained that is lodged in the rind of the lemon. When the substance to be extracted lies more deeply concealed in the plant, or in parts which cannot be easily detached from the rest, it may then become necessary to pound or bruise the whole or a great part of the plant, and to subject it, thus modified, to the action of the press. In this manner seeds are sometimes treated to express their essential oils. If, by the action of bruising or pressing, heterogeneous ingredients have been mixed together, they may generally be separated with considerable accuracy by means of decantation, when the substances held in suspension have been precipitated. Thus the acid of lemons, oranges, gooseberries, and other fruits, may be obtained in considerable purity, when the mucilage that was mixed with them has subsided.

1393. *The chemical processes* are such as are effected by the agency of chemical powers, and may be reduced to the following: distillation, combustion, the action of water, the action of acids and alkalis, the action of oils and alcohols, and lastly fermentation. They are much more intricate in their nature than the mechanical processes, as well as more difficult in their application.

1394. *Of the products of vegetable analysis*, as obtained by the foregoing processes, some consist of several heterogeneous substances, and are consequently *compound*, as being capable of farther decomposition; and some consist of one individual substance only, and are consequently *simple*, as being incapable of further decomposition.

SECT. I. Compound Products.

1395. *The compound products of analysis* are very numerous in themselves, and much diversified in their qualities. They are gum, sugar, starch, gluten, albumen, fibrine, extract, tannin, colouring matter, bitter principle, narcotic principle, acids, oils, wax, resins, gum resins, balsams, camphor, caoutchouc, cork, woody fibre, sap, proper juice, charcoal, ashes, alkalis, earths, and metallic oxides.

1396. *Gum* is an exudation that issues spontaneously from the surface of a variety of plants, in the state of a clear, viscid, and tasteless fluid, that gradually hardens upon being exposed to the action of the atmosphere, and condenses into a solid mass. It issues copiously from many fruit trees, but especially from such as produce stone-fruit, as plum and cherry trees. From plants or parts of plants containing it, but not discharging it by spontaneous exudation, it may be obtained by the process of maceration in water.

1397. *The uses of gum* are considerable. In all its varieties it is capable of being used as an article of food, and is highly nutritive, though not very palatable. It is also employed in the arts, particularly in calico-printing, in which the printer makes choice of it to give consistence to his colours, and to prevent them from spreading. The botanist often uses it to fix his specimens upon paper, for which purpose it is very well adapted. It forms likewise an ingredient in ink; and in medicine it forms the basis of many mixtures, in which its influence is sedative and emollient.

1398. *Sugar* is the produce of the *Saccharum officinarum*. The canes or stems of the plant, when ripe, are bruised between the rollers of a mill, and the expressed juice is collected and put into large boilers, in which it is mixed with a small quantity of quicklime, or strong ley of ashes, to neutralise its acid, and is then made to boil; the scum, which gathers on the top during the process of boiling, being carefully cleared away. When the juice has been boiled down to the consistence of a syrup, it is drawn off and allowed to cool in vessels which are placed above a cistern, and are perforated with small holes through which the impure and liquid part, known by the name of molasses, escapes; while the remaining part is converted into a mass of small and hard granules of a brownish or whitish colour, known by the designation of raw sugar, which when imported into Europe is further purified by an additional process, and converted by filtration or crystallisation into what is called loaf sugar, refined sugar, or candied sugar. The juice of the *Acer saccharinum*, or American maple, yields sugar in such considerable abundance as to make it an object with the North American farmer to manufacture it for his own use. A hole is bored in the trunk of the vegetating tree early in the spring, for the purpose of extracting the sap; of which a tree of ordinary size, that is, of from two to three feet in diameter, will yield from one hundred and fifty to two hundred pints and upwards, in a good season. The sap, when thus obtained and neutralised by lime, deposits, by evaporation, crystals of sugar in the proportion of about a pound of sugar to forty pints of sap. It is not materially different in its properties from that of the sugar-cane. The juice of the grape, when ripe, yields also a sugar by evaporation and the action of potashes, which is known by the appellation of the sugar of grapes, and has lately been employed in France as a substitute for colonial sugar, though it is not so sweet or agreeable to the taste. The root of *Beta vulgaris*, or common beet, yields also, by boiling and evaporation, a sugar which is distinguished by a peculiar and slightly bitter taste, owing perhaps to the presence of a bitter extractive matter which has been found to be one of the constituents of the beet. Sugar has been extracted from the following vegetables also, or from their productions: from the sap of the birch, sycamore, bamboo, maize, parsnep, cow-paranep, American aloë, dulse, walnut tree, and cocoa-nut tree; from the fruit of the common arbutus, and other sweet-tasted fruits; from the roots of the turnip, carrot, and parsley; from the flower of the *Euixine rhododendron*; and from the nectary of most other flowers.

1399. *The utility of sugar*, as an aliment, is well known; and it is as much relished by many animals as by man. By bees it is sipped from the flowers of plants, under the modification of nectar, and converted into honey; and also seems to be relished by many insects, even in its concrete state; as it is also by many birds. By man it is now regarded as being altogether indispensable, and though used chiefly to give a relish or seasoning to food, is itself highly nutritive. It is also of much utility in medicine, and celebrated for its anodyne and antiseptic qualities, as well as thought to be peculiarly efficacious in preventing diseases by worms.

1400. *Starch*. If a quantity of wheat flour is made into a paste with water, and kneaded and washed under the action of a jet, till the water runs off colourless, part of it will be found to have been taken up and to be still held in suspension by the water, which will, by and by, deposit a sediment that may be separated by decantation. This sediment is starch, which may be obtained also immediately from the grain itself, by means of a process well known to the manufacturer, who renders it finally fit for the market by washing and edulcorating it with water, and afterwards drying it by a moderate heat. Starch,

when thrown upon red-hot iron, burns with a kind of explosion, and leaves scarcely any residuum behind. It has been found, by the analysis of Gay Lussac and Thenard, to be composed of carbon 43.55; oxygen 49.68; hydrogen 6.77; total 100. This result is not very widely different from that of the analysis of sugar, into which, it seems, starch may be converted by diminishing the proportion of its carbon, and increasing that of its oxygen and hydrogen. This change is exemplified in the case of the malting of barley, which contains a great proportion of starch, and which absorbs during the process a quantity of oxygen, and evolves a quantity of carbonic acid; and accordingly part of it is converted into sugar. Perhaps it is exemplified also in the case of the freezing of potatoes, which acquire in consequence a sweet and sugary taste, and are known to contain a great deal of starch, which may be obtained as follows. Let the potatoes be taken and grated down to a pulp, and the pulp placed upon a fine sieve, and water made to pass through it; the water will be found to have carried off with it an infinite number of particles, which it will afterwards deposit in the form of a fine powder, separable by decantation; which powder is starch, possessing all the essential properties of wheat starch. It may be obtained from the pith of several species of palms growing in the Moluccas and several other East India islands, by the following process: the stem, being first cut into pieces of five or six feet in length, is split longitudinally so as to expose the pith, which is now taken out and pounded, and mixed with cold water, which, after being well stirred up, deposits at length a sediment that is separated by decantation, and is the starch which the pith contained, or the sago of the shops.

1401. *Stalop* is also a species of starch that is prepared, in the countries of the East, from the root of the *O'rchis mörbo*, *mäsula*, *bifolia*, and *pyramidalis*; and, in the Isle of Portland, from the *A'rum maculatum*. So also is *assava*, which is prepared from the root of *Jünipha Männhot*, a native of America, the expressed juice of which is a deadly poison used by the Indians to poison their arrows; but the sediment which it deposits is a starch that is manufactured into bread, retaining nothing of the deleterious property of the juice. So also is *sowans*, which is prepared from the husk of oats, as obtained in the process of grinding.

1402. *Starch* may be extracted from a number of plants; as *A'rcetium Läpps*, *A'tropa Belladöna*, *Polypogonum bistörta*, *Bryonia alba*, *Cölcichium autumnäle*, *Spiræa Filipéndula*, *Ranunculus bulbosus*, *Scrophularia nodosa*, *Sambucus E'tulus* and *nigra*, *O'rchis mörbo* and *mäsula*, *Imperatoria Ostruthium*, *Hyoöcyamus nigler*, *Rumex obtusifolius*, *acutus*, and *aquaticus*, *A'rum maculatum*, *M'ris Pseudacorus* and *fetidissima*, *O'robus tuberosus*, and *Bunium Bulbocastanum*. It is found also in the following seeds: wheat, barley, oats, rice, maize, millet seed, chestnut, horsechestnut, peas, beans, and acorns.

1403. *Starch* is an extremely nutritive substance, and forms one of the principal ingredients in almost all articles of vegetable food used by man or by the inferior animals. The latter feed upon it in the state in which nature presents it; but man prepares and purifies it so as to render it pleasing to his taste, and uses it under the various modifications of bread, pastry, and confectionary. Its utility is also considerable in medicine and in the arts; in the preparation of nodyne and strengthening medicaments; in the composition of cements; in the clearing and stiffening of linen; and in the manufacture of hair-powder.

1404. *Gluten* is that part of the paste formed from the flour of wheat, which remains unaffected by the water, after all the starch contained in it has been washed off. It is a tough and elastic substance, of a dull white colour, without taste, but of a very peculiar smell. It is soluble in the acids and alkalies, but insoluble in water and in alcohol. Gluten has been detected, under one modification or other, in a very considerable number of vegetables or vegetable substances, as well as in the flour of wheat.

1405. *Gluten* is one of the most important of all vegetable substances, as being the principle that renders the flour of wheat so fit for forming bread, by its occasioning the panary fermentation, and making the bread light and porous. It is used also as a cement, and is capable of being used as a varnish and a ground for paint.

1406. *Albumen*, which is a thick, glairy, and tasteless fluid, resembling the white of an unboiled egg, is a substance that has been but lately proved to exist in the vegetable kingdom. Its existence was first announced by Fourcroy, and finally demonstrated by the experiments of Vauquelin on the dried juice of the papaw tree. It is nearly related to animal gluten.

1407. *Fibrine* is a peculiar substance which chemists extract from the blood and muscles of animals. This substance constitutes the fibrous parts of the muscles, and resembles gluten in its appearance and elasticity. A substance possessing the same properties has been detected by Vauquelin in the juice of the papaw tree, which is called vegetable fibrine.

1408. *Extract*. When vegetable substances are macerated in water, a considerable portion of them is dissolved; and if the water is again evaporated, the substance held in solution may be obtained in a separate state. This substance is denominated extract. But it is evident that extract thus obtained will not be precisely the same principle in every different plant, but will vary in its character according to the species producing it, or the soil in which the plant has grown, or some other accidental cause. Its distinguishing properties are the following:— It is soluble in water, as it is obtained from the vegetable, but becomes afterwards insoluble in consequence of the absorption of oxygen from the atmosphere. It is soluble in alcohol; and it unites with alkalies, and forms compounds which are soluble in water. When distilled it yields an acid fluid impregnated with ammonia, and seems to be composed principally of hydrogen, oxygen, carbon, and a little nitrogen. Extract, or the extractive principle, is found in a greater or less proportion in almost all plants whatever, and is very generally an ingredient of the sap and bark, particularly in barks of an astringent taste; but still it is not exactly the same in all individual plants, even when separated as much as possible from extraneous substances. It may therefore be regarded as constituting several species, of which the following are the most remarkable:—

1409. *Extract of catechu*. This extract is obtained from an infusion of the wood or powder of catechu in cold water. Its colour is pale brown; and its taste slightly astringent. It is precipitated from its solution by nitrate of lead, and yields by distillation carbonic and carburetted hydrogen gas, leaving a porous charcoal.

1410. *Extract of senna*. This extract is obtained from an infusion of the dried leaves of *Cassia Senna* in alcohol. The colour of the infusion is brownish, the taste slightly bitter, and the smell aromatic. It is precipitated from its solution by the muriatic and oxymuriatic acids; and, when thrown on burning coals, consumes with a thick smoke and aromatic odour, leaving behind a spongy charcoal.

1413. *Extracts were formerly much employed in medicine*; though their efficacy seems to have been overrated. But a circumstance of much more importance to society is that of their utility in the art of dyeing. By far the greater part of colours used in dyeing are obtained from vegetable extracts, which have a strong affinity to the fibres of cotton or linen, with which they enter into a combination that is rendered still stronger by the intervention of mordants.

1414. *Colouring matter*. The beauty and variety of the colouring of vegetables, chemists have ascribed to the modifications of a peculiar substance which they denominate the colouring principle, and which they have accordingly endeavoured to isolate and extract; first, by means of maceration or boiling in water, and then by precipitating it from its solution. The chemical properties of colouring matter seem to be as yet but imperfectly known, though they have been considerably elucidated by the investigations of Berthollet, Chaptal, and others. Their affinities to oxygen, alkalies, earths, metallic oxides, and cloths fabricated of animal or vegetable substances, such as wool or flax, seem to be among its most striking characteristics. But its affinity to animal substances is stronger than its affinity to vegetable substances;

1411. *Extract of quinquina*. This extract was obtained by Fourcroy, by evaporating a decoction of the bark of the quinquina of St. Domingo in water, and again dissolving it in alcohol, which finally deposited by evaporation the peculiar extractive. It is insoluble in cold water, but very soluble in boiling water; its colour is brown, and its taste bitter. It is precipitated from its solution by lime water in the form of a red powder; and when dry it is black and brittle, breaking with a polished fracture.

1412. *Extract of saffron*. This extract is obtained in great abundance from the summits of the pistils of *Crocus sativus*, which are almost wholly soluble in water.

and hence wool and silk assume a deeper dye, and retain it longer, than cotton or linen. Colouring matter exhibits a great variety of tints, as it occurs in different species of plants; and as it combines with oxygen, which it absorbs from the atmosphere, it assumes a deeper shade; but it loses at the same time a portion of its hydrogen, and becomes insoluble in water; and thus it indicates its relation to extract. Fourcroy reduced colours to the four following sorts: extractive colours, oxygenated colours, carbonated colours, and hydrogenated colours; the first being soluble in water, and requiring the aid of saline or metallic mordants to fix them upon cloth; the second being insoluble in water, as altered by the absorption of oxygen, and requiring no mordant to fix them upon cloth; the third containing in their composition a great proportion of carbon, but soluble in alkalies; and the fourth containing a great proportion of resin, but soluble in oils and alcohol. But the simplest mode of arrangement is that by which the different species of colouring matter are classed according to their effect in the art of dyeing. The principal and fundamental colours in this art are the blue, the red, the yellow, and the brown.

1415. *The finest of all vegetable blues* is that which is known by the name of indigo. It is the produce of the *Indigofera tinctoria* Lin., a shrub which is cultivated in Mexico and the East Indies for the sake of the dye it affords. The plant reaches maturity in about six months, when its leaves are gathered and immersed in vessels filled with water till fermentation takes place. The water then becomes opaque and green, exhaling an odour like that of volatile alkali, and evolving bubbles of carbonic acid gas. When the fermentation has been continued long enough, the liquid is decanted and put into other vessels, where it is agitated till blue flakes begin to appear. Water is now poured in, and flakes are precipitated in the form of a blue powdery sediment, which is obtained by decantation; and which, after being made up into small lumps and dried in the shade, is the indigo of the shops. It is insoluble in water, though slightly soluble in alcohol; but its true solvent is sulphuric acid, with which it forms a fine blue dye, known by the name of liquid blue. It affords by distillation carbonic acid gas, water, ammonia, some oily and acid matter, and much charcoal; whence its constituent principles are most probably carbon, hydrogen, oxygen, and nitrogen. Indigo may be procured also from several other plants besides *Indigofera tinctoria*, and particularly from *Jussia tinctoria* or woad, a plant indigenous to Britain, and thought to be the plant with the juice of which the ancient Britons stained their naked bodies, to make them look terrible to their enemies. If this plant is digested in alcohol, and the solution evaporated, white crystalline grains, somewhat resembling starch, will be left behind; which grains are indigo, becoming gradually blue

by the action of the atmosphere. The blue colour of indigo, therefore, is owing to its combination with oxygen.

1416. *The principal red colours* are such as are found to exist in the root, stem, or flower, of the five following plants: *Rubia tinctorum*, *Roseella tinctoria*, *Lecanora parellis*, *Carthamus tinctorius*, *Cassipouia crista*, and *Hemastizylon campechianum*.

1417. *Yellow*, which is a colour of very frequent occurrence among vegetables, and the most permanent among flowers, is extracted for the purpose of dyeing, from a variety of plants. It is extracted from the *Reseda luteola* L., by the decoction of its dried stems. The colouring matter is precipitated by means of alum, and is much used in dyeing wool, silk, and cotton. It is also obtained from the *Morus tinctoria*, *Bixa Orellana* or annatto, *Serratula tinctoria*, *Genista tinctoria*, *Rhus Cotinus*, *Rhadinus infectarius*, and *Quercus tinctoria*, or quercitron, the bark of which last affords a rich and permanent yellow at present much in use.

1418. *The brown colouring matter of vegetables* is very abundant, particularly in astringent plants. It is obtained from the root of the walnut tree, and rind of the walnut; and also from the sumach and alder, but chiefly from nut-galls, which are excrecences formed upon the leaves of a species of *Quercus*, indigenous to the south of Europe, in consequence of the puncture of insects. The best in quality are brought from the Levant. They are sharp and bitter to the taste, and extremely astringent; and soluble in water by decoction when ground or grated to a powder. The decoction strikes, with the solution of iron, a deep black, that forms the basis of ink, and of most dark colours used in dyeing cloths.

1419. *Tannin*. If a quantity of pounded nut-galls, or bruised seeds of the grape, is taken and dissolved in cold water, and the solution evaporated to dryness, there will be left behind a brittle and yellowish substance of a highly astringent taste, which substance is tannin, or the tanning principle. It is soluble both in water and alcohol, but insoluble in ether. With the salts of iron it strikes a black; and when a solution of gelatine is mixed with an aqueous solution of tannin, the tannin and gelatine fall down in combination, and form an insoluble precipitate. When tannin is subjected to the process of distillation, it yields charcoal, carbonic acid, and inflammable gases, with a minute quantity of volatile alkali, and seems accordingly to consist of the same elements with extract, from which, however, it is distinguished by the peculiar property of its action upon gelatine. Tannin may be obtained from a great variety of other vegetables also, as well as those already enumerated, but chiefly from their bark; and of barks, chiefly from those that are astringent to the taste. The following table exhibits a general view of the relative value of different species of bark, as ascertained by Sir Humphry Davy. It gives the average obtained from 480 lbs. of the entire bark of a middle-sized tree of the different species, taken in the spring, when the quantity of tannin is the largest: —

	lb.		lb.		lb.
Oak	29	Beech	10	Blackthorn	16
Spanish chestnut	21	Horsechestnut	9	Coppice oak	32
Leicester willow (large)	18	Sycamore	11	Juniper	73
Elm	13	Lombardy poplar	16	Oak cut in autumn	21
Common willow (large)	11	Birch	8	Larch cut in autumn	8
Ash	16	Hazel	14		

1420. *Tannin is of the very first utility in its application to medicine and the arts*; being regarded by chemists as the general principle of astringency. The medical virtues of Peruvian bark, so celebrated as a febrifuge and antiseptic, are supposed to depend upon the quantity and purity of its tannin. In consequence of its peculiar property of forming an insoluble compound with gelatine, the hides of animals are converted into leather, by the important art of tanning. The bark of the oak tree, which contains tannin in great abundance, is that which is most generally used by the tanner. The hides to be tanned are prepared for the process by steeping them in lime water, and scraping off the hair and cuticle. They are then soaked, first in weaker and afterwards in stronger infusions of the bark, till at last they are completely impregnated. This process requires a period of from ten to eighteen months, if the hides are thick; and four or five pounds of bark are necessary on an average to form one pound of leather.

1421. *Bitter principle*. The taste of many vegetables, such as those employed in medicine, is extremely bitter. The quassia of the shops, the roots of the common gentian, the bark and wood of common broom, the calyx and floral leaves of the hop, and the leaves and flowers of chamomile, may be quoted as examples. This bitter taste has been thought to be owing to the presence of a peculiar substance, different from every other vegetable substance, and has been distinguished by the name of the bitter principle. When water has been digested for some time over quassia, its colour becomes yellow, and its taste intensely bitter; and if it is evaporated to dryness, it leaves behind a substance of a brownish yellow, with a slight degree of transparency, that continues for a time ductile, but becomes afterwards brittle. This substance Dr. Thompson regards as the bitter principle in a state of purity. It is soluble in water and in alcohol; but the solution is not much affected by re-agents. Nitrate of silver and acetate of lead are the only two that occasion a precipitate. The bitter principle is of great importance, not only in the practice of medicine, but also in the art of brewing; its influence being that of checking fermentation, preserving the fermented liquor, and when the bitter of the hop is used, communicating a peculiar and agreeable flavour. The bitter principle appears to consist principally of carbon, hydrogen, and oxygen, with a little nitrogen.

1422. *Narcotic principle*. There is a species of medical preparations known by the name of narcotics, which have the property of inducing sleep; and, if administered in large doses, of occasioning death. They are obtained from the milky and proper juices of some vegetables, and from the infusion of the leaves or stem of others, all which have been supposed to contain in their composition some common ingredient, which chemists have agreed to designate by the name of the narcotic principle. It exists in great abundance in opium, which is the concrete juice of *Papaver somniferum* var. *album*, or the white poppy, from which it is obtained pure, in the form of white crystals. It is soluble in boiling water and in alcohol, as well as in all acid menstrua; and it appears that the action of opium on the animal subject depends on this principle. When distilled it emits white vapours, which are condensed into a yellow oil; some water and carbonate of ammonia pass into a receiver; and at last carbonic acid gas, ammonia, and carburetted hydrogen are disengaged, and a bulky charcoal left behind. Many other vegetable substances

besides opium possess narcotic qualities though they have not yet been minutely analysed. The following are the most remarkable:—The inspissated juice of lettuce, which resembles opium much in its appearance, is obtained by the same means, and possesses the same medical virtues; the leaves of *A. tropa Belladonna*, or deadly nightshade, and indeed the whole plant; the leaves of *Digitalis purpurea*, or foxglove, and lastly, the following plants, *Hyoscyamus niger*, *Conium maculatum*, *Datura Stramonium*, and *Zedum palustre*, with many others belonging to the Linnean natural order of *Liliada*.

1423. *Acids*. Acids are a class of substances that may be distinguished by their exciting on the palate the sensation of sourness. They exist not only in the animal and mineral, but also in the vegetable kingdom; and such of them as are peculiar to vegetables have been denominated vegetable acids. Of acids peculiar to vegetables chemists enumerate the following: the oxalic, acetic, citric, malic, gallic, tartaric, benzoic, and prussic, which exist ready formed in the juices or organs of the plant, and are accordingly denominated native acids; together with the mucous, pyromucous, pyrotartarous, pyrolignous, camphoric, and suberic, which do not exist ready formed in the plant, and are hence denominated artificial acids. They are consequently not within the scope of the object of the present work.

1424. *Oxalic acid*. If the expressed juice of the *Oxalis Acetosella* is left to evaporate slowly, it deposits small crystals of a yellowish colour and saltish taste, which are known by the name of the acidulum of sorrel, and which exist with excess of acid, from which the acid may be obtained pure by processes well known to the chemist. It is not used in medicine or the arts, except in its state of acidulum, in which it is employed to make a sort of lemonade, and to dissolve stains of ink. It has been found also in *Oxalis corniculata*, *Peltargonium didymum*, in the several species of *Fumex*, and in the pubescence of *Cloer aristatum*.

1425. *Acetic acid*. The acetic acid, or vinegar, which is generally manufactured from wine in a certain stage of fermentation, has been found also ready formed in the sap of several trees, as analysed by Vauquelin; and also in the acid juice of the *Cloer aristatum*, of which it forms a constituent part. It was obtained by Scheele from the sap of the *Sambucus nigra*; and is consequently to be regarded as a native vegetable acid. It is distinguished from other vegetable acids by its forming soluble salts with the alkalis and earths.

1426. *Citric acid*. Citric acid is the acid which exists in the juice of lemon. Its taste is very sour in a state of purity, but exceedingly pleasant when diluted with water. By a red heat it yields carbonic acid gas and carbonated hydrogen gas, and is reduced to a charcoal, nitric acid converts it into oxalic and acetic acid, and with lime it forms a salt insoluble in water. It has been found unmixed with other acids in the following vegetable substances: in the juice of oranges and lemons, and in the berries of *Citric acid*, *Ficus Indica*, *Ficus Vespa*, *Cerasus Fildus*, *Solanum Dulcamara*, and *Rosa canina*. It has been found also in many other fruits, mixed with other acids.

1427. *Malic acid*. Malic acid is found chiefly in the juice of unripe apples, whence it derives its name; but it is found also in the juice of barberries, elderberries, gooseberries, plums, and common house-leek.

1428. *Gallic acid*. Gallic acid, as it is obtained in the greatest abundance, so it derives its name, from the nut-gall, from which it may be extracted by exposing a quantity of the powder of nut-galls to a moderate heat in a glass retort; when the acid will sublime and form crystals of an octahedral figure. Its taste is austere and astringent. It strongly reddens vegetable

blues. It is soluble both in water and alcohol; and is distinguished by its property of communicating to solutions of iron a deep purple colour. When exposed to a gentle heat it sublimes without alteration, but a strong heat decomposes it. Nitric acid converts it into the malic and oxalic acids. It is of great utility in the art of dyeing, and forms the basis of all black colours, and of colours with a dark ground. It forms also the basis of ink; and chemists use it as a test to detect the presence of iron.

1429. *Tartaric acid*. If wine is kept for a length of time in a cask or other close vessel, a sediment is precipitated which adheres to the sides or bottom, and forms a crust known by the name of tartar, which is a combination of potash and a peculiar acid in excess. The compound is tartarate of potash, and the acid, in its state of purity, is the tartaric acid. It is characterized by its property of forming with potash a salt that is soluble with difficulty. It has been found in the following vegetable substances also: in the pulp of tamarinds, in the juice of the grape, and mulberries, sorrel, and sumach, and the roots of *Agropyrum repens* and *Lactodon Taraxacum*. It does not occur used except among chemists; but the tartarate, from which it is usually obtained, is well known for its medical virtues under the name of cream of tartar.

1430. *Benzoic acid*. From the *Styrax Benzin* there exudes a resinous substance, known in the shops by the name of benzoin, and in which the benzoic acid is contained. It is distinguished from the other acids by its aromatic odour and extreme volatility. It has been obtained also from the balsams of tolu and storax; and is used in pharmacy, in the preparation of boluses and electuaries.

1431. *Prussic acid*. The prussic acid is generally classed among the animal acids; because it is obtained in the greatest abundance from animal substances. But it has been proved to exist in vegetable substances also, and it is procured by distilling laurel leaves, or the kernels of the peach and cherry, or bitter almonds. When pure, it exists in the form of colourless fluid, with an odour resembling that of peach tree blossoms. It does not reddens vegetable blues; but it is characterised by its property of forming a bluish-green precipitate, when it is poured, with a little alkali added to it, into solutions containing iron.

1432. *All vegetable acids contain carbon, oxygen, and hydrogen, in one proportion or other; and the prussic acid contains also a portion of nitrogen.* The gallic acid contains more of carbon than any other vegetable acid, and the oxalic more of oxygen.

1433. *Vegetable oils are of two kinds, the fixed and the volatile.* The former are not suddenly affected by the application of heat; the latter are very inflammable.

1434. *Fixed oils*. Fixed oils are but seldom found, except in the seeds of plants, and chiefly in such as are dicotyledonous. They are found also, though rarely, in the pulp of fleshy fruits, as in that of the olive, which yields the most abundant and valuable species of all fixed oils. But dicotyledonous seeds, which contain oil, contain also at the same time a quantity of mucilage and fecula, and for, when bruised in water, a mild and milky fluid, known by the name of emulsion; and on this account they are sometimes denominated emulsive seeds. Some seeds yield their oil merely by means of pressure, though it is often necessary to reduce them first of all to a sort of pulp, by means of pounding them in a mortar: others require to be exposed to the action of heat (which is applied to them by means of pressure between warm plates of tin,) or of the vapour of boiling water, or of roasting, before they are subjected to the press. Fixed oil, when pure, is generally a thick and viscous fluid, of a mild or insipid taste, and without smell; but it is never entirely without some colour, which is for the most part green or yellow. Its specific gravity is to water as 9403 or 1000. It is insoluble in water; it is decomposed in the acids, but with the alkalis it forms soap. When exposed to the atmosphere it becomes inspissated and opaque, and assumes a white colour and a resemblance to fat. This is in consequence of the absorption of oxygen; but owing to the appearance of a quantity of water in oil that is exposed to the action of the air, it has been thought that the oxygen absorbed by it is not yet perhaps assimilated to its substance. When exposed to cold it congeals and crystallises, or assumes a solid and granular form; but not till the thermometer has indicated a degree considerably below the freezing point. When exposed to the action of heat it is not volatilised till it begins to boil, which is at 600° of Fahrenheit. By distillation it is converted into water, carbonic acid, and carburetted hydrogen gas, and charcoal; the product of its combustion is nearly the same; and hence it is a compound of carbon, oxygen, and hydrogen. Fixed oils are generally divided into two sorts, fat oils and drying oils. The former are readily inspissated by the action of the air, and converted into a sort of fat. The latter are capable of being dried by the action of the air, and converted into a firm and transparent substance.

1435. *The principal species of fat oils are the following:—*

1436. *Olive oil*, which is expressed from the pulpy part of the fruit of *Olea europæa*. The fruit is first broken in a mill, and reduced to a sort of paste. It is then subjected to the action of a press, and the oil, which is now easily separated, swims on the top of the water in the vessel beneath. It is manufactured chiefly in France and Italy, and is much used throughout Europe instead of butter, and to give a seasoning to food.

1437. *Oil of almonds*, which is extracted from the fruit of the *Almondalus communis* or common almond. The almonds are first well rubbed or shook in a coarse bag or sack, to separate a bitter powder which covers their epidermis. They are then

pounded in mortars of marble into a paste, which is afterwards subjected to the action of the press; and the oil is now obtained as in the olive.

1438. *Rapeseed oil*, which is extracted from the *Brassicæ Napus* and campestris. It is less fixed and less liable to become rancid than the two preceding, and is manufactured chiefly in Flanders.

1439. *Oil of lehen*, which is extracted from the fruit of the *Moringa pterygosperma*, common in Egypt and Africa. It is apt to become rancid; but it is without odour, and is on this account much used in perfumery.

1440. *The principal species of drying oils are linsced oil, nut oil, poppy oil, and hempseed oil.*

1441. *Lined oil* is obtained from the seeds of flax, which are generally roasted before they are subjected to any other process, for the purpose of drying up their mucilage and separating more oil.

1442. *Nut oil* is extracted from the fruit of *Corylus Avellana*, or *Juglans regia*. The kernel is first slightly roasted, and the oil then expressed. It is used in paintings of a coarser sort; and also in the seasoning of food, by many of the inhabitants of the middle departments of France; but it is apt to become rancid.

1445. *Volatile oils*. Volatile oils, which are known also by the name of essential oils, are of very common occurrence in the vegetable kingdom, and are found in almost all the different organs of the plant. They are found in many roots, to which they communicate a fragrant and aromatic odour, with a taste somewhat acrid. The roots of *Coriaria Helænum*, *Genista canariensis*, and various other plants, contain essential oils. They are found also in the bark of *Cinnabrum verum*, of *Laurus Sassafras*, and of *Pinus*; and in the leaves of labiate plants, such as mint, rosemary, marjoram; of the odorous Umbelliferae, such as acherville, fennel, angelica; and of plants which compound flowers, such as wormwood. They are found also in the flower itself, as in the flowers of chamomile, and the rose; in the fruit, as in that of pepper and ginger; and in the external integuments of many seeds, but never in the cotyledon. They are extracted by means of expression or distillation, and are extremely numerous, and perhaps every plant possessing a peculiar odour possesses also a peculiar and volatile oil. The aroma of plants, therefore, or the substance from which they derive their odour, and which is cognisable only to the sense of smell, is perhaps merely the more volatile and evaporable part of their volatile oil, disengaging itself from its combinations. Volatile oils are characterised by their strong and aromatic odour, and rather acrid taste. They are soluble in alcohol, but are not readily converted into soaps by alkalies. They are very inflammable, and are volatilised by a gentle heat. Like fixed oils, their specific gravity is generally less than that of water, on the surface of which they will float; though in some cases it is found to be greater than that of water, in which they consequently sink. They are much in request on account of their agreeable taste and odour, and are prepared and sold by apothecaries and perfumers, under the name of distilled waters or essences; as well as employed also in the manufacture of varnishes and pigments.

1446. *Wax*. On the upper surface of the leaves of many trees there may often be observed a sort of varnish, which, when separated by certain chemical processes, is found to possess all the properties of bees' wax, and is consequently a vegetable wax. It exudes, however, from several other parts of the plant besides the leaf, and assumes a more waxy and concrete form, as from the catkins of the poplar, the alder, and the fir; from the fruit of the *Myrica cerifera* and *Stillingia sebifera*; but particularly from the antheræ of the flowers, from which it is probable that the bees extract it unaltered. It was the opinion of Reaumur, however, that the pollen undergoes a digestive process in the stomach of the bee before it is converted into wax, though a late writer on the subject endeavours to prove that the wax is elaborated from the honey extracted by the bee, and not from the pollen. It is found also in the interior of many seeds, from which it is extracted, by means of pounding them and boiling them in water. The wax is melted and swims on the top. Wax, when pure, is of a whitish colour, but without taste and without smell. The smell of bees' wax is indeed somewhat aromatic, and its colour yellow: but this is evidently owing to some foreign substance with which it is mixed; because it loses its smell and colour by means of bleaching, and becomes perfectly white. This is done merely by drawing it out into thin stripes, and exposing it for some time to the atmosphere. Bleached wax is not affected by the air. Its specific gravity is 0.9600. It is insoluble in water and in alcohol. It combines with the fixed oils, and forms with them a composition known by the name of cerate. It combines also with the fixed alkalies, and forms with them a compound possessing the properties of common soap. The acids have but little action on it, and for this reason it is useful as a lute to confine them, or to prevent them from injuring cork. When heat is applied to wax it becomes soft, and melts at the temperature of 145° if unbleached, and of 155° if bleached, into a colourless and transparent fluid, which, as the temperature diminishes, concretes again and resumes its former appearance. At a higher temperature it boils and evaporates, and the vapour may be set on fire by the application of red heat; hence its utility in making candles, and hence an explication of the singular phenomenon observable in the *Dictamnus Fraxinella*. This plant is fragrant, and the odour which it diffuses around forms a partial and temporary atmosphere, which is inflammable; for if a lighted candle or other ignited body is brought near to the plant, especially in the time of drought, its atmosphere immediately takes fire. This phenomenon was first observed by the daughter of the celebrated Linnæus, and is explained by supposing the partial and temporary atmosphere to contain a proportion of wax exuded from the plant, and afterwards reduced to vapour by the action of the sun. The result of its combustion in oxygen gas was, according to Lavoisier, carbonic acid and water, in such proportion as to lead him to conclude that 100 parts of wax are composed of 82.28 of carbon and 17.72 of hydrogen; but, owing to the little action of acids upon it, there seems reason to believe that it contains also oxygen as an ingredient.

1447. *Wax possesses all the essential properties of a fixed oil*; and fixed oils have the property of becoming concrete, and of assuming a waxy appearance when long exposed to the air, in consequence, as it seems, of the absorption of oxygen. Wax therefore may be considered as a fixed oil rendered concrete, perhaps by the absorption of oxygen during the progress of vegetation. But if this theory is just, the wax may be expected to occur in a considerable variety of states according to its degrees of oxygenation; and this is accordingly the case. Sometimes it has the consistency of butter, and is denominated butter of wax, as butter of cocoa, butter of galam. Sometimes its consistency is greater, and then it is denominated tallow, as tallow of croton; and when it has assumed its last degree of consistency, it then takes the appellation of wax. The following are its principal species: butter of cocoa, butter of cocoa, butter of nutmeg, tallow of croton, and wax of myrtle.

1448. *The butter of cocoa* is extracted from the seeds of the *Theobroma Cacao* or chocolate plant, either by boiling them in water, or by subjecting them to the action of the press after having exposed them to the vapour of boiling water.

1449. *Butter of cocoa* is found in the fruit of *Coccoloba nucifera* or cocoa-nut tree. It is expressed from the pulp of the nut, and is even said to separate from it when in a fluid state, as cream separates from milk.

1453. *Resins*. Resins are volatile oils rendered concrete by means of the absorption of oxygen, or rather perhaps by the abstraction of part of their hydrogen. They have a slight degree of transparency, and their colour is generally yellowish. Their taste is somewhat acrid; but they are without smell when pure. Their specific gravity varies from 1.0180 to 1.2389. They are non-conductors of electricity, and when excited by friction their electricity is negative. The species of resins are numerous.

1454. *Resin* is a species of resin, of which there are several varieties. From different species of the pine, larch, and fir tree, there exudes a juice which concretes in the form of tears. Its extrication is generally aided by means of incisions, and it receives different appellations, according to the species from which it is obtained. If it is obtained from the *Pinus sylvestris*, it is denominated *common turpentine*; from *Abies europæa*, *Venice turpentine*; from *Abies toxicaria*, *bitumen of Canada*. This juice consists of two ingredients, oil of turpentine and resin. The oil is extricated by distillation, and the resin remains behind. If the distilled oil is continued to dryness, the residuum is *common resin* or *colophonian*; but if water

1445. *Poppy oil* is extracted from the seeds of *Papaver somniferum*, which is cultivated in France and Holland for this purpose. It is clear and transparent, and dries readily; and when pure it is without taste or odour. It is used for the same purposes as the olive oil, for which it is often sold, and possesses nothing of the narcotic properties of the poppy.

1444. *Hempseed oil* is extracted from the seed of the hemp. It has a harsh and disagreeable taste, and is used by painters in this country, and very extensively for food in Russia.

1450. *Butter of nutmeg* is obtained from the seeds of the *Myristica officinalis*, or nutmeg tree.

1451. *Tallow of croton* is obtained from the fruit of the *Stillingia sebifera*.

1452. *The wax of myrtle* is obtained from the berry of the *Myrica cerifera*.

is mixed with it while yet fluid, and incorporated by violent agitation, the residuum is *yellow resin*. The yellow resin is the most ductile, and the most generally used in the arts.

1455. *Pitch and tar* are manufactured from the resinous juices of the fir. The trunk is cut or cleft into pieces of a convenient size, which are piled together in heaps, and covered with turf. They are then set on fire, and the resinous juice which is thus extricated, being prevented from escaping in a volatile state by means of the turf, is precipitated and collected in a vessel beneath. It is partly converted into an empyreumatic acid, and is now in tar, which, by being further imbibed, is converted into pitch.

1456. *Mastic* is extracted from the *Pistacia Lentiscus*.
 1457. *Sindura* is obtained from the *Juniperus communis*, by spontaneous exudation.
 1458. *Elemi* is extracted from the *Amryris elemifera*.
 1459. *Tucasobac* is the produce of the *Fugaria octandra* and *Poppulus balsamifera*.
 1460. *Lobdanum* is obtained from the *Cistus creticus*.
 1461. *Opobalsamum*, or *balm of Gilead*, which has been so much famed for its medical virtues, is the produce of the *Balsamodendron gileadense*, a shrub which grows in Judæa and in Arabia; but it is so much valued by the Turks that its importation is prohibited. This is the balm of Gilead so much celebrated in Scripture. Pliny says it was first brought to Rome by the generals of Vespasian. It is obtained in a liquid state from incisions made in the bark, and is somewhat bitter to the taste.
 1462. *Copraiva*, or *balsam of copaitiva* is obtained from the *Copaffera officinalis*.
 1463. *Dragon's blood* is obtained from the *Dracæ-na draco*, *Pterocarpus draco*, and *Citimus Rotang*.
 1464. *Guaicac* is the produce of the *Guaicacum officinale*.
 1465. *Dotany Bay resin*, the produce of the *Eucalyptus resinifera*, a native of New Holland, and found in great abundance about Botany Bay.
 1466. *Greca resin* constitutes the colouring matter of the leaves

1471. *The use of resins in the arts is very considerable; but their medical virtues are not quite so great as has been generally supposed. They are employed in the arts of painting, varnishing, embalming, and perfumery; and they furnish us with two of the most important of all materials to a naval power, pitch and tar.*

1472. *Gum-resins.* This term is employed to denote a class of vegetable substances, which have been regarded by the ancients as consisting of gum and resin. They are generally contained in the proper vessels of the plant, whether in the root, stem, branches, leaves, flowers, or fruit. But there is this remarkable difference between resins and gum-resins, that the latter have never been known, like the former, to exude spontaneously from the plant. They are obtained by means of bruising the parts containing them, and expressing the juice, which is always in the state of an emulsion, generally white, but sometimes of a different colour; or they are obtained by means of incisions from which the juice flows. This juice, which is the proper juice of the plant, is then exposed to the action of the sun, by which, in warm climates, it is condensed and inspissated, and converted into the gum-resin of commerce. Gum-resins, in their solid state, are brittle, and less transparent than resins. They have generally a strong smell, which is sometimes alliaceous, and a bitter and nauseous taste. They are partially soluble both in water and in alcohol. When heated, they do not melt like the resins, nor are they so combustible; but they swell and soften by heat, and at last burn away with a flame. By distillation they yield volatile oil, ammonia combined with an acid, and have a bulky charcoal. The principal species of gum-resins which have been hitherto applied to any useful purpose are:—

1473. *Galbanum*, obtained from the stem of the *Bibon galbanum*.
 1474. *Annoniacæ*, brought from Africa, in the form of small tears; the plant which yields it is thought to be a species of *Férula*.
 1475. *Scammony*, the produce of the *Convolvulus Scammonia*.
 1476. *Opoponax*, obtained from the *Pastinaca opopanax*.
 1477. *Zuphorbium*, the produce of the *Euphorbia officinalis*. Its taste is caustic; it is considered as a poison, but is occasionally employed in medicine.
 1478. *Olibanum* is obtained from the *Boswellia serrata*, which grows in Arabia, particularly by the borders of the Red Sea. It is the frankincense of the ancients. It exudes from incisions made in the tree, and concretes into masses about the size of a chestnut.
 1479. *Sagepeumum* is supposed to be obtained from the *Férula persica*.
 1480. *Gamboge*, or *gungust*, the produce of the *Garcinia Cambogia*.

1483. *Balsams.* The substances known by the name of balsams are resins united to the benzoic acid. They are obtained by means of incisions made in the bark, from which a viscous juice exudes, which is afterwards inspissated by the action of the fire or air, or they are obtained by means of boiling the part that contains them. They are thick and viscid juices, but become readily concrete. Their colour is brown or red; their smell aromatic when rubbed; their taste acid; their specific gravity 1.090. They are unalterable in the air after becoming concrete. They are insoluble in water, but boiling water abstracts part of their acid; they are soluble in the alkalies and nitric acid. When heated they melt and swell, evolving a white and odorous smoke. The principal of the balsams are the following: benzoin, storax, styrax, balsam of tolu, and balsam of Peru.

1484. *Benzoin* is the produce of the *Styrax Benzoin*.
 1485. *Storax* is obtained from the *Styrax officinale*.
 1486. *Styrax* is a semi-fluid juice, the produce of a tree said to be cultivated in Arabia.

1489. *Camphor.* The substance known by the name of camphor is obtained from the root and stem of the *Laërus Càmphora* and *Dryobalanops Càmphora*, by distillation. When pure it is a white brittle substance, forming octagonal crystals or square plates. Its taste is hot and acrid; its odour strong but aromatic; its specific gravity 0.9887. When broken into small fragments and put into water, on the surface of which it swims, a singular phenomenon ensues. The water surrounding the fragments is immediately put into commotion, advancing and retiring in little waves, and attacking the fragments with violence. The minuter fragments are driven backwards and forwards upon the surface as if impelled by contrary winds. If a drop of oil is let fall on the surface of the water it produces an immediate calm. This phenomenon has been attributed to electricity. Fourcroy thinks it is merely the effect of the affinities of the camphor, water, and air, entering into combination. Though camphor is obtained chiefly from the *Laërus Càmphora*, yet it is known to exist in a great many other plants, particularly labiate plants, and has been extracted from the roots of zedoary, saffrafas, thyme, rosemary, and lavender.

1490. *Cautouchou.* The substance denominated cautouchou was first introduced into Europe about the beginning of the eighteenth century; but, from a use to which it is very generally applied of rubbing out the marks made upon paper by a black-lead pencil, it is better known to most people in this country by the name of Indian rubber. It is obtained chiefly from *Siphonia Cahuchu*, a tree indigenous to South America; but it has been obtained also from several trees which grow in the East Indies, such as *Ficus indica* and *elastica*, *Artocarpus integrifolia*, and *Urcoba elastica*. If an incision is made into the bark of any of these plants a milky juice exudes, which, when exposed to the air, concretes and forms cautouchou. As the object of the natives in collecting it had been originally to form it into vessels for their own use, it is generally made to concrete in the form of bags or bottles. This is done by applying the juice, when fluid, in thin layers to a mould of dry clay, and then leaving it to concrete in the sun or by the fire. A second layer is added to the first, and others in succession, till the vessel acquires the thickness that is wanted. The mould is then broken and the vessel fit for use, and in this state it is generally brought

of trees and of almost all vegetables. It is insoluble in water, but soluble in alcohol. When treated with oxymuriatic acid, it assumes the colour of a withered leaf, and exhibits the resinous properties more distinctly.

1467. *Copal* is the produce of the *Rhus copallinum*, a tree which is found in North America.

1468. *Anime*, is obtained from the *Hymenæa Costaribaril*, or locust tree, a native of North America.

1469. *Lac* is the produce of the *Aleurites lacifera*, a native of the East Indies.

1470. *Bloom.* Upon the epidermis of the leaves and fruit of certain species of plants, there is to be found a fine, soft, and glaucous powder. It is particularly observable upon cabbage leaves, and upon plums, to which it communicates a peculiar shade. It is known to gardeners by the name of bloom. It is easily rubbed off by the fingers; and when viewed under the microscope seems to be composed of small opaque and unpolished granules, somewhat similar to the powder of starch; but with a high magnifying power it appears transparent. When rubbed off, it is again reproduced, though slowly. It resists the action of dews and rains, and is consequently insoluble in water; but it is soluble in spirits of wine; from which circumstance it has been suspected, with some probability, to be a resin.

1481. *Myrrh*, the plant yielding which grows in Alysia and Arabia. Bruce says it belongs to the genus *Mimosa*; but however this may be, myrrh is the juice of the plant concreted in the form of tears. Its colour is yellow, its odour strong but agreeable, and its taste bitter; it is employed in medicine, and is esteemed an excellent stomachic.

1482. *Assafetida*, a substance which is well known for its strong and fetid smell, is obtained from the *Férula assafetida*. At four years old the plant is dug up by the root. The root is then cleaned, and the extremity cut off; a milky juice exudes, which is collected; and when it ceases to flow another portion is cut off, and more juice extricated. The process is continued till the root is exhausted. The juice which has been collected soon concretes, and constitutes assafetida. It is brought to Europe in small agglutinated grains of different colours, white, red, yellow. It is hard, but brittle. Its taste is bitter, and its smell insufferably fetid; the Indians use it as a seasoning for their food, and call it the food of the gods. In Europe, it is used in medicine as an antispasmodic.

1487. *Balsam of tolu* is obtained from the *Touffera Balsamum*.

1488. *Balsam of Peru* is obtained from the *Myrospermum peruffurum*.

into Europe. It has been brought, however, even in its milky state, by being confined from the action of the air. If the milky juice is exposed to the air, an elastic pellicle is formed on the surface. If it is confined in a vessel containing oxygen gas, the pellicle is formed sooner. If oxynitric acid is poured into the milky juice, the caoutchouc precipitates immediately. This renders it probable that the formation of the caoutchouc is owing to the absorption of oxygen. Caoutchouc, when pure, is of a white colour, without taste and without smell. The black colour of the caoutchouc of commerce is owing to the method of drying the different layers upon the moulds on which they are spread. They are dried by being exposed to smoke. The black colour of the caoutchouc, therefore, is owing to the smoke or soot alternating with its different layers. It is soft and pliable like leather, and extremely elastic, so that it may be stretched to a very great length, and still recover its former size. Its specific gravity is 0.9335. Gough, of Manchester, has made some curious and important experiments on the connection between the temperature of caoutchouc and its elasticity, from which it results that ductility as well as fluidity is owing to latent heat. Caoutchouc is not altered by exposure to the air. It is perfectly insoluble in water; but if boiled in water for some time its edges become so soft that they will cement, if pressed and kept for a while close together. It is insoluble in alcohol, but soluble in ether. It is soluble also in volatile oils and in alkalis. And from the action operated upon by acids it is thought to be composed of carbon, hydrogen, oxygen, and azote. It seems to exist in a great variety of plants combined with other ingredients. It may be separated from resins by alcohol. It may be separated from the berries of the mistletoe by means of water, and from other vegetable substances by other processes. It is said to be contained both in opium and in mastic; but from these substances it cannot be extracted in sufficient quantities to make it worth the labour. It is applied to a great many useful purposes both in medicine and the arts, to which, from its great pliability and elasticity, it is uncommonly well adapted. In the countries where it is produced the natives make boots and shoes of it, and often use it by way of candle.

1491. *Cork.* The substance known by the name of cork is the outer and exfoliated bark of the *Quercus* *Süber* or cork tree, a species of oak that grows in great abundance in France, Spain, and Italy: but to prevent its natural exfoliation, which is always irregular, and to disengage it in convenient portions, a longitudinal incision is made in the bark from the root to the top of the stem; and a transverse and circular incision at each extremity. The outer layer, which is cork, is then stripped off, and to flatten and reduce it to sheets it is put into water and loaded with weights. The tree continues to thrive, though it is thus stripped of its cork once in two or three years. Cork is a light, soft, and elastic substance, distinguished by the following properties:— Its colour is a sort of light tan. It is very inflammable, and burns with a bright white flame, leaving a black and bulky charcoal behind. When distilled it yields a small quantity of ammonia. Nitric acid corrodes and dissolves it, changing its colour to yellow; and finally decomposes it, converting it partly into an acid, and partly into a soft substance resembling wax or resin. The acid which is thus formed is denominated the suberic acid, and has been proved by the experiments of Lagrange to be an acid of a peculiar nature. It seems probable that cork exists in the bark of some other trees, as well as that of the *Quercus* *Süber*. The bark of the *Ulmus* *suberba* assumes something of the external appearance of cork, which it resembles in its thickness, softness, and elasticity, and in its loose and porous texture, as well as also in its chemical properties. Fourcroy seems, indeed, to regard the epidermis of all trees whatever to be a sort of cork, but does not say on what grounds his opinion is founded.

1492. *Woody fibre.* The principal body of the root, stem, and branches of trees, is designated by the appellation of wood; but the term is too general for the purpose of analytical distinction, as the part designated by it often includes the greater part of the substances that have been already enumerated. It remains, therefore, to be ascertained whether there exists in the plant any individual substance different from those already described, and constituting more immediately the fabric of the wood. If a piece of wood is well dried and digested, first in water and then in alcohol, or such other solvent as shall produce no violent effects upon the insoluble parts; and if the digestion is continued till the liquid is no longer coloured, and dissolves no more of the substance of the plant, there remains behind a sort of vegetable skeleton, which constitutes the basis of the wood, and which has been denominated woody fibre. It is composed of bundles of longitudinal threads, which are divisible into others still smaller. It is somewhat transparent. It is without taste and smell, and is not altered by exposure to the atmosphere. It is insoluble in water and alcohol; but the fixed alkalis decompose it with the assistance of heat. When heated in the open air it blackens without melting or frothing, and exhales a thick smoke and pungent odour, leaving a charcoal that retains the form of the original mass. When distilled in a retort it yields an empyreumatic oil, carburetted hydrogen gas, carbonic acid, and a portion of ammonia, according to Fourcroy, indicating the presence of nitrogen as constituting one of its elementary principles; and yet this ingredient does not appear in the result of the later analysis of Gay Lussac and Thenard, which is, carbon, 52.53; oxygen, 41.78; hydrogen, 5.69; total 100.

1493. *Charcoal.* When wood is burnt with a smothered flame, the volatile parts are driven off by the heat, and there remains behind a substance exhibiting the exact form, and even the several layers of the original mass. This process is denominated charring, and the substance obtained charcoal. As it is the woody fibre alone which resists the action of heat, while the other parts of the plants are dissipated, it is plain that charcoal must be the residuum of woody fibre, and that the quantity of the one must depend upon the quantity of the other, if they are not rather to be considered as the same. Charcoal may be obtained from almost all parts of the plants, whether solid or fluid. It often escapes, however, during combustion, under the form of carbonic acid, of which it constitutes one of the elements. From a variety of experiments made on different plants and on their different parts, it appears that the green parts contain a greater proportion of charcoal than the rest; but this proportion is found to diminish in autumn, when the green parts begin to be deprived of their glutinous and extractive juice. The wood contains more charcoal than the albumum, the bark more than both; but this last result is not constant in all plants; because the bark is not a homogeneous substance, the outer parts being affected by the air and the inner parts not. The wood of the *Quercus* *Süber*, separated from the albumum, yielded from 100 parts of its dried substance 19.75 of charcoal; the albumum, 17.5; the bark, 26; leaves gathered in May, 80; in September, 26. But the quantity of charcoal differs also in different plants, as well as in different parts of the same. According to the experiments of Muschet, 100 parts of the following trees afforded as follows:—

<i>Lignum vite</i>	25.8	Walnut	20.6	<i>Norway fir</i>	19.2
Mahogany	25.4	Holly	19.9	Sallow	18.4
Laburnum	24.5	Beech	19.9	Ash	17.9
Chestnut	23.2	American maple	19.9	Birch	17.4
Oak	22.6	Elm	19.5	Scotch pine	16.4
American black birch	21.4				

1494. *The properties of charcoal* are insolubility in water, of which, however, it absorbs a portion when newly made, as also of atmospheric air. It is incapable of putrefaction. It is not altered by the most violent heat that can be applied, if all air and moisture are excluded; but when heated to about 800 it burns in atmospheric air or oxygen gas, and if pure, without leaving any residuum. It is regarded by chemists as being a triple compound, of which the ingredients are carbon, hydrogen, and oxygen. Charcoal is of great utility both to the chemist and artist as a fuel for heating furnaces, as well as for a variety of other purposes. It is an excellent filter for purifying water. It is a very good tooth-powder; and is also an indispensable ingredient in the important manufacture of gunpowder.

1495. *The sap.* If the branch of a vine is cut asunder early in the spring, before the leaves have begun to expand, a clear and colourless fluid will issue from the wound, which gardeners denominate the tears of

the vine. It is merely, however, the ascending sap, and may be procured from almost any other plant by the same or similar means, and at the same season; but particularly from the maple, birch, and walnut tree, by means of boring a hole in the trunk. It issues chiefly from the porous and mixed tubes of the albumum; though sometimes it does not flow freely till the bore is carried to the centre. A small branch of a vine has been known to yield from twelve to sixteen ounces, in the space of twenty-four hours. A maple tree of moderate size yields about 200 pints in a season, as has been already stated; and a birch tree has been known to yield, in the course of the bleeding season, a quantity equal to its own weight. In the sap of *Fagus sylvatica* Vauquelin found the following ingredients:— Water, acetate of lime with excess of acid, acetate of potash, gallic acid, tannin, mucous and extractive matter, and acetate of alumina. In 1039 parts of the sap of the *Ulmus campestris* he found 1027 parts of water and volatile matter, 9240 of acetate of potash, 1060 of vegetable matter, 0796 of carbonate of lime, besides some slight indications of the presence of sulphuric and muriatic acids; and at a later period of the season he found the vegetable matter increased, and the carbonate of lime and acetate of potash diminished. From the above experiments therefore, as well as from those of other chemists, it is plain that the sap consists of a great variety of ingredients, differing in different species of plants; though there is too little known concerning it to warrant the deduction of any general conclusions, as the number of plants whose sap has been hitherto analysed is but very limited. It is the grand and principal source of vegetable aliment, and may be regarded as being somewhat analogous to the blood of animals. It is not made use of by man, at least in its natural state; but there are trees, such as the birch, whose sap may be manufactured into a very pleasant wine; and it is well known that the sap of the American maple tree yields a considerable quantity of sugar.

1496. *The proper juice.* When the sap has received its last degree of elaboration from the different organs through which it has to pass, it is converted into a peculiar fluid, called the proper juice. This fluid may be distinguished from the sap by means of its colour, which is generally green, as in periwinkle; or red, as in logwood; or white, as in spurge; or yellow, as in celandine; from the last two of which it may readily be obtained by breaking the stem asunder, as it will then exude from the fracture. Its principal seat is in the bark, where it occupies the simple tubes; but sometimes it is situated between the bark and wood, as in the juniper tree; or in the leaf, as in the greater parts of herbs; or it is diffused throughout the whole plant, as in the fir and hemlock; in which case, either the proper juice mixes with the sap, or the vessels containing it have ramifications so fine as to be altogether imperceptible. It is not, however, the same in all plants, nor even in the different parts of the same plant. In the cherry tree it is mucilaginous; in the pine it is resinous; in spurge and celandine it is caustic, though resembling in appearance an emulsion. In many plants the proper juice of the bark is different from that of the flower; and the proper juice of the fruit different from both. Its appearance under the microscope, according to Senebier, is that of an assemblage of small globules connected by small and prism-shaped substances placed between them. If this juice could be obtained in a state of purity, its analysis would throw a considerable degree of light upon the subject of vegetation; but it seems impracticable to extract it without a mixture of sap. Senebier analysed the milky juice of *Euphórbia Cyparissias*, of which, though its pungency was so great as to occasion an inflammation of the eyes to the person employed to procure it, he had obtained a small quantity considerably pure. It mixed readily with water, to which it communicated its colour. When left exposed to the air, a slight precipitation ensued; and, when allowed to evaporate, a thin and opaque crust remained behind. Alcohol coagulated it into small globules. Ether dissolved it entirely, as did also oil of turpentine. Sulphuric acid changed its colour to black; nitric acid to green. The most accurate experiments on the subject are those of Chaptal. When oxymuriatic acid was poured into the peculiar juice of *Euphórbia*, a very copious white precipitate fell down, which, when washed and dried, had the appearance of starch, and was not altered by keeping. Alcohol, aided by heat, dissolved two thirds of it, which the addition of water again precipitated. They had all the properties of resin. The remaining third part possessed the properties of woody fibre. The same experiment was tried on the juice of a variety of other plants, and the result uniformly was that oxymuriatic acid precipitated from them woody fibre.

1497. *The virtues of plants have generally been thought to reside in their proper juices, and the opinion seems indeed to be well founded.* It is at least proved by experiment in the poppy, spurge, and fig. The juice of the first is narcotic, of the last two corrosive. The diuretic and balsamic virtues of the fir reside in its turpentine, and the purgative property of jalap in its resin. If sugar is obtained from the sap of the sugar-cane and maple, it is only because it has been mixed with a quantity of proper juice. The bark certainly contains it in greatest abundance, as may be exemplified in cinnamon and quinquina. But the peach tree furnishes an exception to this rule: its flowers are purgative, and the whole plant aromatic; but its gum is without any distinguished virtues. Malpighi regarded the proper juice as the principle of nourishment, and compared it to the blood of animals; but this analogy does not hold very closely. The sap is perhaps more analogous to the blood, from which the proper juice is rather a secretion. In one respect, however, the analogy holds good, that is, with regard to extravasated blood and peculiar juices. If the blood escapes from the vessels it forms neither flesh nor bones, but tumours; and if the proper juices escape from the vessels containing them, they form neither wood nor bark, but a lump or deposit of inspissated fluid. To the sap or to the proper juice, or rather to a mixture of both, we must refer such substances as are obtained from plants under the name of expressed juices, because it is evident that they can come from no other source. In this state they are generally obtained in the first instance, whether with a view to their use in medicine or their application to the arts. It is the business of the chemist or artist to separate and purify them afterwards, according to the peculiar object he may happen to have in view, and the use to which he purposes to apply them. They contain, like the sap, acetate of potash or of lime, and assume a deeper shade of colour when exposed to the fire or air. The oxymuriatic acid precipitates from them a coloured and flaky substance as from the sap, and they yield by evaporation a quantity of extract; but they differ from the sap in exhibiting no traces of tannin or gallic acid, and but rarely of the saccharine principle.

1498. *Ashes.* When vegetables are burnt in the open air the greatest part of their substance is evaporated during the process of combustion; but ultimately there remains a portion which is altogether incombustible, and incapable of being volatilised by the action of fire. This residuum is known by the name of ashes. Herbaceous plants, after being dried, yield more ashes than woody plants; the leaves more than the branches; and the branches more than the trunk. The albumum yields also more ashes than the wood; and putrefied vegetables yield more ashes than the same vegetables in a fresh state, if the putrefaction has not taken place in a current of water. The result of Saussure's experiments on 1000 parts of different plants was as follows:—

Gathered in May, dried leaves of the oak	53 parts of ashes.
green leaves of the oak	13
dried leaves of the <i>Rhododéndron</i>	50
dried leaves of the <i>Æsculus Hippocástanum</i>	72
trunk and branches of <i>Æsculus Hippocástanum</i>	35
Gathered in September, dried leaves of the <i>Æsculus Hippocástanum</i>	86
dried leaves of the oak	35
green leaves of the oak	24
Gathered when in flower, leaves of <i>Pisum sativum</i>	95
Gathered when in fruit, leaves of <i>Pisum sativum</i>	81
leaves of <i>Faba vulgaris</i>	20
Gathered before coming into flower, the leaves of the <i>Faba vulgaris</i>	16
Oak, the dried bark 60, the albumum 4, wood	2

1499. *The analysis of the ashes* of plants, with a view to the discovery of the ingredients of which they are composed, produces alkalies, earths, and metals, which must therefore be considered as ingredients in the composition of the vegetable. But vegetable ashes contain also a variety of other principles, occurring, however, in such small proportions as generally to escape observation. Perhaps they contain also substances not capable of being volatilised by the action of fire.

1500. *Alkalies.* The alkalies are a peculiar class of substances, distinguished by a caustic taste and the property of changing vegetable blues to green. They are generally regarded as being three in number, potass, soda, and ammonia, of which the two former only are found in the ashes of vegetables. Ammonia is, indeed, often obtained from vegetable substances by means of distillation, but then it is always formed during the process. If the ashes of land vegetables, burnt in the open air, are repeatedly washed in water, and the water filtered and evaporated to dryness, potass is left behind. The potass of commerce is manufactured in this manner, though it is not quite pure: but it may be purified by dissolving it in spirits of wine, and evaporating the solution to dryness in a silver vessel. When pure it is white and semi-transparent, and is extremely caustic and deliquescent. It dissolves all soft animal substances, and changes vegetable blues into green. It dissolves alumina, and also a small quantity of silicx, with which it fuses into glass by the aid of fire. It had been long suspected by chemists to be a compound substance: and according to the notable discovery by Sir H. Davy, its component parts are at last ascertained to be oxygen and a highly inflammable metal, which he denominates potassium, one proportion of each. Soda is found chiefly in marine plants, from the ashes of which it is obtained by means of lixiviation. It exists in great abundance in *Salsola Sôda*, *Zostera maritima*, and various species of *Fuci*. It is generally obtained in the state of a carbonate, but is purified in the same manner as potass, to which it is similar in its properties; but from which it is easily distinguished by its forming a hard soap with oil, while potass forms a soft soap. It consists, according to Sir H. Davy, of one proportion of a metal which he denominates sodium, and two proportions of oxygen. Such are the only vegetable alkalies, and the modes of obtaining them. They are found generally in the state of carbonates, sulphates, or muriates, salts which form, beyond all comparison, the most abundant ingredient in the ashes of green herbaceous plants whose parts are in a state of vegetation. The ashes of the golden rod, growing in an uncultivated soil, and of the bean, turnsole, and wheat, were found by Saussure to contain at least three fourths of their weight of alkaline salts. This was nearly the case also with the leaves of trees just bursting from the bud. But the proportion of alkaline salts is found to diminish, rather than to augment, as the parts of the plant are developed. The ashes of the leaves of the oak, gathered in May, yielded 47 parts in the 100 of alkaline salts; and, in September, only 17.

1501. *The utility of the alkalies*, as obtained from vegetables, is of the utmost importance in the arts, particularly in the formation of glass and of soaps. If a mixture of soda, or potass, and silicx, or sand, in certain proportions, is exposed to a violent heat, the ingredients are melted down into a fluid mass, which is glass in a state of fusion. In this state it may be moulded into almost any form, at the pleasure of the artist: and, accordingly, we find that it is manufactured into a great variety of utensils and instruments, under the heads of flint glass, crown glass, bottle glass. Bottle glass is the coarsest; it is formed of soda and common sand, and is used in the manufacture of the coarser sort of bottles. Crown glass is composed of soda and fine sand: it is moulded into large plates for the purpose of forming window-glasses and looking-glasses. Flint glass is the finest and most transparent of all: that which is of the best quality is composed of 120 parts of white silicious sand, 40 parts of pearl-ash, 35 of red oxide of lead, 13 of nitrate of potass, and 25 of black oxide of manganese. It is known also by the name of crystal, and may be cut and polished so as to serve for a variety of ornamental purposes, as well as for the more important and more useful purpose of forming optical instruments, of which the discoveries made with the telescope and the microscope are the curious or sublime results. If a quantity of oil is mixed with half its weight of a strong solution of soda or potass, a combination takes place which is rendered more complete by means of boiling. The new compound is soap. The union of oil with potass forms a soft soap, and with soda hard soap; substances of the greatest efficacy as detergents, and of the greatest utility in the washing and bleaching of linen. The alkalies are used also in medicine, and found to be peculiarly efficacious in the reduction of urinary calculi.

1502. *Earths.* The only earths which have hitherto been found in plants are the following: lime, silica, magnesia, and alumina.

1503. *Lime* is by far the most abundant earth. It is generally combined with a portion of phosphoric, carbonic, or sulphuric acid, forming phosphates, or carbonates, or sulphates of lime. The phosphate of lime is, next to the alkaline salt, the most abundant ingredient in the ashes of green herbaceous plants whose parts are all in a state of vegetation. The leaf of a tree, bursting from the bud, contains in its ashes a greater portion of earthy phosphate than at any other period: 100 parts of the ashes of the leaves of the oak, gathered in May, furnished 24 parts of earthy phosphate; in September, only 18.25. In annual plants the proportion of earthy phosphate diminishes from the period of their germination to that of their flowering. Plants of the bean, before flowering, gave 14.5 parts of earthy phosphate; in flower, only 13.5. Carbonate of lime is, next to phosphate of lime, the most abundant of the earthy salts that are found in vegetables. But if the leaves of plants are washed in water the proportion of carbonate is augmented. This is owing to the subtraction of their alkaline salts and phosphates in a greater proportion than their lime. In green herbaceous plants whose parts are in a state of increase, there is but little carbonate of lime; but the ashes of the bark of trees contain an enormous quantity of carbonate of lime, and much more than the albumum, as do also the ashes of the wood. The ashes of most seeds contain no carbonate of lime; but they abound in phosphate of potass. Hence the ashes of plants, at the period of the maturity of the fruit, yields less carbonate of lime than at any previous period.

1504. *Silica* is not found to exist in a great proportion in the ashes of vegetables, unless they have been previously deprived of their salts and phosphates by washing; but, when the plants are washed in water, the proportion of their silica augments. The ashes of the leaves of the hazel, gathered in May, yielded 2.5 parts of silica in 100. The same leaves, washed, yielded four parts in 100. Young plants, and leaves bursting from the bud, contain but little of silica in their ashes; but the proportion of silica augments as the parts are developed. Perhaps this is owing to the diminution of the alkaline salts. The ashes of some stalks of wheat gathered a month before the time of flowering, and having some of the radical leaves withered, contained 12 parts of silica and 65 of alkaline salts in 100. At the period of their flowering, and when more of their leaves were withered, the ashes contained 32 parts of silica and 54 of alkaline salts. Seeds divested of their external covering, contain less silica than the stem furnished with its leaves; and it is somewhat remarkable that there are trees of which the bark, albumum, and wood contain scarcely any silica, and the leaves a great deal, particularly in autumn. This is a phenomenon that seems inexplicable. The greater part of the grasses contain a very considerable proportion of silica, as do also the plants of the genus *Equisetum*. Sir H. Davy has discovered that it forms a part of the epidermis of these plants, and in some of them the principal part. From 100 parts of the epidermis of the following plants the proportions of silica were, in honnet cane, 90; bamboe, 71.4; common reed, 48.1; stalks of corn, 66.5. Owing to the silica contained in the epidermis, the plants in which it is found are sometimes used to give a polish to the surface of substances where smoothness is required. The Dutch rush (*Equisetum hyemale*), a plant of this kind, is used to polish even brass.

1505. *Magnesia* does not exist so abundantly in the vegetable kingdom, as the two preceding earths. It has been found, however, in several of the marine plants, particularly the *Fuci*; but *Salsola Sôda* contains

more of magnesia than any other plant yet examined. According to Vauquelin, 100 parts of it contain 17.929 of Magnesia.

1506. *Alumina* has been detected in several plants, but never except in very small quantities.

1507. *Metallic oxides.* Among the substances found in the ashes of vegetables, we must class also metals. They occur, however, only in small quantities, and are not to be detected except by the most delicate experiments. The metals hitherto discovered in plants are iron, manganese, and perhaps gold. Of these iron is by far the most common. It occurs in the state of an oxide; and the ashes of hard and woody plants such as the oak, are said to contain nearly one twelfth of their own weight of this oxide. The ashes of Salsola contain also a considerable quantity. The oxide of manganese was first detected in the ashes of vegetables by Scheele, and afterwards found by Proust in the ashes of the pine, calendula, vine, green oak and fig tree. Becher, Kunckel, and Sage, together with some other chemists, contend also for the existence of gold in the ashes of certain plants; but the very minute portion which they found, seems more likely to have proceeded from the lead employed in the process, than from the ashes of the plant. It has been observed by Saussure, that the proportion of the oxides of iron and of manganese augments in the ashes of plants as their vegetation advances. The leaves of trees furnish more of these principles in autumn than in spring, as do those of annual plants. Seeds contain metals in less abundance than the stem and if plants are washed in water, the proportions of their metallic oxides are augmented.

1508. *Such are the principal ingredients* that enter into the vegetable composition. They are indeed numerous, though some of them, such as the metallic oxides, occur in such small proportions as to render it doubtful whether they are in reality vegetable productions or not. The same thing may be said of some of the other ingredients that have been found in the ashes of plants, which it is probable have been absorbed ready formed by the root, and deposited unaltered, so that they can scarcely be at all regarded as being the genuine products of vegetation.

1509. *Other substances.* Besides the substances above enumerated, there are also several others which have been supposed to constitute distinct and peculiar genera of vegetable productions, and which might have been introduced under such a character; such as the mucus, jelly, sarcocol, asparagin, inulin, and ulmin of Dr. Thomson, as described in his well known *System of Chemistry*; but as there seems to be some difference of opinion among chemists with regard to them, and a belief entertained that they are but varieties of one or other of the foregoing ingredients, it is sufficient for the purposes of this work to have merely mentioned their names. Several other substances, of a distinct and peculiar character, have been suspected to exist in vegetable productions: such as the febrifuge principle of Seguin, as discovering itself in Peruvian bark; the principle of causticity or acidity of Senbier, as discovering itself in the roots of Ranunculus bulbosus, Scilla maritima, Bryonia alba, and Arum maculatum, in the leaves of Digitalis purpurea, in the bark of Daphne Mezereum, and in the juice of the spurge; to which may be added the fluid exuded from the sting of the common nettle, the poisons inherent in some plants, and the medical virtues inherent in others; together with such peculiar principles as may be presumed to exist in such regions of the vegetable kingdom as remain yet unexplored. The important discoveries which have already resulted from the chemical analysis of vegetable substances encourage the hope that further discoveries will be the result of further experiment; and, from the zeal and ability of such chemists as are now directing their attention to the subject, every thing is to be expected.

SECT. II. *Simple Products.*

1510. *A very few constituent and uncompounded elements* include all the compound ingredients of vegetables. The most essential of such compounds consist of carbon, oxygen, and hydrogen; a small proportion of nitrogen is said to be found only in cruciform plants. The remaining elementary principles which plants have been found to contain, although they may be necessary in the vegetable economy, yet they are by no means principles of the first importance, as occurring only in small proportions, and being dependent in a great measure on soil and situation; whereas the elements of carbon, oxygen, and hydrogen form as it were the very essence of the vegetable subject, and constitute by their modifications the peculiar character of the properties of the plant. This is conspicuously exemplified in the result of the investigations of Gay Lussac, and Thenard, who have deduced from a series of the most minute and delicate experiments the three following propositions, which they have dignified by the name of *Laws of Vegetable Nature* (*Traité de Chem. Element.*, tom. iii. chap. iii.): — 1st, Vegetable substances are always acid, when the oxygen they contain is to the hydrogen in a greater proportion than in water; 2dly, Vegetable substances are always resinous, or oily, or spirituous, when the oxygen they contain is to the hydrogen in a smaller proportion than in water; 3dly, Vegetable substances are neither acid nor resinous, but saccharine, or mucilaginous, or analogous to woody fibre or starch, when the oxygen and hydrogen they contain are in the same proportion as in water. (See *Dr. Thomson's System of Chemistry.*)

CHAP. IV.

Functions of Vegetables.

1511. *The life, growth, and propagation of plants* necessarily involve the several following topics: germination, nutriment, digestion, growth and development of parts, anomalies of vegetable development, sexuality of vegetables, impregnation of the vegetable germen, changes consequent upon impregnation, propagation and dispersion of the species, causes limiting the dispersion of the species, evidence and character of vegetable vitality.

SECT. I. *Germination of the Seed.*

1512. *Germination* is that act or operation of the vegetative principle, by which the embryo is extricated from its envelopes, and converted into a plant. This is universally the first part of the process of vegetation; for it may be regarded as an indubitable fact, that all plants spring originally from seed. The conditions necessary to germination relate either to the internal state of the seed itself, or to the circumstances in which it is placed with regard to surrounding substances.

1513. *The first condition necessary to germination is, that the seed must have reached maturity.* Unripe seeds seldom germinate, because their parts are not yet prepared to form the chemical combinations on which germination depends. There are some seeds, however, whose germination is said to commence in the very seed-vessel, even before the fruit is ripe, and while it is yet attached to the parent plant. Such are those of the *Tangetkôli* of Adanson, and *Agave vivipara* of East Florida, as well as those of the *Cyamus Nelumbo* of Sir J. E. Smith, or sacred bean of India; to which may be added the seeds of the common garden radish, pea, lemon, &c. But these are examples of rare occurrence; though it is sometimes necessary to sow or plant the seed almost as soon as it is fully ripe, as in the case of the coffee-bean; which will not germinate unless it is sown within five or six weeks after it has been gathered. Most seeds, however, if guarded from external injury, will retain their germinating faculty for a period of many years. This has been proved by the experiment of sowing seeds which have been long so kept; as well as by the deep ploughing up of fields which have been long left without cultivation. A field which was thus ploughed up, near Dunkeld, in Scotland, after a period of forty years' rest, yielded a considerable blade of black oats without sowing. This could have only been by the plough's bringing up to the surface seeds which had been formerly too deeply lodged for germination.

1514. *The second condition is, that the seeds sown must be defended from the action of the rays of light.* This has no doubt been long known to be a necessary condition of germination, if we regard the practice of the harrowing or raking in of the grains or seeds sown by the farmer or gardener as being founded upon it.

1515. *A third condition necessary to germination is the necessity of heat.* No seed has ever been known to germinate at or below the freezing point. Hence seeds do not germinate in winter, even though lodged in their proper soil: but the vital principle is not necessarily destroyed in consequence of this exposure; for the seed will germinate still, on the return of spring, when the ground has been again thawed, and the temperature raised to the proper degree. This degree varies considerably in different species of seeds, as is obvious from observing the times of their germination, whether in the same climate or in different ones: for if seeds, which naturally sow themselves, germinate in different climates at the same period, or in the same climate at different periods, the temperature necessary to their germination must of consequence be different. Now these cases are constantly occurring and presenting themselves to our notice; and have also been made the subject of particular observation. Adanson found that seeds which will germinate in the space of twelve hours in an ordinary degree of heat, may be made to germinate in the space of three hours by exposing them to a greater degree of heat; and that seeds transported from the climate of Paris to that of Senegal, have their periods of germination accelerated from one to three days. (*Essai des Plantes*, vol. i. p. 84.) Upon the same principle, seeds transported from a warmer to a colder climate, have their periods of germination protracted till the temperature of the latter is raised to that of the former. This is well exemplified in the case of green-house and hot-house plants, from which it is also obvious that the temperature must not be raised beyond a certain degree, otherwise the vital principle is totally destroyed.

1516. *A fourth condition necessary to germination is the access of moisture.* Seeds will not germinate if they are kept perfectly dry. Water, therefore, or some liquid equivalent to it, is essential to germination. Hence rain is always acceptable to the farmer or gardener, immediately after he has sown his seeds; and, if no rain falls, recourse must be had, if possible, to artificial watering. But the quantity of water applied is not a matter of indifference. There may be too little or there may be too much. If there be too little, the seed dies for want of moisture; if there be too much, it then rots. The case is not the same, however, with all seeds. Some can bear but little moisture, though others will germinate even when partially immersed; as was proved by an experiment of Du Hamel's, at least in the case of peas, which he placed merely upon a piece of wet sponge, so as to immerse them by nearly the one half, and which germinated as if placed in the soil. But this was found to be the most they could bear; for when totally immersed in the water they rotted. There are some seeds, however, which will germinate even when wholly submerged. The seeds of aquatics must of necessity germinate under water; and peas have been known to do so under certain conditions.

1517. *A fifth condition necessary to germination is the access of atmospheric air.* Seeds will not germinate if placed in a vacuum. Ray introduced some grains of lettuce-seed into the receiver of an air-pump, which he then exhausted. The seeds did not germinate. But they germinated upon the readmission of the air, which is thus proved by consequence to be necessary to their germination. Aehard proved that no seed will germinate in nitrogen gas, or carbonic acid gas, or hydrogen gas, except when mixed with a certain proportion of oxygen gas; and hence concluded that oxygen gas is necessary to the germination of all seeds, and the only constituent part of the atmospheric air which is absolutely necessary. Humboldt found that the process of germination is accelerated by means of previously steeping the seed in water impregnated with oxymuriatic acid. Cress seed treated in this manner germinated in the space of three hours, though its ordinary period of germination is not less than thirty-two hours.

1518. *The period necessary to complete the process of germination is not the same in all seeds, even when all the necessary conditions have been furnished.* Some species require a shorter, and others a longer period. The grasses are among the number of those plants whose seeds are of the most rapid germination; then perhaps cruciform plants; then leguminous plants; then labiate plants; then umbelliferous plants; and in the last order rosaceous plants, whose seeds germinate the slowest. The following table indicates the periods of the germination of a considerable variety of seeds, as observed by Adanson:—

	Days.		Days.		Days.
Wheat, Millet-seed	2	Radish, Beet-root	5	Hysop	30
Spinach, Beans, Mustard	3	Barley from	4 to 7	Farsley	40 or 50
Lettuce, Aniseed	4	Orache	8	Almond, Chestnut, Peach	1 year
Melon, Cucumber, Cress } seed	5	Purslane	9	Rose, Hawthorn, Filbert	2 years.
		Cabbage	10		

1519. *Physical phenomena.* When a seed is committed to the soil under the conditions which have been just specified, the first infallible symptom of germination is to be deduced

from the prolongation of the radicle (*fig. 188. a*), bursting through its proper integuments, and directing its extremity downwards into the soil. The next step in the process of germination is the evolution of the cotyledon or cotyledons (*c*), unless the seed is altogether acotyledonous, or the cotyledons hypogean, as in the oak (*b*). The next step, in the case of seeds furnished with cotyledons, is that of the extrication of the plumule (*c*), or first real leaf, from within the cotyledon or from between the cotyledons, and its expansion in the open air. The development of the rudiments of a stem (*d*), if the species is furnished with one, is the last and concluding step, and the plant is complete. Whatever way the seed may be deposited, the invincible tendency of the radicle is to descend and fix itself in the earth; and of the plumule, to ascend into the air. Mar conjectures have been offered to account for this. Knight accounts for it on the old but revived principle of gravitation. Keith conjectures that it takes place from a power inherent in the vegetable subject, analogous to what we call instinct in the animal subject, infallibly directing it to the situation best suited to the acquisition of nutriment and consequent development of its parts.

1520. *The chemical phenomena of germination consist chiefly in the changes which are effected in the nutriment destined for the support and development of the embryo till it is converted into a plant. This nutriment either passes through the cotyledons, or is contained in them; because the embryo dies when they are prematurely cut off. But the farinaceous substance of the cotyledons, at least in exalbuminous seeds, is a proof that they themselves contain the nutriment. They are to be regarded, therefore, as repositories of the food destined for the support of the embryo in its germinating state; and, if the seed is furnished with a distinct and separate albumen, then is the albumen to be regarded as the repository of food, and the cotyledon or cotyledons as its channel of conveyance. But the food thus contained in the albumen or cotyledons is not yet fitted for the immediate nourishment of the embryo: some previous preparation is necessary; some change must be effected in its properties. This change is effected by the intervention of chemical agency. The moisture imbibed by a seed placed in the earth is immediately absorbed by the cotyledons or albumen, which it readily penetrates, and on which it immediately begins to operate a chemical change, dissolving part of their farina, or mixing with their oil particles, and forming a sort of emulsive juice. The consequence of this change is a slight degree of fermentation, induced, perhaps, by the mixture of the starch and gluten of the cotyledons in the water which they have absorbed, and indicated by the extraction of a quantity of carbonic acid gas, as well as by the smell and taste of the seed. This is the commencement of the process of germination, which takes place even though no oxygen gas is present. But if no oxygen gas is present, then the process stops; which shows that the agency of oxygen gas is indispensable to germination. Accordingly, when oxygen gas is present, it is gradually inhaled by the seed; and the farina of the cotyledons is found to have changed its savour. Sometimes it becomes acid, but generally sweet, resembling the taste of sugar and is consequently converted into sugar or some substance analogous to it. This is a further proof that a degree of fermentation has been induced; because the result is precisely the same in the process of the fermentation of barley when converted into malt, as known by the name of the saccharine fermentation, in which oxygen gas is absorbed, heat and carbonic acid evolved, and a tendency to germination indicated by the shooting of the radicle. The effect of oxygen, therefore, in the process, is that of converting the farina of the albumen or cotyledons into a mild and saccharine food, fit for the nourishment of the infant plant, by diminishing the proportion of its carbon, and in augmenting, by consequence, that of its oxygen and hydrogen. The radicle gives the first indications of life, expanding and bursting its integuments, and at length fixing itself in the soil: the plumule next unfolds its parts, developing the rudiments of leaf, branch, and trunk: and, finally, the seminal leaves decay and drop off; and the embryo has been converted into a plant, capable of abstracting immediately from the soil or atmosphere the nourishment necessary to its future growth.*

SECT. II. Food of the vegetating Plant.

1521. *The substances which plants abstract from the soil or atmosphere, or the food of the vegetating plant, have long occupied the phythological enquirer. What then are the component principles of the soil and atmosphere? The investigations and discoveries of modern chemists have done much to elucidate this dark and intricate subject. Soil, in general, may be regarded as consisting of earths, water, vegetable mould, decayed animal substances, salts, ores, alkalies, gases, perhaps in a proportion corresponding to the order in which they are now enumerated; which is at any rate the fact with regard to the first three, though their relative proportions are by no means uniform. The atmosphere has been also found to consist of at least four species of elastic matter, nitrogen, oxygen, carbonic acid gas, and vapour; together with a multitude of minute particles detached from the solid bodies occupying the surface of the earth, and wafted upon the wind. The two former ingredients exist in the proportion of about four to one; carbonic acid gas in the proportion of about one part in 100; and vapour in proportion still less. Such then are the component principles of the soil and atmosphere, and the sources of vegetable nourishment. But the whole of the ingredients of the soil and atmosphere are not taken up indiscriminately by the plant and converted into vegetable food, because plants do not thrive indiscriminately in all varieties of soil. Part only of the ingredients are selected, and in certain proportions: as is evident from the analysis of the vegetable substance given in the foregoing chapter, in which it was found that carbon, hydroge:*

oxygen, and nitrogen, are the principal ingredients of plants; while the other ingredients contained in them occur but in very small proportions. It does not however follow, that these ingredients enter the plant in an uncombined and insulated state, because they do not always so exist in the soil and atmosphere; it follows only that they are inhaled or absorbed by the vegetating plant, under one modification or another. The plant then does not select such principles as are the most abundant in the soil and atmosphere; nor in the proportions in which they exist; nor in an uncombined and insulated state. But what are the substances actually selected; in what state are they taken up; and in what proportions? In order to give arrangement and elucidation to the subject, it shall be considered under the following heads: Water, Gases, Vegetable Extracts, Salts, Earths, Manures.

1522. *Water.* As water is necessary to the commencement of vegetation, so also is it necessary to its progress. Plants will not continue to vegetate unless their roots be supplied with water; and if they be kept long without it, the leaves will droop and become flaccid, and assume a withered appearance. Now this is evidently owing to the loss of water; for if the roots be again well supplied with water, the weight of the plant is increased, and its freshness restored. But many plants will grow, and thrive, and effect the development of all their parts, if the root be merely immersed in water, though not fixed in the soil. Tulips, hyacinths, and a variety of plants with bulbous roots, may be so reared, and are often to be met with so vegetating; and many plants will also vegetate though wholly immersed. Most of the marine plants are of this description. It can scarcely be doubted, therefore, that water serves for the purpose of a vegetable aliment. But, if plants cannot be made to vegetate without water; and if they will vegetate, some when partly immersed without the assistance of soil, and some even when totally immersed, so as that no other food seems to have access to them; does it not follow that water is the sole food of plants, the soil being merely the basis on which they rest, and the receptacle of their food? This opinion has had many advocates; and the arguments and experiments adduced in support of it were, at one time, thought to have completely established its truth. It was indeed the prevailing opinion of the seventeenth century, and was embraced by several philosophers even of the eighteenth century; but its ablest and most zealous advocates were Van Helmont, Boyle, Du Hamel, and Bonnet, who contended that water, by virtue of the vital energy of the plant, was sufficient to form all the different substances contained in vegetables. Du Hamel reared in the above manner plants of the horsechestnut and almond to some considerable size, and an oak till it was eight years old. But though he informs us that they died at last only from neglect of watering, yet it seems extremely doubtful whether they would have continued to vegetate much longer, even if they had been watered ever so regularly: for he admits, in the first place, that they made less and less progress every year; and, in the second place, that their roots were found to be in a very bad state. The result of a great variety of experiments is, that water is not the sole food of plants, and is not convertible into the whole of the ingredients of the vegetable substance, even with the aid of the vital energy; though plants vegetating merely in water do yet augment the quantity of their carbon.

1523. *Gases.* When water was found to be insufficient to constitute the sole food of plants, recourse was next had to the assistance of the atmospheric air; and the vital energy of the plant was believed to be at least capable of furnishing all the different ingredients of the vegetable substance, by means of decomposing and combining, in different ways, atmospheric air and water. But as this extravagant conjecture is founded on no proof, it is consequently of no value. It must be confessed, however, that atmospheric air is indispensably necessary to the health and vigour of the plant, as may be seen by looking at the different aspects of plants exposed to a free circulation of air, and plants deprived of it: the former are vigorous and luxuriant; the latter weak and stunted. It may be seen also by means of experiment even upon a small scale. If a plant be placed under a glass to which no new supply of air has access, it soon begins to languish, and at length withers and dies: but particularly if it be placed under the exhausted receiver of an air-pump; as might indeed be expected from the failure of the germination of the seed in similar circumstances. The result of experiments on this subject is, that atmospheric air and water are not the only principles constituting the food of plants. But as in germination, so also in the progress of vegetation, it is part only of the component principles of the atmospheric air that are adapted to the purposes of vegetable nutrition, and selected by the plant as a food. Let us take them in the order of their reversed proportions.

1524. *The effect of the application of carbonic acid gas* was found to be altogether prejudicial in the process of the germination of the seed: but in the process of subsequent vegetation its application has been found, on the contrary, to be extremely beneficial. Plants will not indeed vegetate in an atmosphere of pure carbonic acid, as was first ascertained by Dr. Priestley, who found that sprigs of mint growing in water, and placed over wort in a state of fermentation, generally became dead in the space of a day, and did not even recover when put into an atmosphere of common air. Of a number of experiments the results are: 1st, That carbonic acid gas is of great utility to the growth of plants vegetating in the sun, as

applied to the leaves and branches, and whatever increases the proportion of this gas in their atmosphere, at least within a given degree, forwards vegetation; 2d, That, as applied to the leaves and branches of plants, it is prejudicial to vegetation in the shade, if administered in a proportion beyond that in which it exists in atmospheric air; 3d, That carbonic acid gas, as applied to the roots of plants, is also beneficial to their growth, at least in the more advanced stages of vegetation.

1525. As oxygen is essential to the commencement and progress of germination, so also it is essential to the progress of vegetation. It is obvious, then, that the experiment proves that it is beneficial to the growth of the vegetable as applied to the root; necessary to the development of the leaves; and to the development of the flower and fruit. The flower-bud will not expand if confined in an atmosphere deprived of oxygen, nor will the fruit ripen. Flower-buds confined in an atmosphere of pure nitrogen faded without expanding. A bunch of unripe grapes introduced into a globe of glass which was luted by its orifice to the bough, and exposed to the sun, ripened without effecting any material alteration in its atmosphere; but when a bunch was placed in the same circumstances, with the addition of a quantity of lime, the atmosphere was contaminated, and the grapes did not ripen. Oxygen, therefore, is essential to the development of the vegetating plant, and is inhaled during the night.

1526. Though nitrogen gas constitutes by far the greater part of the mass of atmospheric air, it does not seem capable of affording nutriment to plants; for as seeds will not germinate, so neither will plants vegetate, in it, but for a very limited time, with the exception of the *Vinca minor*, *Lýthrum Salicaria*, *Znula dysenterica*, *Epilóbium hirsutum*, and *Polygonum Persicaria*, which seem to succeed equally well in an atmosphere of nitrogen gas as in an atmosphere of common air. Nitrogen is found in almost all vegetables, particularly in the wood, in extract, and in their green parts, derived, no doubt, from the extractive principle of vegetable mould.

1527. *Hydrogen gas*. A plant of the *Epilóbium hirsutum*, which was confined by Priestley in a receiver filled with inflammable air or hydrogen, consumed one third of its atmosphere and was still green. Hence Priestley inferred, that it serves as a vegetable food, and constitutes even the true and proper pabulum of the plant. But the experiments of later phytologists do not at all countenance this opinion. The conclusion from various experiments is, that hydrogen is unfavourable to vegetation, and does not serve as the food of plants. But hydrogen is contained in plants, as is evident from their analysis; and if they refuse it when presented to them in a gaseous state, in what state do they then acquire it? To this question it is sufficient for the present to reply, that if plants do not acquire their hydrogen in the state of gas, they may at least acquire it in the state of water, which is indisputably a vegetable food, and of which hydrogen constitutes one of the component parts.

1528. *Vegetable extract*. When it was found that atmospheric air and water are not, even conjointly, capable of furnishing the whole of the aliment necessary to the development of the plant, it was then alleged that, with the exception of water, all substances constituting a vegetable food must at least be administered to the plant in a gaseous state. But this also is a conjecture unsupported by proof; for even with regard to such plants as grow upon a barren rock, or in pure sand, it cannot be said that they receive no nourishment whatever besides water, except in a gaseous state. Many of the particles of decayed animal and vegetable substances, which float on the atmosphere and attach themselves to the leaves, must be supposed to enter the plant in solution with the moisture which the leaves imbibe; and so also similar substances contained in the soil must be supposed to enter it by the root: but these substances may certainly contain vegetable nourishment; and they will perhaps be found to be taken up by the plant in proportion to their degree of solubility in water, and to the quantity in which they exist in the soil. Now one of the most important of these substances is vegetable extract. When plants have attained to the maturity of their species, the principles of decay begin gradually to operate upon them, till they at length die and are converted into dust or vegetable mould, which, as might be expected, constitutes a considerable proportion of the soil. The chance then is, that it is again converted into vegetable nourishment, and again enters the plant. But it cannot wholly enter the plant, because it is not wholly soluble in water. Part of it, however, is soluble, and consequently capable of being absorbed by the root, and that is the substance which has been denominated extract.

1529. *Saussure* filled a large vessel with pure mould of turf, and moistened it with distilled or rain water, till it was saturated. At the end of five days, when it was subjected to the action of the press, 10,000 parts in weight of the expressed and filtered fluid yielded, by evaporation to dryness, 26 parts of extract. In a similar experiment upon the mould of a kitchen-garden which had been manured with dung, 10,000 parts of a fluid yielded 10 of extract; and, in a similar experiment upon mould taken from a well-cultivated corn field, 10,000 parts of fluid yielded 4 parts of extract. Such was the result in these particular cases. But the quantity of extract which may be separated from the common soil is not in general very considerable. After twelve decoctions, all that could be separated was about one eleventh of its weight; and yet this seems to be more than sufficient for the purposes of vegetation: for a soil containing this quantity was found by experiment to be less fertile, at least for peas and beans, than a soil containing only one half or two thirds of the quantity. But if the quantity of extract must not be too much, neither must it be too little. Plants that were put to vegetate in soil deprived of its extract, as far as repeated decoctions could deprive it, were found to be much less vigorous and luxuriant than plants vegetating in soil not deprived of its extract: and yet the only perceptible difference between them is, that the former can imbibe and retain a much greater quantity of water than the latter. From this last experiment, as well as from the great proportion in which it exists in the living plant, it evidently follows that extract constitutes a vegetable food. But extract contains nitrogen; for it yields by distillation a fluid impregnated with ammonia. The difficulty, therefore, of accounting for the introduction of nitrogen into the vegetating plant, as well as for its existence in the mature vegetable substance, is done away; for, although the plant refuses it when presented in a gaseous state, it is plain that it must admit it along with the extract it seems also probable that a small quantity of carbonic acid gas enters the plant along with the extractive principle, as it is known to contain this gas also.

1530. *Salts*, in a certain proportion, are found in most plants, such as nitrate, muriate and sulphate of potass or soda, as has been already shown. These salts are known to exist in the soil, and the root is supposed to absorb them in solution with the water by which the plant is nourished. It is at least certain that plants may be made to take up by the roots a considerable proportion of salts in a state of artificial solution. But i

salts are thus taken up by the root of the vegetating plant, does it appear that they are taken up as a food? Some plants, it must be confessed, are injured by the application of salts, as is evident from the experiments of Saussure; but others are as evidently benefited by it. Trefoil and lucerne have their growth much accelerated by the application of sulphate of lime, though many other plants are not at all influenced by its action. The parietaria, nettle, and borage will not thrive, except in such soils as contain nitrate of lime, or nitrate of potass; and plants inhabiting the sea-coast, as was observed by Du Hamel, will not thrive in a soil that does not contain muriate of soda. It has been thought, however, that the salts are not actually taken up by the root, though converted to purposes of utility, by acting as astringents or corrosives in stopping up the orifices of the vessels of the plant, and preventing the admission of too much water: but it is to be recollected that the salts in question are found by analysis in the very substance of the plant, and must consequently have entered in solution. It has been also thought that salts are favourable to vegetation, only in proportion as they hasten the putrefaction of vegetable substances contained in the soil, or attract the humidity of the atmosphere. But sulphate of lime is not deliquescent; and if its action consists merely in accelerating putrefaction, why is its beneficial effect confined but to a small number of plants? Grisenthwaite (*New Theory of Agriculture*, 1819, p. 111.) answers this question by stating, that as in the principal grain crops which interest the agriculturist, there exists a particular saline substance peculiar to each, so, if we turn our attention to the clovers and turnips, we shall still find the same discrimination. Saintfoin, clover, and lucerne have long been known to contain a notable quantity of gypsum (sulphate of lime); but such knowledge, very strange to relate, never led to the adoption of gypsum as a manure for these crops, any more than that of phosphate of lime for wheat, or nitrate of soda or potassa for barley. It is true that gypsum has been long, and in various places, recommended as a manure, but its uses not being understood, it was recommended without any reference to crop, or indeed to the accomplishment of any fixed object. It is very well known that some particular ingredient may be essential to the composition of a body, and yet constitute but a very small proportion of its mass. Atmospheric air contains only about one part in the 100 of carbonic acid; and yet no one will venture to affirm that carbonic acid gas is merely an adventitious and accidental element existing by chance in the air of the atmosphere, and not an essential ingredient in its composition. Phosphate of lime constitutes but a very small proportion of animal bodies, perhaps not one part in 500; and yet no one doubts that it is essential to the composition of the bones. But the same salt is found in the ashes of all vegetables; and who will say that is not essential to their perfection.

1531. *Earths.* As most plants have been found by analysis to contain a portion of alkaline or earthy salts, so most plants have been found to contain also a portion of earths: and as the two substances are so nearly related, and so foreign in their character from vegetable substances in general, the same enquiry has consequently been made with regard to their origin. Whence are the earths derived that have been found to exist in plants? Chiefly from the soil. But in what peculiar state of combination do they enter the vessels of the plant? The state most likely to facilitate their absorption is that of their solution in water, in which all the earths hitherto found in plants are known to be in a slight degree soluble. If it be said that the proportion in which they are soluble is so very small that it scarcely deserves to be taken into the account, it is to be recollected that the quantity of water absorbed by the plant is great, while that of the earth necessary to its health is but little, so that it may easily be acquired in the progress of vegetation. Such is the manner in which their absorption seems practicable; and Woodward's experiments afford a presumption that they are actually absorbed by the root.

1532. *The proportion of earths contained in the ashes of vegetables* depends upon the nature of the soil in which they grow. The ashes of the leaves of the *Rhododendron ferrugineum*, growing on Mount Jura, a calcareous mountain, yielded 43·25 parts of earthy carbonate, and only 0·75 of silica: but the ashes of the leaves of a plant of the same species, growing on Mount Breven, a granitic mountain, yielded two parts of silica, and only 16·75 of earthy carbonate. It is probable, however, that plants are not indebted merely to the soil for the earthy particles which they may contain. They may acquire them partly from the atmosphere. Margray has shown that rain-water contains silica in the proportion of a grain to a pound; and which, if it should not reach the root, may possibly be absorbed along with the water that adheres to the leaves. But although the earths are thus to be regarded as constituting a small proportion of vegetable food, they are not of themselves sufficient to support the plant, even with the assistance of water. Gilbert mixed together lime, alumine, silica, and magnesia, in such proportions as are generally to be met with in fertile soils, and moistened them with water. Several different grains were then sown in this artificial soil, which germinated indeed, but did not thrive; and perished when the nourishment of the cotyledons was exhausted. It is plain, therefore, that the earths, though beneficial to the growth of some vegetables, and perhaps necessary to the health of others, are by no means capable of affording any considerable degree of nourishment to the plant.

1533. *Supply of food by manures and culture.* With regard to the food of plants derived from the atmosphere, the supply is pretty regular, at least, in as far as the gases are concerned; for they are not found to vary materially in their proportions on any part of the surface of the globe: but the quantity of moisture contained in the atmosphere is continually varying, so that in the same season you have not always the same quantity,

though in the course of the year the deficiency is perhaps made up. From the atmosphere, therefore, there is a regular supply of vegetable food kept up by nature for the support of vegetable life, independent of the aid of man: and if human aid were even wanted, it does not appear that it could be of much avail. But this is by no means the case with regard to soils; for if soils are less regular in their composition, they are at least more within the reach of human management. The supply of food may be increased by altering the mechanical or chemical constitution of soils; and by the addition of food in the form of manures. The mechanical constitution of soils may be altered by pulverisation, consolidation, draining, and watering; their chemical properties by aeration and torrifaction; both mechanical and chemical properties, by the addition of earths or other substances; and manures, either liquid or solid, are supplied by the distribution of prepared fluids, dungs, and other nourishing matters, with or without their interment. (See Book III.)

1534. *Soils in a state of culture, though consisting originally of the due proportion of ingredients, may yet become exhausted of the principle of fertility by means of too frequent cropping; whether by repetition of the same, or rotation of different, crops.* In this case, it should be the object of the phytologist, as well as of the practical cultivator, to ascertain by what means fertility is to be restored to an exhausted soil, or communicated to a new one. In the breaking up of new soils, if the ground has been wet or marshy, as is frequently the case, it is often sufficient to prepare it merely by means of draining off the superfluous and stagnant water, and of paring and burning the turf upon the surface. If the soil has been exhausted by too frequent a repetition of the same crop, it often happens that a change of crop will answer the purpose of the cultivator; for, although a soil may be exhausted for one sort of grain, it does not necessarily follow that it is also exhausted for another. Accordingly, the practice of the farmer is to sow his crops in rotation, having in the same field a crop, perhaps, of wheat, barley, beans, and tares in succession; each species selecting in its turn some peculiar nutriment, or requiring, perhaps, a smaller supply than the crop which has preceded it. But even upon the plan of rotation, the soil becomes at length exhausted, and the cultivator is obliged to have recourse to other means of restoring its fertility. In this case, an interval of repose is considerably efficacious, as may be seen from the increased fertility of fields that have not been ploughed up for many years, such as those used for pasture; or even from that of the walks and paths in gardens when they are again broken up. Hence also the practice of fallowing, and of trenching, or deep ploughing which in some cases has nearly the same effect as trenching.

1535. *The fertility of a soil is restored, in the case of draining, by means of its carrying off all such superfluous moisture as may be lodged in the soil, which is well known to be prejudicial to plants not naturally aquatics, as well as by its rendering the soil more firm and compact.* In the case of burning, the amelioration is effected by means of the decomposition of the vegetable substances contained in the turf, and subjected to the action of the fire, which disperses part also of the superfluous moisture, but leaves a residue of ashes favourable to future vegetation. In the case of the rotation of crops, the fertility is not so much restored, as more completely developed and brought into action; because the soil, though exhausted for one species of grain, is yet found to be sufficiently fertile for another, the food necessary to each being different, or required in less abundance. In the case of the repose of the soil, the restored fertility may be owing to the decay of vegetable substances which are not now carried off in the annual crop, but left to augment the proportion of vegetable mould; or to the accumulation of fertilising particles conveyed to the soil by rains; or to the continued abstraction of oxygen from the atmosphere. In the case of fallows, it is owing undoubtedly to the action of the atmospheric air upon the soil, whether in rendering it more friable, or in hastening the putrefaction of noxious plants; or it is owing to the abstraction and accumulation of oxygen. In the case of trenching, or deep ploughing, it is owing to the increased facility with which the roots can now penetrate to the proper depth, by which their sphere of nourishment is increased. But it often happens that the soil can no longer be ameliorated by any of the foregoing means, or not at least with sufficient rapidity for the purposes of the cultivator; and in this case there must be a direct and actual application made to it of such substances as are fitted to restore its fertility. Hence the indispensable necessity of manures, which consist chiefly of animal and vegetable remains that are buried and finally decomposed in the soil, from which they are afterwards absorbed by the root of the plant, in a state of solution.

1536. *But as carbon is the principal ingredient furnished by manures, as contributing to the nourishment of the plant, and is not itself soluble in water, nor even disengaged by fermentation in a state of purity; under what state of chemical combination is its solution effected? Is it effected in the state of charcoal? It has been thought, indeed, that carbon in the state of charcoal is soluble in water; because water from a dunghill, when evaporated, constantly leaves a residuum of charcoal, as was first ascertained by the ex-*

periments of Hassenfratz. But there seem to be reasons for doubting the legitimacy of the conclusion that has been drawn from it; for Senebier found that plants whose roots were immersed in water took up less of the fluid in proportion as it was mixed with water from a dunghill. Perhaps then the charcoal of water from a dunghill is held merely in suspension, and enters the plant under some other modification. But if carbon is not soluble in water in the state of charcoal, in what other state is it soluble? It is soluble in the state of carbonic acid gas. But is this the state in which it actually enters the root? On this subject phytologists have been somewhat divided in opinion. Senebier endeavoured to prove that carbonic acid gas, dissolved in water, supplies the roots of plants with almost all their carbon, and founds his arguments upon the following facts:—In the first place, it is known that carbonic acid gas is soluble in water; in the second place, it is known to be contained in the soil, and generated by the fermentation of the materials composing manures; and, in the next place, it is known to be beneficial to vegetation when applied artificially to the roots, at least in a certain degree. This is evident from the following experiment of Ruckert, as well as from several experiments of Saussure's previously related. Ruckert planted two beans in pots of equal dimensions, filled with garden mould; the one was moistened with distilled water, and the other with water impregnated with carbonic acid gas. But the latter appeared above ground nine days sooner than the former, and produced twenty-five beans; while the former produced only fifteen. Now the result of this experiment, as well as the preceding facts, is evidently favourable to the presumption of Senebier, and shows that if carbonic acid is not the state in which carbon enters the plant, it is at least a state preparatory to it; and there are other circumstances tending to corroborate the opinion, resulting from the analysis of the ascending sap of plants. The tears of the vine, when analysed by Senebier, yielded a portion of carbonic acid and earth; and as the ascending sap could not be supposed to have yet undergone much alteration, the carbonic acid, like the earth, was probably taken up from the soil. But this opinion, which seems to be so firmly established upon the basis of experiment, Hassenfratz strenuously controverts. According to experiments which he had instituted with an express view to the investigation of this subject, plants which were raised in water impregnated with carbonic acid differed in no respect from such as grew in pure water, and contained no carbon that did not previously exist in the seed. Now if this were the fact, it would be decisive of the point in question. But it is plain from the experiments of Saussure, as related in the preceding section, that Hassenfratz must have been mistaken, both with regard to the utility of carbonic acid gas as furnishing a vegetable aliment, and with regard to the augmentation of carbon in the plant. The opinion of Senebier, therefore, may still be correct. It must be acknowledged, however, that the subject is not yet altogether satisfactorily cleared up; and that carbon may certainly enter the plant in some state different from that either of charcoal in solution, or of carbonic acid gas. Is not carbonic acid of the soil decomposed before entering the plant? This is a conjecture of Dr. Thomson's, founded upon the following facts:—The green oxide of iron is capable of decomposing carbonic acid; and many soils contain that oxide. Most soils, indeed, contain iron, either in the state of the brown or green oxide, and it has been found that oils convert the brown oxide into green. But dung and rich soils contain a quantity of oily substance. One effect of manures, therefore, may be that of reducing the brown oxide of iron to the green, thus rendering it capable of decomposing carbonic acid gas, so as to prepare it for some new combination, in which it may serve as an aliment for plants. All this, however, is but a conjecture; and it is more probable that the carbonic acid of the soil enters the root in combination with some other substance, and is afterwards decomposed within the plant itself.

SECT. III. *Process of Vegetable Nutrition.*

1537. *Plants are nourished in a manner in some degree analogous to that in which animals are sustained.* The food of plants, whether lodged in the soil, or wafted through the atmosphere, is taken up by introssusception in the form of gases or other fluids; it is then known as their sap: this sap ascends to the leaves, where it is elaborated as the blood of animals is in the lungs; it then enters into the general circulation of the plant, and promotes its growth.

1538. *Introssusception.* As plants have no organ analogous to the mouth of animals, they are enabled to take up the nourishment necessary to their support only by absorption or inhalation, as the chyle into the animal lacteals, or the air into the lungs. The former term is applied to the introssusception of non-elastic fluids; the latter to that of gaseous fluids. The absorption of non-elastic fluids by the epidermis of plants does not admit of a doubt. It is proved indisputably, that the leaves not only contain air, but do actually inhale it. It was the opinion of Priestley that they inhale it chiefly by the upper surface; and it has been shown by Saussure that their inhaling power depends entirely upon their organisation. It has been a question, however, among phytologists, whether

it is not also effected by the epidermis of the other parts of the plant. We can scarcely suppose it to be effected by the dry and indurate epidermis of the bark of aged trunks, of which the original organisation is obliterated; nor by that of the larger and more aged branches. But it has been thought that there are even some of the soft and succulent parts of the plant by which it cannot be effected, because no pores are visible in their epidermis. Decandolle found no pores in the epidermis of fleshy fruits, such as pears, peaches, and gooseberries; nor in that of roots, or scales of bulbs; nor in any part not exposed to the influence of air and light. It is known, however, that fruits will not ripen, and that roots will not thrive, if wholly deprived of air; and hence it is probable that they inhale it by their epidermis, though the pores by which it enters should not be visible. In the root, indeed, it may possibly enter in combination with the moisture of the soil; but in the other parts of the plant it enters no doubt in the state of gas. Herbs, therefore, and the soft parts of woody plants, absorb moisture and inhale gases from the soil or atmosphere by means of the pores of their epidermis, and thus the plant effects the introsusception of its food.

1539. *Ascent of the sap.* The means by which the plant effects the introsusception of its food, is chiefly that of absorption by the root. But the fluids existing in the soil when absorbed by the root, are designated by the appellation of sap or lymph; which, before it can be rendered subservient to the purposes of vegetable nutrition, must either be intermediately conveyed to some viscus proper to give it elaboration, or immediately distributed throughout the whole body of the plant. Our present object, therefore, is that of tracing out the progress of its distribution or ascent. The sap is in motion in one direction or other, if not all the year, at least at occasional periods, as the bleeding of plants in spring and autumn sufficiently illustrates. The plant always bleeds most freely about the time of the opening of the bud; for in proportion as the leaves expand the sap flows less copiously, and when they are fully expanded it entirely ceases. But this suspension is only temporary, for the plant may be made to bleed again in the end of the autumn, at least under certain conditions. If an incision is now made into the body of the tree, after the occurrence of a short but sharp frost, when the heat of the sun or mildness of the air begins to produce a thaw, the sap will again flow. It will flow even where the tree has been but partially thawed, which sometimes happens on the south side of a tree, when the heat of the sun is strong and the wind northerly. At the seasons now specified, therefore, the sap is evidently in motion; but the plant will not bleed at any other season of the year. It has been the opinion of some phytologists, that the motion of the sap is wholly suspended during the winter. But though the great cold of winter, as well as the great heat of summer, is by no means so favourable to vegetation as the milder though more changeable temperature of spring and autumn, yet it does not wholly suspend the movement of the sap. Palms may be made to bleed at any season of the year; and although this is not the case with plants in general, yet there is proof sufficient that the colds of winter do not, even in this climate, entirely prevent the sap from flowing. Buds exhibit a gradual development of parts throughout the whole of the winter, as may be seen by dissecting them at different periods. So also do roots. Evergreens retain their leaves; and many of them, such as the arbutus, laurustinus, and the beautiful tribe of the mosses, protrude also their blossoms, even in spite of the rigour of the season. But all this could not possibly be accomplished, if the motion of the sap were wholly suspended.

1540. *Thus the sap is in perpetual motion, with a more accelerated or more diminished velocity, throughout the whole of the year;* but still there is no decided indication exhibited in the mere circumstance of the plant's bleeding, of the direction in which the sap is moving at the time; for the result might be the same whether it was passing from the root to the branches, or from the branches to the root. But as the great influx of the sap is effected by means of the pores of the epidermis of the root, it follows that its motion must, at least in the first place, be that of ascent; and such is its direction at the season of the plant's bleeding, as may be proved by the following experiment:—If the bore or incision that has been made in the trunk is minutely inspected while the plant yet bleeds, the sap will be found to issue almost wholly from the inferior side. If several bores are made in the same trunk, one above another, the sap will begin to flow first from the lower bore, and then from those above it. If a branch of a vine be lopped, the sap will issue copiously from the section terminating the part that remains yet attached to the plant; but not from the section terminating the part that has been lopped off. This proves indubitably that the direction of the sap's motion, during the season of the plant's bleeding, is that of ascent. But if the sap flows so copiously during the season of bleeding, it follows that it must ascend with a very considerable force; which force has accordingly been made the subject of calculation. To the stem of a vine cut off about two feet and a half from the ground, Hales fixed a mercurial gauge which he luted with mastic; the gauge was in the form of a siphon, so contrived that the mercury might be made to rise in proportion to the pressure of the ascending sap. The mercury rose accordingly,

and reached, at its maximum, to a height of thirty-eight inches. But this was equivalent to a column of water to the height of forty-three feet three and one third inches; demonstrating a force in the motion of the sap that, without the evidence of experiment, would have seemed altogether incredible.

1541. *Thus the sap, in ascending from the lower to the upper extremity of the plant, is propelled with a very considerable force, at least in the bleeding season.* But is the ascending sap propelled indiscriminately throughout the whole of the tubular apparatus, or is it confined in its course to any particular channel? Before the anatomy of plants had been studied with much accuracy, there was a considerable diversity of opinion on the subject. Some thought it ascended by the bark; others thought it ascended by the bark, wood, and pith, indiscriminately; and others thought it ascended between the bark and wood. The first opinion was maintained and supported by Malpighi; and Grew considered that the sap ascends by the bark, wood, and pith, indiscriminately. Du Hamel stripped several trees of their bark entirely, which continued, notwithstanding, to live for many years, protruding new leaves and new branches as before. Knight stripped the trunks of a number of young crab trees of a ring of bark half an inch in breadth; but the leaves were protruded, and the branches elongated, as if the operation had not been performed. Du Petit Thouars removed the central wood and pith from the stems of several young sycamore trees, leaving the upper part to be supported only by four pillars of bark: in others he removed the bark, liber, and alburnum, leaving the upper part of the tree to be supported solely by the central wood. In each case the tree lived, so that he concludes that both the bark and wood are competent to act as conductors to the sap. (*Hist. d'un Morceau de Bois, Hort. Tour.* 481.)

1542. *That the sap does not ascend exclusively by the bark* is thus rendered sufficiently evident. But it is equally evident that it does not ascend by the pith, at least after the first year; for then, even upon Grew's own supposition, it becomes either juiceless or wholly extinct: and even during the first year it is not absolutely necessary, if at all subservient to the ascent of the sap, as is proved by an experiment of Knight's. Having contrived to abstract from some annual shoots a portion of their pith, so as to interrupt its continuity, but not otherwise materially to injure the fabric of the shoot, Knight found that the growth of the shoots which had been made the subject of experiment was not at all affected by it.

1543. *The sap ascends neither by the bark nor pith, but by the wood only.* But the whole mass of the wood throughout is not equally well adapted for the purpose of conveying it. The interior and central part, or that which has acquired its last degree of solidity, does not in general afford it a passage. This is proved by what is called the girdling of trees, which consists in making a circular gap or incision quite round the stem, and to the depth of two or three inches, so as to cut through both the bark and alburnum. An oak tree on which Knight had performed this operation, with a view to ascertain the channel of the sap's ascent, exhibited not the slightest mark of vegetation in the spring following. The sap then does not ascend through the channel of the matured wood. But if the sap ascends neither through the channel of the bark, nor pith, nor matured wood, through what other channel does it actually ascend? The only remaining channel through which it can possibly ascend is that of the alburnum. In passing through the channel of the alburnum, does the sap ascend promiscuously by the whole of the tubes composing it, or is it confined in its passage to any peculiar set? The earliest conjectures recorded on this subject are those of Grew and Malpighi, who, though they maintained that the sap ascends chiefly by the bark, did not yet deny that it ascends also partly by the alburnum or wood. It occurred to succeeding phytologists that the progress of the sap, and the vessels through which it passes, might be traced or ascertained by means of making plants vegetate in coloured infusions. Du Hamel steeped the extremities of branches of the fig, elder, honeysuckle, and filbert in common ink. In examining the two former, after being steeped for several days, the part immersed was found to be black throughout, but the upper part was tinged only in the wood, which was coloured for the length of a foot, but more faintly and partially in proportion to the height. The pith, indeed, exhibited some traces of ink, but the bark and buds none. In some other examples the external layers of the wood only were tinged. In the honeysuckle the deepest shade was about the middle of the woody layers; and in the filbert there was also observed a coloured circle surrounding the pith, but none in the pith itself, nor in the bark.

1544. *Thus it is proved that the sap ascends through the vessels of the longitudinal fibre composing the alburnum of woody plants, and through the vessels of the several bundles of longitudinal fibre constituting the woody part of herbaceous plants.* But it has been already shown that the vessels composing the woody fibre are not all of the same species. There are simple tubes, porous tubes, spiral tubes, mixed tubes, and interrupted tubes. Through which of these, therefore, does the sap pass in its ascent? The best reply to this enquiry has been furnished by Knight and Mirbel. Knight prepared some annual shoots of the

apple and horsechestnut, by means of circular incisions, so as to leave detached rings of bark with insulated leaves remaining on the stem. He then placed them in coloured infusions obtained by macerating the skins of very black grapes in water; and, on examining the transverse section at the end of the experiment, it was found that the infusion had ascended by the wood beyond his incisions, and also into the insulated leaves, but had not coloured the pith nor bark, nor the sap between the bark and wood. From the above experiment, Knight concludes that the sap ascends through what are called the common tubes of the wood and alburnum, at least till it reaches the leaves. Thus the sap is conveyed to the summit of the alburnum. But Knight's next object was to trace the vessels by which it is conveyed into the leaf. The apple tree and horsechestnut were still his subjects of experiment. In the former the leaves are attached to the plants by three strong fibres, or rather bundles of tubes, one in the middle of the leaf-stalk, and one on each side. In the latter they are attached by means of several such bundles. Now the coloured fluid was found in each case to have passed through the centre of the several bundles, and through the centre only, tinging the tubes throughout almost the whole length of the leaf-stalk. In tracing their direction from the leaf-stalk upwards, they were found to extend to the extremity of the leaves; and in tracing their direction from the leaf-stalk downwards, they were found to penetrate the bark and alburnum, the tubes of which they join, descending obliquely till they reach the pith which they surround. From their position Knight calls them central tubes, thus distinguishing them from the common tubes of the wood and alburnum, and from the spiral tubes with which they were every where accompanied as appendages, as well as from a set of other tubes which surrounded them, but were not coloured, and which he designates by the appellation of external tubes. The experiment was now transferred to the flower-stalk, and fruit-stalk, which was done by placing branches of the apple, pear, and vine, furnished with flowers not yet expanded, in a decoction of logwood. The central vessels were rendered apparent as in the leaf-stalk. When the fruit of the two former was fully formed, the experiment was then made upon the fruit-stalk, in which the central vessels were detected as before; but the colouring matter was found to have penetrated into the fruit also, diverging round the core, approaching again in the eye of the fruit, and terminating at last in the stamens. This was effected by means of a prolongation of the central vessels, which did not however appear to be accompanied by the spiral tubes beyond the fruit-stalk. Such then are the parts of the plant through which the sap ascends, and the vessels by which it is conveyed. Entering by the pores of the epidermis, it is received into the longitudinal vessels of the root by which it is conducted to the collar. Thence it is conveyed by the longitudinal vessels of the alburnum, to the base of the leaf-stalk, and peduncle; from which it is further transmitted to the extremity of the leaves, flower, and fruit. There remains a question to be asked intimately connected with the sap's ascent. Do the vessels conducting the sap communicate with one another by inoculation or otherwise, so as that a portion of their contents may be conveyed in a lateral direction, and, consequently, to any part of the plant; or do they form distinct channels throughout the whole of their extent, having no sort of communication with any other set of tubes, or with one another? Each of the two opinions implied in the question has had its advocates and defenders: but Du Hamel and Knight have shown that a branch will still continue to live, though the tubes leading directly to it are cut in the trunk; from which it follows that the sap, though flowing the most copiously in the direct line of ascent, is at the same time also diffused in a transverse direction.

1545. *Causes of the sap's ascent.* By what power is the sap propelled? Grew states two hypotheses: its volatile nature and magnetic tendency, aided by the agency of fermentation. Malpighi was of opinion that the sap ascends by means of the contraction and dilatation of the air contained in the air-vessels. M. De la Hire attempted to account for the phenomenon by combining together the theories of Grew and Malpighi; and Borelli, who endeavoured to render their theory more perfect, by bringing to its aid the influence of the condensation and rarefaction of the air and juices of the plant.

1546. *Agency of heat.* Du Hamel directed his efforts to the solution of the difficulty, by endeavouring to account for the phenomenon from the agency of heat, and chiefly on the following grounds: because the sap begins to flow more copiously as the warmth of spring returns; because the sap is sometimes found to flow on the south side of a tree before it flows on the north side, that is, on the side exposed to the influence of the sun's heat sooner than on the side deprived of it; because plants may be made to vegetate, even in the winter, by means of forcing them in a hot-house; and because plants raised in a hot-house produce their fruit earlier than such as vegetate in the open air. There can be no doubt of the great utility of heat in forwarding the progress of vegetation; but it will not therefore follow that the motion and ascent of the sap are to be attributed to its agency. On the contrary, it is very well known that if the temperature exceeds a certain degree, it becomes then prejudicial both to the ascent of the sap and also to the growth of the plant. Hales found that the sap flows less rapidly at mid-day than in the morning; and every body knows that vegetation is less luxuriant at midsummer than in the spring. So also, in the case of forcing, it happens but too often that the produce of the hot-house is totally destroyed by the unskillful application of heat. If heat is actually the cause of the sap's ascent, how comes it that the degree necessary to produce the effect is so very variable, even in the same climate? For there are many plants, such as the arbutus, laurustinus, and the mosses, which will continue not only to vegetate,

but to protrude their blossoms and mature their fruit, even in the midst of winter, when the temperature is at the lowest; and, in the case of submarine plants, the temperature can never be very high: so that, although heat does no doubt facilitate the ascent of the sap by its tendency to make the vessels expand, yet it cannot be regarded as the efficient cause, since the sap is proved to be in motion even throughout the whole of the winter. Du Hamel endeavours, however, to strengthen the operation of heat by means of the influence of humidity, as being also powerful in promoting the ascent of the sap, whether as relative to the season of the year or time of the day. The influence of the humidity of the atmosphere cannot be conceived to operate as a propelling cause, though it may easily be conceived to operate as affording a facility to the ascent of the sap in one way or other; which under certain circumstances is capable of most extraordinary acceleration, but particularly in that state of the atmosphere which forbodes or precedes a storm. In such a state a stalk of wheat was observed by Du Hamel to grow three inches in three days; a stalk of barley six inches, and a shoot of a vine almost two feet; but this is a state that occurs but seldom, and cannot be of much service in the general propulsion of the sap. On this intricate but important subject Linnæus appears to have embraced the opinion of Du Hamel, or an opinion very nearly allied to it; but does not seem to have strengthened it by any new accession of argument; so that none of the hitherto alleged causes can be regarded as adequate to the production of the effect.

1547. *Irritability.* Perhaps the only adequate cause ever suggested, prior to the hypothesis of Dutrochet, is that alleged by Saussure. According to Saussure the cause of the sap's ascent is to be found in a peculiar species of irritability inherent in the sap-vessels themselves, and dependent upon vegetable life; in consequence of which they are rendered capable of a certain degree of contraction, according to the affection of the internal surface by the application of stimuli, as well as of subsequent dilatation according to the subsidence of the action of the stimulus; thus admitting and propelling the sap by alternate dilatation and contraction. In order to give elucidation to the subject, let the tube be supposed to consist of an indefinite number of hollow cylinders united one to another, and let the sap be supposed to enter the first cylinder by capillary attraction, or by any other adequate means; then the first cylinder being excited by the stimulus of the sap, begins gradually to contract, and to propel the contained fluid into the cylinder immediately above it. But the cylinder immediately above it, when acted on in the same manner, is affected in the same manner; and thus the fluid is propelled from cylinder to cylinder till it reaches the summit of the plant. So also when the first cylinder has discharged its contents into the second, and is no longer acted upon by the stimulus of the sap, it begins again to be dilated to its original capacity, and prepared for the intrusception of a new portion of fluid. Thus a supply is constantly kept up, and the sap continues to flow. The above is by far the simplest as well as most satisfactory of all theories accounting for the ascent of the sap.

1548. *Contraction and dilatation.* Knight has presented us with a theory which, whatever may be its real value, merits at least our particular notice, as coming from an author who stands deservedly high in the list of physiological writers. This theory rests upon the principle of the contraction and dilatation, not of the sap-vessels themselves, as in the theory of Saussure, but of what Knight denominates the *stiver grain*, assisted perhaps by heat and humidity expanding or condensing the fluids. (*Phil. Trans.*, 1801.) Keith considers this theory of Knight as beset with many difficulties, and the agency of the alleged cause as totally inadequate to the production of the effect to be accomplished.

1549. *Necessity of an equilibrium in the plant.* Du Petit Thouars attributes the motion of the sap to an inherent power, with which nature has been pleased to endow vegetables. But the cause of the renewal of its motion in the spring, after remaining in a quiescent state for several months, he ascribes to the necessity of maintaining a perfect equilibrium in the system of a plant. So that, if a consumption of sap is produced at any given point, the necessity of making good the space so occasioned consequently throws all the particles of sap into motion; and the same effect will continue to operate as long as any consumption of sap takes place. The first cause of this consumption of sap he declares to be the development of the buds, and already formed young leaves, by the stimulating action of light and heat, but particularly of the latter. As soon as this development occurs, an assimilation and absorption of sap is occasioned for the support of the young leaves, a vacancy in the immediate vicinity of the leaves is produced, and a motion immediately takes place. (*London Encyc.*, art. *Bot.*)

1550. *Electricity.* The most satisfactory hypothesis for the ascent of the sap is that of M. Dutrochet. This philosopher, by careful examination with a microscope, found that the minute conical termination of the radicle was furnished with other projecting bodies, like sponges, which perform the office of the piston of a syringe, and have the power of introducing into their cavity, and through their sides, the water which comes in contact with the exterior surface, and which spongioles oppose, at the same time, the exit of any fluid which they may imbibe. The motions of the sap and juice in plants take place, according to this author, in consequence of the operations of two distinct currents of electricity: the one negative, by which the vessels have the power of absorption, which M. Dutrochet calls *endosmose*, and by which the vessels become turgid; and the other positive, by which the vessels exude or secrete, which power M. Dutrochet calls *exosmose*. (*Gardener's Mag.*, vol. iii. p. 78; *Dutrochet, Agent Immédiat du mouvement vital*, Paris, 8vo, 1826.)

1551. *Elaboration of the sap.* The moisture of the soil is no sooner absorbed into the plant than it begins to undergo a change. This is proved by the experiment of making a bore or incision in the trunk of a tree during the season of bleeding; the sap that issues from the wound possesses properties very different from the mere moisture of the soil, as is indicated by means of chemical analysis and sometimes also by means of a peculiar taste or flavour, as in the case of the birch tree. Hence the sap has already undergone a certain degree of elaboration; either in passing through the glands of the cellular tissue, which it reaches through the medium of a lateral communication, or in mingling with the juices contained in the cells, and thus carrying off a portion of them; in the same manner, we may suppose, that water, by filtering through a mineral vein, becomes impregnated with the mineral through which it passes. But this primary and incipient stage of the process of elaboration must always of necessity remain a mystery to the physiologist, as being wholly effected in the interior of the plant, and consequently beyond the reach of observation. All he can do, therefore, is to trace out its future progress, and to watch its succeeding changes, in which the *rationale* of the process of elaboration may be more evident.

1552. *The process of elaboration is chiefly operated in the leaf:* for the sap no sooner reaches the leaf, than part of it is immediately carried off by means of perspiration, perceptible or imperceptible; effecting a change in the proportion of its component parts, and by consequence a change in its properties.

1553. *Hales* reared a sun-flower in a pot of earth till it grew to the height of three feet and a half; he then covered the mouth of the pot with a plate of lead, which he cemented so as to prevent all evaporation from the earth contained in it. In this plate he fixed two tubes, the one nine inches in length and of but small diameter, left open to serve as a medium of communication with the external air; the other two

inches in length and one in diameter, for the purpose of introducing a supply of water, but kept always shut except at the time of watering. The holes at the bottom of the pot were also shut, and the pot and plant weighed for fifteen successive days in the months of July and August: hence he ascertained not only the fact of transpiration by the leaves, from a comparison of the supply and waste; but also the quantity of moisture transpired in a given time, by subtracting from the total waste the amount of evaporation from the pot. The final result proved that the absorbing power of the root is greater than the transpiring power of the leaves, in the proportion of five to two. Similar experiments were also made upon some species of cabbage, whose mean transpiration was found to be 1 lb. 3 oz. per day; and on some species of evergreen, which were found, however, to transpire less than other plants. The same is the case also with succulent plants, which transpire but little in proportion to their mass, and which as they become more firm transpire less. It is known, however, that they absorb a great deal of moisture, though they give it out thus sparingly; which seems intended by nature for the purpose of resisting the great droughts to which they are generally exposed, inhabiting, as they do for the most part, the sandy desert or the sunny rock. Along with his own experiments Hales relates also some others that were made by Miller of Chelsea; the result of which was that, other circumstances being the same, transpiration is in proportion to the transpiring surface, and is affected by the temperature of the air; sunshine or drought promoting it, and cold and wet diminishing or suppressing it entirely. It is also greatest from six o'clock in the morning till noon, and is least during the night. But when transpiration becomes too abundant, owing to excess of heat or drought, the plant immediately suffers and begins to languish; and hence the leaves droop during the day, though they are again revived during the night. For the same or for a similar reason, transpiration has been found also to increase as the heat of summer advances; being more abundant in July than in June, and still more in August than in either of the preceding months, from which last period it begins again to decrease.

1554. *A fluid little different from common water is exhaled, according to the experiments of Hales and Guettard; in some cases it had the odour of the plant; but Du Hamel found that it became sooner putrid than water.* Such then are the facts that have been ascertained with regard to the imperceptible perspiration of plants, from which it unavoidably follows that the sap undergoes a very considerable modification in its passage through the leaf.

1555. *Perceptible perspiration, which is an exudation of sap too gross or too abundant to be dissipated immediately, and which hence accumulates on the surface of the leaf, is the cause of its further modification.* It is very generally to be met with, in the course of the summer, on the leaves of the maple, poplar, and lime tree; but particularly on the surface exposed to the sun, which it sometimes wholly covers.

1556. *The physical as well as chemical qualities of perspired matter are very different in different species of plants; so that it is not always merely an exudation of sap, but of sap in a high state of elaboration, or mingled with the peculiar juices or secretions of the plant.* Sometimes it is a clear and watery fluid conglomeration into large drops, such as are said to have been observed by Miller, exuding from the leaves of the *Musa paradisiaca*, or plantain tree; and such as are sometimes to be seen in hot and calm weather exuding from the leaves of the poplar or willow, and trickling down in such abundance as to resemble a slight shower. This phenomenon was observed by Sir J. E. Smith, under a grove of willows in Italy, and is said to have occurred even in England. Sometimes it is glutinous, as on the leaf of the lime tree; sometimes it waxy, as on the leaves of rosemary; sometimes it is saccharine, as on the orange leaf; or resinous, as on the leaves of the *Cistus créticus*. The cause of this excess of perspiration has not yet been altogether satisfactorily ascertained; though it seems to be merely an effort and institution of nature to throw off all such redundant juices as may have been absorbed, or secretions as may have been formed, beyond what are necessary to the due nourishment or composition of the plant, or beyond what the plant is capable of assimilating at the time. Hence the watery exudation is perhaps nothing more than a redundancy of the fluid thrown off by imperceptible perspiration, and the waxy and resinous exudations nothing more than a redundancy of secreted juices; all which may be still perfectly consistent with a healthy state of the plant. But there are cases in which the exudation is to be regarded as an indication of disease, particularly in that of the exudation known by the name of honey-dew, a sweet and viscid substance covering the leaves like a varnish, and sometimes occasioning their decay. Such at least seems to be the fact with regard to the honey-dew of the hop, which, according to the observations of Linnæus, is the consequence of the attacks of the caterpillar of the ghost-moth injuring the root; and such seems also to be the fact with regard to the honey-dew of the beech tree, and perhaps also the honey-dew of the oak. The sap then, in the progress of its ascent from the extremity of the root to the extremity of the leaf, undergoes a considerable change, first in its mixing with the juices already contained in the plant, and then in its throwing off a portion at the leaf.

1557. *The sap is further affected by means of the gases entering into the root along with the moisture of the soil, but certainly, by means of the gases inhaled into the leaf; the action and elaboration of which shall now be elucidated.*

1558. *Elaboration of carbonic acid.* The utility of carbonic acid gas, as a vegetable food, has been already shown; plants being found not only to absorb it by the root along with the moisture of the soil, but also to inhale it by the leaves, at least when vegetating in the sun or during the day. But how is the elaboration of this gas effected? Is it assimilated to the vegetable substance immediately upon entering the plant, or is its assimilation effected by means of intermediate steps? The gas thus inhaled or absorbed is not assimilated immediately, or at least not wholly: for it is known that plants do also evolve carbonic acid gas when vegetating in the shade, or during the night. Priestley ascertained that plants vegetating in state of their atmospheres after experiment is owing to that evolution; and Sausure that the elaboration of carbonic acid gas is essential to vegetation in the sun; and, finally, Senebier and Sausure proved that the carbonic acid gas contained in water is abstracted and inhaled by the leaf, and immediately decomposed; the carbon being assimilated to the substance of the plant, and the oxygen in part evolved and in part also assimilated. The decomposition of carbonic acid gas takes place only during the light of day, though Sausure has made it also probable that plants decompose a part of the carbonic acid gas, which they form with the surrounding oxygen, even in the dark. But the effect is operated chiefly by means of the leaves and other green parts of vegetables, that is, chiefly by the parenchyma; the wood, roots, petals, and leaves that have lost their green colour, not being found to exhale oxygen gas. It may be observed, however, that the green colour is not an absolutely essential character of the parts decomposing carbonic acid; because the leaves of a peculiar variety of the *Atriplex hortensis*, in which all the green parts change to red, do still exhale oxygen gas.

1559. *Elaboration of oxygen.* It has been already shown that the leaves of plants abstract oxygen from confined atmospheres, at least when placed in the shade, though they do not inhale all the oxygen that disappears; and it has been further proved, from experiment, that the leaves of plants do also evolve a gas in the sun. From a great variety of experiments relative to the action and influence of oxygen on the

plant, and the contrary, the following is the sum of the results:—The green parts of plants, but especially the leaves, when exposed in atmospheric air to the successive influence of light and shade, inhale and evolve alternately a portion of oxygen gas mixed with carbonic acid. But the oxygen is not immediately assimilated to the vegetable substance; it is first converted into carbonic acid by means of combining with the carbon of the plant, which withers if this process is prevented by the application of lime or potash. The leaves of aquatics, succulent plants, and evergreens consume, in equal circumstances, less oxygen than the leaves of other plants. The roots, wood, and petals, and in short all parts not green, with the exception of some coloured leaves, do not effect the successive and alternate inhalation and extrication of oxygen; the inhale it indeed, though they do not again give it out, or assimilate it immediately, but convey it under the form of carbonic acid to the leaves, where it is decomposed. Oxygen is indeed assimilated to the plant but not directly, and only by means of the decomposition of carbonic acid; when part of it, though in a very small proportion, is retained also and assimilated along with the carbon. Hence the most obvious influence of oxygen, as applied to the leaves, is that of forming carbonic acid gas, and thus presenting to the plants elements which it may assimilate; and perhaps the carbon of the extractive juices absorbed even by the root, is not assimilated to the plant till it is converted by means of oxygen into carbonic acid. But as an atmosphere composed of nitrogen and carbonic acid gas only is not favourable to vegetation, it is probable that oxygen performs also some other function beyond that of merely presenting to the plant, under the modification of carbonic acid, elements which it may assimilate. It may affect also the disengagement of caloric by its union with the carbon of the vegetable, which is the necessary result of such union. But oxygen is also beneficial to the plant from its action on the soil; for when the extractive juices contained in the soil have become exhausted, the oxygen of the atmosphere, by penetrating into the earth and abstracting from it a portion of its carbon, forms a new extract to replace the first. Hence we may account for a number of facts observed by the earlier phytologists, but not well explained. Du Hamel remarked that the lateral roots of plants are always the more vigorous the nearer they are to the surface; but it now appears that they are the most vigorous at the surface because they have there the easiest access to the oxygen of the atmosphere, or to the extract which it may form. It was observed, also, by the same phytologist, that perpendicular roots do not thrive so well, other circumstances being the same, in a stiff and wet soil as in a friable and dry soil; while plants with slender and divided roots thrive equally well in both; but this is, no doubt, owing to the obstacles that present themselves to the passage of the oxygen in the former case, on account of the greater depth and smaller surface of the root. It was further observed, that roots which penetrate into dung or into pipes conducting water, divide into immense numbers of fibres, and form what is called the fox-tail root; but it is because they cannot continue to vegetate, except by increasing their points of contact, with the small quantity of oxygen found in such mediums. Lastly, it was observed that plants, whose roots are suddenly overflooded with water remaining afterwards stagnant, suffer sooner than if the accident had happened by means of a continued current. It is because in the former case the oxygen contained in the water is soon exhausted, while in the latter it is not exhausted at all. Hence also we may account for the phenomenon exhibited by plants vegetating in distilled water under a receiver filled with atmospheric air, which, having no proper soil to apply the root with nourishment, effect the development of their parts only at the expense of their own proper substance; the interior of the stem, or a portion of the root, or the lower leaves, decaying and giving up their extractive juices to the other parts.—Thus it appears that oxygen gas, or that constituent part of the atmospheric air which has been found to be indispensable to the life of animals, is also indispensable to the life of vegetables. But, although the presence and action of oxygen are absolutely necessary to the process of vegetation, plants do not thrive so well in an atmosphere of pure oxygen, as in an atmosphere of pure or common air. This was proved by an experiment of Saussure's, who, having introduced some plants of *Plum sativum*, that were but just issuing from the seed, into a receiver containing pure oxygen gas, found that in the space of six days they had acquired only half the weight of such as were introduced at the same time into a receiver containing common air. Whence it follows that oxygen, though the principal agent in the process of vegetation, is not yet the only agent necessary to the health and growth of the plant, and that the proportion of the constituent parts of the atmospheric air is well adapted for the purposes both of vegetable and animal life.

1560. *Decomposition of water.* Although the opinion was proved to be groundless, by which water had been supposed to be convertible into all the different ingredients entering into the composition of the vegetable substance, by means of the action of the vital energy of the plant; yet when water was ultimately proved to be a chemical compound, it was by no means absurd to suppose that plants may possess the power of decomposing part, at least, of what they absorb by the root, and thus acquire the hydrogen as well as a portion of the oxygen which, by analysis, they are found to contain. This opinion was, accordingly, pretty generally adopted, but was not yet proved by any direct experiment. Senebier pointed out several phenomena from which he thought it was to be inferred, but particularly that of the germination of some seeds moistened merely with water, and so situated as to have no apparent contact with oxygen. The decomposition of water was inferred also by Ingenhouz, from the amelioration of an atmosphere of common air into which he had introduced some succulent plants vegetating in pure water. Saussure having gathered a number of plants, of the same species, as nearly alike as possible in all circumstances likely to be affected by the experiment, dried part of them to the temperature of the atmosphere, and ascertained their weight; the rest he made to vegetate in pure water, and in an atmosphere of pure oxygen for a given period of time, at the end of which he dried them as before, and ascertained their weight also, which it was thus only necessary to compare with the weight of the former, in order to know whether the plants had increased in solid vegetable substance or not. But after many experiments on a variety of plants, the result always was, that plants when made to vegetate in pure water only, and in an atmosphere of pure oxygen, or of common air deprived of its carbonic acid, scarcely added any thing at all to their weight in a dried state; or if they did, the quantity was too small to be appreciated. But from a similar experiment, in which carbonic acid gas was mixed with common air, the decomposition and fixation of water by the vegetating plant are legitimately inferred. It does not appear, however, that plants do in any case decompose water directly; that is, by appropriating its hydrogen and at the same time disengaging its oxygen in the form of gas, which is extricated only by the decomposition of carbonic acid.

1561. *Descent of the proper juice.* When the sap has been duly elaborated in the leaf

by means of the several processes that have just been described, it assumes the appellation of the *cambium*, or proper juice of the plant. In this ultimate state of elaboration it is found chiefly in the bark, or rather between the bark and wood, and may very often be distinguished by a peculiar colour, being sometimes white, as in the several species of spurge, and sometimes yellow, as in celandine. It is said to be the principal seat of the medical virtues of plants; and was regarded by Malpighi as being to the plant what the blood is to the animal body, the immediate principle of nourishment and grand support of life; which opinions he endeavours to establish by the following analogies: if the blood escapes from the vessels of the animal body, it forms neither flesh nor bone, but tumours; if the proper juices of the plant are extravasated, they form neither bark nor wood, but a lump of gum, resin, or inspissated juice. The disruption of the blood-vessels, and consequent loss of blood, injure and often prove fatal to the animal; the extravasation of the proper juice injures and often proves fatal to vegetables, unless the evil is prevented by the skill and management of the gardener. Whatever may be the value of these remarks as tending to establish the analogy in question, it cannot be doubted that the *cambium*, or proper juice, constitutes at least the grand principle of vegetable organisation; generating and developing in succession the several organs of the plant, or furnishing the vital principle with the immediate materials of assimilation.

1562. *The proper juice is conveyed to the several parts of the plant by an appropriate set of vessels.* One of the earliest and most satisfactory experiments on this subject, at least as far as regards the return of the proper juice through the leaf and leaf-stalk, is that of Dr. Darwin, which was conducted as follows: a stalk of the *Euphórbia helioscopia*, furnished with its leaves and seed-vessels, was placed in a decoction of madder-root, so as that the lower portion of the stem and two of the inferior leaves were immersed in it. After remaining so for several days the colour of the decoction was distinctly discerned passing along the midrib of each leaf. On the upper side of the leaf many of the ramifications, going from the midrib towards the circumference, were observed to be tinged with red; but on the under side there was observed a system of branching vessels, originating in the extremities of the leaf, and carrying not a red but a pale milky fluid, which, after uniting in two sets, one on each side the midrib, descended along with it into the leaf-stalk. These were the vessels returning the elaborated sap. The vessels observable on the upper surface Darwin calls arteries, and those on the under surface he calls veins. To this may be added the more recent discoveries of Knight, who, in his experiments instituted with a view to ascertain the course of the sap, detected in the leaf-stalk, not only the vessels which he calls central tubes, through which the coloured infusion ascended, together with their appendages, the spiral tubes; but also another set of vessels surrounding the central tubes, which he distinguishes by the appellation of external tubes, and which appeared to be conveying in one direction or other a fluid which was not coloured, but which proved, upon further investigation, to be the descending proper juice. In tracing them upwards they were found to extend to the summit of the leaf, and in tracing them downwards they were found to extend to the base of the leaf-stalk, and to penetrate even into the inner bark. According to Knight, then, there are three sets of vessels in leaves, the central tubes, the spiral tubes, and the external tubes. But by what means is the proper juice conducted from the base of the leaf-stalk to the extremity of the root? This was the chief object of the enquiry of the earlier phytologists who had not yet begun to trace its progress in the leaf and leaf-stalk; but who were acquainted with facts indicating at least the descent of a fluid in the trunk. Du Hamel stript sixty trees of their bark in the course of the spring, laying them bare from the upper extremity of the trunk and branches to the root; the experiment proved indeed fatal to them, as they all died in the course of three or four years. But many of them had made new productions both of wood and bark from the buds downwards, extending in some cases to the length of a foot; though very few of them had made any new productions from the root upwards. Hence it is that the proper juice not only descends from the extremity of the leaf to the extremity of the root, but generates also in its descent new and additional parts. The experiments of Knight on this subject are, if possible, more convincing than even those of Du Hamel. From the trunks of a number of young crab trees he detached a ring of bark of half an inch in breadth. The sap rose in them, and the portion of the trunk above the ring augmented as in the other subjects that were not so treated, while the portion below the ring scarcely augmented at all. The upper lips of the wounds made considerable advances downwards, while the lower lips made scarcely any advances upwards; but if a bud were protruded under the ring, and the shoot arising from it allowed to remain, then the portion of the trunk below that bud began immediately to augment in size, while the portion between the bud and incision remained nearly as before. When two circular incisions were made in the trunk so as to leave a ring of bark between them with a leaf growing from it, the portion above the leaf died, while the portion below the leaf lived; and when the upper part of a branch was stripped of its leaves the bark withered as far as it was stript. Whence it is evident that the sap which has been elaborated in the leaves and converted into proper juice, descends through the channel of the bark, or rather between the bark and alburnum to the extremity of the root, effecting the development of new and additional parts. But not only is the bark thus ascertained to be the channel of the descent of the proper juice after entering the trunk; the peculiar vessels through which it immediately passes have been ascertained also. In the language of Knight they are merely a continuation of the external tubes already noticed, which after quitting the base of the foot-stalk he describes as not only penetrating the inner bark, but descending along with it and conducting the proper juice to the very extremity of the root. In the language of Mirbel they are the large or rather simple tubes so abundant in the bark of woody plants, though not altogether confined to it; and so well adapted by the width of their diameter to afford a passage to the proper juice.

1563. *Causes of descent.* The proper juice then, or sap elaborated in the leaf, descends by the returning vessels of the leaf stalk, and by the longitudinal vessels of the inner bark, the large tubes of Mirbel and external tubes of Knight, down to the extremity of the root.

1564. *The descent of the proper juice* was regarded by the earlier phytologists as resulting from the agency of gravitation, owing perhaps more to the readiness with which the conjecture suggests itself than to the satisfaction which it gives. But the insufficiency of this cause was clearly pointed out by Du Hamel, who observed in his experiments with ligatures that the tumour was always formed on the side next to the leaves, even when the branch was bent down, whether by nature or art, so as to point to the earth, in which case the power propelling the proper juice is acting not only in opposition to that of gravitation, but with such force as to overcome it. This is an unanswerable argument; and yet it seems to have been altogether overlooked, or at least undervalued in its importance, by Knight, who endeavours to account for the effect by ascribing it to the joint operation of gravitation, capillary attraction, the waving motion of the tree, and the structure of the conducting vessels; but the greatest of these causes is gra-

vitation. Certain it is that gravitation has considerable influence in preventing the descent of the sap in young shoots of trees which have grown upright; these, when bent down after being fully grown, form larger buds, and often blossom instead of leaf buds. This practice, with a view to the production of blossom-buds, is frequently adopted by gardeners (*Hort. Trans.* i. 237.) in training fruit trees. — These causes are each, perhaps, of some efficacy; and yet even when taken altogether they are not adequate to the production of the effect. The greatest stress is laid upon gravitation; but its agency is obviously over-rated, as is evident from the case of the pendent shoots of the weeping willow; and if gravitation is so very efficacious in facilitating the descent of the proper juice, how comes its influence to be suspended in the case of the ascending sap? The action of the silver grain will scarcely be sufficient to overcome it; and if it should be said that the sap ascends through the tubes of the albumen by means of the agency of the vital principle, why may not the same vital principle conduct also the proper juice through the returning vessels of the bark? In short, if, with Saussure, we admit the existence of a contracting power in the former case sufficient to propel the sap from ring to ring, it will be absolutely necessary to admit it also in the latter. Thus we assign a cause adequate to the production of the effect, and avoid at the same time the transgression of that most fundamental principle of all sound philosophy which forbids us to multiply causes without necessity. M. Dutrochet's hypothesis (1550.) for the ascent of the sap accounts equally for its descent.

SECT. IV. *Process of Vegetable Developement.*

1565. *The production of the different parts and organs of plants* is effected by the assimilation of the proper juice. The next object of our enquiry, therefore, will be that of tracing out the order of the developement of the several parts, together with the peculiar mode of operation adopted by the vital principle. But this mode of operation is not exactly the same in herbaceous and annual plants as in woody and perennial plants. In the former, the process of developement comprises as it were but one act of the vital principle, the parts being all unfolded in immediate succession, and without any perceptible interruption till the plant is complete. In the latter, the process is carried on by gradual and definite stages easily cognisable to the senses, commencing with the approach of spring, and terminating with the approach of winter; during which, the functions of the vital principle seem to be altogether suspended, till it is aroused again into action by the warmth of the succeeding spring. The illustration of the latter, however, involves also that of the former; because the growth of the first year exemplifies at the same time the growth of annuals, while the growth of succeeding years exemplifies whatever is peculiar to perennials.

1566. *Elementary organs.* If the embryo, on its escape from the seed and conversion into a plant, is taken and minutely inspected, it will be found to consist of a root, plumulet, and incipient stem, which have been developed in consecutive order; and if the plant is taken and dissected at this period of its growth, it will be found to be composed merely of an epidermis enveloping a soft and pulpy substance, that forms the mass of the individual; or it may be furnished also with a central and longitudinal fibre; or with bundles of longitudinal fibres giving tenacity to the whole. These parts have been developed, no doubt, by means of the agency of the vital principle operating on the proper juice; but what have been the several steps of operation?

1567. *No satisfactory explication of this phenomenon has yet been offered.* It is likely, however, that the rudiments of all the parts of the plant do already exist in the embryo in such specific order of arrangement as shall best fit them for future developement, by the introsection of new and additional particles. The pellicle constituting the vegetable epidermis has generally been regarded as a membrane essentially distinct from the parts which it covers, and as generated with a view to the discharge of some particular function. Some phytologists, however, have viewed it in a light altogether different, and have regarded it as being merely the effect of accident, and nothing more than a scurf formed on the exterior and pulpy surface of the parenchyma indurated by the action of the air. It is more probably, however, formed by the agency of the vital principle, even while the plant is yet in embryo, for the very purpose of protecting it from injury when it shall have been exposed to the air in the process of vegetation. There are several respects in which an analogy between the animal and vegetable epidermis is sufficiently striking: they are both capable of great expansion in the growth of the subject; they are both easily regenerated when injured (except in the case of induration), and seemingly in the same manner; they are both subject, in certain cases, to a constant decay and repair; and they both protect from injury the parts enclosed.

1568. *Composite organs.* The elucidation of the developement of the composite organs involves the discussion of the two following topics: — the formation of the annual plant, and of the original shoot of the perennial; and the formation of the subsequent layers that are annually added to the perennial.

1569. *Annuals and annual shoots.* If a perennial of a year's growth is taken up in the beginning of winter, when the leaves, which are only temporary organs, have fallen, it will be found to consist of a root and trunk, surmounted by one bud or more. The root is the radicle expanded into the form peculiar to the species, but the trunk and buds have been generated in the process of vegetation.

1570. *The root or trunk,* if taken and cut into two by means of a transverse section, will be found to consist abroad of bark, wood, and pith. Here, then, is the termination of the growth of the annual, and of the first stage of the growth of the perennial: how have their several parts or organs been formed?

1571. *The pith* seems only a modification of the original pulp, and the same hypothesis that accounts for the formation of the one will account also for the formation of the other; but the pith and pulp, or parenchyma, are ultimately converted into organs essentially distinct from one another, though phytologists have been much puzzled to assign to each its respective functions. In the ages in which physiological opinions were formed without enquiry, one of the vulgar errors of the time seems to have been that the function of the pith was that of generating the stone of fruit, and that a tree deprived of its pith would produce fruit without a stone (*Phys. des Arb.*, liv. i. chap. 3.): but this opinion is by much too absurd to merit a serious refutation. Another early opinion, exhibiting, however, indications of legitimacy

enquiry, was, that the pith was analogous to the heart and brain of animals, as related by Malpighi; who did not himself adopt it, but believed the pith to be, like the cellular tissue, the viscera in which the sap was elaborated for the nourishment of the plant, and for the protrusion of future buds. Magnol thought that it produced the flower and fruit, but not the wood. Du Hamel regarded it as being merely an extension of the pulp or cellular tissue, without being destined to perform any important function in the process of vegetation. But Linnaeus was of opinion that it produces even the wood; regarding it not only as the source of vegetable nourishment, but as being also to the vegetable what the brain and spinal marrow are to animals—the source and seat of life. In these opinions there may be something of truth, but they have all the common fault of ascribing to the pith either too little or too much. Mr. Lindsay of Jamaica suggested a new opinion on the subject, regarding it as being the seat of the irritability of the leaves of the Mimosa; and Sir J. E. Smith says, he can see nothing to invalidate the arguments on which this opinion is founded. Plenck and Knight regard it as destined by Nature to be a reservoir of moisture to supply the leaves when exhausted by excess of perspiration. Hence it appears that the peculiar function of the pith has not yet been altogether satisfactorily ascertained; and the difficulty of ascertaining it has been thought to be increased from the circumstance of its seeming to be only of a temporary use in the process of vegetation, by its disappearing in the aged trunk. But although it is thus only temporary as relative to the body of the trunk, yet it is by no means temporary as relative to the process of vegetation, the central part of the aged trunk being now no longer in a vegetating state, and the pith being always present in one shape or other in the annual plant, or in the new additions that are annually made to perennials. The pith, then, is essential to vegetation in all its stages: and from the analogy of its structure to that of the pulp, or parenchyma, which is known, as in the leaf, to be an organ of elaboration, the function of the pith is most probably that of giving some peculiar elaboration to the sap.

1572. *The generation of the layer of wood in woody plants*, or of the parts analogous to wood in the case of herbaceous plants, has been hitherto but little attended to. If we suppose the rudiments of the different parts to exist already in the embryo, then we have only to account for their development by means of the intromission and assimilation of sap and proper juice: but if we suppose them to be generated in the course of vegetation, then the difficulty of the case is augmented; and, at the best, we can only state the result of operations that have been so long continued as to present an effect cognisable to the sense of sight, though the detail of the process is often so very minute as to escape even the nicest observation. All, then, that can be said on the subject is merely, that the tubes, however formed, do, by virtue of the agency of the vital principle operating on the proper juice, always make their appearance at last in a uniform and determinate manner, according to the tribe or species to which the plant belongs, uniting and coalescing so as to form either a circular layer investing the pith, as in woody plants; a number of divergent layers intersecting the pith, as in some herbaceous plants; or bundles of longitudinal and woody fibre interspersed throughout the pith, as in others. In the same manner we may account for the formation of the layer of bark.

1573. *Perennials and their annual layer*. If a perennial is taken at the end of the second year and dissected, as in the example of the first year, it will be found to have increased in height by the addition of a perpendicular shoot, consisting of bark, wood, and pith, as in the shoot of the former year; and in diameter by the addition of a new layer of wood and of bark, generated between the wood and bark of the former year, and covering the original cone of wood, like the paper that covers a sugar-loaf: this is the fact of the mode of augmentation about which phytologists have not differed, though they have differed widely with regard to the origin of the additional layer by which the trunk is increased in diameter. Malpighi was of opinion that the new layer of wood is formed from the liber of the former year.

1574. *The new layer of wood* Linnaeus considered as formed from the pith, which is absurd, because the opinion goes to the inversion of the very order in which the layer is formed, the new layer being always exterior to the old one. But, according to the most general opinion, the layer was thought to be formed from a substance oozing out of the wood or bark—first a limpid fluid, then a viscid pulp, and then a thin layer attaching itself to the former; the substance thus exuding from the wood or bark was generally regarded as being merely an extravasated mucilage, which was somehow or other converted into wood and bark: but Du Hamel regarded it as being already an organised substance, consisting of both cellular and tubular tissue, which he designated by the appellation of the *cambium*, or proper juice.

1575. *Knight has thrown the highest degree of elucidation on this, one of the most obscure and intricate processes of the vegetable economy*, in having shown that the sap is elaborated, so as to render it fit for the formation of new parts, in the leaf only. If a leaf or branch of the vine is grafted even on the fruit-stalk or tendril, the graft will still succeed; but if the upper part of a branch is stripped of its leaves, the bark will wither as far as it is stripped; and if a portion of bark furnished with a leaf is insulated by means of detaching a ring of bark above and below it, the wood of the insulated portion that is above the leaf is not augmented: this shows evidently that the leaf gives the elaboration necessary to the formation of new parts, and that without the agency of the leaf no new part is generated:—Such then is the mode of the augmentation of the plant in the second year of its growth. It extends in width by a new layer of wood and of bark insinuated between the wood and bark of the former year; and in height by the addition of a perpendicular shoot or of branches, generated as in the shoot of the first year. But if the plant is taken and dissected at the end of the third year, it will be found to have augmented in the same manner; and so also at the end of the succeeding year, as long as it shall continue to live; so that the outermost layer of bark, and innermost layer of wood, must have been originally tangent in the first year of the plant's growth; the second layer of bark, and second layer of wood, in the second year; and so on in the order of succession till you come to the layer of the present year, which will in like manner divide into two portions, the outer forming one layer or more of bark, and the inner forming one layer or more of wood. And hence the origin of the concentric layers of wood and of bark in the trunk. But how are we to account for the formation of the divergent layers, which Du Hamel erroneously supposed to proceed from the pith? The true solution of the difficulty has been furnished by Knight, who, in tracing the result of the operation of budding, observed, that the wood formed under the bark of the inserted bud unites indeed confusedly with the stock, though still possessing the character and properties of the wood from which it was taken, and exhibiting divergent layers of new formation which originate evidently in the bark, and terminate at the line of union between the graft and stock.

1576. *But how is the formation of the wood that now occupies the place of the pith to be accounted for?* It appears that the tubes of which the medullary sheath is composed do, in the process of vegetation, deposit a *cambium*, which forms an interior layer that is afterwards converted into wood for the purpose of filling up the medullary canal.

1577. *Opinion of Darwin and Du Petit Thouars*. According to these philosophers, (and the hypothesis, we believe, was originally proposed by Dr. Darwin,) “the phenomena which took place at the period of germination are renewed by every leaf which successively unfolds itself. The cotyledons were the source of the fibres which were sent down into the earth through the root; in like manner every leaf is enabled to maintain a communication between itself and the soil, by the means of fibres. Hence arises another kind of increase, of which no notice has yet been taken—the increase in thickness. A stem, which at the

hour of its birth was no thicker than a pin, in a few months acquires the diameter of an inch, or more. This arises from the successive superposition of the bundles of fibres which are created upon the development of each leaf, and of every leaf-bud. The latter makes its first appearance under the form of a green point, which originates from the inner layers of the ligneous body, which it traverses, and penetrates into the bark. A short time after its first appearance, it may be perceived that the bud is surrounded by a portion of woody fibre, which passes downwards, covers over the wood previously formed, and thus forms a new layer. The existence of this it is easy to demonstrate; for the fibres of the leaves separate easily from the wood, but the leaf-buds, when broken off, evidently arise from the interior of the wood. All the new parts formed by the leaf-bud soon become so completely identified with the old wood, that, after a short period, no marks of separation remain." (*London Encyclopædia*, art. *Botany*.)

1578. *Conversion of the alburnum into perfect wood.* In consequence of the increase of the trunk by means of the regular and gradual addition of an annual layer, the layers, whether of wood or of bark, are necessarily of different degrees of solidity in proportion to their age, the inner layer of bark and the outer layer of wood being the softest; and the other layers increasing in their degree of solidity till you reach the centre on the one hand, and the circumference on the other, where they are respectively the hardest, forming perfect wood or highly indurated bark, which bark sloughs or splits into chinks, and falls off in thick crusts, as in the plane tree, fir, and birch. What length of time, then, is requisite to convert the alburnum into perfect wood, or the liber into indurated bark; and by what means are they so converted? There is no fixed and definite period of time that can be positively assigned as necessary to the complete induration of the wood or bark, though it seems to require a period of a good many years before any particular layer is converted from the state of alburnum to that of perfect wood; and perhaps no layer has received its final degree of induration till such time as the tree has arrived at its full growth. The induration of the alburnum, and its consequent durability, are attributed by many to the loss of sap which the layer sustains after the period of its complete development, when the supply from the root diminishes, and the waste by evaporation or otherwise is still kept up, inducing a contraction or condensation of its elementary principles which augments the solidity of the layer, in the first degree, and begins the process that future years finish. But Knight believes the induration of the alburnum, as distinguishable in the winter, to be owing rather to some substance deposited in it in the course of the preceding summer, which he regards as being the proper juice in a concrete or inspissated state, but which is carried off again by the sap as it ascends in the spring.

1579. *Circulation of vegetable juices.* After the discovery of the circulation of the blood of animals, phytologists, who were fond of tracing analogies between the animal and vegetable kingdoms, began to think that there perhaps existed in plants also a circulation of fluids. The sap was supposed to be elaborated in the root. The vessels in which it was propelled to the summit of the plant were denominated arteries; and the vessels in which it was again returned to the root were denominated veins. Du Hamel, while he admits the ascent of the sap, and descent of the proper juice, each in peculiar and appropriate vessels, does not, however, admit the doctrine of a circulation, which seems, about the middle of the last century, to have fallen into disrepute. For Hales, who contended for an alternate ascent and descent of fluids in the day and night, and in the same vessels, or for a sort of vibratory motion, as he also describes it, gave no countenance whatever to the doctrine of a circulation of juices. But the doctrine, as it appears, has been again revived, and has met with the support of some of the most distinguished of modern phytologists. Hedwig is said to have declared himself to be of opinion, that plants have a circulation of fluids similar to that of animals. Corti is said to have discovered a species of circulation in the stem of the *Châra*, but confined, it is believed, within the limits of the internodia. Willdenow has also introduced the subject, and defended the doctrine (*Principles of Botany*, p. 85.); but only by saying he believes a circulation to exist, and that it is impossible for the leafless tree to resist the cold if there is not a circulation of fluids. Knight has given his reasons somewhat in detail; and though his doctrine of a circulation should be false, yet the account which he gives of the progress and agency of the sap and proper juice, short of circulation, may be true. The sum of the account is as follows:—When the seed is deposited in the ground under proper conditions, moisture is absorbed and modified by the cotyledons, and conducted directly to the radicle, which is by consequence first developed. But the fluid which has been thus conducted to the radicle, mingling no doubt with the fluid which is now also absorbed from the soil, ascends afterwards to the plumelet through the medium of the tubes of the alburnum. The plumelet now expands and gives the due preparation to the ascending sap, returning it in its elaborated state to the tubes of the bark, through which it again descends to the extremity of the root, forming in its progress new bark and new alburnum; but mixing also, as he thinks, with the alburnum of the former year, where such alburnum exists, and so completing the circulation.

1580. *Decomposite organs.* To the above brief sketch of the agency of the vital principle in the generation or growth of the elementary and composite organs, there now remains to be added that of the progress and mode of the growth of the decomposite organs, or organs immediately constituting the plant, as finishing the process of the vegetable development. This will include the phenomena of the ultimate development of the root, stem, branch, bud, leaf, flower, and fruit.

1581. *The root.* From the foregoing observations and experiments, it appears that the roots of plants or at least of woody plants, are augmented in their width by the addition of an annual layer, and in their length by the addition of an annual shoot, hursting from the terminating fibre. But how is the development of the shoot effected? Is it by the intromission of additional particles throughout the whole of its extent; or only by additions deposited at the extremity? In order to ascertain the fact, with regard to the elongation of the root, Du Hamel instituted the following experiment:—Having passed several threads of silver transversely through the root of a plant, and noted the distances, he then immersed the root in water. The upper threads retained always their relative and original situation, and the lowest thread, which was placed within a few lines of the end, was the only one that was carried down. Hence he concluded that the root is elongated merely by the extremity. Knight, who from a similar experiment

obtained the same result, deduced from it also the same conclusion. We may regard it, then, as certain, that the mode of the elongation of the root is such as is here represented, though in the progress of its development, it may affect a variety of directions. The original direction of the root is generally perpendicular, in which it descends to a considerable depth if not interrupted by some obstacle. In taking up some young oak trees that had been planted in a poor soil, Du Hamel found that the root had descended almost four feet, while the height of the trunk was not more than six inches. If the root meets with an obstacle, it then takes a horizontal direction, not by the bending of the original shoot, but by the sending out of lateral shoots. The same effect also follows if the extremity of the root is cut off, but not always; for it is a common thing in nursery gardens to cut off the tap-roots of drills of seedling oaks, without removing them, by a sharp spade, and these generally push out new tap-roots, though not so strong as the former. When a root ceases of its own accord to elongate, it sends out lateral fibres which become branches, and are always the more vigorous the nearer they are to the trunk; but the lateral branches of horizontal roots are the less vigorous the nearer they are to the end next the trunk. In the former case, the increased luxuriance is perhaps owing to the easy access of oxygen in the upper divisions; but, in the latter case, the increased luxuriance of the more distant divisions is not so easily accounted for, if it is not to be attributed to the more ample supply of nutriment which the fibres meet with as they recede from the trunk, particularly if you suppose a number of them lying horizontally, and diverging like the radii of a circle. But the direction of roots is so liable to be affected by accidental causes, that there is often but little uniformity even in roots of the same species. If plants were to be sown in a soil of the same density throughout, perhaps there might be at least as much uniformity in the figure and direction of their roots, as in those of their branches; but this will seldom happen. For if the root is injured by the attacks of insects, or interrupted by stones, or earth of too dense a quality, it then sends out lateral branches, as in the above cases; sometimes extending in length, by following the direction of the obstacle, and sometimes ceasing to elongate, and forming a knot at the extremity. But where the soil has been loosened by digging or otherwise, the root generally extends itself to an unusual length; and where it is both loosened and enriched, it divides into a multiplicity of fibres. This is also the case with the roots of plants vegetating in pots, or near a river, but especially in water. Where roots have some considerable obstacle to overcome, they will often acquire a strength proportioned to the difficulty: sometimes they will penetrate through the hardest soil to get at a soil more nutritive; and sometimes they will insinuate their fibres into the crevices even of walls and rocks, which they will burst or overturn. This of course requires much time, and does much injury to the plant. Roots consequently thrive best in a soil that is neither too loose nor too dense; but as the nourishment which the root absorbs is chiefly taken up by the extremity, so the soil is often more exhausted at some distance from the trunk than immediately around it. Du Hamel regards the small fibres of the root, which absorb the moisture of the soil, as being analogous to the lacteals of the animal system, which absorb the food digested by the stomach: but the root is rather to be regarded as the mouth of the plant, selecting what is useful to nourishment, and rejecting what is yet in a crude and indigestible state; the larger portions of it serving also to fix the plant in the soil, and to convey to the trunk the nourishment absorbed by the smaller fibres, which, ascending by the tubes of the albuminum, is thus conveyed to the leaves, the digestive organs of plants. Du Hamel thinks that the roots of plants are furnished with pre-organised germs, by which they are enabled to send out lateral branches when cut, though the existence of such germs is not proved; and affirms, that the extremities of the fibres of the root die annually, like the leaves of the trunk and branches, and are again annually renewed; which last peculiarity Professor Willdonn affirms also to be the fact, but without adducing any evidence by which it appears to be satisfactorily substantiated. On the contrary, Knight, who has also made some observations on this subject, says, it does not appear that the terminating fibres of the roots of woody plants die annually, though those of bulbous roots are found to do so: but the fibres of creeping plants, as the common crowfoot and strawberry, certainly die annually, as do those of the vine.

1582. *The stem.* The stem, like the root, or at least the stem of woody plants, is also augmented in width by the addition of an annual layer, and in length, by the addition of an annual shoot bursting from the terminating bud. Is the development of the shoot issuing from the stem effected in the same manner also? The development of the shoot from the stem is not effected in the same manner as the development of that from the root, by additions to the extremity only, but by the intromission of additional particles throughout its whole extent, at least in its soft and succulent state: the longitudinal extension diminishing in proportion as the shoot acquires solidity, and ceasing entirely when the wood is perfectly formed, though often continuing at the summit after it has ceased at the base. The extension of the shoot is inversely as its induration, rapid while it remains herbaceous, but slow in proportion as it is converted into wood. Hence moisture and shade are the most favourable to its elongation, because they prevent or retard its induration; and hence the small cone of wood which is formed during the first year of the plant's growth increases no more after the approach of winter, either in height or thickness. Such is the mode of the growth and development of the trunk of perennial and woody plants, to which there exists a striking exception in the growth of the trunk of palms. Their internal structure has been already taken notice of as possessing no concentric or divergent layers, and no medullary canal, but merely an assemblage of large and woody fibres, interspersed without order in a pulp or parenchyma, softer at the centre, and gradually becoming harder as it approaches the circumference. When the seed of the palm tree germinates, it protrudes a circular row of leaves, or of fronds, which crowns the radicle, and is succeeded in the following year by a similar row issuing from the centre or bosom of the former leaves, which ultimately die down to the base. This process is continued for four or five years successively, without exhibiting as yet any appearance of a stem, the remaining bases of the leaves or frond forming by their union merely a sort of knob or bulb. At last, however, they constitute by their union an incipient stem, as thick as the first year as it ever is after; which in the following year is augmented in height as before, and so in succession as long as the plant lives, the leaves always issuing from the summit and crowning the stem, which is a regular column, but decaying at the end of the year, and leaving circular marks at the points of insertion, which furrow the surface of the plant, and indicate the years of its growth.

1583. *The branches,* in their mode of growth and development, exhibit nearly the same appearances as the trunk from which they issue. They originate in a bud, and form also a cone which consists of pith, wood, and bark; or rather they form a double cone: for the insertion of the branch into the trunk resembles also a cone whose base is at the circumference, and whose apex is at the centre, at least if it is formed in the first year of the plant's growth, or on the shoot of the present year; but falling short of the centre in proportion to the lateness of its formation, and number of intervening layers. Branches in their development assume almost all varieties of position, from the reflected to the horizontal and upright; but the lower branches of trees are found to be generally parallel to the surface of the soil on which they grow, even though that surface should be the sloping side of a hill, owing, as some have thought, to the evolution of a greater number of buds on the side that forms the obtuse angle with the soil, in consequence of its being exposed to the action of a greater mass of air.

1584. *The bud,* which in the beginning of spring is so very conspicuous on the trees of this country as to be obvious to the most careless observer, is by no means common to all plants, nor to plants of all climates; shrubs in general, and annuals universally, as well as all plants whatever growing within the tropics, are destitute of buds, the leaf being in them immediately protruded from the bark. It is only in the woody plants of cold climates, therefore, that we are to look for buds; and in them no new part is added, whether proper to the leaf or flower, without the intervention of a bud. For when the young shoot is produced, it is at the same time furnished with new buds, which are again extended into new

shoots in the following spring; and thus the bud is to be regarded as forming, not only the cradle, but also the winter quarters of the shoot, for which its coat of tiled and glutinous scales seems admirably adapted. It is found chiefly in the extremity, or on the surface of the young shoot or branch, and but rarely on the stem, except it be at the collar where it produces suckers. It is also generated for the most part in the axils of the leaves, as may be seen by inspecting the annual shoot of almost any tree at random: but it is not universally so; for to this rule there exists a curious and singular exception in the bud of the *Plantanus*, which is generated in the very centre of the base of the foot-stalk, and is not discoverable till after the fall of the leaf. But how are the buds formed which are thus developed? Malpighi thought they were formed from the pith or cellular tissue, which Grew regarded as viscera destined for the elaboration of the sap and protrusion of future buds. Du Hamel thinks the exterior scales of the bud originate in the interior part of the bark, and Knight relates an experiment from which he thinks it follows that the buds are formed from the descending proper juice. But whatever may be the actual origin of the bud, it is evident that its development does not take place except through the medium of the proper juice, which has been elaborated in the leaves of preceding buds, and originally in those of the plumlet, as the young bud does not make its appearance till the leaves of the preceding buds have expanded, and will not ultimately succeed if deprived of them too soon.

1585. *The bark*, it is probable, performs the same functions as the leaves in the early state of the buds, and occasionally in all states. Otherwise it would not be easy to account for the growth of cactuses, euphorbias, some apocynaceous plants, &c., which are all destitute of leaves. In fine, the bark may be compared to a universal leaf, with one surface only. (*London Ency. art. Bot.*)

1586. *Buds* are so very similar to buds both in their origin and development, as to require no specific investigation.

1587. *The leaf*. When the leaves burst from the expanding bud, and even long before that period, as may be seen by the dissection of the bud in the winter, they are complete in all their parts. Hence it is obvious that the leaf, like the young shoot, effects its final development by means of the intromission of new particles throughout the whole of its dimensions; and yet this law of development is not common to all leaves whatever, for the leaves of liliaceous plants extend chiefly at the point of their junction with the bulb. The effect, perhaps, of their peculiarity of structure, in being formed of parallel tubes which extend throughout their whole length, without those transverse and branching fibres that constitute what are called the nerves of the leaves of woody plants.

1588. *The flower and fruit*. When the flower bursts from the expanding bud, and even long before that period, it is already complete in all its parts, as may be seen also by the dissection of the bud in winter. Linnæus represents the pistil as originating in the pith, the stamens in the wood, and the corolla and calyx in the inner and outer bark respectively: but this account of their origin, though extremely plausible at first sight, will not bear the test of minute examination, being contradicted by the anatomy of the parts themselves; particularly in the case of compound flowers. Knight, in investigating the organisation of the apple and pear, endeavoured to ascertain the origin of the several parts by tracing the organs of the fruit-stalk to their termination. In the fruit-stalk he thought he could discover the pith, the central tubes, spiral tubes, and tubes of the bark, together with its epidermis: and in tracing them to their termination, he thought the pith seemed to end in the pistils; the central vessels in the stamens, after diverging round the core and approaching again in the eye of the fruit; and the bark and epidermis in the two external skins. Hence he infers that the flower is a prolongation of the pith, wood, and bark. A question of some considerable importance has arisen out of this subject: does the flower or fruit elaborate sap for its own development, or is it supplied with nourishment from the leaf? By placing small branches of the apple, pear, and vine, with blossoms not expanded, in a decoction of logwood, Knight found that the central vessels were coloured by the decoction. By means of a similar experiment on the same subjects after the fruit was formed, the colouring matter was traced through the mass of the fruit to the base of the stamina. And hence it appears that the flower and fruit do possess the power of elaborating sap for their own development. Knight infers from the foregoing data, that the blossom is nourished from the albumum, by means of the mingling of the proper juice, which the albumum may be supposed to contain, with the sap in its ascent.

SECT. V. *Anomalies of Vegetable Development.*

1589. *A deviation from the general laws of development* is occasioned by the intervention of some accidental cause; or of some cause operating permanently in certain subjects. Hence the anomaly may regard the development either of an individual or a species, and may occur either in the root, stem, branch, leaf, bud, flower, or fruit, according to the circumstances in which it is placed; or it may affect the habit, duration, or physical virtues of the plant.

1590. *The root*. According to the general laws of vegetable development, plants of the same species are furnished with the same species of root, not producing at one time a woody or fibrous root, and at another time a bulbous root: and yet it is found that there are cases in which changes of this kind do occur. If part of the root of a tree, planted by a pond or river, protrudes beyond the bank so as to be partially immersed, it divides at the extremity into innumerable ramifications, or sends out innumerable fibres from the surface, which become again subdivided into fibres still more minute, and give to the whole an appearance something resembling that of the tail of a fox; and it has accordingly been denominated by Du Hamel the fox-tail root. (*fig. 189.*)

1591. *The root of the Phileum pratense*, when growing in a moist soil, which it naturally affects, is uniformly fibrous; but when growing in a dry soil, where it is also often to be found, it is furnished with a bulbous root. The same is the case with the *Alopecurus geniculatus*; which, when growing in its native marshes, protrudes a fibrous root, though, when growing in a very dry situation, as on the top of a dry wall, it is found to be furnished with an ovate and juicy bulb. This anomaly also seems to be merely the result of a provision of nature by which the plant is endowed with the capacity of collecting a supply of moisture suited to existing circumstances, and hence of adapting itself to the soil in which it grows.

1592. *The roots of Utricularia minor*, which consist of a number of slender and hair-like filaments, exhibit the singular anomaly of being furnished with a multitude of small and membranous bladders, each containing a transparent and watery fluid, and a small bubble of air, by means of which the plant is kept floating in the water.

189

1593. *The descending root*, an anomaly which attends some perennials, is at first spindle-shaped and perpendicular, sending out some lateral fibres, but dies at the lower extremity in the course of the succeeding winter, and protrudes new fibres from the remaining portion, and even from the lower portion of the stem, in the course of the following spring, which, by descending into the soil, draw down the plant with them, so that part of what was formerly stem is now converted into root. This process is repeated every year, and by consequence a portion of the stem is made to descend every year into the earth. The anomaly may be exemplified in the roots of *Vateriæno diolca*, *Tanacetum vulgare*, and *Oxalis Acetosella*; and will also account for the bitten and truncated appearance of *Scabiosa succisa*, or devil's bit.

1594. *Migratory roots* depend on a principle similar to the foregoing. If the stem of a descending root happens to be creeping or procumbent instead of being erect, then the lateral shoots from above are carried forward in the direction of that procumbency, so that in the course of a few years the plant has actually changed its place by so much as the stem has been converted into a root. This is well exemplified in the genus *Vicia*, a plant of which, as it enlarges in circumference, dies in the centre, and presents a ring of plants instead of a solitary one. In the case of some aquatics, which float about on the surface of the water as they happen to be driven by the winds, the whole plant may be said to be migratory, as in the genus *Lemna*, and some marine plants.

1595. *The beet-root*, if dissected when about a year old, presents the singular anomaly of being already furnished with from five to eight distinct and concentric circles of longitudinal tubes or sap-vessels, imbedded at regular intervals in its pulp; whereas other biennial roots form only an individual circle each year, and are, consequently, at no time furnished with more than two.

1596. *Roots changed to branches and branches to roots*. If the stem of a young plum or cherry tree, but particularly of a willow, is taken in the autumn, and bent so as that one half of the top may be laid in the earth, one half of the root being at the same time taken carefully out, but sheltered at first from the cold and then gradually exposed to it, and the remaining part of the top and root subjected to the same process in the following year, the branches of the top will become roots, and the ramifications of the root will become branches, protruding leaves, flowers, and fruit in due season.

1597. *The stem*. If the stem of a tree planted by a pond or river is so bent in its growth as to come near to the surface of the water and to be occasionally immersed in it, it will sometimes send out from the under surface a multitude of shoots that will descend into the water, and develop themselves in the manner of the fox-tail root. Sometimes it happens that a stem, instead of assuming the cylindrical form common to the species, assumes a compressed and flattened form similar to the berbage of the *Cactus*, as in the fir tribe, ash, &c.

1598. *The anomaly of the flattened stem* (fig. 190.) is accounted for by Du Hamel, by supposing that an unnatural junction must have taken place in the leaf-bud; and so united shoots that would otherwise have been distinct. Sometimes the stem is disfigured by accidental tumours or bunches projecting from the surface, and forming ultimately what are called knots in the wood. They are very common in the oak and elm, and are produced, perhaps, by means of some obstruction in the channel of the sap's motion, by which the vessels become convoluted and swell up into a bunch.

1599. But *bunches* are also to be met with on the stems of herbaceous plants, as on that of the *Cárdaus praténsis*; of which you will often find a portion near the top swollen out into an egg-shaped or egg-oblong bunch, extending from an inch to two inches in length, and about an inch across. If this bunch is cut open in the month of August, it will be found to contain several large and white maggots. It has consequently been occasioned by the puncture of the parent insect depositing its eggs. It does not seem to affect the general health of a vigorous plant, though it might prove seriously injurious to a weak one.

1600. *Bundled stem*. Sometimes two or more contiguous stems, extending in the process of their growth till they meet and press against one another, become incorporated at length into one, and form a sort of bundle. This is what may be termed a natural graft, in opposition to an artificial graft, of which it is the model and prototype. The natural graft is always effected by means of the union of the liber of the respective stems composing it; so that the perfection of the art of grafting consists in applying the liber of the graft and stock together, in such a manner as shall most facilitate their incorporation.

1601. *The branch*. If the branch of a tree is situated, as in the foregoing case of the stem, so as to be partially or periodically immersed in water, it will send out also the same sort of brush-like shoots.

1602. *Bunches or knots, exhibiting a plexus of young shoots* (fig. 191. a) issuing from nearly the same point,

190

191

crossing in all directions, and finally incorporating together by means of a sort of natural graft, frequently disfigure the branch. These bunches are frequently to be met with on the branches of the birch tree, and are

known among the peasantry of Scotland by the name of witches' knots. They are occasioned, like the bunches of the stem, by some obstruction in the channel of the sap or proper juice. A peculiar sort of knot or bunch is also formed on the branches of the dog-rose. The nucleus, which is generally from an inch to an inch and a half in diameter, is covered with a long and winged shag, first of a green and then of a purple colour, presenting the appearance of a small bunch of moss. (fig. 192.) It has been occasioned, like that of the stem of the thistle, by the puncture of an insect depositing its eggs in the tender shoot; for if it is cut open about the month of August, it contains maggots. These anomalies remind us always of that singular disease in the human species, the *Pilca polonica*.

1603. *The bud.* The regular developement of the bud is also often prevented by means of the puncture of insects, and converted into a large globular tumour.

1604. *The gall tumour* is very often effected by a species of *Cynips*, which drives its piercer into the heart of the bud while yet tender, and penetrates with its saw into the very pith; injecting at the same time a drop of the corroding liquor contained in its bag, and then laying its eggs. The bud being thus wounded, and the juices corrupted by the injected poison, the circulation is not only impeded, but a fermentation is induced which burns the contiguous parts and changes their colour. The extravasated juice flows round the egg, and is there accumulated and converted into a sort of spongy lump, which vegetates and augments till it forms what is called a gall. The gall thus formed affords both shelter and nourishment to the young maggot, which, after being converted into a fly, pierces its enclosure and launches into the open air. The most remarkable of such galls are those produced on the oak tree, and known in this country by the vulgar name of oak-apples. (fig. 191. b) The bud of the willow, particularly *Sàlix Hélix*, is apt to be punctured by insects and converted into a gall; but the conversion is not always complete; and in this case the shoot remains dwarfish, and the leaves, which are now protruded from nearly the same point, assume something of the figure of a rose. Hence it has obtained the common name of the rose-willow. The galls of the *Sàlvia pomifera*, formed in the above manner, are said to be of a very pleasant flavour, and are esteemed a great delicacy in Eastern countries.

1605. *The leaves.* These, like the buds, are also frequently chosen for the nidus of insects, and disfigured with galls or excrescences. But the most remarkable gall produced on the leaf, and indeed the most remarkable and important of all galls, is that which is so extremely useful in the arts of dyeing and making ink, the nut-gall of the shops.

1606. *The nut-gall* is generated on the leaf of a species of oak that grows plentifully in the Levant, and is so well known in commerce as to require no particular description. It is occasioned by the puncture of the *Cynips quercifili*, which deposits its egg in the substance of the leaf by making a small perforation on the under surface. Galls and tumours are to be found on the leaves of many plants; and indeed almost all leaves are liable to deformities, giving them a blistered, wrinkled, or curled appearance, and often producing disease.

1607. *The excess or deficiency of leaves* protruded in a group sometimes constitutes the anomaly, as in the case of the trefoils.

1608. Sometimes it is found in the natural figure of the leaf itself, as in *Asparagus officinàlis*, where they are bristle-shaped; *Salsòla Kùli*, awl-shaped; and *Allium Cèpa*, in which they are tubular, tapering to a point. But one of the most remarkable anomalies of figure is that which occurs in the genus *Sarracènia*, the lower portion of the leaves of which is tubular, ascending, and approaching to funnel-shaped, or rather pitcher-shaped reversed, with a flattened and concave limb attached by the one side to the orifice of the tube, and constituting the upper portion of the leaf. Linnæus, who was acquainted with this singularity of structure, accounted for it by supposing that it was an institution of Nature, meant for the purpose of furnishing the plant with a supply of water, which it could thus catch and retain in the leaf; but as some species of the genus do not readily admit water, notwithstanding their capacity to retain it, this hypothesis is regarded by Sir J. E. Smith as being extremely doubtful, who accordingly offers a different solution, founded upon the following facts. An insect, of the *Sphèx* or *Ichneumon* kind, had been observed by one of the gardeners of the botanic garden at Liverpool to drag several large flies to a leaf of *Sarracènia adnca*, and to force them into the tubular part of it. On examination the leaf was found to be about half filled with water, in which the flies were now struggling; the other leaves were also examined, and were found crammed with dead or drowning flies. The leaves of *Sarracènia purpurea* are said to exhibit also the same phenomena, and seem peculiarly well adapted to entrap and confine flies, by having the margin beset with inverted hairs, which render the escape of such insects as may have accidentally fallen into the watery tube, or are intentionally forced into it, impracticable; so that the putrid exhalation from the dead insects contained in the leaf often offends the nostrils, even in passing near the plant. Hence Sir J. E. Smith infers, that the growth of the plant is perhaps benefited by means of the air evolved by the dead flies, which the water has been intended to tempt, and the leaves to entrap and retain. This ingenious conjecture is, no doubt, sufficiently plausible as far as the plant may be affected; but cannot be regarded as quite satisfactory till such time as it shall have been shown that the health of the plant is injured when insects are prevented from approaching it.

1609. *The Nepenthes distillatobia* exhibits also an anomaly similar to that of *Sarracènia*, in holding an ounce or two of a fluid which appears to be secreted from the leaf, and to be intended as a lure to insects, which gain admission either by the spontaneous opening of the lid, or by forcibly raising it themselves. The consequence is that they fall into the fluid and are drowned, no insect being capable of living in it except a certain small squilla or shrimp, with a protuberant back, which, according to Rumphius, sometimes crawls into it and can live there. To this phenomenon Sir J. E. Smith applies the same explanation as above, which is of course liable to the same objection.

1610. *The figure of the leaf, however singular, is generally the same throughout the same individual, except in the case of accidental deformity, and yet there are exceptions even to this rule; for sometimes the lower leaves of a plant are entire while the upper leaves are divided, as occurs in a variety of mountainous plants, such as burnet, saxifrage, anise, coriander; and sometimes the lower leaves are divided while the upper leaves are entire, as in the case of a variety of aquatics, particularly *Ranunculus aquatilis*, in which the lower leaves are capillary and immersed, and the upper leaves flat and circular, floating on the surface of the water. But sometimes the dissimilitude of the leaves is still more remarkable: the Chinese mulberry, a Botany Bay tree, has not two leaves alike in form on the whole plant. And, lastly, there are some plants, as in the case of the *Fóngi*, that are wholly destitute of leaves, and hence called aphyllous; while there are others, as in the case of the *Pùci*, that seem to be wholly leaf.*

1611. *The flower.* The principal anomaly of the flower is that by which one of its parts is unduly augmented, to the exclusion or diminution of some of the rest. The

flower is then said to be luxuriant; and comprises the three following varieties: the multiplicate, the full, and the proliferous flower.

1612. *The multiplicate flower* is sometimes, though rarely, occasioned by an unusual multiplication of the divisions of the calyx, as in *Dianthus Caryophyllus*, and some of the alpine grasses. But the anomaly most generally consists in the undue multiplication of the divisions of the corolla, by the conversion of part of the stamens into petals, which is occasionally to be met with both in monopetalous and polypetalous flowers. It occurs but seldom, however, in flowers growing in their natural state and habit, though now and then a double flower is met with even in such circumstances.

1613. *The full flower* is generally described to be that in which the divisions of the corolla are so multiplied as to exclude the stamens and pistils wholly by means of their conversion into petals; which conversion is most readily effected in polypetalous flowers, such as the tulip, poppy, pink, and ranunculus; monopetalous flowers seldom being found full. This complete metamorphosis is always either the effect of cultivation, or of some concurrence of natural circumstances analogous to it, and is indeed one of the principal objects of the art of the florist; the beauty of the flower, according to general estimation, being thus much augmented. In the full flower the stamens are almost always converted into petals, whence we should perhaps infer their identity of origin. But the pistil is often converted into a leaf, as may be seen by inspecting the flower of the double-blossomed cherry, which generally protrudes from the centre a leaf in miniature. But a flower may become full also by the multiplication of the parts of the nectary, as is sometimes the case in the genus *Aquilegia*, which produces full flowers in three different ways: by the multiplication of the petals to the exclusion of the nectaries; by the multiplication of the nectaries to the exclusion of the petals; and by the multiplication of the nectaries while the proper petals remain. There are also some peculiarities in the manner in which compound flowers become full. Radiated flowers become full sometimes by the multiplication of the foscules of the ray to the exclusion of the foscules of the disk, as in *Heliánthus*, *Anthemis*, and *Centauria*; and sometimes by the multiplication of the foscules of the disk to the exclusion of those of the ray, as in *Matricaria* and *Bellis*.

1614. *The proliferous flower* (fig. 193.) is that out of which another flower or another shoot is produced. It is seldom found but in flowers already full; from the centre of which, that is, from the ovary or pistil, it sometimes happens that a new flower and foot-stalk is produced, if the flower is simple, as in the ranunculus, anemone, and pink; or several flowers and foot-stalks issuing from the common calyx, if the flower is compound, as in the daisy, hawkweed, and marigold; or a new umbel issuing from the centre of the original umbel, if the flower is umbellate, as in *Cornus*.

1615. *Various anomalies.* Sometimes the proliferous issue of the full flower is not itself a flower, but a shoot furnished with leaves, as has been sometimes, though rarely, observed in the case of the anemone and rose. Such are the several varieties of luxuriant flowers, constituting anomalies of excess; but it sometimes happens that there is also in the flower an anomaly of defect in the absence of one of its parts. Examples of this sort are occasionally to be met with in the flowers of *Cheiranthus Chelvi*, *Campánula pentagona*, and *Tussilago anándria*, in which the corolla is altogether wanting, though proper to the species; and in this case the flower is said to be mutilated. Sometimes the anomaly consists in the situation of the flower, which is generally protruded from the extremity or sides of the branches; but the flower of the *Ruscus* is protruded from the surface of the leaf. Or it may consist in the relative situation of the several parts of the flower. In simple flowers, the pistil is invariably central with regard to the stamens; but in compound flowers the pistils are often situated in the circumference and the stamens in the centre. This seems to be the case, also, with some monœcious plants, having their flowers on the same peduncle, as in the example of the *Carex* and *Arum*, in which the stamens are more central than the pistils. Sometimes the anomaly consists in the color of the corolla, which will often deviate even in the same species. The general colour of the common cowslip (*Primula veris*) is a bright yellow; but an individual is occasionally to be met with, though very rarely, in which the limb or expansion of the corolla is purple with a line of yellow around the border. Sometimes the anomaly consists in the time of flowering. The season proper for the flowering of the apple and pear tree is the month of May; but trees of that sort have been known to protrude both buds and blossoms even in the month of November. Some plants, however, blow only in the winter, as in the case of the laurustinus and *Arbutus Unedo*; while others blow only in the night, and refuse to expand their petals to the light of the sun. Such is the case of the *Cactus grandiflora*, that produces one of the most magnificent of flowers, but blows only in the night; and is hence known also by the appellation of the night-blowing cereus. Some plants, such as the *Alice*, and *Fúnga*, are altogether destitute of conspicuous flowers; and are hence called *Cryptogamous*.

The flower of the fig is perhaps one of the most singular in respect of concealment. The flowers of perfect plants, which, in other cases, uniformly precede the fruit, are in this case concealed within what is generally denominated the fruit; as may be proved by cutting open a green fig (fig. 194.) by means of a longitudinal section passing through its axis. Great numbers of flowers are then discovered lining a sort of cavity in the axis of the fruit; and hence what is called the fruit or fig, in common language, is rather the receptacle of the flower than any thing else. Most plants have their flowers furnished both with stamens and pistils, and are hence hermaphrodite. But there are also many genera that have the stamens in one flower and the pistils in another, both on the same individual; these are denominated *Monœcious* plants, and are exemplified in the oak and hazel. Other genera have the flowers with stamens on one plant, and the flowers with pistils on another; these are denominated *Diœcious*, and are exemplified in the hop and willow. Others have unisexual flowers of each kind on one and the same plant, as in *Monœcia*; on separate plants, as in *Diœcia*; and on others mixed with those which are hermaphrodite: these are denominated *Polygamous*, and are exemplified in the genus *Atriplex*. In a species of *Eutérpe*, found on the island of Bourbon, the flowers are visible eight years before they are expanded. The summit is formed of twelve leaves, each supplied with a bunch of flowers in its axilla. Three leaves only expand each year, so that four years will have elapsed between the expansion of the first flowers and of the last, although even the former were discoverable four, and the latter eight, years previously. (*London Encyc.*, art. *Botany*.)

1616. *The fruit.* The anomalies of the fruit may affect either its number, figure, colour, or appendages.

1617. The common hazel-nut produces in general but one kernel in one shell; but in the course of opening a considerable number, you will now and then meet with one containing two or three kernels in a shell. This is, perhaps, best accounted for by supposing, with Du Hamel, that it is the result of an unnatural graft effected in the bud; though some think that the shell does always contain the rudiments of

two or more kernels, although it rarely happens that more than one is developed. But if two apples or pears are developed in an incorporated state, which is a case that now and then occurs, it is no doubt best accounted for by the graft of Du Hamel. Sometimes the anomalies consist in the figure of the fruit, which is deformed by tumours or excrescences, in consequence of the bite of insects, or injuries of weather producing warts, moles, or specks. Sometimes it consists in the colour, producing green melons and white cucumbers. Sometimes it consists in an appendage of leaves. (*fig. 195.*)

195

1618. *Habit.* The anomalies of habit are principally occasioned by soil and cultivation.

1619. *Some plants*, which, when placed in a rich soil, grow to a great height, and affect the habit of a tree, are, when placed in a poor soil, converted into dwarfish shrubs. This may be exemplified in the case of the box-tree; it also occurs in the case of herbaceous plants; as in that of *Myrsine*, which in dry situations is but short and dwarfish, while in moist situations it grows to such a size as to seem to be altogether a different plant. The habit of the plant is sometimes totally altered by means of cultivation: the *Pyrus sativa*, when growing in a wild and uncultivated state, is furnished with strong thorns; but when transferred to a rich and cultivated soil the thorns disappear. This phenomenon, which was observed by Linnæus, was regarded as being equivalent to the taming of animals: but this explanation is, like some others of the same great botanist, much more plausible than profound, in place of which Professor Willdenow substitutes the following: the thorns protruded in the uncultivated state of the plant, are buds rendered abortive from want of nourishment, which when supplied with a sufficiency of nourishment are converted into leaves and branches.

1620. *Physical virtues.* When plants are removed from their native soil and taken into a state of culture, it alters not only their habit but their physical virtues. Thus the sour grape is rendered sweet; the bitter pear, pleasant; the dry apricot, pulpy; the prickly lettuce, smooth; and the acrid celery, wholesome. Potherbs also are rendered more tender, by means of cultivation, and better fitted for the use of man; and so are all our fine fruits.

1621. *Duration.* Plants are either annuals, biennials, or perennials, and the species is generally of the same duration in every climate. But it has been found that some plants, which are annuals in a cold climate, such as that of Sweden, will become perennials in a hot climate, such as that of the West Indies; this anomaly has been exemplified in *Tropæolum*, beet root and *Málva arborea*: and, on the contrary, some plants, which are perennials in hot climates, are reduced to annuals when transplanted into a cold climate; this has been exemplified in the climbing kidneybeans.

SECT. VI. Of the Sexuality of Vegetables.

1622. The doctrine that *plants are of different sexes*, and which constitutes the foundation of the Linnæan system, though but lately established upon the basis of logical induction, is by no means a novel doctrine. It appears to have been entertained even among the original Greeks, from the antiquity of their mode of cultivating figs and palms. Aristotle and Theophrastus maintained the doctrine of the sexuality of vegetables; and Pliny, Dioscorides, and Galen adopted the division by which plants were then distributed into male and female; but chiefly upon the erroneous principle of habit or aspect, and without any reference to a distinction absolutely sexual. Pliny seems to admit the distinction of sex in all plants whatever, and quotes the case of a palm tree as exhibiting the most striking example.

1623. *Linnæus*, reviewing with his usual sagacity the evidence on which the doctrine rested, and perceiving that it was supported by a multiplicity of the most incontrovertible facts, resolved to devote his labours peculiarly to the investigation of the subject, and to prosecute his enquiries throughout the whole extent of the vegetable kingdom; which great and arduous enterprise he not only undertook, but accomplished with a success equal to the unexampled industry with which he pursued it. So that by collecting into one body all the evidence of former discovery or experiment, and by adding much that was original of his own, he found himself at length authorised to draw the important conclusion, that no seed is perfected without the previous agency of the pollen, and that the doctrine of the sexes of plants is consequently founded in fact.

1624. *Proofs from the economy of the aquatics.* Many plants of this class which vegetate for the most part wholly immersed in water, and often at a considerable depth, gradually begin to elevate their stems as the season of flowering advances, when they at last rear their heads above the surface of the water, and present their opening blossoms to the sun, till the petals have begun to fade, after which they again gradually sink down to the bottom to ripen and to sow their seeds. This very peculiar economy may be exemplified in the case of *Ruppia maritima*, and several species of *Potamogeton* common in our ponds and ditches. From this we may fairly infer, that the flowers rise thus to the surface merely to give the pollen an opportunity of reaching the stigma uninjured. But the most remarkable example of this kind is the *Valisneria spiralis* (*fig. 196.*), a plant which grows in the ditches of Italy. The plant is of the class *Dioecia*, producing its fertile flowers on the extremity of a long and slender stalk (*a*) twisted spirally like a corkscrew, which uncoiling of its own accord, about the time of the opening of the blossom, elevates the flowers to the surface of the water, and leaves them to expand in the open air. The barren flowers (*b*) are produced in great numbers upon short upright stalks issuing from a different root, from which they detach themselves about the time of the

expansion of the female blossom, mounting up like little air bubbles, and suddenly expanding when they reach the surface (c), where they float about in great numbers among the female blossoms, and often cling to them in clusters, so as to cover them entirely; thus bringing the stamens and pistils into immediate contact, and giving the anthers an opportunity of discharging their pollen immediately over the stigma. When this operation has been performed, the now uncoiled stalk of the female plant begins again to resume its original and spiral form, and gradually sinks down, as it gradually rose, to ripen its fruit at the bottom of the water. In 1819, we gathered these stalks, in the canals near Padua, upwards of ten feet long.

SECT. VII. *Impregnation of the Seed.*

1625. *The stamens and pistils are the male and female organs of vegetable generation, and the pollen is the substance by which the impregnation of the seed is effected; but how is the pollen conveyed to the ovary, and what is the amount of its action?*

1626. *Access of the pollen.* When the stamens and pistils are situated near each other, the elastic spring with which the anther flies open, will generally be sufficient to disperse the pollen, so as that part of it must infallibly reach the stigma, in such flowers as do not perfect their stamens and pistils at the same time. The pollen is very generally conveyed from the anther to the stigma, through the instrumentality of bees, and other insects peculiar to a species. The object of the insect is the discovery of honey, in quest of which, whilst it roves from flower to flower, and rummages the recesses of the corolla, it unintentionally covers its body with pollen, which it conveys to the next flower it visits, and brushes off as it acquired it by rummaging for honey; so that part of it is almost unavoidably deposited on the stigma, and impregnation thus effected. Nor is this altogether so much a work of random as it at first appears: for it has been observed that even insects, which do not upon the whole confine themselves to one species of flower, will yet very often remain during the whole day upon the species they happen first to alight on in the morning. Hence the impregnation of the females of Diœcious plants where no male is near; hence also a sort of natural crossing of the breed of plants, which might probably otherwise degenerate.

1627. *Fecundation of the ovary.* Admitting that the pollen is conducted to the ovary through the tubes of the style, how after all is the ovary fecundated, or the seed rendered fertile? On this subject naturalists have been much divided; and, according to their several opinions, have been classed under the respective appellations of ovarists, animalculists, and epigenesists.

1628. *Ovarist.* According to the opinion of the *Ovarist*, the embryo preexists in the ovary, and is fecundated by the agency of the pollen, as transmitted to it through the style.

1629. *Animalculist.* But the theory of the ovarists is not without its difficulties; for, as the embryo is never found to make its appearance till after fecundation, it has been thought that it must necessarily pre-exist in the pollen of the anther; from which it is conveyed to the ovary through the medium of the style, and afterwards matured. This theory was founded upon that of Leuwenhoeck, with regard to animal generation, which supposes the preexistence of animalcula in the seminal principle of the male; the animalcula being conveyed *in coitu* to the ovary of the female, where alone they are capable of development.

1630. *Epigenesist.* The difficulties inseparable from both theories, together with the phenomenon of hybrid productions, have given rise also to a third; this is the *Theory of the Epigenesists*, who maintain that the embryo preexists neither in the ovary nor pollen, but is generated by the union of the fecundating principles of the male and female organs; the former being the fluid issuing from the pollen when it explodes, and the latter the fluid that exudes from the surface of the stigma when mature.

1631. *Hybrids.* Although the arguments of the epigenesists are by no means satisfactory, yet it cannot be denied, that hybrid productions partake of the properties both of the male and female from which they spring. This was long ago proved to be the fact by Bradley, and more recently confirmed by the experiments of Knight; as well as happily converted to the advantage of the cultivator.

1632. *Vegetable crossing.* Observing that farmers who rear cattle improve the progeny by means of *crossing*, the breed, Knight argued from analogy, that the same improvement might be introduced into vegetables. His principal object was that of procuring new and improved varieties of the apple and pear, to supply the place of such as had become diseased and unproductive. But as the necessary slowness of all experiments of the kind, with regard to the fruit in question, did not keep pace with the ardour of his desire to obtain information on the subject, he was induced to institute some tentative experiments upon the common pea; a plant well suited to his purpose, both from its quickness of growth, and from the many varieties in form, size, and colour which it afforded. In 1757, a degenerate sort of pea was growing in his garden, which had not recovered its former vigour even when removed to a better soil. Being thus a good subject of experiment, the male organs of a dozen of its immature blossoms were destroyed, and the female organs left entire. When the blossoms had attained their mature state, the pollen of a very large and luxuriant grey pea was introduced into the one half of them, but not into the other. The pods of both grew equally; but the seeds of the half that were impregnated withered away without having augmented beyond the size to which they had attained before the blossoms expanded. The seeds of the other half were augmented and matured, as in the ordinary process of impregnation; and exhibited no perceptible difference from those of other plants of the same variety; perhaps because the external covering of the seed was furnished entirely by the female. But when they were made to vegetate in the succeeding spring, the effect of the experiment was obvious. The plants rose with great luxurance, indicating in their stem, leaves, and fruit, the influence of this artificial impregnation; the seeds produced were of a dark grey. By impregnating the flowers of this variety with the pollen of others, the colour was again changed, and new varieties obtained, superior in every respect to the original on which the experiment was first made, and attaining, in some cases, to a height of more than twelve feet. (*Phil. Trans.*, 1759.) Knight thinks his experiments on this subject afford examples of superfœtation, a phenomenon, the existence of which appears doubtful amongst animals, and of which the proof amongst vegetables is not yet quite satisfactory. Of one species of superfœtation he has certainly produced examples; that is, when, by impregnating a white pea-blossom with the pollen both of a white and grey pea, white and grey seeds were obtained. But of the other species of superfœtation, in which one seed is supposed to be the joint issue of two males, the example is not quite satisfactory. Such a production is perhaps possible, and further experiments may probably ascertain the fact; but it seems to be a matter of mere curiosity, and not apparently connected with any views of utility.

1633. *The practicability of improving the species* is rendered strikingly obvious by these experiments; and the ameliorating effect is the same, whether by the male or female; as was ascertained by impregnating the largest and most luxuriant plants with the pollen of the most diminutive and dwarfish, or the contrary. By such means any number of varieties may be obtained, according to the will of the experimenter, amongst which some will no doubt be suited to all soils and situations. Knight's experiments of this kind were extended also to wheat; but not with equal success: for, though some very good varieties were obtained, yet they were found not to be permanent. But the success of his

experiments on the apple tree were equal to his hopes. This was, indeed, his principal object, and no means of obtaining a successful issue were left untried. The plants which were obtained in this case were found to possess the good qualities of both of the varieties employed, uniting the greatest health and luxuriance with the finest and best-flavoured fruit.

1654. *Improved varieties of every fruit and esculent plant may be obtained by means of artificial impregnation, or crossing, as they were obtained in the cases already stated.* Whence Knight thinks, that this promiscuous impregnation of species has been intended by nature to take place, and that it does in fact often take place, for the purpose of correcting such accidental varieties as arise from seed, and of confining them within narrower limits. All which is thought to be countenanced from the consideration of the variety of methods which nature employs to disperse the pollen, either by the elastic spring of the anthers, the aid of the winds, or the instrumentality of insects. But although he admits the existence of vegetable hybrids, that is, of varieties obtained from the intermixture of different species of the same genus, yet he does not admit the existence of vegetable mules, that is, of varieties obtained from the intermixture of the species of different genera; in attempting to obtain which he could never succeed, in spite of all his efforts. Hence he suspects that where such varieties have been supposed to take place, the former must have been mistaken for the latter. It may be said, indeed, that if the case exists in the animal kingdom, why not in the vegetable kingdom? to which it is, perhaps, difficult to give a satisfactory reply; but from the narrow limits within which this intercourse is in all cases circumscribed, it scarcely seems to have been the intention of nature that it should succeed even among animals. Salisbury is of a different opinion, and considers (*Hort. Trans.*, i. 364.) that new species may be created both by bees and by the agency of man; and the recent experiments of Herbert, Sweet, and others, seem to confirm this opinion. Sweet's experience leads him to conclude that the plants of all orders strictly natural may be reciprocally impregnated with success, and he has already, in the nursery-gardens of Messrs. Colville, produced many new *Gerania* and *Rhodoracem*.

1655. *A singular or anomalous effect of crossing, or extraneous impregnation, is the change sometimes undergone by the seed or fruit which is produced by the blossom impregnated.* These results are not uniform, but they are of frequent occurrence, and have attracted notice from a very early period. John Turner observes (*Hort. Trans.*, v. 63.) that Theophrastus and Pliny (*Theophrast. Hist. Plant.*, l. ii. c. 4; *Plinii Hist. Nat.*, l. xvii. c. 25.) seem to allude to it, and that the notion was entertained by Bradley, who, in his *New Improvements in Planting and Gardening*, after giving directions for fertilising the female flowers of the hazel with the pollen of the male, says, "By this knowledge we may alter the property and taste of any fruit, by impregnating the one with the farina of another of the same class, as, for example, a codlin with a pearmaio, which will occasion the codlin to last a longer time than usual, and be of a sharper taste; or, if the winter fruit should be fecundated with the dust of the summer kinds, th will decay before their usual time; and it is from this accidental coupling of the farina of one kind with the other, that in an orchard, where there is a variety of apples, even the fruit gathered from the same tree differs in its flavour and times of ripening; and, moreover, the seeds of those apples so generated, being changed by that means from their natural qualities, will produce different kinds of fruit, if they are sown." Turner, after quoting several instances, and, among others, one from the *Philosophical Transactions* "concerning the effect which the farina of the blossoms of different sorts of apples had on the fruit of a neighbouring tree," states upwards of six cases of hybridised apples, that had come within his own observation; and concludes with the remark, that, if there does exist in fruits such a liability to change, it will at once be evident to the intelligent cultivator how much care is requisite in growing melons, cucumbers, &c., to secure their true characters, even without reference to saving seed for a future crop. In the same volume of the *Horticultural Transactions* (p. 23A.) an account is given of different-coloured peas being produced in the same pod, by crossing the parent blossom. All these facts seem to contradict the generally received opinion, that crossing only affects the next generation; here it appears to affect the embryo offspring; and a gardener, who had no keeping apples in his orchard, might communicate that quality in part to his summer fruit by borrowing the use of a neighbour's blossoms from a late variety. It is probable, however, that such counter-impregnations do not take place readily; otherwise the produce of a common orchard would be an ever-varying round of monstrosities.

SECT. VIII. *Changes consequent upon Impregnation.*

1636. *The peculiar changes consequent upon impregnation, whether in the flowers or fruit, may be considered as external and internal.*

1637. *External changes.* At the period of the impregnation of the ovary the flower has attained to its ultimate state of perfection, and displayed its utmost beauty of colouring and richness of perfume. But as it is now no longer wanted, so it is no longer provided for in the economy of vegetation. Its period of decline has commenced; and, as is indicated, first by the decay of the stamens, then of the petals, and then of the calyx, which wither and shrink up, and finally detach themselves from the fruit altogether, except in some particular cases in which one or other of them becomes permanent and falls only with the fruit. The stigma exhibits also similar symptoms of decay, and the style itself often perishes. The parts contiguous to the flower, such as the bracts and floral leaves, are sometimes also affected; and finally the whole plant, at least in the case of annuals, begins to exhibit indications of decay. But while the flower withers and falls, the ovary is advancing to perfection, swelling and augmenting in size, and receiving now all the nutriment by which the decayed parts were formerly supported. Its colour begins to assume a deeper and richer tinge; its figure is also often altered, and new parts are even occasionally added, wings, crests, prickles, hooks, bloom, down. The common receptacle of the fruit undergoes also similar changes, becoming sometimes large and succulent, as in the fig and strawberry; and sometimes juicyless and indurated, as in compound flowers.

1638. *Internal changes.* If the ovary is cut open as soon as it is first discoverable in the flower, it will be found to be divisible into several distinct parts, exhibiting an apparatus of cells, valves, and membranes, constituting the pericarp, and sometimes the external coats of the seed. Impregnation has no sooner taken place than its influence begins to be visible; the umbilical cord, which was formerly short and distended, is in some cases converted into a long and slender thread. Sometimes the position of the seed is altered. Before impregnation the seeds of *Caryophyllus aromaticus* and *Metrosideros gumifera* are horizontal; after impregnation they become vertical. Before impregnation the *Magnolia* seeds are erect; after impregnation they become inverted and pendulous. The figure of the seed is also altered in passing from its young to its mature state; changing from smooth to angular, from tapering to oval, from oval to round, and from round to kidney-shaped. But all the seeds are not brought to maturity, of which the rudiments may exist in the ovary. *Lagocia* and *Hasselquistia* produce uniformly the rudiments of two seeds, of which they mature but one. But the principal changes resulting from impregnation are operated in the seed itself, which, though previously a homogeneous and gelatinous mass, is now converted into an organised body, or embryo. Such are the phenomena, according to the description of Gartner, accompanying or following the impregnation of all flowers producing seeds; exceptions occur where the fecundation is spurious and incomplete; where the ovary swells, but exhibits no traces of perfect seed within, as often happens in the vine and *Tamus*; or where barren and fertile seeds are intermingled together in the same ovary. This proceeds from some defect either in the quantity or quality of the pollen; but rather in the quality, as it is not always plants having the most pollen that produce the most seeds. The two stamens of the *Orchidea* fecundate 8000 seeds, and the five stamens of tobacco fecundate 900; while

the 50 stamens of *Barringtonia*, the 230 of *Thaëa*, and the 80 of the *Caryophyllus fecundate* only two or three ovules.

SECT. IX. *The Propagation of the Species.*

1639. *As the life of the vegetable, like that of the animal, is limited to a definite period, and as a continued supply of vegetables is always wanted for the support of animals, what we call art, or nature operating by means of the animal man, has taken care to institute such means as shall secure the multiplying and perpetuating of the species in all possible cases.*

1640. *Equivocal generation.* It was long a vulgar error, countenanced even by the philosophy of the times, that vegetables do often spring up from the accidental mixture of earth and putrid water, or other putrid substances, in the manner of what was called the equivocal generation of animals; or, at the very least, that the earth contains the principle of vegetable life in itself, which, in order to develop, it is only necessary to expose to the action of the air. The former alternative of the error has been long ago refuted; the latter has lost its hold, having been refuted by Malpighi, who proved that the earth produces no plant without the intervention of a seed, or of some other species of vegetable germ deposited in it by nature or by art.

1641. *Propagation by seeds.* When the seed has reached maturity in the due and regular course of the development of its several parts, it detaches itself sooner or later from the parent plant, either singly or along with its pericarp, and drops into the soil, where it again germinates and takes root, and springs up into a new individual. Such is the grand means instituted by nature for the replenishing and perpetuating of the vegetable kingdom.

1642. *Dispersion of seed.* If seeds were to fall into the soil merely by dropping down from the plant, then the great mass of them, instead of germinating and springing up into distinct plants, would grow up only to putrefy and decay; to prevent which consequence nature has adopted a variety of the most efficacious contrivances, all tending to the dispersion of the seed. The first means to be mentioned is that of the elasticity of the pericarp of many fruits, by which it opens when ripe, with a sort of sudden spring, ejecting the seed with violence, and throwing it some considerable distance from the plant. This may be exemplified in a variety of cases; the seeds of oats when ripe are projected from the calyx with such violence, that in a fine and dry day you may even hear them thrown out with a slight and sudden snap, in passing through a field that is ripe. The pericarp of the dorsiferous ferns (*fig. 197.*) is furnished with a sort of peculiar elastic ring, intended, as it would appear, for the very purpose of projecting the seeds. The capsules of the squirting cucumber, geranium, and *Fraxinella*, discharge their seeds also when ripe with an elastic jerk. But the pericarp of *Impatiens*, which consists of five cells with five valves, exhibits perhaps one of the best examples of this mode of dispersion. If it be accidentally touched when ripe it will immediately burst open, while the valves, coiling themselves up in a spiral form, and springing from the stem, discharge the contained seeds, and scatter them all around. The bursting of the pericarp of some species of pines is also worthy of notice. The pericarp, which is a cone, remains on the tree till the summer succeeding that on which it was produced, the scales being still closed; but when the hot weather has commenced and continued for some time, so as to dry the cone thoroughly, the scales open of their own accord with a sudden jerk, ejecting the contained seeds: and if a number of them happen to burst together, which is often the case, the noise is such as to be heard at some considerable distance. The twisted awn of *Avena fatua* (*fig. 198.*) or wild oat, as well as that of *Erdium cicutarium*, and some others, seems to have been intended particularly for the purpose of aiding the

also furnished with a resource. One of the most common modes by which seeds are conveyed to a distance from their place of growth is that of the instrumentality of animals. Many seeds are thus carried to

the further dispersion of the seed, after being discharged from the plant or pericarp. This spiral awn or spring, which is beset with a multitude of fine and minute hairs, possesses the property of contracting by means of drought, and of expanding by means of moisture. Hence it remains of necessity in a perpetual state of contraction or dilatation, dependent upon change of weather; from which, as well as from the additional aid of the fine hairs, which act as so many fulcra, and cling to whatever object they meet, the seed to which it is attached is kept in continual motion till it either germinates or is destroyed. The awn of barley, which is beset with a multitude of little teeth, all pointing to its upper extremity, presents also similar phenomena. For when the seed with its awn falls from the ear and lies flat upon the ground, it is necessarily extended in its dimensions by the moisture of the night, and contracted by the drought of the day: but as the teeth prevent it from receding in the direction of the point, it is consequently made to advance in the direction of the base of the seed, which is thus often carried to the distance of many feet from the stalk on which it grew. If any one is yet sceptical with regard to the travelling capacity of the awn, let him only introduce an awn of barley with the seed uppermost between his coat and shirt sleeve at the wrist, when he walks out in the morning, and by the time he returns to breakfast, if he has walked to any great distance, he will find it up at his armpit. This journey has been effected by means of the continued motion of the arm, and consequently of the teeth of the awn acting as feet to carry it forward.

1643. *Where distance of dispersion is required, nature is*

a distance from their place of growth, merely by their attaching themselves to the bodies of such animals as may happen accidentally to come in contact with the plant, in their search after food; the hooks or hairs with which one part or other of the fructification is often furnished, serving as the medium of attachment, and the seed being thus carried about with the animal till it is again detached by some accidental cause, and at last committed to the soil. This may be exemplified in the case of the Bidons and *Myosotis*, in which the hooks or prickles are attached to the seed itself; or in the case of *Galium Aparine* and others, in which they are attached to the pericarp; or in the case of the thistle and the burdock, in which they are attached to the general calyx. Many seeds are dispersed by animals in consequence of their pericarp being used as food. This is often the case with the seeds of the drupe, as cherries and sloes, and with the berries of the hawthorn, which birds often carry away till they meet with some convenient place for devouring the pulpy pericarp, and then drop the stone into the soil. And so also fruit is dispersed that has been hoarded for the winter, though even with the view of feeding on the seed itself, as in the case of nuts hoarded up by squirrels, which are often dispossessed by some other animal, which, not caring for the hoard, scatters and disperses it. Sometimes the hoard is deposited in the ground itself, in which case part of it is generally found to take root and to spring up into plants; though it has been observed that the ground squirrel often deprives the kernel of its germ before it deposits the fruit it collects. Rooks have been also observed to lay up acorns and other seeds in the holes of fence-posts, which being either forgot or accidentally thrust out, fall ultimately into the earth and germinate. But sometimes the seed is even taken into the stomach of the animal, and afterwards deposited in the soil, having passed through it unhurt. This is often the case with the seed of many species of berry, such as the mistletoe, which the thrush swallows and afterwards deposits upon the boughs of such trees as it may happen to alight upon. The seeds of the *Loranthus americanus*, another parasitical plant, are said to be deposited in like manner on the branches of the *Coccoloba grandiflora* and other lofty trees; as also the seeds of *Phytolacca decandra*, the berries of which are eaten by the robin, thrush, and wild pigeon. And so also the seeds of currants or roans are sometimes deposited, after having been swallowed by blackbirds or other birds, as may be seen by observing a currant bush or young roan tree growing out of the cleft of another tree, where the seed has been left, and where there may happen to have been a little dust collected by way of soil; or where a natural graft may have been effected by the insinuation of the radicle into some chink or cleft. It seems indeed surprising that any seeds should be able to resist the heat and digestive action of the stomach of animals; but it is undoubtedly the fact. Some seeds seem even to require it. The seeds of *Magnolia glauca*, which have been brought to this country, are said generally to have refused to vegetate till after undergoing this process, and it is known that some seeds will bear a still greater degree of heat without any injury. Spallanzani mentions some seeds that germinated after having been boiled in water: and Du Hamel gives an account of some others that germinated even after having been exposed to a degree of heat measuring 255° of Fahrenheit. In addition to the instrumentality of brute animals in the dispersion of the seed might be added also that of man, who, for purposes of utility or of ornament, not only transfers to his native soil seeds indigenous to the most distant regions, but sows and cultivates them with care. "A farmer in the west of Scotland has been in the practice, for some years, of feeding his cows upon potato-apples, and using their dung, and raising seedling plants from it the seeds; having passed through the stomach of the cow, without having undergone such a change as to prevent them from vegetating." (*Note of Mr. Cleghorn, Ed. of the Edinburgh Farm. Mag.*)

1644. *The agency of winds* is one of the most effective modes of dispersion instituted by nature. Some seeds are fitted for this mode of dispersion from their extreme minuteness, such as those of the mosses, lichens and Fungi, which float invisibly on the air, and vegetate wherever they happen to meet with a suitable soil. Others are fitted for it by means of an attached wing, as in the case of the fir tree and *Liriodendron tulipifera*, so that the seed, in falling from the cone or capsule, is immediately caught by the wind, and carried to a distance. Others are peculiarly fitted for it by means of their being furnished with an aigrette or down, as in the case of the dandelion, goat's-beard, and thistle, as well as most plants of the class Syngenesia; the down of which is so large and light in proportion to the seed it supports, that it is wafted on the most gentle breeze, and often seen floating through the atmosphere in great abundance at the time the seed is ripe. Some have a tail, as in *Clématis Vitalba*. Others are fitted for this mode of dispersion by means of the structure of the pericarp, which is also wafted along with them, as in the case of *Staphylèa triflora*, the inflated capsule of which seems as if obviously intended thus to aid the dispersion of the contained seed, by its exposing to the wind a large and distended surface with but little weight; and so also in the case of the maple, elm, and ash, the capsules of which are furnished, like some seeds, with a membranous wing, which when they separate from the plant the wind immediately lays hold of and drives before it.

1645. *The instrumentality of streams, rivers, and currents of the ocean*, is a further means adopted by nature for the dispersion of the seeds of vegetables. The mountain-stream or torrent washes down to the valley the seeds which may accidentally fall into it, or which it may happen to sweep from its banks when it suddenly overflows them. The broad and majestic river, winding along the extensive plain, and traversing the continents of the world, conveys to the distance of many hundreds of miles the seeds that may have vegetated at its source. Thus the southern shores of the Baltic are visited by seeds which grew in the interior of Germany, and the western shores of the Atlantic by seeds that have been generated in the interior of America. But fruits indigenous to America and the West Indies have sometimes been found to be swept along by the currents of the ocean to the western shores of Europe, and even on the coasts of Orkney and Shetland. Fruits of *Mimosa scandens*, *Stizolobium pruriens*, *Gulandina Bônduc*, and *Anacardium occidentale*, or cashew nut, have been thus known to be driven across the Atlantic to a distance of upwards of 2000 miles; and although the fruits now adduced as examples are not such as could vegetate on the coast on which they were thrown, owing to soil or climate, yet it is to be believed that fruits may have been often thus transported to climates or countries favourable to their vegetation.

1646. *Propagation by gems*. Though plants are for the most part propagated by means of seeds, yet many of them are propagated also by means of gems; that is, hulls and buds.

1647. *The caulinary bulb* is often the means of the propagation of the species: it generally appears in the axils of the leaves, as in *Dentaria bulbifera* and *Lilium bulbiferum*; or between the spokes of their umbels, as in *Allium canadense*; or in the midst of the spike of flowers, as in *Polygonum viviparum* and *Poa alpina*. As plants of this last kind are mostly alpine, it has been thought to be an institution or resource of nature, to secure the propagation of the species in situations where the seed may fail to ripen.

1648. *The bud*, though it does not spontaneously detach itself from the plant and form a new individual, will yet sometimes strike root and develop its parts if carefully separated by art and planted in the earth: but this is to be understood of the leaf-bud only, for the flower-bud, according to Mirbel, if so treated, always perishes.

1649. *Propagation by the leaves*. The species may sometimes be propagated even by means of the leaves, as in the aloe, *Xylophyla*, sea-onion, and some species of *Arum*; which if carefully deposited in the soil will grow up into new plants, by virtue, no doubt, of some latent gem contained in them. The Fungi and lichens, according to Gærtner, are all gemmiferous, having no sexual organs, and no pollen impregnating a germ. In the genus *Lycopëdon*, the gelatinous substance that pervades the cellular tissue is converted into a proliferous powder; and in *Clavaria*, the fluid contained in the cavities of the plant is converted into a proliferous powder also; and in the agarics, *Hypnum*, and *Boletus*, vesicles containing spheriferous granules are found within the lamellæ, pores, or tubes. Hedwig, on the contrary, ascribes to the Fungi a sexual apparatus, and maintains that the pollen is lodged in the volva: but here it is to be recollected, as in the cases of the scutellæ of the lichens, that all Fungi are not furnished with a volva, and consequently not furnished with pollen. The *Confervæ* and *Ulvæ*, together with the genera *Blasia* and *Ruticia* are

also, according to Gærtner, propagated only by gems; while *Marchántia*, *Anthoceros*, *Jungermánnia*, and *Lycopédon*, are said to be propagated both by gems and seeds.

1650. *Runners* are young shoots issuing from the collar or summit of the root, and creeping along the surface of the soil; but producing a new root and leaves at the extremity, and forming a new individual, by the decay of the connecting link, as in the strawberry.

1651. *Slips*. The process of raising perennials by slips is well known to gardeners, and should, perhaps, be regarded as an extension of the old plant, rather than as the generation of a new one; though it serves the purpose of the cultivator equally well as a plant raised from seed, with the additional advantage of bearing fruit much sooner. But how is the root generated which the slip thus produces? If the trunk of a tree is lopped, and all its existing buds destroyed, then there will be protruded from between the wood and bark a sort of protuberant lip or ring formed from the proper juice, and from which there will spring a number of young shoots. The formation of the root, in the case of the slip, is effected in the same manner, the moisture of the soil encouraging the protrusion of buds at and near the section; and the bud that would have been converted into a branch above ground is converted into a root below.

1652. *Layers*. The mode of propagation by layers is practised upon trees that are delicate, and which cannot readily be propagated by means of slips; in which case the root is generated nearly as in the former case, the soil stimulating the protrusion of buds which are converted into roots. In many plants, such as the currant and laurel, this is altogether a natural process, effected by the spontaneous bending down of a branch to the surface of the soil.

1653. *Suckers or offsets*. Many plants protrude annually from the collar a number of young shoots, encircling the principal stem and depriving it of a portion of its nourishment, as in the case of most fruit trees. Others send out a horizontal root from which there at last issues a bud that ascends above the soil, and is converted into a little stem, as in the case of the elm tree and *Syringa*. Others send out a horizontal shoot from the collar or its neighbourhood; or a shoot that ultimately bends down by its own weight till it reaches the ground, in which it strikes root, and again sends up a stem as in the currant bush and laurel. The two former are called *suckers* or *offsets*, though the term offset should, perhaps, be restricted to the young bulbs that issue and detach themselves annually from bulbous roots. The latter is not designated by any particular name, but may be regarded as a sort of natural layer, resembling also, in some respects, the runner; from which, however, it is distinguished in that it never detaches itself spontaneously from the parent plant, as is the case also with the two former: but if either of them is artificially detached, together with a portion of root or a slice of the collar adhering to it, the detached part will now bear transplanting, and will constitute a distinct plant.

1654. *Grafting and budding*. The species is also often propagated, or at least the variety is multiplied, by means of *grafting*; which is an artificial application of a portion of the shoot or root of one tree or plant to the stem, shoot, branch, or root of another, so that the two shall coalesce together and form but one plant. The shoot which is to form the summit of the new individual is called the scion; the stem to which it is affixed is called the stock; and the operation, when effected, the graft. As the graft is merely an extension of the parent plant from which the scion came, and not properly speaking a new individual, so it is found to be the best method of propagating approved varieties of fruit trees without any danger of altering the quality of the fruit, which is always apt to be incurred in propagation from seed, but never in propagating from the scion. The scion will also bear fruit much sooner than the tree that is raised from seed; and, if effected on a proper stock, will be much more hardy and vigorous than if left on the parent plant. Hence the great utility of grafting in the practice of gardening. Till lately, grafting was confined to the ligneous plants, but it is now successfully practised on the roots and shoots of herbaceous vegetables; and the dahlia is grafted by the root; the melon on the gourd; the love-apple on the potato; the cauliflower on the cabbage, &c., by the shoot. A very ingenious tract has been published on this subject, entitled, *Essai sur la Greffe de l'Herbe des Plantes et des Arbres, par Monsr. le Baron de Tschoudy, Bourgeois de Glaris*. Paris, 1819.

SECT. X. Causes limiting the Propagation of the Species.

1655. *Though plants are controlled chiefly by animals, yet they also control one another.* From the various sources of vegetable reproduction, but particularly from the fertility and dispersion of the seed, the earth would soon be overrun with plants of the most prolific species, and converted again into a desert, if it were not that nature has set bounds to their propagation by subjecting them to the control of man, and to the depredations of the great mass of animals; as well as by confining the germination of their seeds to certain and peculiar habitations arising from soil, climate, altitude, and other circumstances. In order to form an idea of the manner in which the latter act upon vegetation, imagine that every year an enormous quantity of seeds, produced by the existing vegetables, are spread over the surface of the globe, by the winds and other causes already mentioned; all of these seeds which fall in places suitable for their vegetation, and are not destroyed by animals, germinate and produce plants; and then among these plants, the strongest, and largest, and those to which the soil is best suited, develope themselves in number and magnitude so as to choke the others. Such is the general progress of nature, and among plants, as among animals, the strong flourish at the expense of the weak. These causes have operated for such a length of time, that the greater number of species are now fixed in, and considered as belonging to, certain soils, situations, and climates, beyond which they seldom propagate, otherwise than by the hands of man.

SECT. XI. Evidence and Character of Vegetable Vitality.

1656. *The power of counteracting the laws of chemical affinity is reckoned the best and most satisfactory evidence of the presence and agency of a vital principle, as inherent in any subject.* This principle, which seems first to have been instituted by Humboldt, is obviously applicable to the case of animals, as is proved by the process of the digestion of the food, and its conversion into chyle and blood; as well as from the various secretions and excretions effected by the several organs, and causing the growth and development of the individual, in direct opposition to the acknowledged laws of chemical affinity, which, as soon as the vital principle is extinct, begin immediately to give evidence of their action, in the incipient symptoms of the putrefaction of the dead body. But the rule is also applicable to the case of vegetables, as is proved by the

introsuption, digestion, and assimilation of the food necessary to their development; all indicating the agency of a principle capable of counteracting the laws of chemical affinity, which, at the period of what is usually called the death of the plant, begin also immediately to act, and to give evidence of their action in the incipient symptoms of the putrefaction of the vegetable. Vegetables are therefore obviously endowed with a species of vitality. But, admitting the presence and agency of a vital principle inherent in the vegetable subject, what are the peculiar properties by which this principle is characterised?

1657. *Excitability.* One of the most distinguishable properties of the vital principle of vegetables is that of its excitability, or capacity of being acted upon by the application of natural stimuli, impelling it to the exertion of its vegetative powers; the natural stimuli thus impelling it being light and heat.

1658. *The stimulating influence of light* upon the vital principle of the plant is discoverable, whether in the stem, leaf, or flower. The direction of the stem is influenced by the action of light, as well as the colour of the leaves. Distance from direct rays of light or weak light produces etiolation, and its absence blanching. The luxuriance of branches depends on the presence and action of light, as is particularly observable in the case of hot-house plants, the branches of which are not so conspicuously directed, either to the fire in quest of heat, or to the door or open sash in quest of air, as to the sun in quest of light. Hence also the branches of plants are often more luxuriant on the south, than on the north, side; or at least on the side that is best exposed to light. The position of the leaf is also strongly affected by the action of light, to which it uniformly turns its upper surface. This may be readily perceived in the case of trees trained to a wall, from which the upper surface of the leaf is by consequence always turned; being on a south wall turned to the south, and on a north wall turned to the north: and if the upper surface of the leaf is forcibly turned towards the wall and confined in that position for a length of time, it will soon resume its primitive position upon regaining its liberty, but particularly if the atmosphere be clear. The leaves of the mallow are said to exhibit but slight indications of this susceptibility, as also sword-shaped leaves; and those of the mistletoe are equally susceptible on both sides. It had been conjectured that these effects are partly attributable to the agency of heat; and to try the value of the conjecture, Bonnet placed some plants of the *Atriplex* in a stove heated to 25° of Reaumur. Yet the stems were not inclined to the side from which the greatest degree of heat came; but to a small opening in the stoves. Heat, then, does not seem to exert any perceptible influence in the production of the above effects. Does moisture? Bonnet found that the leaves of the vine exhibited the same phenomenon when immersed in water, as when left in the open air. Whence it seems probable that light is the sole agent in the production of the effects in question. But as light produces such effects upon the leaves, so darkness or the absence of light produces an effect quite the contrary; for it is known that the leaves of many plants assume a very different position in the night from what they have in the day. This is particularly the case with winged leaves, which, though fully expanded during the day, begin to droop and bend down about sunset and during the fall of the evening dew, till they meet together on the inferior side of the leaf-stalk; the terminal lobe, if the leaf is furnished with one, folding itself back till it reaches the first pair; or the two side lobes, if the leaf is trifoliate, as in the case of common clover. So, also, the leaflets of the false acacia and liquorice hang down during the night, and those of *Mimosa pudica* fold themselves up along the common foot-stalk so as to overlap one another. Linnæus has designated the above phenomenon by the appellation of *The Sleep of Plants*. The expansion of the flower is also effected by the action of light. Many plants do not fully expand their petals except when the sun shines; and hence alternately open them during the day and shut them up during the night. This may be exemplified in the case of papilionaceous flowers in general, which spread out their wings in fine weather to admit the rays of the sun, and again fold them up as the night approaches. It may be exemplified also in the case of compound flowers, as the dandelion and hawkweed. But the most singular case of this kind is perhaps that of the lotus of the Euphrates, which is described by Theophrastus as rearing and expanding its blossoms by day, closing and sinking down beneath the surface of the water by night so as to be beyond the grasp of the hand, and again rising up in the morning to present its expanded blossom to the sun. The same phenomenon is related also by Pliny. But although many plants open their flowers in the morning and shut them again in the evening, yet all flowers do not open and shut at the same time. Plants of the same species are tolerably regular as to time, other circumstances being the same; and hence the daily opening and shutting of the flower botanists have denominated *The Horologium Fibræ*. Flowers requiring but a slight application of stimulus open early in the morning, while others, requiring more, open somewhat later. Some do not open till noon, and some, whose extreme delicacy cannot bear the action of light at all, open only at night; such as the *Cactus grandiflora*, or night-blowing cereus. But it seems somewhat doubtful whether or not light is the sole agent in the present case; for it has been observed that equatorial flowers open always at the same hour, and that tropical flowers change their hour of opening according to the length of the day. It has been observed, also, that the flowers of plants which are removed from a warmer to a colder climate expand at a later hour in the latter. A flower that opens at six o'clock in the morning in Senegal, will not open in France or England till eight or nine, nor in Sweden till ten; a flower that opens at ten o'clock in Senegal, will not open in France or England till noon or later, and in Sweden it will not open at all; and a flower that does not open till noon or later in Senegal, will not open at all in France or England. This seems as if heat or its absence were also an agent in the opening or shutting of flowers; though the opening of such as blow only in the night cannot be attributed either to light or heat. But the opening or shutting of some flowers depends not so much on the action of the stimulus of light as on the existing state of the atmosphere, and hence their opening or shutting betokens change. If the Siberian sow-thistle shuts at night, the ensuing day will be fine; and if it opens, it will be cloudy and rainy. If the African marigold continues shut after seven o'clock in the morning, rain is near at hand; and if the *Convolvulus arvensis*, *Caléndula pluviális*, or *Anagallis arvensis*, is even already open, it will shut upon the approach of rain, the last of which, from its peculiar susceptibility, has obtained the name of the poor man's weatherglass. But some flowers, besides expanding during the light of day, incline also towards the sun, and follow his course, looking towards the east in the morning, towards the south at noon, and towards the west in the evening; and again returning in the night to their former position in the morning. Such flowers are designated by the appellation of *Heliotropes*, on account of their following the course of the sun; and the movement they thus exhibit is denominated their *rotation*. This phenomenon had been observed by the ancients long before they made any considerable progress in botany, and had even been interwoven into their mythology, having originated, according to the records of fabulous history, in one of the metamorphoses of early times. Clytie, inconsolable for the loss of the affections of Sol, by whom she had been formerly beloved, and of whom she was still enamoured, is represented as brooding over her griefs in silence and solitude; where, refusing all sustenance, and seated upon the cold ground, with her eyes invariably fixed on the sun during the day, and watching for his return during the night, she is at length transformed into a flower, retaining, as much as a flower can retain it, the same unaltered attachment to the sun. This is the flower which is denominated *Heliotropium* by the ancients, and described by Ovid as *Flos qui ad solem vertitur*. But it is to be observed, that the flower alluded to by Ovid cannot be the *Heliotropium* of the moderns, because Ovid describes it as resembling the violet; much less can it be the sun-flower, which is a native of America, and could not consequently have been known to Ovid; so that the true *Heliotro-*

plum of the ancients is perhaps not yet ascertained. Bonnet has further remarked that the ripe ears of corn, which bend with the weight of grain, scarcely ever incline to the north, but always less or more to the south; of the accuracy of which remark any one may easily satisfy himself by looking at a field of wheat ready for the sickle; he will find the whole mass of ears nodding, as if with one consent, to the south. The cause of the phenomenon has been supposed to be a contraction of the fibres of the stem or flower-stalk on the side exposed to the sun; and this contraction has been thought by De la Hire and Dr. Hales to be occasioned by an excess of transpiration on the sunny side; which is probably the fact, though there seems upon the principle to be some difficulty in accounting for its returning at night; because if you say that the contracted side expands and relaxes by moisture, what is it that contracts the side that was relaxed in the day? The moisture, of which it is no doubt still full, would counteract the contraction of its fibres, and prevent it from resuming its former position in the morning.

1659. *Heat* as well as light acts also as a powerful stimulus to the exertions of the vital principle. This has been already shown in treating of the process of germination; but the same thing is observable with regard to the development and maturation of the leaves, flower, and fruit; for although all plants produce their leaves, flower, and fruit annually, yet they do not all produce them at the same period or season. This forms the foundation of what Linnæus has called the *Calendarium Flôræ*, including a view of the several periods of the frondescence and efflorescence of plants, together with those of the maturation of the fruit.

1660. *Frondescence.* It must be plain to every observer, that all plants do not protrude their leaves at the same season, and that even of such as do protrude them in the same season, some are earlier and some later. The honeysuckle protrudes them in the month of January; the gooseberry, currant, and elder, in the end of February, or the beginning of March; the willow, elm, and lime tree, in April; and the Platanus, oak, and ash, which are always the latest among trees, in the beginning or towards the middle of May. Many annuals do not come up till after the summer solstice; and many mosses not till after the commencement of winter. This gradual and successive unfolding of the leaves of different plants seems to arise from the peculiar susceptibility of the species to the action of heat, as requiring a greater or less degree of it to give the proper stimulus to the vital principle. But a great many circumstances will always concur to render the time of the unfolding of the leaves somewhat irregular; because the mildness of the season is by no means uniform at the same period of advancement; and because the leafing of the plant depends upon the peculiar degree of temperature, and not upon the return of a particular day of the year. Hence it has been thought that no rule could be so good for directing the husbandman in the sowing of his several sorts of grain, as the leafing of such species of trees as might be found by observation to correspond best to each sort of grain respectively, in the degree of temperature required. Linnæus (Stillingfleet informs us) instituted some observations on the subject about the year 1750, with a view chiefly to ascertain the time proper for the sowing of barley in Sweden; he regarded the leafing of the birch tree as being the best indication for that grain, and recommended the institution of similar observations with regard to other sorts of grain, upon the grounds of its great importance to the husbandman, who may be said to attend to it in a manner instinctively; but as all the trees of the same species do not come into leaf precisely at the same time, and as the weather may alter even after the most promising indications, no guide, natural or artificial, can be absolutely depended on with a view to future results.

1661. *Efflorescence.* The flowering of the plant, like the leafing, seems to depend upon the degree of temperature induced by the returning spring, as the flowers are also protruded pretty regularly at the same successive periods of the season. The mezerion and snowdrop protrude their flowers in February; the primrose in the month of March; the cowslip in April; the great mass of plants in May and June; many in July, August, and September; some not till the month of October, as the meadow saffron; and some not till the approach or middle of winter, as the laurustinus and arbutus. Such at least is the period of their flowering in this country; but in warmer climates they are earlier, and in colder climates they are later. Between the tropics, where the degree of heat is always high, it often happens that plants will flower more than once in the year; because they do not there require to wait till the temperature is raised to a certain height, but merely till the development of their parts can be effected in the regular operation of nature, under a temperature already sufficient. For the greater part, however, they flower during our summer, though plants in opposite hemispheres flower in opposite seasons. But in all climates the time of flowering depends also much on the altitude of place, as well as on other causes affecting the degree of heat. Hence plants occupying the polar regions, and plants occupying the tops of the high mountains of southern latitudes, are in flower at the same season; and hence the same flowers are later in opening in North America than in the same latitudes in Europe, because the surface of the earth is higher, or the winters more severe.

1662. *Maturation of the fruit.* Plants exhibit as much diversity in the warmth and length of time necessary to mature their fruit, as in their frondescence and flowering; but the plant that flowers the soonest does not always ripen its fruit the soonest. The hazel tree, which blows in February, does not ripen its fruit till autumn; while the cherry, which does not blow till May, ripens its fruit in June. It may be regarded, however, as the general rule, that if a plant blows in spring, it ripens its fruit in summer, as in the case of the currant and gooseberry; if it blows in summer, it ripens its fruit in autumn, as in the case of the vine; and if it blows in autumn, it ripens its fruit in winter; but the meadow-saffron, which blows in the autumn, does not ripen its fruit till the succeeding spring.

1663. Such are the primary facts on which a *Calendarium Flôræ* should be founded. They have not hitherto been minutely attended to by botanists; and perhaps their importance is not quite so great as has been generally supposed; but they are at any rate sufficiently striking to have attracted the notice even of savages. Some tribes of American Indians act upon the very principle suggested by Linnæus, and plant their corn when the wild plum blooms, or when the leaves of the oak are about as large as a squirrel's ears. The names of some of their months are also designated from the state of vegetation. One is called the budding month, and another the flowering month; one the strawberry month, and another the mulberry month; and the autumn is designated by a term signifying the fall of the leaf. Thus the proposed nomenclature of the French for the months and seasons was founded in nature as well as in reason.

1664. *Cold.* As the elevation of temperature induced by the heat of summer is essential to the full exertion of the energies of the vital principle, so the depression of temperature consequent upon the colds of winter has been thought to suspend the exertion of the vital energies altogether. But this opinion is evidently founded on a mistake, as is proved by the example of those plants which protrude their leaves and flowers in

the winter season only, such as many of the mosses; as well as by the dissection of the yet unfolded buds at different periods of the winter, even in the case of such plants as protrude their leaves and blossoms in the spring and summer, in which, it has been already shown, there is a regular, gradual, and incipient development of parts, from the time of the bud's first appearance till its ultimate opening in the spring. The sap, it is true, flows much less freely, but is not wholly stopped. Du Hamel planted some young trees in the autumn, cutting off all the smaller fibres of the root, with a view to watch the progress of the formation of new ones. At the end of every fortnight he had the plants taken up and examined with all possible care to prevent injuring them, and found that, when it did not actually freeze, new roots were uniformly developed.

1665. *Energies of life in plants like the process of respiration in animals.* Hence it follows, that even during the period of winter, when vegetation seems totally at a stand, the tree being stripped of its foliage, and the herb apparently withering in the frozen blast, still the energies of vital life are exerted; and still the vital principle is at work, carrying on in the interior of the plant, concealed from human view, and sheltered from the piercing frosts, operations necessary to the preservation of vegetable life, or protrusion of future parts; though it requires the returning warmth of spring to give that degree of velocity to the juices which shall render their motion cognizable to man, as well as that expression to the whole plant which is the most evident token of life: in the same manner as the processes of respiration, digestion, and the circulation of the blood are carried on in the animal subject even while asleep; though the most obvious indications of animal life are the motions of the animal when awake. Heat then acts as a powerful stimulus to the operations of the vital principle, accelerating the motion of the sap, and consequent development of parts; as is evident from the sap's beginning to flow much more copiously as the warmth of spring advances, as well as from the possibility of anticipating the natural period of their development by forcing them in a hot-house. But it is known that excessive heat impedes the progress of vegetation as well as excessive cold; both extremes being equally prejudicial. Hence the sap flows more copiously in the spring and autumn than in either the summer or winter; as may readily be seen by watching the progress of the growth of the annual shoot, which, after having been rapidly protruded in the spring, remains for a while stationary during the great heat of the summer, but is again elongated during the more moderate temperature of autumn.

1666. *Artificial stimulants.* There are also several substances which have been found to operate as stimulants to the agency of the vital principle, when artificially dissolved in water, and applied to the root or branch. Oxygenated muriatic acid has been already mentioned: and the vegetation of the bulbs of the hyacinth and narcissus is accelerated by means of the application of a solution of nitre. Dr. Barton of Philadelphia found that a decaying branch of *Liriodendron tulipifera*, and a faded flower of the yellow iris, recovered and continued long fresh when put into water impregnated with camphor; though flowers and branches, in all respects similar, did not recover when put into common water.

1667. *Irritability.* Plants are not only susceptible of the action of the natural stimuli of light and heat, exciting them gradually to the exercise of the functions of their different organs in the regular progress of vegetation; they are susceptible also of the action of a variety of accidental or artificial stimuli, from the application of which they are found to give indications of being endowed also with a property similar to what we call irritability in the animal system. This property is well exemplified in the genus *Mimosa*; particularly in that species known by the name of the *Sensitive Plant*; in the *Dionæa muscipula*, and in the *Drósera*. But sometimes the irritability resides in the flower, and has its seat either in the stamens or style. The former case is exemplified in the flower of the berberry and *Cactus Trina*, and the latter in *Stylidium glandulosum*.

1668. *Sensation.* From the facts adduced in the preceding sections, it is evident that plants are endowed with a capacity of being acted upon by the application of stimuli, whether natural or artificial, indicating the existence of a vital principle, and forming one of the most prominent features of its character. But besides this obvious and acknowledged property, it has been thought by some phytologists that plants are endowed also with a species of *sensation*. Sir J. E. Smith seems rather to hope that the doctrine may be true, than to think it so.

1669. *Instinct.* There are also various phenomena exhibited throughout the extent of the vegetable kingdom, some of which are common to plants in general, and some peculiar to certain species, which have been thought by several botanical writers to exhibit indications, not merely of sensation, but of *instinct*. The tendency of plants to incline their stem and to turn the upper surface of their leaves to the light, the direction which the extreme fibres of the root will often take to reach the best nourishment, the folding up of the flower on the approach of rain, the rising and falling of the water lily, and the peculiar and invariable direction assumed by the twining stem in ascending its prop,

are among the phenomena which have been attributed to instinct. Keith has endeavoured (*Lin. Trans.* xi. p. 11.) to establish the doctrine of the existence and agency of an instinctive principle in the plant, upon the ground of the direction invariably assumed by the radicle and plumet respectively, in the germination of the seed.

1670. *Definition of the plant.* But if vegetables are living beings endowed with sensation and instinct, or any thing approaching to it, so as to give them a resemblance to animals, how are we certainly to distinguish the plant from the animal? At the extremes of the two kingdoms the distinction is easy; the more perfect animals can never be mistaken for plants, nor the more perfect plants for animals; but at the mean, where the two kingdoms may be supposed to unite, the shades of discrimination are so very faint or evanescent that of some individual productions it is almost impossible to say to which of the kingdoms they belong. Hence it is that substances which have at one time been classed among plants, have at another time been classed among animals; and there are substances to be met with whose place has not yet been satisfactorily determined. Of these may be mentioned the genus *Corallina* (*fig.* 199.), which Linnæus placed among

animals, but which Gærtner places among plants. Linnæus, Bonnet, Hedwig, Mirbel, and Link, have each given particular definitions. According to Link, a plant is a compound organic body, deriving nourishment from the soil in which it grows. According to Keitli, a vegetable is an organised and living substance springing from a seed or gem, which it again produces; and effecting the development of its parts by means of the intro-susception and assimilation of unorganised substances which it derives from the atmosphere or the soil in which it grows. The definition of the animal is the counterpart: an animal is an organised and living being proceeding from an egg or embryo, which it again produces, and effecting the development of its parts by means of the intro-susception of organised substances or their products. For all practical purposes, perhaps plants may be distinguished from animals with sufficient accuracy by means of the trial of burning; as animal substances in a state of ignition exhale a strong and phosphoric odour, which vegetable substances do not.

CHAP. V.

Vegetable Pathology, or the Diseases and Casualties of Vegetable Life.

1671. As plants are, like animals, organised and living beings, they are, like animals, also liable to such *accidental injuries and disorders* as may affect the health and vigour, or occasion the death, of the individual. These are wounds, accidents, diseases, and natural decay.

SECT. I. *Wounds and Accidents.*

1672. *A wound* is a forcible separation of the solid parts of the plant effected by means of some external cause, intentional or accidental.

1673. *Incisions* are sometimes necessary to the health of the tree, in the same manner, perhaps, as bleeding is necessary to the health of the animal. The trunks of the plum and cherry tree seldom expand freely till a longitudinal incision has been made in the bark; and hence this operation is often practised by gardeners. If the incision affects the epidermis only, it heals up without leaving any scar; if it penetrates into the interior of the bark, it heals up only by means of leaving a scar; if it penetrates into the wood, the wound in the wood itself never heals up completely, but new wood and bark are formed above it as before.

1674. *Boring* is an operation by which trees are often wounded for the purpose of making them part with their sap in the season of their bleeding, particularly the birch tree and American maple. A horizontal, or rather slanting, hole is bored in them with a wimble, so as to penetrate an inch or two into the wood; from this the sap flows copiously; and though a number of holes are often bored in the same trunk, the health of the tree is not very materially affected. For trees will continue to thrive, though

subjected to this operation for many successive years; and the hole, if not very large, will close up again like the deep incision, not by the union of the broken fibres of the wood, but by the formation of new bark and wood projecting beyond the edge of the orifice, and finally shutting it up altogether.

1675. *Girdling* is an operation to which trees in North America are often subjected, when the farmer wishes to clear his land of timber. It consists in making parallel and horizontal incisions with an axe into the trunk of a tree, and carrying them quite round the stem, so as to penetrate through the *alburnum*, and then to scoop out the intervening portion. If this operation is performed early in the spring, and before the commencement of the bleeding season, the tree rarely survives it; though some trees that are peculiarly tenacious of life, such as *Acer saccharinum* and *Nyssa integrifolia*, have been known to survive it a considerable length of time.

1676. *Fracture*. If a tree is bent so as to fracture part only of the cortical and woody fibres, and the stem or branch but small, the parts will again unite by being put back into their natural position, and well propped up. Especially cure may be expected to succeed if the fracture happens in the spring; but it will not succeed if the fracture is accompanied with contusion, or if the stem or branch is large; and even where it exceeds the woody fibres do not contribute to the union, but the granular and herbaceous substance only, which exudes from between the wood and liber, insinuating itself into all interstices, and finally becoming indurated into wood.

1677. *Pruning*. Wounds are necessarily inflicted by the gardener or forester in pruning or lopping off the superfluous branches; but this is seldom attended with any bad effects to the health of the tree, if done by a skillful practitioner: indeed, no further art is required, merely for the protection of the tree, beyond that of cutting the branch through in a sloping direction, so as to prevent the rain from lodging. In this case the wound soon closes up by the induration of the exposed surface of the section, and by the protrusion of a granular substance, forming a sort of circular lip between the wood and bark; and hence the branch is never elongated by the growth of the same vessels that have been cut, but by the protrusion of new buds near the point of section.

1678. *Grafting*. In the operation of grafting there is a wound both of the stock and graft, which are united, not by the immediate adhesion of the surfaces of the two sections, but by means of a granular and herbaceous substance exuding from between the wood and bark, and insinuating itself as a sort of cement into all open spaces: new wood is finally formed within it, and the union is complete.

1679. *Felling* is the operation of cutting down trees close to the ground, which certain species will survive, if the stump be protected from the injuries of animals, and the root fresh and vigorous. In this case the fibres of the wood are never again regenerated, but a lip is formed as in the case of pruning; and buds, which spring up into new shoots, are protruded near the section; so that from the old shoot, ten, twelve, or even twenty, new stems may issue, according to its size and vigour. The stools of the oak and ash tree will furnish good examples; but there are some trees, such as the pine and fir tribe, which never send out any shoots after the operation of felling. The frankincense pine is said to be an exception; but any specimens we have seen do not incline us to the belief of such an anomaly.

1680. *If buds are destroyed* in the course of the winter, or in the early part of the spring, many plants will again generate new buds, which will develop their parts as the others would have done, except that they never contain blossom or fruit. Du Hamel thought these buds sprang from preorganised germs, which he conceived to be dispersed throughout the whole of the plant; but Knight thinks he has discovered the true source of the regeneration of buds, in the proper juice that is lodged in the albumen. Buds thus regenerated never contain or produce either flower or fruit; perhaps because the fruit-bud requires more time to develop its parts, or a peculiar and higher degree of elaboration; and that this hasty production is only the effect of a great effort of the vital principle for the preservation of the individual, and one of those wonderful resources to which nature always knows how to resort when the vital principle is in danger. But though such buds do not produce flowers directly, as in the case of plants which bear their blossoms on last year's wood; yet they often produce young shoots which produce blossoms and fruit the same season, as in the case of cutting down an old vine or pruning the rose.

1681. Sometimes the leaves of a tree are destroyed partially or totally as soon as they are protruded from the bud, whether by the depredations of caterpillars or other insects, or by the browsing of cattle. But if the injury is done early in the spring, new leaves will be again protruded without subsequent shoots. Some trees will bear to be stripped even more than once in a season, as is the case with the mulberry tree, which is cultivated in the south of France and Italy for the purpose of feeding the silkworm; but if it be stripped more than once in a season, it requires now and then a year's rest.

1682. *The decortication* of a tree, or the stripping it of its bark, may be either intentional or accidental, partial or total. If it is partial, and affects the epidermis only, then it is again regenerated, as in the case of slight incision, without leaving any scar. But if the epidermis of the petal, leaf, or fruit is destroyed, it is not again regenerated, nor is the wound healed up, except by means of a scar. Such is the case also with all decortications that penetrate deeper than the epidermis, particularly if the wound is not protected from the action of the air. If the decortication reaches to the wood, then new bark issues from between the bark and wood, and spreads till it covers the wound. But the result is not the same when the wound is covered from the air. In the season of the flowing of the sap Du Hamel detached a ring of bark of three or four inches in breadth, from the trunks of several young elm trees, taking care to defend the decorticated part from the action of the air, by surrounding it with a tube of glass cemented above and below to the trunk. After a few days the tubes became cloudy within, particularly when it was hot; but when the air became cool, the cloud condensed and fell in drops to the bottom. At last there began to appear, as if exuding from between the bark and wood of the upper part of the wound, a sort of rough scurfy substance; and on the surface of the wood, as if exuding from between the longitudinal fibres of the albumen, a number of gelatinous drops. They were not connected with the scurfy substance at the top, but seemed to arise from small slips of the liber that had not been completely detached. Their first appearance was that of small reddish spots changing by degrees into white, and finally into a sort of grey, and extending in size till they at last united and formed longitudinal ridges, which constituted a new bark.

1683. *Abortion or failure in the produce of flowers, fruits, or of perfect seeds*, is generally the effect of accidental injuries, either directly to the flower or fruit, by which they are rubbed off or devoured by insects; or to the leaves by insects; or to the roots by exposure to the air or cutting off so much of them as essentially to lessen their power of drawing up nourishment. Other causes will readily suggest themselves; and one of the commonest, as to seeds and fruits, is want of sufficient impregnation.

1684. *Premature flowering or fruiting* is sometimes brought on by insects, but more generally by checks produced by cold, or injuries from excessive heat, or long-continued drought. Fruit is often ripened prematurely by the puncture of insects; and a pine-apple plant of almost any age may be thrown into fruit by an hour or two's exposure to a frosty atmosphere in winter, or by scorching the roots in an overhot tan-bed at any season.

SECT. II. Diseases.

1685. *Diseases* are corrupt affections of the vegetable body, arising from a vitiated state of its juices, and tending to injure the habitual health either of the whole or part of the plant. The diseases which occur the most frequently among vegetables are the following: — Blight, smut, mildew, honey-dew, dropsy, flux of juices, gangrene, etiolation, suffocation, contortion, consumption.

1686. *Blight*. Much has been written on the nature of blight; and in proportion as words have been multiplied on the subject, the difficulties attending its elucidation have increased.

1687. *The blight, or blast*, was well known to the ancient Greeks, who were, however, totally ignorant of its cause, regarding it merely as a blast from heaven, indicating the wrath of their offended deities, and utterly incapable of prevention or cure. It was known also to the Romans under the denomination of *rubigo*, who regarded it in the same light as the Greeks, and even believed it to be under the direction of a particular deity, Rubigus, whom they solemnly invoked that blight might be kept from corn and trees. It is still well known from its effects to every one having the least knowledge of husbandry or gardening; but it has been very differently accounted for: and, perhaps, there is no one cause that will account for all the different cases of blight, or disease going by the name of blight; though they have been supposed to have all the same origin. If we take the term in its most general acceptation, it will include at least four distinct species,—blight originating in cold and frosty winds; blight originating in a sort of sultry and pestilential vapour; blight originating from want of nourishment; and blight originating in the immoderate propagation of a sort of small and parasitical fungus.

1688. *Blight originating in cold and frosty winds*, is often occasioned by the cold and easterly winds of spring, which nip and destroy the tender shoots of the plant, by stopping the current of the juices. The leaves which are thus deprived of their due nourishment wither and fall, and the juices which are now stopped in their passage swell and burst the vessels, and become the food of innumerable little insects which soon after make their appearance. Hence they are often mistaken for the cause of the disease itself; the farmer supposing they are wafted to him on the east wind, while they are only generated in the extravasated juices as forming a proper nidus for their eggs. Their multiplication will no doubt contribute to the spread of the disorder, as they always breed fast where they find plenty of food. But a similar disease is often occasioned by the early frost of spring. If the weather is prematurely mild, the blossom is prematurely protruded, which, though it is viewed by the unexperienced with delight, yet it is viewed by the judicious with fear. For it very often happens that this premature blossom is totally destroyed by subsequent frosts, as well as both the leaves and shoots, which consequently wither and fall, and injure if they do not actually kill the plant. This evil is also often augmented by the unskilful gardener, even in attempting to prevent it; that is, by matting up his trees too closely, or by keeping them covered in the course of the day, and thus rendering the shoots so tender that they can scarcely fall to be destroyed by the next frost.

1689. *Blight, originating in sultry and pestilential vapour*, generally happens in the summer, when the grain has attained to its full growth, and when there are no cold winds or frosts to occasion it. Such was the blight that used to damage the vineyards of ancient Italy, and which is yet found to damage our hop-plantations and wheat-crops. The Romans observed that it generally happened after short but heavy showers occurring about noon, and followed by clear sunshine, about the season of the ripening of the grapes, and that the middle of the vineyard suffered the most. This corresponds pretty nearly to what is in this country called the fire-blast among hops, which has been observed to take place most commonly about the end of July, when there has been rain with a hot gleam of sunshine immediately after; the middle of the hop-ground is also the most affected, whether the blight is general or partial, and is almost always the point in which it originates. In a particular case which was minutely observed, the damage happened a little before noon, and the blight ran in a line forming a right angle with the sunbeams at that time of the day. There was but little wind, which was, however, in the line of the blight. (*Hale's Body of Husbandry*.) Wheat is also affected with a similar sort of blight, and about the same season of the year, which totally destroys the crop. In the summer of 1809, a field of wheat, on rather a light and sandy soil, came up with every appearance of health, and also into ear with a fair prospect of ripening well. About the beginning of July it was considered as exceeding any thing expected from such a soil. A week afterwards a portion of the crop on the east side of the field, to the extent of several acres, was totally destroyed; being shrunk and shrivelled up to less than one half the size of what it had formerly been, and so withered and blasted as not to appear to belong to the same field. The rest of the field produced a fair crop.

1690. *Blight from want of nourishment* may happen to all plants, wild or cultivated; but it is most commonly met with in corn fields, in very dry seasons, in those thin gravelly surfaces which do not sufficiently retain the moisture. In such spots the plants are thrown prematurely into blossom, and the ear or seed-pod ripens before it is filled. In England the farmers call this the white blight.

1691. *Blight, originating in Fungus*, attacks the leaves or stems both of herbaceous and woody plants, such as *Euphorbia Cyparissias*, *Berberis vulgaris*, and *Zhannus catharticus*; but more generally grasses, and particularly our most useful grains, wheat, barley, and oats. It always appears in the least ventilated parts of a field, and has generally been preceded by cold, moist weather, which, happening in the warm month of July, suddenly chills and checks vegetation. It generally assumes the appearance of a rusty-looking powder, that soils the finger when touched. In March, 1807, some blades of wheat attacked with this species of blight were examined by Keith; the appearance was that of a number of rusty-looking spots or patches dispersed over the surface of the leaf, exactly like that of the seeds of dorsiferous ferns bursting their indusium. Upon more minute inspection, these patches were found to consist of thousands of small globules collected into groups beneath the epidermis, which they raised up in a sort of blister, and at last burst. Some of the globules seemed as if embedded even in the longitudinal vessels of the blade. They were of a yellowish or rusty brown, and somewhat transparent. But these groups of globules have been ascertained by Sir J. Banks to be patches of a minute fungus, the seeds of which, as they float in the air, enter the pores of the epidermis of the leaf, particularly if the plant is sickly; or they exist in the manure or soil, and enter by the pores of the root. (*Sir J. Banks on Blight*, 1805.) This fungus has been figured by Sowerby, and by F. Bauer and Grew. It is known among farmers by the name of red rust, and chiefly affects the stalks and leaves. But there is another species of fungus known to the farmer by the name of red gum, which attacks the ear only, and is extremely prejudicial. In the aggregate it consists of groups of minute globules interspersed with transparent fibres. The globules are filled with a fine powder, which explodes when they are put into water. It is very generally accompanied with a maggot of a yellow colour, which preys also upon the grain, and increases the amount of injury.

1692. The only means of preventing or lessening the effect of any of the different varieties of blight mentioned is proper culture. Palliatives are to be found in topical applications, such as flower of sulphur, and where the disease proceeds from, or consists of, innumerable minute insects, it may occasionally be removed. Grisebawite conjectures that in many cases in which the blight and mildew attack corn-crops, it may be for want of the peculiar food requisite for perfecting the grain; it being known that the fruit or seeds of many plants contain primitive principles not found in the rest of the plant. Thus the grain of wheat contains gluten and phosphate of lime, and where these are wanting in the soil, that is, in the manured earths in which the plant grows, it will be unable to perfect its fruit, which of consequence becomes more liable to disease. (*New Theory of Agr.*)

1693. *Smut* is a disease incidental to cultivated corn, by which the farina of the grain, together with its proper integuments and even part of the husk, is converted into a black soot-like powder. If the injured ear be struck with the finger, the powder will be dispersed like a cloud of black smoke; and if a portion of the powder be wetted by a

drop of water and put under the microscope, it will be found to consist of millions of minute and transparent globules, which seem to be composed of a clear and glairy fluid encompassed by a thin and skinny membrane. This disease does not affect the whole body of the crop, but the smutted ears are sometimes very numerous dispersed throughout it. Some have attributed it to the soil in which the grain is sown, and others have attributed it to the seed itself, alleging that smutted seed will produce a smutted crop; but in all this there seems to be a great deal of doubt. Willdenow regards it as originating in a small fungus, which multiplies and extends till it occupies the whole ear (*Princip. of Bot.* p. 556.): but F. Bauer of Kew seems to have ascertained it to be merely a morbid swelling of the ear, and not at all connected with the growth of a fungus. (*Smith's Introd.* p. 282.) It is said to be prevented by steeping the grain, before sowing, in a weak solution of arsenic. But, besides the disease called smut, there is also a disease analogous to it, or a different stage of the same disease, known to the farmer by the name of bags or smut balls, in which the nucleus of the seed only is converted into a black powder, whilst the ovary, as well as the husk, remains sound. The ear is not much altered in its external appearance, and the diseased grain contained in it will even bear the operation of threshing, and consequently mingle with the bulk: but it is always readily detected by the experienced buyer, and fatal to the character of the sample. It is said to be prevented as in the case of smut.

1694. *Mildew* is a thin and whitish coating with which the leaves of vegetables are sometimes covered, occasioning their decay and death, and injuring the health of the plant. It is frequently found on the leaves of *Tussilago Färfara*, *Hümulus Lupulus*, *Córylus avellána*, and the white and yellow dead-nettle. It is found also on wheat in the shape of a glutinous exudation, particularly when the days are hot and the nights without dew. J. Robertson (*Hort. Trans.* v. 178.) considers it as a minute fungus of which different species attack different plants. Sulphur he has found to be a specific cure. In cultivated crops mildew is said to be prevented by manuring with soot; though by some this is denied, and soot, by rendering the crop more luxuriant, is said to be an encourager of mildew, the richest parts of a field being always most infected by it. As it is least common in airy situations, thinning and ventilation may be considered as preventives.

1695. *Honey-dew* is a sweet and clammy substance which coagulates on the surface of the leaves during hot weather, particularly on the leaves of the oak tree and beech, and is regarded by Curtis as being merely the dung of some species of aphides. This seems to be the opinion of Willdenow also, and it is no doubt possible that it may be the case in some instances or species of the disease: but Sir J. E. Smith contends that it is not always so, or that there are more species of honey-dew than one, regarding it particularly as being an exudation, at least in the case of the beech, whose leaves are, in consequence of an unfavourable wind, apt to become covered with a sweet sort of glutinous coating, similar in flavour to the fluid obtained from the trunk.

1696. It is certain, however, that *saccharine exudations are found on the leaves of many plants*, though not always distinguished by the name of honey-dew; which should not perhaps be applied except when the exudation occasions disease. But if it is to be applied to all saccharine exudations whatever, then we must include under the appellation of honey-dew, the saccharine exudations observed on the orange tree by De la Hire, together with that of the lime tree which is more glutinous, and of the poplar which is more resinous; as also that of the *Cistus créticus*, and of the manna which exudes from the ash tree of Italy and larch of France. It is also possible that the exudation or excrement constituting honey-dew may occasionally occur without producing disease; for if it should happen to be washed off soon after by rains or heavy dews, then the leaves will not suffer. Washing is therefore the palliative; judicious culture the preventive.

1697. *Dropsy*. Plants are also liable to a disease which affects them in a manner similar to that of the dropsy in animals, arising from long-continued rain or too abundant watering. Willdenow describes it as occasioning a preternatural swelling of particular parts, and inducing putrefaction. It is said to take place chiefly in bulbous and tuberous roots, which are often found much swelled after rain. It affects fruit also, which it renders watery and insipid. It prevents the ripening of seeds, and occasions an immoderate production of roots from the stem.

1698. *In succulent plants* this disease generally appears in consequence of excessive waterings, and is for the most part incurable. The leaves drop, even though plump and green; and the fruit rots before reaching maturity. In this case the absorption seems to be too great in proportion to the transpiration; but the soil when too much manured produces similar effects. Du Hamel planted some elms in a soil that was particularly well manured, and accordingly they pushed with great vigour for some time; but at the end of five or six years they all died suddenly. The bark was found to be detached from the wood, and the cavity filled up with a reddish-coloured water. The symptoms of this disease suggest the palliatives; and the preventive is ever the same — judicious culture.

1699. *Flux of juices*. Some trees, but particularly the oak and birch, are liable to a great loss of sap, which bursts out spontaneously, owing to its superabundance, or issues from accidental wounds: sometimes it is injurious to the health of the plant, and sometimes not.

1700. There is a *spontaneous extravasation* of the sap of the vine, known by the name of the tears of the vine, which is not always injurious. As it often happens that the root imbibes sap, which the leaves are not yet prepared to throw off, because not yet sufficiently expanded, owing to an inclement season, the

sap which is first carried up, being propelled by that which follows, ultimately forces its way through all obstructions, and exudes from the bud. But this is observed only in cold climates; for in hot climates, where the development of the leaves is not obstructed by cold, they are ready to elaborate the sap as soon as it reaches them. There is also a spontaneous extravasation of proper juice in some trees, which does not seem in general to be injurious to the individual. Thus the gum which exudes from cherry, plum, peach, and almond trees is seldom detrimental to their health, except when it insinuates itself into the other vessels of the plant and occasions obstructions.

1701. *But the exudation of gum is sometimes a disease, and one for which there is seldom any remedy. It is generally the consequence of an unsuitable soil, situation, or climate. Cold raw summers will produce it in the peach, apricot, and more tender sorts of plum and cherry; or grafting these fruits on diseased stocks. Cutting out the part and applying a covering of loam, or tar and charcoal, to exclude the air, are palliatives; but the only effectual method, where it can be practised, is to take up the tree and place it in a suitable soil and situation.*

1702. *The extravasation and corruption of the ascending or descending juices, have been known to occasion a fissure of the solid parts. Sometimes the fissure is occasioned by means of frost, and forms what is called a double albumum; that is, first a layer that has been injured by the frost, and then a layer that passes into wood. Sometimes a layer is partially affected, and that is generally owing to a sudden and partial thaw on the south side of the trunk, which may be followed again by a sudden frost. In this case the albumum is split into clefts or chinks, by means of the expansion of the frozen sap.*

1703. *Chilblains.* But clefts thus occasioned often degenerate into chilblains which discharge a blackish and acrid fluid, to the great detriment of the plant, particularly if the sores are so situated that rain or snow will readily lodge in them and become putrid. The same injury may be occasioned by the bite or puncture of insects while the shoot is yet tender; and as no vegetable ulcer heals up of its own accord, the sooner a cure is attempted the better, as it will, if left to itself, ultimately corrode and destroy the whole plant, bark, wood, and pith. The only palliative is the excision of the part affected, and the application of a coat of grafting wax. (*Willdenow, p. 354.*)

1704. *Gangrene.* Of this disorder there are two varieties, the dry and the wet. The former is occasioned by means of excessive heat or excessive cold. If by means of cold, it attacks the leaves of young shoots, and causes them to shrink up, converting them from green to black; as also the inner bark, which it blackens in the same manner, so that it is impossible to save the plant except by cutting it to the ground. If by means of heat, the effects are nearly similar, as may oftentimes be seen in gardens, or even in forests, where the foresters are allowed to clear away the moss and withered leaves from the roots. Sometimes the disease is occasioned by the too rapid growth of a particular branch, depriving the one that is next it of its due nourishment, and hence inducing its decay. Sometimes it is occasioned by means of parasitical plants, as in the case of the bulbs of the saffron, which a species of *Lycopèdon* often attaches itself to and totally corrupts.

1705. *Dry gangrene.* The harmattan winds of the coast of Africa kill many plants, by means of inducing a sort of gangrene which withers and blackens the leaves, and finally destroys the whole plant. The nopal of Mexico is also subject to a sort of gangrene which begins with a black spot, and extends till the whole leaf or branch rots off, or the plant dies. But plants are sometimes affected with a gangrene by which a part becomes first soft and moist, and then dissolves into foul ichor. This is confined chiefly to the leaves, flowers, and fruit. Sometimes it attacks the roots also, but rarely the stem. It seems to be owing, in many cases, to too wet or too rich a soil; but it may originate in contusion, and may be caught by infection. But the nopal is subject also to a disease called by *Thierry la dissolution*, considered by Sir J. E. Smith, as distinct from gangrene, and which appears to be *Willdenow's dry gangrene*. A joint of the nopal, or a whole branch, and sometimes an entire plant, changes in the space of a single hour from a state of apparent health to a state of putrefaction or dissolution. Now its surface is verdant and shining, and in an instant it changes to a yellow, and its brilliancy is gone. If the substance is cut into, the parts are found to have lost all cohesion, and are quite rotten. The attempt at a cure is by speedy amputation below the diseased part. Sometimes the vital principle, collecting and exerting all its energies, makes a stand as it were against the encroaching disease, and throws off the infected part. (*Smith's Introduction, p. 276, edit. 6.*)

1706. *Etiolation.* Plants are sometimes affected by a disease which entirely destroys their verdure, and renders them pale and sickly. This is called *etiolation*, and may arise merely from want of the agency of light, by which the extrication of oxygen is effected, and the leaf rendered green. Hence it is that plants placed in dark rooms, or between great masses of stone, or in the clefts of rocks, or under the shade of other trees, look always peculiarly pale. But if they are removed from such situations, and exposed to the action of light, they will again recover their green colour. Etiolation may also ensue from the depredations of insects nestling in the radicle, and consuming the food of the plant, thus debilitating the vessels of the leaf so as to render them insusceptible of the action of light. This is said to be often the case with the radicles of *Secale cereale*; and the same result may also arise from poverty of soil.

1707. *Suffocation.* Sometimes it happens that the pores of the epidermis are closed up, and transpiration consequently obstructed, by means of some extraneous substance which attaches itself to, and covers, the bark. This obstruction induces disease, and the disease is called *suffocation*.

1708. Sometimes it is occasioned by the *immoderate growth of lichens* upon the bark, covering the whole of the plant, as may be often seen in fruit trees, which it is necessary to keep clean by means of scraping off the lichens, at least from the smaller branches. For if the young branches are thus coated, so as that the bark cannot perform its proper functions, the tree will soon begin to languish, and will finally become covered with fungi, inducing or resulting from decay, till it is at last wholly choked up.

1709. But a similar effect is also occasionally produced by *insects*, in feeding upon the sap or shoot. This may be exemplified in the case of the aphides, which sometimes breed or settle upon the tender shoot in such multitudes as to cover it from the action of the external air altogether. It may be exemplified also in the case of *Coccus hesperidum* and *A'carus telarius*, insects which infest hot-house plants, the latter by spinning a fine and delicate web over the leaf, and thus preventing the access of atmospheric air. Insects are to be removed either by the hand or other mechanical means, or destroyed by excess of some of the elements of their nutrition, as heat, cold, or moisture, where such excess does not prove injurious to the plant; or by a composition, either fluid or otherwise, which shall have the same effects. Prevention is

to be attempted by general culture, and particular attention to hinder the propagation of the insects or vermin, whether oviparous or otherwise, by destroying their embryo progeny.

1710. Sometimes the disease is occasioned by an *extravasation of juices* which coagulate on the surface of the stalk, so as to form a sort of crust, investing it as a sheath, and preventing its farther expansion.

1711. Sometimes the disease arises from *want of an adequate supply of nourishment* as derived from the soil, in which case the lower part of the plant is the best supplied, while the upper part of it is starved. Hence the top shoots decrease in size every succeeding year, because a sufficient supply of sap cannot be obtained to give them their proper development. This is analogous to the phenomena of animal life, when the action of the heart is too feeble to propel the blood through the whole of the system: for then the extremities are always the first to suffer. And perhaps it may account also for the fact, that in bad soils, and unfavourable seasons, when the ear of barley is not wholly perfected, yet a few of the lower grains are always completely developed. (*Smith's Introduction*, p. 278.)

1712. *Contortion.* The leaves of plants are often injured by means of the puncture of insects, so as to induce a sort of disease which discovers itself in the contortion or convolution of the margin, or wrinkled appearance of the surface. The leaves of the apricot, peach, and nectarine, are extremely liable to be thus affected in the months of June and July. The leaves of the apple are affected by the *Aphis lanigera*; those of the larch by another woolly aphid (*A. laricio*); those of the hawthorn by a species of *Tenthredo*, &c. (*See Major's Treatise on the Insects prevalent in Fruit Trees and Garden Produce.*)

1713. The leaf which has been punctured soon begins to assume a rough and wrinkled figure, and a reddish and scrofulous appearance, particularly on the upper surface. The margins roll inwards on the under side, and enclose the eggs which are scattered irregularly on the surface, giving it a blackish and granular appearance, but without materially injuring its health. In the vine, the substance deposited on the leaf is whitish, giving the under surface a sort of frosted appearance, but not occasioning the red and scrofulous aspect of the upper surface of the leaf of the nectarine. In the poplar, the eggs when first deposited resemble a number of small and hoary vesicles containing a sort of clear and colourless fluid. The leaf then becomes retracted and conduced, enclosing the eggs, and exhibiting a few reddish protuberances on the upper surface. The embryo is nourished by this fluid; and the hoariness is converted into a fine cottony down, which for some time envelopes the young fly. The leaf of the lime tree in particular, when fully expanded, is liable to attacks from insects; and hence the gnawed appearance it so often displays. The injury seems to be occasioned by some species of puceron depositing its eggs in the parenchyma, generally about the angles that branch off from the midrib. A sort of down is produced, at first green, and afterwards hoary; sometimes in patches, and sometimes pervading the whole leaf; as in the case of the vine. Under this covering the egg is hatched; and then the young insect gnaws and injures the leaf, leaving a hole or scar of a burnt or singed appearance. Sometimes the upper surface of the leaf is covered with clusters of wart-like substances somewhat subulate and acute. They seem to be occasioned by means of punctures made in the under surface, on which a number of openings are discoverable, penetrating into the warts, which are hollow and villous within. The disease admits of palliation by watering frequently over the leaves; and by removing such as are the most contorted and covered by larvæ.

1714. *Consumption.* From barren or improper soil, unfavourable climes, careless planting, or exhaustion from too frequent flowering, it often happens that disease is induced which terminates in a gradual decline and wasting away of the plant, till at length it is wholly dried up. Sometimes it is also occasioned by excessive drought, or by dust lodging on the leaves, or by fumes issuing from neighbouring manufactories, or by the attacks of insects.

1715. There is a *consumptive affection* frequently attacking the pine tree (*Willdenow, Prine. Bot. p. 351.*), which affects the albumen and inner bark chiefly, and seems to proceed from long-continued drought, or from frost suddenly succeeding mild or warm weather, or from heavy winds. The leaves assume a tinge of yellow, bordering upon red. A great number of small drops of resin, of a putrid odour, exude from the middle of the boughs. The bark exfoliates, and the albumen presents a livid appearance; the tree swarms with insects (*Dypterigia pinâstri Steph.*), and the disease is incurable, inducing inevitably the total decay and death of the individual. The preventive is obviously good culture, so as to maintain vigorous health: palliatives may be employed, according to the apparent cause of the disease.

SECT. III. *Natural Decay.*

1716. Although a plant should not suffer from the influence of accidental injury, or from disease, still there will come a time when its several organs will begin to experience the approaches of a *natural decline* insensibly stealing upon it, and at last inducing death. The duration of vegetable existence is very different in different species. Yet in the vegetable, as well as in the animal kingdom, there is a term or limit set, beyond which the individual cannot pass. Some plants are annuals, and last for one season only, springing up suddenly from seed, attaining rapidly to maturity, producing and sowing their seeds, and afterwards immediately perishing. Such is the character of the various species of corn, as exemplified in oats, wheat, and barley. Some plants continue to live for a period of two years, and are therefore called biennials, springing up the first year from seed, and producing roots and leaves, but no fruit; and in the second year producing both flower and fruit, as exemplified in the carrot, parsnep, and caraway. Other plants are perennials, that is, lasting for many years; of which some are called under-shrubs, and die down to the root every year; others are called shrubs, and are permanent both by the root and stem, but do not attain to a great height or great age; others are called trees, and are not only permanent by both root and stem, but attain to a great size, and live to a great age. But even of plants that are woody and perennial, there are parts which perish annually, or which are at least annually separated from the individual; namely, the leaves, flowers, and fruit, leaving nothing behind but the bare caudex, which submits in its turn to the ravages of time, and ultimately to death.

1717. *The decay of the temporary organs*, which takes place annually, is a phenomenon

familiar to every body, and comprehends the fall of the leaf, the fall of the flower, and the fall of the fruit.

1718. *The fall of the leaf*, or annual defoliation of the plant, commences for the most part with the colds of autumn, and is accelerated by the frosts of winter, which strip the forest of its foliage, and the landscape of its verdure. But there are some trees which retain their leaves throughout the whole of the winter, though changed to a dull and dusky brown, and may be called *ever-clothed trees*, as the beech; and there are others which retain their verdure throughout the year, and are denominated evergreens, as the holly. The leaves of both sorts ultimately fall in the spring. Sir J. E. Smith considers that leaves are thrown off by a process similar to that of the sloughing of diseased parts in the animal economy; and Keith observes, that if it is necessary to illustrate the fall of the leaf by any analogous process in the animal economy, it may be compared to the shedding of the antlers of the stag, or of the hair of beasts or feathers of birds, which being, like the leaves of plants, distinct and peculiar organs, fall off, and are regenerated annually, but do not slough. According to Professor Vancher every leaf consists of a distinct system of fibres, having only a temporary continuity with the shoot, kept up by an adhesive substance, probably formed by a portion of the parenchyma interposed between the two systems of fibres. While this parenchyma is under the influence of vegetable action the adhesion is maintained; when this action ceases the union is dissolved and the leaf falls.

1719. *The flowers*, which, like the leaves, are only temporary organs, are for the most part very short-lived; for as the object of their production is merely to effect the impregnation of the germs, that object is no sooner attained than they begin to give indications of decay, and speedily fall from the plant; so that the most beautiful part of the vegetable is also the most transient.

1720. *The fruit*, which begins to appear conspicuous when the flower falls, expands and increases in volume, and, assuming a peculiar hue as it ripens, ultimately detaches itself from the parent plant, and drops into the soil. But it does not in all cases detach itself in the same manner: thus, in the bean and pea the seed-vessel opens and lets the seeds fall out, while in the apple, pear, and cherry, the fruit falls entire, enclosing the seed, which escapes when the pericarp decays. Most fruits fall soon after ripening, as the cherry and apricot; but some remain long attached to the parent plant after being fully ripe, as in the case of the fruit of *Eubonymus* and *Mespilus*. But these, as well as all others, though tenacious of their hold, detach themselves at last, and bury themselves in the soil, to give birth to a new individual in the germination of the seed. The fall of the flower and fruit is accounted for in the same manner as that of the leaf.

1721. *Decay of the permanent organs*. Such, then, is the process and presumptive rationale of the decay and detachment of the temporary organs of the plant. But there is also a period beyond which even the permanent organs themselves can no longer carry on the process of vegetation. Plants are affected by the infirmities of old age as well as animals, and are found to exhibit also similar symptoms of approaching dissolution. The root refuses to imbibe the nourishment afforded by the soil, or if it does imbibe a portion, it is but feebly propelled, and partially distributed, through the tubes of the albumen; the elaboration of the sap is now effected with difficulty as well as the assimilation of the proper juice, the descent of which is almost totally obstructed; the bark becomes thick and woody, and covered with moss or lichens; the shoot becomes stunted and diminutive; and the fruits palpably degenerate, both in quantity and quality. The smaller or terminal branches fade and decay the first, and then the larger branches also, together with the trunk and root; the vital principle gradually declines without any chance of recovery, and is at last totally extinguished. "When life is extinguished, nature hastens the decomposition; the surface of the tree is overrun with lichens and mosses, which attract and retain the moisture; the empty pores imbibe it; and putrefaction speedily follows. Then come the tribes of fungi, which flourish on decaying wood, and accelerate its corruption; beetles and caterpillars take up their abode under the bark, and bore innumerable holes in the timber; and woodpeckers in search of insects pierce it more deeply, and excavate large hollows, in which they place their nests. Frost, rain, and heat assist, and the whole mass crumbles away, and dissolves into a rich mould." (*Dial. on Bot.* p. 365.)

CHAP. VI.

Vegetable Geography and History, or the Distribution of Vegetables relatively to the Earth and to Man.

1722. *The science of the distribution of plants*, Humboldt observes (*Essai sur la Géographie des Plantes*, 1807), considers vegetables in relation to their local associations in different climates. It points out the grand features of the immense extent which plants occupy, from the regions of perpetual snow to the bottom of the ocean, and to the interior of the globe, where, in obscure grottoes, cryptogamous plants vegetate, as unknown as the insects which they nourish. The superior limits of vegetation are known, but not the inferior; for every where in the bowels of the earth are germs which develop themselves when they find a space and nourishment suitable for vegetation. On taking a general view of the disposition of vegetables on the surface of the globe, independently of the influence of man, that disposition appears to be determined by two sorts of causes, *geographical* and *physical*. The influence of man, or of cultivation, has introduced a third cause, which may be called *civil*. The different aspects of plants, in different regions, have given rise to what may be called their *characteristic* or *picturesque distribution*; and the subject of distribution may be also considered relatively to the *systematic* divisions of vegetables, their *arithmetical* proportions, and *economical* applications.

SECT. I. *Geographical Distribution of Vegetables.*

1723. *The territorial limits to vegetation* are determined in general by three causes : — 1. By sandy deserts, which seeds cannot pass over either by means of winds or birds, as that of Sahara, in Africa ; 2. By seas too vast for the seeds of plants to be drifted from one shore to the other, as in the ocean ; while the Mediterranean sea, on the contrary, exhibits the same vegetation on both shores ; and, 3. By long and lofty chains of mountains. To these causes are to be attributed the fact that similar climates and soils do not always produce similar plants. Thus in certain parts of North America, which altogether resemble Europe in respect to soil, climate, and elevation, not a single European plant is to be found. The same remark will apply to New Holland, the Cape of Good Hope, Senegal, and other countries, as compared with countries in similar physical circumstances, but geographically different. The separation of Africa and South America, Humboldt considers, must have taken place before the development of organised beings, since scarcely a single plant of the one country is to be found in a wild state in the other.

SECT. II. *Physical Distribution of Vegetables.*

1724. *The natural circumstances* affecting the distribution of plants may be considered in respect to temperature, elevation, moisture, soil, and light.

1725. *Temperature* has the most obvious influence on vegetation. Every one knows that the plants of hot countries cannot in general live in such as are cold, and the contrary. The wheat and barley of Europe will not grow within the tropics. The same remark applies to plants of still higher latitudes, such as those within the polar circles, which cannot be made to vegetate in more southern latitudes ; nor can the plants of more southern latitudes be made to vegetate there. In this respect, not only the medium temperature of a country ought to be studied, but the temperature of different seasons, and especially of winter. Countries where it never freezes, those where it never freezes so strongly as to stagnate the sap in the stems of plants, and those where it freezes with strength sufficient to penetrate into the cellular tissue, form three classes of regions in which vegetation ought to differ. But this difference is somewhat modified by the effect of vegetable structure, which resists, in different degrees, the action of frost. Thus, in general, trees which lose their leaves during winter resist the cold better than such as retain them ; resinous trees, more easily than such as are not so ; herbs of which the shoots are annual and the root perennial, better than those where the stems and leaves are persisting ; annuals which flower early, and whose seeds drop and germinate before winter, resist cold less easily than such as flower late, and whose seeds lie dormant in the soil till spring. Monocotyledonous trees, which have generally persisting leaves and a trunk without bark, as in palms, are less adapted to resist cold than dicotyledonous trees, which are more favourably organised for this purpose, not only by the nature of their proper juice, but by the disposition of the cortical and alburnous layers, and the habitual carbonisation of the outer bark. Plants of a dry nature resist cold better than such as are watery ; all plants resist cold better in dry winters than in moist winters ; and an attack of frost always does most injury in a moist country, in a humid season, or when the plant is too copiously supplied with water.

1726. Some plants of firm texture, but *natives of warm climates, will endure a frost of a few hours' continuance*, as the orange at Genoa, (*Humboldt, De Distributione Plantarum*) ; and the same thing is said of the palm and pine-apple, facts most important for the gardener. Plants of delicate texture, and natives of warm climates, are destroyed by the slightest attack of frost, as the *Phaseolus*, *Nasturtium*, &c.

1727. *The temperature of spring* has a material influence on the life of vegetables ; the injurious effects of late frosts are known to every cultivator. In general, vegetation is favoured in cold countries by exposing plants to the direct influence of the sun ; but this excitement is injurious in a country subject to frosts late in the season ; in such cases, it is better to retard than to accelerate vegetation.

1728. *The temperature of summer*, as it varies only by the intensity of heat, is not productive of so many injurious accidents as that of spring. Very hot dry summers, however, destroy many delicate plants, and especially those of cold climates. A very early summer is injurious to the germination and progress of seeds ; a short summer, to their ripening, and the contrary.

1729. *Autumn* is an important season for vegetation, as it respects the ripening of seeds ; hence where that season is cold and humid, annual plants, which naturally flower late, are never abundant, as in the polar regions ; the effect is less injurious to perennial plants, which generally flower earlier. Frosts early in autumn are as injurious as those which happen late in spring. The conclusion, from these considerations, obviously is, that temperate climates are more favourable to vegetation than such as are either extremely cold or extremely hot ; but the warmer climates, as Keith observes, are more favourable,

upon the whole, to vegetation than the colder, and that nearly in proportion to their distance from the equator. The same plants, however, will grow in the same degree of latitude, throughout all degrees of longitude, and also in correspondent latitudes on different sides of the equator; the same species of plants, as some of the palms and others, being found in Japan, India, Arabia, the West Indies, and part of South America, which are all in nearly the same latitudes; and the same species being also found in Kamschatka, Germany, Great Britain, and the coast of Labrador, which are all also in nearly the same latitudes. (*Willdenow, p. 374.*)

1730. *Rules for determining the temperature of a country.* "The fact that a degree of latitude is equal to a degree of Fahrenheit, and that 400 feet of elevation is equal also to a degree of Fahrenheit, is original and curious, and will go far to assist us in determining the climate of any country." (*Amer. Quart. Rev. March, 1829. p. 174.*)

1731. *The most remarkable circumstances respecting the temperature in the three zones* are exhibited in the following Table by Humboldt. The temperature is taken according to the centigrade thermometer. The fathom is 6 French feet, or 6·39453 English feet.

	Torrid zone.		Temperate zone.			Frigid zone.
	Andes of Quito, Lat. 0°.	Mountains of Mexico, Lat. 20°	Caucasus, Lat. 42°½.	Pyrenees, Lat. 42½°.	Alps, Lac. 45½° to 46°	Lapland, Lat. 67° to 70°.
Inferior limit of perpetual snow - - }	2460 fa.	2350 fa.	1650 fa.	1400 fa.	1370 fa.	550 fa.
Mean annual heat at that height - - }	1½°.	—	—	3½°.	4°.	6°.
Mean heat of winter, do.	1½°.	—	—	—	10°.	20½°.
Mean heat of Aug. do.	1¾°.	—	—	—	6°.	9½°.
Distance between trees and snow - }	600 fa.	350 fa.	650 fa.	230 fa.	450 fa.	300 fa.
Upper limit of trees	1800 fa.	2000 fa.	1000 fa.	1170 fa.	920 fa.	250 fa.
Last species of trees towards the snow }	Escalònia Alstònia.	Pinus occident.	Bétula álba	A'bies ròbra	A'bies commùnis	Bétula álba.
Upper limit of the Ericíneæ - - }	Bejàriez, 1600 fa.	—	Rhodod. caucás. 1380 fa.	—	Rhodod. ferrug. 1170 fa.	Rhodod. lapónic. 480 fa.
Distance between the snow and corn - }	800 fa.	—	630 fa.	—	700 fa.	450 fa.

1732. *Elevation*, or the height of the soil above the level of the sea, determines, in a very marked manner, the habitation of plants. The temperature lessens in regular gradation, in the same manner as it does in receding from the equator, and 600 feet of elevation, Humboldt states, are deemed equal to one degree of latitude, and occasion a diminution of temperature equal to 23° of Fahrenheit; 300 feet being nearly equal to half a degree. Mountains 1000 fathoms in height, at 46° of latitude, have the mean temperature of Lapland; mountains of the same height between the tropics enjoy the temperature of Sicily; and the summits of the lofty mountains of the Andes, even where situated almost directly under the equator, are covered with snow as eternal as that of the north pole. The highest land in Scotland where corn has been found to attain maturity in favourable seasons is said to be at the mining ground on Lead Hills. (*See General Reports of Scotland, chap. Climate.*)

1733. Hence it is that *plants of high latitudes live on the mountains of such as are much lower*, and thus the plants of Greenland and Lapland are found on the Alps and Pyrenees. At the foot of Mount Ararat, Tournefort met with plants peculiar to Armenia; above these he met with plants which are found also in France; at a still greater height he found himself surrounded with such as grow in Sweden; and at the summit with such as vegetate in the polar regions. This accounts for the great variety of plants which are

often found in a Flora of no great extent; and it may be laid down as a botanical axiom, that the more diversified the surface of the country, the richer will its Flora be, at least in the same latitudes. It accounts, also, in some cases, for the want of correspondence between plants of different countries, though placed in the same latitudes; because the mountains or ridges of mountains, which may be found in the one and not in the other, will produce the greatest possible difference in the character of their Floras. To this cause may generally be ascribed the diversity which often actually exists between plants growing in the same latitudes, as between those of the north-west and north-east coasts of North America, and also between those of the south-west and south-east coasts; the former being more mountainous, the latter more flat. Sometimes the same sort of difference takes place between the plants of an island and those of the neighbouring continent; that is, if the one is mountainous and the other flat; but if they are alike in their geographical delineation, then they are generally alike in their vegetable productions.

1734. *Cold and lofty situations are the favourite habitations of most cryptogamic plants of the terrestrial class, especially the fungi, algæ, and mosses; as also of plants of the class Tetradynamia, and of the Umbelliferous and Syngenesious tribes; whereas trees and shrubs, ferns, parasitic plants, lilies, and aromatic plants, are most abundant in warm climates: but this is not to be understood merely of geographical climates, because, as we have seen, the physical climate depends upon altitude; in consequence of which, combined with the ridges and directions of the mountains, America and Asia are much colder in the same degrees of northern latitude than Europe. American plants, vegetating at forty-two degrees of northern latitude, will vegetate very well at fifty-two degrees in Europe; the same, or nearly so, may be said of Asia; which, in the former case, is perhaps owing to the immense tracts of woods and marshes covering the surface, and in the latter, to the more elevated and mountainous situation of the country affecting the degree of temperature. So, also, Africa is much hotter under the tropics than America; because in the latter, the temperature is lowered by immense chains of mountains traversing the equatorial regions, while in the former it is increased by means of the hot and burning sands which cover the greater part of its surface.*

1735. *Elevation influences the habits of plants in various ways: by exposing them to the wind; by causing them to be watered by a very fresh and pure water from the melting of adjoining snow; and to be covered in winter by a thick layer of snow, which protects them from severe frosts. Hence many alpine plants become frozen during winter in the plains, and in gardens which are naturally warmer than their proper stations. In great elevations, the diminution of the density of the air may also have some influence on vegetation. The rarity of the atmosphere admits a more free passage for the rays of light, which, being in consequence more active, ought to produce a more active vegetation. Experience seems to prove this on high mountains; and the same effect is produced in high latitudes by the length of the day. On the other hand, vegetables require to absorb a certain quantity of oxygen gas from the air during the night; and as they find less of that in the rarefied air of the mountains, they ought to be proportionably feeble and languishing. According to experiments made by Theodore de Saussure, plants which grow best in the high Alps are those which require to absorb least oxygen during the night; and, in this point of view, the shortness of the nights near the poles corresponds. These causes, however, are obviously very weak, compared to the powerful action of temperature.*

1736. *Great anomalies are found in the comparative height at which the same plant will grow in different circumstances. In countries situated under the equator, the two sides of the mountain are of the same temperature, which is solely determined by elevation; but in countries distant from it, the warmest side is that towards the south, and the zones of plants, instead of forming lines parallel to the horizon, incline towards the north. The reason, in both cases, is sufficiently obvious. In the temperate zone we find the same plants frequently on low and elevated situations, but this is never the case between the tropics.*

1737. *Altitude influences the habits of aquatics: thus some aquatics float always on the surface of the water, as Lemna, while others are either partially or wholly immersed. Such aquatics as grow in the depths of the sea are not influenced by climate; but such as are near the surface are influenced by climate, and have their habitations affected by it.*

1738. *The moisture, or mode of watering, natural to vegetables, is a circumstance which has a powerful influence on the facility with which plants grow in any given soil. The quantity of water absolutely necessary for the nourishment of plants, varies according to their tissue: some are immersed, others float on its surface; some grow on the margin of waters, with their roots always moistened or soaked in it; others, again, live in soil slightly humid or almost dry. Vegetables which resist extreme drought most easily are, 1. Trees and herbs with deep roots; because they penetrate to, and derive sufficient moisture from, some distance below the surface; 2. Plants, which, being furnished with*

few pores on the epidermis, evaporate but little moisture from their surface, as the succulent tribe.

1739. *The qualities of water*, or the nature of the substances dissolved in it, must necessarily influence powerfully the possibility of certain plants growing in certain places. But the difference in this respect is much less than would be imagined, because the food of one species of plant differs very little from that of another. The most remarkable case is that of salt marshes, in which a great many vegetables will not live, whilst a number of others thrive there better than any where else. Plants which grow in marine marshes, and those which grow in similar grounds situated in the interior of a country, are the same. Other substances naturally dissolved in water appear to have much less influence on vegetation, though the causes of the habitations of some plants, such as those which grow best on walls, as *Peltaria*, and in lime-rubbish, as *Thlaspi*, and other *Cruciferae*, may doubtless be traced to some salt (nitrate of lime, &c.) or other substance peculiar to such situations.

1740. *The nature of the earth's surface* affects the habitations of vegetables in different points of view: 1. As consisting of primitive earths, or the *débris* of rocks or mineral bodies; and, 2. As consisting of a mixture of mineral, animal, and vegetable matter.

1741. *Primitive surfaces* affect vegetables mechanically according to their different degrees of movability or tenacity. On coarse sandy surfaces plants spring up easily; but many of them, which have large leaves or tall stems, are as easily blown about and destroyed. On fine, dry, sandy surfaces, plants with very delicate roots, as *Prœtea* and *Erica*, prosper; a similar earth, but moist in the growing season, is suited to bulbs. On clayey surfaces plants are more difficult to establish, but when established are more permanent: they are generally coarse, vigorous, and perennial in their duration.

1742. With respect to *the relative proportions of the primitive earths* in these surfaces, it does not appear that their influence on the distribution of plants is so great as might at first sight be imagined. Doubtless different earths are endowed with different degrees of absorbing, retaining, and parting with moisture and heat; and these circumstances have a material effect in a state of culture, where they are comminuted and exposed to the air; but not much in a wild or natural state, where they remain hard, firm, and covered with vegetation. The difference, with a few exceptions, is never so great but that the seeds of a plant which has been found to prosper well in one description of earth, will germinate and thrive as well in another composed of totally different earths, provided they are in a nearly similar state of mechanical division and moisture. Thus, Decandolle observes, though the box is very common on calcareous surfaces, it is found in as great quantities in such as are schistous or granitic. The chestnut grows equally well in calcareous and clayey earths, in volcanic ashes, and in sand. The plants of Jura, a mountain entirely calcareous, grow equally well on the Vosges or the granitic Alps. But though the kind or mixture of earths seems of no great consequence, yet the presence of metallic oxides and salts, as sulphates of iron or copper, or sulphur alone, or alum, or other similar substances in a state to be soluble in water, are found to be injurious to all vegetation, of which some parts of Derbyshire and the marennes of Tuscany (*Chateauvieux*, let. 8.) are striking proofs. But except in these rare cases, plants grow with nearly equal indifference on all primitive surfaces, in the sense in which we here take these terms; the result of which is, that earths, strictly or chemically so termed, have much less influence on the distribution of plants than temperature, elevation, and moisture. Another result is, as Decandolle has well remarked, that it is often a very bad method of culture, to imitate too exactly the nature of the earth in which a plant grows in its wild state.

1743. *Mixed or secondary soils* include not only primitive earths, or the *débris* of rocks, but vegetable matters; not only the medium through which perfect plants obtain their food, but that food itself. In this view of the subject the term soil is used in a very extensive acceptation, as signifying, not only the various sorts of earths which constitute the surface of the globe, but every substance whatever on which plants are found to vegetate, or from which they derive their nourishment. The obvious division of soils, in this acceptation of the term, is that of aquatic, terrestrial, and vegetable soils; corresponding to the division of aquatic, terrestrial, and parasitical plants.

1744. *Aquatic soils* are such as are either wholly or partially inundated with water, and are fitted to produce such plants only as are denominated aquatics. Of aquatics there are several subdivisions according to the particular situations they affect, or the degree of immersion they require.

1745. One of the principal subdivisions of aquatics is that of *marine plants*, such as the *Fuci* and many of the *Algæ*, which are very plentiful in the seas that wash the coasts of Great Britain, and are generally attached to the stones and rocks near the shore. Some of them are always immersed; and others, which are situated above low-water mark, are immersed and exposed to the action of the atmosphere alternately. But none of them can be made to vegetate except in the waters of the sea. Another subdivision of aquatics is that of *river plants*, such as *Chara*, *Potamogeton*, and *Nymphæa*, which occupy the beds of fresh-water rivers, and vegetate in the midst of the running stream; being for the most part wholly immersed, as well as found only in such situations.

1746. A third subdivision of aquatics is that of *paludal or fen plants*, being such as are peculiar to lakes, marshes, and stagnant or nearly stagnant waters, but of which the bottom is often tolerably clear. In such situations you find the *leotetes lacustris*, flowering rush, water ranunculus, water violet, and a variety of others, which uniformly affect such situations; some of them being wholly immersed, and others immersed only in part.

1747. *Earthy soils* are such as emerge above the water, and constitute the surface of the habitable globe, which is every where covered with vegetable productions. Plants affecting such soils, which comprise by far the greater part of the vegetable kingdom, are denominated *terrestrial*, being such as vegetate upon the surface of the earth, without having any portion immersed in water, or requiring any further moisture for their support beyond that which they derive from the earth and atmosphere. This division is, like the aquatics, distributed into several subdivisions according to the peculiar situations which different tribes affect.

1748. Some of them are *maritime*, that is, growing only on the sea-coast, or at no great distance from it, such as *Stáctice*, *Gláúx*, *Sámólus*, samphire, sea-pea.

1749. Some are *fluviotic*, that is, affecting the banks of rivers, such as *Lýthrum*, *Lycópous*, *Eupatbrium*.

1750. Some are *champaign*, that is, affecting chiefly the plains, meadows, and cultivated fields, such as *Cardámíne*, *Tragopógon*, *Agrostémma*.

1751. Some are *dumose*, that is, growing in hedges and thickets, such as the bramble.

1752. Some are *ruderate*, that is, growing on rubbish, such as *Senecio viscosus*.

1753. Some are *syvatic*, that is, growing in woods or forests, such as *Stáctis*; *syvática*, *Angélica sylvestria*.

1754. And, finally, some are *alpine*, that is, growing on the summits of mountains, such as *Pòsa alpina*, *Epióbium alpinum*, and many of the mosses and lichens.

1755. *Vegetable soils* are such as are formed of vegetating or decayed plants themselves, to some of which the seeds of certain other plants are found to adhere, as being the only soil fitted to their germination and development. The plants springing from them are denominated *Parasitical*, as being plants that will vegetate neither in the water nor earth, but on certain other plants, to which they attach themselves by means of roots, that penetrate the bark, and from the juices of which they do often, though not always, derive their support. This last circumstance constitutes the ground of a subdivision of parasitical plants, into such as adhere to the dead or inert parts of other plants, and such as adhere to living plants, and feed on their juices.

1756. In the first subdivision we may place *parasitical mosses, lichens, and fungi*, which are found as often, and in as great perfection, on the stumps of rotten trees, and on rotten pales and stakes, as on trees which are yet vegetating; whence it is also plain that they do not derive their nourishment from the juices of the plants on which they grow, but from their decayed parts, and the atmosphere by which they are surrounded; the plant to which they cling serving as a basis of support.

1757. In the second subdivision we may place all *plants strictly parasitical*, that is, all such as do actually abstract from the juices of the plant to which they cling the nourishment necessary to the development of their parts; and of which the most common, at least as being indigenous to Britain, are the mistletoe, dodder, broom-rape, and a sort of tuber which grows on the root of saffron, and destroys it if allowed to spread.

1758. The *mistletoe (Viscum álbum)* is found for the most part on the apple tree; but sometimes also on the oak. If its berry is made to adhere to the trunk or branch of either of the foregoing trees, which from its glutinous nature it may readily be made to do, it germinates by sending out a small globular body attached to a pedicle, which after it acquires a certain length bends towards the bark, whether above it or below it, into which it insinuates itself by means of a number of small fibres which it now protrudes, and by which it abstracts from the plant the nourishment necessary to its future development. When the root has thus fixed itself in the bark of the supporting tree, the stem of the parasite begins to ascend, at first smooth and tapering, and of a pale green colour, but finally protruding a multiplicity of branches and leaves. It seems to have been thought by some botanists that the roots of the mistletoe penetrate even into the wood, as well as through the bark. But the observations of Du Hamel show that this opinion is not well founded. The roots are, indeed, often found within the wood, which they thus seem to have penetrated by their own vegetating power: but the fact is, that they are merely covered by the additional layers of wood which have been formed since the fibres first insinuated themselves into the bark.

1759. The *Cúscuta europæa*, or dodder (fig. 200.), though it is to be accounted a truly parasitical plant in the issue, is yet not originally so. For the seed of this plant, when it has fallen to the ground, takes root originally by sending down its radicle into the soil and elevating its stem into the air. It is not yet, therefore, a parasitical plant. But the stem which is now elevated above the surface lays hold of the first plant it meets with, though it is particularly partial to hops and nettles, and twines itself around it, attaching itself by means of little parasitical roots, at the points of contact, and finally detaching itself from the soil altogether by the decay of the original root, and becoming a truly parasitical plant. Withering describes the plant in his *Arrangement* as being originally parasitical; but this is certainly not the fact.

1760. The *Orobánche*, or broom-rape, which attaches itself by the root to the roots of other plants, is also to be regarded as being truly parasitical, though it sometimes sends out fibres which seem to draw nourishment from the earth. It is found most frequently on the roots of clover and common broom, but also in various other places.

1761. The *Epidéndrum flos æeris* is regarded also by botanists as a parasitical plant, because it is generally found growing on other trees. But as it is found to grow in old tan, it probably derives only support from the bark of trees, and not nourishment.

1762. *Light* is a body which has very considerable influence on the structure of vege-

tables, and some, also, on their habitation. The *Fungi* do not require the usual intervention of day, in order to decompose carbonic acid gas, and can live and thrive with little or no light. In green plants, which require the action of light, the intensity requisite is very different in different species; some require shady places, and hence the vegetable inhabitants of caves, and the plants which grow in the shades of forests; others, and the greater number, require the direct action of the sun, and grow in exposed, elevated sites. Decandolle considers that the great difficulty of cultivating alpine plants in the gardens of plains, arises from the impossibility of giving them at once the fresh temperature and intense light which they find on high mountains.

SECT. III. *Civil Causes affecting the Distribution of Plants.*

1763. *By the art of man plants may be inured to circumstances foreign from their usual habits.* Though plants in general are limited to certain habitations destined for them by nature, yet some are, and probably the greater number may be, inured to climates, soils, and situations, of which they are not indigenous. The means used are acclimation and culture.

1764. *Acclimation* seems to be most easily effected in going from a hot to a cold climate, particularly with herbaceous plants; because it often happens that the frosts of winter are accompanied with snow, which shelters the plant from the inclemency of the atmosphere till the return of spring. Trees and shrubs, on the contrary, are acclimated with more difficulty, because they cannot be so easily sheltered from the colds, owing to the greater length of their stems and branches. The acclimation, or naturalisation of vegetables has been attempted by two modes: by sowing the seeds of successive generations, and by the difference of temperature produced by different aspects. But though the habits of individuals may be altered by what is called acclimation, that is, by diminishing or increasing the supplies of nourishment and of heat, yet no art or device of man will alter the nature of the species. The potato, the kidneybean, the nasturtium, georgina, and many other plants which have been long in culture in Europe, and propagated from seeds ripened there through innumerable generations, there is no reason to suppose are in the least degree more hardy than when first imported from Asia or South America. The same slight degree of autumnal frost blackens their leaves, and of spring cold destroys their germinating seeds. But as summer is nearly the same thing in all lands, the summer or annual plants of the tropics are made to grow in the summers of the temperate zones, and, indeed, in general, the summer plants of any one country will grow in the summer climate of any other. The cucumber is grown in the fields in Egypt, and near Petersburg.

1765. *Domesticated plants.* "Some plants," Humboldt observes, "which constitute the object of gardening and of agriculture, have time out of mind accompanied man from one end of the globe to the other. In Europe the vine followed the Greeks; the wheat, the Romans; and the cotton, the Arabs. In America, the Tultiques carried with them the maize; and the potato and quinoa (*Chenopodium Quinoa*, of which the seeds are used) are found wherever have migrated the ancient Condamarea. The migration of these plants is evident; but their first country is as little known as that of the different races of men, which have been found in all parts of the globe from the earliest traditions." (*Géographie des Plantes*, p. 25.)

1766. *The general effect of culture on plants* is that of enlarging all their parts; but it often also alters the qualities, forms, and colours: it never, however, alters their primitive structure. "The potato," as Humboldt observes, "cultivated in Chile, at nearly twelve thousand feet above the level of the sea, carries the same flower as in Siberia."

1767. *The culinary vegetables of our gardens*, compared with the same species in their wild state, afford striking proofs of the influence of culture on both the magnitude and qualities of plants. Nothing in regard to magnitude is more remarkable than in the case of the *Brássica* tribe; and nothing, in respect to quality, exceeds the change effected on the celery, the carrot, and the lettuce.

1768. *The influence of culture on fruits* is not less remarkable. The peach, in its wild state in Media, is poisonous; but cultivated in the plains of Ispahan and Egypt, it becomes one of the most delicious of fruits. The effect of culture on the apple, pear, cherry, plum, and other fruits, is nearly as remarkable; for not only the fruit and leaves, but the general habits of the tree, are altered in these and other species. The history of the migration of fruit trees has been commenced by Sickler, in a work (*Geschichte, &c.*) which Humboldt has praised as equally curious and philosophical.

1769. *The influence of culture on plants of ornament* is great in most species. The parts of all plants are enlarged; some are numerically increased, as in the case of double flowers; and, what is most remarkable, even the colours are frequently changed, in the leaf, flower, and fruit.

1770. *The influence of civilisation and culture, in increasing the number of plants in a country*, is very considerable, and operates directly, by introducing new species for cul-

ture in gardens, fields, or timber-plantations; and indirectly by acclimstion and final naturalisation of many species, by the influence of winds and birds in scattering their seeds. The vine and the fig are not indigenous to France, but are now naturalised there by birds. In like manner the orange is naturalised in the south of Italy. Many plants of the Levant are naturalised both in France and Britain; some, as the cabbage, cherry, and apple, were probably naturalised in England during its subjection to the Romans. The narrow-leaved elm was brought from the Holy Land during the crusades. *Phasèolus vulgaris* and *Impatiens Balsamina* were brought originally from India; and, *Datura Stramonium*, which is now naturalised in Europe, was brought originally from India or Abyssinia. Buckwheat and most species of corn and peas came also from the East, and along with them several plants found among corn only, such as *Centaurea Cyanus*, *Agrostemma Githago*, *Raphanus Raphanistrum*, and *Myagrum sativum*. The country whence the most valuable grasses migrated is not known. Bruce says he found the oat wild in Abyssinia, and wheat and millet have been found in a wild state in hilly situations in the East Indies. Rye and the potato were not known to the Romans. The country of the former Humboldt declares to be totally unknown.

1771. *The greatest refinement in culture consists in the successful formation of artificial climates, for the culture of tropical plants, in cold regions.* Many vegetables, natives of the torrid zone, as the pine apple, the palm, &c., cannot be acclimated in temperate countries: but by means of hot-houses of different kinds, they are grown, even on the borders of the frozen zone, to the highest degree of perfection; and, in Britain, some of the tropical fruits, as the pine and melon, are brought to a greater size and better flavour than in their native habitations. Casting our eyes on man, and the effects of his industry, we see him spread on the plains and sides of mountains, from the Frozen Ocean to the equator, and every where wishing to assemble around him whatever is useful and agreeable of his own country or those of others. The more difficulties to surmount, the more rapidly are developed the moral faculties; and thus the civilisation of a people is almost always in an inverse ratio with the fertility of the soil which they inhabit. What is the reason of this? Humboldt asks. Habit and the love of native land.

SECT. IV. *Characteristic or Picturesque Distribution of Vegetables.*

1772. *The social and antisocial habits of plants are their most remarkable characteristics.* Like animals, they live in two classes: the one class grows alone and scattered, as *Solanum Dulcamara*, *Lýchnis dioica*, *Polygonum Bistorta*, *Anthéricum Liliago*, &c.; the other class unites in society, like ants or bees, covers immense surfaces, and excludes other species, such as *Fragaria vesca*, *Vaccinium Myrtillus*, *Polygonum aviculare*, *Aira canescens*, *Pinus sylvéstris*, &c. Barton states that the *Mitchella repens* is the plant most extensively spread in North America, occupying all the ground between the 28° and 69° of north latitude; that the *Arbutus úva úrsi* extends from New Jersey to the 72° of north latitude; while, on the contrary, *Gordonia*, *Franklinia*, and *Dionæa muscipula* are found isolated in small spots. Associated plants are more common in the temperate zones than in the tropics, where vegetation is less uniform and more picturesque. In the temperate zones, the frequency of social plants, and the culture of man, have rendered the aspect of the country comparatively monotonous. Under the tropics, on the contrary, all sorts of forms are united; thus cypresses and pines are found in the forests of the Andes of Quindiu and of Mexico; and bananas, palms, and bamboos in the valleys (fig. 201.):

but green meadows and the season of spring are wanting, for nature has reserved gifts for every region. "The valleys of the Andes," Humboldt observes, "are ornamented with bananas and paimis; on the mountains are found oaks, firs, barberies, alders,

brambles, and a crowd of genera believed to belong only to countries of the north. Thus the inhabitant of the equinoctial regions views all the vegetable forms which nature has bestowed around him on the globe. Earth develops to his eyes a spectacle as varied as the azure vault of heaven, which conceals none of her constellations." The people of Europe do not enjoy the same advantage. The languishing plants, which the love of science or luxury cultivates in our hot-houses, present only the shadow of the majesty of equinoctial vegetation; but, by the richness of our language, we paint these countries to the imagination, and cultivated man feels a happiness peculiar to civilisation.

1773. *The features of many plants are so obvious and characteristic, as to strike every general observer.* The Scitamineæ, tree-heaths, firs and pines, Mimosæ, climbers, Cacti, grasses, lichens, mosses, palms, Equisetaceæ, Malvaceæ, Aröideæ, Orchideæ, Liliaceæ, &c., form remarkable groups distinguishable at first sight. Of these groups, the most beautiful are the palms, Scitamineæ, and Liliaceæ, which include the bamboos and plants, the most splendid of umbrageous plants.

1774. *The native countries of plants may often be discovered by their features, in the same manner as the national distinctions which are observable in the looks and colour of mankind, and which are effected chiefly by climate.* Asiatic plants are remarkable for their superior beauty; African plants for their thick and succulent leaves, as in the case of the Cacti; and American plants for the length and smoothness of their leaves, and for a sort of singularity in the shape of the flower and fruit. The flowers of European plants are but rarely beautiful, a great portion of them being amentaceous. Plants indigenous to polar and mountainous regions are generally low, with small compressed leaves; but with flowers large in proportion. Plants indigenous to New Holland are distinguishable by small and dry leaves, which have often a shrivelled appearance. In Arabia they are low and dwarfish; in the Archipelago they are generally shrubby and furnished with prickles; while, in the Canary Islands, many plants, which, in other countries, are merely herbs, assume the port of shrubs and trees. The shrubby plants of the Cape of Good Hope and New Holland exhibit a striking similarity. The shrubs and trees of the northern parts of Asia and America also are very much alike; which may be exemplified in the *Plátanus orientális* of the former, and in the *Plátanus occidentális* of the latter, as well as in *Fágus sylvática* and *Fágus latifolia*, or *Acer cappadocicum* and *Acer saccharinum*; and yet the herbs and undershrubs of the two countries do not in the least correspond. "A tissue of fibres," Humboldt observes, "more or less loose, vegetable colours more or less vivid, according to the chemical mixture of their elements, and the force of the solar rays, are some of the causes which impress on the vegetables of each zone their characteristic features."

1775. *The influence of the general aspect of vegetation on the taste and imagination of a people; the difference in this respect between the monotonous oak and pine forests of the temperate zones, and the picturesque assemblages of palms, mimosas, plantains, and bamboos of the tropics; the influence of the nourishment, more or less stimulant, peculiar to different zones, on the character and energy of the passions; these, Humboldt observes, unite the history of plants with the moral and political history of man.*

SECT. V. *Systematic Distribution of Vegetables.*

1776. *The distribution of plants, considered in respect to their systematic classifications, is worthy of notice.* The three grand systematic divisions of plants are Acotyledonæ, Dicotyledonæ, and Monocotyledonæ. A simplification of this division considers plants as *agamous or phanerogamous*, that is, without or with visible sexes.

1777. *Plants of visible sexes.* Taking the globe in zones, the temperate contain the greater part of all the phanerogamous or visible sexual species of plants. The equinoctial countries contain nearly $\frac{1}{30}$, and Lapland only $\frac{1}{30}$ part.

1778. *Plants with the sexual parts invisible or indistinct.* Taking the whole surface of the globe, the agamous plants, that is, Músci, Fúngi, Fúci, &c., are to the phanerogamous or perfect plants, nearly as 1 to 7; in the equinoctial countries as 1 to 5; in the temperate zones, as 2 to 5; in New Holland, as 2 to 11; in France, as 1 to 2; in Lapland, Greenland, Iceland, and Scotland, they are as 1 to 1, or even more numerous than the phanerogamous plants. Within the tropics, agamous plants grow only on the summits of the highest mountains. In several of the islands of the Gulf of Carpentaria, having a Flora of phanerogamous plants exceeding 200 species, R. Brown did not observe a single moss.

1779. In the whole globe, the *Monocotyledonæ*, including the Gramineæ, Liliaceæ, Scitamineæ, &c., are to the whole of the perfect plants as 1 to 6; in the temperate zones (between 36° and 52°) as one to 4; and in the polar regions as 1 to 20. In Germany, the *Monocotyledonæ* are to the total number of species as 1 to 4½; in France as 1 to 4½; in New Holland the three grand divisions of plants, beginning with the *Acotyledonæ*, are nearly as 1, 2½, and 7¼.

1780. *Dicotyledonæ.* In the whole globe, the *Monocotyledonæ* are estimated by

R. Brown (*Gen. Rem on the Bot. of Terr. Aust.*, 1814.), from Persoon's *Synopsis*, to be to the Dicotyledonæ as 2 to 11; or, with the addition of undescribed plants, as 2 to 9. From the equator to 30° of north latitude, they are as 1 to 5. In the higher latitudes a gradual diminution of Dicotyledonæ takes place, until in about 60° north latitude and 50° south latitude they scarcely equal half their intertropical proportions. The ferns in the temperate regions are to the whole number of species as 1, 2, and 5; that is, in the polar regions as 1, in the temperate countries as 2, and in the intertropical regions as 5. In France, ferns form $\frac{1}{2}$ part of the phanerogamous plants; in Germany, $\frac{1}{3}$; in Lapland $\frac{1}{25}$.

1781. *The natural orders of perfect, or phanerogamous, plants are variously distributed in different countries. The following Table gives a general view of the relative proportions of several natural orders of perfect plants in France, Germany, and Lapland.*

Names of Natural Orders.	Number of Species in different Countries.			Ratio of each Family to the whole of the Phanerogamous plants in these Countries.		
	Fran.	Germ.	Lapl.	Fran.	Germ.	Lapl.
Cyperoidæ - - -	194	102	55	$\frac{1}{27}$	$\frac{1}{13}$	$\frac{1}{9}$

1782. *The most universal plants are the agamous families. Their germs are the only ones which nature develops spontaneously in all climates. The Polytrichum commune (fig. 202.) grows in all latitudes; in Europe and under the equator; on high mountains and on a level with the sea; in short, wherever there is shade and humidity. No phanerogamous plants have organs sufficiently flexible to accomodate themselves in this manner to every zone. The Asine média, Fragaria vesca, and Solanum nigrum have been supposed to enjoy this advantage; but all that can be said is, that these plants are very much spread, like the people of the race of Caucasus, in the northern part of the ancient continent. (Humboldt.)*

202

SECT. VI. *Economical Distribution of Vegetables.*

1783. *The plants chiefly employed in human economy differ in different climates and countries; but some, as the cereal grasses, are in universal use; and others, as the banana and plantain, only in the countries which produce them.*

1784. *The bread-corn of the temperate climates is chiefly wheat and maize; of the hot climates, rice, and of the coldest climates, barley.*

1785. *The edible roots of the old world are chiefly the yam, sweet potato, onion, carrot, and turnip; of the new, the potato.*

1786. *The oleraceous herbs of temperate climates are chiefly the Brassica family, and other Cruciferae. In hot climates potherbs are little used. Legumes, as the pea, bean, and kidneybean, are in general use in most parts of the old world.*

1787. *The fruits of the northern hemisphere belong chiefly to the orders of Pomaceae, Amygdalineae, Grossulariæ, Rosaceae, Viticæ, and Amentaceae.*

1788. *The fruits of the East Indies belong chiefly to Myrtaceae, Guttiferae, Aurantiaceae, Musaceae, Palmæ, Cucurbitaceae, Myristiceae, &c.*

1789. *The fruits of China are chiefly of the orders of Aurantiaceae, Myrtaceae, Rhámneae, Pomaceae, Amygdalineae, Palmæ, &c.*

1790. *The fruits of Africa belong to Sapoteæ, Palmæ, Chrysobalanæ, Guttiferae, Apocynæ, Papilionaceae, Musaceae, and Cucurbitaceae.*

1791. *The fruits of South America belong to Anonaceae, Myrtaceae, Terebinthaceae, Myristiceae, Palmæ, Bromeliaceae, Sapoteæ, Laurineae, Chrysobalanæ, Musaceae, Papilionaceae, and Passifloræ.*

1792. *The most showy herbaceous flowers of the temperate zone belong to Rosaceae, Liliaceae, Iridæ, Ericiæ, Ranunculaceae, Primulaceae, Caryophylleae, Gentianeae, &c. Those of the torrid zone belong to the Scitamineae, Amaryllidæ, Bignoniaceae, Melastomaceae, Magnoliaceae, Papilionaceae, Apocynæ, &c.*

1793. *The most useful timber trees of temperate climates are of the pine or fir kind; of warm climates, the palm and bamboo. The universal agricultural order is the Gramineae.*

SECT. VII. *Arithmetical Distribution of Vegetables.*

1794. *The total number of species of plants known, amounted in 1820 to about 44,000, of which 38,000 have been described. According to Humboldt and R. Brown, they are thus distributed: — in Europe 7000; in temperate Asia 1500; in equinoctial Asia and the adjacent islands 4500; in Africa 3000; in temperate America, in both hemispheres, 4000; in equinoctial America 13,000; in New Holland and the islands of the Pacific Ocean 5000; — in all 38,000. In Spitsbergen there are 30 species of perfect plants; in Lapland 534; in Iceland 533; in Sweden 1299; in Scotland 900; in Britain upwards of 1400; in Brandenburg 2000; in Piedmont 2800; in Jamaica, Madagascar, and the coast of Coromandel, from 4000 to 5000. It is now (anno 1829) believed that there may be from 100,000 to 200,000 species of plants. Such is the progress of discovery and of ideas.*

SECT. VIII. *Distribution of the British Flora, indigenous and exotic.*

1795. *Nearly thirty thousand species are enumerated in London's Hortus Britannicus, including all the indigenous species of Músci, Fúngi, Fùci, Algæ, and Lichènes.*

1796. *The natives of Britain, flowering plants, which enter into this Hortus are upwards of 1400 species; but the native British Flora contains in all above 3300 species. Of these there are about 1437 cotyledonous plants, and nearly 1893 imperfect, or what are termed, in the Jussieuan system, Acotyledonæ.*

1797. *Of the cotyledonous or perfect plants, 182 are trees or shrubs; 855 are perennials; 60 are biennials; and 340 annuals. Of the trees and shrubs, 47 are trees; 25 above 30 feet high, and the remainder under 30, but above 10 feet high. Of the perennials 83 are grasses; the next greatest number belong to the first two orders of the class Pentándria; the next to the Syngenesia; and the third to Monœcia Triándria, or the Cyperaceæ of Jussieu, comprehending chiefly the genus Carex. Most of the biennials belong to the first order of the 19th class, and the first two orders of Pentándria. There are 41 annual grasses; 52 annuals belong to the first two orders of Pentándria; and the next greatest number of annuals to Diadélphia Decándria, which includes the trefoils and vetches.*

1798. *Of the acotyledonous, or imperfect plants, 800 are Fúngi; 18 Algæ; 373 Lichènes; 85 Hepaticæ; 460 Músci; and 130 Filices; according to a rude estimate formed in 1820.*

1799. *In regard to the distribution of the perfect plants as to elevation, little or nothing has been yet generalised on the subject. In regard to soils, 276 are found in bogs, and marshy or moist places; 140 on the sea shores; 128 in cultivated grounds; 121 in meadows and pastures; 78 in sandy grounds; 76 in hedges and on hedge banks; 70 on chalky and other calcareous soils; 64 on heaths; 60 in woods; 30 on walls; 29 on rocks; and 19 on salt marshes; reckoning from Galpine's British Flora, 1820.*

1800. *In the distribution of the imperfect plants, the Filices prevail in rocky places and wastes; most of the Músci, Hepaticæ, and Lichènes, on rocks and trees; most of the Fùci and Algæ in the sea; and of the Fúngi, on decaying vegetable bodies, especially trunks of trees, manures, &c.*

1801. In respect to *geographical distribution*, the mountainous and hilly districts of England and South Wales are most prolific; the greatest number, according to extent of surface, are found in England and Wales, and the smallest number in Ireland.

1802. *The genera of the native British Flora* enter into 23 classes and 71 orders of the former, and 8 classes and 121 orders of the latter system.

1803. With respect to *the uses or application of the native Flora*, there are about 18 sorts of wild fruits which may be eaten, exclusive of the wild apple and pear; but only the pear, fruit, plum, currant, raspberry, strawberry, and cranberry, are gathered wild, or cultivated in gardens. There are about 20 boiling culinary plants natives, including the cabbage, sea-kale, asparagus, turnip, carrot, and parsnep. There are about the same number of spinaceous plants, salading, and pot and sweet herbs, which may be used, but of which a few only enter into the dietetics of modern cooks. There are 3 fungi, in general use, the mushroom, truffle, and morel; and various others, as well as about 8 species of sea-weeds, are occasionally eaten. There are about 6 native plants cultivated as florist's flowers, including the *Prímula elátior*, *Crócus*, *Narcíssus*, *Diánthus*, &c. Nearly 100 grasses, clovers, and leguminous plants are used in agriculture, or serve in their native places of growth as pasturage for cattle. Two native plants, the oat and the big or wild barley, are cultivated as farinaceous grains. Most of the trees are used in the mechanical arts, for fuel, or for tanning: one plant, the flax, not aboriginal, but now naturalised, affords fibre for the manufacture of linen cloth. Various plants yield coloured juices which may be, and in part are, used in dyeing; and some hundred species have been, and a few are still, used in medicine. About 20 cotyledonous plants, and above 50 acotyledonous, chiefly fungi, are, or are reputed to be, poisonous, both to men and cattle.

1804. By *the artificial Flora of Britain*, we understand such of the native plants as admit of preservation or culture in gardens; and such exotics as are grown there, whether in the open ground, or in different descriptions of plant habitations. The total number of species which compose this Flora, or *Hórtus Británnicus*, as taken from Sweet's catalogue of 1819, is about 13,000, including botanists' varieties, and excluding agamous plants. This Flora may be considered in regard to the countries whence the plants were introduced; the periods of their introduction; their obvious divisions; their systematic classification; their garden habitations; their application; and their native habitations.

1805. With respect to *the native countries of the artificial flora*, or *Hórtus Británnicus*, of 970 species, they are unknown; the remaining 12,000 species were first introduced from the following:—

1806. With respect to *the dates of the introduction of the exotics* from those countries, not any are known before the time of Gerard, in Henry VIII.'s reign. From this author and Trew, it appears that 47 species were introduced in or before 1548, including the apricot, fig, pomegranate, &c. Those previously introduced, of which the dates are unknown, may be considered as left here by the Romans, or afterwards brought over from France, Italy, and Spain, by the ecclesiastics, and preserved in the gardens of the

religious houses. Henry died in 1547; but the plants introduced in the year after his death may be considered as properly belonging to his reign.

Edm. VI. 1547 to 1553. During this troublous reign, only seven exotic species were added to the British garden, chiefly by Dr. Turner, director of the Duke of Somerset's (then Lord Protector) garden at Syon House.

Mary. 1553 to 1558. No plants introduced.

Elizabeth. 1558 to 1603. 533 species were introduced during this reign. Of these, 288 are enumerated in the first edition of Gerard's *Herbal*, published 1557. Drake's voyage round the world, Raleigh's discoveries in North America, and the consequent introduction of the tobacco and potato, took place during this reign.

James I. 1603 to 1625. Only 20 plants introduced during this period.

Charles I. 1625 to 1649. 531 plants introduced, which are chiefly mentioned by Parkinson, the first edition of whose work was published in 1629. Parkinson was the king's herbalist, and Tradescant his kitchen-gardener. A taste for plants began to appear among the higher classes during this reign; various private gentlemen had botanic gardens; and several London merchants procured seeds and plants for Lobaj, Johnston, and Parkinson, through their former correspondents.

O. and R. Cromwell. 1649 to 1658. 95 plants introduced by the same means as before. Cromwell encouraged agriculture; but the part he acted fell no leisure for any description of elegant or refined enjoyment.

Charles II. 1660 to 1685. 152 plants introduced chiefly mentioned by Ray, Morrison, and different writers in the *Transactions of the Royal Society*, founded in 1663. The Oxford and Chelsea gardens were founded, or enlarged, during this reign. Sir Hans Sloane and Evelyn flourished. Many native plants were now brought into notice by Ray and Willoughby.

James II. 1685 to 1688. 44 plants introduced.

William and Mary. 1688 to 1702. 298 species introduced, chiefly from the West Indies, and through Sir Hans Sloane and the Chelsea garden. Plukenet succeeded Parkinson as royal herbalist during this reign; and botanists were sent from England, for the first time, to explore foreign countries. As in the two former reigns great additions were now made to the indigenous Flora, by Ray, Sibbald, Johnson, and others. Many of the 30 species annually presented to the Royal Society were natives.

Anne. 1702 to 1714. 230 plants, in great part from the East and West Indies, and through the Chelsea garden.

George I. 1714 to 1727. 182 plants, chiefly through the Chelsea garden.

George II. 1727 to 1760. 1376 plants, almost entirely through the Chelsea garden, now in its zenith of fame under Miller. 375 of these plants are stated as introduced in 1730 and 1731, the letter being the year in which the first folio edition of the *Gardener's and Botanist's Dictionary* appeared. 239 in 1739, in which year the 4th edition of the same work appeared. 196 in 1752, and above 400 in 1758 and 1759, when subsequent editions were published. In the last, in 1763, the number of plants cultivated in England is stated to be more than double the number contained in the edition of 1751.

George III. 1760 to 1817. 6756 plants introduced, or considerably above half the number of exotics now in the gardens of this country. This is to be accounted for from the general progress of civilisation, and the great extension of British power and influence in every quarter of the world; especially in the East Indies, at the Cape of Good Hope, and New South Wales. The increasing liberality of intercourse which now obtained among the learned of all countries, must also be taken into account, by which, notwithstanding the existence of political differences, peace reigned and commerce flourished in the world of science. George III. may also be said to have encouraged botany, aided by the advice, assistance, and unwearied efforts of that distinguished patron of science, Sir Joseph Banks; and the garden of Kew, and its late curator, Aiton, became the Chelsea garden and the Miller of this reign. Most of the new plants were sent there, and first described in the *Hortus Kewensis*. The next greatest numbers were procured by the activity of the London nurserymen, especially Lee, and Loddiges, and described in the *Botanical Magazine*; Andrew's *Herbarium*; the *Botanical Register*; Loddiges' *Cabinet*, and other works. The greatest number of plants introduced in any one year, during this period, is 336 in 1800, chiefly heats and proteas from the Cape of Good Hope, taken from the Dutch in 1795. The following are the numbers annually introduced since that period:—

1801.	- 116	1805.	- 169	1809.	- 48	1815.	- 42
1802.	- 169	1806.	- 224	1810.	- 68	1814.	- 44
1803.	- 267	1807.	- 61	1811.	- 149	1815.	- 192
1804.	- 299	1808.	- 52	1812.	- 316	1816.	- 301

Annual Average of 17 years, ending 1816, 156 species.

1807. With respect to the obvious character of the artificial Flora, 350 species are hardy trees or shrubs; of these 270 are trees above 10, and 100 trees above 30 feet, high. Of these, the larch, spruce fir, silver fir, and Lombardy poplar sometimes attain the height of 100 feet. Above 400 species are hardy grasses. Of the tender exotics, the majority are trees or shrubs, and the next in number annuals and bulbs. The colours of the blossoms are generally rich and vivid in proportion to the warmth of the climate of which the plants are natives.

1808. *Purchasable British Flora.* The whole of the plants enumerated as forming the British Flora, are probably not at any one time all in existence in Britain. Many of them, especially the exotic species which were introduced at Kew, have been lost there through accidents or diseases, and are wanting for a time till new seeds or plants are obtained from abroad. Had they been distributed among the nurserymen, they would have been abundantly multiplied and spread over the country. Casualties happen even to hardy plants, and a species which at one time is to be found in moderate quantities in the nurseries is at another period comparatively scarce. Thus, if we reduce the actual number of species to be found in cultivation at one time to from 9000 to 10,000, it will be found nearer the truth. In the public nurseries, varieties are very much cultivated, in order, as it were, to place the beauties of esteemed species in different points of view; or to produce in vegetables something analogous to what are called variations in musical compositions. The following may be considered as a popular or horticultural distribution of the species and varieties obtainable from British nurseries. It is taken from a catalogue entitled *Prædromus*, &c.; or Forerunner of the collection in Page's Southampton nursery-garden, said to be drawn up by L. Kennedy (late of the Hammersmith nursery), and published in 1818.

1809. *Hardy Plants.*

	Sp. & Var.		Sp. & Var.		Sp. & Var.
Trees above 30 feet high	100	Hardy climbing shrubs	150	Marsh plants	- - - - 70
Trees under 30 and above 10 feet high	200	Herbaceous plants	2800	Biennials	- - - - 300
Deciduous shrubs	500	Grasses introduced in botanic collections	150		
Roses, double and single	339	Bulbous-rooted plants	280		
Evergreen shrubs	400	Aquatics	50		
					Total 4580

1810. *Green-house and Dry-stove plants.*

	Sp. & Var.		Sp. & Var.		Sp. & Var.
Trees and Shrubs	1450	Climbers	90	Herbaceous and stemless plants	340
Heaths	400	Succulents	170

Herbage plants, not grasses	9 15	Mosses used in dyeing	1 1
Herbage grasses, and grasses for the inferior animals	20 25	Mosses used for various purposes in the arts	6 6
Plants used for furnishing oils and essences	5 5		
		Total 85 112	

1819. *Miscellaneous applications of Hardy Perennials, native and exotic.*

	Sp. & Var.		Sp. & Var.
Border-flowers, or such as are used in flower-gardens and shrubberies, in ordinary cases about	300	Used for distillation and perfumery	20
Used in the modern pharmacopoeias	50		
Sold by herbalists, and used by quacks and irregular practitioners	20		
		Total 870	

1820. *Application of curious hot-house exotics, or such plants of ornament as require the protection of glass.* Of these there are in ordinary green-houses seldom more than 100 species and varieties, and not more than half that number in most of our plant-stoves; The remainder of this class are confined to the public and private botanic gardens, and to eminent public nurseries. Many of this division are of great importance in their native countries, as the indigo, sugar-cane, tea-tree, cinnamon, &c.; the mango, durion, and other excellent fruits; the palms, bamboos, &c. Even some, here treated as entirely ornamental, afford useful products in their own countries; as the camellia, sun-flower, &c., from the seeds of which oils are expressed in China and America. The cultivation

or preservation of living specimens of these plants, therefore, in our green-houses and stoves, is an entertainment at once rational and useful; as many species at length become acclimated, and some even naturalised; and uses may in time be discovered for such as are now merely looked on as objects of curiosity. But that they contribute to elegant enjoyment, it is quite enough to justify much more than all the care that is taken to obtain and preserve them; for what is life when it does not exceed mere obedience to the animal instincts?

1821. With respect to the *native habitations of the exotic part of the British Hortus*, little can be advanced with certainty. In general it would appear that moist and moderately warm climates, and irregular surfaces, are most prolific in species; and, judging of the whole world from Europe, we should venture to consider half the species of plants in existence as growing in soft and rather moist grounds, whether low or elevated. The soil of surfaces constantly moist, or inclining to be moist, whether watered from the atmosphere or from subterraneous sources, is generally found to be minutely divided, and of a black vegetable or peaty nature. Immense tracts in Russia and America are of this description, and, even when dry, resist evaporation better than any other. In such soils, the roots of plants are generally small and finely divided, as those of the heaths, most bog plants, and nearly all the American shrubs. The next sort of habitation most prolific in species, appears to us to be arenaceous soils in temperate climates, and in proportion to their moisture. Here the roots of plants are also small, but less so than in soils of the former description. On rocky and calcareous soils the roots of plants are generally strong and woody, or at least long and penetrating. In clayey habitations, exclusive of the alluvial deposits of rivers, few plants are found, and these generally grasses, strong fibrous-rooted herbaceous plants, or tap-rooted trees. Such at least is the amount of our generalisations; but as our observation has been limited to Europe, and does not even extend to the whole of it, those who have visited Africa and Asia are much more capable of illustrating the subject. One conclusion, we think, the cultivator is fully entitled to draw, that the greater number of plants, native or foreign, will thrive best in light soil, such as a mixture of soft, black, vegetable mould or peat and fine sand kept moderately moist; and that on receiving unknown plants or seeds, of the native sites of which he is ignorant, he will err on the safe side by placing them in such soils rather than in any other; avoiding, most of all, clayey and highly manured soils, as only fit for certain kinds of plants constitutionally robust, or suited to become monstrous by culture.

1822. *The Hortus Britannicus of 1829* contains nearly 30,000 species and varieties, and the *Purchasable Flora of Britain* of the same year, contains at least 1000 species and varieties, more than it did in the year 1818 when the above estimate was formed; but the relative proportions of the distribution cannot be materially different now from what they were then, for which reason we have not deemed it requisite to go a second time through the labour of enumeration, for the sake of a result which is by no means essential to a work like the present.

CHAP. VII.

Origin and Principles of Culture, as derived from the Study of Vegetables.

1823. The final object of all the sciences is their *application to purposes subservient to the wants and desires of men*. The study of the vegetable kingdom is one of the most important in this point of view, as directly subservient to the arts which supply food, clothing, and medicine; and indirectly to those which supply houses, machines for conveying us by land or by water, and in short almost every comfort and luxury. Without the aid of the vegetable kingdom, few mineral bodies would be employed in the arts, and the great majority of animals, whether used by man as labourers, or as food, could not live.

1824. *Agriculture and gardening* are the two arts which embrace the whole business of cultivating vegetables, to whatever purpose they are applied by civilised man. Their fundamental principles, as arts of culture, are the same; they are for the most part suggested by nature, and explained by vegetable chemistry and physiology (Chap. III. and IV.); and most of them have been put in practice by man for an unknown length of time, without much reference to principles. All that is necessary, therefore, for effecting this branch of culture, is to imitate the habitation, and to propagate. This is, or ought to be, the case, wherever plants are grown for medical or botanical purposes, as in herb and botanic gardens. Nature is here imitated as exactly as possible, and the results are productions resembling, as nearly as possible, those of nature.

1825. *To increase the number and improve the nutritive qualities of plants*, it is necessary to facilitate their mode of nutrition, by removing all obstacles to the progress of the plant. These obstacles may either exist under or above the surface; and hence the origin of draining, clearing from surface incumbrances, and the various operations, as digging, ploughing, &c., for pulverising the soil. Nature suggests this in accidental ruptures of the surface, broken banks, the alluvial deposits from overflowing rivers, and the earth thrown up by underground animals. Many of the vegetables within the influence of such accidents are destroyed, but such as remain are ameliorated in quality, and the reason is, their food is increased, because their roots being enabled to take a more extensive range, more is brought within their reach.

1826. *It is necessary, or at least advantageous, to supply food artificially*; and hence the origin of manuring. All organised matters are capable of being converted into the food of plants; but the best manure for ameliorating the quality, and yet retaining the peculiar chemical properties of plants, must necessarily be decayed plants of their own species. It is true that plants do not differ greatly in their primary principles, and that a supply of any description of putrescent manure will cause all plants to thrive; but some plants, as wheat, contain peculiar substances (as gluten and phosphate of lime), and some manures, as those of animals, or decayed wheat, containing the same substances, must necessarily be a better food or manure for such plants. Manuring is an obvious imitation of nature, every where observable in the decaying herbage of herbaceous plants, or the fallen leaves of trees, rotting into dust or vegetable mould about their roots; and in the effect of the dung left by pasturing or other animals.

1827. *Amelioration of climate* by increasing or diminishing its temperature, according to the nature of the plant, is farther advantageous in improving the qualities of vegetables; unless, indeed, the plant is situated in a climate which experience and observation show to be exactly suited to its nature. Hence the origin of shelter and shade, by means of walls, hedges, or strips of plantation; of sloping surfaces or banks, to receive more directly or indirectly the rays of the sun; of rows, drills, and ridges, placed north and south in preference to east and west, in order that the sun may shine on both sides of the row, drill, or ridge, or on the soil between rows and drills every day in the year; of soils better calculated to absorb and retain heat; of walls fully exposed to the south, or to the north; of training or spreading out the branches of trees on these walls; of hot-walls; of hot-beds; and, finally, of all the varieties of hot-houses. Nature suggests this part of culture, by presenting, in every country, different degrees of shelter, shade, and surface, and in every zone different climates.

1828. *The regulation of moisture* is the next point demanding attention. When the soil is pulverised, it is more easily penetrated both by air and water; when an increase of food is supplied, the medium through which that food is taken up by the plant should be increased; and when the temperature is increased, evaporation becomes greater. Hence the origin of watering by surface or subterraneous irrigation, manual supplies to the root, showering over the leaves, steaming the surrounding atmosphere, &c. This is only to imitate the dews and showers, streams and floods of nature; and it is to be regretted that the imitation is in most countries attended with so much labour, and requires so much nicety in the arrangement of the means, and judgment in the application of the water, that it is but very partially applied by man in every part of the world, except perhaps in a small district of Italy. But moisture may be excessive; and on certain soils at certain seasons, and on certain productions at particular periods of their progress, it may be necessary to carry off a great part of the natural moisture, rather than let it sink into the earth, or to draw it off where it has sunk in and injuriously accumulated, or to prevent its falling on the crop at all. Hence the origin of surface-drainage by ridges, and of under-draining by covered conduits or gutters; and of awnings and other coverings to keep off the rain or dews from ripe fruits, seeds, or rare flowers.

1829. *The regulation of light* is the remaining point. Light sometimes requires to be increased and sometimes to be excluded, in order to improve the qualities of vegetables; and hence the origin of thinning the leaves which overshadow fruits and flowers, the practice of shading cuttings, seeds, &c., and the practice of blanching. The latter practice is derived from accidents observable among vegetables in a wild state, and its influence on their quality is physiologically accounted for by the obstruction of perspiration, and the prevention of the chemical changes effected by light on the epidermis.

1830. *Increase in the magnitude of vegetables*, without reference to their quality, is to be obtained by an increased supply of all the ingredients of food, distributed in such a body of well pulverised soil as the roots can reach to; by additional heat and moisture; and by a partial exclusion of the direct rays of the sun, so as to moderate perspiration, and of wind, so as to prevent sudden desiccation. But experience alone can determine what plants are best suited for this, and to what extent the practice can be carried. Nature gives the hint in the occasional luxuriance of plants accidentally placed in favourable

circumstances ; man adopts it, and, improving on it, produces cabbages and turnips of half a cwt., apples of one pound and a half, and cabbage-roses of four inches in diameter ; productions which may in some respects be considered as diseased.

1831. *To increase the number, improve the quality, and increase the magnitude of particular parts of vegetables.* It is necessary, in this case, to remove such parts of the vegetable as are not wanted, as the blooms of bulbous or tuberous-rooted plants, when the bulbs are to be increased, and the contrary ; the water-shoots and leaf-buds of fruit-trees ; the flower-stems of tobacco ; the male flowers and barren runners of the *Culcumis* tribe, &c. Hence the important operations of pruning, ringing, cutting off large roots, and other practices for improving fruits and throwing trees into a bearing state. At first sight these practices do not appear to be copied from nature ; but, independently of accidents by fire, already mentioned, which both prune and manure, and of fruit-bearing trees, say thorns or oaks, which, when partially blown out by the roots, or washed out of the soil by torrents, always bear better afterwards, why may not the necessity that man was under, in a primitive state of society, of cutting or breaking off branches of trees, to form huts, fences, or fires, and the consequently vigorous shoots produced from the parts where the amputation took place, or the larger fruit on that part of the tree which remained, have given the first idea of pruning, cutting off roots, &c. ? It may be said that this is not nature but art ; but man, though an improving animal, is still in a state of nature, and all his practices, in every stage of civilisation, are as natural to him as those of the other animals are to them. Cottages and palaces are as much natural objects as the nests of birds, or the burrows of quadrupeds ; and the laws and institutions by which social man is guided in his morals and politics, are not more artificial than the instinct which congregates sheep and cattle in flocks and herds, and guides them in their choice of pasturage and shelter. It is true that the usual acceptation of the words nature and art scarcely justifies this application of them ; but we are viewing the subject in its most extensive light.

1832. *To form new varieties of vegetables,* as well as of flowers and useful plants of every description, it is necessary to take advantage of their sexual differences, and to operate in a manner analogous to crossing the breed in animals. Hence the origin of new sorts of fruits, grains, legumes, and roots. Even this practice is but an imitation of what takes place in nature by the agency of bees and other insects, and of the wind ; all the difference is, that man operates with a particular end in view, and selects individuals possessing the particular properties which he wishes to perpetuate or improve. New varieties, or rather subvarieties, are formed by altering the habits of plants ; by dwarfing through want of nourishment ; variegating by arenaceous soils ; giving or rather continuing peculiar habits when formed by nature, as in propagating from monstrosities, for instance, fasciculi of shoots, weeping shoots, shoots with peculiar leaves, flowers, fruit, &c.

1833. *To propagate and preserve from degeneracy* approved varieties of vegetables, it is in general necessary to have recourse to the different modes of propagating by extension. Thus choice apples and other tree fruits could not be perpetuated by sowing their seeds, which experience has shown would produce progeny more or less different from the parent, but they are preserved and multiplied by grafting ; pine-apples are propagated by cuttings or suckers, choice carnations by layers, potatoes by cuttings of the tubers, &c. But approved varieties of annuals are in general multiplied and preserved by selecting seeds from the finest specimens and paying particular attention to supply suitable culture. Approved varieties of corns and legumes, no less than of other annual plants, such as garden flowers, can only be with certainty preserved by propagating by cuttings or layers, which is an absolute prolongation of the individual ; but as this would be too tedious and laborious for the general purposes both of agriculture and gardening, all that can be done is to select seeds from the best specimens. This part of culture is the farthest removed from nature ; yet there are, notwithstanding, examples of the fortuitous graft ; of accidental layers ; and of natural cuttings, as when leaves, or detached portions, of plants (as of the *Cardamine hirsuta*) drop and take root.

1834. *The preservation of vegetables for future use* is effected by destroying or rendering dormant the principle of life, and by warding off, as far as practicable, the progress of chemical decomposition. When vegetables or fruits are gathered for use or preservation, the air of the atmosphere which surrounds them is continually depriving them of carbon, and forming the carbonic acid gas. The water they contain, by its softening qualities, weakens the affinity of their elements ; and heat produces the same effect by dilating their parts, and promoting the decomposing effect both of air and water. Hence, drying in the sun or in ovens, is one of the most obvious modes of preserving vegetables for food, or for other economic purposes ; but not for growth, if the drying processes are carried so far as to destroy the principle of life in seeds, roots, or sections of the shoots of ligneous plants. Potatoes, turnips, and other esculent roots, may be preserved from autumn till the following summer, by drying them in the sun, and burying them in perfectly dry soil, which shall be at the same time at a temperature but

a few degrees above the freezing point. Corn may be preserved for many years, by first drying it thoroughly in the sun, and then burying it in dry cool pits, and closing these so as effectually to exclude the atmospheric air. In a short time the air within is changed to carbonic acid gas, in which no animal will live, and in which, without an addition of oxygen or atmospheric air, no plant or seed will vegetate. The corn is thus preserved from decomposition, from insects, from vermin, and from vegetation, in a far more effectual manner than it could be in a granary. In this way the Romans preserved their corn in chambers hewn out of dry rock; the Moors, in the sides of hills; the Chinese, at the present time, in deep pits, in dry soil; and the aboriginal nations of Africa, as we have seen (1136.), in earthen vessels hermetically sealed. (*Lasteyrie des Fosses propres à la Conservation des Graines. Chaptal Chimie appliqué à l'Agriculture*, tom. ii. ch. 10.) These practices are all obvious imitations of what accidentally takes place in nature, from the withered grassy tressock to the hedgehog's winter store; and hence the origin of herb, seed, fruit, and root rooms and cellars, and of packing plants and seeds for sending to a distance.

1835. *The whole art of vegetable culture* is but a varied development of the above fundamental practices, all founded in nature, and for the most part rationally and satisfactorily explained on chemical and physiological principles. Hence the great necessity of the study of botany to the cultivator, not in the limited sense in which the term is often taken, as including mere nomenclature and classification, but in that extended signification in which we have here endeavoured, proportionately to our limited space, to present the study of the vegetable kingdom. Those who would enter more minutely into the subject will have recourse to the excellent work of Keith, from whom we have quoted at such length; to Sir J. E. Smith's *Introduction*; and to the familiar introductions to the Linnean and Jussieuan systems of hotany in the *Magazine of Natural History*, vols. i. and ii.

BOOK II.

OF THE STUDY OF THE ANIMAL KINGDOM WITH REFERENCE TO AGRICULTURE.

*1836. *Organised matter is of two kinds, animal and vegetable.* Yet however obvious the difference between them may appear, it is, in point of fact, extremely difficult to state in what this difference consists. The power of locomotion, enjoyed by the more perfect animals, would seem at first an admirable distinction; but there are multitudes of others as completely destitute of this power as plants. If we descend in the scale of animal life, we find beings formed like vegetables, and externally distinguished from them only by their voluntary motion. Yet even this, as an exclusive distinction, will not avail us; because there are very many plants (as the *Dionæa muscipula*, several species of *Mimosa*, and some few of *Cassia*) which are well known to be highly irritable. Macleay, who has discussed this question with great ability, concludes by remarking "that animals are to be distinguished from vegetables by the existence of an absorbent intestinal cavity, and of a nervous system; but that both these marks become indistinct in those animals, which, from the simplicity of their structure, approach nearest to the vegetable nature." (*Hor. Ent.*)

1837. *A partial knowledge of animals is essential to the agriculturist*; as they have frequently a much greater influence over his operations than the most consummate skill, or the most prudent management. This knowledge should be both scientific and practical. Without the first, he cannot communicate to others the established name of any known animal, or an accurate account of any that may be unknown. While, without the second, he will be ignorant of those habits and properties which render animals either hurtful or beneficial to man. In proof of the importance of this knowledge, the following anecdote deserves attention:—In 1788, great alarm was excited in this country by the probability of importing in wheat from North America the insect called the Hessian fly, whose dreadful ravages had spread desolation and almost famine over that country during the two preceding years. The privy council sat day after day anxiously debating what measures should be adopted to ward off a danger, more to be dreaded, as they well knew, than the plague or pestilence. Expresses were sent off in all directions to the officers of the customs at the different out-ports respecting the examination of cargoes. Despatches were sent to the ambassadors in France, Austria, Prussia, and America, to gain that information which only a scientific knowledge of the insect could supply; and so important was the business deemed, that, according to Young, the minutes of

council, and the documents collected, fill upwards of two hundred octavo pages. Fortunately, England contained one illustrious naturalist, whose attention had long been directed to all subjects which connects natural history with agriculture, and to whom the privy council had the wisdom to apply. It was by Sir Joseph Banks's entomological knowledge, and through his suggestions, that they were at length enabled to form some kind of judgment on the subject. This judgment was after all, however, very imperfect. Sir Joseph Banks had never seen the Hessian fly, nor was it described in any entomological system. He called for facts respecting its nature, propagation, and economy, which could be had only in America. These were obtained as speedily as possible, and consisted of numerous letters from individuals; essays from magazines; the reports of the British minister there, &c. One would have supposed that from these statements, many of them drawn up by farmers who had lost entire crops by the insect, which they professed to have examined in every stage, the requisite information might have been obtained. So far, however, was this from being the case, that many of the writers seem ignorant whether the insect be a moth, a fly, or what they term a bug! And though, from the concurrent testimony of several, its being a two-winged fly seemed pretty accurately ascertained, no intelligent description is given from which any naturalist can infer to what genus it belongs, or whether it is a known species. With regard to the history of its propagation and economy, the statements are so various and contradictory, that, though he had such a mass of materials before him, Sir Joseph Banks was unable to form any satisfactory conclusion. (*Young's Ann. of Agriculture*, xi. 406. *Kirby and Spence*, i. 51.)

1838. *An acquaintance with the domesticated and indigenous animals alone of Britain is essential to the agriculturist*, and even of the latter the terrestrial proportion only will come under his notice. A knowledge of the names by which the wild species are universally known is all that he need study in the classification of quadrupeds and birds, and these may be acquired from the *British Zoology* of Pennant; the *quadrupeds and birds* of Bewick, or the *British Fauna* of Dr. Turton. A *British Fauna* has been published by Dr. Fleming, which supplies, in a great measure, the deficiencies of the before-mentioned works. A more perfect acquaintance, however, with insects is essentially necessary, because their influence, in one shape or other, is constantly apparent in the avocations of the husbandman. The cheapest and most comprehensive work on British insects is Samouelle's *Entomologist's useful Compendium*, in which the elements of the science are explained, and a large proportion of our native insects enumerated. But no work on zoology, as it affects agriculture or gardening, has yet appeared. Those who wish to enter deeper into this science, and understand the present state of the "Philosophy of Zoology," will find the discoveries of the celebrated Cuvier, and other modern naturalists, concentrated and digested with much ability by Dr. Fleming, in a work bearing the above title. From these sources we have extracted the principal part of the following chapters, which relate to Animal Anatomy, Chemistry, Physiology, Pathology, Uses, and Artificial Improvement.

CHAP. I.

Systematic Zoology, &c.

1839. *The technical terms in zoology* are much more numerous than those in botany, because there are an infinitely greater variety of forms in animals than in plants. Those made use of in the veterinary art are most important to the agriculturist, and these terms are usually prefixed to treatises on that subject.

1840. *In describing animals*, naturalists select those characters for distinguishing the species which are external: but the sexes of the vertebrated animals can only be ascertained by an internal examination of the reproductive organs. The higher divisions, or those which constitute classes, orders, families, and (in some cases) genera, depend more or less on internal structure.

1841. *The best descriptions are often insufficient*: accurate drawings or preserved specimens should therefore be kept to verify the first examination, or to perpetuate peculiarities that may have escaped previous notice. When the agriculturist requires information from others on any particular insect detrimental to his crops, a simple description of the object is not sufficient. This indeed may lead to a knowledge of the species, but not to the means by which the evil is to be checked. He should carefully note down the time, the manner, and the situation in which the insect first makes its appearance, the period which it remains in the larva or grub state, in what way it changes to the perfect insect, whether above or beneath the ground, and, lastly, in what situations the female deposits her eggs; two or three specimens of the insect, in its various stages,

should likewise be preserved in spirits; and this, from the small size of these beings, can be done with facility, and will supersede the necessity of any laboured description of the objects themselves. With such materials, he will find a most important advantage in submitting his doubts and queries to some one of the societies in London, whose object is more particularly the investigation of such matters. The Zoological Club of the Linnean Society is composed of the most eminent naturalists in the kingdom; and their labours promise to effect much in this department of rural economy. Specimens, &c. may be sent to the secretary, N. A. Vigors, Esq., Soho Square, London; or they may be sent to the same gentleman, as secretary of the Zoological Society, Bruton Street, London.

1842. *The classification of animals*, until the discoveries of the French philosophers, was long regulated by their external characters alone; from this resulted all the artificial systems of the last century. A more intimate acquaintance with nature has convinced naturalists of the present day, that it is only by considering the structure of animals, both internal and external, with reference to their modes of life, that the natural system can ever hope to be discovered. The brilliant anatomical and physiological discoveries of Cuvier, Lamarck, Latreille, and others, in France, have laid the foundation of this system; but it was reserved for our own countryman, Macleay, to generalise their details, and combine these valuable materials into a whole. By a new and most extraordinary mode of investigation, this gifted writer has proved the existence of five primary divisions in the animal world, corresponding to the same number in the vegetable: while, through the doctrine of affinity and analogy, the apparently contradictory opinions of Linnæus, with those of others who succeeded him, are in many instances reconciled and explained. (*Hor. Ent. Trans. of Linn. Society*, 14, p. 46.)

CHAP. II.

Animal Anatomy.

1843. *The leading organs of animal structure* may be conveniently arranged as external and internal.

SECT. I. *External Anatomy of Animals.*

1844. *All animals agree in possessing an exterior covering, or skin*, to modify their surface, regulate their form, and protect them from the action of surrounding elements. In the more perfect animals, this organ consists of the following parts: the cuticle, the corpus mucosum, the corium, the panniculus, and the cellular web.

1845. *The cuticle* is destitute of blood-vessels, nerves, and fibres, and usually consists of a thin transparent membrane possessing little tenacity. In those animals which live on the land, it is more rigid in its texture, and more scaly and dry on its surface, than in those which reside in the water. In aquatic animals, it is in general smooth, often pliable; and, in many cases, its texture is so soft and delicate, that it appears like mucus. It assumes, likewise, other appearances, such as scales, nails, shells and plates, which deserve the attentive consideration of the naturalist, as furnishing him with important characters for the arrangement of animals.

1846. *The mucous web* occurs immediately underneath the cuticle, from which, in general, it may be easily disjoined; but it is often so closely attached to the true skin below, as not to be separated even by maceration in water.

1847. *The corium (cutis vera)*, or true skin, lies immediately underneath the cuticle or mucous web. It is usually destitute of colour. It consists in some animals, as quadrupeds, of solid fibres, which cross one another in every possible direction, and form a substance capable of considerable extensibility and elasticity. It is more obviously organised than the two membranes by which it is covered. Blood-vessels and nerves penetrate its substance, and may be observed forming a very delicate network on its surface.

1848. *The muscular web* varies greatly in its appearance according to the motions which the skin and its appendages are destined to perform. It consists of a layer of muscles, the extremities of whose fibres are inserted into the corium externally, and adhere to the body internally in various directions. This layer is very obvious in the hedgehog and the porcupine, to assist in rolling up the body and moving the spines; and, in birds, to effect the erection of their feathers. In man it can scarcely be said to exist, except in the upper parts, where cutaneous muscles may be observed, destined for moving the skin of the face, cheeks, and head. In the skin of the frog, the only cutaneous muscles which can be observed are seated under the throat; the skin on the other parts of the body being loose and unconnected with the parts beneath. The use of this layer of the integument is to corrugate the skin, and elevate the hairs, feathers or spines with which it is furnished.

1849. *The cellular web* forms the innermost layer of the common integuments, and rests immediately on the flesh of the body. It consists of plates crossing one another in different directions, and forming a cellular membrane, varying in its thickness, tenacity, and contents, according to the species. In frogs it does not exist. The cells of this membrane are filled with various substances, according to the nature of the animal. In general they contain fat, as in quadrupeds and birds. In some of these the layer is interrupted, as in the ruminating animals, while it is continuous in others, as the boar and the whale. In birds, while a part of this web is destined for the reception of fat, other portions are receptacles for air. In the moon-fish the contained matter resembles albumen in its chemical characters.

1850. *The appendices of the skin* are hairs, feathers, horns, scales, shells, and crusts.

1851. *Hairs* differ remarkably not only in their structure, but likewise in their situation. In some cases they appear to be merely filamentous prolongations of the cuticle, and subject to all its changes. This is obviously the case with the hair which covers the bodies of many caterpillars, and which separates along with the cuticle, when the animal is said to cast its skin. In true hair the root is in the form of a bulb, taking its rise in a cellular web. Each bulb consists of two parts, an external, which is vascular, and

from which the hair probably derives its nourishment; and an Internal, which is membranous, and forms a tube or sheath to the hair during its passage through the other layers of the skin. From this bulb, and enveloped by this membrane, the hair passes through the corium, mucous web, and cuticle. It usually raises up small scales of this last layer, which soon become dry and fall off, but do not form the external covering of the hair, as some have supposed. The hair itself consists of an external horny covering, and a central vascular part, termed *medulla* or *pith*. This horny covering consists of numerous filaments placed laterally, to which different kinds of hair owe their striated appearance. These filaments appear of unequal lengths, those nearest the centre being longest; and, consequently, the hair assumes the form of an elongated cone, with its base seated in the skin. This form gives to the hair that peculiar property on which the operation of *felting* depends. In consequence of this structure of the surface, if a hair is seized at the middle between two fingers, and rubbed by them, the root will gradually recede, while the point of the hair will approach the fingers; in other words, the hair will exhibit a progressive motion in the direction of the root, the imbricated surface preventing all motion in the opposite direction. It is owing to this state of the surface of hairs, that woollen cloth, however soft and pliable, excites a disagreeable sensation of the skin in those not accustomed to wear it. It likewise irritates sores by those asperities, and excites inflammation. The surface of linen cloth, on the other hand, feels smooth, because the fibres of which it consists possess none of those inequalities of surface by which hairs are characterised.

1852. *If a quantity of wool be spread upon a table, covered with a woollen cloth, and pressed down in different directions, it is obvious that each hair will begin to move in the direction of its root, as if it had been rubbed between the fingers. The different hairs thus moving in every direction become interwoven with each other, and unite in a continuous mass. This is the felt with which hats are made. Curled hairs entwine themselves with one another more closely than those which are straight, though flexible, as they do not, like these, recede from the point of pressure in a straight line; and hence hatters employ various methods to produce curl in the short fur of rabbits, bares, and moles, which they employ. This is accomplished chiefly by applying the solution of certain metallic salts to the fur by a brush; so that, when the hairs are dry, the surface which was moistened contracts more than the other, and produces the requisite curve.*

1853. *It is owing to the asperities of the surface of hair that the spinning of wool is so difficult. This is in a great measure removed, by besmearing it with oil, by which the inequalities are filled up, or, at least, the asperities become less sensible. When the wool is made into cloth, it is necessary to remove the oil, which is done by the process of fulling. The cloth is placed in a trough, with water and clay, and agitated for some time. The oil is removed by the clay and water, while the agitation, acting like pressure, brings the hairs into closer union, and the cloth is taken out, not only cleansed, but felted. The hairs of every thread entwine themselves with those which are contiguous; so that the cloth may be cut without being subject to ravel. It is from this tendency to felt that woollen cloth and stockings increase in density, and contract in dimensions, on being washed. In many places woollen stuffs are felted, on a small scale, by placing them in running water, or under cascades; and the Zetlanders expose them to the motions of the tides, in narrow inlets of the sea.*

1854. *In general, there is a close connection between the colour of the hair and that of the mucous web. This is displayed in those animals which are spotted, in which the colour of the skin is generally variegated like that of the hair.*

1855. *Hairs differ remarkably in form. In general they are round. Frequently on the body they are thickest in the middle. Sometimes they are flat, or two-edged; and, in the whiskers of seals, they are waved on the margins. In many animals they are long and straight; while, in others, they are crisped, and are then termed *wool*. When stiff, they are termed *bristles*; and, when inflexible, *spines*.*

1856. *Hair grows by the roots. In some species it is renewed annually; and in all it is readily reproduced.*

1857. *Hair is the most permanent of all the substances consisting of animal matter, resisting putrefaction for a great length of time.*

1858. *Feathers are nearly related to hairs; they consist of the quill, shaft, and web. The quill, like the hair, takes its rise in the cellular membrane: the central portion of the shaft has a texture like cork, and the web which usually occupies both sides of it is composed of what are called barbes, and the sides of these with barbules. The colour of feathers exhibits great difference: in some birds it varies with the seasons, in others with food, and in others with the extinction of life. Like hairs, feathers are not only renewed periodically, but they are readily reproduced if accidentally destroyed.*

1859. *Horns take their rise from the same situation as hairs or feathers. They may be regarded as hairs agglutinated, and forming a hollow cone. The fibrous structure of horn may be perceived in many animals at the base, where it unites with the skin. At this part it receives the additions to its growth, the apex of the cone being pushed out in proportion as the increase takes place at the root, and on the inner surface. But horns differ remarkably from hair, in having their central cavity filled by a projection of bone or other solid substance from the body beneath.*

1860. *The different markings of the horns, particularly the transverse ridges, are indications of the different layers of growth; and in many cases the number of these ridges corresponds with the years of life.*

1861. *The colour of the horn is, in general, distributed through the mass; sometimes, however, it is collected into bands or threads. It seldom experiences much change during the life of the animal. It is permanent, or does not experience those periodical renovations which we have stated to take place with hair and feathers. The deciduous horns of the stag are different in their nature from true horns, and will be afterwards taken notice of. The term horn is usually restricted to the coverings of the projections of the frontal bones of oxen, sheep, and similar quadrupeds; but various appendices of the skin, composed of the same materials, and equally permanent, although seated on other parts of the body, may with propriety be included under the same appellation; among these may be enumerated beaks, hoofs, claws, nails, and spurs.*

1862. *Beaks. The substance of these covers the external surface of the maxillary bones of birds, and is composed of horn.*

1863. *Hoofs resemble horns in their manner of growth, and in containing a central support, formed by the termination of the extreme bones of the feet. They grow from*

the inner surface and base, and are thus fitted to supply the place of those parts which are worn away by being exposed to friction against hard bodies. Hoofs are peculiar to certain herbivorous quadrupeds.

1864. *Claws* resemble hoofs in structure and situation, deriving their origin from the skin, having a bony centre, and occurring at the extremities of the fingers and toes.

1865. *Nails* differ from horns and claws, in the circumstance of not being tubular, but consisting of a plate generally convex on the outer surface, and concave beneath.

1866. *Spurs* occur chiefly on what is termed the leg (*carpus*) of gallinaceous birds. They are found, likewise, on the ornithorynchus. Like horns, they are supported in the centre by bone.

1867. *Horns, hoofs, and similar parts*, bear a close resemblance to one another in chemical composition. When heated they soften, and may be easily bent or squeezed into particular shapes. They consist of coagulated albumen, with a little gelatine; and, when incinerated, yield a little phosphate of lime.

1868. *Their use*, in animal economy, is to protect the soft parts from being injured by pressure against hard bodies. They are in general wanting, where the parts are in no danger of suffering from the influence of such agents. When torn off from the base, they are seldom completely renewed, although very remarkable exertions are frequently made by the system to repair the loss.

1869. *Scales* vary remarkably in their form, structure, mode of adhesion, and situation in different animals. In general they are flat plates, variously marked. In some cases each scale consists of several decreasing plates, the lowest of which is largest; so that the upper surface becomes somewhat imbricated. Some scales adhere by the whole of their central surface; while others resemble the human nail, in having the outer extremity free.

1870. *Shells* consist of layers of an earthy salt, with interposed membranes of animal matter, resembling coagulated albumen. They grow by the addition of layers of new matter to the edges and internal surface. When broken, the animal can cement the edges and fill up the crack, or supply the deficiency when a portion is abstracted.

1871. *The earthy matter of shells* is lime, in union with carbonic acid. Phosphate of lime has likewise been detected, but in small quantity. The colour is secreted from the animal, along with the matter of the shell.

1872. *Crusts* are, in general, more brittle in their texture than shells. They exhibit remarkable differences as to thickness and composition. They differ from shells chiefly in containing a considerable portion of phosphate of lime, and in a greater subdivision of parts. In some cases, however, as the crusts of the bodies of insects, the earthy matter is almost absent, and they may be regarded as formed of cuticle alone. When they contain much earthy matter, as in the crusts of lobsters, the epidermis may be detected as a cover, and the corium beneath may be perceived as a very thin film. In many cases, these crusts are renewed periodically; and, in all, they are readily repaired. Crusts occur in insects, the Crustacea, and the Echinodermata, or sea-urchins, and star-fish.

1873. *These different appendices of the skin* pass, by insensible degrees, into one another, as hair into spines, horns into nails, scales into shells, and crusts into membranes. They have all one common origin, namely, the skin; and independently of secondary purposes, they all serve for protection.

1874. *The secretions of the skin* are of three kinds; one class performing the office of lubricating the skin, another of regulating the temperature of the body, and a third that of carrying off the superfluous carbon.

1875. *Unctuous secretions* are confined to animals which have warm blood, and the cells of the cellular web filled with fat, Mammalia and birds.

1876. *Viscous secretions*. In the animals with cold blood, secretions are produced, by the skin, of substances differing in quality from those of warm-blooded animals; but destined to serve the same purposes, namely, to protect the skin from the action of the surrounding element.

1877. *Sweat*, in ordinary cases, exudes from the skin in a state of vapour; and when condensed consists of water with a small portion of acetic acid and common salt. This secretion is considered as intended to regulate the degree of animal heat, and prevent its accumulation beyond certain limits.

1878. *Carbon* is also emitted by the skin, and appears to be in effect a secondary kind of respiration, but the discovery is but recent. (See *Ellis on the Germination of Seeds and Respiration of Animals*, 1807 and 1811.)

1879. *Absorption*. There are several circumstances which prove that the skin of the human body, in particular states, is capable of exerting an absorbing power. Whether the absorption takes place by peculiar vessels, or by the exhaling vessels having their motions reversed, or whether absorption ever takes place in the state of health, are questions to which no satisfactory answer has been given.

SECT. II. *Internal Anatomy of Animals.*

1880. *Animal anatomy* admits of three divisions, the osseous, the muscular, and the nervous structure of animals.

SUBJECT. 1. *Osseous Structure of Animals.*

1881. *The organs of external anatomy* are generally considered as destined for protection; while those of the interior of the animal, or the bones, give stability to the power, support the muscles, and afford levers for the performance of locomotion. Bones may be considered with regard to their composition, articulations, and arrangement. All bones are composed of the periosteum, cartilaginous basis, earthy matter, and fat.

1882. *The periosteum* bears the same relation to the bone as the skin to the body, serving as a covering for its surface, and a sheath for the different cavities which enter it. It varies in thickness according to the nature of the bone. Its texture is obviously fibrous; and it possesses blood-vessels. Its sensibility indicates the existence of nerves.

1883. *The cartilaginous basis* consists of gelatine and coagulated albumen, the *earthy matter* is chiefly phosphate of lime, and the *fat* resembles that of the fixed oils.

1884. *Bones increase in size*, not as in shells, scales, or horns, by the addition of layers to the internal surface, but by the expansion of the cartilaginous basis; which, when it becomes saturated with earthy matter, is incapable of farther enlargement. This is the reason why the bones of young animals are soft and flexible, while those of old animals are hard and brittle.

1885. *The proportion* between the cartilaginous basis and the earthy matter differs, not only in every animal according to age, the earthy matter being smallest in youth, but, likewise, according to the nature of the bone itself, and the purposes which it is destined to serve. The teeth contain the largest portion of earthy matter. Remarkable differences are likewise observable, according to the class or species.

1886. *Bone is readily reproduced*, in small quantities, especially in youth. In the case of fracture, the periosteum inflames and swells, the crevice is filled up by a cartilaginous basis, abounding in vessels, and the earthy matter is at length deposited, giving to the fractured part, in many cases, a greater degree of strength than it originally possessed. In animals of the deer kind, the horns, which are true bone, are annually cast off; a natural joint forming at their base, between them and the bones of the cranium, with which they are connected. They are afterwards reproduced under a skin or periosteum, which the animal rubs off when the new horns have attained their proper size. In some cases of disease, the earthy matter is again absorbed into the system, the cartilaginous basis predominates, and the bones become soft and tender. This takes place in the disease of youth termed *rickets*, and in a similar complaint of advanced life, known under the name of *mollities ossium*. In other instances, bone is formed as a monstrous production, in organs which do not produce it in a state of health, as the brain, the heart, and the placenta. (*Monro's Outlines of Anatomy*, p. 63.)

1887. *Cartilage* can scarcely be said to differ in its nature, from the cartilaginous basis of the bone. It is of a fine fibrous structure, smooth on the surface, and remarkably elastic. It covers those parts of bones which are exposed to friction, as the joints, and is thickest at the point of greatest pressure. By its smoothness, it facilitates the motion of the joints, and its elasticity prevents the bad effects of any violent concussion. It is intimately united with the bone, and can scarcely be regarded as different from an elongation of the cartilaginous basis. Where it occurs at a joint with considerable motion, it is termed *articular* or *obducent* cartilage. In other cases, it occurs as a connecting medium between bones which have no articular surfaces, but where a variable degree of motion is requisite. The ribs are united to the breast-bone in this manner. Between the different vertebrae, there are interposed layers of cartilage, by which the motions of the spine are greatly facilitated. As these connecting cartilages are compressible and elastic, the spine is shortened when the body remains long in a vertical position, owing to the superincumbent pressure. Hence it is that the height of man is always less in the evening than in the morning. All these cartilages are more or less prone to ossification, in consequence of the deposition of earthy matter in the interstices. To this circumstance may be referred, in a great measure, the stiffness of age, the elasticity of the cartilages decreasing with the progress of ossification.

1888. *The articulations of bones* exhibit such remarkable differences, in respect to surface, connection, and motion, that anatomists have found it difficult to give to each manner of union an appropriate name and character. We shall only notice the most obvious kinds and motions, and these admit of two divisions, the *true joints* and the *motionless junctions*.

1889. *In the motionless junctions*, the connecting surfaces come into close and permanent contact, as in the serrated edges of the bones of the human skull, or the even edges of the bones of the heads of quadrupeds and birds. Sometimes a pit in one bone receives the extremity of another like a wedge, as in the case of the human teeth; in other cases, the one bone has a cavity with a protuberance at its centre, which receives another bone, as in the claws of cats, seals, &c. The human ribs are united with the breast-bone by the intervention of cartilage, as are the two sides of the lower jaw with each other in vertebral animals.

1890. *In true joints* the articular surfaces are enveloped with cartilage, remarkable for the smoothness of its free surface, and its intimate union with the bone, of which it forms a protecting covering. The periosteum is not continued over the surface of the cartilage, but is prolonged like a sheath over the joint, until it joins that of the

opposite bone. It thus forms a close bag at the joint, in which nothing from without can enter, and from which nothing can escape. Into this bag the lubricating liquor termed *synovia* is conveyed. It is secreted by a mucous membrane on the interior; on which account, as it in some cases appears like little bags, the term *bursa mucosa* has been bestowed upon it.

1891. *Ligaments.* Besides the sheath formed by the continuation of the periosteum, which is too slender to retain the bones in their proper place, the joints are furnished with *ligaments*. These are membranes of a dense fibrous texture, flexible, elastic, and possessed of great tenacity. They have their insertion in the periosteum and bone, with which they are intimately united. The motions which joints of this kind are capable of performing, may be reduced to three kinds, flexion, twisting, and sliding. In *flexion*, the free extremity of the bone which is moved, approaches the bone which is fixed, describing the segment of a circle, whose centre is in the joint. In *twisting*, the bone which is moved turns round its own axis, passing through the articulation. In *sliding*, the free extremity of the bone moved, approaches the bone which is fixed, in a straight line.

SUBJECT. 2. *Muscular Structure of Animals.*

1892. *The muscles are the organs by which motion is executed:* they unfold the most singular mechanism of parts, and an infinite variety of movements. The muscles appear in the form of large bundles, consisting of cords. These, again, are formed of smaller threads, which are capable of division into the primary filaments. Each muscle, and all its component cords and filaments, are enveloped by a covering of cellular membrane, liberally supplied with blood-vessels and nerves. — At the extremities of the muscular fibres, where they are attached to the more solid parts, there are usually threads of a substance, differing in its appearance from the muscle, and denominated *tendon* or *sinew*. The tendons are, in general, of a silvery white colour, a close, firm, fibrous texture, and possessed of great tenacity. The thread of which they consist, are attached on the one extremity to the surface of a bone, or other hard part; and, on the other, they are variously interspersed among the fibres or bundles of the muscle. — They are considered as destitute of sensibility and irritability, and form a passive link between the muscle and the bone, or other point of support.

1893. *Muscles are the most active members of the animal frame.* They alone possess the power of irritability, and execute all the motions of the body. The causes which excite them to action may be reduced to two kinds. In the first the will, through the medium of the nerves, excites the irritability of the fibres; and, in the second, the action is produced by the application of external objects, either directly or by the medium of the nerves. The changes which take place in the tenacity of muscles after death are very remarkable. The same force which they could resist with ease in a living state is sufficient to tear them to pieces after the vital principle has departed.

1894. *The functions of the muscles* are either those of rest or motion. Many animals protect themselves against the disturbing movements of the air and water, by placing their bodies in a *prone position*. To give still greater efficacy to this protecting attitude, they retire to valleys, woods, or dens, on the earth, or to the deepest places in the waters; and are thus able, by the weight of their own bodies, and the advantage of their position, to outlive the elemental war. — But there are other animals, which, while they are equally cautious to make choice of proper situations for their safety, employ in addition, peculiar organs with which they are provided, to connect themselves more securely with the basis on which they rest.

1895. *Grasping.* The most simple of these expedients, *grasping*, is displayed by bats, birds, and insects, in the employment of their toes and claws in seizing the objects of their support. In birds, the assumption and continuance of this attitude is accomplished by a mechanical process; so that there is no expenditure of muscular energy. In every case of this kind, the claws are so admirably adapted to the station of the animal, that the detention of the body in the same spot, during this state of rest, is accompanied with little exertion.

1896. *Suction.* The sucker by which animals fix themselves varies greatly in its form, and even structure. In the limpet, and other gasteropodous Mollusca, its surface is smooth and uniform; and the adhesion appears to depend on its close application to every part of the opposing surface. In other animals, as the leech and the sea-urchin, the sucker is formed at the extremity of a tube; the muscular motions of which may serve to pump out any air which may remain, after the organ has been applied to the surface of the body.

1897. *Cementation.* The *cementation* which is employed by animals to preserve themselves stationary, consists in a part of their own bodies being cemented to the substance on which they rest. This takes place in the common muscle, by means of strong cartilaginous filaments, termed the *byssus*, united in the body to a secreting gland, furnished with powerful muscles, and, at the other extremity, gined to the rock or other body to which it connects itself. In other cases, as in the oyster, the shell itself is cemented to the rock.

1898. *The muscular motions of animals* are standing, walking, leaping, flying, and swimming.

1899. *In standing* it is necessary that the parts of the body be so disposed, as that the centre of gravity of the whole body fall within the space which they occupy, and that the muscles have sufficient power to counteract those movements which might displace the body from that position. It is obvious that the more numerous the limbs, and the more equally they are distributed on the inferior side of the body, the more securely will the centre of gravity be retained within the space which these feet include.

1900. *Walking* is defined by Cuvier to be a motion on a fixed surface, in which the centre of gravity is alternately moved by one part of the extremities, and sustained by the other, the body never being at any time completely suspended over the ground. It is produced by the alternate flexion and extension of the limbs, aided by the motions of the trunk, advancing the position of the centre of gravity in the intended direction.

1901. *In animals with many feet*, as the Myriópoda, walking is performed by so uniform a motion, that the body may be said to glide along the surface.

1902. *In animals with four feet*, "each step is executed by two legs only; one belonging to the fore pair, and the other to the hind pair; but sometimes they are those of the same side, and sometimes those of opposite sides." (*Cuvier's Comparative Anatomy*, lect. vii, a, 1.) The latter is that kind of motion in horses, which grooms term a *pace*. The right fore-leg is advanced so as to sustain the body, which is thrown upon it by the left hind-foot, and at the same time, the latter bends in order to its being moved forward. While they are off the ground, the right hind-foot begins to extend itself, and the moment they touch the ground, the left fore-foot moves forward to support the impulse of the right foot, which likewise moves forward. The body is thus supported alternately by two legs placed in a diagonal manner. When the right fore-foot moves, in order to sustain the body, pushed forward by the right hind-foot, the motion is then called an *amble*. The body, being alternately supported by two legs on the same side, is obliged to balance itself to the right and left, in order to avoid falling; and it is this balancing movement which renders the gait so soft and agreeable to women and persons in a weak state of body. (*Cuvier's Comp. Anat.*, lect. vii.)

1903. *The serpentine motion* consists in bringing up the tail towards the head by bending the body into one or more curves, then resting upon the tail, and extending the body, thus moving forward, at each step, nearly the whole length of the body, or one or more of the curves into which it was formed. Among the Mollúsca, and many of the annulose animals, the same kind of motion is performed by alternate contractions and expansions, laterally and longitudinally of the whole body, or of those parts which are appropriated to progressive motion.

1904. *A mode of moving analogous to walking*, is performed by animals who have suckers, and is exemplified in the leech, which at every step advances nearly the whole length of its body.

1905. *In the action of leaping*, the whole body rises from the ground, and for a short period is suspended in the air. It is produced by the sudden extension of the limbs, after they have undergone an unusual degree of flexion. The extent of the leap depends on the form and size of the body, and the length and strength of the limbs. The Myriópoda are not observed to leap. Many of the spiders and insects leap with ease forwards, backwards, and laterally. In those which are remarkable for this faculty, the thighs of the hind-legs are in general of uncommon size and strength. Among reptiles the leaping frog is well known, in opposition to the crawling toad. Among quadrupeds, those are observed to leap best, which have the hind legs longer and thicker than the fore-legs, as the kangaroo and the hare. These walk with difficulty, but leap with ease.

1906. *Serpents* are said to leap, by folding their bodies into several undulations, which they unbend all at once, according to the velocity they wish to give to their motion. The jumping maggot, found in cheese, erects itself upon its anus, then forms its body into a circle, bringing its head to the tail; and, having contracted every part as much as possible, unbends with a sudden jerk, and darts forward to a surprising distance. Many crabs and *Podûra* bend their tail, or hairs which supply its place, under their belly, and then, suddenly unbending, give to the body a considerable degree of progressive motion.

1907. *Flying*. Flying is the continued suspension and progress of the whole body in the air, by the action of the wings. In leaping, the body is equally suspended in the air, but the suspension is only momentary; in flying, on the contrary, the body remains in the air, and acquires a progressive motion by repeated strokes of the wings on the surrounding fluid. The centre of gravity is always below the insertion of the wings in the bodies of flying animals to prevent them from falling on their backs, but near that point on which the body is, during flight, as it were suspended. The action of flying is performed by animals belonging to different classes. Among the Mammàlia, bats display this faculty, by means of wings, formed of a thin membrane extending between the toes, which are long and spreading, between the fore and hind legs, and between the hind legs and the tail. In birds, the wings, which occupy the place of the anterior extremities in the Mammàlia, and are the organs of flight, consist of feathers, which are stronger than those on the body, and of greater length. Among reptiles, the flying lizard may be mentioned, whose membranaceous wings, projecting from each side of the body, without being connected with the legs, enable it to fly from one tree to another in search of food. A few fishes are likewise capable of sustaining themselves for a short time by means of their fins; these are termed flying fish. Spiders are able to move in the air by means of their threads.

1908. *Swimming* is the same kind of action in water, as flying is in air. The organs which are employed for this purpose resemble the oars of a boat in their mode of action, and in general possess a considerable extent of surface and freedom of motion. Swimming, however, is not confined to those animals which are furnished with oars or swimmers. Many animals move with ease in the water by means of repeated undulations of the body, as serpents, eels, and leeches; or by varying the form of the body by alternate contractile and expansive movements, as the *Medusæ*.

1909. In these *different displays of voluntary motion*, the muscles are only able to continue in exercise for a limited period, during which the irritability diminishes, and the further exertion of their powers becomes painful. When thus fatigued, animals endeavour to place themselves in a condition for resting, and fall into that state of temporary lethargy, denominated *sleep*.

1910. *The positions assumed by animals during sleep* are extremely various. In the horse, they even differ according to circumstances. In the field he lies down, in the

stable he stands. Dogs and cats form their bodies into a circle, while birds place their heads under their wings.

1911. *The ordinary mode of sleep* is likewise exceedingly various in different animals, and in the same animal is greatly influenced by habit. It in general depends on circumstances connected with food. It is probable, that all animals, however low in the scale, have their stated intervals of repose, although we are as yet unacquainted either with the position which many of them assume, or the periods during which they repose.

SUBSECT. 3. *Structure of the Nervous System.*

1912. *The nervous system*, by containing the organs of sensation and volition, is that which distinguishes animal from vegetable beings. It consists, in the vertebrated animals, of the brain, the spinal marrow, and the nerves.

1913. *The brain*, exclusive of its integuments, appears in the form of a soft, compressible, slightly viscous mass. The spinal marrow originates with the brain, and consists of four cords united in one body. The nerves, also, originate in the brain or spinal marrow. Some of them appear to have a simple origin; but, in general, several filaments, from different parts of the brain or spinal marrow, unite to form the trunk of a nerve. This trunk again subdivides in various ways; but the ramifications do not always exhibit a proportional decrease of size. It frequently happens that the branches of the same nerve, or of different ones, unite and separate repeatedly within a small space, forming a kind of network, to which the name *plexus* has been applied. Sometimes filaments pass from one nerve to another; and, at the junction, there is usually an enlargement of medullary matter termed a *ganglion*. Numerous filaments, from different nerves, often unite to form a ganglion, from which proceed trunks frequently of greater magnitude than the filaments which entered. Thus nerves, very different in their origin, form communications with one another; so that the whole nervous system may be considered as a kind of network, between the different parts of which an intimate connection subsists. In consequence of this arrangement, it is often matter of very great difficulty to ascertain the *origin* of those filaments, which unite to constitute the trunk of a nerve. In some instances, they appear to arise from the surface of the brain or spinal marrow; in other cases, from the more central parts.

1914. *The brain, in the animals without vertebrae*, is destitute of the protecting bony covering, which forms the head and back bone in the vertebral animals. The brain itself is much more simple in its structure. Independently of very remarkable differences in the structure of the nervous system in the different genera of invertebral animals, there may still be perceived two models, according to which, the organs belonging to it are arranged. In the first, the brain is situated upon the œsophagus, and presents different forms according to the species, appearing more like a ganglion than like the brain of the vertebral animals. It sends off several nerves to the mouth, eyes, and feelers. Two, one on each side, pass round the œsophagus, and, uniting below, form a ganglion in some cases larger than what is considered the true brain. From this ganglion, nerves are likewise sent off to different parts of the body. The animals in which this nervous system prevails belong to the great division termed Mollusca. In the second, the brain is situated as in the Mollusca, sending out nerves to the surrounding parts, and likewise one nerve on each side, which, by their union, form a ganglion, from which other nerves issue. This ganglion produces likewise a nervous cord, which proceeds towards the extremity of the body, forming throughout its length ganglia, from which small nerves proceed; this cord, at its commencement, is, in some cases, double for a short distance. It has been compared to the medulla oblongata, and spinal marrow of the vertebral animals. This kind of nervous system is peculiar to the annulose animals. There are usually ganglia on the nervous cord, corresponding with the number of rings of which the body consists.

1915. *The functions of the brain and nervous system*; the organs of perception, as of touch, of heat, of light, of hearing, of smell, and of taste; and also the faculties of the mind, we pass over as belonging chiefly to the anatomy and physiology of the human frame, and therefore less immediately connected with the animals used in agriculture. The reader will find these subjects ably treated by Dr. Fleming.

CHAP. III.

Animal Chemistry; or the Substances which enter into the Composition of the Bodies of Animals.

1916. *The elementary principles of the animal kingdom* have been ascertained with considerable precision; but the binary, ternary, or other compounds which they form, have not been investigated with so much success. As these various ingredients are

brought into union in the animal system by the agency of the vital principle, their state of combination may be expected to differ widely from the ordinary results of electric attraction. When such compounds of organisation are submitted to analysis, the influence of the vital principle having ceased, the products obtained may be regarded, in many cases, as modifications of the elements of the substance, occasioned by the processes employed, rather than the display of the number or nature of the ingredients, as they existed previously to the analytical operations. Hence the great caution requisite in drawing conclusions regarding the composition of animal bodies.

1917. *The elementary substances which are considered as entering into the parts of animals* are, carbon, hydrogen, oxygen, azote, phosphorus, sulphur, fluoric acid, muriatic acid, iodine, potash, soda, ammonia, lime, magnesia, silica, iron, and manganese.

1918. *Carbon* exists in various states of combination in the fluids, as well as in the solids, of every animal; and has been detected in the form of charcoal in the lungs. When animal substances are exposed to a high temperature in closed vessels, the charcoal which is produced differs considerably from that which is obtained by the same means from vegetables. It is more glossy in appearance, and is incinerated with much greater difficulty.

1919. *Hydrogen* is universally distributed in the animal kingdom; it occurs as a constituent ingredient of all the fluids, and of many of the solids. It is invariably in a state of combination with charcoal; for, as far as we know, it has never been detected in an uncombined or separate state. It has been found in the human intestines, in the form of carburetted hydrogen.

1920. *Oxygen* is as widely distributed as the preceding, in the fluids and solids of all animals. A constant supply of it from the atmosphere is indispensably necessary to the continuation of animal life. It occurs, not only in combination with other bodies, but probably, likewise in a separate state, in the air-bag of fishes, in which it is found, varying in quantity, according to the species, and the depth at which the fishes have been caught. It is common, in union with charcoal, forming *carbonic acid*.

1921. *Azote* gas is very widely distributed as a component part of animal substances. It occurs in almost all the fluids, and in those solid parts which have carbon as a base. The almost universal prevalence of this principle in animal substances constitutes one of the most certain marks by which they may be distinguished from vegetables. Azote likewise occurs, in an uncombined state, in the air-bag of some fishes.

1922. *Phosphorus*. This inflammable body exists, in union with oxygen, in the state of phosphoric acid, in many of the solids and fluids of animals. Its existence, however, in an uncombined state, has not been satisfactorily determined, although there appears a tendency to refer the luminescence of several animals to the slow combustion of this substance. Even phosphoric acid can scarcely be said to exist in a separate state, being found in combination with potash, soda, ammonia, lime, or magnesia.

1923. *Sulphur*, in combination, exists in considerable abundance in animal substances. It can scarcely be said to occur in a separate state in animals; at least, the experiments which may be quoted as encouraging such a supposition are by no means decisive. United with oxygen, in the form of sulphuric acid, it exists in combination with potash, soda, and lime.

1924. *Fluoric acid* has been detected in bones and urine, in a state of combination with lime.

1925. *Muriatic acid* exists in a great number of the animal fluids, in combination with an alkali, as in the ammonia and soda of urine.

1926. *Iodine* has been detected in sponge.

1927. *Potash* exists in combination with the sulphuric, muriatic, or phosphoric acids; but it is far from abundant in animal fluids.

1928. *Soda* is present in all the fluids in various states of combination, and is more abundant than the preceding. It gives to many of the secretions the alkaline property of changing vegetable blues into green. It is found in union with the carbonic, phosphoric, sulphuric, and muriatic acids.

1929. *Ammonia* exists in its elements in all the fluids, and many of the solids, of animals, and is frequently produced during putrefaction. These elements are likewise found united in the system, and the alkali then appears in union with the various acids, as the phosphoric, muriatic, and lactic.

1930. *Lime*, of which the hard parts of animals, such as bones and shells, are principally composed, is of universal occurrence. It is always in a state of combination, and chiefly with the carbonic or phosphoric acids.

1931. *Magnesia* occurs sparingly. It has been detected in the bones, blood, and some other substances, but always in small quantity, and chiefly in union with phosphoric acid.

1932. *Silica* occurs more sparingly than the preceding. It is found in the hair, urine, and urinary calculi.

1933. *Iron* has hitherto only been detected in the colouring matter of the blood, in bile, and in milk. Its peculiar state of combination in the blood has given rise to various conjectures; but a satisfactory solution of the question has not yet been obtained. In milk, it appears to be in the state of phosphate.

1934. *Manganese*, in oxide, has been observed, along with iron, in the ashes of hair.

1935. Such are the simple substances which have been detected by chemists in the solids and fluids of animals; but seldom in a free state, and often in such various proportions of combination to render it extremely difficult to determine their true condition.

1936. *The compounds of organisation* are gelatine, albumen, fibrin, mucus, urea, sugar, oils, and acids.

1937. *Gelatine* occurs in nearly a pure state in the air-bags of different kinds of fishes, as, for example, isinglass, which, if dissolved in hot water and allowed to cool, forms jelly. When a solution of tannin is dropped into a solution of gelatine, a union takes place, and an insoluble precipitate of a whitish colour falls to the bottom. It is on the union of the tannin of the oak bark with the gelatine of the hides, that the process of tanning leather depends. Gelatine exists in abundance in different parts of animals, as bones, muscles, skin, ligaments, membranes, and blood. It is obtained from these substances by boiling them in warm water; removing the impurities, by skimming, as they rise to the surface, or by subsequent straining and clarifying. It is then boiled to a proper consistence. It is the characteristic ingredient of the softest and most flexible parts of animals.

1938. *Gelatine* is extensively used in the arts, under the names of glue and size, on account of its adhesive quality, and to give the requisite stiffness to certain articles of manufacture. In domestic economy, it is likewise employed in the form of jelly, and in the formation of various kinds of soup. What is termed *Portable Soup* is merely jelly which has been dried, having been previously seasoned, according to the taste, with different spices.

1939. *Albumen*, the white of an egg, exists in great abundance, both in a coagulated and liquid state, in the different parts of animals. Hair, nails, and horn are composed

of it. It appears likewise as a constituent of bone and shell; and there are few of the fluid or soft parts of animals in which it does not exist in abundance. What has hitherto been termed the *Resin of Bile* is, according to Berzelius, analogous to albumen.

1940. *Albumen is extensively used in the arts.* When spread thin on any substance, it soon dries, and forms a coating of varnish. Its adhesive power is likewise considerable. When rubbed on leather, it increases its suppleness. But its chief use is in clarifying liquors. For this purpose, any substance abounding in albumen, as the white of eggs, or the serum of blood, is mixed with the liquid, and the whole heated to near the boiling point. The albumen coagulates, and falls to the bottom, carrying along with it the impurities which were suspended in the fluid, and which rendered it muddy. If the liquor contains alcohol, the application of heat is unnecessary.

1941. *Fibrin* exists in the blood, and was formerly called the fibrous part of the blood. It likewise exists in all muscles, forming the essential part, or basis, of these organs. It exhibits many remarkable varieties, as it appears in the flesh of quadrupeds, birds, and fishes; but has not hitherto been turned to any particular use.

1942. *Extractive* exists in the muscles of animals, in the blood, and in the brain. It communicates the peculiar flavour of meat to soups. In the opinion of Fourcroy, the brown crust of roasted meat consists of it.

1943. *The soft parts of animals are constituted of these four substances*, which also enter into the composition of the hard parts and of the fluids. They are readily distinguishable from one another. Extractive alone is soluble in alcohol; gelatine is insoluble in cold, but soluble in hot, water; albumen is soluble in cold, and insoluble in hot, water; the fibrin is equally insoluble in hot and cold water. They are variously mixed or united; and as they consist of some elementary principles, chiefly carbon, hydrogen, oxygen, and azote, it is probable that they are in many cases changed, the one into the other, by the living principle; a transmutation which the chemist has succeeded in accomplishing, and which may soon be of advantage in the arts. The proportion of carbon appears to be least in gelatine and greatest in fibrin.

1944. *Mucus* occurs in a liquid state in the animal economy, as a protecting covering to different organs. It necessarily differs in its qualities, according to the purposes it is destined to serve. In the nose, it defends the organ of smell from the drying influence of the air; in the bladder, it protects the interior from the contact of the acid of the urine; while it preserves the gall-bladder from the action of alkaline bile. It does not contain any suspended particles like the blood, but is homogeneous. (*Dr. Young, Annals of Phil.*, vol. ii. p. 117.) When inspissated, it constitutes, in the opinion of some, the basis of the epidermis, horns, nails, and feathers. But the difficulty of obtaining it in a pure state, and the discordant characters assigned to it by different chemists, prevent us from reposing confidence in the accuracy of the analysis of those substances, of which it is considered as forming an essential ingredient.

1945. *Urea* is a substance obtained by evaporation and trituration from the urine of the Mammalia when in a state of health. In the human subject it is less abundant after a meal, and nearly disappears in the disease called diabetes, and in affections of the liver.

1946. *Sugar* exists in considerable abundance in milk, and in the urine of persons labouring under diabetes. In the latter fluid, it is to be considered as a morbid secretion of the kidneys, occupying the natural situation of the urea. In milk, however, it exists as a constituent principle, and may readily be obtained by the following process: evaporate fresh whey to the consistence of honey, dissolve it in water, clarify with the whites of eggs, and again evaporate to the consistence of syrup. On cooling, white cubical crystals will be obtained, but less sweet than vegetable sugar.

1947. *Oils* vary greatly as to colour, consistence, smell, and other characters. They possess, however, in common, the properties of the fixed oils, in being liquid, either naturally or when exposed to a gentle heat, insoluble in water and alcohol, leaving a greasy stain upon paper, and being highly combustible. They are distinguished as spermaceti, ambergris, fat, and common oils.

1948. *Spermaceti* constitutes the principal part of the brain of the whale, and is freed from the oil which accompanies it by draining and squeezing, and afterwards by the employment of an alkaline lye, which saponifies the remainder. It is then washed in water, cut into thin pieces with a wooden knife, and exposed to the air to dry. It is used in medicine and candlemaking.

1949. *Amebergis* is found in the intestines of the spermaceti whale, and in those only which are in a sickly state. It appears to be the excrement, altered by a long retention in the intestines, and therefore scarcely merits a place among the natural ingredients of the animal system. Upon being voided by the animal, it floats on the surface of the sea, and has been found in various quarters of the globe. It usually has the beaks of cuttle-fish adhering to it. It is employed in small quantities by druggists and perfumers.

1950. *Fat* consists of two substances, suet and oil. It is usually purified by separating the vessels and membranes which adhere to it, by repeatedly washing with cold water, and afterwards melting it, along with boiling water.

1951. *Tallow* is the fat of ruminating animals, and is hard and brittle; while the fat of the hog, called *lard*, is soft and gemifluid. Its uses, as an article of food, in the making of candles, hard soap, and ointments, and to diminish friction, are well known.

1952. *The properties of oils* depend in a great degree on the mode of preparation, with the exception of the odour, which arises from the kind of animal from which the oil has been derived. *Spermaceti oil* is considered as the thinnest of the animal oils, and the fittest for burning in lamps. It is obtained from the spermaceti, by draining and pressure. *Train oil* is procured by melting the blubber, or external layer of fat, found underneath the skin of different kinds of whales and seals. From the process employed, it

contains, besides the oil, gelatine, albumen, and other animal matters, which render it thick, dark-coloured, and disposed to become rancid. *Fish oil* is sometimes extracted from the entire fish (as the sprat, pilchard, and herring, when they occur in too great quantities to be salted), by boiling in water, and skimming off the oil, as it appears on the surface. In general, however, the oil is obtained from the livers of fish, in which it is lodged in cells.

1953. The *acids* found in animals consist of various proportions of carbon, hydrogen, oxygen, and azote. Some of them are peculiar to the animal kingdom, and others exist in equal abundance in plants.

1954. The *uric* or *lithic acid* abounds in urine, and appears to be a production of the kidneys. The *lactic acid* is common in the animal fluids. The *amniotic acid* has been found in the uterus of a cow. The *formic acid* is procured by distilling ants. The *benzoic, oxalic, acetic, and malic acids* are common both to plants and animals, but seldom occur in the latter.

1955. These *elements*, by combining in different proportions, exhibit a great variety of separate substances. The earthy salts are likewise abundant; and when they occur in a separate state, they strengthen the albuminous framework, and form the skeleton, giving stability to the body, and acting as levers to the muscles. The alkaline salts occur in the greatest abundance in the secreted fluids.

1956. The *fluids* consist of those juices which are obtained from our food and drink, such as the chyle, and are termed *crude* of the *blood*, or prepared from the crude fluids, and destined to communicate to every part of the body the nourishment which it requires; and of those fluids which are separated from the blood, in the course of circulation, such as the bile, and termed secreted fluids. These are all contained in appropriate vessels, and are subject to motion and change.

1957. The *solids* are derived from the fluids, and are usually divided into the soft and hard. The soft solids consist chiefly of what is termed animal matter, of combinations of carbon, hydrogen, oxygen, and azote. They consist of fibres, which are usually grouped into faggots; of plates, which, crossing one another in various directions, give rise to cellular structure, or of a uniform pulpy mass.

1958. The *fibrous texture* may be observed in all the muscles, tendons, and ligaments, and in the bones of many animals, especially before birth. These fibres, however minutely divided, do not appear to be hollow, like those of the vegetable kingdom.

1959. The *cellular texture* is universally distributed in the form of membranes, which invest every organ, the bundles of fibres in every muscle, and, by forming tubes with the addition of the fibrous texture, constitute the containing vessels. The substance gives form to all the different parts, and is that particular portion which is first formed, and which constitutes the frame on and within which the other materials of the system are deposited. It readily expands by the increase of its contents; and, with equal ease, contracts, when the distending cause is removed.

1960. The *pulpy texture* is confined to the brain and nerves, the liver, kidneys, and other secreting organs of the system. Its composition appears to the eye homogenous, and its form is regulated by its cellular envelope.

1961. These *soft solids* alone are capable of possessing the faculty of sensation. By their aid, the nervous energy is exerted on the different parts of the body; and, through them, the impressions of external objects are received.

1962. The *hard solids* consist either of cartilage, which resembles, in its qualities, coagulated albumen; or of bone, formed by various combinations of earthy salts. They are destitute of sensation, and are chiefly employed in defending the system from injury, giving it the requisite stability, and assisting the muscles in the execution of their movements.

*1963. The *proportion between the solids and fluids* is not only remarkably different in different species, but in the same species, in the various stages of growth.

CHAP. IV.

Animal Physiology; the Digestive, Circulating, and Reproductive Functions of Animals.

SECT. I. *Of the Digestive System.*

1964. The *instinct of animals for food* presides over the organs of the stomach. Hunger is felt when the stomach is empty; it is promoted by exercise, cold air applied to the skin, and cold, acid, or astringent fluids introduced into the stomach. Inactivity, warm covering, the attention diverted, and warm fluids, have a tendency to allay the sensation.

1965. *Thirst* is accompanied with a sensation of dryness in the mouth. This dryness may be occasioned by excessive expenditure of the fluids, in consequence of the dryness or saltness of the food which has been swallowed; or to their deficiency, from the state of the organs.

1966. *Both hunger and thirst*, besides being greatly influenced by habit, exhibit very remarkable peculiarities, according to the species and tribes of animals.

1967. Those which live on the spoils of the animal kingdom are said to be carnivorous, when they feed on flesh; piscivorous, when they subsist on fishes; and insectivorous, when they prey on insects. Again, those animals which are phytivorous, or subsist on the products of the vegetable kingdom, are either granivorous and feed on seeds; graminivorous, pasturing on grass; or herbivorous, browsing on twigs and shrubs.

1968. *Besides those substances which animals make use of as food, water is likewise employed as drink, and as the vehicle of nutritious matter. Salt is necessarily mixed with the drink of the inhabitants of the ocean, and is relished by man and many other animals. Other inorganic substances are likewise employed for a variety of purposes. Many savages make use of steatite and clay along with their food. The common earthworm swallows the soil, from which, in its passage through the intestines, it extracts its nourishment.*

1969. *In some cases, substances are swallowed for other purposes than nourishment. Stones are retained in the stomach of birds to assist in triturating the grain. The wolf is said to satisfy his hunger by filling his stomach with mud.*

SECT. II. *Of the Circulating System.*

1970. *The food being reduced to a pulvaceous mass, and mixed with a variety of secreted fluids, by means of the digestive organs, is in this state denominated chyme. This mixture exhibits a chemical constitution nearly approaching that of blood, into which it is destined to be converted, by the separation of the useless from the useful part. This is effected by certain vessels called lacteals, which absorb the nutritious part of the chyme, and convey it to a particular receptacle. Another set of absorbents, the lymphatics, take up all the substances which have been ejected from the circulation, and which are no longer necessary in the particular organs, and communicate their contents to the store already provided by the lacteals. The veins receive the altered blood from the extremities of the arteries or the glands, in which they terminate, and proceed with it towards the lungs, to be again aerated. In their progress they obtain the collected fluid of the other absorbents, and, in the lungs, again prepare the whole for the use of the system. Thus, during the continuance of life, the arteries supply the materials by which the system is invigorated and enlarged, and oppose that tendency to decay, produced by the influence of external objects. The process continues during the whole of life, new matter is daily added, while part of the old and useless is abstracted. The addition is greatest in early life, the abstraction is greatest in old age.*

1971. *This continued system of addition and subtraction has led some to conclude, that a change in the corporeal identity of the body takes place repeatedly during the continuance of life; that none of the particles of which it consisted in youth remain in its composition in old age. Some have considered the change effected every three, others every seven, years. This opinion, however, is rendered doubtful by many well known facts. Letters marked on the skin by a variety of substances frequently last for life. There are some diseases, such as small-pox and measles, of which the constitution is only once susceptible; but it is observed to be liable to the attack of these diseases at every period of human life.*

SECT. III. *Of the Reproductive System of Animals.*

1972. *Animals are reproduced in consequence of the functions of certain organs, with the exception of some of the very lowest in the scale. In those animals which possess peculiar organs for the preparation of the germ or ovum, some are androgynous (man-woman), and either have the sexual organs incorporated, and capable of generating without assistance, or the sexual organs are distinct, and the union of two individuals is necessary for impregnation: others have the sexual organs separate, and on different individuals. The young of such animals are either nourished at first by the store of food in the egg, or by the circulating juices of the mother. Those species in which the former arrangement prevails are termed oviparous, while the term viviparous is restricted to the latter.*

1973. *In all animals it is the business of the female to prepare the ovum or germ, and bring it to maturity. For this purpose, the germ is produced in the ovary, farther perfected in the uterus or matrix, and finally expelled from the system through the vagina. The office of the male is to impregnate the germ by means of the spermatic fluid. This fluid is secreted in the testicles, transmitted by the spermatic ducts, and finally conveyed by the external organ to its ultimate destination.*

1974. *Among the viviparous animals, the reproductive organs present many points of resemblance, and appear to be constructed according to a common model. It is otherwise with the sexual organs of the oviparous tribes. These exhibit such remarkable differences in form and structure that it is impossible to collect them into natural groups, or assign to them characters which they have in common.*

1975. *The manner in which the eggs of birds are impregnated by the male has not been satisfactorily determined. With the exception of the cicatricula, a female bird, in the absence of the male, can produce an egg. The conjunction of the sexes, however, is necessary for the impregnation of the egg, and the effect is produced previous to the exclusion.*

1976. *In many kinds of fishes and reptiles, the yolks, after being furnished with their glair, are ejected from the body of the female, and the impregnating fluid from the male is afterwards poured over them. Impregnation can be effected readily in such cases, by the artificial application of the spermatic fluid.*

1977. *Impregnation in insects appears to take place while the eggs pass a reservoir containing the sperm, situated near the termination of the oviduct in the volva.*

1978. *The most simple mode of hatching is effected by the situation in which the eggs are placed by the mother, after or during their exclusion. In this mode a place is usually selected where the eggs will be*

exposed to a suitable and uniform temperature, and where a convenient supply of food may be easily obtained for the young animals. Such arrangements prevail in the insect tribe.

1979. In the *second mode*, the mother, aided in some cases by the sire, forms a nest, in which she deposits her eggs, and, sitting upon them, aids their hatching by the heat of her body. Birds in general hatch their young in this manner.

1980. In the *third mode*, the eggs are retained in the uterus, without any connection, however, by circulating vessels, until the period when they are ready to be hatched, when egg and young are expelled at the same time. This takes place in some sharks and Mollusca. The animals which exercise this last kind of incubation are termed ovoviviparous. In the *Rana pipa*, the eggs are deposited in a bag on the back, where they are hatched, and where the young animals reside for some time after birth. Some animals, as the aphids, are viviparous at one season, and ovoviviparous at another.

1981. *The young, after being hatched*, are, in many cases, independent of their parent, and do not stand in need of any assistance: they are born in the midst of plenty, and have organs adapted to the supply of their wants. Thus, many insects are hatched on, or within the very leaves which they are afterwards to devour. In other cases, the young are able to follow their parents, and receive from them a supply of appropriate food; or, if unable to follow, their parents bring their food to the nests.

1982. *The changes which the young of oviparous animals undergo in passing from infancy to maturity* have long attracted the notice of the inquisitive observer. The egg of the frog is hatched in the water, and the young animal spends in that element a part of its youth. While there it is furnished with a tail and external bruchiae; both of which are absorbed, and disappear, when it becomes an inhabitant of the land. The infancy of the butterfly is spent in the caterpillar state, with organs of motion and mastication which are peculiar to that period. It is destined to endure a second hatching, by becoming enveloped in a covering, and suffering a transformation of parts previously to appearing in its state of maturity. These metamorphoses of oviparous animals present an almost infinite variety of degrees of change, differing in character according to the tribes or genera.

1983. In *birds*, it is well known that one sexual union suffices for the production of impregnated eggs during the period of laying. This is a case somewhat analogous to those quadrupeds which produce several young at a birth with one impregnation, differing however, in the circumstance that the eggs are not all produced at the same time, although they are afterwards hatched by the same incubation. In the *Aphides*, or plant-lice, as they are called, one impregnation not only renders fertile the eggs of the individual, but the animals produced from these, and the eggs of those again, unto the ninth generation.

1984. *Androgynous animals* are of two kinds; those where impregnation takes place by the mutual application of the sexual organs of two individuals; and those where the hermaphroditism is complete. The Mollusca exhibit examples of both kinds.

1985. *Gemmiparous animals* are exemplified in the *Hÿdra* or fresh-water polypus, and other zoophytes.

1986. *Hybridous animals*. In the accomplishment of the important purpose of generation, it is observed, that, in the season of desire, individuals of a particular species are drawn together by mutual sympathy, and excited to action by a common propensity. The produce of a conjunction between individuals of the same species partakes of the characters common to the species, and exhibits in due time the characteristic marks of puberty and fertility. In a natural state, the selective attribute of the procreative instinct unerringly guides the individuals of a species towards each other, and a preventive aversion turns them with disgust from those of another kind. In a domesticated state, where numerous instincts are suppressed, and where others are fostered to excess, individuals belonging to different species are sometimes known to lay aside their natural aversion, and to unite in the business of propagation. Instances of this kind occur among quadrupeds, birds, and fishes, among viviparous and oviparous animals, where impregnation takes place within, as well as when it is effected without, the body. The product of such an unnatural union is termed a hybridous animal. The following circumstances appear to be connected with hybridous productions:—

1987. *The parents must belong to the same natural genus or family*. There are no exceptions to this law. Where the species differ greatly in manners and structure, no constraints or habits of domestication will force the unnatural union. On the other hand, sexual union sometimes takes place among individuals of nearly related species. Thus, among quadrupeds, the mule is the produce of the union of the horse and the ass. The jackall and the wolf both breed with the dog. Among birds, the canary and goldfinch breed together, the Muscovy and common duck, and the pheasant and hen. Among fishes, the carp has been known to breed with the tench, the crusian, and even the trout. (*Phil. Trans.*, 1771, p. 318.)

1988. *The parents must be in a confined or domesticated state*. In all those hybridous productions which have yet been obtained, there is no example of individuals of one species giving a sexual preference to those of another. Among quadrupeds and birds, those individuals of different species which have united, have been confined and excluded from all intercourse with those of their own kind. In the case of hybridous fishes, the ponds in which they have been produced have been small and overstocked, and no natural proportion observed between the males and females of the different kinds. As the impregnating fluid, in such situations, is spread over the eggs after exclusion, a portion of it belonging to one species may have come in contact with the unimpregnated eggs of another species, by the accidental movements of the water, and not in consequence of any unnatural effort. In all cases of this unnatural union among birds or quadrupeds, a considerable degree of aversion is always exhibited, a circumstance which never occurs among individuals of the same species.

1989. *The hybridous products are barren*. The peculiar circumstances which are required to bring about a sexual union between individuals of different species sufficiently account for the total absence of hybridous productions in a wild state; and, as if to prevent even in a domesticated state the introduction and extension of spurious breeds, such hybridous animals, though in many cases disposed to sexual union, are incapable of breeding. There are, indeed, some statements which render it probable that hybrid animals have procreated with perfect ones; at the same time there are few which are above suspicion.

CHAP. V.

Animal Pathology; or the Duration, Diseases, and Casualties of Animal Life.

1990. *Each species of animal is destined, in the absence of disease and accidents, to enjoy existence during a particular period.* In no species, however, is this term absolutely limited, as we find some individuals outliving others, by a considerable fraction of their whole lifetime. In order to find the ordinary duration of life of any species, therefore, we must take the average of the lives of a number of individuals, and rest satisfied with the approximation to truth which can thus be obtained. There is little resemblance in respect of longevity between the different classes, or even species, of animals. There is no peculiar structure, by which long-lived species may be distinguished from those that are short-lived. Many species whose structure is complicated live but for a few years, as the rabbit; while some of the testaceous Mollúsca, with more simple organisation, have a more extended existence. If longevity is not influenced by structure, neither is it modified by the size of the species. While the horse, greatly larger than the dog, lives to twice its age, man enjoys an existence three times longer than the former.

1991. *The circumstances which regulate the term of existence in different species exhibit so many peculiarities, corresponding to each, that it is difficult to offer any general observations on the subject.* Health is precarious, and the origin of diseases generally involved in obscurity. The condition of the organs of respiration and digestion, however, appears so intimately connected with the comfortable continuance of life, and the attainment of old age, that existence may be said to depend on the due exercise of the functions which they perform. Whether animals have their blood aerated by means of lungs or gills, they require a regular supply of oxygen gas: but as this gas is extensively consumed in the process of combustion, putrefaction, vegetation, and respiration, there is occasionally a deficiency in particular places for the supply of animal life. In general, where there is a deficiency of oxygen, there is also a quantity of carbonic acid or carburetted hydrogen present. These gases not only injure the system by occupying the place of the oxygen which is required, but exercise on many species a deleterious influence. To these circumstances may be referred the difficulty of preserving many fishes and aquatic Mollúsca in glass jars or small ponds; as a great deal of the oxygen in the air contained in the water is necessarily consumed by the germination and growth of the aquatic Cryptogamia, and the respiration of the infusory Animácula. In all cases, when the air of the atmosphere, or that which the water contains, is impregnated with noxious particles, many individuals of a particular species, living in the same district, suffer at the same time. The disease which is thus at first endemic or local, may, by being contagious, extend its ravages to other districts.

1992. *The epidemical and epidemical diseases which attack horses, sheep, and cows, obtain in this country the name of murrain, sometimes also that of the distemper.* The general term, however, for the pestilential diseases with which these and other animals are infected, is Epizooty (*epi*, amongst, *zoon*, an animal).

1993. *The ravages which have been committed among the domesticated animals, at various times, in Europe, by epizootics, have been detailed by a variety of authors.* Horses, sheep, cows, swine, poultry, fish, have all been subject to such attacks; and it has frequently happened, that the circumstances which have produced the disease in one species have likewise exercised a similar influence over others. That these diseases arise from the deranged functions of the respiratory organs, is rendered probable by the circumstance that numerous individuals, and even species, are affected at the same time; and this opinion is strengthened, when the rapidity with which they spread is taken into consideration.

1994. *Many diseases, which greatly contribute to shorten life, take their rise from circumstances connected with the organs of digestion.* Noxious food is frequently consumed by mistake, particularly by domesticated animals. When cows, which have been confined to the house during the winter season, and fed with straw, are turned out to the pastures in the spring, they eat indiscriminately every plant presented to them, and frequently fall victims to their imprudence. It is otherwise with animals in a wild state, whose instincts guard them from the common noxious substances of their ordinary situation. The shortening of life, in consequence of the derangement of the digestive organs, is chiefly produced by a scarcity of food. When the supply is not sufficient to nourish the body, it becomes lean, the fat being absorbed to supply the deficiency; feebleness is speedily exhibited, the cutaneous and intestinal animals rapidly multiply, and, in conjunction, accelerate the downfall of the system.

1995. *The power of fasting, or of surviving without food, possessed by some animals, is astonishingly great.* An eagle has been known to live five weeks without food; a badger a month; a dog thirty-six days; a toad fourteen months, and a beetle three years. This power of outliving scarcity for a time, is of signal use to many animals, whose food cannot be readily obtained; as is the case with beasts of prey and rapacious birds. But this faculty does not belong to such exclusively: wild pigeons have survived twelve days, an antelope twenty days, and a land tortoise eighteen months. Such fasting, however, is detrimental to the system, and can only be considered as one of those singular resources which may be employed in cases where, without it, life would speedily be extinguished. In situations where animals are deprived of their accustomed food, they frequently avoid the effects of starvation, by devouring substances to which their

digestive organs are not adapted. Pigeons can be brought to feed on flesh, and hawks on bread. Sheep, when accidentally overwhelmed with snow, have been known to eat the wool off each other's backs.

1996. *The various diseases to which animals are subject tend greatly to shorten the period of their existence.* With the methods of cure employed by different species we are but little acquainted. Few accurate observations appear to have been made on the subject. Dogs frequently effect a cure of their sores by licking them. They eat grass to excite vomiting, and probably to cleanse their intestines from obstructions or worms, by its mechanical effects. Many land animals promote their health by bathing, others by rolling themselves in the dust. By the last operation, they probably get rid of the parasitical insects with which they are infested.

1997. *But independently of scarcity, or disease, comparatively few animals live to the ordinary term of natural death.* There is a wasteful war every where raging in the animal kingdom. Tribe is divided against tribe, and species against species, and neutrality is nowhere respected. Those which are preyed upon have certain means which they employ to avoid the foe; but the rapacious are likewise qualified for the pursuit. The exercise of the feelings of benevolence may induce us to confine our attention to the former, and adore that goodness which gives shelter to the defenceless, and protection to the weak, while we may be disposed to turn precipitately from viewing the latter, lest we discover marks of cruelty, where we wished to contemplate nothing but kindness. But we should recollect, that, to the lower animals, destitute as they are of the means of attending to the aged or diseased, sudden death is a merciful substitute for the lingering tortures of starvation.

CHAP. VI.

On the Distribution of Animals.

1998. *On a superficial view, vegetables seem more abundant than animals:* so contrary, however, is this to fact, that the species of animals, when compared with those of plants, may be considered in the proportion of 10 to 1. Hence it follows that botany, when compared with zoology, is a very limited study: plants, when considered in relation to insects alone, bear no proportion in the number of the species. The phanerogamous plants of Britain have been estimated in round numbers at 1500, while the insects that have already been discovered in this country (and probably many hundreds still remain unknown) amount to 10,000, which is more than six insects to one plant. It is therefore obvious that the knowledge acquired on the geographical distribution of animals, in comparison with what is known of plants, is slight and unsatisfactory: it is likewise attended with difficulties inseparable from the nature of beings so numerous and diversified, and which will always render it comparatively imperfect. It rarely happens that a single specimen of a plant is found isolated; the botanist can therefore immediately arrive at certain conclusions: if he is in a mountainous country, he is enabled to trace, without much difficulty, the lowest and the highest elevation at which a particular species is found; and the nature of the soil, which may be considered the food of the plant, is at once known. But these advantages do not attend the zoologist: his business is with beings perpetually moving upon the earth, or hid in the depths of ocean, performing numerous functions in secret; while of the marine tribes he can never hope to be acquainted with more than a very insignificant portion. The following observations must therefore be considered as merely an outline of those general laws which seem to regulate the geography of animals.

1999. *The distribution of animals on the face of the globe must be considered under two heads, general and particular.* The first relates to families or groups inhabiting particular zones, and to others by which they are represented in another hemisphere. The second refers to the local distribution of the animals of any particular country, or to that of individual species. It is to the general distribution of groups, as a celebrated writer has well observed, that the philosophic zoologist should first direct his attention, rather than to the locality of species. By studying nature in her higher groups, we discover that certain functions are developed under different forms, and we begin to discern something of the great plan of providence in the creation of animals, and arrive at general results, which must be for ever hid from those who limit their views to the habitations of species, or to the local distribution of animals.

2000. *Animals, like plants, are generally found to be distributed in zones.* Fabricius, in speaking of insects, divides the globe into eight climates, which he denominates the Indian, Egyptian, southern, Mediterranean, northern, oriental, occidental, and alpine. In the first he includes the tropics; in the second, the northern region immediately adjacent; in the third, the southern; in the fourth, the countries bordering on the Medi-

terranean Sea, including also Armenia and Media; in the fifth, the northern part of Europe, interjacent between Lapland and Paris; in the sixth, the northern part of Asia, where the cold in winter is intense; in the seventh, North America, Japan, and China; and in the eighth, all those mountains whose summits are covered with eternal snow. It is, however, easy to perceive, that this, though a very ingenious, is a very artificial theory: the divisions are vague and arbitrary, and we know that animals of one country differ essentially from those of another, although both may enjoy the same degree of temperature. M. Latreille has therefore attempted a more definite theory. His two primary divisions are the arctic and antarctic climates, according to their situation above or below the equinoctial line; and taking twelve degrees of latitude for each climate, he subdivides the whole into twelve. Beginning at 84° N.L., he has seven arctic climates: viz. the polar, subpolar, superior, intermediate, supratropical, tropical, and equatorial: but his antarctic climates, as no land has been discovered below 60° S.L., amount only to five, beginning with the equatorial, and terminating with the superior. He proposes also a further division of subclimates, by means of certain meridian lines; separating thus the old world from the new, and subdividing the former into two great portions; an eastern, beginning with India; and a western, terminating with Persia. He proposes, further, that each climate should be considered as having 24° of longitude and 12° of latitude. This system certainly approximates more to what we see in nature than that proposed by Fabricius; yet Mr. Kirby observes with truth, that the division of the globe into climates by equivalent parallels and meridians wears the appearance of an artificial and arbitrary system, rather than of one according to nature.

2001. *Mr. Swainson considers that the geographic distribution of animals is intimately connected with the limits of those grand and obvious sections into which the globe is divided; and that in proportion to the geographical proximity of one continent to another, so will be either the proportional identity or the analogy of their respective animals. He considers Europe, Asia, and Africa as agreeing more particularly in possessing certain animals in common, which seem excluded altogether from America and Australia; both of which are not only isolated in situation, but their animals have a decided difference of form and habit from those of the three continents of the old world. He considers that the animal geography of Asia is connected with that of Australia by the intervention of Borneo, New Guinea, and the neighbouring isles; while that of America unites with Europe towards the polar regions. These five great types or divisions will, of course, present certain affinities or analogies dependent upon other causes, arising from temperature, food, and locality. (Swainson's MSS.)*

2002. *Vertebrated animals have a wider range than invertebrated animals, thus resembling man, who is spread over the whole earth: the dog and the crow are found wild in almost every climate; the swallow traverses, in a few days, from the temperate to the torrid zone; and numerous other birds annually perform long migrations. Next to these, insects, above all the other Invertebrata, enjoy the widest range; the house fly of America and of Europe are precisely the same; and Mr. Swainson has observed in Brazil vast flocks of butterflies, which annually migrate from the interior towards the coast.*

2003. *Marine animals have, in general, a wider range than those strictly terrestrial. This may probably originate in their being more independent of the effects of temperature. It is remarkable, that, with the exception of the crow and two or three others, the land birds of America differ entirely from those of Europe, yet that nearly all our aquatic species are found both in the new world and in the southern coasts of Africa.*

2004. *Subordinate to the five geographic groups already noticed, temperature may be considered the principal regulator of the station of animals; it has likewise a remarkable influence on their clothing. Many quadrupeds, inhabiting the colder regions, appear in their natural colours during summer, but become white in winter. The same change takes place in the plumage of several land birds; but is not observable in insects, or the other invertebrate groups. Temperature has likewise a great influence on the size and colour of animals. The *Sphinx convolvuli* of Europe is found also in India, but of a much smaller size and more distinctly coloured: this is usually the effect of heat upon animals whose chief range is in temperate latitudes. On those which may be considered intertropical, a greater degree of heat not only increases the brilliancy of their colours, but adds to their size. There are many birds and insects common both to central Brazil and Cayenne; but from the greater heat of the latter country, the specimens are always larger and their plumage more beautiful. Temperature likewise affects the clothing of animals in respect both to quality and quantity. This is more particularly observed in such domesticated animals as have been transplanted from their natural climates. The covering of swine in warm countries consists of bristles of the same form and texture, thinly dispersed; while the same animals in colder climates have an additional coating of fine frizzled wool next the skin, over which the long bristly hairs project. This difference is very remarkable in the swine of northern Europe and those of tropical America, the latter appearing almost naked: it may be observed in a less*

degree in those of the south of England and the north of Scotland. Similar appearances present themselves among the sheep of warm and cold countries: the fleece of those of England consists entirely of wool, while the sheep of Shetland and Iceland possess a fleece, containing, besides the wool, a number of long hairs, which give it an appearance of being very coarse.

2005. *The particular or local distribution of animals* is affected by various causes which have little influence on their geographic distribution. Thus the purely insectivorous birds of the family *Sylviadæ* feed on all kinds of small insects, without regard to any particular species; yet the *Sylviadæ* of America and those of Europe are each characterised by a peculiarity of structure which invariably designates the continent to which they belong. The wryneck is represented in America by the *Oxyrhynchus cristatus Swains.* (*Zool. Ill. i. p. 149.*); yet neither of these birds are found to inhabit all parts of their respective continents: their range, on the contrary, is regulated by temperature, food, and other circumstances connected with local distribution. (*Swinson's MSS.*)

2006. *From temperature originate all the causes which affect local distribution*, namely, food, situation, and migration. Were the climate of this country as unchanging as that of Brazil, the insects which now have only a single brood in the year might then produce several, and the swallow would no longer be obliged to quit us as now, for food in other climates, as soon as our insect season was at an end. Migration and torpidity are equally the effect of temperature; the first depends upon the effect which the changes of the seasons produce in the abundance or scarcity of food, whether animal or vegetable; the latter is a state of inaction during which the necessity for daily nourishment is suspended.

2007. *The migration of birds and of fish* is more extensive than that of quadrupeds. The birds of the Polar regions migrate to Britain during severe winters; while those of Africa come to us, in that season when the southern heats are most intense; but the same species which is migratory in one country is in some cases stationary in another. It is stated that the linnet is migratory in Greenland, but that it is stationary in Britain.

2008. *The torpidity or hibernation of animals* is evidently designed to suspend the necessity of taking food during the winter; although in some cases a small stock of provisions is laid up, most probably to serve for nourishment previously to entire torpidity taking place. Several quadrupeds are subject to this partial suspension of life, as the dormouse, hedgehog, bat, marmot, &c. It is said that birds have sometimes been found in a similar state; but this is very questionable. Among insects, on the contrary, torpidity is very common, and a large proportion, when undergoing transformation, pass a considerable part of their lives in this state.

2009. *Situation has an extensive influence on the local distribution of animals*, although it has little on the geographical distribution of groups. Air, earth, and water have their distinct inhabitants, which are again restricted to certain situations in their respective elements. The higher regions of the air are frequented by the eagle and falcon tribes; the middle by the air-feeding birds; and the lower by insects which merely jump, or just fly above the ground. The different situations on land, as mountains, plains, woods, marshes, and even sandy deserts, are each peopled by distinct races of beings, whose subsistence is sought for and furnished in peculiar spots. Thus the range of any particular species is seldom or never continuous, or uninterrupted to its confines; but is rather dependent upon local causes, quite unconnected with geographic division. Water is either the total or the partial residence of animals innumerable; but here situation has an equal influence; the deeps and the shallows of the ocean, its exposed or sheltered shores, its sandy, rocky, or muddy bottoms, are each the resort of different beings, widely distinct from those residing in the streams, lakes, rivers, and estuaries of fresh waters. It is principally among insects that we find the perfect animal inhabiting a situation different from that which was essential to its existence in an imperfect state. The larvæ of the May-fly, known to the vulgar by the name of case-worm (*Trichoptera Kirby*), and of all the *Libellulæ* live entirely in the water, preying upon other aquatic insects; but as soon as the period of transformation arrives, they crawl on the plants, just above the surface, and bursting the skin, become winged insects, which immediately commence an uninterrupted war upon others in their new element. The larva of the well known *Ephemera* is likewise aquatic, and spends nearly all its life in water; but the perfect insect is without jaws, mounts into the air, and seems born but to flutter and die. Many of the *Coleoptera* pass the first period of their existence entirely underground, others in the trunks of trees; and others again in putrid substances; situations very different from those which they frequent when arrived at maturity. Lepidopterous insects, after emerging from the eggs, undergo three changes, all of which are in situations totally opposite. In the larva state they reach their full dimensions by feeding upon the leaves of vegetables; they next pass into pupæ, and become torpid

either above or beneath the surface of the ground; from which they emerge, and again become inhabitants of earth and air as perfect winged insects.

2010. *The rapacity of carnivorous animals* has been considered by some writers to have had a considerable effect on the distribution and even on the extinction of others; but no instance has yet been brought forward in support of this argument, nor does history furnish us with any proof of such having been the case. The fossil remains of those stupendous carnivorous animals which have been discovered of late years, and which existed in the antediluvian world, might have suggested this idea as probable, and that the destruction among a host of smaller animals which would alone have satisfied the hunger of a brood of lizards (like the *Plesiosaurus*) forty feet long and six feet high, would soon have extirpated whole tribes; but it must not be forgotten that these gigantic animals belonged to a different creation from that which now covers the earth; and that neither in Africa nor in India, where the present races of carnivorous animals are most abundant, has any change or sensible diminution taken place in the proportion of those upon which they principally feed.

2011. *Man alone has exercised, in various ways, a powerful influence on animals*, and on their distribution: these changes, however, are purely artificial; they have caused the total or partial extinction of some species, and the extension and domestication of others. Against many, hostile to his interests, man carries on a war of extermination, which, as population spreads, is at length effected in particular countries. The wolf, once so abundant in Britain that their heads were received as tribute by our Saxon kings, has for centuries been extirpated from our forests; and a progressive decrease is continually going on among the wild animals, not only of Europe, but of North America. Others, inoffensive in their habits, but valued as food, have been driven from our island. The eyre and crane, as British birds, are no longer known; while the great bustard, which may be called the ostrich of Europe, is now rarely seen; and in all probability (unless its name should be inserted in the game laws), will be totally lost to us in a few years. In like manner that extraordinary bird the dodo (which was the ostrich of Asia) has not been seen for more than a century, and may possibly be no longer in existence. The benefits that have resulted, on the other hand, from the extension and domestication of useful animals are sufficiently known. All the various breeds of our domestic cock have originated from the forests of India, which have likewise furnished Europe with the pheasant and the peacock; the pintado or guinea fowl is of African origin; the horse and domestic ox were unknown in the new world before its discovery by the Spaniards; and the vast island of Australia has been supplied with all its domestic animals from Europe. The turkey is of American origin; and, although nearly extinct in its native forests, is domesticated all over the world. There are doubtless many other animals that might be domesticated, either for use or pleasure; but in a country like this, so variable in its climate, and where land is so valuable, it is much to be feared the necessary experiments will not be made.

2012. *The local distribution of British animals*, however interesting, is too confined a subject to lead to any general or important conclusions regarding the geographic distribution of animals. It is, however, an enquiry that merits attention; and although no one has yet expressly written upon the subject, the observations of White, Montague, and several others will furnish a great deal of valuable information. In arranging the British fauna, all such birds as have been seen apparently as wanderers, and only at long intervals of time, should be excluded, or at least distinctly noticed as accidental visitors; but to introduce the peacock, the domestic cock, and the turkey, into a natural history of British birds, as some have done, is a manifest absurdity; for upon this principle we should include the canary, the gold and silver pheasant, and all other exotic birds which may have accidentally bred in our aviaries.

СНАР. VII.

Of the Economical Uses of Animals.

2013. *On the importance of animals* in the arts, as labourers, and as furnishing food, clothing, medicine, and materials for various manufactures, it is needless to enlarge.

2014. *As labourers* the quadrupeds alone are employed; of these the most generally useful in this country are the horse, the ox, and the ass. The excellent carriage roads through most parts of Europe have superseded the necessity, in a great measure, of beasts of burden, although in the mountainous parts of Spain and Italy, and nearly throughout the whole of Sicily, mules alone are employed to convey goods and produce. Such likewise is the case throughout Mexico and Brazil. The camel in Northern Africa, and

the elephant in Asia, are no less essential to internal commerce. In the south of Italy, and in the European settlements in Africa, the ox alone is used in drawing carts and waggons, and in all other agricultural operations.

2015. *As articles of food* man employs animals belonging to every class, from the quadruped to the zoophyte. In some cases he makes choice of a part only of an animal, in other cases he devours the whole. He kills and dresses some animals, while he swallows others in a live state. The taste of man exhibits still more remarkable differences of a rational kind. The animals which are eagerly sought after by one tribe, are neglected or despised by another. Even those which are prized by the same tribe in one age, are rejected by their descendants in another. Thus the seals and porpoises, which, a few centuries ago, were eaten in Britain, and were presented at the feasts of kings, are now rejected by the poorest of the people.

2016. *Those quadrupeds and birds which feed on grass or grain* are generally preferred by man to those which subsist on flesh or fish. Even in the same animal, the flesh is not always of the same colour and flavour, when compelled to subsist on different kinds of food. The feeding of black cattle with barley straw has always the effect of giving to their fat a yellow colour. Ducks fed on grain have flesh very different in flavour from those which feed on fish. The particular odour of the fat of some animals seems to pass into the system unchanged, and, by its presence, furnishes us with an indication of the food which has been used. No animals have yet been discovered whose flesh is poisonous, although some few among the fishes and the mollusca are deleterious to the human constitution at particular seasons.

2017. *The use of skins, as articles of dress*, is nearly coeval with our race. With the progress of civilisation, the fur itself is used, or the feathers, after having been subjected to a variety of tedious and frequently complicated processes. Besides the hair of quadrupeds, and the feathers of birds, used as clothing, a variety of products of the animal kingdom, as bone, shells, pearls, and corals, are employed as ornaments of dress, in all countries, however different in their degree of civilisation.

2018. *Medicine*. The more efficient products of the mineral kingdom have in the progress of the medical art in a great measure superseded the milder remedies furnished by animals and vegetables. The blister-fly, however, still remains without a rival; and the leech is often resorted to, when the lancet can be of no avail.

2019. *The arts*. The increase of the wants of civilised life calls for fresh exertions to supply them, and the animal kingdom still continues to furnish a copious source of materials for the arts. Each class presents its own peculiar offering, and the stores which yet remain to be investigated appear inexhaustible.

CHAP. VIII.

Principles of improving the Domestic Animals used in Agriculture.

2020. *The animals in use in British agriculture* are few, and chiefly the horse, ox, sheep, swine, goat, and domestic fowls. The first is used solely as a labouring animal, and the rest chiefly as furnishing food. In applying the general principles of physiology to these animals with a view to their improvement for the use of man, we shall consider in succession the principles of breeding, rearing, and feeding.

SECT. I. *Objects to be kept in View in the Improvement of Breeds.*

2021. *The great object of the husbandman*, in every case, is to obtain the most valuable returns from his raw produce; to prefer that kind of live stock, and that breed of any kind, which will pay him best for the food the animal consumes. The value to which the animal itself may be ultimately brought, is quite a distinct and inferior consideration. (*Gen. Rep. Scot.*, c. xiv.)

2022. *To improve the form rather than to enlarge the size*, in almost every case, ought to be the grand object of improvement. Size must ever be determined by the abundance or scarcity of food, and every attempt to enlarge it beyond that standard must prove unsuccessful, and, for a time, destructive to the thriving of the animals, and the interest of their owners. It is certain that animals, too large or too small, will alike approach to that profitable size which is best adapted to their pastures; but the large animal becomes unhealthy, and degenerates in form, and in all its valuable properties; whereas the small one, while it increases in size, improves in every respect. (*Gen. Rep. Scot.*, c. xiv.)

SECT. II. *Of the Means of improving the Breed of Animals.*

2023. *By improvement of a breed* is to be understood the producing such an alteration in shape or description, as shall render the animal better fitted for the labours he has to perform; better fitted for becoming fat; or for producing milk, wool, eggs, feathers, or particular qualities of these. The fundamental principle of this amelioration is the pro-

per selection of parents. Three theories have obtained notice on this subject; the first in favour of breeding from individuals of the same parentage, called the *in-and-in* system; the second in favour of breeding from individuals of two different offsprings or varieties, called the system of *cross breeding*; and the third in favour of breeding from animals of the same variety, but of different parentage, which may be called *breeding in the line*, or in the same race. As is usual in such cases, none of these theories is exclusively correct, at least as far as respects agricultural improvement; for, as it will afterwards appear, the principles on which a selection for breeding so as to improve the carcass of the animal depends, will lead occasionally to either mode. *Breeding in the same line*, however, is the system at present adopted by what are considered the best breeders.

2024. *The size, form, and general properties* of the inferior animals in a state of nature may be always traced to the influence of soil and climate. Abundance of food, though of a coarse quality, will produce an enlargement of size in an animal which has been compelled to travel much for a scanty supply. Early maturity is also promoted by the same abundance; and if the food is of a better quality, and obtained without fatigue, a tendency to fatten at an early age will be gradually superinduced, and combined with a tameness and docility of temper, a general improvement of form, and a diminished proportion of offal; but at the same time such animals will not be capable of enduring the fatigue and privations to which the less fortunate natives of the mountains of Scotland and Wales are habituated from their earliest age.

2025. *Hardiness of constitution* is one of the most desirable properties of live stock, for districts producing only a very scanty supply of food for winter.

2026. *A barren and mountainous surface and rigorous climate* not only prohibit any considerable improvement in the quantity and quality of its produce, but at the same time prescribe to the husbandman the kind of stock which he must employ for consuming that produce. His cattle and sheep must be in a great measure the creatures of his own mountains and of his own climate. He cannot avail himself of the scientific principles which have so eminently improved the live stock of rich pastures. The most esteemed breeds of England, instead of returning a greater quantity of meat for their food, could not subsist at all upon the mountains of the north. The first object of the Highland farmer is to select animals that will live and thrive upon his pastures. Of two breeds nearly equally hardy, he will no doubt prefer the cattle that will give the most valuable carcass, and the sheep that will return the most money in wool and carcass. He has seldom any considerable extent of land which would fatten any breed; and, if he had, there is no market for it within his reach. With his live stock, as with his crops, he must be determined by his situation; and he would judge very ill, if he should lay aside his oats and big (native barley) for the more valuable but precarious crops of wheat and barley.

2027. *Early maturity* is a most valuable property in all sorts of live stock. With regard to those animals which are fed for their carcasses, it is of peculiar importance that they should become fat at an early age, because they not only sooner return the price of their food with the profits of the feeder, but in general also a greater value for their consumption than slow-feeding animals. A propensity to fatten at an early age is a sure proof that an animal will fatten speedily at any after period of its life.

2028. *Tameness and docility of temper* are desirable properties in most of the domesticated animals. These are also in some degree incompatible with the character of the live stock of mountainous districts, merely because they are necessarily subjected to a very slight degree of domestication, and must search for their food over a great extent of country. When they are reared in more favourable situations, plentifully supplied with food, and more frequently under the superintendance of man, their native wildness is in a great measure subdued. The same treatment which induces early maturity will gradually effect this change.

2029. *The quality of the flesh, the proportion which the fine and coarse parts bear to each other, and the weight of both to that of the offal*, constitute the comparative value of two animals of equal weight, destined to be the food of man. The first of these properties seems to be determined by the breed and food; the second by the form and proportions of the animal; and the third by all these and its degree of fatness. The flesh of well-formed small animals, both of cattle and sheep, is well known to be finer grained, of a better flavour, more intermixed with fat, and to afford a richer gravy than that of large animals, and it brings a higher price accordingly in all the principal markets of the island.

2030. *The desirable properties of animals* are different, according to the purposes to which they are applied. The principal productions of live stock are meat, milk, labour, and wool. A breed of cattle equally well adapted to the butcher, the dairy-maid, and the plough or cart, is nowhere to be found. So far as experience enables us to judge, these properties appear to be inconsistent with one another, and to belong to animals of different forms and proportions. It must be evident, that a description of a well formed animal for fattening will not apply to any of the different varieties of horses. And with regard to sheep, there is reason to suspect that very fine wool cannot be produced by such as have the greatest propensity to fatten, and will return the most meat for the food they consume.

2031. *The chief object of most breeders of cattle and sheep* is their carcass. If a demand for dairy produce, for the labour of oxen, or for fine wool, should hereafter make it his

interest to give a preference to any of these commodities, the form and proportions which he studies to obtain, with a view to the greatest produce of animal food, may probably require to be somewhat varied. In the mean time, it is only necessary in this place to notice the shapes which indicate a propensity to fatten in the shortest time, and with the least consumption of food, and to lay the fat on the most valuable parts of the carcass.

2032. *The head* should be fine, clean, and small.

2033. *The collar* full at the breast and shoulders, and tapering gradually to where the neck and head join.

2034. *The breast* broad, and well advanced before the legs.

2035. *The shoulders* wide and full, joining to the collar forward, and the chine backward, so as to leave no hollow in either place.

2036. *The back*, from the shoulders to the tail, broad, flat, and nearly level.

2037. *The chest* full and deep; the ribs rising from the back in a circular form.

2038. *The breadth of the back, and circular form of a deep chest*, are always considered as essential requisites. A flat-ribbed chest, however deep, and large bones, are invariably marks of a slow-feeding animal.

2039. *By a slight touch of the fingers*, a good judge of cattle knows immediately whether an animal will readily make fat or not, and in which part it will be the fattest. The sensation is different from that of softness, being mellow and kindly. This skill, however, is only to be acquired by practice, and the feeling can scarcely be expressed in words. There are several other indications of a propensity to fatten, which, though perhaps not strictly essential, are yet very generally found to accompany it; such as thin ears, hides, and pelts, and small, fine, and straight bones in the legs. Horns are to be chiefly regarded as a criterion for distinguishing one breed from another. A variety of minor circumstances are attended to by skilful breeders, in selecting animals for propagating, to which an unexperienced spectator would attach no importance whatever.

2040. *A breed may be said to be improved*, when some desirable property, which it did not possess before, has been imparted to it, and also when its defects have been removed or diminished, and its valuable properties enhanced. Improvement, in its more extensive application to the live stock of a country, may also be said to be effected, when, by a total or partial change of live stock, the value of the natural produce of the soil is augmented, and a greater quantity of human food and other desirable commodities obtained from it. Whatever may be the merit of that skilful management which is necessary to the formation of a valuable breed, a considerable degree of the same kind of merit may be justly claimed by those, who have introduced and established it in situations where its advantages had never been contemplated, and in which, indeed, the obstacles to its success might have appeared almost insurmountable. The whole of the preceding part of this section is taken from the *General Report of Scotland*, and is understood to contain the sentiments of the best breeders of that country.

2041. *That the breed of animals is improved by the largest males* is a very general opinion; but this opinion, according to some, is the reverse of the truth, and has done considerable mischief. The great object of breeding, by whatever mode, is the improvement of form; and experience has proved that this has only been produced in an eminent degree in those instances in which the females were larger than in the usual proportion of females to males; and that it has generally failed where the males were disproportionately large. (*Culley's Introduction.*) The following epitome of the science of breeding is by the late eminent surgeon, Henry Cline, who practised it extensively on his own farm at Southgate. We present it chiefly because it is the work of an eminent and very scientific man, and because it is almost the only systematic view of the subject produced by a man of science. It is proper at the same time to state that though it is approved and defended by Dr. Coventry at Edinburgh (*Remarks on Live Stock*. Pamph. 8vo. 1806.), it has been, and we believe is now, disapproved of by some eminent practical breeders. (*Farm. Mag.* vol. viii. p. 5.) Mr. Cline's system, however, is translated into most of the continental languages, and has lately been illustrated by M. de Dombasle in France, and M. Hazzi in Bavaria, and others.

2042. *The external form* of domestic animals has been much studied, and the proportions are well ascertained. But the external form is an indication only of internal structure. The principles of improving it must, therefore, be founded on a knowledge of the structure and use of internal parts.

2043. *The lungs* are of the first importance. It is on their size and soundness that the strength and health of animals principally depend. The power of converting food into nourishment is in proportion to their size. An animal with large lungs is capable of converting a given quantity of food into more nourishment than one with smaller lungs; and therefore has a greater aptitude to fatten.

2044. *The chest*, according to its external form and size, indicates the size of the lungs. The form of the chest should approach to the figure of a cone, having its apex situated between the shoulders, and its base towards the loins. Its capacity depends on its form more than on the extent of its circumference; for where the girth is equal in two animals, one may have much larger lungs than the other. A circle contains more than an ellipsis of equal circumference; and in proportion as the ellipsis deviates from the circle, it contains less. A deep chest, therefore, is not capacious unless it is proportionably broad.

2045. *The pelvis* is the cavity formed by the junction of the haunch bones with the bone of the rump. It is essential that this cavity should be large in the female, that she may be enabled to bring forth her young with less difficulty. When this cavity is small, the life of the mother and her offspring is endangered. The size of the pelvis is chiefly indicated by the width of the hips, and the breadth of the waist,

which is the space between the thighs. The breadth of the loins is always in proportion to that of the chest and pelvis.

2046. *The head* should be small, by which the birth is facilitated. Its smallness affords other advantages, and generally indicates that the animal is of a good breed. Horns are useless to domestic animals, and they are often a cause of accidents. It is not difficult to breed animals without them. The breeders of horned cattle and horned sheep sustain a loss more extensive than they may conceive; for it is not the horns alone, but also much bone in the skulls of such animals to support their horns, for which the butcher pays nothing; and besides this, there is an additional quantity of ligament and muscle in the neck, which is of small value. The skull of a ram, with its horns, weighed five times more than a skull which was hornless. Both these skulls were taken from sheep of the same age, each being four years old. The great difference in weight depended chiefly on the horns, for the lower jaws were nearly equal; one weighing seven ounces, and the other six ounces and three quarters, which proves that the natural size of the head was the same in both, independent of the horns and the thickness of bone which supports them. In horned animals the skull is extremely thick. In a hornless animal it is much thinner, especially in that part where the horns usually grow. To those who have reflected on the subject, it may appear of little consequence whether sheep and cattle have horns; but on a moderate calculation it will be found, that the loss in farming stock, and also in the diminution of animal food, is very considerable, from the productions of horns and their appendages. A mode of breeding which would prevent the production of these, would afford a considerable profit in an increase of meat, wool, and other valuable parts.

2047. *The length of the neck* should be proportioned to the height of the animal, that it may collect its food with ease.

2048. *The muscles*, and the tendons which are their appendages, should be large; by which an animal is enabled to travel with greater facility.

2049. *The bones*, when large, are commonly considered an indication of strength; but strength does not depend on the size of the bones, but on that of the muscles. Many animals with large bones are weak, their muscles being small. Animals which have been imperfectly nourished during growth have their bones disproportionately large. If such deficiency of nourishment originated from a constitutional defect, which is the most frequent cause, they remain weak during life. Large bones, therefore, generally indicate an imperfection in the organs of nutrition.

2050. *To obtain the most improved form*, continues Mr. Cline, the two modes of breeding described as the in-and-in and crossing modes have been practised. The first mode may be the better practice, when a particular variety approaches perfection in form; especially for those who may not be acquainted with the principles on which improvement depends. When the male is much larger than the female, the offspring is generally of an imperfect form. If the female be proportionately larger than the male, the offspring is of an improved form. For instance, if a well-formed large ram be put to ewes proportionately smaller, the lambs will not be so well shaped as their parents; but if a small ram be put to larger ewes, the lambs will be of an improved form. The proper method of improving the form of animals consists in selecting a well-formed female, proportionately larger than the male. The improvement depends on this principle, that the power of the female to supply her offspring with nourishment is in proportion to her size, and to the power of nourishing herself from the excellence of her constitution. The size of the fœtus is generally in proportion to that of the male parent; and, therefore, when the female parent is disproportionately small, the quantity of nourishment is deficient, and her offspring has all the disproportions of a starveling. But when the female, from her size and good constitution, is more than adequate to the nourishment of a fœtus of a smaller male than herself, the growth must be proportionately greater. The larger female has also a larger quantity of milk, and her offspring is more abundantly supplied with nourishment after birth.

2051. *Abundant nourishment* is necessary to produce the most perfect formed animal, from the earliest period of its existence until its growth is complete. As already observed, the power to prepare the greatest quantity of nourishment from a given quantity of food, depends principally on the magnitude of the lungs, to which the organs of digestion are subservient. To obtain animals with large lungs, crossing is the most expeditious method; because well-formed females may be selected from a variety of large size to be put to a well-formed male of a variety that is rather smaller. By such a mode of crossing, the lungs and heart become proportionately larger, in consequence of a peculiarity in the circulation of the fœtus, which causes a larger proportion of the blood, under such circumstances, to be distributed to the lungs, than to the other parts of the body; and as the shape and size of the chest depend upon that of the lungs, hence arises that remarkably large chest, which is produced by crossing with females that are larger than the males. The practice, according to this principle of improvement, however, ought to be limited; for it may be carried to such an extent, that the bulk of the body might be so disproportioned to the size of the limbs as to prevent the animal from moving with sufficient facility. In animals where activity is required, this practice should not be extended so far as in those which are intended for the food of man.

2052. *The characters of animals*, or the external appearances by which the varieties of the same species are distinguished, are observed in the offspring; but those of the male parent more frequently predominate. Thus in the breeding of horned animals there are many varieties of sheep and some of cattle which are hornless. If a hornless ram be put to horned ewes, almost all the lambs will be hornless; partaking of the character of the male more than of the female parent. In some counties, as Norfolk, Wiltshire, and Dorsetshire, most of the sheep have horns. In Norfolk the horns may be got rid of by crossing with Ryeland rams; which would also improve the form of the chest and the quality of the wool. In Wiltshire and Dorsetshire, the same improvements might be made by crossing the sheep with South Down rams. An offspring without horns, or rarely producing horns, might be obtained from the Devonshire cattle, by crossing with hornless bulls of the Galloway breed; which would also improve the form of the chest, in which the Devonshire cattle are often deficient.

2053. *Examples of the good effects of crossing* may be found in the improved breeds of horses and swine in England. The great improvement of the breed of horses arose from crossing with the diminutive stallions, Barbs and Arabians; and the introduction of Flanders mares into this country was the

source of improvement in the breed of cart-horses. The form of the swino has been greatly improved by crossing with the small Chinese boar.

2054. *Examples of the bad effects of crossing the breed are more numerous.* When it became the fashion in London to drive large bay horses, the farmers in Yorkshire put their mares to much larger stallions than usual, and thus did infinite mischief to their breed, by producing a race of small-chested, long-legged, large-boned, worthless animals. A similar project was adopted in Normandy, to enlarge the breed of horses there, by the use of stallions from Holstein; and, in consequence, the best breed of horses in France would have been spoiled had not the farmers discovered their mistake in time, by observing the offspring much inferior in form to that of the native stallions. Some graziers in the Isle of Sheppy conceived that they could improve their sheep by large Lincolnshire rams; the produce of which, however, was much inferior in the shape of the carcass, and the quality of the wool; and the flocks were greatly impaired by this attempt to improve them. Attempts to improve the animals of a country by any plan of crossing should be made with the greatest caution; for by a mistaken practice, extensively pursued, irreparable mischief may be done. In any country where a particular race of animals has continued for centuries, it may be presumed that their constitution is adapted to the food and climate.

2055. *The pliancy of the animal economy* is such, that an animal will gradually accommodate itself to great vicissitudes in climate, and alterations in food; and by degrees undergo great changes in constitution; but these changes can be effected only by degrees, and may often require a great number of successive generations for their accomplishment. It may be proper to improve the form of a native race, but at the same time it may be very injudicious to attempt to enlarge their size; for the size of animals is commonly adapted to the soil and climate which they inhabit. Where produce is nutritive and abundant, the animals are large, having grown proportionately to the quantity of food which, for generations, they have been accustomed to obtain. Where the produce is scanty, the animals are small, being proportioned to the quantity of food which they were able to procure. Of these contrasts the sheep of Lincolnshire and of Wales are examples. The sheep of Lincolnshire would starve on the mountains of Wales.

2056. *Crossing the breed of animals may be attended with bad effects* in various ways, and that even when adopted in the beginning on a good principle. For instance, suppose some larger ewes than those of the native breed were taken to the mountains of Wales, and put to the rams of that country, if these foreign ewes were fed in proportion to their size, their lambs would be of an improved form, and larger in size than the native animals; but the males produced by this cross, though of a good form, would be disproportionate in size to the native ewes; and, therefore, if permitted to mix with them, would be productive of a starveling, ill-formed progeny. Thus a cross, which at first was an improvement, would, by giving occasion to a contrary cross, ultimately prejudice the breed. The general mistake in crossing has arisen from an attempt to increase the size of a native race of animals; being a fruitless effort to counteract the laws of nature. No attempt to enlarge the size of animals by any mode of breeding will ever succeed without a corresponding change in the quantity and quality of their food, and their means of procuring it without much fatigue. The climate also requires attention. An improved short horn could never arrive at perfection on the scanty and coarse fare, and severe climate, of the Highlands of Scotland. Size, in fact, is a very subordinate consideration. The great object, as observed above (§ 2021.), is to obtain the greatest possible return for the food consumed; and it is only where both the quantity and quality are in great abundance, that large animals, if of a good description, may be preferred to small ones.

2057. *The Arabian horses* are, in general, the most perfect in the world; which probably has arisen from great care in selection, and also from being unmixed with any variety of the same species; the males, therefore, have never been disproportioned in size to the females.

2058. *The native horses of India* are small, but well proportioned, and good of their kind. With the intention of increasing their size, the India company have adopted a plan of sending large stallions to India. If these stallions should be extensively used, a disproportioned race must be the result, and a valuable breed of horses may be irretrievably spoiled.

2059. *From theory, from practice, and from extensive observation,* the last more to be depended on than either, "it is reasonable," Cline continues, "to form this conclusion: it is wrong to enlarge a native breed of animals, for in proportion to their increase of size, they become worse in form, less hardy, and more liable to disease." (*Communications to the B. of Ag.*, vol. iv. p. 446.)

2060. *The above opinions* may be considered as supported by the most eminent practical breeders, as Bakewell, Culley, Somerville, Parry, and others; and by most theorists, as Coventry, Darwin, Hunt, Young, &c. T. A. Knight writes in the *Communications to the Board of Agriculture* in favour of cross-breeding, as do Pitt and others in the *County Surveys*, but mostly from very limited experience. Sir J. S. Sebright, in a letter addressed to Sir Joseph Banks, on *improving the breed of domestic animals*, 1809, has taken the opposite side of the question; but the meaning he attaches to the term breeding *in-and-in* is so limited, as to render it a very different sort of breeding from that practised by Messrs. Bakewell and Culley, which has been generally so named and recommended by Cline and others, who favour, rather than otherwise, the *in-and-in* system.

He says, "Magnell's fox-hounds are quoted as an instance of the success of breeding in-and-in; but upon speaking to that gentleman upon the subject, I found that he did not attach the meaning that I do to the term *in-and-in*. He said that he frequently bred from the father and the daughter, and the mother and the son. This is not what I consider as breeding in-and-in; for the daughter is only half of the same blood as the father, and will probably partake, in a great degree, of the properties of the mother. Magnell sometimes bred from brother and sister; this is certainly what may be called a *little close*: but should they both be very good, and, particularly, should the same defects not predominate in both, but the perfections of the one promise to correct in the produce the imperfections of the other, I do not think it objectionable: much farther than this the system of breeding from the same family cannot, in my opinion, be pursued with safety." (p. 10.) John Hunt, surgeon at Loughborough, a friend of Bakewell and Darwin, in a reply to Sir J. S. Sebright's pamphlet, entitled *Agricultural Memoirs*, &c. 1812, justly observes, that as Sir John has given no definition of the term *in-and-in*, from what may be gathered from the above extract he seems to have been as near as possible of the same mind as Bakewell, whose practice, it is on all sides allowed, was "to put together those animals which were most perfect in shape, without regard to affinity in blood." This, in fact, is the general practice in all the best breeding districts, and especially in Leicestershire and Northumberland, and may properly be termed breeding in the line.

2061. *George Culley*, a Northumberland farmer of great practice in breeding and feeding, in his *Observations on Live Stock*, not only concurs in this principle as far as respects quadrupeds, but considers it to hold good in the feathered tribe, and, in short, in animals of every kind. His conclusion is, "That of all animals, of whatever kind, those which have the smallest, cleanest, finest bones, are in general the best proportioned, and covered with the best and finest grained meat."—"I believe," he adds, "they are also the hardiest, healthiest, and most inclinable to feed; able to bear the most fatigue while living, and worth the most per lb. when dead." (*Observations*, 222.)

2062. *Cross-breeding, under judicious management*, might probably be often employed to correct the faults of particular breeds, or to impart to them new qualities. "Were I," says Sir J. S. Sebright, "to define what is called the art of breeding, I should say, that it consisted in the selection of males and females, intended to breed together, in reference to each other's merits and defects. It is not always by putting the best male to the best female, that the best produce will be obtained; for should they both have a tendency to the same defect, although in ever so slight a degree, it will in general preponderate so much in the produce, as to render it of little value. A breed of animals may be said to be improved, when any desired quality has been increased by art, beyond what that quality was in the same breed in a state of nature. The swiftness of the race-horse, the propensity to fatten in cattle, and the fine wool in sheep, are improvements which have been made in particular varieties of the species to which those animals belong. What has been produced by art must be continued by the same means; for the most improved breeds will soon return to a state of nature, or perhaps defects will arise, which did not exist when the breed was in its natural state, unless the greatest attention be paid to the selection of the individuals who are to breed together.

2063. *We must observe the smallest tendency to imperfection* in our stock, the moment it appears, so as to be able to counteract it, before it becomes a defect; as a rope-dancer, to preserve his equilibrium, must correct the balance, before it is gone too far, and then not by such a motion as will incline it too much to the opposite side. The breeder's success will depend entirely upon the degree in which he may happen to possess this particular talent.

2064. *Regard should not only be paid to the qualities apparent in animals* selected for breeding, but to those which have prevailed in the race from which they are descended, as they will always show themselves, sooner or later, in the progeny: it is for this reason that we should not breed from an animal, however excellent, unless we can ascertain it to be what is called *well bred*; that is, descended from a race of ancestors, who have, through several generations, possessed in a high degree the properties which it is our object to obtain. The offspring of some animals is very unlike themselves; it is, therefore, a good precaution, to try the young males with a few females, the quality of whose produce has been already ascertained: by this means we shall know the sort of stock they get, and the description of females to which they are the best adapted. If a breed cannot be improved, or even continued in the degree of perfection at which it has already arrived, but by breeding from individuals so selected as to correct each other's defects, and by a judicious combination of their different properties (a position that will not be denied), it follows that animals must degenerate, by being long bred from the same family, without the intermixture of any other blood, or from being what is technically called bred in-and-in."

2065. *Bakewell and Culley* say, "like begets like," therefore breed from the best. Of this, says Sir J. S. Sebright, there can be no doubt; "but it is to be proved how long the same family, bred in-and-in, will continue to be the best." *Breeding in the line* appears more consonant to what takes place in nature than either breeding from very near relationship or crossing one race with another; but, arguing from

analogy, the result of certain experiments, made by T. A. Knight on the vegetable kingdom, seems to justify us in concluding that occasional crossing may become not only advantageous, but even necessary for the purpose of correcting defects. Nevertheless, as the last mentioned writer and Cline observe, it can only be safely resorted to by skilful and experienced breeders. (See the Rev. H. Berry, in *Brit. Farm. Mag.* vols. ii. & iii.)

SECT. III. *Of the General Principles of rearing, managing, and feeding Domestic Animals.*

2066. *Immediately after the birth of every animal*, even of such as are domesticated, the rudiments of its education, as well as its bodily nourishment, are necessarily given by the mother. For this purpose the latter should, during her pregnancy, have been duly protected against all extremes of temperature, well provided with shade and shelter, and abundantly supplied with food and water. When the period of gestation arrives, she should, in general, also be separated from the rest of the flock or herd, and by whatever means the case may demand, kept comfortable and tranquil.

2067. *After the birth*, the first interference on the part of man should be, that of supplying the mother with food of a light and delicate quality, compared with that which she had been in the habit of using, and also of administering the same description of food to the offspring, as far as it may by its nature be able to use it. The gentlest treatment should accompany these operations; and the opportunity taken of familiarising both parent and offspring with man, by gently caressing them, or at least by familiar treatment on the part of the attendant.

*2068. *As the animals increase in size and strength*, they should have abundance of air, exercise, and food, according to their natures; and whatever is attempted by man in the way of taming or teaching should be conducted on mild and conciliating principles, rather than on those of harshness and compulsion. Caresses, or familiar treatment, should generally be accompanied by small supplies of food, at least at first, as an inducement to render the animal submissive to them; afterwards habit will, even in the inferior creation, render the familiarities of man agreeable to them for their own sake; but even then, to keep up this feeling, small portions of select food should frequently be employed as a reward. By contrasting this method with that of taming or teaching animals by fear or compulsion, the advantages of the former mode will be evident.

2069. *Interest is the grand mover of the lower animals* as well as of man. In taming by fear all the interest which the animal has is the avoiding of an evil; in taming by caresses and food it is the attainment of enjoyment. The most extraordinary results are recorded as having been obtained by the mild mode, with almost every species of animal on which it has been tried: to this may be advantageously joined, in the more powerful animals, hunger and fatigue. "The breeder Bakewell, Surgeon Hunt informs us, at an advanced period of life, not only conquered a vicious restive horse, but, without the assistance of either grooms or jockeys, taught this horse to obey his verbal orders with as great attention as the most accomplished animal that was ever educated at Astley's school. Bakewell was accustomed to say, that his horse could do every thing but speak. The method which he took to conquer this vicious animal was never told, even to his own domestics. He ordered his own saddle and bridle to be put on this horse, which at that time was thought to be ungovernable, when he was prepared for a journey of two or three hundred miles; and, that no one might be witness to the contest, he led the horse till he was beyond the reach of observation. How far he walked, or in what manner this great business was accomplished, was never known; but, when he returned from his journey, the horse was as gentle as a lamb, and would obey his master's verbal orders on all occasions. When what are called irrational animals are taught such strict obedience to the command of a superior order, it is in general supposed to be the effect of fear; but Bakewell never made use of either whip or spur. When on horseback he had a strong walking-stick in his hand, which he made the most use of when on foot; he always rode with a slack rein, which he frequently let lie upon the horse's neck, and so great was his objection to spurs, that he never wore them. It was his opinion that all such animals might be conquered by gentle means; and, such was his knowledge of animal nature, that he seldom failed in his opinion, whether his attention was directed to the body or the mind." (*Agr. Mem.*, p. 127.)

2070. *The purposes for which animals are fed or nourished* are for promoting their enlargement or growth; for fitting them for labour; for the increase of certain animal products; or for fattening them for slaughter as human food. We shall confine our remarks to the last purpose as being the most important, and as necessarily including much of what belongs to the three others. In the fattening of cattle the following points require to be attended to: abundance of proper food, a proper degree of heat, protection against extremes of weather, good air and water, moderate exercise, tranquillity, cleanliness, comfort, and health.

2071. *Food*, though it must be supplied in abundance, ought not to be given to satiety. Intervals of resting and exercise must be allowed according to circumstances. Even animals grazing on a rich pasture have been found to feed faster when removed from it once a day, and either folded or put in an inferior pasture for two or three hours. Stall-fed cattle and swine will have their flesh improved in flavour by being turned out into a yard or field once a day; and many find that they feed better, and produce better-flavoured meat, when kept loose under warm sheds or hammels, one or two in a division, a practice now very general in Berwickshire. (See *Hammel.*) Coarser food may be first given to feeding animals; and, as they acquire flesh, that which is of more solid and substantial quality. In general it may be observed, that if the digestive powers of the animal are in a sound state, the more food he eats the sooner will the desired result be obtained; a very moderate quantity beyond sufficiency con-

stitutes abundance ; but, by withholding this additional quantity, an animal, especially if young, may go on eating for several years, without ever attaining to fatness. Properly treated, a well fed ox, of moderate size, will fatten on a rich pasture in from four to six months ; and, in stalls or covered pens, with green or steamed food, in a shorter period.

2072. *In young, growing animals* the powers of digestion are so great that they require less rich food than such as are of mature age ; for the same reason, also, they require more exercise. If rich food is supplied in liberal quantities, and exercise withheld, diseases are generated, the first of which may be excessive fatness ; growth is impeded by very rich food, for experience shows that the coarsest-fed animals have uniformly the largest bones. Common sense will suggest the propriety of preferring a medium course between very rich and very poor nutriment.

2073. *Mastication and cooking.* Unless food be thoroughly deprived of its vegetative powers before it enters the stomach, the whole nourishment which it is capable of affording cannot be derived from it. In the case of the leaves and stalks of vegetables, this is in general effected by mastication ; but it requires some care to accomplish it in the case of grains. Hence the advantage of mixing corn given to horses or cattle with chaff or chopped straw ; and hence it is supposed by some, that the instinct which fowls have to swallow small stones is intended by nature for the same object. But the most effectual mode of destroying the living principle is by the application of heat ; and if vegetable food of every kind could be steamed or boiled before it was given to animals (at least in winter, and for fattening for the shambles, or feeding for milk), it is rendered probable, by analogy and experiment, that much more nourishment would be derived from it.

2074. *Salt*, it appears, from various experiments, may be advantageously given to most animals in very small quantities ; it acts as a whet to the appetite, promotes the secretion of bile, and, in general, is favourable to health and activity. In this way only can it be considered as preventing or curing diseases ; unless perhaps in the case of worms, to which all saline and bitter substances are known to be injurious.

2075. *That degree of heat* which is natural to animals in their original country, or has become so by habit and the breeding for successive generations in a cold climate, is necessary to their wellbeing ; and a somewhat increased degree in the cold months, or diminished degree in such as are oppressively warm, is advantageous in the fattening process. Where a sufficient degree of warmth to promote the ordinary circulation of the blood is not produced by the natural climate, or by exercise, it must be supplied by an artificial climate. Houses and sheds are the obvious resources both for this purpose, and for protection from *extremes of weather*. Cold rains and northerly winds are highly injurious, by depriving the external surface of the body of caloric, more rapidly than it can be supplied from within by respiration, and the action of the stomach ; and also by contracting the pores of the skin, so as to impede circulation. When an animal happens to shed its covering, whether of hair, wool, or feathers, at such inclement seasons, the effects on its general health are highly injurious. The excessive heats of summer, by expanding all the parts of the animal frame, occasion a degree of lassitude, and want of energy, even in the stomach and intestines ; and while the animal eats and digests less food than usual, a greater waste than usual takes place by perspiration. Nature has provided trees, rocks, caverns, hills, and waters, to moderate these extremes of heat and weather ; and man imitates them by hovels, sheds, and other buildings, according to particular circumstances.

2076. *Good air and water* it may seem unnecessary to insist on ; but cattle and horses, and even poultry, pent up in close buildings, where there are no facilities for a change of the atmosphere, often suffer on this account. A slight degree of fever is produced at first, and, after a time, when the habit of the animal becomes reconciled to such a state, a retarded circulation, and general decay or diminution of the vital energies, take place.

2077. *Water ought to be soft and pure*, as being a better solvent than such as is *hard* and charged with earthy particles. It ought to be of a moderate temperature, under that of the open air in hot weather, and exceeding it in winter. Deep wells afford this difference. In particular cases, as in those of animals in a suckling state or milked by man, warmed water has been found advantageous. Meals, or other light rich matters, are sometimes mixed with it ; but it does not clearly appear, except in the last case, that liquid food is so generally advantageous for fattening animals, as that which being equally rich is solid. Some judgment is requisite as to the time most proper for giving water to animals. In general, it does not appear necessary to supply it immediately after eating, for animals in a natural state, or pasturing in a field, generally lie down after filling themselves, and after the process of digestion seems to have gone on for some time, they go in quest of water. Perhaps the immediate dilution of food, after being taken into the stomach, with water, may, at the same time, weaken the digestive powers, by diluting the gastric juice. At all events, the free use of water at any time, but especially during meals, is found to weaken digestion in the human species. As animals of every kind become reconciled to any habit, not ultimately injurious to health, perhaps for housed animals a stated quantity of water, given an hour, or an hour and a half after what may be called their meals, may be the best mode.

2078. *Moderate exercise* ought not to be dispensed with, where the flavour of animal produce is any object ; it is known to promote circulation, perspiration, and digestion, and by consequence to invigorate the appetite. Care must be taken, however, not to carry exercise to that point where it becomes a labour instead of a recreation. In some

cases, as in feeding swine and poultry, fatness is hastened by promoting sleep, and preventing motion rather than encouraging it: but such animals cannot be considered healthy-fed; in fact, their fatness is most commonly the result of disease.

2079. *Tranquillity* is an obvious requisite, for where the passions of brutes are called into action, by whatever means, their influence on their bodies is often as great as in the human species. Hence the use of castration, complete or partial separation, shading from too much light, protection from insects, dogs, and other annoying animals, and from the too frequent intrusion of man.

2080. *Cleanliness* is favourable to health, by promoting perspiration and circulation. Animals in a wild state attend to this part of their economy themselves; but, in proportion as they are cultivated, or brought under the control of man, this becomes out of their power; and to insure their subserviency to his wishes, this part of culture, as well as others, must be supplied by art. Combing and brushing stall-fed cattle and cows are known to contribute materially to health; though washing sheep with a view to cleaning the wool often has a contrary effect, from the length of time the wool requires to dry. This often brings on colds, and aggravates the liver complaint, so incident to these animals. Bathing or steeping the feet of stalled animals occasionally in warm water would no doubt contribute to their health. Bathing swine two or three times a week in hot water, as in that used for boiling or steaming food, has been found a real advantage.

2081. *Comfort*. An animal may be well fed, lodged, and cleaned, without being comfortable in every respect; and in brutes, as well as men, want of comfort operates on the digestive powers. If the surface of a stall, in which an ox or a horse stands, deviates much from a level, he will be continually uneasy; and he will be uneasy during night, if its surface is rough, or if a proper bed of litter is not prepared every evening for him to repose on. The form of racks and mangers is often less commodious than it might be. A hay rack which projects forward is bad; because the animal in drawing out the hay is teased with the hay seeds falling into its eyes or ears; and this form, it may be added, is apt to cause the breath of the animal to ascend through its food, which must after a time render it nauseous. For this reason hay should lie as short a time as possible in lofts, but when practicable be given direct from the rick. Poultry of different kinds are often crowded together, without any regard to the comfort of the particular kinds by attending to their peculiarities, such as a smooth or soft floor for the web feet of the duck tribe, or the proper size of roosting sticks for the grasping-toed feet of the other tribes. Even the crowing of the cock must cause some degree of irritation, and consequently impede health and fattening by disturbing the repose of quiet fowls, such as the turkey or goose. Various other instances will occur to a reflecting mind; and surely it must be a duty as agreeable as it is conducive to our own interest, to promote as much as possible the comfort of those animals whose lives are shortly to be sacrificed for ours.

2082. *Health*. A good state of health will, in general, be the result of the mode of feeding and treatment which we have described; but in proportion as our treatment, either of ourselves or other animals, is refined and artificial, in the same proportion are the functions of nature liable to derangement or interruption from atmospherical changes, and various accidental causes. When this takes place, recourse must be had to art for relief. This is an obvious, natural, and reasonable practice; though some contend that as every disease is only an effort of nature to relieve the being from some evil, it ought to be left to itself. To treat animals when in health artificially, and the moment when they become diseased to abandon them to nature, is a proposition so incongruous and absurd, that one would suppose it would be rejected by the common sense of mankind. There are, however, some solitary instances of medical men having adopted this opinion; but the melancholy result of their acting on it in the human species, as well as its utter rejection by all rational professors, and men in general, has reduced it to its intrinsic value. There may be much of quackery in medicine; and unquestionably there is a great deal in the art, as applied to the brute creation by common practitioners: but to reject the medical art altogether, becomes, on the other hand, a species of quackery just as despicable as the other, and not less dangerous; for it cannot be much better for a patient to be left to die through neglect than to be killed by overmuch care.

2083. *Farristry, as applied to cattle and sheep*, is a department of medicine in which perhaps greater ignorance prevails than in any other. The subject, as applied to horses, has, since the establishment of veterinary schools in this country, and in France, become better understood; but the pupils from these establishments are so thinly scattered, that as Laurence (veterinary surgeon, and author of a *Treatise on Horses*) observes, it were desirable that country surgeons should in their different localities give instructions to the empirical local practitioners in the country, and to intelligent bailiffs; and that gentlemen of property might have such a sense of their own interest as to call in a surgeon in all cases of the least difficulty. All that we can here do is to repeat our advice of

studying the art of prevention rather than of cure ; to suggest that, in general, an analogy subsists between the constitution and diseases of the human and brute creation ; to avoid recipes and specific cures, rarely to bleed animals, unless by regular advice ; and to confine as much as possible the operations of cow-doctors and smiths to giving warm drinks, gentle purges, and clysters, which can seldom do any harm. Proprietors who can afford to employ intelligent bailiffs, or rather who give such men considerable salaries, should ascertain previously to hiring them, by means of general questions, or by reference to a professor, whether they know any thing of the subject. By thus creating a demand for this species of knowledge, it would soon be produced in abundance.

SECT. IV. *Of Feeding for Extraordinary Purposes.*
