[COPYRIGHT SECURED.]

IMPORTED NEGRETTI SHEEP.—Drawn and Engraved for the American Agriculturist.

The various kinds of fine-wooled or Merino sheep are descended from the Spanish Merinos. For centuries the flocks of Spain were celebrated for the quality of their wool, and several families or sub-breeds were well known and had distinct characteristics. Among the noted of these families were the Infantado, Paular, Estramadura, and Negretti. Before the invasion of the French these flocks were kept up with great care, and bred with a view to develop their peculiar excellencies. War, in Spain, as elsewhere, made havoc with agricultural pursuits,

and these celebrated flocks either went to furnish the commissariat of one or the other army, or were so broken up that their high character was lost. Fortunately examples of the leading families had previously been sent to England, Saxony, Silesia, and other European countries, as well as to America, and now the once celebrated Spanish sheep are found in greater perfection elsewhere than in Spain. It is claimed that the Negretti sheep, while they are lost in Spain, have been continued in their purity in Germany; but it is highly probable that these

as well as other families have been essentially modified and improved. The experience in this country with Merinos shows how careful breeding will change the characteristics of sheep. Besides this, climate has an effect upon wool to such an extent that even in the limited area of England certain breeds will only retain their characteristics when kept in particular localities. These sheep shear from four to six pounds of the finest wool. Their faces are covered with wool to a remarkable extent, and the legs are clothed quite down to the toes,

AMERICAN AGRICULTURIST.

NEW YORK, JANUARY, 1872.

We can not tell whether it was in the spring, summer, autumn, or winter that the "evening and the morning was the first day;" and, consequently, we do not know when the old year ends and a new year commences. There are, however, as good reasons for commencing the year in the dead of winter as for commencing the day in the dead of night. Both are purely arbitrary. Some would have the day commence in the morning, and the year in the spring. We think it far better as it is. The best preparation for a day's work is a good night's sleep; and much of a farmer's success the coming year will depend on how he spends his winter. It is the period for preparation. It is the time to think and plan; the time to close up the work of the old year, and get ready for the new.

Hints about Work.

The great work of life is to discipline and educate ourselves. The end of each year finds us better or worse. No matter how prosperous the year may have been, if we are less patient, more inconsiderate, conceited, proud, and selfish, our time has been ill-spent; but if we are growing men—growing in love, joy, peace, long-suffering, gentleness, goodness, faith, meekness, and temperance—we are prospering. We may have seen hard times, but we have not lived in vain. We are better men. A farmer's best field is himself. This field can be plowed and cultivated just as well in the winter as in the summer. The commencement of a new year is a good time to top-dress it, or, if need be, to break it up and commence a new rotation. Kill the weeds, and be careful to sow good seed, and plenty of it. Energy, industry, forethought, patience, and temperance are always profitable crops; temperance in eating, drinking, sleeping, and working. Many farmers work too hard; they are intemperate in this respect. Many more are too anxious. They have not faith enough. Some are too hopeful. They hope for good crops without using the means to obtain them.

Pay your Debts.—Or, at any rate, ascertain exactly what you owe. A running account not unfrequently runs away with a farm. If you are in debt, and

have anything to sell, dispose of it at once, and pay your debts. Nothing deadens a man's energy and destroys all manly feeling like little debts. You will feel like a new man when they are paid.

De Prompt.—Credit is very desirable to any energetic man, and nothing tends so much to secure credit as promptness in meeting all obligations. The way to get credit is to use it, and not abuse it.

Prices are Low, Wages High, and Profits Small.—The two former are beyond our control; and we can not hope to obtain good profits unless we raise large crops. Ten bushels of wheat per acre does not pay, and never ought to pay. Thirty bushels per acre, even now, affords a living profit, and forty bushels affords profit enough to satisfy any man.

Farmers are Manufacturers, and compete with each other. The farmer that can manufacture the best articles at the least cost is the one that makes the most money. His skill and knowledge must be directed to this object.

Thorough Cultivation is always profitable on all land that is cultivated at all. This is true whether we adopt high farming or slow farming; whether we live east or west, on high-priced or low-priced land. If we work it at all, we must cultivate it thoroughly.

Think of these things, and get ready for the work.

Write down all that you intend to do the coming year. Writing is a great help to thought as well as to memory. Write down exactly how you propose to do the work, and what with, and when.

If you have never kept a Diary, now is the time to commence. Nothing is more interesting and useful than a well-kept record of everything done on the farm, state of the weather, condition of the stock, and what you are feeding, etc.

Make an Inventory of everything on the farm and in the house, with an estimate of its value. Do it carefully and thoroughly. In case of fire, it will be a great help in settling insurance claims.

Attend to your Insurance.—See that it is not run out, and that the companies are sound.

What do you do with your Ashes?—Many fires originate from carelessness in placing ashes in barrels, or throwing them in a loose heap where they come in contact with wood. Provide a suitable place for them, either of brick or iron.

Animals must receive constant and regular attention. They can not be neglected for a single day. Be careful to give them abundance of fresh water, and avoid as much as possible compelling them to drink water that is full of melting snow or ice. Provide some kind of shelter for all animals.

Horses that are doing nothing can be wintered on good, bright straw, with four or five pounds of corn per day, cheaper than on hay. If they are worked regularly, they require higher feeding; say ten pounds grain, ten pounds hay, and ten pounds straw per day. On a grain-farm, where straw or corn-stalks are abundant and hay is scarce, one third hay, and one third straw and stalks, cut up together with one third the weight of corn-meal mixed with it, makes a cheaper and more nutritious food than more hay and less grain.

Cows do far better on stalks than on straw. They do not like the latter. Our stalks were so well cured last fall that, after the cows were taken from the pasture and fed in the stables on stalks, they increased in their milk and the quality of the butter improved. Cows that are giving milk will pay for a little corn-meal, say two quarts per day, in addition to the stalks or hay. Keep the stables clean and well ventilated. In stormy weather it is best to keep them in the stable all the time, except to turn them out twice a day to water. Many farmers only water once, and this will do when they run in the yard for two or three hours, but otherwise it is far better to water twice. Give them time enough to drink. Cows are not like horses in this respect. A horse will drink at once all he wants, but a herd of cows needs longer time and more or less humoring.

Sheep will eat straw better than any other stock. With good, bright straw and half a pound of corn

per day, Merino sheep can be kept in good, thriving condition, and with a pound of corn per day the right kind of sheep will get fat. Towards spring the sheep should have a little hay—say one foddering a day. Merino ewes in lamb to a large long-wooled or South Down ram, should have good keep, in order that they may have nourishment enough for the large lamb. Nothing is better for them than bran and clover hay. Corn is a cheaper food, and half a pound per day will not hurt them, unless the ewes are unusually fat. Where roots are scarce it is better to reserve them until March and April than to feed them now. Bran is the best substitute for them. Cattle, horses, and pigs should be fed in the morning, the first thing before breakfast, but sheep need not be fed until after breakfast. It is better to let them lie undisturbed until sunrise.

Littering the Sheep-yards is a point of great importance, and requires good judgment and experience. They will lie down and rest as soon as they have a little fresh straw spread in the yard or under the shed, and this should be attended to every day; but it is exceedingly important not to get so much straw and manure under the sheep as to cause fermentation. Avoid the mud and dirty straw on the one hand, and fermenting manure on the other. Both are injurious. A little straw and often is the rule. Be careful to throw the straw pulled out from the racks, about the yards every day and not let it accumulate. A little attention to this matter will be amply rewarded.

Pigs.—Young growing pigs should have abundance of nutritious food, and warm, dry, comfortable quarters. Feed three times a day, and as much as, and no more than, they will eat up clean. Our own plan is to cook the food, half corn-meal and half bran, and feed warm. Our breeding sows, at this season, get nothing but bran, soaked in water, and we do not give them quite all they will eat, fed twice a day. We soak the bran in warm water about twelve hours, and get some of the milky water out of the bran to mix with the cooked food for the little pigs. The bran is still nutritious enough for old sows that have nothing to do but live, while the young, growing pigs need as much easily digested, nutritious food as they can assimilate.

Pigs well littered make a great quantity of manure. We clean out the wet and soiled part of the bed every day, and put in a little fresh straw. The butts of corn-stalks, left by the sheep and cattle, we put into the pig-pens at the bottom of the pen and cover them with straw. They serve to keep the pen dry and save much straw. When pigs are shut up it is exceedingly important to have the pens well ventilated.

Manure.—Either draw manure out to the field as it is made and spread it, or make it into a large heap in the barn-yard. On the whole, we prefer the latter course. If properly attended to, and the heap is turned in February, the manure will be in good condition for spring crops. It is not uncommon to see a heap of smoking horse manure by the stable-door, another heap near the cow-house, while that from the pigs lies frozen by itself, half mud and half corn-cobs. The whole should be wheeled or drawn in a cart to a central heap and mixed together. They will improve each other. The warm horse manure will induce fermentation in the cold cow-dung and the still colder and more sluggish pig manure. Let the whole be carefully shaken to pieces and thrown into a loose heap. During our cold winters there is no danger of the heap fermenting too rapidly. In fact, where there is an abundance of straw it would be desirable to sprinkle a little dried blood, bone-dust, hen manure, etc., over the heap occasionally, to induce a more active fermentation. A heap so managed, and turned once or twice, will be in admirable condition for root crops in the spring. Any that is too raw for this purpose can be used for corn, or kept over for wheat, or top-dressing grass, next fall.

Swamp-Muck.—Our swamps never were so dry as at the present time, and we can not have a more favorable opportunity for getting out muck. It may be drawn directly to the field and spread on grass land; or draw it to the barn-yard and use it

for absorbing the liquid, or for mixing with the manure in the heap. There are thousands of farms where men and teams could not be more profitably employed this month than in getting out muck.

Do not Waste the Straw.—Farmers often throw large quantities of straw about the yards during winter, for no other purpose except to get rid of it. Better let it be in the stack, and use it next summer for littering the yards where the cows are milked and the pigs run. A much larger amount of manure will be made in this way. Where straw is abundant, use it freely to litter the stable, cow-house, and pig-pens. Clean out all that is soiled or wet and put in fresh litter every day.

Cellars should be ventilated at every opportunity. The vegetables will keep far better and it would prevent much sickness in the family. We can not too often call attention to this matter. Never allow any decaying vegetables or fruit to remain in the cellar. Hang a thermometer in the cellar and keep the temperature down to 40°. If it gets above this open the door or window until the temperature gets down to near the freezing point. White-wash the cellar at least once during the winter.

Shoeing Horses.—Many a good horse is spoiled by not being rough-shod in winter. It is a painful sight to see a horse traveling on an icy road with slippery shoes on—and dangerous withal.

Ice.—Fill the ice-house as soon as the ice is thick enough. The colder the weather at the time the better. Last year when we had ice we had no sleighing—and many farmers who waited for sleighing had empty ice-houses the next summer. Better draw on wagons than go without ice. Where ice is near, if a large heap is drawn together and covered with five or six feet of straw, or stalks, and thatched so as to shed rain, the ice will keep.

Work in the Horticultural Departments.

The beginning of a new year is the proper time to lay work-plans for the coming season, as without a plan of operations the gardener will never accomplish much. It is only by careful forethought and working with a definite end in view, that men engaged in other branches of industry become successful, and our best horticulturists are those who plan for the future, in a thorough, business-like way. No other business requires a knowledge of a greater number of different subjects, and to master these a good library of standard works is essential. A gardener should keep a journal in which the principal operations of each day are recorded, and he can afterwards examine the journal and learn where to avoid mistakes and where to do better. The directions given in these departments each month, contain much that will be useful to the commercial as well as to the amateur gardener.

Orchard and Nursery.

The most that can be done in this department is to put everything in order for early spring use. In Southern latitudes trees and nursery stock should be secured in the fall, if they are ordered from Northern dealers, as the ground will be ready for early planting in a few weeks. If a nursery is near it is well to give an extra price for the privilege of digging your own trees, as they will be in better condition than when dug by the nursery hands.

Rabbits.—Directions were given last month for preventing rabbits from injuring fruit-trees.

Mice.—See that all rubbish is removed from around the trunks of trees, for where there is any chance for mice to harbor they are sure to injure the trees by gnawing away the bark. Tramp down the light snows around the trees.

Scrapping.—During the milder days in thawing weather, the trunks and larger limbs may be scraped.

Tent Caterpillar.—The eggs of the Tent caterpillar are easily seen at this season of the year, and are much easier destroyed now than when they have hatched. A pair of long-handled pruning-shears are the best for large trees, as the higher branches can be easily reached with them, cut off, and then

burned. If there are wild cherry-trees in the vicinity of the orchards, they ought to be cut down, as they only serve to harbor the caterpillars.

Cions, if not already cut, should be attended to at once, as grafts cut early are better than those which have been left exposed to the severity of the winter; this is especially the case when the autumn has been unfavorable for ripening the wood.

Fences.—See that the fences and gates around the orchard and nursery are properly secured, so that stray cattle can not enter and break the trees.

Labels.—The present month is a good time to renew the labels of the different varieties. This is very easily performed if one has a correct plan drawn of his orchard, and the sorts marked or numbered. Prepare a stock of labels for use during the coming spring, so that no delay may occur during the busy season. See that the labels upon trees set out in the fall are not fastened so tight that they will girdle the trees when growth commences.

Manure.—Use plenty of stable-manure upon the orchard; cart during mild weather and lay in heaps.

Fruit Garden.

A person who is satisfied with only one variety of grapes, strawberries, or currants, receives only a small share of the enjoyment he would if he had several sorts of each kind of fruit. In selecting varieties for the fruit garden, due regard should be had to early and late sorts, so that a succession can be had from earliest to latest. A plenty of fruit will afford a family a good part of their living.

Grape Vines that were not pruned in the fall should be attended to during the mild weather, and not left until the sap has commenced to flow, for then the vine is injured by excessive bleeding.

Dwarf Trees.—See that no snow is allowed to accumulate on the branches so as to break them down, as when broken it is very difficult to restore the form of the tree.

Kitchen Garden.

The work here now is mainly that of preparation, especially in the North. Farther south, planting in the open ground can be done now.

Manure.—In the former directions a great deal has been said about this subject, but as success is in a great measure dependent upon manure, the matter can not be referred to too often. See that nothing that can be converted into manure is wasted. Plenty of absorbents for use in the stable and compost heap should have been prepared last fall. Dried earth is as good as anything that can be used in the stable and in the cesspool.

Hot-Bed Sashes and Frames.—Put these in readiness to use when wanted. They ought to be painted with lead-paint or given a coat of crude petroleum, and the broken glass re-set.

Straw Mats.—A good supply of these will be needed if one has many frames to cover; make them during the stormy weather, when it is impossible to work out of doors.

Cold Frames.—These need more attention to keep them cold than to prevent injury from freezing. Open whenever the weather is mild; and during warm days the sashes may be entirely removed, only taking care to close in time.

Tools.—See that everything in the way of tools that will be wanted during the next season is repaired, or else new tools purchased. In selecting those having handles or other parts of wood, take care that the grain of the wood is straight, and that there are no knots in it, as they are then very likely to break. Oil the wood parts of the plow, cultivators, harrows, etc., with petroleum, and see that they are stored where they will be free from moisture. Every tool should have a roller, marker, and line and reel. Directions for making these have been given in the former numbers.

Seed.—Procure a supply early, for if the ordering is left until the seeds are wanted, delays may occur. Use only the best seeds, as much depends upon the quality of these. Do not depend too largely upon

FREE.—The very Best Table Cutlery—Silver-plated Table Articles—Gold Pens—Children's Toys—Flower and Garden Seeds—Nursery Stock—Sewing and Washing Machines and Wringers—Melodeons—Pianos—American Watches—Shooting Irons—Tool Chests—Drawing Instruments—Barometers—Astral Oil—Hay Mowers—Horse-Forks and Hoes—Pumps—Family Weighing Scales—Cyclopedias—Dictionaries—Books—Grape-Vines—Toy Steam-Engines—etc., etc., etc.,

are among the things that we are distributing very largely all over the country to our friends who send in clubs of Subscribers. Some report as getting as many as fifty subscribers a day. Others get one, two, three, or more, as opportunity serves. Some make this their sole business, and sell their premiums received, and thus get large wages. There is no humbug or claptrap about this. At least *Thirteen Thousand* persons have received these premiums with great pleasure, and still, not one in ten of those who ought to read the *American Agriculturist* and *Heath and Home* for their own pleasure and profit, is yet supplied with it. So there is abundant room for thousands of others to obtain these valuable premiums. This work can go on all winter. Full particulars will be found in the Advertising Columns, pages 37 and 38.

The Hoosier School-Master.—This intensely interesting story, which has appeared as a serial in the columns of *HEARTH AND HOME*, is now issued in elegant book form, printed on fine paper, with twelve full-page engravings on tinted paper, and seventeen other illustrations, and bound in extra cloth. It is a truly AMERICAN STORY, and will be read with delight by all. Price, post-paid, \$1.25.

Cundurango.—We have no doubt that a drug bearing this name is brought from South America. As to its being a cure for cancer, we must quote the Scotch verdict, "Not proven." One of the best medical journals in the country does not hesitate to denounce it as a humbug. The thing has been known too short a time, to allow a proper opinion to be formed. We shall look for our information in regard to its alleged virtues to the medical journals, and not to advertisements by interested parties, in the daily papers. Those who wish to pay \$100 (one hundred dollars) a pound for this South American bitter wood, will illustrate an old proverb which we need not quote.

Peerless Potatoes.—We receive so many reports of the yield of the Peerless, that we can not publish all. Geo. Gilliford, Delphi, Ind., bought four pounds of B. K. Bliss & Son, and harvested 14½ bushels.

Pigs of the First Litter.—"J. V." asks "if the first pigs from a sow are as good as those from one older?" As a rule, no. But it depends a great deal on the breed and age of the young sow. If the sow is not allowed to breed until she has attained her full growth, her first litter will be as good as her second, and probably better than her third or fourth. We have now as good pigs from a year-old Essex sow (which mature early) as we ever raised. At the New York State Fair we showed two pens of five pigs each, one pen from a three-year-old sow, and one from a sow only a year old, and the judges awarded the first prize to the latter and the second to the former. And we think they decided justly. This breed of pigs at eight months old are as mature as some of the large breeds would be at sixteen months. If the latter were bred at eight months old, we should expect the first litter to be far inferior to the second litter. If not bred until 16 or 18 months old, the first litter would probably be as good as the second. As a rule farmers breed their sows too young, and consequently the first litters are often weak and inferior.

"Best and Largest of any Other Variety."—Fiddalge Whatcom, W. T.—When a fair list offers premiums for designated varieties, and in addition offers a prize for "the best and largest of any other variety," we understand it to refer to only one other sample, the best and largest of its kind.

Sowing Plaster and Salt on Oats and Clover.—"W." Covington, Ky., asks if plaster or salt sown on oats would not help the clover seeded with them. Plaster is of great benefit to young clover, as is also salt. It has been a practice with us to sow a bushel of each per acre in spring on winter grain or oats, when seeded to clover, and we have found it beneficial.

Bell's History of Shorthorns.—Messrs. L. Tucker & Son, Albany, New York, inform us that they have received a few copies of this work, which is held in esteem by English breeders. They will send it, post-paid, on receipt of \$2.75.

School-Houses.—By James Johannot. Architectural designs by S. E. Hewes. Published by J. W. Scherhorn & Co., New York, who append an extended catalogue of their school furniture. This handsome work seems to be very complete and must prove a great aid to all concerned in schools and school-houses.

Brief History of the United States.—A. S. Barnes & Co., New York. The name of the author is not given. The work presents an attractive appearance, and is illustrated by well-executed engravings and neat maps. \$1.50.

Latin Grammar for Beginners.—By Wm. Henry Waddell, New York. Harper & Brothers.

The Seymours.—A temperance story, published by the National Temperance Society and Publication House, New York.

"The U. S. Banking Association."—What is this concern which publishes the "U. S. Credit Record of Business Men"? The highly respectable London publishing house of Trübner & Co. write us that their name is attached to this Record, and they wish it to be distinctly understood that they know nothing of the concern, and never heard of the "Association" nor its "Record" until their attention was called to the unauthorized use of their name. Is this some hogus thing?

Perkins & House's Lamp.—The favorable opinion we expressed of this lamp when it was first introduced has been confirmed by long use. Our advertising columns set forth its merits, which some of our associates say are not overstated.

The American Entomologist.—A note from Mr. C. V. Riley, the editor, informs us that the publication of this journal will not be resumed this month, as was announced a year ago. Mr. Riley has purchased the illustrations and all interest in the magazine, and hopes to recommence it at no very distant day.

A Good Ten Cents' Worth.—The publishers would be very glad to have everybody see a single copy of *Heath and Home* AS IT IS NOW. Probably a better ten cents' worth was never furnished anywhere, or in anything, than in the number of *Heath and Home* now before us. It is full of good things that will please everybody. Get it for yourselves, and for the children for the holidays. It can be bought of most newsdealers for 8 cents a copy, or the publishers will send it, postpaid, to any address, for 10 cents. Send a dime and get a single copy to look at, to read, and to enjoy.

A Mystery.—When some thousands of people every year collect and send on clubs of subscribers and receive valuable premiums from this office without outlay of money, and when the offer is equally open to all others, it is a mystery to us that tens of thousands of others do not rush into it and do the same thing. Human nature and human wants are the same everywhere; and it is just as easy for 20,000 or 30,000 other people—one or more at every post-office—to get these good articles, as it is for the few thousands who do obtain them. Please turn to pages 37 and 38, and see what is offered.

About "Crabs."—Geo. Pittman, Fulton Co., Pa., has discovered that springs which generally dry up in summer, may be made to run all the time by turning in some crabs. We suppose he means crawfish, or freshwater crabs. He says these animals follow up the streams beneath the ground and make an outlet for the water. Thus even crabs or crawfish have their uses.

Cure for Mange.—"Belleville" sends his cure for mange, which we think well of, as follows: Equal parts of sulphur and cream of tartar, made into a ball with syrup or honey, and administer daily for three or four days. Wash the parts affected with carbolic soap, and anoint with a paste of lard, sulphur, and powdered charcoal ground together.

To Prevent an Iron Kettle from Rusting.—Miss Mattie B., Alleghany, N. Y., is troubled to find a remedy for the rusting of her cauldron. We know of no remedy but to apply the practice by which housekeepers preserve their stove-pots from rusting, viz., to wipe them while still hot, after being used, with a greasy cloth. Iron, when heated, will absorb considerable grease, and perseverance in the above will soon completely fill the pores of the iron and prevent rust.

Guessing.—B. A. Howell, Dutchess Co., N. Y., lives among farmers who "guess," and can never tell exactly what they raise nor what they expect to. He asks information about large crops of corn. Is 100 bushels to the acre ever raised, and does it mean shelled corn, or ears? Guess farmers are as "plenty as blackberries" everywhere. When the number of bushels in a crop of corn is mentioned, *shelled corn* is understood. One hundred bushels are often attained, but only by the best farmers. "Guess" farmers raise about 10 bushels to the acre. Seventy to eighty bushels are common in New Jersey and parts of Pennsylvania.

To Weld Iron.—"A." is a farmer, and wants to do his own welding, and has difficulty in getting a good weld. There is some little sleight of hand, or quickness of eye and precision of motion, needed, which will come with practice. We learned to make a weld by practicing with waste pieces at odd intervals until we were not afraid of it, and then succeeded when the nervousness akin to the "buck fever" wore off. Iron can be welded at a low heat by using borax melted with one tenth part of sal ammoniac, cooled on an iron plate, pulverized, and mixed with an equal weight of quick-lime, powdered. The powder is sprinkled on the iron when red-hot, the iron returned to the fire, and need not be brought to the usual heat to get a good weld.

Precocious Heifer.—S. H. Mattson, of Delaware Co., Pa., says he has a Jersey heifer which produced six and a half pounds of butter in seven days, when but sixteen months old. Jersey stock is precocious, but this is getting to a point which can hardly be beaten.

Sexes at Will.—"An Inquirer," Ghersey Co., O., asks if there is any known means of producing either sex at will, and if a white color in Jersey cattle bred in and in for three generations is a sign of impure blood. To each question we answer No. The writer has seen cattle on the Island of Jersey altogether white, but they are not common.

The Lupin.—"G. D. S." Troy, Ind., asks what is the value of this plant for soiling. The white Lupin is largely grown in France and Belgium for soiling purposes. A light, dry soil is needed for it, and the light soils of some parts of Indiana would be excellently adapted to it. The seeds are very nutritious and the plant makes excellent hay.

The Best Field-Pea for Stock.—"S." Perry Co., Ind., wants the best field-pea for stock. The black-eyed marrow-fat makes a heavy crop of stalks, and the gray pea, called in our markets the "Canada pea," is also a hardy and useful pea, and will thrive on poorer soil than the marrow-fat. It does not yield so heavy a crop, the stalks being shorter. Peas for fodder should be cut while the upper part is in blossom.

Remedy for Hoove.—"W. W. B.," Clark Co., Ind., finds a remedy for hoove in the administration of alum. This may have had an accidental effect in some isolated case, but can not be relied on. Powdered charcoal, which absorbs large quantities of carbonic acid gas, has been given with good results.

Ashes of Hemlock Bark, etc.—"I. G. Q.," Tioga Center, N. Y., has the ashes of 2,500 cords of hemlock bark, 300 bushels of leached hen-dung, and 800 bushels of lime from the vats of a tannery. How shall he use them on sandy land, and a meadow? As the hen manure is spent, no harm can occur from mixing the materials together and sowing them on the grass or the land after plowing and harrowing them in. Do not plow them under. Apply stable manure by itself.

Profitable Farming.—Darius Rice & Son, of Worcester, Mass., send a statement of the value of produce sold from 20 acres of mowing land and five acres of market garden. The items are too numerous to mention in detail, but the total foots up to \$6,829.53. Labor cost \$1,045.93, grain purchased and fed to hogs (which made the manure used and gave a profit besides) \$1,314.67, butchers' offal \$160. There is evidently good management here.

Inflammation of the Brain.—D. Ward, Waterville, Kansas, wants a remedy for what he calls "grub in the head" in his cattle, but which is certainly inflammation of the brain. A wild stare, frothing at the nose (suppuration of the membranes), and death in twelve hours, are the symptoms and effect. For this disease copious bleeding—until fainting—from the jugular vein is necessary, followed by a blister at the back of the horns, and turpentine rubbed on the back of the neck, to induce surface inflammation.

Refuse of Glue Factories.—"Subscriber," Lancaster Co., Pa., should compost this valuable material in his manure pile, or with swamp-muck, or earth. It is too stimulating for grape-vines.

Warts on Cattle.—"S. H.," Washington, D. C. The cause is unknown. The cure is to remove them by excision and cauterize the wound to stop the bleeding. Generally they are better left alone. Ulcers often result from interference with them.

Swinney.—"Dr. W. S.," Austin, Texas, has a mare which was strained and she recovered. A neighbor tells him his mare has had swiney, or sweeny, and will die unless taken care of. What shall he do for her? Swinney is altogether an imaginary disease. If the mare eats and works well, and shows no sign of lameness or any other ailment, she is all right.

Cracked Heel.—Amzi Jones, Smyrna, Tenn., wants a cure for cracked heel. Cause, low condition. Cure: Rest; wash with a lotion of two drams of chloride of zinc in a pint of water; give laxative food, and one ounce of tincture of chloride of iron daily, in some water. If the suppuration continues wash with one ounce carbolic acid in twenty ounces of water.

Power to Drive Sewing-Machines.—Jas. K. Jones, Washington, Ark., wants a good, cheap power to drive sewing-machines. This is a want not yet supplied. For information about patents write to some patent agency.

Wants to be a Tanner.—"G. L. P.," Cedar Mountain, N. C., wants a book to teach him to tan hides. The only one we know of is "Dussance on Tanning," price \$10, but the business can not be learned by means of a book—practical experience is necessary.

Blowed in the Hind Knees.—"Subscriber," Latrobe, Pa., has a valuable horse which is "blowed" in the hind knees. We suppose he refers to wind-galls, which are puffy enlargements along the course of the tendon of the hind leg, and are generally the result of over-work. Remedy: place on the lumps a folded rag wetted, over this place a piece of cork and cover with an india-rubber bandage, which must be constantly worn, except when at work. Rest is absolutely needful. Unless obstinately fixed this will remove them; if not, recourse must be had to iodine ointment, to cause the matter to be absorbed. To puncture these swellings would be to destroy the horse. Beg-spavin, blood-spavin, and thoroughpin are all varieties of this disease, and similar treatment is needed.

Clubs can at any time be increased by remitting for each addition the price paid by the original members; or a small club may be increased to a larger one; thus: a person having sent 10 subscribers and \$12, may afterward send 10 more subscribers with only \$3; making a club of 20 at \$1 each; and so of the other club rates.

How to Make a Saddle-Cloth.—"R. D. S. P.," Kansas City. Take a piece of fine horse blanket of the size required, lay it on the horse's back, slit it where it lies on the withers so that it fits the horse snugly, cut a triangular piece to fit the opening thus made; cut two pieces in the shape of a saddle, which sew or quilt, one on each side of the blanket, to form the pad. Fine corn-husks may be shred to furnish the filling. Bind with colored braid, and make a hole on each side, just beneath the pad, to pass the surcingle or girth through, and bind the edges with the braid.

Trees and Rabbits.—J. W. Allen, Kansas. Tanned paper will answer to prevent rabbits from gnawing trees. It is sold in all large cities for building purposes. Sprinkling the trees with blood, or rabbing them with bloody meat, will keep off the rabbits.

Is it the Canada Thistle?—J. Berry, Cooper Co., Mo. The specimen is not Canada Thistle, but the Wild Teazle. It is a troublesome weed if allowed to spread, but is easily subdued.

Uneven Pulling.—Chas. Shrader, Cassville, Wis., asks if one horse of a team draws ahead of the other, is it any disadvantage to either in working? Unless the double-tree catches on the frame of the wagon or sled, the changing angle makes no difference in the draft. But it is a slovenly mode of working.

Dent Corn at the North.—As a rule, the large Dent corn, under ordinary treatment, does not mature sufficiently early to render its cultivation profitable in New York or in New England. The late Joseph Wright, of Seneca Co., N. Y., has raised this kind of corn with success for many years; but he sent to Illinois every year for his seed, and was careful to plant it on very rich land. His friend and neighbor, S. W., writes us: "The Illinois Dent corn this year was a short crop, from lack of more soaking showers. It was planted in rows 3 feet apart, and 8 inches apart in the rows. Had I planted it 15 inches apart in the rows, it would not have curled its leaves, and every stalk would have perfected an ear. I have proved that the Dent corn will yield one third more than any flint variety; but its large stalks exhaust more water and require more space." This is undoubtedly the case. And for the same reason it also requires richer land.

Fattening Poultry.—Corn is in this country the obviously proper feed for fattening fowls. It makes flesh of fair quality. Oatmeal gives a better flavor but less fat. Corn should predominate, and be fed for the most part ground, because more can be digested than when it must all be reduced by a slow process in the gizzard. The latter is a perfect mill, but if employed too much the muscular exertion of working it takes something from the rate of fattening. The corn-meal should, for a few days, be thoroughly cooked, but the mess will soon pall upon the appetite, and then the meal may be merely scalded and finally fed raw, since fowls like this best, and they should be induced to eat as much as possible. To tempt with variety, give an occasional feed of buckwheat corn, and wheat whole, and oats, which last should be ground and screened, so as to remove all the larger fragments of the hulls. Boiled potatoes and fresh cooked meat should be allowed sparingly, and every other day a little cayenne and salt must be added to the dough. Feed adult poultry, for fattening, three times a day, and chickens four. It is especially necessary, when the days are short, to give the first food at the appearance of light, and the last as late as possible. After they have eaten to satiety, always remove what is left. Feed at stated hours, and keep the feeding-trough clean and sweet. It is best to confine grown fowls in rather small coops, as exercise prevents fattening. If, however, individuals unacquainted with each other are put together, there is no gain in close quarters, for they become uneasy; and also half-grown chickens ought not to be shut up, but rather induced to eat so much that they will roam as little as possible, for if taken from their accustomed run they are apt to worry constantly. Shut out light from the coop, excepting at feeding time, to promote quietness. There should be no perches. Cover the floor with dried earth, often renewed.

A Favorable Introduction to more than 150,000 persons throughout the United States, with a statement to each one of the desirable qualities of the articles you wish to sell, would be worth how much? It can be partially secured by sending to each (if you have the addresses) a circular through the mail, costing somewhat as follows:

150,000 circulars of cheapest kind.....	\$150
150,000 envelopes " "	150
Folding and addressing.....	225
Postage, @ 2c. each.....	3,000
Total cost.....	\$3,525

Many parties have found even this large outlay a paying one, by the resulting increase in business. Apart from its cost, however, this method is unsatisfactory, because few persons will carefully read a common circular, and not one in a hundred will keep such a document—it is glanced at and thrown into the waste-basket. Now, a whole page of the *American Agriculturist*, in which a dealer can fully set forth his business, will at the regular published rates cost \$666. This is less than one fifth the expense by the circular method. It has also the advantage of being placed before not merely 150,000 subscribers, but the many others who regularly read the paper, which is preserved at least a month, and in most cases is kept year by year. But, what is of greater value, the readers of this journal have confidence in the parties thus introduced; they know the care taken to exclude all who can not be indorsed as reliable parties selling good articles.

Is Lime a Manure Directly or Indirectly?—"A Subscriber." If by manure is meant a

substance which contributes anything directly to the soil which plants can appropriate, then lime is a manure in the ordinary sense; for most plants contain lime in larger or smaller quantities. But lime does more—it renders soluble or decomposes vegetable matter, such as swamp-muck, and the roots and refuse of former crops. It also neutralizes the acids existing in a free state in the soil, and renders hurtful matters innocuous, or liberates fertilizing matter. It also acts mechanically on the soil.

Drain Tiles or Round Stones.—D. C. Faris, Walker Co., Ga., needs to drain his land, and can not procure tiles, as there is no manufactory in his locality. Can he use stones?—In "Waring's Draining for Profit," a home-made tile-machine is figured which would be found useful. Round stones will make a substitute. We have prepared an article on their use, with drawings, but it will not be in time for this number.

Bacon without Skippers.—John Miller, Slackwater, Pa., sends his method of curing bacon and hams as follows: For 1000 pounds of meat, take 10 quarts of salt, 3 pounds of sugar, 1 pound saltpeter, 1 pound black-pepper (ground). Dissolve the saltpeter in a pint of water, and mix it with the other ingredients; rub the mixture over the meat on both sides, and keep it in a cool place for ten days. Smoke as usual. Then place the meat in a box, and keep covered with dry salt.

Tile Machine Wanted.—J. B. G., Sandusky, O., wants a tile-machine, and finds none advertised. I. W. Penfield, Willoughby, O., and F. M. Msttee, Cleveland, O., lately advertised their machines in the *American Agriculturist*. Write them.

Analysis of Soils.—"E. W.," Zaleski, O. It would be money wasted for farmers to have their soils analyzed. It is an exploded notion. Put on a plenty of stable manure and you need not go to a chemist to find out what your soil needs.

Medicinal Plants.—E. Wagner asks why farmers do not engage in the cultivation of medicinal plants. They will not take requisite care in cultivation. Labor is too high, and the market too uncertain.

Honey-Locust Seeds.—O. Moffet. The seeds, if not too dry, will usually grow readily, but it is safest to scald them before sowing in spring; or, if mixed with earth and allowed to freeze and thaw, they will grow without difficulty.

The Art of Advertising so as to make it pay is usually acquired only by long experience and costly experiment—even by those who have a natural tact in this direction. For this reason, those intending to do much advertising, generally find it profitable to employ an experienced adept—one who has the "know how" of making advertisements tell. There are several good advertising agencies, and many very poor ones. Among the former we commend to attention Messrs. Fitch & Thain, located in the *American Agriculturist* Building. Mr. Fitch has had charge of our own advertising department for a dozen years past, and still continues that relation. His associate, Mr. Thain, was formerly in charge of the advertising department of the *Western Rural*, and recently one of the advertising firm of Messrs. Sharp & Thain, of Chicago, until they were burned out. While Mr. Fitch will continue as hitherto to take charge of our own advertising columns, the business of the above firm will be wholly independent of any relation to this office. They offer their services to reliable advertisers, and propose to help them prepare their announcements, and to insert them on favorable terms in the newspapers of the country generally, with no charge for their services to the advertisers themselves. From what we know of their skill in this line and their reliability, we commend them to the confidence of the press and of business men who may need their services.

Marengo Crabs.—We have before had a good word to say for these hardy and excellent crab apples. If our friends who live up near the North-pole, can raise such apples as these, they need not complain. The introducer of these apples, C. Andrews, is now associated with Herendeen & Jones at Geneva, N. Y. The specimens recently sent us were fine to look at and excellent to eat, especially when cooked.

Almond upon Peach.—A. F. Smith, Sierra Co., Cal.—The almond would doubtless grow upon the peach stock, but we can not tell how it would last. In Europe it is generally budded upon the almond and plum, the last named being preferred in a cold, wet soil.

A Hundred per Cent Interest.—"Book-farming" is a great bugbear with the majority of cultivators. Why, we could never quite discern. Mr. A. settles on a farm, goes to work hard, and never talks with any neighbor. Mr. B, living alongside Mr. A., with equal advantages in soil, capital, etc., drops in on an evening on Messrs. C, D, E, F., and G.—talks with them about their crops, modes of culture, animals, and marketing crops. He goes to the clubs and fairs for the same purpose. In this way he not only has his own skill and experience, just as Mr. A. has, but he also has the benefit of the experience and the thinking and planning of many others. If he gets no new hints from them, the conversation stimulates his own thoughts to activity, and he plans his work and his crops better. Mr. A., in effect, says: "I know it all; I know so much that nobody can tell me anything." Mr. B. says: "I think I know a good deal, but the rest of the people know some things I do not, and I will try and get these." A good book is only a collection of the thoughts and practices of many men on some subject. Agricultural papers are similar, but they discuss a wider range of subjects, and embody the thought and describe the practices of a larger number. No man or boy can read such papers or books without, sensibly or insensibly to himself, having his mind developed and enlarged, his thinking and his reasoning improved; and his hard labor will be more profitable, whether he suspects it or not. We firmly believe—we know—that every dollar invested in good books and papers to be read, will pay back a dollar every year—a hundred per cent—yes, much more. Farmers, every cultivator of a plot of ground, take our advice, and now, at the beginning of this year, squeeze out a few dollars, even if you have to borrow on 10 per cent interest, and buy a few good books and papers and read them this year. Let your sons and workmen read them. After you have done so, you will not part with the knowledge and the mind-power gained for many times the cost of the books and papers. Try it. Take a step forward and upward in knowledge and mind-power this year. It will pay in many ways—it will pay in dollars. Sell, if it need be, an acre of land, put it into good reading matter for your sons; they will grow up with developed minds, and be far happier and more successful in the world than if you kept them ignorant of their business, and left them that extra acre at your death. They will be happier while at work if you give them something to read and think about, especially if it relates to the work they are doing—the soil, the crops, the animals they daily handle. You will find in the premium list and in the advertising columns some books worth getting.

Worms in Hogs.—Allen Cope sends a description of a worm, a foot in length, which infests his hogs. He administered the common remedies: salt, ashes, sulphur, copperas, and finally calomel, which brought away the worms. Had some simple remedy been given as a preventive, probably no trouble would have occurred. The treatment was judicious otherwise.

Cure for Crib-Biting and Wind-Sucking.—J. Teakle, Baltimore, has discovered a method of curing this unpleasant vice, but without a drawing we can not fully understand it. Send a sketch.

To Stain Leather.—"A Reader." A solution of sulphate of iron (copperas), applied to sole-leather, will color it black. When leather has from exposure become whitish, the black may be restored by wetting it with a solution of gallic acid, before using the sulphate.

Cure for Curb.—"A Reader" may cure curb, if not of long standing, by using fomentations of hot water for twenty minutes, followed by a blistering ointment of biniodide of mercury and lard. Continue daily until a good blister is formed. As this is a very poisonous substance, the greatest caution in using it is necessary.

No Fences in Ottawa Co., Kansas.—Frank Philbrick thinks a golden opportunity is offered to men of small means in Ottawa, and six adjoining counties of Kansas, where they can open a farm on the broad prairie at no cost for fences, as cattle, by law, must be herded by their owners. Ottawa is on the Solomon River, north of the Pacific Railroad.

Shall the Boy be Allowed to Climb?—A farmer whose father was a sailor, has a six-year-old boy who delights in climbing on to the roof of the house and other high places. Shall he endeavor to curb this propensity? Why should he? There must be sailors, and this boy is evidently destined to "a life on the ocean wave." A sailor's life is hard, and so is a farmer's, and a good sailor may be an indifferent farmer. Let him follow his bent, and educate him so that he may have every facility for success.

Flower Seeds Gratis.—Last spring we published an offer from Charles D. Copeland, of Lima, Livingston County, N. Y., offering free parcels of flower seeds to any subscriber to the *American Agriculturist*. We learn that some six thousand of our readers responded, and that much satisfaction has been expressed by them in numerous letters. Mr. Copeland informs us that he renews the offer this year, having enough extra seeds fresh grown the past year to supply over fifty thousand such parcels, if called for. Each paper contains mixed seed of fancy Pinks and Sweet Williams, embracing an almost endless variety of the best German, Indian, Chinese, and Japanese varieties. We believe Mr. Copeland to be reliable, and that he will promptly respond to any calls from our readers. All that is required is the post-office address, a statement that the seeds will be acceptable, and the inclosure of a post-office stamp to prepay postage. Send to Lima, N. Y., as above.

How his Scales paid the Interest on their Cost.—"D. R.," of Worcester, Mass., has put up a pair of large hay scales. One item of saving was 24 bushels of corn, the difference between the figures on the bill and actual weight of a car-load.

Shall he Sell the Milk or Butter?—J. H. Y. asks which is best, to sell milk at 5 cents per quart at his door, or make butter at 30 cents, and pay freight, etc., out of that. There is double the money in milk at 5 cents, and less labor.

Cotton-Seed Meal.—"C. W. C.," of Bricksburg, N. J., writes: "Won't you please tell us about feeding oil or cotton-seed cake? I am feeding five quarts of wheat bran a day to my cows, and think of using cotton-seed cake during the winter. Had I better use that alone, or alternate with bran?"—If you are feeding for milk or for fat, use cotton-seed meal (or cake) with bran. If for butter, leave it alone. It will make your butter flaky and tallowy.

Which is the Best Churn?—We do not know. Twenty dairymen, each using a churn of different pattern, will each testify that his own is "superior to all others." So it is, for his use, so long as he is better satisfied with it than with any other. Next to good butter, perhaps, a satisfaction with one's self and possessions (including churns) is one of the most enjoyable blessings. Without disparagement to other makers, however, we can freely say the Blanchard Churn is very popular, eminently satisfactory, and deservedly so. The claim of the manufacturers that they make the churn of the best materials and workmanship we know to be well founded, and this fact has given it wide celebrity and immense success.

Mr. Sheldon Stephens, a farmer and a breeder of Jerseys near Montreal, writes: "While I was away I did not see the Country Gentleman, and I now find, in an October number, a paragraph announcing the sale of all my Jerseys, and that I have 'changed my business.' This would imply a want of confidence on my part in Jerseys as a breed, and dissatisfaction with farming as a pursuit. I wish you would correct this erroneous impression in the *Agriculturist*, and say that I have no intention of giving up the breeding of Jerseys or of changing my business in the least. I hope I shall be able to finish tile-draining, and working up my farm to the best condition; and I have not the slightest desire to open a shop of any sort."

Blue Gum—Eucalyptus.—"T. A. W.," Elgin, Ill. This quick-growing Australian tree has proved a great success in California. We have not heard of its being tried in Colorado, but doubt if the climate would be suited to it. French writers, speaking of its growth in Algiers, say that it will flourish wherever the orange will grow. Its northern limit is not well ascertained.

Judson's Branching Corn.—In December last we published the statement of one of our associates that he had tried three varieties of Judson's Branching Corn, and failed to get over two ears to the stalk. We have now evidence which shows different results in other hands. "T. D.," Sharon, Pa., planted the sweet variety and found it most prolific. One stalk produced eight good ears, some stalks five, others four, and never less than three. O. F. Treadwell, of New Haven, Ct., planted the Branching Sweet; "nearly every stalk had two ears and a good share of branching." Another lot planted in another place had among its stalks with five and six ears, but they were not well formed. There is much complaint in other quarters in regard to this corn, and we infer that there has been unfair dealing somewhere in relation to it.

Best Floor for a House without a Cellar.—Wm. Webb, Huntington, Ind. After the joists are placed, fill in with coarse gravel and ram down hard; on this put a coat of cement and fine gravel and beat down level with the joists; lay the floor close on this as soon as it is dry. No rats or mice will work under it.

To Measure Hay in the Mow.—"A Reader" wants a rule for measuring hay in the mow. 500 cubic feet of close-packed timothy hay will make a ton, or 800 feet of loosely packed clover hay. Between these limits the difference is relative to the condition of the hay.

How to use a Siphon.—"A Subscriber," Raleigh, N. C., has on a hill a well twelve feet deep; a ravine, 200 feet distant, is four feet lower than the water in the well; will a siphon cause the water to flow into the ravine? Yes. To start the water, solder a short piece of pipe into the siphon, just below the bend, over the edge of the well; close with a plug the lower end; fill the long leg of the siphon with water through the pipe soldered on; when full, plug up the orifice and cement air-tight; withdraw the plug at the lower end, and the water will flow, and continue until it is all drawn off. If the supply remains constant, the stream will be constant too.

Pennsylvania Fruit-Growers' Association.—This, one of the most thoroughly active and useful bodies in the country, will hold its next annual meeting at Horticultural Hall, in Philadelphia, on January 17th. Addresses will be given by several prominent fruit-growers and others, and the discussions which will follow will be well worth hearing. Josiah Hoopes is President, and a number of other live men are upon the list of officers.

Cabbage-Louse.—"A Subscriber," Succasunna, N. Y., has had nearly all his turnips destroyed by lice, which consumed the leaves. How shall he destroy them? The best remedy is lime, slaked dry with water in which carbolic acid has been dissolved, one part, and dry air-slaked lime three parts; mix together and sprinkle on the leaves, while wet with dew. Where they are very numerous on a leaf, it is better to remove it and destroy them by burning.

A Freak in Corn.—A gentleman sends from Pittsburgh, Pa., a specimen of corn having well-developed grains upon the tassel. This is not rare.

Tobacco.—"Z. G. H.," Salem, N. C. It would take several long articles to answer your queries. You had better procure our pamphlet upon Tobacco Culture. See book list. The quality is greatly influenced by soil and climate, and you should endeavor to find out what kind does best in your vicinity. Connecticut seed-leaf grown in your State would be quite unlike that raised in the Connecticut Valley from the same lot of seed. New York is usually the best market for all products.

How to Raise a Calf.—F. Prade, Rockville, Ct., takes a bladder and fills it with warm milk and allows the calf to suck. Better teach it to drink from the pail at once, which may be readily done.

Marl from Iowa.—N. J. Bart & Co., Burlington, Iowa, send a sample of marl and asks its value. The specimen is carbonate of lime, and has evidently resulted from the decomposition of a limestone rock. It will be of value as a top-dressing to grass land, especially so to clover, and also to soils which contain much vegetable matter. It may be spread in quantities of 50 to 100 bushels per acre.

Queer Eggs.—A subscriber in Charleston, S. C., writes an interesting letter graphically describing the effect produced upon the colored people of his neighborhood by black eggs which have been laid for two seasons by a duck which he keeps. Such an occurrence as a black egg may, naturally enough, be construed into an omen by the superstitious, and is quite as anomalous as a white blackbird. He says: "The duck is of an ordinary English breed, with a white neck-ring and breast. She lays about fifteen eggs, then stops a while and resumes. The first egg of each laying is as black as the ink with which your journal is printed, and each successive one is a shade lighter, until a dark slate color is reached. The color can not be washed or rubbed off, but can be removed by scraping with a knife." Our correspondent asks us to explain the occurrence. We can only say that in many cases of discoloration of various animal secretions, carbon is the pigment deposited, and very likely it is in this instance. The eggs must be considered abnormal, yet they may produce ducklings that are perfectly healthy. It is worth while to raise some in order to find whether the trait will prove hereditary, as it may.

IF.—If you persuade a neighbor to take and read a wide-awake, instructive, reliable journal, treating specially of his business, you set him to thinking, you elevate him and his family. He will experiment, and you will have the benefit of his experiments. His family will read and be more intelligent neighbors. The tone of society will improve; and your own property even will be improved in value. Every additional reader in the place will have a like tendency. Scatter annually in any neighborhood \$50 worth of good periodicals and books, on agriculture, horticulture, and domestic economy, and it will change the character of the neighborhood, and increase the intelligence and the desirableness of the place, and raise its product many hundreds of dollars in the aggregate, every year. One easy, cheap way of accomplishing this is, for the people to unite, raise a club, and each receive this journal, or *Hearth and Home*, or *both*, and get one of the book premiums as a library for common use by all. It only needs some wide-awake, enterprising, public-spirited man or woman—young or old—to start the enterprise in each neighborhood. See premiums 94 to 106, pages 37 and 38. By a little effort any man or boy may secure quite a lot of good books for himself as a premium without money.

Pacific Railroad Lands.—The Directors of the Northern Pacific Railroad have established the rule "That land exploration tickets over the Northern Pacific Railroad be sold at full fare, and that persons who take such tickets and within sixty days thereafter purchase lands of the Company to the amount of 40 acres or more, shall be credited the fare on their purchase and be entitled to free tickets for themselves and families when going to settle upon the lands purchased."

Our Staff.—The *Agriculturist* commences the new year with an unusually full corps of editors, special contributors, correspondents, etc. In looking over the list we are gratified to notice that there is not a man among them who is, ever has been, nor, so far as we know, expects to be a Member of Congress or of a State Legislature, a City Alderman, or even a Mayor. We therefore feel assured that all engaged upon the paper will be able to devote their time to the interests of our readers.

Fowls Sneezing.—"G. H.," Cleveland, O. Poultry sometimes sneeze when swallowing soft food, for the same reason that children do, *i. e.*, they eat too fast. But if your fowls frequently sneeze at other times, you had better look closely for a discharge at the beak, and other signs of roup. Sneezing in the poultry-yard is a thing not to be sneezed at, for it is often the first intimation of this troublesome disease. A careful poultry-keeper will go the rounds of the roosts by lantern-light, listening for such warnings.

The Best Clover to Sow on Poor Land.—A. D. Cloyd, Nashville, Tenn., wants to sow clover, on poor land worn out with corn, as a fertilizer, and asks if the small Red or the Mammoth clover is the best. The large clover makes the largest amount of matter to plow under, but it is often difficult to get it properly covered. We tried it once, but abandoned it for the common Red.

How to Dye a Permanent Red.—A lady asks for a permanent red dye for cotton. There is no permanent red except the old-fashioned "Turkey" or Madder red. This is obtained by means of a bath of boiling solution of alum in water. When the cloth is saturated with alum, it is to be placed in a decoction of Madder-root for an hour, rinsed in clear water, and plunged into a lye of common soda, and again washed in clear water.

A Ditching Machine.—A person asks us to notice favorably a ditching machine in which he is interested. It is altogether contrary to our practice to recommend or even advertise anything, unless we are satisfied it is really what it is represented to be. Our advertising columns would be the proper means of introducing it to our readers.

To Tan Sheep-Skins for Whip-Lashes.—R. S. H., Middletown, Ct., can tan sheep-skins for this purpose by soaking them in weak lime-water, to remove the wool, and then rubbing them with oil or grease with pressure of a roller thicker in the centre than at the ends. They will absorb a large quantity of grease. Finish with chalk or whiting.

Asparagus Beetle.—"A. C. K.," Elizabeth, N. J. The insect undergoes its transformation below the surface of the earth or under rubbish. It requires over a month from the egg to the perfect insect. Three broods are produced in a year. The perfect insects of the last brood, which hatches in September, pass the winter hidden under loose bark or in some similar shelter.

Walks and Talks.—J. S. Bowles, Hamilton Co., O.—These papers have never been collected in a book form. You can only obtain them by purchasing the back volumes of the *Agriculturist*.

SUNDRY HUMBUGS.—We are thoroughly tired of the constant labor, watching, and care involved in keeping up, month after month, and year after year, the chapter under this head. But the thousands of letters commendatory of its great usefulness, and the reports of hundreds of thousands, if not millions, of dollars in the aggregate saved to the people of the country, compel us to keep up an unceasing warfare upon swindlers who grow rich by taking advantage of ignorant people, and those easily imposed upon, because, honest in themselves, they are unsuspecting of fraud in others. So we shall in future cheerfully continue the work as in the past. The chapter this month is crowded out from its usual place, but we have made room for it by leaving out a page of advertisements—see page 39.

School Geographies.—Messrs. Wilson, Hinkle & Co., Cincinnati, publish a series of school geographies by Gen. Von Steiuwehr, called the Eclectic Series. It includes a primary work and two of a higher grade. It is difficult to conceive of anything finer in the way of school-books. The maps and engravings are exquisite, and when we consider how firmly fixed are the first impressions too much importance can not be attached to excellence and accuracy in the pictorial and topographical illustrations. The works are brought up to the present time, and we have derived much pleasure in studying the beautiful maps, which, though made for children, will be found useful to all. Map-drawing occupies a considerable space in the course, and physical geography receives proper attention.

Dry Murrain.—W. H. Catlin, Burton Co., Mo., asks the cause and remedy for dry murrain. The only symptom given to us is one not generally belonging to this disease, and it is therefore doubtful if the cows were suffering from it. Murrain is consequent in a low, debilitated condition, and tonics or astringents are administered with sulphur. In the absence of a more exact description it is impossible to advise.

The Best Churn.—"J. P. C.," Dayton, O., asks which is the best churn? He wants one "that has no dash and is innocent of inside works." Such churns are rare in this country. We believe the Kalmanck Tartars use something of that sort, made of a goat's skin, but their butter would not fetch much in our markets. We use a churn which turns by means of a crank and cog-wheels, and has a double dash, but no other inside works. When the butter comes the dash will gather it by turning back and forth.

Paint for Farm Implements.—"G. R. W.," wants to know how to mix paints for painting farm implements or wagons. A coat of crude petroleum will make a good ground to commence with. To cover this, boiled linseed oil should be used, mixed with a portion of litharge, or patent dryer—about a pound to the pint of oil. For colors, use red-lead, lamp-black, Paris green, Prussian blue, or red or brown oxides of iron (commonly called fire-proof mineral paint). The green and blue are costly colors.

How to Ascertain when it is Noon.—"W. H. C.," wants to know how to ascertain the correct time at noon any day in the year, so that he may be able to keep a clock regulated by it. To do this correctly requires the use of delicate instruments by which the highest altitude of the sun is taken. When the sun is in this position it is on the meridian, and it is noon at that particular place. An approximation may be made by getting up two plumb lines in such a position that they are in a direct line with the north star; a post is then set perpendicularly beneath each plumb bob. When the shadow of the south post falls exactly on a straight line, drawn from the foot of one post to that of the other, it is noon, for the sun is then exactly in the south. This can be reduced to mean time by comparing it with the time on which the sun is on the meridian for that day as given in the almanacs, and set the clock accordingly.

Cattle Licks.—"A Subscriber," Greenwood, Del., has some spots on his farm, which the cattle keep bare by continually licking them, and on which the corn is affected injuriously. What is the cause and remedy? The above description, and the fact that lime injures the crop, would seem to point to salt as the trouble. If so, no surface application will avail. Deep drains through the spots would possibly intercept the supply of salt and permit the rains in time to wash the surface free from it.

White Daisy.—Henry Zehner, Butler Co., Pa., has purchased foul timothy seed and has filled his land with white daisy. How shall he get rid of it? If it is inconvenient to plow the land in May, pasture it with sheep, which are very fond of this weed. But if plowed early in summer and any daisies that come up afterwards are pulled or destroyed before they seed, the land may be cleared of them.

Value of Liquid Manure.—"S.," Long Island, asks if it will pay to cart liquid manure half a mile; if so, how shall he apply it. It will pay, unless much diluted, and even then, if it can easily be hauled, it is worth the expense. Throw on to dry absorbents, or, what is preferable, spread directly.

Is Stable Manure at Two Dollars per Load better than Artificial Manures?—"W.," asks advice on this point. We would rather take the stable manure, if of average quality, at this price, than depend wholly on artificial manures. But we favor the use of bone-dust, superphosphate, and guano occasionally, as a help to barn-yard or stable manure. Plaster and lime, occasionally, are also indispensable.

The Cost of Draining.—"G. W.," wants information about the cost of underdraining. Draining by means of tiles, put four feet beneath the surface and forty feet apart, will cost from \$35 to \$50 per acre. The ditches will cost 50 cents per rod or less, according to the nature of the ground, the tiles 20 cents per rod, including the laying, and filling the ditches 10 cents, in all 80 cents.

Exhibition in Bermuda.—A fair will be held at Hamilton, Bermuda, commencing on January 23d. A glance at the premium list at once impresses one with the wonderful difference in climate between Bermuda and our Northern States. Prizes are offered for such fruits and vegetables as would be shown with us in August and September, as well as for many quite unknown in this country.

Subsoil from Utah.—S. J. Andersen, St. Peter's Co., Utah, sends a sample of the subsoil from his farm which kills young trees as soon as the roots penetrate it. What is it? The soil, which appears like a grayish clay finely pulverized, is evidently the remains of a rock containing a feldspar rich in soda. This in a rainless country would make a soil injurious to vegetation. Irrigation will, in time, remove the excess of soda.

"...Exceedingly Valuable to me are your pages of advertisements," writes an old subscriber, "for I have learned to turn to them with confidence, since knowing that the publishers give careful attention to editing this department of the *American Agriculturist* and *Hearth and Home*. It is such a relief to see business announcements that are not sandwiched with 'patent medicines,' 'gift enterprises,' humbugs, and the like. And then the feeling that unreliable parties are excluded from these columns, and that I can order from any advertiser who is admitted, without fear of being unfairly dealt with, is surely a comfort. I value this feature of the paper so highly that I should continue a subscriber for it even if you sent me nothing but the advertising pages. I doubt not you could make ten times as much present money, if you let in the excluded class, who, giving little for the much money they get, can afford to pay big prices for advertisements, but I am sure your course will pay best in the long run...." The above is an epitome of a multitude of letters received—and we value such testimony. We hope our readers who think thus will make their feelings known to our advertisers, when writing to them with orders, or for circulars, etc., or at least tell them where their advertisements were seen.

Chinese Yam.—"Subscriber," Taunton, Mass. There is no difficulty in growing the yam, but the trouble is to get the crop out of the ground. The tubers are often three feet long, largest at the lower end, and as brittle as glass. In view of the difficulty of digging them, some one proposed to go to China and pull them through.

A German Edition of this Journal has been issued for 14 years past, and is still continued. It contains the engravings and principal articles of the English edition, with a special German department, edited by Hon. Fred. Münch, a distinguished culturist of Missouri. This edition ought to be in the hands of every German cultivator in the country, and is of special value to the multitudes constantly coming hither from the old world. Many subscribers to the English edition also take the German edition for their German gardeners and laborers. Our friends will oblige us, and their German neighbors also, by informing them of the above facts. The German edition is supplied at the same price as the English, and may form a part of clubs for the latter.

"Ten Dollars a Day."

Advertisements like the above are very common, with the addition of "expenses paid." An investigation will generally (not always) show that, to get a chance at such a prize, one must first advance more or less money, which is gone in any case, and then he must trust to luck in selling some "glimcrack" to get his salary and expenses out of a commission.—We think a much better opportunity is presented in the premiums offered on page 37. No advance money is required, and no expenses needed. One has only to show specimen copies of the papers (presented free) to his friends and neighbors, explain their character, and solicit their subscriptions. It will be seen that a very few names will secure a \$10 article free, that is worth this amount of cash, either for use or for sale. This can usually be done evenings, and when not engaged in one's regular occupation. We make no promises of any sure amount per day or hour, but we do know that a multitude of persons have realized as much as ten dollars a day—often much more—in canvassing for our premium articles, and that there are thousands of others who may do the same thing, with profit to themselves, to the publishers, and to those they secure as subscribers. See pages 37 and 38.

Prolific Ewes.—Mr. Wm. Woodsell, Bath County, Va., writes that he has two ewes which are each two years old this spring, and the two together have given birth to fourteen lambs. A year ago this spring they were yearlings and had three lambs each, but as these came in cold weather they froze to death. This year the ewes had each four lambs, seven of which are living, of good size and lively. This is a remarkable case.

Manuring a Garden.—"A. McM." If the manure is at hand haul it on whenever you can. We manure and plow in the fall and plow again in spring.

"Missionary" Grape-Vine.—Geo. W. Baldock, Clark County, Ind. We know of no vine of this name. The Mission grape, so common in California, is an European variety, and if you have bought this you are, as you suspect, "humbugged," in so far as it will not succeed with you in out-door culture.

The Advantage of a Pair of Platform Scales.—Geo. H. Russell, Oakville, Pa., writes us setting forth the trouble farmers labor under in selling their grain, both in being cheated in weight and being compelled, for want of storage, to sell at unfavorable periods. We have impressed on farmers the advantage of weighing the whole of their produce accurately before taking it to market, and insisting on receiving the true proceeds. This can only be done by procuring and using correct platform scales—steel yards are not reliable. Safe bins for storing grain have been already figured and described in the *American Agriculturist*.

How to Kill Old Horses.—"Mass." Taunton, Mass., asks how to kill an old horse most speedily. This is a humane proceeding, and a far more "Christian work" than selling them to draw canal-boats. A bullet from a rifle or Colt's navy revolver at the base of the ear is the most speedy and painless mode of destroying an animal. But let some person apply it that is free from nervousness and can do it with certainty.

Ayrshires or Jerseys for Butter.—A Massachusetts farmer asks which are better, Ayrshires or Jerseys, for butter? There is no doubt but the Jersey cow is preferable for yielding butter in quantity and quality. We think the Ayrshires come next. Some prefer Devons to Ayrshires. In their native county—Ayr, in Scotland—they are considered as "butter cows" as well as cheese cows. We have had excellent cows of the Ayrshire and Jersey breeds, and could hardly say which we prefer for the ordinary uses of the farm. It is the mode of preparation which makes it necessary for "Jersey" (not New Jersey) butter to be eaten fresh. Properly salted it will keep a year or longer.

Age to Market Poultry.—"J. W. A." Kansas City, Mo. No precise age can be given at which hens cease to be profitable as layers. This depends on breed, degree of thrift, and amount of previous laying. Hens forced by high feeding to lay profusely during the early part of their lives will lay correspondingly less afterwards.

➔ See Page 37.

Food for Thorough-bred Pigs.—II.

K. Smith, of Illinois, writes that he has just bought a pair of thorough-bred Essex pigs. "I am," he says, "pleased with them. They are as quiet as cats. I would like to ask your opinion as to how they should be fed to produce the best results. I am now giving a mush made of unboiled wheat and oatmeal mixed with good milk. I thought it best not to give too much corn while young." We can suggest no improvement to the above diet. It is very nutritious food, but as long as the pigs are growing rapidly it will not hurt them. The point is to feed them as much as they can digest and turn into flesh. If they eat more than they can digest, it will produce scours. In this case reduce the quality of the food by mixing bran with it. A few potatoes, parsnips, beets, or mangolds may be given with advantage. Let them have as much exercise as possible.

Onions.—"Mrs. J. S." As we can not make out your locality we must answer on general principles. If you intend to raise onions to sell green, you must buy the sets, which will cost this year about \$7 or \$8 per bushel. Much depends on the size of the sets, but the ordinary size will require 15 to 20 bushels to plant an acre. However, as the labor on onions so planted is great, though the profits are large, you had better not attempt more than an eighth part of an acre at most. If you intend to sell onions dry, then you must sow the seed. The red is most generally grown. Price of seed about \$2 per pound; quantity sown with seed sower, in drills, per acre, two or three pounds. We can not estimate the crop, as all depends on the condition of the land and the care with which it is cultivated. The seed can be purchased of any of the seedsmen advertising in our columns. It is best to buy at once, before the rush of orders begins, as if you delay it late in the season you may not be able to get your order filled in time. The rush on our seedsmen is so great as the season is opening in spring that many orders are necessarily delayed until it is too late.

Growing Timothy Seed.—"W. J. J." asks "if timothy seed draws heavily on the land." Probably not. The main difference between raising a crop of timothy hay and a crop of timothy seed is that the nutriment in the one case is distributed through the hay, while in the other a portion of it is taken from the hay and concentrated in the seed. The formation of seed draws heavily on the hay, but not necessarily on the land.

Best Variety of Winter Wheat for Illinois.—An Illinois farmer says he raises Mediterranean wheat, and that "the yield is not satisfactory—only twenty bushels per acre," and he wants a better variety. We shall be glad to hear from our readers on this point. Our varieties of wheat are better than our culture.

Red Ink and Pencil.—Some people will write with red ink and others will use pencil. An editor who has much to do will usually drop communications written with either of these mediums into the waste basket. Black ink if you please, and leave these reds, mauves, and all other colored abominations to school-girls.

Thorns for Hedges.—"Young Farmer," Ont. We do not know what you mean by "Common Thorn," without specimens. There are three or four that are common. Thorns are used for hedges, but they come out too late, and are too liable to attacks of insects, to be popular. The seed generally remains a year in the ground before germinating.

Florida Oranges.—Mr. Day, Jr., Daytona, Fla., left with us a twig bearing a cluster of 28 oranges.

Strawberry Queries.—W. M. Allen, O. The Wilson does not need any other variety to fertilize it. Comstock's Pony Cultivator has a runner-cutter attachment, but we have never seen it in use.

Smoking Out Hen-Lice.—S. Underwood, Harwich, Mass., writes us that after whitewashing his hen-roosts and trying change of location, both of which afforded only temporary relief from vermin, he smoked the roost very thoroughly so that the poles and walls were impregnated with the odor of the smoke for a long while, and though eight years have elapsed, no hen-lice have been seen in the apartment since.

Potato-Seeds.—"G. W. B." Charlestown, Ind. Let the seeds remain in the balls until time to sow them, then treat them as you would tomato-seeds. Start in a hot-bed or in a warm room, and when the weather is suitable transplant them.

Patent Beodorizer.—"G. W. G." Washington, D. C. We do not see that this patent matter is any better for the public than dry earth, which is not patented (as yet), but if the patentee thinks differently he will find our advertising terms on page 29.

Evergreen Seeds and Plants.—"J. M. P., N. H." Keep the seeds of evergreens in the cones until spring. They are sown like any other seeds. It will be of little use to try to raise evergreens from the seed unless shade is provided. Hemlock and white pine are transplanted in spring. The precise time is not of so much consequence as is keeping the roots moist whenever the work is done.

A Good Barley Crop and What to do with it.—A correspondent in Iowa says he raised this year 290 bushels of barley from 6 acres. He can only get 35 cents per bushel for it, and asks whether he had better sell it at that price or feed it to his sheep. He can buy corn at 20 cents a bushel in the ear. Corn is as nutritious as barley, weight for weight. Barley weighs 48 pounds per bushel, corn 56 pounds. If corn is worth 20 cents per bushel, barley is worth 17 1/7 cents. Our correspondent had better sell his barley and buy corn.

Grinding Grain for Sheep.—A Western farmer says he is ten miles from mill, and asks us if it will pay to take his grain that distance, and pay one seventh toll to have it ground for sheep. Certainly not; grain does not need grinding for sheep.

Lime for Wheat.—An Iowa farmer asks when it is best to apply lime to winter wheat. Spread it broadcast on the land any time during the previous spring or summer, or just before sowing the wheat, and harrow and cultivate it in.

"The Cancer Plant."—That man or association of men, who calls himself or themselves the "New York Medical University," is or are not to be outdone by the Cundurango folks. Before these people were fairly ready with their South American cancer cure, the "University" folks were out with "their Cancer Plant," and a pamphlet, entitled a "History of the Cancer Plant," is spread broadcast. This pamphlet says: "The Cancer Plant (*Plantago Cancerorum*) evidently belongs to the natural order *Plantaginaceae*, and sexual system *Tetrandria Monogynia*." It is a little remarkable that a *Plantago* should belong to the order *Plantaginaceae*, isn't it? "It is a small plant, having several sea-green, purple-veined leaves, with a central, upright stalk bearing diminutive yellow flowers, found in the vicinity of swamps and in moist earth, on the borders of pine forests in the Southern and Middle States. We may err in claiming it as a recent discovery, but we have shown specimens to several physicians and botanists, who say they have never seen anything like it before. It is certainly not laid down in any medical or botanical work with which we are acquainted." We do not know with what kind of botanists and botanical works these "University" chaps are acquainted, but we do not know of any botanist, even the merest student, so utterly ignorant and stupid as not to know that the figure given of this precious plant is not that of a *Plantago*, and that it "evidently" does not belong to the *Plantaginaceae*, but is an undoubted *Composita*, being a tolerably fair picture of the very common and well-known *Hieracium venosum*, the Rattlesnake-weed, so called because it has in common with many other native plants a popular reputation in some localities as an antidote for the bites of snakes. With the medical properties of this plant, if it has any, we have nothing to do. The story of the "University" chaps in relation to them is sufficiently set forth and illustrated by the most repulsive engravings in the pamphlet before us. The point we wish to make is this: Here are persons calling themselves "doctors," and blowing their own trumpets under the false pretense that they are a "University," who know nothing about the plant they profess to use. They are fools enough to suppose that a *Hieracium* is a *Plantago*. To be sure they are both plants, and so are a robin and a turkey-buzzard both birds.

Bee Notes for January.—By M. Quindy.

This is the trying month for bees in the open air. Such as have too much honey can not pack close enough together to keep warm. The very heavy hives should be protected with an outside covering during the severest weather. The bees in those hives that have only a moderate quantity of honey have empty cells to creep into, and can pack close for mutual protection, but are in danger of starving, even with stores in the hive. If the weather does not change from extremely cold to moderate at least once in two weeks, so as to melt the frost in

the hive, and allow the bees to leave the cluster and go among the stores for a supply, they will starve. Take such hives into a dark, warm room for a short time. It is seldom that severe weather is sufficiently protracted to make it necessary to take this trouble with strong, good stocks. Keep air-passages unobstructed, particularly those at the bottom. If mice have found their way into the hive, the fact may be known by crumbs of comb scattered on the bottom-board. Exclude them by wire-cloth over the entrance, allowing room for only one bee to pass at a time, and set traps for the mice. Now is the time to prepare the hives for next summer. Of course my preference for movable-comb hives, such as I use, is well understood, and I would impress on all intelligent beekeepers the advantage of frames of some sort. We are just getting acquainted with bees, and without movable combs we shall progress no more rapidly than we did hundreds of years before they appeared. We can not afford to do without movable combs.

SNOW.—Snow, philosophically or poetically considered, is very beautiful; practically, while it is often very useful, it is generally a nuisance. Especially on a December morning is it so, when, on turning out to do the chores, one finds it more than a foot deep, and the ax with which the day's wood must be cut covered up and not to be found without much digging and rooting. Then roads and paths must be shoveled out, and the pig-troughs, which are also covered up, be found and dug out. Then the breast-chains and neck-yoke, which were thrown down as usual last night, can not be found, and much trouble is caused thereby. Then the shovel is under the snow, and the hoes were left in the field where some potatoes are yet undug, and the log-chain was left in a fence corner somewhere, but as it is under the snow it takes a day to search for it, without success, and a new one must be purchased. And this is all the consequence of not having "a place for everything and keeping everything in its place." There is nothing like a good, deep fall of snow for teaching the value of this old saw.

Ice-Houses that will Keep Ice.

J. W. M. Creary, Cave, Ill., has trouble with his ice-house; the ice does not keep in it, and in his description of it he says it is raised off the ground one to two feet. Here is sufficient cause, without looking any further, for the loss of the ice. In accordance with the request of our correspondent, we give a plan for building an ice-house that will keep ice the year round. Choose a sloping piece of ground for the site, and dig out a space one foot deep, lowest at one corner, to provide for drainage. Bed the sills in the soil (a sandy or gravelly piece should be chosen, on account of its being sufficiently dry), and lay a plank floor immediately on the bottom, leaving no space for air to penetrate. Build up from the foundation a building not less than ten feet square, with double walls one foot or eighteen inches apart. Batten the inner walls with rough boards, and fill in between these walls with sawdust, tan-bark, charcoal dust, or cut straw, well tramped down. The roof is not of great importance, so that it is made to shed the rain perfectly. Close in the gable ends, and make a door in one of them large enough to allow of putting the ice in, and of getting it out when wanted. A ventilator should be made in the roof in such a manner as to prevent rain from entering. A drain should be dug all around the building deeper than the foundation, so as to keep that perfectly dry. If water penetrates the bottom, the ice will waste. Fill the house during cold weather. Spread a layer of sawdust, tan-bark, or cut straw, a foot thick, on the bottom. On this place the blocks of ice, cut all of equal size, so as to fit compactly together;

build up the blocks, and keep a space of one foot at least between the ice and inside wall, which must be packed well with whatever material you are using. Thus go on until the house is filled, when two feet of the packing may be placed on the top. As ice is taken out, no part should be disturbed but the top, and the loose packing should always be replaced before the ice is left. If there is a knoll convenient to the house, and the ice-house can be located there, the foundation may be dug six feet or more beneath the surface (always being careful to have perfect drainage). It will be more convenient to fill, and also to take out ice. A shade of climbing plants, such as beans, morning-glory, hops, etc., planted around the house, would help to keep it cool, and ornament the otherwise bare walls.

The Causes of Disease in Sheep.

The report of the Agricultural Department for 1870 states that "there was during that year no loss amongst flocks that had been well fed and properly treated; and that nearly all the losses reported were traceable to cruel neglect and reckless disregard of the health and comfort of the sheep affected." We can not but indorse the truth of all this. Not that we would be understood to say that either the "cruel neglect or reckless disregard" was intentional, but it was not the less to be deprecated that it was the result of a want of knowledge of the proper mode of treatment. It is widely believed that sheep do not need water in winter. This is a great mistake, and leads to cruel neglect. If sheep are permitted access to water it will be seen that not only do they drink often but that they are very choice about the quality of what they drink. In a pasture there may be a spring brook and a pure, bubbling spring. The sheep will pass twenty rods down the bank of the brook to drink from the spring. And yet we have seen sheep shut up in a filthy yard, and compelled to drink the liquid manure that filled the holes trodden in the snow and dung. Is not the severity of the above-quoted remark justified in such cases? Then, again, sheep suffer from irregularity in feeding; from close, damp atmosphere; from sudden changes in temperature; and of all stock kept on a farm, the sheep generally fare the worst, are subject to most neglect in feeding, have the poorest lodging, and are not seldom left to lie out in the storm, supposing that they can stand all this on account of the warm coat nature has provided for them; forgetting all the while that this coat depends for its quality and warmth on the care and treatment they receive. The fact is, many farmers pick up a few sheep for the reason that they can "browse around," and cost nothing for their keep. The result generally is discovered to be that what costs nothing is worth just what it costs and no more. Now all this leads to disease, loss, and unfavorable ideas of the value of sheep as stock, when with proper care and well-judged treatment they may be made to pay as well, or better, than any investment a farmer can make.

Ogden Farm Papers.—No. 24.

I have just been making a calculation of my sales of Jersey cattle, and the result is not discouraging. The first sale was made in September, 1869 (a yearling heifer for \$300). In the twenty-six months since that time there have been sold from the herd of thorough-bred ani-

mals, fourteen females of all ages, at prices varying from \$100 to \$750, and averaging \$344.64, and males (mostly calves), at prices varying from \$25 to \$200, and averaging \$84.50. The average for all animals sold, all ages and both sexes, is \$236.25. Eight of these were full-grown cows, whose average price was \$453.12. Six were heifers averaging eleven months old, whose average price was \$200. Four of the bulls were between one and two years old, and their average price was \$137.50. Six were calves averaging less than six months old, and their average price was \$49.16. I have made these computations to show that in every class the animals have been sold at prices that pay a handsome profit on the cost of production. I am glad, too, to feel sure that every animal sold will be a source of satisfactory profit to its purchaser, if only he will attend to the purity and quality of the blood with which he crosses. Especially so as the belief is daily extending that the Jersey is the great butter-blood of the country. The late D. B. Fearing, of Newport, who owned some very fine specimens of the breed, was for many years in the habit of giving away his bull-calves to the farmers in the neighborhood. The result is that even with the most careless neglect in the matter of breeding, high-grade Jerseys are quite common all about us, and the superiority of the blood for butter-making is as fully demonstrated in the minds of our farmers as is the superiority of the Ayrshire blood for milk. Mr. C. S. Sargent, of Brookline, Mass., to whom I have before referred, writes me that the cows from which he has made butter during the past year have averaged him nearly \$300, in butter alone. His animals are nearly all of the choicest, and have been fed better than most farmers would be able to feed the whole year around. He gets, too, the enormous price of \$1.15 per pound for his butter, at wholesale, which is nearly twice as much as most farmers could hope to get for an equally good article. I have recently had evidence in my own herd of the persistency with which this breed gives a large yield of butter under even the most unfavorable circumstances. My cows, during the month of October, had the kin-pox, nearly the whole herd having it at the same time. This reduced their flow of milk fully fifty per cent, yet the greatest reduction of butter was less than twenty per cent.

They have now (end of November) nearly all recovered, and the flow of milk has increased, in the case of the cows that are not too near their calving time, without any material increase of butter. This seems to indicate that the tendency of a Jersey cow to convert her food into butter may continue independently of a disturbance of the milk-producing faculty. It helps, too, to confirm an opinion that is quite common among the older breeders of the race, that it is not the largest milking Jerseys that are the most desirable, for the reason that these are not the ones that produce the most butter from one end of the year to the other. They prefer rather an animal that gives say twelve quarts (at her flush) of very rich milk, and holds out well, giving almost as much cream when she has run down to seven or eight quarts as she did with her full flow. My personal observation has not been sufficient for me to give an opinion on this point. But I am convinced that, in my own herd, it is not the largest milkers that give the most butter, twelve months together. But this may be due to some other quality in the cow than merely her milking capacity.

I am glad to see evidences of a weakening of the passion for "solid color and full black points,"

and of an increasing conviction that the real point of excellence is the *butter point*. It is rare to find a thorough-bred Jersey that has not the characteristic beauty of the race, and your first-class butter-maker is very likely to be an extra-fine looking cow. The public taste is fast turning in the direction of this class, and it would be well for the breeders to turn their attention to their production. It will not be long that we can make even a greenhorn from the city satisfied with a black switch in the place of a good udder.

Early in November I was away from home for ten days, and the weather became very cold; so much so that the cream which had, since the hot weather ceased, been kept in the old milk-room, got so chilled that it took several hours to churn. The dairy woman at once suspected the cold water in which the milk cans are kept, and she not only moved them into the old room, but built a fire there to keep them warm. The result was that when I came home I found bitter butter, and less of it, than there should have been. It would, of course, have done very well to set the milk in shallow pans in the heated room, but in such masses as the large cans hold (say 15 quarts) the heat was fatal. We at once put the cans back into the water, but left the cream-kettles in the warm room, at a temperature of from 60° to 65°. The result is as fine a lot of rich, sweet butter, made on the 24th of November, as we have ever had, although the weather has been cold and wintry. The only remaining test that is now needed to determine the advisability of setting the milk in deep cans immersed in cold spring-water (which is, relatively, warm water in winter), must be determined by the severely cold weather that is almost at hand. If we can make as much and as good butter when the thermometer outside is at zero, as we can when it stands at 30°, then there is no more question whether the plan is a good one, than there is whether it is a good plan to use a mowing machine. Indeed, I am convinced already that those who do not adopt this system for their summer dairies are decided losers in quality of butter and in the labor of making it, and slightly in the quantity they make.

I suppose that after having had three years of cheap hay, I have no right now to complain, but I am not a bit the better satisfied to pay \$30 a ton because I have hitherto bought for from \$16 to \$20. Fortunately I have less stock this year than I had last, and I have a good lot of corn-fodder and roots to help me out, but I must still be a considerable buyer, and, fix it the best way I can, I shall have to pay out more money for feed than I had counted on. The temptation has been strong to come down to short rations, but a little exercise of the faculty of common sense saved me from that, for if I am sure of anything in farming, it is that it costs a good deal more to make flesh than it does to keep it, and that starvation will never bring good calves; so I shall face the music, and try to bring my stock out in good order in the spring, even though hay goes to \$50. I shall, however, use only so much hay or other coarse fodder as is necessary to health—necessary for what they call in the South-west “roughness.” The *nutriment* I can get more cheaply in other ways. In my calculations I take as a basis Boussingault's tables of nutritive values—being the mean of experiment and theory—the present market prices of feed in Newport, and Lawes's estimates of the value of the manurial

residuum of each article, and allow sufficient margin for safety.

In the table below, the first column of figures shows the quantity of the article named that equals 100 pounds of good hay; the second, the cost of that quantity in our markets; the third, the amount to be deducted for the manure produced by the consumption of the quantity named; and the fourth, the actual cost of the nutritive effect produced.

MATERIAL.	1	2	3	4
Hay.....	100 lbs.	\$1.50	-.33	= \$1.17
Wheat (2d quality).....	46 lbs.	1.20	-.18	= 1.02
Wheat bran.....	105 lbs.	1.81	-.84	= .97
Oats.....	59 lbs.	1.18	-.25	= .93
Indian corn.....	57 lbs.	.90	-.20	= .70

If this computation is not *absolutely* correct it is *relatively* so; at least it constitutes as good a guide as any calculation we can make with our present very slight knowledge of the processes of animal life. Indian corn is too heavy a food to be given largely to cows, but I shall mix a little of it with ground oats and add them to my cut fodder and bran before steaming, increasing the quantity gradually until the animals will be satisfied with a minimum amount of “roughness.”

If the effect of such feeding is what Mr. Hors-

Fig. 1.—WINTER QUARTERS FOR LAYING STOCK.

fall's experiments would indicate, it is not impossible that we may learn a lesson that will be worth all that the high hay market will cost us. We shall see.

A correspondent in Maryland asks me to define the quality of the bran of which I recommend that ten quarts per day be fed to a cow. I refer to what is known in the New York market as “50-lb. feed,” *i. e.*—a 3-bushel bag full weighs 50 pounds. Say 16 pounds to the bushel; or, about a half-pound per quart.

An Egg Farm.

BY H. H. STODDARD.—*Ninth Article.*

Quarters for the laying stock during cold weather are shown in fig. 1. When the house is located for winter, the doors in the north roof are covered with building-paper in overlapping sheets tacked on slightly so that it may be removed in spring. Straw is laid over the paper to the depth of a foot. A temporary shed is made for a rod east, and the same distance west of the building, connecting with the roof of the latter, the platforms for drying earth (figured in the third article, p. 258) being used for this purpose and supported by stout rails. By turning a corner, as at the post A, east and also west of

the building, this shed is made to inclose three sides of a court which is open to the south. The gaps in the roof of the shed at the corners, and the cracks between the platforms, are covered with straw and boards. There is nothing that fowls love better than convenient nooks where they can retreat from the crowd of their fellows, and select their own company. Confinement brings not only loss of health but the vices of feather-eating and egg-eating. No system of diet will remove the liability of fowls that are habitually kept in-doors learning to pluck each other. If the room is large and the flock small there may be no risk of this, but the expense of such quarters would be fatal to success. When fowls are allowed freedom they never learn to eat feathers. If anybody wants to keep poultry under some highly artificial plan, and prevent out-door range in winter in order to promote laying, he is welcome to do so. But nature if thwarted is sure to have her revenge, if not in one way then in another. Whether in-doors or out, the birds must be busily employed every day, and then they will be happy and contented, and not learn egg-eating or other abnormal practices. Without a chance to scratch in earth or straw, they will be as badly off as a rich man with nothing to do.

Straw is scattered under the sheds, and on pleasant days a few handfuls of feed are buried under it, using a fork. When the weather admits, a larger pile is used for a scratching-place, situated south of the feed-room, where it can be moved by the aid of a team, as stated in a previous article. The arrangements for burying grain in-doors have also been already described. The ground is raised a few inches by plowing in the fall, where the sheds are to be placed.

When the house is placed upon the dust-bin, B, waste strips of cloth, called “headings,” obtained at the woolen factories, are used to make the joints air-tight between the two. The passage leading to the feed-room is represented at C. The feed-room itself is not shown in the illustration, because figured in a former number. A small opening (D) at each end of the house is for ventilation, and must never be closed. A projecting cap over it keeps out rain, and wire-cloth of 3-inch mesh breaks the force of entering air in case of high winds, though ordinarily the current will be outward. Fresh air is admitted through the passage C, and as it must enter the feed-room through an outside door in the latter, and pass several angles before gaining admission to the roosting room, strong draughts will be avoided. Care must be taken during cold spells to partially close this door at night, so as to raise the temperature at the

roost about 10 degrees higher than it is outside, but further than this no effort should be made

is put under the foundations of the walls. The floor of an underground fowl-house

Fig. 2.—HOUSE FOR EARLY-HATCHED PULLETS.

to retain heat at the risk of impure air. Fowls that have free range in the daytime the year round, and roost in buildings open on all sides in summer and partially open in spring and fall, will not be injured by an attempt to strike a balance between warmth and ventilation during a few brief periods of extreme cold.

Figure 2 represents a house for the earliest hatched pullets that are expected to lay more in winter than the others, and are, therefore, sheltered at greater expense. Winter laying depends more on breed, age, feeding, and health, than upon warm rooms. Heat is necessary to productiveness, but a fowl kept in full vigor and good appetite by exercise, will be warm where a dull, mopeish one would shiver. It will not pay to build expensive fowl-houses, and the arrangement we are about to describe involves as much outlay as is advisable, in order to secure warmth, excepting for some special purposes. A mound of earth, nearly circular, and 25 feet broad at the narrowest point, is raised by scraping with the team. It should be 3½ feet high at the center, and slope gradually to a level with the surface of the field. Upon this mound a cellar is dug 7½ feet by 14½, and 3 feet deep, the bottom being 6 inches higher than the average of the surface beyond the mound. The cellar is walled substantially with stone, laid in cement, and floored with the latter material. Stations furnished with such cellars are upon

must always be a little higher than the adjoining field, not on account of drainage alone, but for ventilation. No room is fit to be occupied by stock, that can not be ventilated at bottom. In this cellar the walled passage at A admits air within 8 inches of the floor, which is covered with dry earth to that depth. The walls are

topped with plank-sills, upon the outer edges of which the runners of the itinerant building rest, caulking being resorted to as in the previous case. It will not answer to house fowls in such a place unless there is plenty of glass above, and the south roof, therefore, contains five long windows, instead of two short ones, as in the other cases, each door being furnished with one. There is a shutter (B) to correspond with each window. Otherwise the house is of the usual pattern, and the winter sheds and feed-room are attached to it, though omitted in the figure so as to show the embankment plainer. The house and mound have a bleak look in the illustration, but the sheds will make the whole sheltered and cosy. The usual boarded passage (not shown in the cut) connects the feed-room with the tunnel at A. There are sunny days enough in winter to keep the earth-bed inside perfectly dry, and the air will be no damper than in an unglazed apartment entirely above ground. Straw mats of the greenhouse pattern are used at night upon the north roofs of all the buildings for about two months in winter. The amount of solar heat accumulated during a clear winter's day in a pit roofed with glass is surprising, and this is to be retained as long as possible, always remembering, however, to give ventilation its due. Summer and winter the admission of air must be gauged by every change of wind and

it would not pay to attend to with one flock, may be afforded where there are many.

The buildings are kept over the cellars only in winter, and are drawn on and off the sills above the walls by the use of small rollers, and a horse attached to tackle. The cellars must not lie idle after the houses are moved, but be roofed with the platforms for drying earth, and a few movable greenhouse sashes, and used as shelter for chickens.

The stations when arranged for winter should preserve the dissimilar appearance mentioned in the first article, so that the fowls may be able to distinguish their own houses. Each building being colored in summer unlike those immediately adjoining it, the plan is carried out in winter by coloring the sheds attached to each house like itself. By using a very wide brush, the lime-wash, or coal-tar, is applied in a short time.

In addition to the sheds above described, other protection against the weather in winter is provided by adjusting some of the earth plat-

Fig. 3.—SHELTERS FOR CHICKENS.

Fig. 4.—TEMPORARY SHELTERS.

a part of the farm where there is a gentle slope, and, wherever necessary, a tile drain

weather. It is one of the advantages of business upon a large scale, that operations which

forms as seen at A (fig. 3), and the basement part of the chicken-coops are propped up (B) and covered with boards, and the floors to the same are arranged as at C (fig. 4). In the same cut D represents a shade for chickens in summer, made of the rails used in winter for the sheds, covered by straw from the north roof of the layers' houses, with brush or corn-stalks added to keep the wind from blowing it away. Shade for the laying stock is provided by taking the winter dust-bins and propping them in a slanting position (E, fig. 3), and nailing slightly a few boards across, and thatching with the mats used in winter upon the houses. This contrivance is drawn upon the ground, by the team, occasionally, so as to never be very far from the building when the latter is shifted, and some of the platforms are moved about for the same purpose when not employed in the dry-earth harvest. By using earth platforms at one station, straw-mat screens at another, and movable booths of ever-green boughs at a third, neighboring premises are made to look unlike. In this way all the various fixtures in the whole establishment are kept in use summer and winter, and chickens and grown fowls are sheltered from sun, wind, and rain under structures that afford a great deal of ground room, which is what counts, yet they are low like the houses, and, therefore, made with but little lumber.

The Golden-Winged Woodpecker.

BY ERNEST INGERSOLL, OBERLIN, O.

It is almost impossible and entirely useless to discover the various names the Golden-winged Woodpecker has received from the persons whose orchards, and occasionally whose corn-fields, he visits. In the West he is commonly called "High-holder," in Ohio and Pennsylvania "Flicker," "Yellow-hammer," and "Pint," while New Yorkers simplify the thing, and dub him "Clape." His ornithological name is *Colaptes auratus*. Like the most of his class he is migratory in his habits, arriving upon Lake Erie from the South the second week in April, and leaving again in October. Their migrations are performed by night, as we are informed by the whistling of their wings overhead. Less shy and retiring in his disposition than many of his congeners, you may seek him in the edge of the woods and in old orchards, where, perched upon some tall stub or fence stake, he calls out so joyously his clear, ringing, sonorous chant, that we are certain even "High-hole" appreciates the glad revival of sunny days, and contributes, to the best of his ability, music to the awakening melody. It is, indeed, the best he can do, and though we may not perhaps name it a song, it is always welcomed as the announcement of returning warmth and life.

The Golden-wing is a type of one form among the woodpeckers. It is distinguished from the true woodpeckers by its curved and compressed beak, and by the broad, strong shafts, dyed bright, golden yellow, which are so conspicuous during flight, and furnish the bird its name. The upper plumage is amber brown, barred with black; beneath, buff yellow, with numerous spots of black, prevails; a lunated mark of vivid red glows amid the iron-gray of the hind-head, while a collar of jet black, meeting upon the breast, separates the buff of the lower parts from the cinnamon of the throat. The tail is beautifully marked with brown, yellow, black, and white, and the shaft of each feather pro-

trudes beyond the vane in a hard spine. The use of this conformation is evident, when we consider that the tail, pressed against the trunk, is used by the bird as a support in climbing.

We have said that the Golden-wing differed,

Of course by the destruction of myriads of ants our friend is of great benefit to the farmer. He no doubt understands this, and feeling that one good turn deserves another, when the farmer's corn is nicely ripening, makes frequent

visits to his field, tearing open the husks with his powerful beak, and devouring with the greatest avidity the succulent kernels. Not seldom, however, the farmer himself, stealing through the waving corn, espies him at his delicious feast, and ere poor Yellow-hammer can escape, brings him fluttering down with his cruel shot. Undoubtedly, farmer John, he stole an ear or two of your growing corn, but undoubtedly he has killed a thousand or two industrious ants in yonder stump in the fence-corner, which repays you a hundred-fold. About the middle of May in this latitude the Golden-wing, having wooed and won a mate, seeks a nesting-place. The pair fly from tree to tree, run up and down the trunk and along the branches, chase each other in queer, twisted spirals all over the tree, peering

THE GOLDEN-WINGED WOODPECKER.—(*Colaptes auratus*.)

into crevices, prying off loose scales of bark, digging a little way into the yielding trunk of a dead cotton-wood, or rapping vigorously upon the sound surface of a hard maple, until a proper site is discovered. This is generally in the tall, dead stub of some ancient tree, a monument of the seathing fires which felled its companions long ago; often in the dead, top limb of an old apple-tree; sometimes, in remote orchards, within five or six feet of the ground. After the location is fixed upon, all their time is occupied in the preparation of the nest, and so intent are they upon their work that you may approach quite near without exciting alarm, and often they continue their labor, affectionately relieving each other, long after other birds are asleep. A hole is first dug

straight forward a few inches, and then perpendicularly downward, eight, twelve, even eighteen inches, according to season and circumstances. It is exactly circular, smooth, and gourd-shaped within, and chiseled out of the firm wood by the unassisted beaks of the two birds, of whose

PLYMOUTH ROCK FOWLS.—(See page 13.)

upon them. Young ants, however, of which he is passionately fond, form his regular diet. These inhabit old, decaying stumps and prostrate logs in prodigious numbers, and his stout bill, seemingly shaped for this very purpose, unearths them as readily as with a pickax.

power in cutting wonderful stories are narrated. This dry, snug cranny is soon the receptacle of six eggs of the most beautiful pearly white, without a blemish, which a few days of maternal care replace with as many callow young, in all their naked helplessness.

Then there is care, and enough of it, too, delightful though it be, in the woodpecker family. The young must be fed and protected from enemies—snakes, for instance; they must soon be taught to fly, and by slow degrees to shift for themselves, for ere the summer is ended a second brood will take their places in the care of the parent birds. All this time, too, the nest must be kept clean, and the birds must provide themselves as well as their clamorous young with ants and young beetles, extracted from their hiding-places under the bark, and Sour-gum berries, and what not, so that they are at no loss for something to do in that lively home up in the cotton-wood. When the autumn is dyeing the leaves, the Golden-wings fly South.

Audubon says that the Golden-wing lives well in confinement, never allowing his spirits to droop, "and, by way of amusement, will continue to destroy as much furniture in a day as can well be mended by a different kind of workman in a week." Wilson's success in keeping one was, however, indifferent, and there is nothing about the bird which will ever cause its introduction generally into our houses.

Walks and Talks on the Farm—No. 97.

I have just had a visit from one of the most enterprising and successful farmers in Western New York. It was a stormy day—just such a day when, it being impossible to do anything out of doors, a farmer feels no compunction in spending a few hours in conversation with a friend. We had a long and interesting talk, and as the storm continued unabated he spent the night with me. At home, he said, he went to bed every night between nine and ten, and was up, winter and summer, at five. He boards his men in the house. Breakfast is ready at six. Horses are fed, watered, cleaned, and harnessed before breakfast, and are expected to be *in the field* by seven o'clock at the latest. He uses three-horse teams, and insists on having two acres a day plowed by each team. He is very particular to have his land carefully plowed, and uses a "jointer." He thinks highly of the latter, as it completely buries the sod, stubble, weeds, etc.

The Deacon enjoyed these remarks in regard to plowing. He has always contended that I make a mistake in not using a jointer or double plow. The mass of testimony is certainly against me. My aim has been to get the weed seeds to grow and then kill the young plants, rather than to bury them for a year or two, and then have them start in the barley or wheat crop, where I could not get at them with a hoe or cultivator. If I was going to plant corn two years in succession, or potatoes the first year followed by corn, then I would use a jointer in breaking up the sod. The weed seeds which lie dormant under the sod the first year would spring up after the next plowing, and then I should have a chance at them.

"I am surprised," remarked our visitor, "that you do not raise more beans. Your land is better suited to the crop than ours, and yet we raise ten acres where you raise one. We find it one of our most profitable crops—though an

exhaustive one. I once made over \$100 an acre from my bean crop."

"Exactly," I replied, "and the next year we outsiders rushed into the business, and got our fingers burned. We paid a high price for seed, and planted ten, twenty, or thirty acres. It was a wet season, and the weeds got the start of us. When we came to harvest the crop we could hardly discover the rows, and found it difficult to get any one willing to pull the beans without extra pay. Our expenses were extra heavy, the yield extra light, the quality very inferior, and the price, even after hand-picking, anything but satisfactory. I bought some of those beans, to feed sheep, at 35 cents a bushel. And I imagine the yield was not over ten bushels per acre. If your land is clean, and in good condition, and you live where you can get plenty of boys to harvest the crop, beans can be raised to advantage, but not otherwise."

"What I particularly want to learn," he said, "is how to make manure enough to keep my land in good condition. I sell nothing but beans, potatoes, wheat, and apples. I feed out all my corn, oats, stalks, straw, and hay on the farm, and draw into the barn-yard the potato vines and everything else that will rot into manure. I make a big pile of it. But the point with me is to find out what is the best stock to feed this straw, stalks, hay, oats, and corn to, so as to make the best manure and return the largest profit. Last year I bought a lot of steers to feed in winter, and lost money. This fall I bought 38 head of cows to winter, intending to sell them in the spring."

"What did they cost you?"

"I went into Wyoming and Cattaraugus Counties, and picked them up among the dairy farmers, and selected a very fair lot of cows at an average of \$22 per head. I expect to sell them as new milk cows in the spring. Such cows last spring would have been worth \$60 to \$70 each."

"That will pay. But it is not often that the grain-grower gets such a chance to feed out his straw, stalks, and other fodder to advantage. It can not be adopted as a permanent system. It is bad for the dairyman, and no real help to the grain-grower. The manure is not rich enough. Straw and stalks alone can not be fed to advantage. And when you winter cows to sell again in the spring it will not pay to feed grain. If you were going to keep the cows it would pay well. The fat and flesh you put on in the winter would be returned in the form of butter and cheese next summer."

"Why is not the manure good? I am careful to save everything, and expect seven or eight hundred loads in the spring."

"You had 60 acres of wheat that yielded 25 bushels per acre, and have probably about 50 tons of wheat straw. You had also 30 acres of oats, that yielded 50 bushels per acre, say 35 tons of straw. Your 20 acres of corn produced 40 bushels of shelled corn per acre; say the stalks weigh 30 tons. And you have 60 tons of hay, half clover and half timothy. Let us see what your manure from this amount of grain and fodder is worth (see 'Harris on the Pig,' p. 139):

Manure from		
50 tons wheat straw, @ \$2.68.....		\$134.00
35 tons oat straw, @ \$2.90.....		101.50
30 tons corn-stalks, @ \$3.58.....		107.40
30 tons timothy hay, @ \$6.43.....		192.90
30 tons clover hay, @ \$9.64.....		289.20
14 tons oats (1,500 bush) @ \$7.70.....		107.80
24 tons corn (800 bush.) @ \$6.65.....		159.60
Total, 213 tons.....		\$1,092.40

"This is the value of the manure on the land.

Assuming that there are 600 loads, and that the labor of cleaning out the stables, piling, carting, and spreading the manure is worth 30 cents per load, or \$180, we have \$912.40 as the net value of the manure.

"Now, your 250-acre farm *might* be so managed that this amount of manure annually applied would soon greatly increase its fertility. But you do not think you can afford to summer-fallow, and you want to raise thirty or forty acres of potatoes every year."

"I propose to do so," he replied, "until the potato-bug arrives in this section. Situated as I am, close to a good shipping station, no crop pays me better. My potatoes this year have averaged me over \$100 per acre."

"Very good. But it is perfectly clear to my mind that, sooner or later, you must either farm slower or feed higher. And in your case, situated close to a village where you can get plenty of help, and with a good shipping station near by, you had better adopt the latter plan. You must feed higher, and make richer manure. You now feed out 213 tons of stuff, and make 600 loads of manure, worth \$912.40. By feeding out *one third*, or 71 tons more, you can *more than double* the value of the manure.

50 tons of bran or mill-feed would give manure worth.....	\$729.50
21 tons decorticated cotton-seed cake.....	585.06
	\$1,314.56

"Buy and feed out this amount of bran and cake, and you would have 800 loads of manure, worth *on the land* \$2,226.96, or, estimating as before that it cost 30 cents a load to handle it, its net value would be \$1,986.96."

I am well aware that comparatively few farmers in this section can afford to adopt this plan of enriching their land. We want better stock. I do not know where I could buy a lot of steers that it would pay to fatten in winter. Those farmers who raise good grade Short-horn or Devon cattle are not the men to sell them half-fat at low rates. They can fatten them as well as I can. For some time to come the farmer who proposes to feed liberally will have to raise his own stock. He can rarely buy well-bred animals to fatten. A good farmer must be a good farmer throughout. He can not be good in spots. His land must be drained, well worked, and free from weeds. If he crops heavily he must manure heavily, and to do this he must feed liberally—and he can not afford to feed liberally unless he has good stock.

It is a poor time to talk about the profits of raising and feeding good stock. Meat of all kinds is very low. I do not know that the consumers find it so, but at any rate farmers are getting unusually low prices. But I do not feel discouraged. It is almost certain that the next few years will give us good if not high prices for good meat. And he is the wise farmer who prepares for it now.

One of my neighbors bought a corn-husking machine, and a cheap sweep-power to drive it. The latter was made to sell and not to use, and soon broke. The husker did good work. And we may take it for settled that corn-husking by machinery is an accomplished fact. But it is equally certain that, at present, it costs more to husk with one of these machines than by hand. There were two horses, a man to drive, one to feed, one to give him the corn, and another to take away the stalks, and their best day's work, when everything went right, was less than 100 bushels of ears.

I would like to raise 40 acres of corn on my

farm (of 285 acres) every year; and I would do so if it were not for the labor of harvesting. It is slow, tedious work. But one of my day-dreams is to have my farm (exclusive of garden, orchard, permanent meadow, grass and wood land, and a few small lots near the barns) divided into ten fields of 20 acres each, with a neat stone wall round every field, the land well drained, clean, and rich. Then, I think, I could keep it rich and make it richer by some such a rotation as this:

FIRST YEAR—*Field No. 1.*—Clover sod the previous year, plowed early in the fall, and planted or drilled to corn in the spring.

Field No. 2.—Clover sod, heavily top-dressed the previous fall with well-rotted manure, plowed late in the spring, and corn drilled in as fast as plowed and harrowed.

SECOND YEAR—*No. 1.*—Sown with rye the previous August among the corn. Rye fed off on the land the next spring with sheep. Then plowed, thoroughly cultivated, harrowed, and made mellow, and then sown at different times with white mustard. This crop to be eaten off on the land with sheep, and the land to be plowed, and sown to winter wheat.

No. 2.—Oats and peas sown together. The land having been heavily manured for corn, and thoroughly cultivated while the corn was growing, and then plowed in the fall after the corn was harvested, might be sown early without plowing in the spring—it would be rich and clean, and a great crop might be expected, and after harvest one or two plowings would make the field in splendid order for winter wheat.

THIRD YEAR—*No. 1* and *No. 2.*—Both in winter wheat, seeded in the spring with clover and timothy.

FOURTH YEAR—*No. 1.*—Clover pastured close with sheep until the first of June, then left to grow up for seed.

No. 2.—Clover, mown for hay, and then pastured the rest of the season.

FIFTH YEAR—*No. 1.*—Clover seed stubble, pastured, and heavily manured in the fall.

No. 2.—Clover and timothy mown for hay, and afterward pastured until time to break up in the fall for corn.

SIXTH YEAR.—Corn again.

This would give me every year 40 acres of corn, 20 acres of oats and peas, 40 acres of hay, 20 acres clover seed, 20 acres of rye, 20 acres of mustard, 40 acres of pasture, and 40 acres of winter wheat. I should sell nothing but wheat and clover seed; but I should expect, at any rate after a few years, to get from 35 to 40 bushels of wheat per acre, and in a favorable season 5 bushels of clover seed. I think I could keep 15 grade Shorthorn cows, 12 calves, 12 yearlings, 12 two-year-olds, and sell a dozen fat steers and cows every year.

Then I should hope to be able to keep a flock of 100 long-wool ewes, 150 lambs, and sell 150 fat sheep at from twelve to twenty months old every year.

"You have left out the black pigs," remarks the Deacon, "and I thought you considered them your most profitable stock."

I have not forgotten them at all. But I will leave the profits from them to pay my oil-cake and bran bills, and they will much more than do it. The receipts from such a farm we may estimate as follows:

40 acres wheat @ 35 bush. per acre, @ \$1.50.....	\$2,100.00
20 acres clover seed @ 5 bush. per acre, @ \$6....	600.00
12 head of fat cattle.....	1,000.00
Butter from 15 cows.....	500.00
150 fat sheep, @ \$10.....	1,500.00
Wool from 250 sheep, 8 lbs. each, @ 60c.....	1,200.00
5 acres of apple orchard.....	1,000.00
	\$7,900.00

Feeding out such a large amount of stock would soon give me more than manure enough for 20 acres of corn every year; and, as soon as this was the case, I should take a few acres of the fall-plowed clover sod, manure it well, and sow mangold wurzel instead of corn.

Manure is like money. The more you have, the easier it is to make more. You can not grow a big crop of mangolds without thorough cultivation and a heavy dressing of manure. But when you have got the mangolds the land is not only left in splendid condition for future crops, but the consumption of the mangolds, besides being of great benefit to stock, leaves a splendid lot of rich manure. We can raise just as good mangolds here as they can in England—in fact, I think better, as our hotter climate matures them more perfectly, and renders them more nutritious. We can easily grow twenty-five tons per acre, and as the manure from a ton of mangolds is worth \$1.07, we have left from each acre of mangolds, besides the leaves, manure worth \$26.75.

If we could grow 100 bushels of shelled corn per acre—and the climate is capable of doing it—the manure from the corn and stalks would be about equal to that from 25 tons of mangolds. And, as I have said before, if it was not for the labor of harvesting I should aim to grow much more corn than I now do. It is the grand crop of this continent—the sheet-anchor of American agriculture. But what we want are larger crops per acre, and a cheaper and more expeditious method of harvesting them. We have made little or no progress in this respect. We harvest our corn crop just as we did thirty years ago. Great improvements have been made in drills, planters, and cultivators. We can raise corn much easier, but nothing has been done to lessen the labor of cutting and husking it.

I believe corn will yet be harvested as we harvest wheat—cut with a reaper, bound into bundles of a convenient size for pitching, and then thrashed or husked by a big machine, driven by ten horses or a steam-engine. It must be powerful enough to take in a bundle at a time, strip off the ears and husk them, and the stalks as they pass through can be cut up and elevated by a straw carrier. I believe in less than ten years we shall see hundreds of such machines traveling from farm to farm as thrashing-machines now do, and we shall wonder how we ever got along without them.

The late Robert Russell, of Scotland, the eminent meteorologist, farmer, editor, and author, whose recent death is a great loss to agricultural science, visited me shortly after his arrival in this country. He was not very favorably impressed with our soil or our manner of working it; but one charming afternoon in the early part of September, while standing in a recently sown field of wheat, with a note-book in hand, jotting down some facts for the book he afterwards published, he suddenly stopped, looked at a new made straw-stack, and then at the growing crops of corn, and at a large peach orchard that happened to be loaded with fine fruit. He was silent for some minutes, and then, thinking aloud, rather than talking, he remarked: "Harvest all gathered and thrashed; the next wheat crop now in the ground, and ten or twelve weeks of fine, growing weather before winter. We would like such a chance in Scotland." And it is undoubtedly true that after harvest is finished and the wheat all sown, we have a splendid op-

portunity for plowing and cleaning our land. If we could only expedite the corn harvest, and get the crop off the land, every acre of corn ground might be plowed and got ready for spring sowing before winter sets in.

Autumn is the time to work land, and spring the time to drain it. Winter is the time to draw the tiles to make manure, and to do everything that will facilitate the work of the spring and summer. In the spring, while the ground is wet and loose from the effect of the frost, an under-drain can be dug with one third less labor than in the fall. When the plans are all laid and the tiles on hand, a good deal of draining may be done in the five or six weeks in spring before we need to plow for corn. Some one writes to the *Agriculturist* that he thinks "Walks and Talks has underdraining on the brain." If I have, and the disease is contagious, I should like to communicate it to half a dozen of the most intelligent farmers in every town and post-office where the *American Agriculturist* is taken. Underdraining will be the great farm work of the next quarter of a century. Wherever draining is needed—and I have never yet happened to see a farm where some portions of it did not need draining—no real and permanent improvement can be effected until this work is done. I recommend no extravagant expenditure of money. Those who have the capital to drain their land completely at once, would find it to their interest to devote a year or two principally to this work. But there are few such men. Most of us must drain a few acres each year, as we can afford the time and money. Only commence and do the work thoroughly as far as you go, and there is scarcely a man who will stop until his whole farm is drained wherever needed. If I could induce every reader of the *Agriculturist* to make up his mind never to let a year go past without making a few rods of ditch, I should feel that I had accomplished something worth living for.

Put in stone drains if you can not get tile; but the latter, where they can be obtained at any reasonable price, are far cheaper and better. I have some stone drains that work well, and two or three brush drains that do more or less good, but I have one stone drain that is stopped up, and several brush drains that are useless, while I have not a single tile drain that does not do good service. I have some that are not deep enough, but I was bothered to get a good outlet. Some of my neighbors have not "underdraining on the brain," and it is not always easy to persuade them to join in cutting ditches deep enough to carry off the water. The only cure for this is, more light, more agricultural papers, and more neighborhood Farmers' Clubs.

A Farmer's Dog-Cart.

The two-wheeled vehicle known as the "Dog-Cart" (from having a space under the seats in which dogs may be carried for hunting expeditions), is very useful for ordinary knocking-about, in a country that is not too hilly. It is capable of stowing away baskets, and bundles, and bags, to an almost unlimited extent—all out of sight. One reason why it has not been more generally adopted in this country is, probably, that the only specimens we have had have been imported or made here for fancy driving, and have been too heavy and far too costly for common use. The cheap imitations that some of our country makers have produced have been but very miserable imitations, with all the faults and few of the advantages of the foreign article. In Montreal, they have a cart that we might

with great advantage adopt for our own use. It is not an aristocratic "trap" developed by the circumstances of an extravagant sporting life,

hand. What is needed is a couple of white-oak poles for the runners, about four or five inches thick. Shave off with a draw-knife about half the thickness where the bend or crook is wanted. With an inch-and-a-half auger bore holes for the posts, and one to receive the end of the rave at the nose of the jumper. The rave may be made of a piece of timber similar to the runner, flattened or not, as may be wished. When the sides are finished connect them together by three or four beams, the ends of which are let into holes bored into the inside of the raves. These holes should be bored so that the runners spread a little; this makes the jumper firmer, also less liable to upset with a load. Thills similar to those of a cutter are required, as this is a "one-horse machine."

MONTREAL DOG-CART.

but a sort of "self-made" affair that has grown from the ordinary horse-cart, and has been made, by one addition after another, a most useful and by no means inelegant vehicle for all who have much running about to do, and who are liable to have friends or bundles to carry at any time. The cart-body, as shown in the engraving, rests upon a pair of elliptic springs. Each side has a top-rail supported by rungs, and inside of the rungs there is a thin boarding which extends about one half the height of the open space. The tail-board is arranged to be held at any desired angle by means of straps. The seats rest upon the boarding, and are held in place by means of notches which fit the rungs, and hold four persons, two of whom face to the rear and rest their feet upon the tail-board. Strong iron uprights support a heavy strap which answers as a back to the seats. Mud-guards are placed over the wheels, and steps at each side, front and rear. In the engraving a part of the mud-guard is removed to show the seats. It is a vehicle combining strength, convenience, comfort, lightness, and cheapness—the lamps and mud-guards, and the back to the seat, giving it a certain *air* that it is pleasant to have when more essential things do not have to be sacrificed to it.

To Make a Jumper.

A "jumper" which will answer many of the ordinary purposes of the farm, such as drawing light loads of wood, feed, or fodder from one

A JUMPER.

part of the farm to another, running to mill, or to the post-office, or the village, can be made at home with a little ingenuity, a few tools, and such materials as are almost everywhere at

The top represented in the engraving is of wicker-work, but it may be a box, a rude hamper, or whatever the owner chooses.

Cutting Roots.

As the practice of feeding roots is becoming

HOME-MADE ROOT-CUTTER.

more general, it is well to consider the best mode of doing it. As it is often done, it is far from being safe. We often hear of choking cattle, and are asked for modes of relief. Now, prevention is much easier than a remedy in this case. If the roots are cut there is no danger of choking. The cattle, more especially fattening cattle, are able to consume them with so much greater ease that they thrive better. Sheep can hardly eat turnips without being cut, and hogs also find difficulty in dealing with them. The simplest mode is chopping them in a box with a sharply ground shovel. Where but a few bushels a day are used, this may answer the purpose very well, but it is not a neat practice. A turnip slicer, which is a machine armed with knives, which slices up all sorts of roots, is probably the best apparatus that can be used.

Of these there are various kinds that may be purchased from \$15 upwards. We give an engraving of one that may be made at home, that will probably be found as useful, in a small way, as any. It is made of a circular piece of plank, 30 inches in diameter, hung with a crank like a grindstone. Sloping mortises are cut through in four places sufficiently large to admit of broad steel blades being fixed in, which slice up the roots, as they come in contact with them, as they pass the open side of a hopper in which

Fig. 1.—A LIGHT SOD.

the roots are fed. With the exception of the blades this machine may be built at home. For the sketch of this machine we are indebted to a correspondent in Western New York.

What a Heavy Sod will Do.

The sod makes the corn. This may be taken as an axiom, as undoubted as that a straight line is the shortest distance between two points. If the sod is right the corn can take care of itself. What is wanted is a mass of roots, filling the soil to the depth of three, four, or five inches or more, and such a mat of vegetation on the surface as will inevitably belong to such a mass of roots. Now, what such an amount of veg-

etable matter, easily decomposed, and such as corn loves to feed upon, would measure, can very easily be estimated. It would certainly be within bounds to say that there would be on every square rod of ground 90 cubic feet of matter equal in fertilizing power to average barn-yard manure. This is over three quarters of a cord per square rod; and 160 rods going to make up an acre, there would be over 120 cords of manure to the acre. This amount of barn-yard manure would seem perfectly bewildering to a farmer, and would be beyond the power of many

to haul out and spread. And here it is, on the spot, in the most perfect shape possible to be utilized. Does it then need any further argument to show clearly that a heavy sod is the best, cheapest, and most easily handled manure a farmer can procure or invent? The vexed question of whether one should plow deep

Fig. 2.—A HEAVY SOD.

or shallow for corn, here gets a satisfactory and simple reply. With such a sod, or any sod, we may say, one must plow sufficiently deep to get enough loose soil on the top to allow the harrow to work and make a seed-bed. No more,

no less. If our sod is such a one as we lately saw cut from a pasture on a farm in Eastern Pennsylvania, the plow must necessarily go seven or eight inches beneath the surface before enough soil can be obtained wherewith to make a seed-bed. The average crop on this farm is over 100 bushels of shelled corn per acre. And the secret, if there is any, is in this sod. Why should it be doubted? Compare the sods represented in figures 1 and 2, and compare 100 bushels against the average corn crop. It is a simple example in proportion: as sod is to sod, so is corn to corn. And by this we may learn what a heavy sod will do.

Blasting and Breaking Rocks.

There are many localities in the East where stone is too valuable to waste, and yet where the land is too valuable to remain occupied or encumbered with it. At the West stone is less abundant, but what there is is valuable for many uses. Making foundations for buildings, walls for barn-yards, fences for fields, and protecting walls for banks of streams liable to be washed away, are all uses for which stone is valuable. We give some directions for breaking up the largest rocks which a farmer is likely to meet on his farm. This is most easily done by blasting. A few ounces of powder is sufficient to reduce to "sizable" fragments a rock of several tons' weight. To do this, let a hole be

Fig. 1.—TOOLS FOR BLASTING AND BREAKING ROCKS.

drilled in such a part of the stone that the resistance to the powder will be as near as possible equal on all sides. A little examination and judgment will show where the hole should be placed, and in which direction it should be bored. Then take the drill (a, fig. 1), which is of octagonal steel, one inch in diameter (American steel made at Pittsburg is to be chosen in preference to the more brittle and costly English steel), on which the blacksmith has fashioned a "bit," shaped as in the cut (fig. 1), and, holding it with the left hand, strike with smart, light strokes on the head of the drill with the mallet (b) held in the right hand. After each stroke the drill must be turned one eighth round. The eight sides of the drill furnish a guide for this. When the hole has been worked dry two or three inches deep, water may be used to soften the rock, taking care to use only just so much as to keep the powdered rock in a state of soft mud; a little and often is the rule. To keep the water from splashing, a round piece of leather is used, large enough to lay over the hole in the stone, with a hole in the center of it to admit the drill. A cloth is laid on this, and wound loosely round the drill, and prevents all slopping over. The mud is taken out of the hole when necessary with a "swab-stick,"

which is a piece of sapling, the end of which is battered up so as to make a sort of mop. This is dipped in the hole, and the mud which adheres to it as it is withdrawn is jarred off. When the hole is sufficiently deep it is cleaned out with the swab, dried with some perfectly dry sand thrown in, and swabbed out dry. It is now ready for the blast. The powder used is coarse blasting powder. The quantity to be used greatly depends on circumstances, learned only by experience. It is better to use too little, and do it over again, than use too much and blow out the top of the stone only, and spoil all the work. The object is to break the rock into a few large fragments, and not all to "flin-

Fig. 2.—BLAST READY TO FIRE.

ders." Then about two inches of powder will be sufficient for a rock that requires a hole two feet deep. The powder being poured out of the can into the cup which covers the top of the neck of the can, and which should be about three inches deep, is poured into the hole, a piece of fuse long enough to reach from the powder about a foot out of the hole is cut off the roll (which is seen in its proper place on the powder-can), and one end put to the bottom of the powder. The powder is gently pressed down with the small end of the swab-stick, and dry sand is poured on to it until the hole is filled. The point of the swab-stick is thrust into the sand to "tamp" it, so that the powder may be confined. The loose end of the fuse is split with a knife for half an inch to expose the powder, and when the tools are removed into a place of safety a match may be applied. It will be advisable to retire to a safe distance, where the effect of the explosion may be viewed.

Smaller stones may be broken with the hammer and the wedge and feathers. With the

Fig. 3.—BREAKING A ROCK.

chisel end of the hammer (d) a shallow groove is made across the stone where the fracture is wanted, with a small drill three or four holes six inches deep are drilled, wedges (e) are placed in the holes with the feathers on each side of them between the stone and wedge, and they are driven gradually, with light, steady blows, on one wedge after the other, in regular order, until the stone breaks, when the split will be found straight and smooth enough for any sort of rough farm-work.

Tools for Cutting Ice.

Cutting ice is a very simple operation, and requires only such tools as any farmer can command. All that are necessary are a common cross-cut saw, properly arranged, an ax, and a board on which to draw the blocks out of the water and into the sled or wagon. Ice-tongs may be used with advantage, but they may easily be dispensed with. An ordinary cross-cut

Fig. 1.—BOARD FOR HAULING OUT ICE. Fig. 2.—SAW.

saw of small size may be used by taking off the socket for the handle at one end. In the other socket a handle may be fitted which will be handier to use if it is set in at right angles to the blade of the saw, as in fig. 2. To start cutting, first make a hole with the ax large enough

Fig. 3.—GETTING OUT ICE ON THE FARM.

If everything is just right the stone will fall apart with a dull, dead sound, and no fragments will fly. If too much powder is used, a great noise will be made, but little good done.

to start the saw, and cut strips eighteen inches wide. These may be cut across into squares with the ax, first cutting a slight channel in the direction in which the ice should break,

then with a smart blow the square piece will be loosened. To get it out of the water, take the board, fig. 1, which is about five feet long, with handles on one end and a cleat fastened on the other. This is slipped under the block of ice, the cleat takes hold of it, and it is drawn out. A pair of light runners of strong hoop may be fixed underneath, and the board will make a sort of hand-sled, on which the piece of ice may be drawn up to and into the sled. Nothing else is necessary to perform this job as well as it can be done with the most costly tools. Directions for packing away the ice will be found in the *Agriculturist* for November, 1871.

California Forage Plants.

BY "GREENWOOD," LOS ANGELES, CAL.

In the November *Agriculturist* is an article upon Lucern, and a desire is expressed to hear from California readers about it and kindred plants. Three kinds of clover (as commonly called) grow here, samples of each being inclosed—viz.: Alfalfa, or Chilian-Clover, Burr-Clover, and a third variety, name unknown.

Alfalfa, or Lucern (*Medicago sativa*, fig. 1), is largely grown as a grazing and soiling crop, and for hay. When it is well established, its roots, which penetrate twenty or thirty feet deep in the earth, will keep it alive and green through drouths that would kill almost any other plant. With water it will yield increased crops, which may be cut every few weeks all the

Fig. 1.—LUCERN.

year round; in all, aggregating an astonishing amount of forage or hay, per acre, in a year. It is sometimes planted in orchards, as it succeeds well in partial shade, but it draws so largely upon the soil for food and water that it must greatly injure the trees, both in growth and in the quantity and quality of their fruit. At this season it is brought into the city and sold, fresh, to stablemen and to those who keep cows. I don't know what Southern California would do without it.

The second kind, Burr-Clover (*Medicago denticulata*, fig. 2), as commonly called, is a most valued forage plant, growing wild all over the plains and foot-hills, and affording the most nutritious and acceptable pasturage to all kinds of stock. It grows in such profusion that the burrs containing the seeds remain upon the ground after the leaves and stalks of the plant have entirely disappeared, and afford a supply of dry, yet, as it were, concentrated fodder, for the dry months, when no green pasturage is to be had. These burrs lie in vast quantities in the hollows of the ground where the winds have blown them. Even now, after two dry summers, the crop of burrs of three years ago is plentiful in places.

In habit Burr-Clover is low, almost or quite creeping; the stems running two or three feet upon the ground, forming with the leaves a dense, thick mat of verdure, that, while it gives

the best of pasturage, would be difficult to gather for hay. It is tenacious of life, and will grow notwithstanding the crowding of weeds,

Fig. 2.—BURR-CLOVER.

trampling under foot, etc., as will White-Clover. It roots very strongly in the ground, like Red-Clover, and will bear over-close feeding better than Alfalfa. In some places its tenacity of life and disregard of ill-usage may entitle it to the name of "weed," but if so, its value and usefulness will give it grace to endure the epithet.

The third plant (fig. 3) is not so plentiful as

Fig. 3.—SMALL-FLOWERED MELILOT.

Burr-Clover; has a more upright habit, like Alfalfa or Red-Clover; is not tap-rooted, and is not so hardy against weeds, or drouth, or neglect; does not afford quite so much or so succulent fodder as Alfalfa, yet is more nutritious, and is eagerly eaten by all kinds of stock, either green or cured into hay. Alfalfa seed is sold at

15 cents per pound. Burr-Clover seed is not in market, as, growing wild all over the country, it is never cultivated, but the seed could be had for the cost of gathering the burrs and thrashing. The third variety could only be had in small quantities and by special effort. I see no reason why Burr-Clover could not be raised at the East for soiling or for hay as readily as Red-Clover; the only difficulty would be in gathering it, on account of its creeping habit. It would make a most valuable fall pasturage.

To sum up: for hay or green fodder, Alfalfa; for dry pasturage, where rainless months must be withstood, Alfalfa; for moist pasturage, for grazing only, Burr-Clover; for trial, the third variety. Value of crop: for weight, or succulence, Alfalfa; for nutriment in a given weight, either of the others.

[The third plant spoken of by our correspondent, and of which he sent a specimen, is *Melilotus parviflorus*, the Small-flowered Melilot. Figure 3 gives the upper part of a stem of the natural size; the flowers are yellow, and the plant in drying, like other Melilots, exhales a powerful vanillalike odor. We have seen it growing abundantly along the banks of streams in Northern Mexico, where our animals, having an abundance of grass, did not seem to be very fond of the Melilot.—Ed.]

Plymouth Rock Fowls.

This is one of the few cases of crosses which when bred pure have given rise to a valuable breed. The cases are so rare where *crossing* is successful in forming a *breed*, that the doubt has been often expressed that the Plymouth Rocks are a cross. Still the evidence of breeders and the appearance of the fowls indicate that this is the case. They are said to have a mingling of the blood of Cochins, Dorkings, and Malays, in proportion of one half of the first to one fourth of each of the others.

The plumage of the Plymouth Rocks is very similar to that of the well-known Dominiques, and by a little care in selection it may be bred identical with it. In the most beautiful specimens, the feathers have a dark blue ground color, shaded with cross-bands of dark slaty blue, this coloring prevailing all over the bodies of both cocks and hens.

Single combs are preferred, and the only ones admitted according to the "standard of excellence." They should be of only medium size in cocks, and small in hens. Double or rose-combs often occur, but birds having them are "disqualified" at exhibitions.

The cock has a noble carriage, with a tail large and full, carried well up. The legs should be clear yellow, and free from feathers, which are also a disqualification. The hens are very hardy, good winter layers, good sitters and mothers. The eggs are of a pale buff color, and of good size.

The chicks are hardy, mature early, and attain a good weight in the autumn. Adult fowls should weigh ten pounds for cocks and seven for hens—though this is above the average. The flesh is decidedly superior to that of any of the Asiatic breeds, which quality is supposed to come from the Dorking blood.

The breed originated in Eastern Massachusetts, and is hardly known outside of New England. It can not be regarded as fixed in all its characteristics, but in good hands is bred to a high degree of symmetry, size, beauty, and usefulness. The pair shown on page 13 belong to C. C. Corbett, Norwich, Ct.

The Effect of Steaming Food on the Productiveness of Cows.

So much attention is now being given to the question of steaming food for cattle, that any facts concerning it are especially interesting. It is often asked: "Do the farmers of England, the best cattle feeders and the best farmers in the world, steam their food to any considerable extent?" So far as we know, no very encouraging affirmative reply can be made to this question. But then circumstances alter cases, and we are very differently situated from English farmers, in that our winters are very much colder, and that—owing chiefly to the scarcity of labor—we can not compete with them in the production of root crops; roots being less improved by steaming than any other winter food. Yet while, from their less necessity for cooking, the English give less attention to it than we do, it is to an English farmer that we must go for the most conclusive evidence in favor of cooking that we have yet seen—evidence so conclusive that we give it more space than we like to devote to a single subject.

Mr. Thomas Horsfall, of Yorkshire, England, is very high authority in dairy matters. In one of his elaborate reports to the Royal Society, he describes an experiment undertaken to show the comparative effect of feeding cooked and uncooked food. The experiment commenced January 1st. He selected one of his own cows, one of Mr. Smith's, and one of Mr. Pawson's (neighbors), thinking that if he changed some of his own stock from his steamed food to dry hay, they would not do so well on it as would cows that had been kept in the ordinary way.

Mr. Smith's cow was small, but a noted milker. She had been in good condition at calving (her third calf), but fell away sensibly during three weeks thereafter. She was fed on hay only—eating 28 lbs. per day. Mr. Pawson's was a heifer three years old, with her first calf. She, too, fell away very much in her condition. Until late in November she was grazed during the day and housed (with turnips) at night. From that time until Feb. her food was (per day): inferior meadow hay, 18 lbs.; Swede turnips, 45 lbs.; ground oats, 9 lbs. After the first week in Feb. the oats were discontinued, and hay given *ad libitum*. Mr. Horsfall's cow was of small size, but a large milker. She was in good condition at calving, and gained flesh on her diet. She was fed on "steamed mixture," and 1½ lbs. bean-meal, fed raw—the mixture consisting, for each day's rations, of 5 lbs. rape-cake, 1½ lbs. bran, and 1½ lbs. malt combs, mixed with enough bean-straw, oat-straw, and shells of oats, in equal proportions, to give three times a day as much as she would eat. After each feed she received 3 lbs. of dry hay.

The following table shows the condition and performance of each animal:

When calved	Yield at Calving	January 1st.		March 5th.	
		Weight.	Yield.	Weight.	Yield.
Smith's, Nov. 12th.	17 qts.	980 lbs.	15½ qts.	896 lbs.	9½ qts.
Pawson's, Oct. 6th.	16 "	840 "	12 "	812 "	6¼ "
Horsfall's, Oct. 8th.	18 "	1092 "	15½ "	1148 "	12½ "

Mr. Smith's cow lost 84 lbs. in nine weeks, with an average yield of 12½ quarts per day. Mr. Pawson's lost 28 lbs., but nearly her whole loss of both flesh and milk occurred after Feb. 6th, when her oats were stopped. At that time she still weighed 840 lbs., and gave 11 quarts of milk per day. Mr. Horsfall's cow, on the

other hand, gained an average of 6¼ lbs. per week, with an average yield of 14 quarts. She gave, Jan. 1st, 15½ qts., Feb. 4th, 14 qts., and March 4th, 12½ qts.

Computed at the local prices, the average profit and loss in each case per week was:

Mr. Smith's cow.—		
Milk.....	\$3.64	
Deduct for loss in flesh.....	\$1.16	
" " hay.....	1.75	
	2.91	
	Weekly profit.....	.73
Mr. Pawson's cow (average of weeks before oats were stopped).—		
Milk.....	\$3.35	
Deduct for hay.....	\$0.75	
" " oats.....	1.16	
" " turnips.....	.37	
	2.28	
	Weekly profit.....	\$1.07
Mr. Horsfall's cow.—		
Milk.....	\$4.08	
Add for gain in flesh.....	.78	
	\$4.86	
Deduct for hay, straw, and oats.....	\$1.13	
" " rape-cake, bran, etc.....	1.00	
	2.13	
	Weekly profit.....	\$2.73

The richer quality of the manure compensated Mr. H. for the extra cost of attendance.

So much for the experiment to March 5th. On March 12th, Mr. Horsfall bought Mr. Smith's cow for the purpose of trying her on steamed food. At that time her yield had fallen to 8 quarts per day. March 31st—four weeks from the former weighing, and after 19 days of steamed food—her milk had increased to 9½ qts., and she had gained 28 lbs. in weight. Mr. Pawson's cow, with no change of food, had fallen off to 5 qts. per day, without change of weight. Mr. Horsfall's cow at this date gave 12 qts., and had gained 28 lbs.

Mr. Horsfall mentions another cow that had given at her flush 13 qts. of milk. Fed on 22 lbs. hay and 35 lbs. mangels, she fell off in eight weeks to 9 qts. She was then, April 20th, put on the steamed mixture. Soon after this her yield increased to 11 qts., at which point it remained until May 16th, when she had gained 14 lbs. in weight. He says, in concluding one section of his report:

"These results are important, and completely establish the conclusions I had previously formed, that the quantity and quality of butter depend essentially on the food and treatment; and that by suitable means you can produce *as much and as rich butter in winter as in summer.*"

The point of greatest value in the experiments described above is the improved condition of Mr. Smith's cow when she was put upon steamed food. But for this there would have remained the possibility that Mr. Horsfall's cow was intrinsically much the best of the three. Another point to consider is that both Mr. Smith and Mr. Pawson had their cows in their own keeping, and that each probably did his best to prove the superiority of his own system.

What are Artificial Manures?

There does not seem to be a clear understanding as to what are natural and what are artificial manures. Many farmers have a prejudice against what are called chemical manures, probably for the reason that they can not see the connection which exists between a product of a chemical manufactory and the needs of the vegetable products of their soil. Such manures, therefore, as nitrate of potash, nitrate of soda, chloride of sodium (salt), sulphate of lime (plaster), etc., are looked upon as either useless or of doubtful advantage. But there are

many so-called artificial manures which are really as much the natural product of the farm as the manure from the stables or hog-pen. For instance, bone-dust and superphosphate of lime return to the soil precisely the same elements which they derived from it. So with many articles manufactured from blood, refuse flesh, waste of tanneries and soap-works. If these are not adulterated with useless foreign articles they but bring back to the soil what was originally taken from it. For this reason, if these manures can be procured at their actual value, their use should become as regular a part of the farm economy as that of barn-yard manure. Every calf, hog, or sheep sold off the farm creates a demand for the return of a portion of one or another of these incorrectly called artificial manures, as much so as the feeding of an animal calls for the return of its waste.

How to Catch an Owl.

One of our associates who had lost some of his poultry by the depredations of owls, gave in March last an article with the above heading. This has called out letters from several correspondents, some of whom protest against catching owls at all, as they do much good in destroying mice, and say that owls do not trouble poultry, especially if they are shut up. There are altogether in North America some forty species of owls, and while some of these confine their attention to small game, like mice, others are destructive to the farmer's poultry—young turkeys, which seldom will roost under cover, being especially apt to fall a prey to the owls. Among the advice given as to catching owls, one is founded on the belief that if the owl has killed a bird without carrying it off it will soon return for it, and the writer advises to put a part-ridge trap over the dead fowl, which should be fastened to the trigger, and await the return of the bird of prey, which may be after an interval of several days. The plan of several others is founded upon the fact that an owl or hawk will perch upon any elevated point to take an observation before darting upon its prey, and proposes the use of steel traps attached to a small platform elevated upon a pole, which may stand by itself or be thrust up through the tree-tops, and project above them. The trap needs no bait, as it is intended to serve only as an alighting place or observatory for the owl or hawk. The trap should of course be fastened in such a manner that the bird can not fly off with it. Sometimes the owl, when caught, will remain quiet and pretend that nothing is the matter, and it is only when disturbed that its capture is ascertained.

How to Improve our Stock.

It is a matter of certainty, and we never yet met a farmer who did not admit it, that stock-raising is the most important branch of a farmer's business. It is the life blood of the farm. Then it is a great point to have stock that will bring in the most money at least cost. This can only be done by improving the common native stock by the means of pure-blood male animals. These cost money, and few farmers have sufficient stock to need for their own use the entire services of such an animal. But five, eight, or ten farmers, jointly, may purchase an animal, or a set of them, as bull, boar, and ram, for say \$1,000, whose services will repay the cost in a single year, and raise in a few years the character of the stock in a whole township. We know

QUARRYING PHOSPHATES IN SOUTH CAROLINA.—Drawn and Engraved for the American Agriculturist.

of an instance where the introduction of a herd of Jersey cattle into a county in five years led to the dissemination of the stock all through it, and the increase, of course, now is in a much greater ratio than in the first five years. We know that already the butter in that particular district has shown a marked improvement, and that the storekeepers in the different villages are in consequence beginning to grade the butter. Now, this is an important thing, as a farmer who produces a superior article likes to know that he gets a higher price than is brought

FOSSIL SHARKS' TEETH.

by a lardy, greasy one, and that all the butter from various dairies is not dumped together. Again, in hogs an improvement is much needed, more particularly east of the Alleghenies. We want an early maturing pig that does not need to be wintered over, and that can be made into pork any time after three or four months. An Essex or Berkshire boar would bring such stock, and five farmers might jointly secure a very choice one, that each one singly would not be warranted in purchasing. It is unnecessary to carry this subject further. This is the time to think and act upon it, and the season is approaching when it might be carried into operation.

The South Carolina Phosphates.

Without discussing the question whether the various treasures hidden beneath the earth's surface were deposited there in former ages expressly for man's use, it is not the less interesting to notice that when these deposits are really needed they come to light. It was only when wood became scarce and the population large that coal was discovered. When whales became much reduced in numbers, and their capture costly, then petroleum came to supply the place of oil. And, later still, when impoverished fields are nearly valueless, an almost inexhaustible supply of phosphates is opened and utilized. The South Carolina phosphates are the remains of fishes and other animals, and though the deposit has long been known to geologists, it is only within a few years that it has assumed an economical importance. The principal beds are seven miles above Charleston, upon the Ashley River, along the banks of which they extend for ten or fifteen miles.

Mr. Woodward, one of our artists, while at the South visited these beds and made some sketches. To get out the phosphate, a trench is opened by digging first through the shallow but rich top-soil, then through sandy subsoil, when, about two feet below the surface, is found a stratum of phosphates in the form of nodules, packed closely together. This bed is from four to eighteen inches in thickness, sometimes increasing to two or three feet. The nodules are irregular in form, and appear as if water-worn, the majority presenting no organic forms to the ordinary observer, but a microscopic examination reveals the structure of bone. Well-preserved animal remains are however found with

the nodules, among these the teeth of huge sharks in excellent condition, the teeth of mastodons, and enormous vertebrae, which geologists say belonged to some monsters which lived ages ago. Not only do these organic forms indicate the animal origin of these deposits, but their chemical composition affords further evidence. The nodules, being loosened by a pick, are thrown out of the trench and taken to a washing apparatus, where a stream of water clears them of adhering clay and sand, and they are ready for sale in their crude state or to go to the factory to be manipulated. So

TOOTH OF MASTODON (set in plaster).

abundant is this deposit, that an acre is estimated to contain about thirteen hundred tons. These natural phosphates contain sixty per cent, more or less, of phosphate of lime, which by the action of sulphuric acid is easily converted into superphosphate, the form in which it is most available as a fertilizer. There are a number of factories engaged in the manufacture of fertilizers upon the spot where the deposits are found. So great is the consumption of sulphuric acid for this purpose that establishments have been erected at hand for making it.

The Sensitive Briar.

Last spring some very unpromising-looking roots were sent from Louisiana, with the assur-

less sensitive. The genus was named in honor of Schrank, a German botanist. The specific name, *uncinata*, means hooked, and has reference to the short recurved prickles on the stem.

although rarely to be found in the collections of our fashionable florists. It was formerly called *Achania*, but botanists now place it in the genus *Malvaviscus*, a name which means Sticky or

SENSITIVE BRIAR.—(*Schrankia uncinata*.)

VISCID MALLOW.—(*Malvaviscus arboreus*.)

ance that they produced a most beautiful flower. The roots were set out, and the only one that lived showed itself to be an old friend, the Sensitive Briar, *Schrankia uncinata*. It is found as far north as Virginia, and further south it is very common. The prostrate stems are three or four feet long and abundantly supplied with sharp-hooked prickles. The leaves are twice-pinnate, with very small leaflets. At the axil of each leaf is a globular cluster of very small, rose-colored flowers, which are very closely crowded together; they are followed by short pods. The most noticeable thing about the plant is the sensitiveness of its leaves. It bears some resemblance in appearance to the true Sensitive-plant, and though not as sensitive as that, the leaves close with sufficient rapidity to make it interesting. In Texas we have seen it cover the prairie by the acre, and it was amusing to observe the change produced as a horseman passed over it, and to see how shortly after the disturbance the "wake" would be obliterated by the opening of the leaves. There is another species of *Schrankia* and a *Mimosa* in our Southern States, which are also more or

Viscid-Mallow — Malvaviscus — Achania.

Among the old greenhouse plants that have been in a good measure crowded aside by newer accessions is the one which we here figure.

Viscid Mallow, on account of the gluey pulp of the fruit. There are three or four species, the best known one being *M. arboreus*. The plant is a rather straggling shrub, which will grow to the height of ten or fifteen feet, though usually kept much smaller. It has the soft foliage so common in the Mallow Family, and bears almost all the year round flowers of the most brilliant scarlet color. The flowers do not open any more than the one shown in the engraving, the petals remaining twisted together, with one edge of each turned out to form a kind of ridge. The column of stamens and the pistil are protruded for some distance beyond the corolla. The fruit differs from that of most of the Mallow Family, in being pulpy and berry-like. In the present species the fruit is yellowish, changing to red. This shrub is an admirable one for parlor culture, as it is not liable to be attacked by insects, and if it has a plenty of light remains almost constantly in bloom. By a little care in pruning, it may be grown in the form of a round-headed tree. In greenhouses and conservatories it is sometimes trained against a wall. We have in Texas a native species of

ARUM-LEAVED PEPEROMIA.—(*Peperomia arifolia*. See next page.)

Every now and then a specimen has come from some far-off reader for a name, showing that it is still cherished as a house plant in many places,

Malvaviscus—*M. Drummondii*—worthy of cultivation. It is not hardy at the North, where it must be housed during the winter months.

The Peperomias as Basket Plants.

It often strangely happens that a plant suddenly springs into popularity that has before been known only in rare stove and hot-house collections. Of this kind is the Peperomia, figured on page 21, which within a few years has come into common use with our florists as one of the many plants suitable for flower-baskets. We have received it from more than one florist under the name of *Peperomia maculosa*, but upon referring to the original figure of that plant we found that the name could not be correct. Mr. Taplin, of South Amboy, N. J., has it as *P. arifolia*, which we think is the right name. At all events, the plant is a very neat and pleasing one, and last winter did very well with us in a warm living room. The foliage is of a dark green, beautifully marked with lighter silvery stripes. The genus Peperomia is a large one, and belongs in South America and other tropical climates. Their foliage is generally pleasing, but their flowers are not at all showy. It is closely related to the plant *Piper nigrum*, which furnishes the black pepper of commerce.

Market-Gardening in Maryland.

BY PETER HENDERSON.

A most intelligent cultivator, W. F. Massey, of Chestertown, Md., writing under date of Nov. 21, asks me the following questions, requesting a reply through your columns. He says: "Our climate here is rather a local one. I find that the thermometer has reached zero but once in the last seven years, and then only for a few hours. On March 1st of this year I planted Early Rose potatoes, and am now digging the second crop, on the same ground, from potatoes planted from the first crop. On May 13th, Early Wakefield was first marketed, and on June 24th Trophy tomatoes were fully ripe. I can buy stable manure at \$1 per ton, having only a quarter of a mile to haul it. Night-soil delivered at 40c. per barrel. The land is first-rate, and lying within a hundred yards of railroad depot, five hours from Philadelphia. Now, having no experience of shipping vegetables to Northern markets, I ask your advice in the matter. Can they be made to pay under such conditions?"

Most unquestionably they can, and that too, under proper management, at a profit of from \$500 to \$1,000 per acre, according to the article grown. The most profitable articles to cultivate I will name in the order of their value: Asparagus, the "Colossal"—plant no other. From the fact that it requires two years from time of planting before a crop can be obtained, it will pay now, and likely continue to pay, a greater profit per acre than any other vegetable that can be grown; besides, as it is ready for market at a cool season, it can be shipped without loss, even if it be three or four days in transit.

The next best article for a Northern market would be Linneus or Victoria rhubarb, as it, too, like asparagus, must be waited on a year or two before a full crop can be gathered.

As to annual vegetables, much would depend on the demand in the particular locality, and as this could only be got at by a year or two of experience, I could not give advice with any certainty, but would name them thus: Beets

(Egyptian), peas (Daniel O'Rourke or Extra Early), cucumber (Improved White Spine), tomatoes (Trophy or New York Market), radish (Turnip and Long short-top), spinach (Round-leaved), melon (Skillman's Netted or Nutmeg), watermelon (Mountain Sprout or Black Spanish). Early cabbages and potatoes, being of less value per pound than most of the articles named, would not be so profitable if freights were high. Lettuce is a vegetable used more by Germans than other nationalities, and its supply should be determined by the amount of that element in a city. Cabbages, on the other hand, are used more by the Irish, and the very poorest of them buy the first crops sent in.

A word about shipping. Take care that the packages in which vegetables are shipped are not too large nor too close. Thousands of cases have been shipped to New York during the past few years, of both fruits and vegetables, that from bad packing never sold for enough to pay freights. Let it be understood that masses of green vegetables, such as peas, radishes, etc., when packed in such packages as a flour-barrel or close box of that size, are certain to "heat" if kept so for two or three days in a temperature of 70° or 80°. The object then should be to govern the size of the package according to the temperature and the distance to be transported. Fruit-growers know the importance of this, and have their baskets and boxes so made that the air passes freely through them. Vegetable shipping is fast becoming as important as fruit shipping, and with a little more experience those engaged in it will soon devise means to insure the safe transit of their crops.

Orchards in Cold Climates.

An intelligent correspondent in the Province of Quebec presents several questions as follows:

"I am intending to plant out an orchard, and want to know whether by planting a double row of Norway spruce on the north and west sides of the orchard I can grow any more tender varieties than without doing so (1). Also, whether there is any truth in what they say here—viz., that trees brought from New York State will not live here, about ten miles from Sherbrooke, lat. 45½°, but must be grown near by. If so, is it the same with the Norway spruce (2)? Also, I am going to plant out about four acres of orchard. The soil is from one and a half to four feet deep before coming to the subsoil, which is hard-pan. The land is very dry, and a loam not more clayey than sandy. The situation is an elevated slope, and I want to know whether it would do to plant one acre in dwarfs, instead of standards, for market, and if not, why (3)? What pears, plums, etc., would be adapted to such a northerly locality as ours (4)?"

(1.) It is a well-established fact that protection in the direction of the prevailing winds is of great advantage to orchards, even in those localities that are usually regarded as mild. The Norway spruce screen will doubtless allow him to grow varieties that he could not succeed with without, but just which varieties fall into this category we are unable to say.

(2.) We do not believe that it makes any difference—at least in that range of country where the thermometer ever reaches anywhere near zero—where a tree is grown, provided it is well ripened, and we think that a tree grown in New York or Pennsylvania will do as well

in Canada as one raised in Canada. We know that this is in opposition to the views of some nurserymen, but if those who hold differently will present us with any facts to prove that we are wrong we shall be glad to see them.

(3.) Dwarfs are generally abandoned in orchard culture except for Duchess. We can not go into the various reasons. It is a well-settled fact that they don't pay.

(4.) It is very difficult to give a selection of varieties for any particular locality, as latitude is no guide. Some parts of Canada are especially favorable to fruit culture, while others are most forbidding. It is a question of locality. Among the pears that have succeeded best in northern localities are Buffum, Beurre d'Anjou, Onondaga, Lawrence, Tyson, and Oshand's Summer, all excellent varieties. As to plums, we should try some of the improved natives, such as the Miner, Wild Goose, etc.

Wintering Cabbage Plants in Mild Climates.

BY PETER HENDERSON.

Mr. Massey, the gentleman mentioned in an article on Market-Gardening in Maryland, gives the following valuable information about his manner of wintering early cabbage plants without the use of sashes. He says: "The seed is sown here (Chestertown, Md.) about Sept. 20th, and the plants are ready to plant by Nov. 1st, which we do in ridges, of which the figure is a cross-section. These ridges run north-west and south-east. The plants are set on the face of the ridge sloping south-west. These slopes are about four feet wide, with alleys two feet between. The plants we set about as thickly as in the frames, and in the same manner—that is, putting the stems up to the lower leaves to save them from the frost."

Mr. Massey's plan is entirely new to me, and will be a very valuable one in all such latitudes as his, for it not only saves all the expense of sashes and frames, but the plants will be in better condition in spring than if grown under

SECTION OF BEDS FOR WINTERING CABBAGE PLANTS.

glass. The plan will be a safe one to adopt in sheltered situations in any section of the country where the thermometer does not fall below zero. Mr. Massey prefers it—and I think he is right—to putting out the plants in fall where they are to remain for next spring's crop, preferring to manure and plow up the land fresh in March, and set out from the plants in his ridges. Lettuce, and in warmer sections cauliflower, could be wintered in the same way.

Window Garden for Cold Country Houses.

BY "W.," HAVERHILL, MASS.

Many directions have been given for window gardening and window ornaments, and I wish to describe one which, for its possibilities of novelty and variety, will suit those who fear frost will kill their plants if they cultivate those usually recommended for window culture.

Provide a wooden box, the length of the window-sill, and of a depth sufficient to allow a wooden bowl of moderate depth to be placed

in the middle. The box can be made of black walnut, and finished in a style to suit any taste, or it can be rough, and covered with bark or lichens, and if so, the legs should be finished in a rustic manner to correspond. A hole should be bored in the bottom of the bowl, also one in the box under the orifice in the bowl, and it would be well to have a short tin or lead pipe, to connect the two openings, which should be closed by a long wooden stopper, which could be raised and taken out at one's pleasure by striking the stopper (under the box) with a hammer. Inside, a flat stone should be placed over the head of the stopper, and the bowl should be lined with pebbles, placed closely together until the upper edge is reached. This bowl is intended to be filled with water, but before adding the water the sides and ends of the box should be filled with good soil, brought from the woods if possible. The edges around the bowl should be covered with mats of mosses, *Mitchella* with its red berries, or any other hardy plants which flourish in moist places. A few rock ferns of a small size can be introduced with good effect. The Partridge-berry, or Checker-berry, and the Prince's-Pine are of a beautiful habit of growth, especially the Partridge-berry, which is more of a shrub than the *Mitchella*, and in winter, having red leaves and berries intermingled with the green leaves, is very beautiful. When the small plants are arranged, room must be left for branches of hemlock boughs with the small cones upon them, or, if these are not readily obtainable, white-pine branches may be used with excellent effect. With care in the arrangement, thus

you have a miniature forest with a pond, and if placed before a window the light will be charmingly reflected through the branches. It can be used as a small aquarium, if the bowl is large, and care is taken to change the water daily by opening the orifice through the bowl and box. One can vary this window garden, and in its possibility of variety consists its greatest charm. It is invaluable where there is an invalid child in the family who can not seek amusement out of doors. Children can place for their amusement toy houses and animals among the trees, and even the pebbles, in their changing colors, as the light or the shadow passes over them, are attractive.

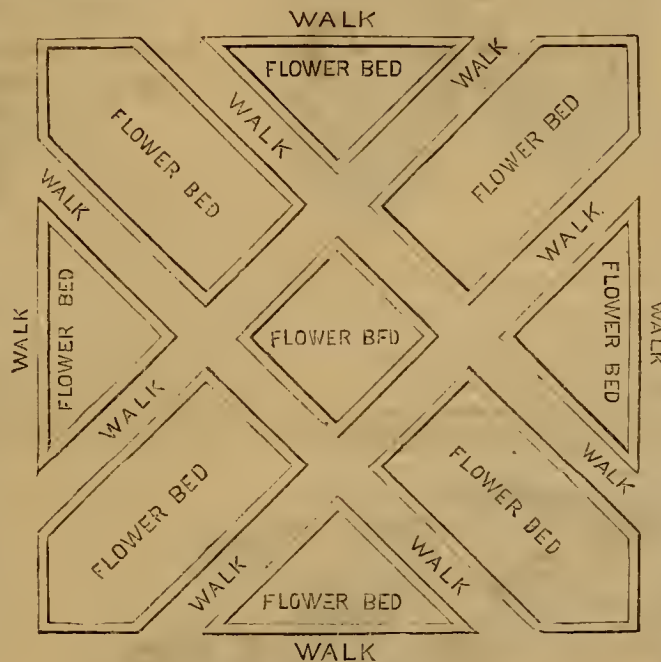

If it is necessary to protect this garden from dust, place four sticks in the corners of the box, of a height to come above the trees, and keep a light curtain to throw over while sweeping.

As one has opportunity, it is well to collect a few roots of *Hepatica*, or Liver-leaf, and some Violet roots; place them in the cellar, and in February add them to the garden, and they will blossom more than a month in advance of those in the woods. Those who have English violets can always take them up when budded, and they will blossom in the house, and they can then be returned to the ground to grow through the summer. They are not injured at all thereby, as they multiply by underground runners. To

this kind of hardy window garden one can at any time make additions and alterations. If one set of trees begin to drop their leaves, another and different set is easily added at pleasure.

Laying Out Flower-Beds.

Winter is the proper season for planning garden improvements, and it is well to put one's ideas upon paper in order that they may be properly considered and discussed. For masses of flowers, beds cut in the lawn are most effective, but if one wishes to grow a large collection of flowers there must be borders or beds of some kind. If circumstances restrict to a simple straight border, very well, accept the situation and let the beauty and variety of its contents so engross the attention of the spectator that he

LAYING OUT FLOWER-BEDS.

will not consider the kind of bed in which they are grown. It is a puzzling problem to lay out a flower-garden for a miscellaneous collection. The elaborate patterns given in the journals and works upon horticulture are only effective when carried out in masses of color. A flower-garden for a lover of flowers—one who regards his plants as individuals, and not as parts of a mass of red, yellow, or blue—should be so planned that the beds can be accessible from all sides, and not inconveniently wide.

We give an illustration of a garden plan sent by Miss Kate Hitchcock, of Jefferson Co., Ill., in which the forms are all angular, and we hope at another time to present other designs. In all designs of this kind there are two troublesome elements, the paths and the edgings. It is about as much trouble to keep the walks in order as it is the beds, and unless they are well kept the whole design will have a slipshod look. Where good gravel can be obtained—gravel that will pack—the walks can be kept in order with comparatively little labor, but this is not generally to be had, and perhaps the next best thing is some of the different asphalts. Grass edgings look well, but they require great care to keep them in order. Box is not available in northern localities, but where it will stand the winters, it answers well, if kept properly clipped, and is re-set when it becomes too

old. Bricks set on end are often used, but we hold them, at least in our light soil, an abomination. Having a lot of spare bricks, we last spring used them to edge some beds, and have been quite dissatisfied with them ever since. Some tiles are made expressly for edging, but never having tried them we can not say how they will answer. Boards are sometimes used upon the margins of beds, but these are too perishable. The cheap, handsome, easily put down and easily cared for edging, live or otherwise, is among the things hoped for by garden workers.

Defense against the Elements.

BY PETER HENDERSON.

The hurricane on the night of the 14th of November last, forcibly reminded me of the disaster and destruction that similar gales had many years ago inflicted on our sashes and greenhouse structures, and the simple means at that time discovered to render hot-bed or cold-frame sashes, in particular, secure from blowing off. The method of constructing frames in use for many years has been to simply rest the ends of a six-foot sash on the edges of two boards running parallel, dispensing entirely with the rafter-bar. Sashes so placed will stand any ordinary wind in safety, but in case of extraordinary gales they are in great danger of being blown off. After trying various expedients, we found that the simplest and quickest was to have wedges made, about six inches long, tapering from an inch square at one end, to a point at the other. These, when driven in between every 15 or 20 sashes, tightens them so that they are entirely secure from any gale.

The weather predications made at Washington, are now so generally correct that it is well to heed their warning. On the day preceding the night of the gale of the 14th, a red flag hung from the signal station, in Broadway, New York, warning all who knew the signal of the coming danger. Had your correspondent seen that flag flying and known its import, it would have saved him and a dozen men the unpleasant and even dangerous duty of securing hundreds of sashes in the darkness and drenching rain. We are now at the season when we have to fight another and often treacherous foe, "Jack Frost," in our greenhouses. When the thermometer indicates but a few degrees above the freezing point, while the flues or hot-water pipes are strained to their utmost and yet fail to defend the tender plants from his ravages, an excellent expedient is to dash water on the flue or pipes. Do not put the water upon the hottest part of the flue, as it may crack it, but at points where it is hot enough to rapidly convert the water into steam. The steam flies to the glass, and condenses in the form of ice on its under surface, so as to cover up many a crevice through which the cold penetrates, besides rendering the glass itself a worse conductor by the hoar-frost lining. We have often resorted to this expedient with most satisfactory results, in cases where our heating apparatus was insufficient.

LOOK TO THE LABELS.—However familiar one may be with his own collection of fruit-trees and flowering shrubs, we hold it to be his duty to have all properly labeled. We should endeavor to spare our successors the annoyances that attend the possession of trees and shrubs without names. On mild winter days labels may be looked after, and such as are not sufficiently fresh to last another year renewed.

A Bit of the Sub-Tropical.

For some years the English horticultural journals have had much to say about sub-tropical gardening, and last spring Mr. Robinson brought out a book exclusively devoted to the subject. We have had several inquiries as to what is meant by sub-tropical gardening, and we do not wonder, as the name is not a happily chosen one. Like the absurd term "foliage-plants," sub-tropical gardening has been adopted into our horticultural literature, and however inappropriate, it is likely to remain there. Mr. Robinson very concisely and accurately defines it as "beauty of form in the flower-garden." It is producing pleasing effects by the use of plants of striking habit or peculiar character of foliage, in either a single specimen or in groups. Flowers and color are secondary considerations—beauty of form is the chief thing sought after. Almost every one has admired a fine specimen of the Castor-oil plant. There is a luxuriance of growth, a breadth of foliage of an attractive form, and an altogether unusual air and port about the plant, that arrest the attention of the most indifferent observer. There are a great many other plants, large and small, hardy and tender, that please the lover of the beautiful in form equally with the Castor-oil plant. It is the use of plants of this kind that the term sub-tropical gardening is intended to express. Those who have greenhouses and conservatories can employ a large number of tender things to decorate their grounds during summer, but the great majority must confine their attempts at ornamentation of this kind to those annual plants that can be raised from seed each year, or to those the roots of which can be kept in the cellar with the potatoes and carrots. Our efforts in the past summer in the sub-tropical line were confined to two beds, of the simplest kind, yet so effective as to be a constant source of enjoyment. One was a bed of cannas, about ten feet across, and filled with a number of varieties, presenting foliage of various shades of green, and running into blackish purple. A splendid effect was produced, not only in form but in color. The roots of the cannas can be easily kept through the winter, and they are plants that one never tires of. The other bed was an oval, which was planted without much forethought, but which proved to be the pride of our grounds. Late last spring we saw at a florist's a lot of neglected tubers of *Caladium esculentum*, which he was very glad to have taken off his hands; these were planted along the outer line of the oval. A friend in Africa had sent us some seeds, and, among others, those of the Castor-oil plant. Thinking that these might possibly prove different from our ordinary forms of *Ricinus* (which they did not), they were started with others in a hot-bed,

and when the weather became warm enough, two of the strongest plants were set in the oval. At first, the *Caladiums* had it all their own way, but at length the *Ricinus* got ahead, and how the two together did grow! The bed was a

POD OF "SEA-BEAN."—(*Mucuna urens*.)

daily wonder. There were the great elephant's-ear-like leaves of the *Caladium*, and the beautiful crimped and rayed leaves of the Castor-oil plant, each striving to look more "sub-tropical" than the other. Our artist has given a view of this bed, which we merely present as an example of what may be done with very little outlay.

SUB-TROPICAL GROUP.

The glory of this bed departed with the frosts. The *Caladium* roots were put in a warm room to dry off, and the Castor-oils went to the muck heap, and the bed was made ready for bulbs. It is well to begin even thus early to think over our successes and our failures, and make plans for another year. We can heartily advise our friends to try a bit of the sub-tropical.

"Sea-Beans"—"Asses'-Eyes."

Several of our friends who have passed the winter in Florida have brought home interesting seeds, which they procured under the name of "Sea-Beans," they having been told by the Floridians that they were the product of some marine plant. Mr. B. F. Stevens, of San Augustine, sent us some months ago specimens by mail, with the following account of them: "They are found all along the coast of Florida after the north-east storms in September, October, and November. Thousands of them were collected last fall, and quite a little trade was carried on by the sale of them to Northern visitors. They will take a good polish, and good specimens are used as ornaments. We have had several debates as to what they are and where they come from. Some are of the opinion that they grow on trees, others claim that they grow in the water, either in the Atlantic or Amazon."

These seeds are the product of a vine, *Mucuna urens*, that grows in the various West Indian islands and tropical America. The vine has somewhat the appearance of the Hyacinth Bean (*Dolichos Lablab*), frequently cultivated as an ornamental climber. The flowers are yellow, and are succeeded by short, broad pods, which are roughened by transverse ridges, as shown in the engraving. These pods are externally clothed with brownish barbed hairs, which penetrate the skin with the greatest ease, and

"SEA-BEANS."

produce an intolerable itching. These hairs are the Cowhage (vulgarly Cow-itch) of the drug-stores, which is produced by this species and a closely related one. The seeds, which are shown in the engraving of the average size, are double convex. These convex surfaces are slightly roughened, and of a dark, chestnut-brown color, which towards the edges suddenly becomes very light, and presents the appearance of a distinct yellowish-brown margin. The two convex surfaces are joined by a black band, which extends nearly around the seed. The seed is susceptible of a handsome polish. The specimens that we have seen have been polished by the use of a file and glass, followed by fine emery-paper and flour of emery

and oil. The French inhabitants of the West Indies call the seed *Oeil de bourrique*, the Eye of the Jackass. These beans are carried by the ocean currents from some other shore and thrown upon that of Florida, where their appearance naturally gives rise to the conjecture that they grow upon some plant in the sea. None of the proper marine plants bear seeds.

THE HOUSEHOLD.

(For other Household Items, see "Basket" pages.)

Sewing-Machine Accessories.

A sewing-machine, of whatever make, is a wonder of mechanical skill. These ingenious machines have called out a number of accessories, some of which display almost as much ingenuity as the

Fig. 1.—BASKET FOR SEWING-MACHINE.

sewing-machine itself. Several of these inventions have been purchased by the makers of the different machines, and there are still others, some of which are very convenient attachments to a machine that must be purchased separately and of outside parties. We figure some of these devices that have been used in the families of our associates, and found useful. There are several besides these.

Basket for Holding Work.—This is a handsome wicker-basket, made with hooks, which allow it to be hung to the cast-iron frame that supports the machine, as is shown in fig. 1, where it is attached to the frame of a Wheeler & Gibbs machine.

Thread-Cutter.—A small blade in a plated guard is attached to the machine, as shown at A, figure 2, where it is shown upon a Singer machine. It is always at hand ready to cut a thread whenever required, and is so completely guarded that there is no danger of accidentally cutting the fingers.

Casters.—A sewing-machine should stand firm while in use, and yet it is often a great convenience to be able to move it from place to place. We give in figures 3 and 5 illustrations of Sargent & Co.'s

Fig. 2.—THREAD-CUTTER.

casters, attached to a Wheeler & Wilson machine. These casters may be quickly thrown in and out of gear at will. Upon two of the legs are casters which only receive the weight of the machine when it is tipped, and at other times do not interfere

with its steadiness. Attached to the iron frame, and at the opposite end of the machine, is a caster of such construction that when that end of the table is lifted the jointed caster falls into position, and the joint is caught and made solid. This tipping also brings the weight of the machine upon the other two casters, and being supported thus upon three rollers is readily moved about. The long caster is readily unshipped, and the machine placed on a firm foundation by a very simple movement.

The Tuck-Marker.—This is an ingenious appendage to a machine, invented by H. C. Goodrich, and is used in sewing tucks. While sewing one tuck it marks the material in such a manner as to serve as a guide in sewing the next. The marker is laid upon the plate of the machine, and the wire A is attached by a slide in such a manner that it is moved by the needle. At each motion of the needle the end of this wire is brought in contact with the part B. The curved end of B has a notch in it, which strikes upon a sharp ridge immediately below it. The cloth passes between this ridge and B, which has a slight motion, and as the needle moves is struck with a blow from A, which indents the cloth sufficiently to make a mark which serves as a guide

got—such help from outside to see my particular faults and failings—I dare say the process would have hurt me "awfully." In the criticism she received there was truth of a kind most wholesome for her to take to heart, if she would only believe it true, and if it had been given with more of a

Fig. 3.—CASTERS ON MACHINE AT REST.

fellow-feeling for human weakness. One great drawback to its efficacy was the fact that it was given in the presence of others.

Is it not a pity that any of us should grow up with such immoderate love of approbation that we

Fig. 4.—TUCK-MARKER.

in sewing the next tuck. An adjustable scale allows the marks to be made at any desired distance.

Home Topics.

BY FAITH ROCHESTER.

FAMILY CRITICISM.—What a good thing it would be if we each had the "giftie" "to see ourselves as others see us"! What an excellent thing if we were only willing to see ourselves as others see us! "We don't know ourselves." This used to be the frequent remark of a person who considered it abuse never to be forgiven if any one frankly undertook to set a fault of his in clear light before him. A young woman once came to claim my sympathy on account of the abusive criticism a mutual acquaintance had given her. Her wounded feelings distressed me at first, but as she gave me the report, and I saw how clearly her inveterate mental vices had been bared before her, I forgot her present pain and exclaimed: "I wish some one would give me such a talking to!" She looked at me in utter astonishment, and said: "Then you think the criticism a just one?" What could I say? The suffering girl had been wounded again, in the house of her friends, and nothing I could ever say would heal the smart.

Though I was honest at the time in wishing I could have such a good lashing as that girl had

can not endure a word of disapproval—so tender in our self-esteem that we can not live happily with those who do not feed us upon some sort of flattery? In my opinion, over-praise and over-blame both tend to produce these unlovely characters.

A child is to be pitied for its faults, and should be helped to overcome them. To reproach it for its inherited defects of temperament is unreasonable. It is cruel. Just so in our treatment of the moral failings of the members of society. The

Fig. 5.—CASTERS ON MACHINE READY TO MOVE.

same "old Adam" is in us all to some extent, so we may as well

"Let a mournful fellow-feeling Temper all with love."

It would be well to deal with the faults of those

who are under our care with good-natured frankness. Children will hear our corrections better, and get more benefit from them, if given privately. They will understand—will dimly feel, if they can not clearly see—that we wish to spare pain; that we have no wish to disgrace them in the esteem of others, but aim to assist them in overcoming a bad habit, or in preventing the forming of one.

I was going to speak of another kind of criticism

Fig. 1.—CUT-PAPER TOY.

—fault-finding. It is quite too common in families, especially with regard to food. No doubt every kind of food is capable of being prepared in perfection. No one but the cook—no one, indeed, but a cook who has the care of young children—can realize how many are the drawbacks to the attainment of one's ideal in the preparation of a meal. It should be expected that *sometimes* the meat will be scorched or the bread slack-baked, even where there are no small children to break up one's plans for good dinners. The housekeeper need not be reminded of each unpleasant fact in respect to her short-comings; but she ought not to be hurt by a sympathetic remark on the subject. She ought not to expect that the members of her family will be absolutely blind to her failures, and fly into hysterics at any mention of them. In this matter the children of a family will usually follow the example of the "paternal head." Persons who have been trained to be as polite at home as they are abroad are comparatively free from fault-finding in the family. A meddling, dictatorial spirit is to be avoided always; but the heart upon which the law of love is written can not help looking upon "the things of others" with neighborly interest. "Bear ye one another's burdens, and so fulfill the law of Christ."

CUTTING PAPER TOYS.—Children find wonderful pleasure in the use of scissors. Give them some-

Fig. 2.—CUT-PAPER TOY.

thing that it is lawful to cut, or they will probably cut off their eye-lashes or front locks of hair, or scallop their own little frocks. At first they cut for the pure pleasure of cutting, but soon they want to "make something." Paper-cutting is one of the occupations of the Kindergarten. Good Froebel! No observant mother needs to be assured that he was acquainted with live children. Before

we knew what the occupations of the Kindergarten were, paper-cutting had become a favorite employment at our house.

"I am going to cut something pretty for you," said a young auntie in our household to a three-year-old boy who was whining over some disappointment. She folded a square piece of paper, and after cutting it for a few minutes, unfolded a form of beauty that seemed quite marvelous to the child. "There, sir! That is a toy for you," said she, giving it to him. Now the boy cuts prettier "toys" than she ever showed him. Until very lately he expected some one to mark them for him, but now he does the whole alone. I am delighted to see the little fingers learning care and precision in following the marks exactly with the scissors. Habits of industry will come from such employment, as well as from any other, better than from work that is hated. Are not children sometimes made indolent by parents who think that "good children" are those that "keep still" most of the time, and scold children for getting into mischief, but provide no pleasant occupation for the natural activities of childhood?

In the Kindergarten, paper-cutting is scientifically taught, step by step, until the results are very beautiful. The children are helped to mount their cuttings on Bristol-board, and give them as presents to others. If I could be a *whole mother* to each of my children, I would try to carry out the Kindergarten course exactly; but I would try still more to put each child into a genuine "garten" as soon as it was three years old. As it is (I am not repining) I can be only a fraction of a mother to each child, and, like most mothers, I have to devise ways and means to keep my children out of my way!

Half a dozen "toys," doubled and marked, will

Fig. 3.—FIGS. 1 AND 2 FOLDED AND MARKED.

Keep a child busy and happy a good while. For the benefit of those who have had no experience in this line, and who do not get my meaning clearly, I give a few examples. Better ones can be found in Weiber's "Paradise of Childhood." The first ones should be very simple. The fortunate "kinder" who cut paper in their "garten" have soft, colored paper to work with. My children use most the wrappers that come around newspapers.

CORN BREAD.—Let me tell you how grandma made some corn bread that was pronounced "perfect" not long ago. She had no kind of milk for mixing. She just scalded the sifted meal thoroughly, mixing it quite soft with nothing but water and a little salt. She steamed it two hours, and then baked it one hour. A little wheat flour was stirred in. Graham would have been better.

Children's Dresses.

Mrs. J. W. T. writes: I have often seen the children of parents in moderate circumstances more neatly, prettily, and more comfortably dressed than the children of the rich. This is due in some measure to the fact that those who have just enough means get materials that are warm and durable both in fabric and color; while those who have a plenty of money will load their children with finery. I don't like to see a child dressed up so much, and so conscious of it, that all the simplicity and innocence of childhood is lost. Though, again, there are children whom no amount of dress can spoil—they wear it as naturally as a rose its bloom.

I have just been making a pretty dress for my

little girl out of two which she had outgrown. One dress was a striped brown and drab mohair; the other a handsome red and black all-wool plaid, which latter I took for trimming. I put bias shoulder-pieces and strips down the sleeves, around the wrists, and under the arms, and a band around the waist—apparently for ornament, but actually for the purpose of making the brown dress large

A CHILD'S DRESS MADE OUT OF TWO.

enough. I cut out the linings by a pattern that fitted the child nicely, taking the precaution to leave the buttons and button-holes in the back intact, and make the enlargement on the opposite side, under the arm and around the shoulder. As three inches had been turned in at the time of making the skirt in the first place, I had merely to trim it with two bias folds of the plaid, one somewhat wider than the other.

Nothing adds more to the neat appearance of a child than well-fitting shoes, and stockings smooth on the leg. It is impossible to keep stockings smooth with the old-fashioned garter without hindering the proper circulation of the blood. I make a garter for my children which is used very generally by parents in cities, but may not have been thought of by mothers in some parts of the country. It is made as follows: Take two strips of broad elastic, each four inches in length. Insert two of the ends together in a calico end large enough to allow a button-hole to be made. Keep the other two ends separate, and finish them off in the same way with a button-hole in each. There must be a button on the corset or waist under the arm, and two buttons on each stocking. Any one would know how to put them on, and there is no danger of the stocking being wrinkled, while the blood has free course.

A Convenient Cutting-Board.

The board here figured is nothing new, but it is not in near as general use as it would be were it

LAP-CUTTING BOARD.

better known. A lady of our acquaintance who recently had one made, now wonders how she ever did without one. It is made to hold in the lap, and with a semicircular place cut out to accommodate it to the body. This board will be found very convenient in cutting and fitting work for the sewing machine, as it can be used without the fatigue that attends standing over an ordinary table.

BOYS & GIRLS' COLUMNS.

The Doctor's New Year's Word.

Hurrah! boys; and hurrah! girls, too, for girls below a certain age—I don't know exactly what it is—hurrah as well as boys. There is my niece Alice, who a few years ago was half a Fourth-of-July celebration, she made so much noise; but since her mother was ill she has been a demure little house body. But that is not what I started to say. Did all of you, boys and girls both, see my proposition last month? There are probably so many new youngsters that I shall have to briefly repeat it. I offered for the best map made by any boy or girl of the place on which he or she lives, \$5 in money; for the next best, *Hearth and Home* for 1872, equal to \$3; and for the third best, the *Agriculturist* for 1872, equal to \$1.50. More particulars are given in December, 1871. It will do you all a great deal of good to try, and it will be very pleasant to have a great many of our boys and girls all working together on the same thing. I have some other premiums in view, but let us get through with this first. The time for this premium will be on February 1st; that is, all competing maps must reach me on or before that date. Let us have all hands wide awake, and go in for a happy new year, not only now while the year is young, but every month, and all through to the end.

The Snow-Birds.

Hurrah for winter! Is there not ice for skating, and snow for sleighing and sledding, and no end of fun for boys and girls generally? Then, isn't it fine to look from the window and see the snow come sitting down so

422.—*Illustrated Rebus.*—This, when made out, will be found to be a maxim which is none the worse for being a rhymed one.

silently? As we look out there is not a living thing to be seen. Ah! yes there is; there come the snow-birds—the merry little fellows. They have been hiding long enough in the edge of the woods, and now that snow has come they fit about, and give their little chirp to announce that they, too, have come. There is something very pleasant about these birds—they like to be neigh-

borly, and come about the house, but they usually put off making their calls until the snow has come. It may be that, like some other visitors, they come for what they can get—and we will not disappoint them. Let us open the window and throw out a few crumbs or seeds. It is a pleasure to see the cunning airs of the little fellows as they pick up the food. These birds have good memories, and will be likely to come again to-morrow, and if we throw out food every day we can daily enjoy looking at them. "Where do they go in summer?"—We thought you would ask that question. They go off for a little

SNOW-BIRDS.

quiet housekeeping, some to the mountains, and others, the majority, go very far north, where they find suitable retreats where they can build their nests and raise their young. In autumn the snow-birds make their way southward. What a journey it must be for these bits of birds to flap their tiny wings for hundreds of miles! There is scarcely any other bird found in so many parts of the country as this. Our boys and girls in the Gulf States, as well as those away up in Canada, can make its acquaintance. When they first arrive from the north they stay in the woods, as they there find sufficient food; later they may be seen around the barn-yard, where they follow the fowls, and pick up the little bits that the larger birds have overlooked; and when cold weather fairly sets in, they then come about the house, apparently knowing that there must be some kind-hearted boy or girl there, ready to give them a little food.

The Game of "Succotash."

Our young folks at home have been kept wide-awake many evenings by the new game of Succotash. As every boy and girl ought to know, Succotash has two parts—viz., beans and corn. It is best in learning the game to commence with the first part, *beans*—in this way: All the players being seated, one begins by counting "one," his next right-hand neighbor says "two," the next "three," and so on, until "seven" is reached, but instead of saying "seven" the player says "beans." Then keep right on counting, each naming his proper number in turn, "eight," "nine," "ten," etc., until "fourteen;" but say "beans" instead of fourteen. Go on again, saying "beans" instead of "seventeen," or "twenty-one," or "twenty-seven." In other words, the rule of the game is: "Beans" is to be said instead of seven or any multiple or compound of seven. Of course, when seventy is reached it will be "beans" all the way through, with "beans, beans" for seventy-seven. Whoever fails to say "beans" in the right place, or says it at a wrong number, is "out," and the others play on, until all are out. The counting is continued up to "eighty-four," then begins at one again.

When "beans" are mastered, begin with "corn," using it wherever "nine" occurs, or any multiple or compound of nine, and continue the counting up to one hundred and eight.

Next try and mix them, for "Succotash;" naming "beans" and "corn" in all the right places at the sevens, nines, etc. Be sure and call out "succotash" at twenty-seven, because it is a multiple of nine and also a compound of seven; at forty-nine, which is a multiple of seven and a compound of nine, and at any other number where these parts both occur as multiples or compounds. To play the game lively, without mistakes, will require

quick thinking and careful speaking. The game can be varied by using any other numbers, and those who have had hard work to remember the multiplication table will find it a capital exercise to fix the figures in mind so that they will stay in their places.

Something about Games.

Who invents games, and where do they come from? How do boys and girls all over the country seem to know the same games? And, as far as out-door games are concerned, the boys all know exactly when the proper time comes for them. That boy who would play marbles in top time, or fly a kite in the season of hop-scotch, would be looked upon by his fellows as a ninny. We wonder who fixed the times and seasons for games, and how do boys know when they come around? Perhaps it is because it is so long since we were a boy. Well, never mind that. We wanted to say a word about social indoor games, which are much more timely just now. We believe in innocent games, and take as much enjoyment in playing them as the veriest boy or girl of you all. We nearly laughed the buttons off of our venerable vest over the mistakes that we made at the game of Succotash,

described elsewhere. These games have a good influence in sharpening one's wits and strengthening the memory. But that is only incidental. We do not play them for that, but for the fun that there is in them—for the genial, jolly laughter they bring. We notice, by the way, that in games we follow the way of the world, and see the mistakes of others much quicker than we do our own. Now, there are games all over the country that seem to be unknown outside of a particular locality. Let us try and bring the good ones out, so that all the boys and girls can enjoy them. If a game is played at your home that you think is not generally known, just write it out

423.—*Word Puzzle.*—Here are several cats. There is the cat sepulchral, and the one found in the Sunday-school; and there is the cat to be avoided, and the one that you like to have with you in the library. Indeed, we may say there is a concatenation of cats.

for us, and if it seems to us desirable we shall be glad to tell all the rest about it. There are books of games, but we never saw one that contained them all, and there must be many unpublished ones known to our young readers.

Teaching Zip to Read.

Master Phil is much like other boys we have seen—he is not contented with any one thing for a very long while. He had a short time ago a military turn, and beat his toy drum until all in the house hoped it might burst. The martial fever gave way to an educational one, and the drum and wooden soldiers are put aside for the book with large letters. Phil has recently mastered his A, B, C's, and being already in a-b, ab's, he thinks that he knows so much that he is qualified to teach. The only available pupil is the dog Zip, who is made to come to school. Master Phil does not seem to be making much progress as a teacher, and Zip does not promise well as a scholar. Probably Phil thinks his pupil frightened by the great A B in the book, but we can see that the dog has his attention taken from his studies in a manner for which we can pardon him. We have seen boys at school quite as inattentive to their books as Zip appears to be, and without anything like as good an excuse. Very likely if the school-mistress would give her evidence, she has found it almost as difficult to fix Master Phil's attention upon his book as he now finds it difficult to engage his pupil studying in the simplest elements of learning.

TEACHING ZIP TO READ.—Drawn and Engraved for the American Agriculturist.

How Minnie Washes Dishes.

Minnie Wiley, a little girl of eleven, writes us a letter to tell how she washes dishes. That is right. We like to have our boys and girls tell us how they do things, and we hope that there are a great many of our girls who, like Minnie, take enough interest in washing dishes to try and do it right. Remember that dishes have to be washed in most families three times a day, and somebody has to do it. What a pleasure it will be to be able to do this so nicely that mother is willing to allow you to relieve her of this portion of her labors! Minnie says: "First I scrape the dishes and stack them up very neatly; then I remove them to the pantry table, close to the sink and to the cupboard, into which I can easily place them as I wash and wipe them. First I wash my glass, then the spoons, then the cups, and so on. Then I place the spoons in the spoon-stand, for mother says it is not right to put spoons with knives. Then I put the knives and forks into the knife-box, and also the cooking spoons and ladle. Then I wash out my dish-pan and cloth, and hang them up to dry."

Aunt Sue's Puzzle-Box.

CHARADE.

My first, when connected with good, is a treasure,
You love it, and gratitude glows in the mind.
My second's restricted to limit and measure,
Ingenuously fitted to loose or to bind.

My whole, as a station, you can not admire;
My second's his care, whilst too many, distressed
Beneath his coercion, would gladly retire,
Seek other retreats, and feel inwardly blest.

F. H. C.

OMISSIONS.

Omit my 3, 4, and I am a gift.
Omit my 3, 5, 6, and I am a reptile.
Omit my 1, 2, 3, 6, and I am either adverb or preposition.
Omit my 1, 2, 4, 6, and I am either adverb, conjunction, or interjection.
My whole is a city in the United States.

I. K. P.

SQUARE WORD.

1. An insect. 2. Variety. 3. A box. 4. Part of a ship.
A. M. NAGEL.

GRAMMATICAL ENIGMA.

I am composed of 45 letters.
My 1, 5, 20, 27, 10, is a preposition.
My 18, 12, 28, 10, 25, is an adjective.
My 14, 15, 24, 25, is a conjunction.
My 7, 20, 35, 39, is an adjective.
My 35, 2, 32, 8, is a preposition.
My 6, 19, 39, is a conjunction.
My 29, 36, is a preposition.
My 5, 9, 17, 25, 3, 43, is an adjective.
My 14, 44, 23, 11, 28, is an accident of the verb.
My 40, 35, 41, 30, is a part of speech.
My 28, 41, 42, 43, 44, 33, is an accident of the noun.
My 16, 17, is a pronoun.
My 4, 37, 25, is a noun.
My 25, 26, 21, 32, is a noun.
My 31, 22, 7, is a noun.
My 13, 34, is a verb.
My whole is one of the rules of Syntax.

CLARENCE CLIFFORD.

CROSS-WORD.

My first is in *window* but 'tis not in house.
My next is in *rat* but it is not in mouse.
My third is in *cow* but it is not in calf.
My fourth's in the *middle* but 'tisn't in half.
My fifth is in *water* but 'tis not in milk.
My sixth is in *damask* but it is not in silk.
My seventh is in *Albert* but 'tis not in Joe.
My eighth is in *rain* but 'tis not in snow.
My ninth is in *many* but 'tis not in one.
My whole is an animal very well known.

AUNT SUE'S NOTICES TO CORRESPONDENTS.

A. H. I do not "write for the New York Observer." I do "write every week for the *Hearth and Home*."

DOLLY. It is sufficient to write the answer without writing out the whole enigma as published.

MORRIS P. S. Yes, you were quite right.

HARRY S. There is so little change made in the old "M T grate" puzzle you send, that we can scarcely call it original.

HESSA M. W. If you will compare your answers, dear, with those published in this number, you can see for yourself whether you were right or not. See remarks to Dolly.

Of several communications I take no notice, because I can not tell whether they are intended for the *Agriculturist* or for *Hearth and Home*.

Glad to hear from Mrs. H. J. N. and F. W. H., S. H. B., W. H., Jr., Blue-Bird, and Charlie D. S.

Thanks for puzzles, etc., to F. W. H., A. H., R. S. Isbester, Harry S., W. H. C., and Alpha.

A Favorite New England Security.

To all seeking absolute safety for their investments, rather than high rates of interest (which very rarely accompany each other), we confidently recommend the joint sinking fund bonds of the three corporations composing the Vermont Division of the Portland and Ogdenburg Trunk Railroad Line, the most important link in a line shorter by more than Fifty Miles than any other between the Great Lakes and the Sea-board, and having a Local Business more than sufficient to pay operating expenses and all interest obligations, in addition to the immense Through Traffic which must be attracted to the Shortest Line and Easiest Grades. As a route for Tourists and Pleasure Travel, this road has no equal on the American Continent.

The road is nearly completed for one half the entire distance, at a cost considerably below the original estimates; and will be opened for business, with first-class equipment, in a few days.

The Bonds are in denominations of \$1,000, \$500, and \$100, and can not be issued for more than \$20,000 per mile of road. The interest (Six Per Cent Gold) is payable semi-annually, free of Government Tax, principal also redeemable in gold in 1891, and are offered until further notice at 90 and accrued interest in currency.

No bonds in the market offer equal security and profit to those having Five-Twenties and other high-priced securities to convert. Many of the most conservative investors in the country have subscribed largely to this popular loan, and the balance remaining unsold, it is believed, will be rapidly absorbed. Liberal subscriptions have been made to the Capital Stock at par; and the management, which is in the hands of some of the best-known New England business men, has been such as to inspire confidence in the honest purpose of the projectors of this great enterprise, as well as in the safety and value of the security offered.

For further information, pamphlets, maps, etc., apply to Financial Agents,

Derrom Building Co.

This Company furnish ready-made buildings, of any size or style, suitable for any locality which can be put together in a few hours by any ordinary laborer, at less prices than they can be built where wanted. Estimates promptly furnished on receipt of plans. They also manufacture everything wanted in house building from the smallest to the largest article. All who contemplate building will find it to their advantage to address, for full information,

Derrom Building Co., Paterson, N. J.

A Sensible Holiday Present.—No present can be more acceptable to a Wife, Mother, Sister, or lady friend, than a DOTY WASHING MACHINE, price \$15, and a UNIVERSAL WRINGER, \$8, which are warranted to give entire satisfaction. Mr. R. C. BROWNING, General Agent, 32 Cortlandt Street, New York, will, on receipt of the price, send either or both Machines, free of freight, to places where no one is selling; and, after using them a month, according to directions, if not entirely satisfactory, they may be returned, free of freight, and the money will be refunded. Can anything be more fair?

Twenty-five per Cent Saved

By using DOOLEY'S YEAST POWDER in the preparation of biscuits, rolls, pastry, etc., over any of the ordinary baking powders in market. This is occasioned by the full net weight in each package, and the fact that it is composed of articles strictly pure, healthy, and nutritious, which insures satisfactory results every time. By using DOOLEY'S YEAST POWDER, thirty pounds more bread can be made from a barrel of flour than by any other process of raising dough. A trial will satisfy any one of its standard excellence. For sale by Grocers generally.

Harper's Periodicals FOR 1872.

The Publishers take pleasure in announcing that they have secured for the new Volumes of HARPER'S MAGAZINE, HARPER'S WEEKLY, and HARPER'S BAZAR the most brilliant and fascinating array of literary and artistic attractions ever offered simultaneously to the American public. They comprise, for immediate issue, besides others that will be in due time announced, the following works:

"Middlenarch," a new serial story by GEORGE ELIOT, to commence in HARPER'S WEEKLY for December 16.

"Miss or Mrs.?" by WILKIE COLLINS, illustrated with striking full-page engravings from original drawings, to commence December 30.

"Blade-o'-Grass," by B. L. FARJEON, Author of "Joshua Marvel," with many beautiful illustrations, is just commenced in HARPER'S BAZAR.

"The Golden Lion of Granpere," by ANTHONY TROLLOPE, with illustrations, to commence in the February Number of HARPER'S MAGAZINE.

They have also secured the plates and advance sheets of "London: a Pilgrimage," by GUSTAVE DORE and BLANCHARD JERHOLD, a new and magnificent series of illustrations from the pencil of the great French artist.

A new Novel by Miss THACKERAY, whose writings have won deserved popularity by their purity of tone, genial imagination, and fascinating style, will be commenced early in the year.

The great Spanish statesman, EMILIO CASTELAR, will furnish an important and interesting paper for an early number of HARPER'S MAGAZINE on "Republicanism in Europe."

Mr. GEORGE WILLIAM CURTIS, under the now familiar sobriquet of "AN OLD BACHELOR," will continue his weekly contributions to the BAZAR, entitled "Manners upon the Road." This series of Social Lessons, commenced with the first issue of the BAZAR, has proved one of the most attractive features of that journal.

"PORTE CRAYON" will begin in an early number of the MAGAZINE a series of illustrated papers portraying life and character in the Southern States under existing conditions. Colonel T. B. THORPE will contribute to the March Number of the MAGAZINE an interesting illustrated paper on the United States Treasury Department. Mr. EUGENE LAWRENCE will continue his contributions on important historical subjects. Mr. MONCURE D. CONWAY will resume his "South-Coast Saunterings" in an early number, and will contribute other illustrated papers on interesting European topics.

These unprecedented attractions will require occasional literary Supplements to HARPER'S BAZAR and HARPER'S WEEKLY, which will be included in the regular issue, free of charge to subscribers.

The readers of HARPER'S MAGAZINE, WEEKLY, and BAZAR are to be congratulated on the rich and tempting intellectual repast provided for their enjoyment, and upon the rare privilege of sitting down to their monthly or weekly feast of fancy and flow of soul with such a select and excellent company of entertainers as GEORGE ELIOT, WILKIE COLLINS, ANTHONY TROLLOPE, CHARLES LEVER, Professor DE MILLE, B. L. FARJEON, GUSTAVE DORE, Miss MILCOCK, Miss BRADDON, GEORGE WILLIAM CURTIS, M. D. CONWAY, PORTE CRAYON, BAYARD TAYLOR, R. H. STODDARD, JOHN HAY, HARRIET PRESCOTT SPOFFORD, EUGENE LAWRENCE, Dr. I. I. HAYES, THOMAS NAST, SOL EYTINGE, Jun., CHARLES PARSONS, W. L. SHEPPARD, JULES TAVERNIER, and many others of high rank in the world of letters and art. In securing this unprecedented array of splendid names, the Publishers are only carrying out their original design, and fulfilling what they conceive to be the legitimate duty of the conductors of widely circulated and popular periodicals. They intend that wherever their periodicals circulate they shall exert a healthful influence in every department of literature and art; and that in the future, as in the past, they shall be not only unsurpassed but unapproachable in the sphere of illustrated journalism.

HARPER'S MAGAZINE, WEEKLY, and BAZAR meet and satisfy the intellectual wants of the great mass of intelligent American readers; and in treating of literary, political, social, or domestic themes, offer an amount of wholesome instruction, recreation, and amusement which will be sought elsewhere in vain. They represent, therefore, for every American household the Graphic Literature of the World.

TERMS for 1872.

HARPER'S MAGAZINE, One Year.....\$4 00

58 Cortlandt St., New York.

J. J. H. GREGORY'S
ILLUSTRATED CATALOGUE
 OF
GARDEN and FLOWER SEEDS
FOR 1872.

Having introduced to the public the Hubbard Squash, American Turban Squash, Marblehead Mammoth Cabbage, Mexican Sweet Corn, Phinney's Watermelon, Brown's New Dwarf Marrowfat Pea, Boston Curled Lettuce, and other

New and Valuable Vegetables,

with the return of another season I am again prepared to supply the public with Vegetable and Flower Seeds of the purest quality. My Annual Catalogue is now ready, and will be sent free to all. My customers of last year will receive it without writing for it. It abounds in fine engravings, many of which were taken from photographs of the vegetables themselves. It has not only all novelties, but the standard vegetables of the farm and garden (over one hundred of which are of my own growing), and a carefully selected list of Flower Seeds. As stated in my Catalogue, all my seed is sold under three warrants—1st, That all money sent shall reach me. 2d, That all seed ordered shall reach the purchaser. 3d, That my seeds shall be fresh, and true to name. Catalogues free to all.
 JAMES J. H. GREGORY, Marblehead, Mass.

COLUMBUS NURSERY.—Greenhouse and Bedding Plants give universal satisfaction. Spring Catalogue mailed to applicants.
R. G. HANFORD, Columbus, Ohio.

To Farmers and Gardeners.

I invite all who have been in the habit of buying their garden seed from boxes left at the stores to give my seed a trial, side by side, and mark the difference in their germinating, and in the purity and quality of the vegetables raised from them. I have made it my mission for several years past to drive bad seed from the market, and so save farmers and gardeners the immense loss they annually suffer from the purchase of it.
 The public have well appreciated my efforts, and I have now fifty thousand customers in the United States and Canada. I sell no seed I do not warrant, and what is the real pith of the matter I stand by my warranty. To enable me to do this I grow myself a large proportion of the seed I sell. Catalogues sent free to any applicant.
JAMES J. H. GREGORY, Marblehead, Mass.

NEW INVENTIONS—NEW STYLES.

MASON & HAMLIN
CABINET ORGANS.

Highest Excellence, Lowest Prices.

We introduce this season several new inventions of great value; including **DAY'S TRANSPOSING KEY-BOARD,** enabling every performer to transpose the key without slightest difficulty.

Also, **NEW STYLES** of Cabinet Organs in very rich and beautiful cases, at **extraordinarily low prices.** Full particulars in circulars and **ILLUSTRATED CATALOGUES,** sent free to any address.

It can hardly be longer necessary to advertise the quality of the **Mason & Hamlin Organs,** for it is scarcely disputed by any that they are **THE BEST IN THE WORLD;** the

VERY STANDARD OF EXCELLENCE

among instruments of the class.

Every purchaser may be sure that he is obtaining, in proportion to its size, capacity, style, and class, the very best instrument which it is practicable to produce. We are not afraid to warrant all our work as up to even this high standard.

But while the superiority of the **Mason & Hamlin Organs** is established, it is not so widely known that the prices are not higher than those of ordinary instruments. We offer the largest variety in the country—one to thirteen stops—at from \$50 to \$1,000 each.

Every one interested should at least send for the **ILLUSTRATED CATALOGUE** and **CIRCULARS** of the Company, which **COST NOTHING,** being sent post-paid.

MASON & HAMLIN ORGAN CO.,

596 BROADWAY, NEW YORK,

900,000 ACRES
OF
EXCELLENT FARMING
AND **SPLendid**
Michigan Pine Lands
FOR SALE,

On which are **ONE THOUSAND MILLIONS OF PINE TIMBER,** and inexhaustible quantities of Maple, Beech, Elm, Ash, Hemlock, Oak, etc.

The grant of lands to the **Grand Rapids and Indiana Railroad Company,** to build their Road from Fort Wayne, Ind., to Traverse Bay and Mackinaw, Michigan, comprises in its farming lands every variety of soil, from the **rich clay loam** to the light sandy, and they are found in that section of Michigan, north of the city of Grand Rapids, and contiguous to the great fruit belt on the eastern shores of Lake Michigan, now being rapidly developed by railroad and other enterprises.

Farming Lands are sold to actual settlers, on credit, one quarter down, balance in yearly payments, interest 7 per cent. Persons desiring of locations for farms will, on application at the **Office in Grand Rapids,** be furnished with **Tickets over the Road,** entitling them to **Return of Fares,** in the event of purchasing any of the Company's farming land. For information about the lands, prices, location, etc., etc., address

WM. A. HOWARD, Land Commissioner, TITLE PERFECT. Grand Rapids, Michigan.

1,500,000 ACRES
of the
RICHEST FARMING LANDS
IN THE WORLD
FOR SALE TO **ACTUAL SETTLERS.**
NEOSHO VALLEY, KANSAS.

Missouri, Kansas, and Texas Railway Co.
CARS NOW RUNNING 400 MILES.

The Lands offered by this Company are mainly within 20 miles of each side of the road, extending 170 miles along the **NEOSHO VALLEY,** the richest, finest, and most inviting valley for settlement in the West.

One third of the labor required at the East in the culture of farms will insure here double the amount of crops.

PRICE OF LAND.—\$3 to \$8 per acre; credit of ten years' time.

TERMS OF SALE.—One tenth down at time of purchase. No payment the second year. One tenth every year after, until completion of payments, with annual interest. For further information, address

ISAAC T. GOODNOW, Land Commissioner, Neosho Falls, Kansas.

IMPORTERS, GROWERS, AND DEALERS IN
Garden, Field, and Flower Seeds,
SMALL FRUITS,
Horticultural Implements,
Fertilizers, and Other Requisites for the
Farm and Garden.

The Eighteenth Annual Edition of their celebrated Seed Catalogue and Amateur's Guide to the Flower and Kitchen Garden, will be ready for distribution early in January, and mailed to their customers of 1871 as rapidly as possible, and to all applicants, upon receipt of 25 cents, an edition beautifully bound in cloth, 75 cents. This is without exception the largest and best Catalogue ever published in this or any other country. It will contain nearly 200 pages, including several hundred finely executed engravings of favorite flowers and vegetables, and a beautifully colored chromo of a group of twenty of the most popular flowers in cultivation. Also a descriptive list of 2,500 species and varieties of flower and vegetable seeds, including all the novelties of the past season, with full directions for culture. Address

B. K. BLISS & SONS,
P. O. Box 5,712, New York City.

LATE ROSE POTATO.

This valuable Potato, which is now for the first time offered for sale, differs from all other varieties so far introduced, inasmuch as it is not claimed to be a new seedling, but a sub variety or sport of the well-known Early Rose, which it strongly resembles in quality, color, and form—but is three weeks later, hardier, and more productive, having yielded the past season 25 to 30 bushels to the acre.
Circulars giving a full description will be mailed to all applicants. Address **B. K. BLISS & SONS,**
23 Park Place, and 20 Murray St., New York.

**What to Plant:
How to Plant:
What the Cost:
For the Garden,
For the Flower Bed,
For the Farm.**

FIRE CAMPAIGN!

FOR COUNTRY AND TOWN! FOR OLD AND YOUNG!

STILL AT THE FRONT!!

FROM THE PEOPLE.—"I am not only delighted but surprised to see it out from the ruins so soon."—F. A. Springer, Springfield, Ill. "I must congratulate you on the extraordinary and unlooked for enterprise you have shown in issuing your paper so soon."—F. M. Munn, Newark, N. J. "The Farmers must support their paper, for it has supported the Farmer."—John Vasey, Jacksonville, Ill. "The Farmer was my guide in farming seventeen years ago."—C. C. Hutchinson, Atchison, Kan. "We can't do without the dear Farmer."—C. Bateman, Fort Calhoun, Neb. "You can count me a life subscriber, for I value The Farmer more than any other agricultural journal in the United States."—L. D. Watkins, Manchester, Mich. "My father took it when I was a boy. I take it now. We farmers love The Prairie Farmer."—L. S. Eldred, Carrollton, Ill. "My name is on your free list, from which strike it off, and inclosed find \$2.00."—A. S. Fuller (Asst. Edr. Rural New Yorker), Ridgewood, N. J. "You have the esteem and confidence of the Great West."—N. C. Dudley, Nursery Hill, Neb. "You can't think how overjoyed we were to hear from our dear old Prairie Farmer."—Kitty R. Jordan, Rochester, Minn. "Have taken The Prairie Farmer for nearly a quarter of a century. It must live."—W. T. Nelson, Wilmington, Ill. "When I heard of the great fire my first thought was about my dear old Farmer."—Wm. Lindell, Jerseyville, Ill.

Though our convenient and well-appointed Offices, together with their entire contents, were totally destroyed by the recent Great Fire, yet the reliable old PRAIRIE FARMER, which for more than THIRTY YEARS had wended its way, winter and summer, through storm and sunshine, without intermission, to the firesides of its thousands of readers, true to its record, never missed an issue, but has been mailed regularly, every week since the fire, to all subscribers. It has put on an entire new dress, and goes forth as neat and attractive, as handsomely illustrated, and as replete with varied and instructive contents as ever. But our loss has been very heavy, and years of hard labor and frugality can hardly repair it; yet, with God's blessing and the help of our friends, we shall strive to earn prosperity, and win a greater measure of success for THE PRAIRIE FARMER than has ever yet been vouchsafed it. The brethren of the press have unanimously uttered noble and cheering words of praise and encouragement, and our patrons everywhere—the old wheel-horses of Western agriculture, and the readers of but half a year's standing, the wives and mothers, the boys and girls—have spoken and acted words and deeds of sympathy and support far beyond what we could have expected or hoped for. And now, as the long winter evenings are coming, we are casting about to see how it may come to pass that we can, to some extent, repay all this spontaneous outburst of generosity and ardent support that indeed proves the whole world kin. We hope to do it by sending to the fireside of each patron something that shall instruct, something that shall improve, something that shall amuse, something that shall suggest thought, something that shall stimulate to experiment, something that shall make better and nobler every member of the family. With the farmer we shall discuss the matters of the field, the orchard, and the stable. With the farmer's wife we shall gossip over the topics of the kitchen, the dining room, and the flower garden. With the children we shall chat about all the little and big affairs of the world, that we think will do them good and make them excellent citizens and members of society. With all we shall fairly and fearlessly discuss the Topics of the Day. For all we shall condense the News of the Week, as we gather it from all parts of the world, and for the farmers everywhere we shall endeavor to maintain their rights, protect their interests, and warn them against frauds and rascalities, of whatever name or nature. In brief, we shall endeavor in THE PRAIRIE FARMER to supply everything that we know how to supply, or that the reader can expect, in a farm and fireside journal.

EVERY PERSON

Living at the East who contemplates removing to the West, and every person, East or West, who is not already a subscriber, and who desires the latest, most thorough, and reliable information of practical value concerning the growth and development of the West and North-west, particulars relating to the public domain, character of Western soils, the most successful modes for their cultivation, tree planting, fruit growing, etc., etc., should not fail to subscribe for THE PRAIRIE FARMER for 1872.

AGENTS! FRIENDS! EVERYBODY!!

We call upon you who have heretofore interested yourselves in our behalf, and also you who have not, to push on the good work of extending the circulation and influence of THE PRAIRIE FARMER. We do not want you to work for nothing, but ask you to remember that no other weekly journal of its class in the world offers more splendid inducements to subscribers and agents alike, and that no other is so easy and so profitable to canvass for among the industrial masses. Remember that our List comprises **150 PREMIUM ARTICLES**; also, that if you prefer a **CASH COMMISSION** to Premium Articles, you can deduct (in remitting) **TWENTY PER CENT** from yearly or half-yearly subscriptions.

SUBSCRIPTION TERMS:

\$2.00 per Year, in Advance. Three Months on Trial, 50 Cents.

Ask for Premium List, Specimen Numbers, and Canvassing Documents, and they will be sent **FREE.** Address, in all cases,

THE PRAIRIE FARMER COMPANY, CHICAGO.

Remit at our risk by Registered Letter, Draft, or Post-Office Money Order.

THE CHICAGO FIRE
DESTROYED
The Little Corporal
PUBLISHING HOUSE

with all its contents, but notwithstanding this terrible "baptism of fire," the gallant little **Juvenile Still Lives,** to be more attractive and charming than ever before.

The Little Corporal.

"THE LITTLE CORPORAL MAGAZINE, for boys and girls, is the very best juvenile magazine published. It employs the best and most entertaining writers for children in the country, and furnishes more valuable reading matter for its price than any other magazine."—*Medical Journal, Elmira, N. Y.*

The Little Corporal.

"In selecting reading matter for the family, the children should not be overlooked. It is quite probable that the impression they receive from books has as much influence upon their lives as any other. This neat and well-illustrated monthly is so well adapted to the wants of the class, that it is rapidly taking the place of all others."—*Enterprise, Barnesville, O.*

The Little Corporal.

All New Subscribers for 1872, whose names and money (\$1.50) are received before January 1st, will receive the last month of this year Free.

Elegant Premiums for Clubs!

JOHN E. MILLER, Publisher,
CHICAGO, ILL.

TO ALL WHO CAN READ.

The Weekly Sun Doubled in Size without Increase in Price.

With the beginning of the year 1872 THE WEEKLY SUN will be double its present size, and will contain eight pages instead of four, making it equal in dimensions to any other weekly secular journal published in this country. At the same time its price will not be increased. It will be furnished to subscribers at the uniform rate of one dollar a year for each copy. To this rate no exception will be made, and no reduction will be possible, either to clubs or agents. Every subscriber who sends a dollar will receive a copy for a year.

While THE WEEKLY SUN will thus furnish as much reading matter as other papers published at double or treble the price, it will contain new features which will add greatly to its interest and value as a family newspaper. Its independence of opinion, and its unqualified hostility to Tweedism and Grantism, and every form of public robbery, bribery, and corruption, will be maintained, while in point of political news its readers may rely upon always receiving the most accurate as well as the freshest intelligence that can possibly be obtained. The enlargement will enable us also to devote additional space to valuable agricultural intelligence, and to print interesting stories and romances more extensively than hitherto. For miscellaneous reading presenting the quaint and humorous aspects of life, and for useful information respecting not only what takes place in this metropolis and this country, but in all other parts of the world, we shall now have ample room.

In its new form, THE WEEKLY SUN will be the cheapest paper of its class in the United States; and we appeal to such of our readers as approve its ideas and objects, and find it interesting and valuable, not only to renew their own subscriptions, but to recommend the paper to their friends and neighbors.

The coming year is destined to be a memorable one in the history of the country. We are on the eve of a most significant Presidential election, and political movements will for many months be watched with unusual interest. As a journal, free from the trammels of party, THE WEEKLY SUN will continue to uphold the principles of true republican government. Its readers are invited to sustain it in that work. The truth, irrespective of party prejudice or official influence, will always be told in its columns.

Terms of the Weekly Sun—

A journal containing eight large pages, published every Wednesday morning—To all mail subscribers whether single or in clubs, one dollar a year each, always in advance.

DAILY SUN, by mail, 50 cents a month, or \$6 a year
SEMI-WEEKLY SUN, by mail, \$2 a year.
Address THE SUN, New York City.

L. A. CHASE, 245 Broadway, New York.

FARM IMPLEMENTS AND MACHINERY.

The principles of their construction and use; with simple and practical explanations of the laws of motion and force as applied on the farm. By **John J. Thomas.** With 287 illustrations. Price \$1.50.

The basis of this admirable work was an essay published in 1850, in the Transactions of the N. Y. State Agricultural Society, which was enlarged, and in 1854 published by the Harpers. It has been, and remains, the only work in which the principles of Natural Philosophy, namely, the mechanical powers, and the powers of water, wind, and heat, are systematically discussed as applied to the operations of the farm. This work has now been most carefully revised by the author. It is much enlarged, and a great part has been re-written, while the illustrations, before abundant, now number two hundred and eighty-seven. There is not an agricultural writer that could be named more respected than John J. Thomas, or one whose judgment and freedom from personal bias in discussing new implements could be more implicitly relied upon.

Sent post-paid on receipt of price by
ORANGE JUDD & CO., 245 Broadway, New York.

MARION WATCHES.

What they think at the White House of the United States Watch Co.'s MARION WATCHES.

The following is from General PORTER, President GRANT'S Private Secretary:

EXECUTIVE MANSION, WASHINGTON, D. C., Oct. 15th, 1871.

DEAR SIR—My watch has kept excellent time since I have carried it. Yesterday, in some unaccountable way, the crystal was broken. Will you please replace it, and oil the works? They have never been oiled or examined since the watch left the factory. I expect to be in New York a day, about Thursday or Friday of next week, and I shall call at your place 13 Maiden Lane, for the watch.

Yours very truly,
(Signed) HORACE PORTER.

F. A. GILES, Esq.

The Watch referred to above is No. 27,335, Stem Winder, Trade Mark "John W. Lewis"—manufactured by the United States Watch Co. (Giles, Wales & Co.), Marion, N. J.—and has been carried by Gen. Porter for over a year. We are glad to see that our officials in high places appreciate fine American mechanism, and set the example of patronizing home productions, instead of sending our gold abroad for inferior articles.

Watch No. 1,105, Stem Winder—bearing Trade Mark "Frederic Atherton & Co., Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), Marion, N. J., has been carried by me eleven months; its total variation from mean time being only seven seconds in the entire time.—A. H. KING, Vice-Pres't Elastic Cone Sp'g Co., N. J. Car Sp'g & R. Co., No. 7 Park Place, N. Y.

Watch No. 2,291, Stem Winder—bearing Trade Mark "Fayette Stratton, Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me eighteen months; its total variation from mean time, five seconds per month.—E. O. WHIFFLE, Con. U. & B. R. R.

Watch No. 21,039, Stem Winder—manufactured by United States Watch Co. (Giles, Wales & Co.), Marion, N. J., has been carried by me four months; its total variation from mean time being seven seconds per month.—S. M. BEARD, firm of Beards & Cummings, 123 Front st., N. Y.

Watch No. 2,755—bearing Trade Mark "Fayette Stratton, Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me two months; its total variation from mean time being one second.—Jas. B. WEAVER, with A. S. Barnes & Co., 111 and 113 William street, N. Y.

Watch No. 12,003, Stem Winder—bearing Trade Mark "United States Watch Co., Marion, N. J."—manufactured by the United States Watch Co. (Giles, Wales & Co.), has been carried by me two months; its total variation from mean time being six seconds in the entire time.—W. S. DUNN, of H. B. Claffin & Co., N. Y.

Watch No. 1,096, Stem Winder—bearing Trade Mark "Frederic Atherton & Co., Marion, N. J."—manufactured by the United States Watch Co. (Giles, Wales & Co.), has been carried by me three and one half months; total variation thirty seconds.—Geo. G. ROCKWOOD, 345 Broadway.

Gov. Merrill on the Marion Watches.

Messrs. GILES BROS. & Co., Chicago, Ill.: I take pleasure in saying that the watch I bought of you, being 21,767, "Fayette Stratton, Marion, N. J." made by the United States Watch Co. (Giles, Wales & Co.), has given perfect satisfaction; its variation from mean time since regulated being scarcely perceptible.—SAM'L MERRILL, Gov. of Iowa.

Watch No. 24,008, Stem Winder—Trade Mark "United States Watch Co. (Giles, Wales & Co.), Marion, N. J."—has been worn by me about five months, during that time has varied but eight seconds. I have worn it while riding on horseback and in railroad cars.—CHAS. H. WOLF, firm Chas. H. Wolf & Co., Pearl st., Cincinnati, O.

Watch No. 1,079, Stem Winder—bearing Trade Mark "Frederic Atherton & Co., Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me two months; its total variation from mean time being half a second.—J. CALVIN SHAFER, 76 Cortland street, New York.

The United States Watch Co. (Giles, Wales & Co.) employ 500 hands in their works at Marion, N. J., and are turning out 250 of their celebrated time-keepers daily, or one watch per day for each two hands employed; their working time is 10 hours per day, or 600 minutes, producing a fine watch complete every two and a half minutes, and a little more, and even at that are unable to keep pace with the constantly increasing demand caused by the extraordinary records the watches are making as accurate and reliable time-pieces, an instance of patient and persevering energy and enterprise, rewarded by prosperity which we are glad to see.

Watch No. 1,994, Stem Winder—bearing Trade Mark "Frederic Atherton & Co., Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me six months; its total variation from mean time being eight seconds.—H. COTTRELL, 123 Front street, N. Y.

Watch No. 24,061, Stem Winder—bearing Trade Mark "United States Watch Co., Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me three months; its total variation from mean time being one second.—NOAH D. PAVNE, Publisher Providence (R. I.) Herald.

Watch No. 60,324—manufactured by United States Watch Co. (Giles, Wales & Co.), Marion, N. J., has been carried by me two months; its total variation from mean time being seven seconds in the entire time.—G. B. GAYVET, Jr., of L. G. Tillotson & Co., 8 Dey st., N. Y.

UNITED STATES WATCH CO.—This Company, we observe, continues to hold the leading position among American manufacturers; at the Fairs held in different parts of the country, where there has been great competition in this line, the Marion (Giles, Wales & Co.) United States Watches, have been regarded as greatly superior in every particular to any on exhibition, and have been awarded the first premiums, over all competitors, in every fair where they have been exhibited.

Watch No. 20,019, Stem Winder—bearing Trade Mark "Wm. Alexander, Marion, N. J."—manufactured by the United States Watch Co. (Giles, Wales & Co.), has been carried by me six months, and subject to very severe tests in my vocation; its total variation from mean time being less than one second.—Geo. W. McDONALD, Supt Brooklyn Water Works.

Watch No. 2,266, Stem Winder—bearing Trade Mark "Fayette Stratton, Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me four months; its total variation from mean time being five seconds.—DAVID T. BROWN, Supt Lackawanna & Bloomsburg R.R., Kingston, Pa.

Watch No. 1,789—bearing Trade Mark "Frederic Atherton & Co., Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me five and a half months; its total variation from mean time being twenty seconds, being compared by me personally with Greenwich time, London, April 24th, 1871.—HENRY MORFORD, 129 Broadway, N. Y.

Watch No. 2,283, Stem Winder—bearing Trade Mark "Fayette Stratton, Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me twelve months; its total variation from mean time being fifteen seconds.—S. B. JOHNSTON, 83 Nassau st., N. Y. City.

The United States Watch Co. (Giles, Wales & Co.), Marion, N. J., have just brought out and applied to their celebrated time-keepers a novel dust excluder, extremely simple and tasty, and being fastened by an eccentric screw is easily put on or removed. A perfect protection against dust or dirt getting inside the movement, and possessing the advantage over all other contrivances of the kind, of completely closing the aperture round the barrel equally as well as the balance of the space between the plates, and at the same time is so protected by lips resting on the edges of the plates, above and below, that it can not interfere with the barrel by being pressed on to it by a tight-fitting case.

Watch No. 2,226, Stem Winder—bearing Trade Mark "Fayette Stratton, Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me eight months; its total variation from mean time being only ten seconds per month.—OSCAR M. SANFORD, Utica, N. Y.

Watch No. 1,176, Stem Winder—bearing Trade Mark "Frederic Atherton & Co., Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me three months; its total variation from mean time being only five seconds during that time.—HENRY DR LANCY, Engineer Phila. & Erie R.R.

Report of Judges to the General Committee Cincinnati Industrial Exposition, on the United States Watch Co.'s (Giles, Wales & Co.) Watches, Marion:

GENTLEMEN—The Judges appointed to examine into the merits of the articles contained in Class 10, beg leave to make the following report: No. 1,650, United States Watch Company, Marion, New Jersey.—These Watch movements, the result of American capital, skill, and perseverance, as specimens of this branch of science and manufacture, rival those of European make. The watches exhibited by this Company are of all grades, from that of the most exact time-keeper, to the cheaper kind for the million. All are excellent of the kind, and are too well known and appreciated by the people to need further comment. First Premium is awarded to the United States Watch Company.

E. S. WAYNE,
JAMES POWELL,
WILLIAM M. DAVIS, } Judges.

Watch No. 12,012, Stem Winder—bearing Trade Mark "United States Watch Co., Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me five months; its total variation from mean time being only twelve seconds.—GEORGE LOUIS, General Eastern Passenger Agent Toledo, Wash & Western Railway.

Watch No. 1,259, Stem Winder—bearing Trade Mark "Frederic Atherton & Co., Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me six months; its total variation from mean time being only eight seconds per month. I have been traveling through different sections of the country, from New York to Galveston, Texas, and back, by steamer and railroad.—E. RIOZ, of Whitney & Hice, 179 Broadway, N. Y.

Marion United States Watch Co.'s Watches (Giles, Wales & Co.) were awarded the First Premiums at Fair of American Institute, New York, 1870; at Fair of "Ohio Mechanics' Institute," Cincinnati, 1870; at "Louisiana State Fair," New Orleans, La., 1870; at "Texas State Fair," Houston, Tex., 1871, and at every Fair where they have been exhibited, over all competitors.

Most Wonderful Time-Keeping.

Watch No. 1,089—bearing Trade Mark "Frederic Atherton & Co., Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me from December, 1868, to Jan. 17th, 1870, its total variation being only two seconds in the entire time.—L. E. CHITTEPEN, late Register U. S. Treasury.

Watch No. 1,124, Stem Winder—bearing Trade Mark "Frederic Atherton & Co., Marion, N. J."—manufactured by the United States Watch Co. (Giles, Wales & Co.), has been carried by me seven months; its total variation from mean time being only six seconds.—A. L. DENNIS, President N. J. R. & T. Co.

Watch No. 1,037, Stem Winder—bearing Trade Mark "Frederic Atherton & Co., Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me since June, 1867; its total variation from mean time being only five seconds per month.—HENRY SMITH, Treas. Panama R.R. Co., 88 Wall st., N. Y.

BEWARE of worthless imitations of Marion United States Watch Co. (Giles, Wales & Co.) Watches, with which the country is flooded. To avoid imposition, see that the words MARION, N. J., are engraved on the plate over the Main-Spring Barrel. All others are spurious.

Watch No. 2,617—bearing Trade Mark "Fayette Stratton, Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me twelve months; its total variation from mean time being fifteen seconds.—I. VROOMAN, Engineer, N. Y. C. & H. R. R.

Watch No. 10,548, Stem Winder—bearing Trade Mark "Frederic Atherton & Co., Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me twenty months; its total variation from mean time being five seconds per month.—Z. C. PRIEST, Ass't Supt N. Y. C. & H. R. R.

Watch No. 1,143, Stem Winder—bearing Trade Mark "Frederic Atherton & Co., Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me eight months; its total variation from mean time being five seconds per month.—JAMES B. RYAN, of Kelly & Co., 417 Broadway, N. Y.

Watch No. 1,658—bearing Trade Mark "Frederic Atherton & Co., Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me three months; its total variation from mean time being three seconds.—JOHN LINDSTROOM, 314 Atlantic st., Brooklyn, N. Y.

Watch No. 4,026—bearing Trade Mark "Edwin Rollo, Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me two months; its total variation from mean time being three seconds.—JOSUUA I. BRAGO, Conductor N. J. R.R.

Watch No. 4,130—bearing Trade Mark "Edwin Rollo, Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me four months; its total variation from mean time being eighteen seconds.—THOMAS E. MINZER, Pier No. 5, Elizabethport, N. J.

Watch No. 4,284—bearing Trade Mark "Edwin Rollo, Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me six months; its total variation from mean time being only two thirds of a second per day.—DAVID H. PECK, Ferry Master Central R.R. of N. J., foot of Liberty st., North River, N. Y.

Watch No. 1,125, Stem Winder—bearing Trade Mark "Frederic Atherton & Co., Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me fourteen months—six months of that time at sea, and in all the various climates of Europe. During that time, and since my return, it has not varied one second a week.—H. LASSING, Manager Knickerbocker Life Ins. Co., 161 Broadway, N. Y. City.

Watch No. 2,656—bearing Trade Mark "Fayette Stratton, Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me three months; its total variation from mean time being only thirteen seconds.—JACOB WEART, Collector of Internal Revenue, 5th Dist. N. J., Jersey City.

Watch No. 1,706—bearing Trade Mark "Frederic Atherton & Co., Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me from Oct., 1869, to Feb. 22, 1870; its total variation during the entire time being only seven seconds.—JNO. W. SMITH, State Agent Amsterdam Ins. Co., Dubuque, Iowa.

Watch No. 1,064, Stem Winder—bearing Trade Mark "Frederic Atherton & Co., Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me fifteen months; its total variation from mean time being only fifteen seconds.—WILLARD DEBBY, of Derby, Snow & Prentiss, Jersey City, N. J.

Watch No. 1,031, Stem Winder—bearing Trade Mark "Frederic Atherton & Co., Marion, N. J."—manufactured by United States Watch Co. (Giles, Wales & Co.), has been carried by me six months; its total variation from mean time being only three seconds per month.—JOHN D. ROBERT, Plainfield, N. J., 5 College Place, Room 8, N. Y.

SIMONSON'S IMPROVED

**FILTER and CISTERN.
PUREST WATER FOR EVERY
HOUSE.**

Rain water, freed from impurities by filtering, is the most HEALTHFUL, palatable, and readily obtained in most parts of the country.
By the improvement illustrated above, showing the material parts of Simonson's Patent Improved Filter and Cistern a full supply can be had for household and other purposes.
As ordinarily made, filtering cisterns are costly, require much larger room, are frequently inoperative, and are troublesome to put in order when the filter needs cleansing.
This improvement can be readily attached to any cistern already built, at moderate cost. It has been thoroughly tested for three years past, and gives entire satisfaction wherever tried. The condition of the filter can at any time be readily ascertained, and new materials supplied when needed. This, however, will not be necessary except at very long intervals.
For fuller description and particulars, send for Circular.

A Paying Business

can be had by any industrious man of ordinary ability in introducing this improvement in his own neighborhood. It is fully secured by letters patent, and exclusive right will be given to the right men throughout different sections. Most liberal terms will be given to suitable men. County and State rights for sale. For full particulars, address

**JOHN Q. SIMONSON,
Box 127, West New Brighton, Staten Island, N. Y.**

**CARHART'S
Patent Two-Horse
Pulverizing Cultivator**

was awarded the First Premium at State and County Fairs in 1870 and '71.
It is superior to the best Wheel Cultivator.
The draft is reduced nearly one half.
The depth you wish it to run is regulated without the use of wheels.
It can be drawn close to a tree or plant without injuring it.
It is not disturbed by short undulations of earth like the Wheel Cultivator; but pulverizes, levels, and fits the ground for the Mowing Machine better than any Cultivator in use, and can be used for more purposes than any other implement on the farm. Price \$20.

 Either English or German Edition, at these prices.
HEARTH AND HOME: \$3 a year for less than four. Four to nine copies, \$2.75 each; 10 or more copies, \$2.50 each.
Hearth and Home (weekly) with **American Agriculturist** sent to one address for \$4 a year.

for themselves or for presents to others, all without the use of working hours, and at no money cost.

As a constant Business Employment, some persons canvass all the time, receive the premium articles, and sell them for cash, and thus secure large salaries. One lady has averaged over \$3,000 a year for years past, and others are getting large pay for their time, often \$5 to \$20 a day. Some who did poorly at first have, by perseverance, acquired the art of canvassing, and become very successful. The work is honorable. The Journals are useful in every family—in City, Village, and Country.

The American Agriculturist is everywhere known and approved. HEARTH AND HOME is now without a superior in the world as a splendidly illustrated Weekly Newspaper, for real value, cheapness, and adaptability to every home in America. The papers are entirely different. Taken together, they supply over \$35,000 worth of fine engravings, and more good reading than can be found in 100 books costing one Dollar each.

Premium Clubs can be made up of subscribers to either paper, or partly of both, as noted over the Table. We call especial attention to the last column of figures, showing the small number of names required where both papers are taken, at the reduced price of \$4 a year.

You, Reader, can get a Premium. TRY IT.

Explanatory Notes.

Read and carefully Note the following Items:
 (a) All subscribers sent by one person count, though from one or a dozen different Post-offices. But... (b) Tell us with each name or list of names sent, that it is for a premium.... (c) Send the names as fast as obtained, that the subscribers may begin to receive the paper at once. You can have any time, from one to six months, to fill up your list.... (d) Send the exact money with each list of names, so that there may be no confusion of money accounts.... (e) Old and new subscribers all count in premium clubs, but a portion, at least, should be new names; it is partly to get these that we offer premiums to canvassers.... (f) Specimen Numbers, Cards, and Show-bills will be supplied free as needed by canvassers, but they should be used carefully and economically, as they are very costly.... (g) Remit money in Checks on New York Banks or Bankers, payable to order of Orange Judd & Co., or send Post-office Money Orders. If neither of these is obtainable, Register Money Letters, affixing stamps both for the postage and registry; put in the money and seal the letter in the presence of the Postmaster, and take his receipt for it. Money sent in any of the above ways is at our risk; otherwise it is not.

[In the following table is given the price of each article, and the number of subscribers required to get it free, at the regular rates, \$1.50 and \$3.00 a year, for the two papers; also at the club rates of \$1 and \$2.50; also at the rates of \$4 a year for both papers together.]

N. B.—In all Premium Clubs for either paper, TWO copies of American Agriculturist at \$1.50 each, and ONE copy of *Hearth and Home* at \$3.00, will count exactly the same. So also TWO copies of American Agriculturist at \$1 each, and one copy of *Hearth and Home* at \$2.50, will count exactly the same. In this way Premium Clubs can be made up from the 2nd and 4th columns, or from the 3d and 5th, or wholly from the 6th column.

Table of Premiums and Terms, For American Agriculturist, and for *Hearth and Home*, for the Year 1872.

Open to all—No Competition.

No.	Names of Premium Articles.	Price of Premiums.		Number of Subscribers required		Number of Subscribers required		Number of Subscribers required	
		at \$1.50	at \$3.00	(1) Or (2) Or (3)	(4) Or (5)	(6)	Or (6) Papers together.

 Nurserymen, Everybody!

YOU CAN GET A
GOOD THING
 (YOUR OWN CHOICE OF 106)
WITHOUT MONEY,
 AND WITH
Very Little Trouble
 DURING
THIS MONTH
 OF
January, 1872.

Full Descriptions

of all the Premiums are given in our last October number, which will be mailed free to applicants. Read over the descriptions, and you will find many desirable articles—indeed, all are desirable. We have room in this paper only for the following DESCRIPTIVE NOTES:

Nos. 1, 2, 3, 4, 5, 6.—American Table Cutlery.—We are glad to be able to offer really good articles of American manufacture, such as are competing successfully with the best foreign goods. Messrs. Patterson Bros., 27 Park Row, who supply us with these articles, are also importers of English goods. They recommend these Knives, manufactured by the Meriden Cutlery Co., as equal to any Cutlery in the market, and their recommendation is a guarantee, wherever they are known. We offer four kinds of Knives, and three sizes of each kind. No. 1 have Rubber Handles, which are actually boiling-water proof, so that, if they were accidentally to remain in it for several minutes, or even hours, they would not be injured. The Blades are of the best steel, and warranted. Dessert size, with Forks, sold at \$14. For 23 subscribers at \$1.50, or 73 at \$1, we will give either the medium size or the table size, sold at \$15.50. No. 2 have Ivory Handles, are selected with great care, have Steel Blades, and are beautiful goods. Dessert size, with Forks, sold at \$18.50. For 31 subscribers, at \$1.50, or 100 at \$1, we will send the medium size, sold at \$20.50. For 34 at \$1.50, or 112 at \$1, we will send the Table size, sold at \$22.50. No. 3 are made of Solid Steel and are triple-plated all over with pure silver, which will wear for a long time, while the Knife is actually indestructible by ordinary use. Dessert size with Forks, sold at \$22. For 37 subscribers at \$1.50, or 118 at \$1, we will give the medium size, sold at \$24.50. For 38 at \$1.50, or 120 at \$1, we will send the Table size, sold at \$25. No. 4 have Steel Blades, triple-plated with silver, and larger Ivory Handles, and are really splendid goods. Dessert size with Forks, sold at \$25.50. For 42 subscribers at \$1.50, or 128 at \$1, we will give the medium size, sold at \$28. For 45 subscribers at \$1.50, or 143 at \$1, we will give the Table size, sold at \$30.50. The Forks, which accompany these Premiums, Nos. 1, 2, 3, are made of genuine Alhata, and warranted double-plated with coin-silver. The Forks with No. 4 are warranted Triple-plated with coin-silver. These Forks are also furnished to us by Messrs. Patterson Bros. The Carving-Knife and Fork and the Fluted Steel are made by The Meriden Cutlery Co., with the best Ivory, balanced Handles.

Nos. 8, 9, 10, 11.—Pocket Knives.—HERE'S FOR THE BOYS AND GIRLS!—These Premiums are among the most pleasing and useful that we have ever offered. Every boy, and girl too, wants a pocket knife. We give them an opportunity to obtain a most valuable one for merely a little effort. These knives are made by Messrs. Smith & Clark, Bronxville, N. Y., whose work is equal to any done in this country or Europe. No. 8 is a neat, substantial Knife, with three blades and buck-horn handle. No. 9 is a still finer article, with four blades and buck-horn handle. No. 10 is an elegant Knife, with four blades and shell handle. No. 11 is a Lady's Pocket Knife, a beautiful article, with four blades and shell handle.

No. 12.—Multum in Parvo Pocket Knife.—This is a most attractive as well as useful Premium. It comprises, in one knife-handle, a large and a small blade, a screw-driver, a saw, a strong hook, a nut-cracker, a brad-awl, a gimlet, a corkscrew, a pointer, a slim punch, and, in addition to this, it can be used for various other purposes which will at once suggest themselves to any smart boy or man. The knives will be sent anywhere in our country, post-paid.

No. 13.—Cake Basket.—A new pattern, oval-shaped, nicely chased—a very taking, useful, and beautiful table ornament. This, with other articles that follow, is made by the Lucius Hart Manufacturing Co., of Nos. 4 and 6 Burling Slip, New York City, and is warranted by them to be of the best triple plate. Mr. Hart, "the veteran Sunday-school man," was engaged in the same place and business for nearly a quarter of a century. We have known him and his work for many years, and have taken pleasure in commending and guaranteeing its value to be as represented. We believe the Company which bears his name is fully sustaining his reputation. The amount of silver upon plated ware depends wholly upon the will and integrity of the manufacturer. We could give nearly as good-looking plated ware for less than half the money.

No. 14.—Casters and Fruit or Cake Basket Combined.—This is a new pattern, both novel and beautiful. It can be used as large, showy Casters, with six cut-glass bottles, or be instantly changed into complete Casters, with Call-Bell, and a separate Cake or Fruit Basket, with a colored glass dish inside. Every one receiving it will be delighted. It is from the same makers and of equally good quality as the preceding.

No. 17.—Nut Picks and Crackers.—Here are twelve nut-picks, elegantly chased, of medal-line pattern, with two handsome nut-crackers, in a morocco-covered case. From the same house as No. 13.

No. 18.—Half-Dozen Napkin Rings.—These rings are beautifully chased, and in a morocco-covered case. From the same house as No. 13.

No. 19.—One Dozen Teaspoons.—

No. 20.—One Dozen Table-Spoons.—These are "figured tips," Olive-leaf Pattern, all of the same metal, plating, etc., and from the same makers as No. 13. They are far cheaper than anything we have found at half the price, and well worth working for.

No. 21.—One Dozen Table-Forks.—The same description and remarks apply to these as to No. 20. We select as premiums only such articles as we can warrant in quality and price. All these articles come from the Lucius Hart Manufacturing Co.

No. 22.—Child's Cup.—A beautiful gift for the little one-year-old. It is made by the Lucius Hart Manufacturing Co. Triple-plated on the outside and gilded on the inside. It never breaks, and will last for many years—indeed, be a life keepsake.

Nos. 23, 24, 25.—Gold Pens: with ever-pointed Pencils, in extension, coin-silver cases.—Premium No. 23 contains the best No. 4 Gold Pen; and No. 24 the best No. 6 Gold Pen, which is the same style, but larger. No. 25 contains No. 7 Gold Pen, in Gold-tipped Ebony Holder. Each pen will be sent in a neat leather case by mail, post-paid. These pens are made by Geo. F. Hawkes, No. 64 Nassau St., and have obtained an excellent reputation. We have known the maker and his goods for many years, and can recommend them.

No. 26.—Ladies' Fine Gold Pen, in Rubber Case, Gold Mounted, with Screw Extension, and Gold Ever-pointed Pencil. A beautiful present for a lady teacher or friend. Same makers as above.

Nos. 27, 28.—Ludden's Patent Magic Revolving Pencil.—This is a beautiful Pocket Pencil, which is extended or closed by pulling or pressing the head. They are made with great care, and every Pencil warranted to work perfectly. They are gold-plated, and will last for years. We offer two patterns, one for ladies, with ring for chain, at \$1.50 each, and one of heavier and firmer plate, at \$3.50. They are made by Ludden's Gold P. and P. Co., Wm. A. Ludden, Agent, 195 Broadway, who has been in the business thirty years.

No. 29.—Amusette.—We believe in home entertainment for both young and old people. Our observation is, that the increase of entertaining home games is already doing much to keep not only the boys but their fathers away from drinking and gambling rooms, and other places of evening resort not conducive to good morals. This premium, the "Amusette," as it is called, will afford interest to the older as well as the younger members of the family, male and female. It only needs a smooth table of any kind covered with a cloth. The play with the balls will develop much of ingenuity and skill, and give a capital study of the laws of motion, force, etc. The price has been reduced from \$10 to \$6, and our premium will place it in the power of very many to secure this additional source of home amusements. The Amusette is supplied by E. I. Horsman, 100 William Street, N. Y., who will send any desired circulars giving information. It packs in small space and can be safely sent anywhere by express at small cost.

No. 30.—Baby's Chair.—This beautiful Premium will delight mothers and babies everywhere. It is a chair, in combination with a limited spring, suspended from a hook in the ceiling of a room. It gives a young child such a variety of amusement, such varied and healthful exercise, allowing free motion and action for limb and muscle, that it becomes almost an indispensable article to the nursery. It is made of black walnut, nicely finished, upholstered in green, blue, or red, with cords to match, and sold, with the hook, for \$4. L. O. Colvin, 94 Waverley Place, Newark, N. J.

No. 33.—Steam-Engine.—This is a veritable steam-engine; one that will GO; and a capital, intensely interesting, and instructive article for boys, and grown-up people too. Our eleven-year-old boy ran his engine an average of an hour or more a day for six months; he has exhibited it in motion to many of his playmates; has hitherto on various toy machinery, and it appears to go just as well as when first started.

No. 34.—Garden Seeds.—A valuable selection of 40 varieties of the best seeds for a family garden, each parcel large enough for a garden of ordinary size. This premium and the next two are put up for us by Messrs. B. K. Bliss & Sons, Seed & Horticultural Warehouse, 23 Park Place and 20 Murray St., whose seed establishment is well known as one of the best in the country. This premium will be of great value and convenience to many, as we send the seeds post-paid.

No. 35.—Flower Seeds.—Like No. 34 this is a valuable premium. It consists of 100 different kinds of beautiful flower seeds, all in separate papers, and includes the finer common varieties, and many of the newer and rarer kinds that are costly. Delivered free.

No. 42.—Doty's Improved Clothes Washer, with the Metropolitan Balance Weight. Over sixty thousand families in the United States are now using the Doty Washing Machine, and we believe the improved machine has no superior. The "help" use it and like it. Send for descriptive circulars to R. C. Browning, 32 Cortlandt St., New York, or to Metropolitan Washing Machine Co., Middlefield, Ct. It goes cheaply by freight or Ex.

No. 43.—Universal Clothes Wringer.—A very useful, time-saving, strength-saving, clothes-saving implement, that should be in every family. The wringing of clothes by hand is hard upon the hands, arms, and chest, and the twisting stretches and breaks the fibers with lever power. With the Wringing Machine, the garments are passed rapidly between elastic rollers, which press the water out better than hand wringing, and as fast as one can pick up the articles. We have given thousands of these premiums, with almost universal satisfaction. They are made by the Metropolitan Washing Machine Co., Middlefield, Ct.

No. 48.—A Good Watch.—The Watches made by the American Watch Co., Waltham, Mass., have peculiarities of excellence which place them above all foreign rivalry. The substitution of machinery for hand labor has been followed not only by greater simplicity, but by a precision in detail, and accuracy and uniformity in their time-keeping qualities, which by the old method of manufacture are unattainable. A smoothness and certainty of movement are secured which proceed from the perfect adaptation of every piece to its place. The extent of the Waltham establishment, the combination of skilled labor, with machinery perfect and ample, enable them to offer watches at lower rates than any other manufacturers. Their annual manufacture is said to be double that of all other makers in this country combined, and much larger than the entire manufacture of England. The mechanical improvements and valuable inventions of the last fifteen years, whether home or foreign in their origin, have been brought to their aid, and the presence of over 400,000 Waltham Watches in the pockets of the people, is the best proof of the public approval. We offer a Silver watch, jeweled, with chronometer balance, warranted by this Company as made of the best materials in the best manner, and in pure coin-silver "hunting" case; weight 3 oz. This watch we offer as one of our Premiums, with the fullest confidence. Upon the movement of each of these watches will be engraved, "AMERICAN AGRICULTURIST, MADE BY THE AMERICAN WATCH CO., WALTHAM, MASS."

No. 49.—Ladies' Fine Gold Watch.—This elegant Premium will delight our friends who may receive it. Our arrangement with the American Watch Co. (see No. 40 above) includes these beautiful gold watches. They are full-jeweled, in 13-carat "hunting" cases, warranted to be made of the best materials, and possessing every requisite for a reliable Time-keeper. Upon the movement of each Premium Watch will be engraved "AM. AGRICULTURIST, MADE BY THE AM. WATCH CO., WALTHAM, MASS."

No. 87.—Farmer's Boy's Library.—A few dollars' worth of books pertaining to the farm will give the boys new ideas, set them to thinking and observing, and thus enable them to make their heads help their hands. One such book will, in the end, be of far more value to a youth than to have an extra acre of land on coming to manhood. Any smart boy can easily secure this Premium, and he will have two sterling works by a well-known, practical farmer. They are Allen's New American Farm Book, and Allen's American Cattle.

No. 91.—Farmer's Boy's Library.—The ten books in No. 90, with the addition of Fuller's Grape Cultivist, Breck's New Book of Flowers, and Hunter and Trapper—in all 13 fine volumes.

Nos. 92, 93.—Bound Volumes of Health and Home.—These volumes are neatly and uniformly bound in cloth, with title in gilt on back and side. With their beautiful engravings, and abundance of useful and entertaining reading for all the members of a family, they will prove valuable additions to any library.

No. 106.—General Book Premium.—Any one sending 25 or more names, may select books from our list to the amount of 10 cents for each subscriber sent at \$1; or 20 cents for each name sent at \$1.20; or 60 cents for each name at \$1.50. This offer is only for clubs of 25 or more. The books will be sent by mail or express, prepaid through, by us.

SUNDRY HUMBUGS.

This column is not open for any individual to vent his spleen. Anonymous letters making charges of fraud against others receive no attention. No man should ask the editor to make accusations which he himself dare not back up. Some complain that we have failed to expose swindles which they have forwarded. Very likely. Sometimes we can not find room for all. In other cases there is not sufficient evidence to warrant us in putting some names and business enterprises in these columns. We try to be very careful, and when, after faithful examination, there remains a doubt as to the real character of any person or business, we give the benefit of that doubt. In these exposures of swindlers we have only the best interests of our readers and of the public in view, with no animosities to gratify; and if, through deception of others, or by error, any mistake is made, we will be most happy at any time to make prompt correction or retraction. Though often prosecuted by those who *hope* that we may not be fortified with legal proofs, and by those who *hope* to get notoriety and free advertising, or at least to scare us into silence by beginning libel suits, we are glad to be able to state that in a long course of years, and after having shown up more than *Fifteen Hundred* swindling schemes, no libel suit has yet been successful against us, and our exposures have never been successfully controverted in more than one or two instances, and these only when the work has been necessarily delegated to others for a brief time. Nine tenths of all our Humbug columns have been written by the senior editor, and he has never yet been shown to be in error in a single item. Our readers seldom hear through our columns of the libel suits commenced against us, for intimidation or advertisement. The intimidation is of course a failure; and we will not gratify by advertising those who hope to get notoriety or sympathy by assuming the innocence implied in bringing a libel suit, which can be done at slight expense. **Bank of England Notes.**—An expensive cable telegram from London recently appeared in the daily and other journals, respecting the operations of a swindler who offers to supply *fac-simile* Bank of England notes. Our readers, especially those residing in the Dominion, were fully informed of this fellow's schemes many months ago. **Queer—Sawdust.**—The "sawdust" class, is so called because in return for money privately sent for C.G.D. boxes of first-class counterfeit bills, the senders receive neatly put up parcels of sawdust or other trash. As already stated, we have no sympathy for the thousands of victims of this specific swindle. None but dishonest persons, who wish to defraud their neighbors or the Government by circulating what they are led to believe to be perfect *fac-similes* or imitations of real money, would ever send their money for this "queer" stuff. The money so lost is merely transferred from one swindler's pocket to that of another—and millions in the aggregate have been so transferred within three years past. No counterfeit money has gone out. The operators escape free because their victims can not appear against them without convicting themselves of an attempt to circulate counterfeit money. For the \$10 to \$100 remittances forwarded, nothing is ever returned, except the C.O.D. sawdust boxes to be paid for *before* delivery. Those who call at the dens of the operators are fleeced by bogus policemen, who nab them as counterfeiters, and let them off after taking all they have, even to watches, etc., as hush-money; or they pay for packages of good money, which are dexterously changed for the sawdust. One operator sends out large numbers of newspaper slips, ingeniously printed and cut to make them appear to be from the New York Herald, which state that certain plates have been stolen from the Government. In a lithograph letter he pretends to have these stolen plates, and offers genuine bills printed from them for 10 cents on the dollar. He signs no name, but puts in a loose card, "Benj. F. Grayson, No. 2 Whitehall street, N. Y. (late of Houston, Texas);" also "Robert M. Jameson (late of New Orleans, La.);" He adds on his card, "Collections made South and West," which he is doubtless doing—from greenhorns. Of course it would be difficult to prove that the man on the card wrote the unsigned lithograph letter, and so he escapes arrest. He asks for money by express, and for letters by mail. The letters are of course stopped by Mr. Gayler. Wm. & Jno. Wood, 192 Broadway, to be addressed by express at 33 Park Row, offer the "good" queer, and add a P.S., requesting letters for them to be addressed to one in their employ—viz., Wm. Potter, 190 Broadway. Mr. Gayler will please note this—a new dodge to get letters. Hudson, Wood & Co., 44 Liberty st., adopt I.G.G.F. symbols, and pretend to be forming an extensive secret society for sundry operations, and want you to take a \$10 share, in return for which they will send \$1,000 of good "queer." Among other assumed names in this line we have: Dr. Lorand, Williamsburgh, N. Y. (no street or number), Dr. J. Hermans, 310 Canal street, N. Y. ;

G. M. Washburn, 3 Beckman street, New York; B. H. Longstreet, 50 Maiden Lane, *alias*, G. W. Washburn, 3 Beckman street, who promises to send you the plan of his real "dex," if you promise to come on and get fleeced; John Hood, Jr., who dates some of his swindling circulars at Wilmington, Del., some at 198 Broadway, and some at 907 Broadway; H. Miller, 688 Broadway, *alias* S. Wing, 16 South Fifth avenue, who pretends to have a book-store, and who uses secret society symbols as a blind, etc. **"Spanish Policy."**—This is a dangerous humbug, because so many ignorant people are Micawbers, trusting to luck, and a "Spanish" lottery has to them always some charm. The persistence of the operator, who adopts one or two new names each month, shows that he finds paying dupes. Under each of two names, G. W. Jackson and Wm. T. Neal, both at 16 S. 5th Avenue, N. Y., he claims to be sole agent in the United States of a Spanish Policy. The printed schemes and tickets he scatters so widely at great expense are entirely of his own manufacture, and he pockets all the money he receives—which must be a large amount to meet his expenses only, besides *profits*, which are doubtless large also. **Gift Enterprises** abound—many of them so taking and plausible as to draw in large numbers of foolish people. We judge that not less than \$100,000 a month are thus extracted from the pockets of the people. The Louisville, Ky., Library scheme is just now the most active and glaring. The million dollars wanted not being quite made up, the "drawing," "owing to the Chicago fire," was necessarily "postponed" to December 15th. The "Library" will stand a poor chance, judging from the daily "expenses" of the Broadway office near us, and the extensive advertisements constantly appearing. Of a like character is the Kentucky lottery of certain schools; ditto the Omaha, Neb., Lotteries, dubbed Gift Concerts, and put under the patronage of Libraries, Hospitals, etc.; ditto the South Carolina Land and Immigration Association Lottery, *alias* "Gift Concerts." We have circulars, ostensibly from "the Sisters of Visitation, Mount de Chantal Academy, (near) Wheeling, W. Va.," which may be genuine, and the Academy may, for aught we know, be a very worthy one, but the Sisters are certainly degrading the livery of Heaven when they stimulate subscriptions by offering for each dollar a ticket in the lottery of a farm of 100 acres near Washington, D. C. Perhaps we may aid them by hinting the expediency of telling something about that farm, how much it is worth, and how many shares there are to be. The inducement to subscribe will be increased, if some taking particulars are given. Another strong inducement we did not note when writing the above, viz., every purchaser of 10 tickets (\$10) "will be entitled to the registry of his name for a weekly Mass to be offered for the next ten years (Jan. 1870 to Jan. 1880) for the benefit of Mount de Chantal Academy." We are further informed that subscribers can have dead relatives or friends entered on this registry! If such a lottery will not draw, we don't know what will. To have one's dead relatives remembered weekly at mass for ten years is worth (?) paying well for. Luther & Son, proprietors, and John De Armond, manager, Buchanan, Mich., have a small lottery, only \$34,000, in a brick store, gothic residence, etc. Tickets only \$1 each, giving you a choice from three weekly papers. We thought lotteries were prohibited by law in Michigan. This has another name, however. If people want the papers offered, the publishers will gladly receive their money direct. If they consent to this lottery stimulant, their papers better be unsubscribed for. Such schemes debauch public morals more than the best papers can do them good.—[P. S. A letter from a cotemporary says, "Luther & Son have been doing business in Berrien Co. for fifteen years, and are known to be men of honor and integrity. Under pressing pecuniary embarrassment they are attempting to dispose of their property at a fair value by means of a Gift Concert," and further says the affair will be conducted fair and honestly; that the property is most desirable, etc. All of which we will not call in question; but if Messrs. L. & Son are right in this mode of selling property, may not all other embarrassed parties—and there are tens of thousands of them—adopt the same plan of getting relief, and so inaugurate a general system of Lotteries all over the country? If it is right in one case, it is right in all, and the more respectable the parties in this case, the worse is the example.] **Vile Books and Pictures** are covertly advertised by sundry parties, and pretty openly by a "Book Company" in Minneapolis, Minn. We suggest to the proper authorities of that city to look into this affair and see that, for the credit of their fine place, there be no dissemination of vice. Lest any imprudent youth be tempted to try this (so-called) company's "Turkish lozenges," we advise all who have not done so to read the item on "Love Powders" in our Nov. paper, page 406. This so-called company also offers "EXACT COPIES" of U. S. Treasury notes and National Bank bills, but claims to only offer them as detectors of counterfeit money. Why better for this purpose than the good money, which is accessible to

everybody? Parents should have a care that the "our catalogue" of this so-called company does not get into the hands of their children, with its tempting bait of corrupting pictures. **Medical.**—About the meanest cheats we know of are the tribe of "Consumption cures" who impose upon the hopes and fears of a class of persons needing sympathy. One man has during a dozen years grown rich by his skill in giving and selling books and medicines to consumptives. He has the art of persuading his dupes that he has great experience and skill, and few that listen to him once get off without putting into his pockets from \$25 to \$1,000 each. He publishes records of many cures—all of them cases which had doubtless no vestige of consumption to start with, except in imagination. There is a large number of impostors who dub themselves "Rev.," and claim to have obtained a sure cure for consumption, while missionaries away down in Brazil, or among the Western Indians, or in the East Indies. Some of them offer a free recipe, which always contains some curiously named plant that you ultimately find can only be obtained of themselves. N. B.—Every one of these benevolent "Revs." is a downright swindler. We met one of them the other day that, from his circulars, you would suppose to be a very venerable old gentleman; he was a young scapegrace who under another name conducted a pretended counterfeit-money scheme. The "Sands of Life" man was one of this stamp. He is probably now a very reverend in sheep's clothing—a returned missionary anxious to send you a free consumption cure, and his "at cost" preparations, that is, a parcel or bottle of it, costing 10 cents, he will send for \$3 or so. The Chundrang cancer cure will be treated in a separate item by our M.D. Editor. The "University Medicines," and the Company Medicines inquired about, we rank among other quack medicines, and advise people to let them all alone severely. Other downright swindlers we have not room to describe, such as R. H. Foster, Williamsburgh, N. Y., \$50 Watches for \$2.75; Mrs. (?) Sarah B. Lambert, Greenpoint, N. Y., Love Perfumes (rank poison), and Matrimonial Agency; sundry offers of "Books of Secrets," paying (?) Recipes, etc.; the "Seeding Machine," patent paid for by notes to be divided (already noticed).—Wise people, young and old, will promptly burn the "Prophylactical Star" and the "Good Samaritan," sheets sent out from Albany, N. Y. A Tennessee subscriber writes us that he counted fifteen bad advertisements in a single number of the *Toledo Blade*, besides an uncounted host of quack-medicine advertisements. We hope he and all other readers will write to that and similar papers and remonstrate with them. If all subscribers to newspapers would take this course, and then drop the papers if the advertisements be not dropped, we should soon have a great reform in this matter throughout the entire press. Postmasters are *promised* a "good, useful present," not described, if they will distribute the vile sheet called "Journal of Health," sent out from Albany, N. Y.—an old thing, with a new name for the doctor. In this sheet you are offered medicines for vile diseases, secret of taming horses, honey recipes, etc.—a poor humbug. We hope no postmasters are so green as to want the presents, and are sorry there are ignorant people enough to support this extensively circulated trash. Another so-called "M.D." sends out the old story about his finding a cure-all down in Brazil, for Uncle Joe, and wants agents to sell his "Wine of Apocynum," which nobody else knows. We suppose there must be people so ignorant and gullible as to patronize such a pretender, or he would not operate in this way, but we pity his poor victims. Maine State has several ingenious persons located within her borders (so as to get out of reach of the mass of their customers, we suppose) who are very anxious to make all the rest of the world rich by the sale of sundry notions—sewing-machines, the best in the world, to be sold for a song; thousands of most valuable (?) recipes, etc., etc. Those who put faith in these wonderful pretensions (on paper) can prove their truthfulness by sending the money required, always in advance, or C. O. D., which amounts to the same thing, as the money must be paid to the Express Co. *before* the articles can be seen. Perhaps it will benefit the country at large if half a hundred or so of the victims of these Maine concerns will send us an account of their *experience* in past investment—giving full, reliable particulars. **Burning Oils.**—Michigan is afflicted with sundry sellers of recipes for manufacturing burning oils, with various luminous and scientific names, claimed to be non-explosive, etc. They are all humbugs. We have probably seen all these recipes from "Sun-light" to "French;" the naphtha found in most of them is a dangerous thing in any burning-oil for common use, and is one of the things to be *carefully* taken out of all safe illuminating oils. **Honey Recipes** are still largely advertised by sundry parties. They tell how to scent up simple syrup of sugar and water to resemble honey. Nobody should invest 25 cents in any such recipe for home use or sale.

ATWOOD'S

**Country and Suburban
HOUSES.**

By **DANIEL T. ATWOOD,**
ARCHITECT.

Illustrated with about 150 Engravings.

NOTICES BY THE PRESS.

The work is one that can well be read by every man about to build or buy a place of residence, as the author has much to say—and says it in a direct and simple manner—on all points connected with a matter so important, and which so closely concerns the comfort and the health of all persons. —*Traveler* (Boston).

The part of the volume preceding the designs contains useful suggestions on selection of localities, modes of building, properties of timber, painting, etc.—*Country Gentleman* (Albany, N. Y.)

It is a volume of nearly three hundred pages, amply illustrated, containing hints and suggestions as to the general principles of house-building, style, cost, location, symmetry, and modes of building. It is especially designed to encourage a taste for pleasant country houses.—*The Freeman* (Montpelier, Vt.)

This is a useful and valuable work, filled with suggestions as to the general principles of house-building, illustrated with about one hundred and fifty engravings.—*Watchman and Reflector* (Boston).

There is much in the book to recommend it to the attention of all; particularly the remarks on building material, appropriateness, the effects of different combinations of paints to produce harmonious colors, etc.—*State Republican* (Lansing, Mich.)

A splendid volume, illustrated with about 150 engravings. The directions and statements it gives are eminently plain and practical, and seem sufficient for the establishment of something more than houses merely, and that is homes.—*Rutland Herald* (Vt.)

An admirable work. It is just the book for any one contemplating the erection of a house or barn.—*Farmers' Cabinet* (Amherst, N. H.)

There are single chapters in it which are worth more than the price of the work (\$1.50), not only to those who are building anew or building greater, but to such as contemplate improvements, and, unfortunately—owing to bad jobs at the beginning, or decay's effacing fingers—there are few homes about which improvements are not needed.—*The World* (New York.)

A valuable work, gotten up in the best style. It must prove both interesting and useful to all who wish a home in which beauty, taste, convenience, and economy are combined.—*United Presbyterian* (Pittsburgh, Pa.)

It contains some practical and common-sense advice as to the selection of sites, etc., which should be carefully considered by every one who is seeking where to locate his home, while the information given as to the principles and details of building is also of the utmost value for putting one in a position to know if he is having his work well done and getting his money's worth.—*Evening Mail* (New York).

PRICE, POST-PAID.....\$1.50.

ORANGE JUDD & CO.,

245 Broadway, N. Y.

A Valuable Home Library.

BACK VOLUMES

OF

American Agriculturist,

AND OF

Hearth and Home.

The publishers of the *American Agriculturist* can supply any of the back volumes of that paper from the Sixteenth to the Thirtieth. These volumes contain more varied and interesting information on all matters pertaining to the Farm, Garden, and Household, than can be obtained in books costing three times as much money. Price of each bound volume, at the Office, \$2.00; sent post-paid, \$2.50.

The publishers can also supply the back volumes of their finely illustrated Weekly Journal, *Hearth and Home*, for the years 1869, 1870, and 1871. These volumes are neatly and uniformly bound in cloth, with title in gilt on back and side. With their beautiful engravings, and abundance of useful and entertaining reading, they will prove valuable additions to any library. Price of each bound volume, at the Office, \$1.00; if sent by express, the purchaser will pay express charges.

ORANGE JUDD & CO., 245 Broadway, New York.

THE MARKET ASSISTANT,

Containing a brief description of every Article of Human Food Sold in the Public Markets of the cities of New York, Boston, Philadelphia, and Brooklyn; including the various Domestic and Wild

Animals, Poultry, Game, Fish, Vegetables, Fruits, etc., with many Curious Incidents and Anecdotes, by

THOMAS F. DE VOIE,

Author of "The Market Book," etc.

ILLUSTRATED.

The object of this volume is to present that which may be found practically useful as well as interesting. It aims at bringing together, in as small compass as possible, and in a form easy of reference, those items of information which many would desire to possess when called upon to cater for the household.

SENT POST-PAID, - - - - - PRICE \$2.50.

Not One Failed in 20,000.**

NEW YORK, AMERICAN INSTITUTE FAIR BUILDING, Nov. 4th, 1871: E. M. BOYNTON, 78 Beekman St., New York—Sir: This certifies that I saw the Lightning Cross-Cut Saw, worked by hand, by two men, November 2d, at this Fair. Said men had saw cut off a sound 8x9 inch chestnut log in 3 1/2 seconds; and 16 cuts of same, continuously, in 2 minutes and 18 seconds, or at a rate of a cord of wood in less than nine minutes. I am satisfied that for all purposes of cross-cutting large and small timber, your cross-cuts and wood saws have no rival in speed, in ease, and in simplicity. I believe their universal use would save a vast amount of money and time, and lighten the toil of millions of men.—**J. W. BLAKE**, Superintendent and Engineer, American Institute Fair.

A 6-foot Cross-Cut and a Wood Saw sent on receipt of \$6. Most of the large Hardware Jobbing Houses in America now handle my goods. Agents wanted where the hardware trade do not sell the genuine, which has my name and warrant on the saw. **E. M. BOYNTON**, 78 Beekman St., New York.

PRIZE DEVON CATTLE.—PROPERTY OF MR. E. H. HYDE.—Drawn and Engraved for the American Agriculturist

Devon Cattle, or more properly North Devon (for there is also a distinct breed known as South Devon), are without doubt the oldest existing race of cattle which can claim the distinction of a breed. They have been known in the county of Devonshire, in the southern part of England, from time immemorial, and from the certainty and distinctness with which their peculiar marks are transmitted from generation to generation, the entire purity of the race is shown. Devonshire is a country of hills, interspersed with moors and a few rich valleys, and this peculiarity of the surface has given some qualities

to this stock, which make them well adapted to similar circumstances elsewhere. As a dairy stock they are not the most desirable; but where they are to be used as draft cattle, and graziers in pastures of ordinary character, they are without doubt the most desirable of any stock. Easily fed, remaining in fair order where a Shorthorn or Hereford would starve, fattening rapidly when put up, remarkably docile and active under the yoke, of fair size and rotund figure, giving the idea of greater weight than they really possess, and finally as furnishing to the butcher the choicest kind of meat, beautifully

marked with fat, not laid on the surface, but mixed with a marbled appearance amongst the lean, they are peculiarly the cattle for our hilly districts. Their color is a dark blood-red, with orange streaks around the nose and eyes. Not a spot of white is seen on them when pure, and no breed is so certain to retain the evenness of color, size, and form as the Devons. At the plow or in the wagon they are as active as ordinary farm-horses. A pair of four-year-old steers of this breed will plow an acre per day, and will follow a pair of horses in the furrow throughout a long summer's day with perfect ease.

Calendar for February.

Table with columns for Day of Month, Day of Week, and Sun rises, Sun sets, Moon rises, Moon sets for Boston, N. England, N. York State, Mich., Wiscon., Ill., Ind., and Oregon; N. Y. City, Ct., Philadelphia, N. Jersey, Penn., Ohio, Indiana, and Illinois; and Washington, Maryland, Virginia, Kentucky, Missouri, and California.

PHASES OF THE MOON. Table with columns for MOON, DOSTON, N. YORK, WASH'N, CHA' STON, CHICAGO. Rows for 3d Quart., New Moon, 1st Quart., Full.

AMERICAN AGRICULTURIST.

NEW YORK, FEBRUARY, 1872.

"As the days begin to lengthen, the cold begins to strengthen." With us, February is usually one of the coldest months in the year. Some people think that they can stand cold better towards the conclusion of winter than at the beginning—that they get "hardened." The facts all point the other way. An Englishman stands the heat and cold of our climate far better the first year than the second. The thermometer often falls lower with us than in Russia, but there the cold weather lasts longer, and is steadier and more continuous. And the inhabitants feel it more and make greater preparations to guard against it than we do. The last half-hour of a cold ride is far more trying than the first half-hour. It is continuous cold that tests our strength. It is said that our climate is changing. Cutting down forests undoubtedly increases the severity of the wind. But otherwise there is no evidence of a change of climate. Our winters are no colder; our summers no hotter. By setting out evergreens and other trees for screens, and otherwise providing shelter, we can make the climate on any particular farm, garden, homestead, or barnyard just as favorable for grain, fruit, animals, or man, as it ever was. No change has taken place that man can not obviate. When the country was first cleared, the roots in the soil, probably, to some extent provided drainage, while the accumulated organic matter from centuries of fallen leaves, furnished plant-food, and rendered the soil rich and porous. Such soils are now in many instances wet, compact, and poor. We have the power to restore its original condition by underdraining, good tillage, and manuring. We can raise just as good wheat as we ever could, and more of it to the acre, because our land is free from stumps. And so of all other crops. Shame to the man that can not beat Nature! We highly venerate the great and good men of the past, but we have great faith in the men of the future, and are not wanting in respect for those of the present. We like to hear the fathers talk of the good old times; but depend upon it, times are no harder and the world no worse than in former days. We rejoice to believe that they are better.

It may be said that we could grow fruit easier when the country was new than we can now. Better shelter, richer land, and fewer insects and diseases sufficiently explain this fact, without attributing it

to a change of climate. And it may be that the varieties of fruit were not as good as those we now cultivate. Our common seedling-apple trees, choke-pears, and frost-peaches still bear abundantly. We have a peach-tree that bears bushels of fruit every year, and the tree is as vigorous and healthy as any peach-tree could have been a hundred years ago. But the labors of our pomologists have given us such delicious peaches that no one ever thinks of touching the fruit of this tree whenever the other trees in the orchard bear a crop.

It is quite possible that it is our taste and not the climate that has changed. We demand better articles, and we must pay a better price. No good thing can be had without care and labor.

On the other hand, if we will bestow the necessary attention, the choicest varieties of grain, vegetables, and fruit and the best breeds of animals always afford the greatest profit to the producer and the greatest satisfaction to the consumers. Every intelligent farmer and fruit grower, therefore, should aim to produce the best. It is the constant aim of the Agriculturist to teach and enforce this truth.

Hints about Work.

We have thousands of readers in the Southern States who will be busy this month preparing their land for spring crops, but with us in the North nothing can be done in the fields, except during a temporary thaw. Then we must be careful that no water is allowed to remain on the land. The outlets of underdrains should be looked to, and watercourses cleaned of any impediments. Few farmers seem to have any idea of how much water they can remove from their land by a little well-directed labor. Wherever you see water on the surface, no matter whether the field is occupied by a crop or not, get rid of it at once. It may be doing no harm now, but it will soak into the soil and keep the land cold and wet, or delay the operations of tillage several days or perhaps weeks in the spring. We are aware that when the ground is frozen underneath, it is not always easy to let off the water, but this should be no excuse for neglecting the matter altogether. Every gallon let off and thus prevented from soaking into an undrained soil, saves all the heat that would be required to evaporate it in the spring. Recollect that the sun must first evaporate the surplus water before it warms the soil.

Winter Wheat.—When the soil is frozen and comparatively free from snow, a little manure, or straw even, may be spread out on the wheat with advantage. As a rule, the prospects for winter wheat are not favorable. The ground was very dry last fall, and the growth small, and the winter, so far, has been very severe, with little snow. If March and April are unfavorable, much wheat will be damaged.

Good Prices for Wheat next Fall are highly probable. Everything points this way. Anything we can do in the way of top-dressing our winter wheat, will pay better than usual. Well-rotted manure, or 200 lbs. of guano and nitrate of soda, applied very early in the spring, will help the crop of wheat, and benefit the clover afterwards. The artificial manures can be sown broadcast and need not be harrowed in. The barn-yard manure should be spread evenly and then harrowed with Thomas's smoothing harrow. If it pulls any of the manure into small heaps, spread them out again. We would go over the field with the harrow two or three times in opposite directions. The harrow will not injure the wheat—quite otherwise.

Spring Wheat.—We think farmers will do well, in spring-wheat sections, to sow largely this year. But do not sow unless the land can be got into good condition. We expect good prices; but a large crop at a moderate price pays far better than a poor crop at high prices. We allude to this matter now, in hopes of inducing the readers of the American Agriculturist to get ready for putting in a good area of spring wheat, and of putting it in well.

Manure.—We should be glad to know that thousands of our readers have adopted our plan of piling manure as fast as it was made, and not allowed it to

lie in frozen heaps about the premises. Our own heap is fermenting nicely, even with the thermometer below zero. After the first fermentation slackens, turn over the heap, being careful to break up all the lumps and shake out the tangled corn-stalks, etc. It will facilitate the operation of turning to cut the heap with a hay-knife into sections three or four feet wide. If a large quantity of straw has been used, fermentation may be promoted and the quality of the manure greatly improved by scattering 25 lbs. of dry blood or 100 lbs. of bone-dust to each cord of manure as it is turned over. If this work is performed now, the manure will be in excellent condition for use in spring.

Milk-Cows.—Farrow cows that are being milked and fattened at the same time, must have an abundance of rich food—say four or five quarts of corn-meal per day, with cut stalks or hay. Beef is now low, but so are milk-cows, and it will probably be better to dispose of furrow cows that are fat than to keep them another season. If liberally fed we have known them milked up to the time they were sold to the butcher, and still prove very fat inside. As a rule, however, the butchers will pay a little more if they have been dry a few weeks.

Cows that come in before the first of April will now, in ordinary dairies, be allowed to go dry. In the majority of cases they cease to give milk of their own accord. With warm stables and liberal food, some cows will continue to give milk nearly or quite up to calving. A cow with great digestive powers, that will keep in high condition, nourish her calf, and give milk, may be allowed to do so. In fact, it is probably better to keep on milking her. There will be less danger of milk-fever after calving. But such cases, in our experience, are rare. It requires liberal food and the best of treatment to keep such a cow in vigorous health. As a rule, the average good dairy cow requires and will well repay a few weeks' rest at this season. And we need seldom be afraid to feed liberally. Any fat accumulated before calving will in the case of a good milkor find its way to the butter tub.

For ten days or two weeks before calving, it is well to give laxative food, such as bran-mash and linseed tea, or, if this is not sufficient, give a pound of Glauber salts, or half-pound of Epsom salts, and a table-spoonful of ginger. In case of very fat cows, it is well to give this dose once a week for three weeks or a month before calving, as a preventive of milk-fever.

Carding the Cows regularly and thoroughly is a point of great importance, especially where liberal feeding in warm stables is adopted. A dirty cow is a disgrace to a farmer and a direct pecuniary loss. We hope no reader of the *Agriculturist* will say carding is unnatural. Such a remark, though not uncommon, is simply silly. Furnishing shelter, providing hay, pumping water, giving the cows salt, and milking them, are just as unnatural.

Lice have never yet troubled any of our cows, horses, or pigs. Liberal feeding, carding, and clean stables and pens, are the best preventives. For a cure we should resort, first, to thoroughly cleansing the premises, and sprinkling crude carbolic acid in every nook and corner. Then mix an ounce of carbolic acid with a quart of crude petroleum, and rub it over the animal. It will kill every insect that it touches, and will not hurt the animal unless applied in excessive quantity. Care should be taken to mix the acid with the oil by thorough shaking. Should it not be well mixed, the carbolic acid would blister the skin and injure the animal. In such a case apply warm water freely, or rub on oil, or grease of any kind. If crude petroleum can not be obtained, use carbolic acid and water, an ounce of the acid to a quart of water. Tobacco water will destroy the lice, but the above remedies are less trouble and more effective.

Horses running in the barn-yard and fed on straw ought to have a comfortable shed to sleep in. A few ears of corn in severe weather will not be thrown away, and as spring approaches the quality of the feed should be gradually improved. This is particularly true of old horses, and of young horses that have not attained their growth.

Horses kept in the stables and not doing much work should be regularly cleaned and fed. Some farmers seem to think that unless a horse is to be taken out to work he does not need cleaning. Such a man, to be consistent, ought not to wash himself unless he is going to town! We feed our horses one bushel of chopped straw (say 8 lbs.), moistened with water and mixed with two quarts of corn meal, to each team, three times a day. They are allowed straw in their racks; but it is a good plan to take it out of the racks at say eight o'clock in the morning, and let them have no food before them until noon. Then feed them and remove all that is left in the rack at two o'clock, and feed again at night, letting them have all the straw they will eat until morning. In this way, horses that are standing in the stable will eat much more heartily than if the food is before them all the time. If they are worked feed a little more grain or hay. A few rutabagas or carrots may be fed to the horses with great advantage, say half a bushel per day to each team. As spring approaches feed more liberally.

Fattening Sheep should be allowed from a pound to a pound and a half of grain per day, according to their size, and it is well to give them one foddering of hay per day and all the straw they will eat. Wool is in demand, and most farmers will desire to keep their sheep and clip them before selling. On this account it is not improbable that those who sell their fat sheep the latter part of February or first of March, may realize more profit than by keeping them later.

Early Lambs for the butcher must have warm, dry quarters, and the ewes must be well fed. Nothing is better than clover hay and bran, with say half a pound of grain per day. Roots, of course, would be a great help. Water regularly. The lambs should have a place, into which they can run through a small opening, separate from the ewes, and be fed in a small trough all the corn-meal and bran they will eat.

Yearling Sheep should be kept in a flock by themselves and be fed more liberally than the older store sheep. If fed principally on straw they should have from half to three quarters pound of grain per day, and if of the long-wooled or South Down breed, a pound per day will be none too much.

Store Sheep, and ewes not expected to lamb until April or May, can be wintered very well on straw or stalks, with half a pound of corn or other grain per day. It is a great mistake to winter them on straw alone. Separate old or feeble sheep from the rest of the flock and feed more liberally.

Salt all animals at least once a week. Get rock salt, and let them have access to it at all times.

Pigs should have warm, dry, well-ventilated pens. Where straw is abundant let them have enough to bury themselves in, and change it frequently. Clean out the pens every day. It is little trouble if done regularly. Let the young, growing pigs have all the food they can eat. Feed three times a day. If they leave any in the troughs, remove it and feed it to the old hogs, and do not let it remain to freeze. See that they do not suffer from want of water. There is no cheaper food for pigs than corn-meal and mawgold wuzel—and nothing that will push them forward more rapidly. If they get fatter than you wish, lessen the corn-meal and replace it with bran.

Work in the Horticultural Departments.

This month everything ought to be made ready for active work, as out-door operations will be commenced next month, and no time should be consumed then in doing such things as can be done now. Send orders for trees, seeds, tools, etc., to the dealers at once, so that no delay may occur in waiting for them when they are needed. An enterprising horticulturist will make a trial of some of the new sorts of flowers, vegetables, etc., each season, but for the main crops it is safer to rely upon old sorts which are known to be good. It is well to test all seeds before planting, so that no failures

may happen from sowing poor seeds. Market-gardeners can not be too careful in purchasing seeds of reliable dealers only, even if at a higher price than that asked for seeds sold at the country stores.

Orchard and Nursery.

Buds may be cut now and packed in sawdust or earth and preserved in a cool place where the buds will not start.

Scraping.—This is a good time to remove all dead bark from trees in the orchard. Trees which have been neglected for several years are soon covered with mosses and lichens, and are thus rendered unsightly. The best wash that can be applied to trees is one of strong, home-made soft-soap, thinned with water so as to be easily applied with a brush.

Planting.—The time for planting will vary in different localities. In the Southern States trees may be set this month, while in Northern localities the ground will not be in condition for several weeks.

Varieties.—In planting an orchard regard should be had to the proper selection of varieties from the earliest to the latest. It is well, however, not to plant too many varieties, but have the larger portion of late-keeping sorts. Kinds known to succeed well in the neighborhood should be selected.

Young Trees are the best for orchard planting, many orchardists preferring those of only one year from the bud or graft, as these are more likely to be healthy and vigorous than older ones which have been crowded in nursery rows.

Injured Trees that have had their branches broken by winds or storms, should have the wounded surface smoothly pared and then covered with a coating of shellac varnish or melted grafting wax, to prevent the water penetrating and causing decay.

Insects.—Now is the time to prevent canker-worms from ascending the trees, the warm days which often occur this month being favorable for their movements. Their ascent can be partially prevented by placing around the trunks bands of paper which are to be kept coated with tar, taking care to renew the coating every few days, or as often as it hardens. Other methods, such as a gutter of tin or lead surrounding the trees, have been used, but the success of all of these contrivances depends upon constant inspection and care. A great many Tent-caterpillar's eggs can be destroyed by carefully searching the trees before they commence to develop their leaves; the eggs are attached in rings to the branches near their extremities.

Nursery Trees which are received early in the season will sometimes be found frozen or dried; if frozen put the packages in a cool place and allow to thaw gradually; if shriveled by drying, they will recover if buried in the ground for a few days.

Manure.—Cart to the orchard whenever convenient and place in small heaps, but not in piles around the trunks of the trees, as it does no good there, and often serves as a harbor for mice, especially if it is coarse and littery.

Fruit Garden.

Trees in the fruit garden proper should only be those grafted upon dwarfing stocks, and those that are trained upon walls or trellises. Many of the directions given in the "Orchard and Nursery," under Washing, Insects, etc., apply equally here.

Grape-Vines.—Prune when not frozen, if it has not already been done. Go over the vines pruned last fall and remove the extra buds which were left as a precaution against the severity of the winter.

Blackberries and Raspberries.—Set as soon as the ground will admit of being worked, as when left until late, the under-ground shoots, which form the canes of next season, start very early and are liable to be injured if left until late.

Strawberries.—Make new plantings as soon as the weather will permit.

Trellises will be needed for training grape-vines and trees, and the timber should be got ready now, so that it may be at hand when wanted. Posts of chestnut, cedar, or locust are the most durable.

Kitchen Garden.

Little can be done in this department at this season in the North, if no glass is used, except to have everything ready for early planting when the soil is ready. Very few market-gardeners, or even farmers, can afford to do without one or more hot-beds. The earliness of lettuce, tomatoes, and other crops more than compensates for the time spent in properly preparing a hot-bed, and no farmer who has once tried the raising of early plants in this way will be willing to give it up. In the South many of the early crops of hardy vegetables, such as beets, parsnips, onions, lettuce, etc., can be sown this month. It is never safe to sow the tender vegetables, such as cucumbers, beans, etc., until all danger from frost is over, and the ground has become thoroughly warmed.

Manure.—Do not allow the manure to become overheated, but turn over and mix with earth. When dry, water occasionally. Save the horse-manure in a separate pile, to use in hot-beds.

Cold Frames.—As the weather becomes milder, see that plenty of air is allowed the plants in the frames, and on warm days the sashes may be removed entirely; they should never be left open during the night, even if it is very warm, for fear of a sudden snow-storm or change in the temperature.

Hot-Beds will not be needed at the North until next month, unless very early plants are desired. In some parts of the South they may be prepared, and seeds of early vegetables planted. Shelter from prevailing winds should be given, and if necessary to make them in an exposed place, it will pay to erect a temporary board fence.

Straw-Mats or Shutters will be needed for protecting the plants in hot-beds and frames during cold spells, and from too much sun.

Brush and Poles for peas and beans should be cut, as it is poor policy to leave them until needed.

Root Crops.—Whenever the ground thaws, the roots left in the ground over winter, may be dug.

Potatoes.—A few may be started for early planting by placing in a warm room and allowing the sprouts to start, and then planting in a warm spot.

Boxes.—A few boxes, four inches deep, may be made and filled with rich garden soil, and many of the early vegetables started in these; they are a cheap and convenient substitute for hot-beds, if only a few plants are wanted.

Flower-Garden and Lawn.

Complete all plans for improvements which were begun during the winter, and have everything that is needed for carrying them out, ready for immediate use. All shrubs, trees, and seeds that will be needed, should be ordered at once.

Half Hardy Plants, which have been stored in pits or cellars, will need looking to, in order to prevent their starting into growth. See that plenty of air is given, and if the plants in the cellar become too dry, give them a little water occasionally.

Cannas and other roots stored in the cellar will need to be examined, as they are liable to suffer from dampness. If any signs of rotting appear, remove at once to a dry place, where there is no danger of frost, and cut away all decaying parts.

Wood Work.—All trellises, arbors, etc., will need a coat of paint or oil, to prevent their decay.

Annuals.—Seeds of hardy annuals may be sown in shallow boxes and placed in a kitchen window, as recommended for vegetable seeds.

Greenhouse and Window Plants.

Air should be given to the greenhouse every mild day, taking care to open the ventilators on the side opposite that from which the wind blows.

Sprinkling.—Give the plants a good sprinkling every two or three days, so that they may be kept free from dust. The best time to do this is in the afternoon, when the ventilators can be closed.

Bulbs.—Cut away the flower-stalks of all bulbs which have finished flowering, and gradually dry them off, when they may be taken out of the pots and stored in a dry place, ready to be planted in the open ground next fall. Bring a few pots from the cellar every week, so as to produce a succession of flowers during the early spring months.

Propagation of bedding and other plants should be continued; as soon as rooted, pot into thumb-pots.

Neatness.—Keep all the plants free from insects by fumigation and washing, and remove all yellow and dead leaves, as they detract very much from the beauty of a flowering or specimen plant.

Commercial Matters—Market Prices.

Gold has been down to 108 3/4, closing January 15th at 108 1/2, against 109 1/4 on the 16th of December. Business in breadstuffs has been on a restricted scale, with the main call for spring and red winter wheat, and mixed Western corn and Western rye, for shipment, at easier and irregular prices. The home-trade demand has been light and mostly for job lots, needed to meet pressing wants. Holders have been prompt in responding to the requirements of buyers, as a rule, at the current figures. Cotton has been active, excited, and higher, the principal dealings having been for home use, and on speculative account. Wool has advanced on a livelier inquiry, chiefly for manufacturing purposes, closing with prices in favor of sellers, on light stocks of desirable grades, particularly of fleece. Clover-seed has been freely purchased for export, at uniform rates. Hay, Hops, and Tobacco, quiet. Provisions have been moderately active, closing firmly at our quotations.

CURRENT WHOLESALE PRICES.

Table with columns for Dec. 16, 109 1/2, and Jan. 15, 108 3/4. Lists various commodities like Flour, Wheat, Corn, Rye, Barley, Oats, and their prices.

The following condensed, comprehensive tables, carefully prepared specially for the American Agriculturist, from our daily record during the year, show at a glance the transactions for the month ending Jan. 15th, 1872, and for the corresponding month last year; also for the year ending December 31, 1871.

Summary tables for Transactions at the New York Markets, Receipts, Comparison with same period at this time last year, Exports from New York, and Stock of grain in store at New York.

5. Receipts at head of tide-water at Albany each season to Dec. 1st:

Table showing receipts of Flour, Wheat, Corn, Rye, Barley, Oats at Albany.

6. Receipts of Breadstuffs in New York in each of the last eight years:

Table showing receipts of Flour, Wheat, Corn, Rye, Barley, Oats in New York for the last eight years.

7. Exports from New York, Jan. 1 to Dec. 31:

Table showing exports of Flour, Wheat, Corn, Rye, Barley, Oats from New York.

8. Comparative Stock of Flour in New York, Jan. 1:

Table comparing stock of Flour in New York for 1869, 1870, 1871, and 1872.

9. Comparative Stock of Grain in New York, Jan. 1:

Table comparing stock of Grain in New York for 1869, 1870, 1871, and 1872.

New York Live-Stock Markets.

Table showing Week Ending Receipts for Bees, Cows, Calves, Sheep, Swine.

Table showing Average per Week for Bees, Cows, Calves, Sheep, Swine.

Beef Cattle.—There has been a falling off of 1,800 cattle per week when compared with the receipts of the previous month. Closing up the year we have 380,934 cattle against 356,026 in 1870. The light run of cattle for a month past has caused a steadily improving market, and prices are now 1c. higher than they were last month. Since the former report a large number of very fine holiday cattle were sent in, but they did not bring over 13c. @ 15c., or little more than prime stock is worth now. There were too many of them to sell well. One yard of 12 head was sold for \$2,000. The market closes very firm, Texans, which are scarce, selling at 9 1/2c. @ 10 1/2c., with fair Western at 11 1/2c., and prime 12 1/2c.; the best cattle selling at 12c. @ 13 1/2c., save a few head, very fine, at 14c., on the scales, 60 lbs. per cwt.

Below we give the range of prices, average price, and figures at which large lots were sold:

Dec. 18th, ranged 8 @ 15 c. Large sales 10 @ 13 c. A.V. 11 1/2

Dec. 25th, do. 8 1/2 @ 18 c. do. do. 10 @ 12 1/2 c. do. 11

Jan. 1st, do. 9 @ 18 c. do. do. 10 1/2 @ 12 1/2 c. do. 11 1/2

Jan. 6th, do. 9 @ 18 c. do. do. 10 1/2 @ 12 c. do. 11 1/2

Milk Cows.—The supply has been large during the past month, and trade has been unsatisfactory. Milk has seldom ruled at the present low rates, during the winter season, and this is discouraging for the producers. Besides, dry cows have been hard to sell until within the past week. Fresh cows vary from \$40 to \$55 each for poor, \$65 to \$75 for medium to good, with a few choice at \$80 to \$90. Calves.—The run is light, as is always the case during this season of the year, and prices have advanced. Most of the calves are now sent in dressed, on account of cheaper freights and the ability to send them long distances. Good to prime milk-fed calves are worth 10c. @ 11c. @ 12c. @ 13c.; common to fair sell at 8c. @ 9c.; mixed lots, of large size, 4 1/2c. @ 7c. Hog-dressed are worth 12c. @ 14c. for milk-fed, and 6c. @ 9c. for grassers. Sheep and Lambs.—There has been quite a falling off in receipts, and prices have worked up from 7 1/2c. to 1c. @ 20c. There were some extra holiday sheep of 175 @ 200 lbs. sent in for Christmas, which were sold at 9c. @ 9 1/2c. @ 10c., live weight. The advance in wool helps the sheep trade, while farmers incline to increase their flocks, hence send in sparingly. Few sheep now sell below 7c. @ 8c., while good lots of 80 to 90 lbs. bring 7 1/2c. @ 8c. Lambs are now selling with sheep at same prices. Poor to medium sheep are selling at 6 1/2c. @ 7 1/2c. @ 8c.; fair to good at 7 1/2c. @ 8c.; and prime to best selections at 8 1/2c. Swine.—These are falling off in numbers, but there are somewhat few receipts of Western dressed, amounting to 26,321 during the past five weeks. Prices have ruled rather steady, the demand being unusually good. Live are worth 4 1/2c. @ 5 1/2c.; city-dressed Western 5 1/2c. @ 6 1/2c.; State and Jersey, 6c. @ 7 1/2c.; Western dressed, 5 1/2c. @ 5 3/4c.

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Remitting Money:—Checks on New York City Banks or Bankers are best for large sums; make payable to the order of **Orange Judd & Co.** Post-Office Money Orders, for \$50 or less, are cheap and safe also. When these are not obtainable, register letters, affixing stamps for postage and registry; put in the money and seal the letter in the presence of the postmaster, and take his receipt for it. Money sent in the above three methods is safe against loss.

Postage: On American Agriculturist, 3 cents a quarter, in advance; on *Hearth and Home*, 5 cents per quarter. Double rates if not paid in advance at the office where the papers are received. For subscribers in British America, the postage must be sent to this office for prepayment here.

Bound Copies of Volume Thirty are now ready. Price, \$2, at our office; or \$2.50 each, if sent by mail. Any of the last fifteen volumes (16 to 30) will also be forwarded at same price. Sets of numbers sent to our office will be neatly bound in our regular style, at 75 cents per vol. (50 cents extra, if returned by mail.) Missing numbers supplied at 12 cents each.

Clubs can at any time be increased by remitting for each addition the price paid by the original members; or a small club may be increased to a larger one; thus: a person having sent 10 subscribers and \$12, may afterward send 10 more subscribers with only \$3; making a club of 20 at \$1 each; and so of the other club rates.

Newspaper Recommendations.—Many parties advertise that such and such a newspaper says so and so of their wares or business enterprises, etc. Actual editorial commendations from papers which are honestly and ably edited, and which never sell editorial notices, are frequently valuable—when received by reliable parties, who give exact, ungarbled quotations, with the date of their publication. But it is always to be remembered that very many of these notices are taken from the parties' own advertisements in the papers referred to. Thus, a party inserts in the *Tribune*, *Times*, or other paper an advertisement praising himself and his wares in the strongest terms; and then in other newspapers or circulars he quotes from his own advertisement, and says the *Tribune* or other paper says so and so, when the editor of the quoted paper probably never even read the advertisement, and knows nothing of the matter.

Cheap Watches.—To several inquirers we answer, as often before, put no faith in the advertisements in newspapers or circulars, of very cheap watches. Good watches are, like gold and silver coin, standard articles which are sold at their cost and worth. It is nonsense to expect to buy "solid-gold hunting-case, full-jeweled watches, accurate time-keepers," etc., for \$20 or \$30, no matter how many respectable newspapers are said to commend them. The cases would cost all the price and more, and the running gear must be poor indeed. As a rule, the safe way to get a watch is through a known, responsible party, to whom you can look for redress if a watch prove poor. It is impossible for us to personally investigate every advertiser inquired after by our numerous readers. Advertisements in our own papers are believed to be trustworthy, or they would not be inserted.

The Hoosier School-Master.—This intensely interesting story, which has appeared as a serial in the columns of *HEARTH AND HOME*, is now issued in elegant book form, printed on fine paper, with twelve full-page engravings on tinted paper, and seventeen other illustrations, and bound in extra cloth. It is a truly AMERICAN STORY, and will be read with delight by all. Price, post-paid, \$1.25.

Will it Pay to Borrow Money to Drain Land?—A young farmer, Wilmington, asks if it would be advisable to borrow \$500 to remove stone from, and drain 8 acres of land which he wishes to improve. If the productive capacity of that land will be increased to the value of \$10 per acre per year, the cost will be repaid, with interest, in eight years. The contemplated improvement ought to be of even greater bene-

fit to the field, so that we can not but advise a young farmer to go ahead. Debt is to be avoided, but where the land is improved in value, no real debt is incurred.

Please Speak of our German Edition.—This has all the principal articles and engravings of the English edition, besides a Special German Department, by Hon. Frederick Münch, a practical cultivator in Missouri. This paper is useful to the great number of German-speaking cultivators of the country, and especially so to the scores of thousands of new-comers from Faderland. Terms the same as for the English edition. Clubs may consist of either edition, or partly of both.

A Pump for a Deep Well.—A "Central Pennsylvanian" wants a pump for a well 40 feet deep, that will supply both the house and barn. Just the pump wanted is the Submerged Pump advertised in our columns, and offered as a premium for clubs for *American Agriculturist*.

Golden Rod.—"H." Naugatuck, Ct., has known this weed to be destroyed by two years' pasturing with sheep on ground that could not be plowed.

Club-Root in Cabbage.—E. G. Howland, Erie Co., N. Y.—It is supposed that club-root is due to some insect, but we believe it is not yet proven what insect it is.

Do Brahmas Mature Early?—It is said over and over again in books and periodicals that the Brahmas, light and dark, excel in the valuable quality of early maturity. We have asserted the same ourselves, but there should be some qualification. If by early maturity precocious laying is meant, then Brahma pullets are certainly entitled to that distinction. We have raised broods of which every pullet has laid within a week after attaining the age of six months. Mr. Wright, in his "Monograph on the Brahma Fowl," says that they lay with great regularity when from six to seven months, and when hatched early and highly fed from the shell, will sometimes begin at five. But if we turn from laying to increase in size, we find that the Brahma, like all other Asiatic breeds, arrives at maturity very late. Growth is not completed until the age of from fifteen to eighteen months. Though the Brahmas are so large when fully developed, the White Leghorns, a medium or small race, will, if hatched at the same time, and fed and managed in the same way, attain a good "broiler" size, say three pounds, live weight, at an earlier age. The Brahma cocks go stalking about, looking as stilly and awkward as so many young ostriches, for months after the cockerels of most other breeds appear nearly mature.

The Rural Alabamian.—Our Southern friends make the mistake of having an agricultural paper—and sometimes two—in each State. One good paper devoted to the Agriculture proper to the Gulf States, would be better than one in each State; however, that is a matter that will regulate itself. Our present business is to welcome the *Rural Alabamian*, a monthly of 40 pages, published at Mobile, Ala., at \$2 a year. Mr. C. C. Langdon, the editor, is no novice in agricultural and horticultural matters, and his first number is very creditable in both matter and manner.

Peach Grubs.—"O. W.," Newfane, N. Y. We suppose you mean the peach-borer. Borers already in the trees must be killed, by the use of a sharp knife and flexible wire for a probe. The parent insect begins to lay its eggs in June, and continues until September and sometimes October.

Cancer—The Latest Cure.—Cancer is such a terrible affliction that many sensitive persons imagine that they are visited by it, and assume that any obstinate tumor is the dreaded cancer. It is from this class of persons that the cancer-curers derive their patients and their pay. The latest dodge of these cancer chaps is now being practiced by a man in Pennsylvania. He writes to the various papers that he was cured by drinking "wild tea," and applying the grounds thereof to the cancer. Many papers have given this man the benefit of an advertisement by publishing his notice. If the editors of these papers are applied to to know what "wild tea" is, inquirers will be referred to the writer of the article.—Somebody has a "cancer cure" to sell, and takes this method of getting his advertising done, which some editors are green enough to do gratuitously. Those fearing they have or may have cancers will do well to read an article on the subject in *Hearth and Home* for Feb. 3d.

Bermuda Grass.—C. L. Huffman, Chambers Co., Texas. This grass rarely or never seeds. It is propagated by cutting the turf in small squares, scattering them over the field, and rolling. It should be put only where the pasture is intended to be permanent, as it is claimed to be impossible to eradicate it. In many parts of the South the problem is to get the grass out rather than to get it in.

The Poultry World.—This is a new poultry monthly of 12 pages, published at Hartford, Ct., at \$1 per annum. One of its editors is Mr. Stoddard, whose articles, including those upon "The Egg Farm," have frequently appeared in our columns. The first number is very neat in appearance, and gives promise of usefulness in its particular line.

IT WILL PAY to supply yourself, your sons, and your workmen with good papers and books. \$5 to \$20, or more, expended in this way, will come back every year. Your sons will be kept from idleness and mischievous company; they will understand and respect their work more; they will gain new ideas and learn to think and reason better; they will learn to make their heads help their hands; they will labor more intelligently and be happier because their minds will be developed, and they will have something to think about while at work. Better sell an acre of land than not to have these mind-cultivators. Any intelligent man will make more off from 9 acres than the unintelligent one will from 10 acres. Think of this in planning and providing for your sons in the future. Store their growing minds with useful ideas, or the devil will fill the vacancies with very undesirable tenants (ideas). (The premium list on page 73 will afford to many an opportunity to get some books free of expense; and plenty of good books, to be delivered by mail or otherwise, will be found in the advertising pages.)

Labels.—Sewall Fisher writes that he finds that chrome yellow, mixed with linseed oil, and rubbed upon wooden labels, is preferable to white lead.

Beans.—A. Walker, Randolph, Wis. The specimens sent arrived in fragments. Likely the Mottled Lima, but we are not sure.

Mr. Sargent's Butter.—It was stated in the *Ogden Farm Papers* for January, that Mr. Sargent's cows had yielded nearly \$900 each, during the year, in butter alone. He has since sent a definite statement on the subject. "Our total yield of butter for the year was 1,812 lbs.; number of cows, 10. Of these 'Anna' has not yielded one cent during the year, and supposing that the yield of two others has been consumed at the house, in milk and cream, it leaves seven butter-makers, or 253 lbs. per cow. This, at \$1.15 per lb., makes \$296.70. So, you see, my statement was not so very far out of the way. I do not consider this as good as it should be, and probably would be another year, for I have had hard luck in getting cows with calf. It has been a year of unusual drouth, to say nothing of the preceding year of drouth and heat, from which the cows have never recovered."

SUNDRY HUMBUGS.—There is a large class of swindlers, pretty widely scattered, who deal, or profess to deal, in vile books, pictures, instruments, stimulants, and the like. They now mainly locate in small country towns, where they are in less danger from the sharp city detectives. Mr. Gayler's stern course in withholding letters addressed to this class, has driven most of them from this city. (Pity he could not have an eye and hand in every P. O.) These operators secure mainly the names of young persons, though they do not all confine themselves to such customers, and send out alluring circulars describing their books, pictures, and articles. Most States have severe laws against the vendors of such literature, but they evade detection by withholding their names from the circulars, and slipping in a loose card with the address; or they carefully exclude all samples of their articles from their offices, and deal only through the mails or express, having the articles forwarded (if sent at all) from some other locality. These precautions, however, are only needed to avoid detectives, for, as a rule, those dealing with them are not likely to expose themselves by publicly prosecuting them for any awindling practiced. A majority of them pocket all the money received, and send nothing in return. We have complaints of loss of money sent by P. O. Order, and received by one calling himself M. Depan & Co., Hoboken, N. J., who advertises such things as no decent persons ought to have ordered or thought of ordering, and they deserve little sympathy in their losses. Others complain of a "Tailor & Co.," who is flooding Maryland and other States with offers of similar articles and pocketing the money sent to him. Another villainous circular, offering obscene books, prints, and articles, incloses a card of "Scott & Co., 22 Ann St., N. Y." To

those foolish and depraved enough to want and order these things, we say first, that almost invariably, your money will be coolly pocketed and nothing returned; and second, that the articles, if sent, are not as represented, and are dangerous to yourself, morally and physically. To Parents and Guardians we again say, be very careful to know what those under your care receive through the mails. Multitudes of reports come to us from parents who have found their sons (sometimes daughters, too) patronizing these vile, seductive swindlers. . . . A Wisconsin writes us that he sent \$2 to a Maine concern, on the promise of, post-paid, or express paid, a canvasser's outfit of 200 papers, samples of splendid chromos, etc., but after three letters of inquiry can get no response; that a neighbor, a lady, wrote for the same and received a box with a C. O. D. bill of \$4, and express charges of \$2.25. . . . A Salem, Mass., subscriber writes us regretting that so good a paper as the *YOUTH'S COMPANION* should not be more careful in what it admits to its advertising columns, and we join in the regrets—which extend to many other good journals. We hope the complainants will write directly to the editors of such papers, and let them plainly understand what their readers think about the matter, and what they intend to do about it if persisted in. . . . The "Queer" operators still find dupes enough to keep them going. This month we have, among others, J. P. Strang, *alias* J. D. Wolston, 16 South Fifth avenue, N. Y., who pretends to I. O. O. F. ship—and under other names circulates the "Spanish Policy" humbug circulars; Noah Judson & Co., 109 William St., N. Y., *alias* F. Drake & Co., 51 Liberty st., N. Y.; Hudson, Wood & Co., 44 Liberty st.; Jno. Hood, Jr., Wilmington, Del., whose letters are forwarded by express to 198 Broadway, N. Y., where he has his head-quarters, as a pretended collecting agent. The same man operates under the name of Amos Wainwright, 170 Broadway, N. Y., and same street and No. in Trenton, N. J., with Masonic and I. O. O. F. symbols, his letters being post-marked at N. Y. City.

PROFITABLE.—Money can be easily made by any one, old or young, with little time or attention required. How it is done will be learned by a careful reading of what is said on page 73.

Those Dob-Sleds.—"H.," Rileyville, Pa., thinks the sleds figured in the *American Agriculturist* of December last, would come to "pi" if a stone was struck when they had a heavy load on. This may seem so, but such sleds are extensively used in the great pine-ries in Wisconsin and Michigan, where the logs are much larger than the Pennsylvania logs, and are found to be strong and durable.

Washing Machines are commonly used only for the storage of articles sure to be found in every family, which are not good enough to keep, and still a little too good to throw away. They must be put somewhere, and what place so appropriate as the washing machine, which is often just the same kind of property? The Continental washing machine is not one of this kind. We have tried it, and found it to work rapidly, easily, and effectually. It is a great labor-saving machine, and it would prove a blessing in any house that is not already furnished with a good washing machine.

Do Water-Rams Waste any Water?—"J. C.," Kansas, asks if water-rams waste any water? Undoubtedly. The water elevated is raised by the power gained by the fall of a certain amount of water, depending on the height to which the water elevated is raised, and the fall from the spring. A large quantity of water is used to raise a comparatively small quantity.

Small-Fruit Notes and Queries.—"C. S.," La Porte, Ind. A single question (or two) is usually answered at once. A perfect swarm like yours must wait. We will try and condense: *Wilson's Black-berry.*—The fruit is imperfect because the flowers are sometimes incomplete. They are not "the poorest we ever tasted," but very good. Still valued at the East as a market berry. *Philadelphia Raspberry.*—If yours are of superior flavor to the Clarke, then you can not have the right Clarke, or tastes unaccountably differ. No variety in the New York market equals the Hudson River Antwerp. *Mulching Grape-Vines.*—We should not advise this except upon a very light soil. The roots of a vine need to be warm and dry. *Mulching Strawberries.*—Leave the mulch on until after the fruit is gathered; pull up such large weeds as force their way through the mulch. When the crop is off, remove the straw and cultivate. *Rogers's Hybrids.*—No. 15 is Agawam; the other numbers mentioned have not been named.

Forest-Tree Seeds.—"D. A. S.," Bellevue, O., asks about raising chestnut, sugar-maple, hickory, and white oak from seeds. Unless he can find

seeds that have been properly preserved in sand, he can do nothing next spring. Seeds that have become thoroughly dried will not germinate. The first two may be sown in drills and covered with leaf-mold, and transplanted when one or two years old. The hickory and oak are best planted where they are to grow, putting two or three seeds together, and when they have started removing all but one. They do not transplant readily.

IF.—If you persuade a neighbor to take and read a wide-awake, instructive, reliable journal, treating specially of his business, you set him to thinking, you elevate him and his family. He will experiment, and you will have the benefit of his experiments. His family will read and be more intelligent neighbors. The tone of society will improve; and your own property even will be improved in value. Every additional reader in the place will have a like tendency. Scatter annually in any neighborhood \$30 worth of good periodicals and books, on agriculture, horticulture, and domestic economy, and it will change the character of the neighborhood, and increase the intelligence and the desirableness of the place, and raise its product many hundreds of dollars in the aggregate every year. One easy, cheap way of accomplishing this is, for the people to unite, raise a club, and each receive this journal, or *Hearth and Home*, or both, and get one of the book premiums as a library for common use by all. It only needs some wide-awake, enterprising, public-spirited man or woman—young or old—to start the enterprise in each neighborhood. See premiums 94 to 106, pages 73 and 74. By a little effort any man or boy may secure quite a lot of good books for himself as a premium without money.

Coal Ashes.—"G. D. C.," Philadelphia. Coal ashes are worth so much less than wood ashes that we can not give their relative values. Coal ashes are useful on some soils, and the more wood or charcoal is used in kindling the coal the better the ashes. They are not worth carting far. We use them on roads and paths, for which, in our sandy soil, they answer a good purpose.

"Insects Sent."—"C. S.," Ind. The "insects" sent in a quill are not properly insects, but crustaceans. They are popularly known as Sow-bugs, and belong to the genus *Porcellio*. As they live upon decayed wood and other vegetable matter, it is probable that they do no injury.

Mistletoe.—R. H. Dixon, Canandaigua, N. Y. Mistletoe can not be grown from alips. The English propagate it by means of the seed, raising a sliver of bark upon the underside of a branch, and inserting a berry beneath it. We have not known the European Mistletoe, which is quite different from our native one, to be grown in this country.

"Smilax."—"J. F. F.," St. Paul, Minn. The proper name of this plant is *Myrsiphyllum*. Your want of success is doubtless due to your not having heat enough. It does best in a warm greenhouse. Your temperature, 35° to 55°, is cool.

Steaming Feed with Hot Water.—"A. C. W.," Washington Co., Md., asks, "Will it do to steam feed in a tight box, by pouring hot water on and covering until cool, where there is no steaming apparatus?" It will answer to some extent as a substitute for proper steaming, and will be found proportionately but not equally useful.

Lilac Bushes.—"A. W.," Randolph, Wis. It is the nature of Lilac bushes to spread. You may be able to keep them within a certain space by digging a trench, removing all roots outside of it, and filling up the trench with coal ashes.

Apple Orchard.—"O. W.," Newfaun. If your orchard has been manured "heavily" every year, you probably have stimulated a growth of wood at the expense of fruit. Let it rest for a few years; then use lime.

House and Garden is the title of a monthly made up from the weekly columns of the *Ohio Farmer*. Published by Gen. E. Blakelee, Cleveland, O., at 80 cents per annum.

Cabbages after Potatoes.—"J. H. G." (some-kind-of-town, can't read it), Md.—Cabbages may follow potatoes. Use a plenty of manure.

How to Use Peas most Profitably.—A "Subscriber" has two barrels of gray peas and wants to use them most profitably. We do not know of a better use than to sow them with oats and feed the crop to stock, either green or dry. It is an excellent crop for soiling, or feeding green to horses, cows, or hogs.

FREE.—The very Best Table Cutlery—Silver-plated Table Articles—Gold Pens—Children's Toys—Flower and Garden Seeds—Nursery Stock—Sewing and Washing Machines and Wringers—Melodeons—Pianos—American Watches—Shooting Irons—Tool Chests—Drawing Instruments—Barometers—Astral Oil—Hay Mowers—Horse-Forks and Hoes—Pumps—Family Weighing Scales—Cyclopedias—Dictionaries—Books—Grape-Vines—Toy Steam-Engines—etc., etc., etc.,

are among the things that we are distributing very largely all over the country to our friends who send in clubs of Subscribers. Some report as getting as many as fifty subscribers a day. Others get one, two, or three, or more, as opportunity serves. Some make this their sole business, and sell their premiums received, and thus get large wages. There is no humbug or claptrap about this. At least *Fourteen Thousand* persons have received these premiums with great pleasure, and still not one in ten of those who ought to read the *American Agriculturist* and *Hearth and Home* for their own pleasure and profit, is yet supplied with it. So there is abundant room for thousands of others to obtain these valuable premiums. This work can go on all winter. Full particulars will be found in the Advertising Columns, pages 73 and 74.

Rain at Will.—Mr. Edward Powers, a civil engineer of Chicago, finds that battles both in this country and in Europe have been followed by rain which he attributes to the effect of cannonading. He petitions Congress to allow him the use of 300 cannon with powder for the purpose of experimenting.

Ring-Bone.—"C. W. P.," W. Va., has a horse lame of ring-bone in the fore feet, and wants a cure. If of late appearance let the horse rest, feed liberally, and apply a hot bran-and-water poultice, with one drachm of camphor. Afterwards rub with an ointment of iodide of lead, one part to eight parts of lard. Continue this for two weeks. An old ring-bone is incurable, but rest will relieve the lameness.

Post-Hole Digger.—"T. S.," Greenwood, Miss., wants the best post-hole digger. Where there are no stones to interfere, the common post-auger is the best; where there are stones, the post-spoon and a crowbar to loosen the earth are the best tools.

Peach-Trees and Canker-Worms.—"J. A. H.," Roxborough, Mass.—We do not think a "little salt" would injure your peach-trees, nor do we think it will do any good; better use ashes or lime. It is doubtful if any application can be made to the soil to destroy canker-worm.

Breeding from a Young Sow.—"H. H. S. II." asks if it is wise to breed from a sow that is only five months old. Hardly. Her growth will be checked and the pigs will not be worth raising. Better wait for pigs until September next.

Size of Ox-Yokes.—"A Subscriber," Wis., gives the size of timber necessary for an ox-yoke, used in the Western prairies, viz., 8 x 12 inches. There, where heavy draft is common, a wide yoke is used and two-inch bows.

The Copper-Strip Hay-Cutter.—"W. H. P." asks if the copper-strip hay-cutter is the best. We have used it, and for a small stock think very highly of it.

Lime-Spreaders.—"S. & Co.," Bellefonte, Pa., asks who makes lime-spreaders, and if a plaster-sower, mentioned in the N. Y. Tribune, is able to do it? That plaster-sower is useless for spreading lime, however much the N. Y. Tribune may recommend it. It can only sow plaster and finely ground materials in small quantities. No plan of spreading lime is better than from a sled that will hold 25 bushels, with a long-handled shovel.

To Prevent Skippers in Hams.—"Z. D. R." keeps hams free from skippers by lying them closely in a paper sack and hanging in a dry room.

The "World" Agriculturally Considered.—We do not refer to the "Wide, Wide World," but to the newspaper of that name. It has become the custom, of late, for the daily newspapers to devote a share of their weekly editions to agricultural matters, and the agricultural departments of these papers are good or bad, according to the ability of the editors in charge of them. Persons who differ with the World in political matters, will agree that its agricultural department is not surpassed, if it is equaled, by any of its rivals. There are not so many long "original" articles as in some papers, but a great variety of original and well-selected matter, which shows much conscientious labor on the part of Mr. A. B. Crandall, who has charge of this department. Its reports of the Farmers' Club are the fullest that are given, and if one cares to know how much people can talk and say little, he can find it in the World the next morning after the Club meeting. Other dailies wait a week before they publish the Club reports, and whatever faint sparkle they may have, has subsided.

What We Sleep On, has much to do with enjoyment in and refreshment from slumber. The perfection of a bed consists in its giving support to as much as possible of the surface of the body lying upon it. A straight, unyielding surface touches few points of the curves of the person, and as these must bear the whole weight, aching limbs and restless slumber are often the result. Thick feather-beds relieve pressure, but are not healthful. We have found the woven wire-mattress meet the requirements of a good bed in the highest degree, giving the fullest support by conforming to the body, requiring only moderate covering to insure comfort, being highly elastic, cleanly, durable—in short, a great advance in the art of bed-making.

Drying up Cows.—"I. H. H.," referring to our article on "Drying up Cows" in *American Agriculturist* of December, 1871, and also to "Hints on Work" in same number, where this subject is also treated, asks which course he must take, as a seeming contradiction occurs. There is no contradiction. If I. H. H. wishes to improve his stock in milking capacity, let him follow the course pointed out in the first-mentioned article; if he desires to follow the "old plan," under ordinary circumstances, he will follow that in "Hints upon Work." Another correspondent, "W. A.," indorses fully the course indicated in the article entitled as above. It is certain that improvement may be made in our dairy stock, and we have indicated one way in which it may be begun.

How to make a Heifer Fat, which refuses to eat.—"B. S.," Muncy, Pa. This is a difficult business. The appetite must be tempted. Probably cut turnips, sprinkled with salt, would be eaten, then some mill feed may be sprinkled on them. If this is not successful, give her a half-pound of Glauber salts, followed with a little powdered gentian root and tincture of iron, daily, in something she will take, until her appetite is invigorated.

Suffolk Swine.—"L. H. T." has looked in vain in the columns of the *Agriculturist* for breeders of Suffolk swine. As this is a favorite breed with many, those who have them for sale should take note.

Grubs in Cattle.—Jos. H. Moffat, Colorado, removes "warbles" (the larvae of the cattle Gad-fly) by pressing the swelling between the two thumb-nails, which discharges the grub, and the wound heals. He says, killing them by puncturing, which leaves the dead grub in the skin, causes a sore spot. If forced out in the above manner, the grubs should be destroyed.

Blood and Bone Spavin.—"Jas. D. W.," Carroll Co., Md., wants a remedy for blood and bone spavin. On page 6, *American Agriculturist*, we gave the proper treatment for blood spavin; for bone spavin firing is the only remedy that may effect a cure, but generally it is incurable. Bone spavin is an enlarged growth of the bone of the hock, which the contraction of the skin, by firing, tends to prevent. When a spavin becomes confirmed, it is best let alone.

Large Crocks for Setting Milk.—Mr. Eaton, of Erie Co., Pa., writes to "Ogden Farm": "Your plan of setting milk in deep vessels is not new among the Scotch-Irish inhabitants of Pennsylvania. We use stone crocks holding one gallon each. We have a spring house; set our crocks in spring-water. They are flaring, about one foot across on top, can be bought for from 12½c. to 15c. apiece, will last a great many years if not broken, are easily cleaned, and will not rust in water like tin. We gather our cream in a stone jar, from three or four cows; save about a quart of strippings at a milking, which we strain in a crock by itself, and leave it until the next milking to cool, when it is poured in

with the cream. I may state also that many of our neighbors who have no spring-house use the same kind of crocks to set their milk in their cellars."—This plan we have long been familiar with. It is very different from the "deep-can" system, where even 10 or 15 gallons may be set in one vessel if ice-water is used for the bath. Metal has a decided advantage over earthenware, in the greater ease with which it transmits heat, allowing the milk to cool more rapidly—a very important point.

Hen-Lice.—B. Drake, Lexington, Ky., recommends as a preventive and cure for lice on poultry, a dry sand bath, given in a box 4 feet square and 6 inches deep. Another correspondent, "T. T. F.," says dry, slaked lime is effectual when dusted over the house, nests, and roosts.

Comparative Value of Roots.—"C. S.," Laporte, Ind., asks the value of carrots and white turnips as compared with potatoes at 65 cents per bushel, for feeding to cows or hogs. Carrots ought to be worth 40 cents and white turnips 30 cents per bushel, but at these prices neither could be fed with economy unless hay and corn or other grain should be excessively dear.

Fleas.—"O. E.," Montour Co., Pa., thinks that the abundance of fleas in some localities is due to allowing the hogs to run at large, and that the remedy is to keep the swine shut up and supplied with clean litter.

How to get an Old, Poor Field into Clover.—W. J. Thorn, Juno, Tenn., has an old field, soil red clay, which has no lime in it, and is covered with broom-sedge; he wants to know how to apply lime to get it into clover. After the field is plowed apply 25 bushels of lime per acre, harrow it in, sow a peck of clover seed, and brush it in with a brush harrow.

Black Leg—Anthrax or Splenic Fever.—"A Correspondent" describes the symptoms of a disease affecting the cattle in the neighborhood of Winchester (Va.?). Swellings appear on various parts of the body, which are soft and appear full of blood and water, and on pressure give forth a gurgling sound; after death decomposition is very rapid. The liver is full of green blisters, the gall bladder is filled with bile.—This disease is Anthrax, or splenic fever. Causes, bad food, musty fodder, exposure to swamp exhalations, or impure drinking water. Treatment: Good stables must be provided, dry bedding, pure water, nutritious food, and the prompt separation of sick from healthy animals. Sulphate of soda (Glauber salts) may be administered, and if the animal is not weak, bleeding has been recommended. If the animal is weak, stimulants, such as camphor, whisky, and carbonate of ammonia, are to be administered. The tumors may be opened, and washed with carbolic acid, dissolved in twenty parts of water.

Plants Named.—The following was crowded out by press of matter, but, though late, we publish it to clear our files. Those whose plants are not enumerated, will understand that their specimens were not in proper condition for determination. H. T. Yates, Glencoe, Miss. *Helenium tenrifolium*, or Sneezeweed, a common weed in low lands, at the South. J. B. Fairfield, Hickman Co., Ky. No. 1. *Hibiscus Trionum*, or Bladder Ketmia; No. 3. Some species of *Malva*; No. 5. *Cleome pumgens*; No. 8. *Amarantus paniculatus*, one of the red-leaved Amaranths. The other specimens are too poor to be determined. Lewis Horning, Montgomery Co., Pa. The plant sent is probably a species of *Lycopus*, or Water Horehound. It usually grows in a damp and poorly cultivated soil, and is easily eradicated by good cultivation. J. B. Briggs, Russellville, Ky. *Iysanthus gratioloides*, or False Pimpernel. As this plant is an annual, there is no difficulty in eradicating it, if the meadow is mowed often enough to prevent its seeding. "W. L. W.," Charlestown, Ohio. *Eunymus radicans variegatus*, a very pretty greenhouse and house plant, does well in the open ground during the summer. P. H. Adams, Florence, Texas. *Hibiscus Trionum*. L. F. Tapp, Liberty, Mo. *Christum lanceolatum*, or Common Thistle, and not the Canada Thistle, as you suppose. The Canada Thistle was figured in the *Agriculturist* for 1863. The plant sent is a biennial; its seeds are furnished with down, and they are scattered over a large extent of country by means of the wind. To destroy them, do not allow them to run to seed, and cultivate the land thoroughly. "Chemist," New York City. The plant you call "Ripple Grass" is probably *Plantago lanceolata*, and is quite common everywhere. "M. E. F.," Waltham, Mass. *Euphrasia officinalis*, or Eyebright—a very pretty flower, found upon the White Mountains and northward. "J. B. F.," Clinton, Ky.—No. 1. *Cleome pumgens*. A very pretty, free, flowering annual, with showy, purple flowers, which change to white as they grow old. Further South it is found growing wild. No. 2. *Amarantus panicula-*

lus, has green flowers, slightly tinged with red, of no particular beauty as a flower. No. 3 is the old Bouncing Bet, *Saponaria officinalis*, which is so common around old houses. No. 4. *Hibiscus Trionum*, or Bladder Ketmia, a low-growing annual, with bright, yellow flowers and a blackish eye in the center; it is very pretty in cultivation, but the flower soon drops, whence it has been called "Flower-of-an-hour." No. 5. *Tradescantia Virginica*, or Spiderwort, often cultivated at the North, but a native of the Southern States; it has beautiful blue flowers, which grow in dense clusters, and which open early in the spring. No. 6. *Ansonia salicifolia*. A branching perennial, with small, blue flowers, of no especial beauty. No. 7. *Leptopoda brachypoda*, a coarse growing composite, with yellow flowers.... "J. G. P.," Piqua, O. *Artemisia caudata*, or Slender Wormwood; a biennial with pretty, finely divided leaves, and small, yellowish flowers.... "G. L. C." *Gentiana crinita*, a very pretty plant with blue flowers, opening late in the fall; commonly known as Fringed Gentian.... "Mrs. J. T. W.," Minneapolis, Minn. *Malva crissa*, or Curled Mallow; an annual with small and insignificant flowers in the axils of the leaves.... "W. M. H.," Fairfield, N. Y. *Sicyos angulatus*, One-seeded Star Cucumber; a weed, with fruit covered with prickly bristles.... "M. R. A.," York Co., Me. No. 1. *Smilax herbacea*, Carrion Flower; a climbing prickly vine, which bears black berries. It is called Carrion Flower from the bad odor of its flowers. No. 2. *Trientalis Americana*, or Star Flower; one of the prettiest and most delicate wild-flowers we have at the North. No. 3. *Lysimachia thysiflora*, or Loosestrife; a perennial bearing a spike of light, yellow flowers.... "N. S. W.," Blakeville, N. H. *Goodyera pubescens*, or Rattlesnake Plantain; a member of the beautiful Orchid family.... "E. E. F." No State given. *Kerria Japonica*, or Japan Globe Flower. Described in *American Agriculturist* for February, 1871.... "W. S.," Logan, O. *Gentiana Andrewsii*, or Closed Gentian.... "A. S. M. A.," Franklin Co., Pa. *Soya hispida*; a pea-like native of the East Indies, the seeds of which are used in preparing a kind of sauce.... "M. W.," Lancaster Co., Pa. *Sedum ternatum*. Three-leaved Stone Crop; an old garden plant, but, like all members of this genus, very difficult to destroy when once established.... "F. S.," St. Joseph, Minn. *Medicago maculata*, Spotted Medick.... "Mrs. W. B.," New Haven, Mich. A species of *Tradescantia*, and not the *Myrsiphyllum asparagoides*; a very rapid-growing vine for covering mounds, etc.... "Subscriber," Canaan, Me. *Crassula coccinea*; a thick-leaved plant with beautiful pink flowers, common in greenhouse cultivation.... "R. C. H.," Kingston, N. C. *Quamoclit coccinea*, an annual climber, with beautiful, small, light scarlet flowers. "Miss R. C. McF.," Newton Co., Texas. *Dioscorea villosa*, Wild Yam; a high-climbing vine with handsome leaves, and small, greenish-yellow flowers.... "M. W.," Lancaster Co., Pa. No. 1. *Lilium Philadelphicum*, or Orange Red Lily; an erect, bell-shaped flower, quite common in many parts of the United States. No. 2. *Eriogonum bellidifolium*, or Robin's Plantain; a troublesome weed in grass lands, where very abundant.... "E. A. G.," Willsborough, N. Y. *Solanum Dulcamara*, or Bittersweet; has small, red berries and purple flowers, sometimes cultivated for its handsome berries.

Hand-Thrashing Machine.—"Connecticut" asks if the hand-thrashing machines are to be classed in the "sundry humbugs," that they are no more heard of. Probably not. Still the days of hand labor on farms are run out, and band machines of all sorts are too slow and too laborious to suit the times.

East Tennessee as a Sheep Country.—C. L. Kellog, Braden's Knob, E. Tenn., has been two years on the table-lands of the Cumberland mountains, and finds it very healthy and well adapted for sheep raising. Peaches and chestnuts are plenty, the soil good, and all vegetables and grasses thrive abundantly. Thirty families from the Northern States comprise the settlement. Lands are very cheap and a railroad is soon to pass through the district.

Foul in the Foot.—"F. P.," Pa., has had his cows troubled with sore feet between the hoofs for more than a year, and wants a remedy. Washing with soap and water and applying sulphur ointment, and feeding a table-spoonful of sulphur in salt twice a week, will probably cure this.

The Best Stable Floor.—"F. E.," Salem, Ct., wants an economical and durable stable floor. Chestnut plank would make a very poor floor, being too soft. Oak plank is cheap and durable. A good, cheap, lasting floor may be made by paving with cobble-stones and pounding a mixture of coal-tar and gravel or coal-ashes firmly between the stones. Rats will not penetrate it, and the horses' feet will not cut it up. Coal-tar is very cheap, and one barrel is enough for an ordinary stable.

How to Raise Ducks.—"J. M.," St. Michaels, Md., writes that he and many of his neighbors have found duck-raising extremely profitable, and one of the number has, in fact, made a small fortune at the business. He says the best way is to set ducks' eggs under hens, and commence incubation not earlier than the first of April, and stop not later than June 1st, and claims that ducklings from eggs set later than the latter date can seldom be reared.

Will Hens Lay Half the Year?—"D. B. S.," Brooklyn, N. Y., asks this question. Ordinarily they will not. In some instances they will lay eight or nine months of the twelve. There is much variation, depending on breed and management. It is not wise to base calculations on the remarkable yield of an occasional flock, published far and wide, for the very reason that it is remarkable. Some fowls will lay twelve dozen apiece yearly, but seven or eight dozen is a fair yield. Now, it will be seen that there can be but few instances of fowls laying daily, or two days out of three, during about one hundred and eighty days in a year.

His Apple-Tree.—W. Hayden, Stringer, Kansas. Tent-caterpillars' eggs is what's the matter. Cut off and burn all you can find.

Cions—Grafting.—"J. H. L.," Hancock Co., Ohio. Choose short-jointed, well-ripened wood; "water shoots" are not usually of this character. Grafting wax can be made hard or soft by the use of more or less linseed oil or lard.

Wheat and Chess.—Joseph Weaver, Wayne Co., Ind. Your view of the occurrence of chess is said to be the result of "searching." We can not accept it without specimens to prove it. We know perfectly well that wheat makes secondary roots, but we do not know that the primary roots will, as you claim, produce chess. Let us have proof.

What to do with a Scabby Pig.—"H. S.," has two pigs four months old, of the same litter and kept in the same pen. One thrives well; the other, in spite of repeated washings, gets scabby, or scabby, and appears tight in the skin and poor. "What," he asks, "would you do to set him to rights?"—We have no faith in physicising pigs, but would suggest giving him a table-spoonful of a mixture of sulphur and saltpeter every other day in his food. Add carbolic acid to the water in which he is washed—an ounce to a gallon.

Proper Temperature for Scalding Hogs.—"K.," wants to know how hot water should be to scald a hog just right. A few degrees below boiling heat is best. It is not well to scald too much.

The Value of Charcoal Dust.—"A Subscriber," Camden, S. C., asks the best mode of using charcoal dust as manure. It is of little use directly otherwise than as an absorbent. We at one time burned a large quantity for the ashes, which were more valuable than the charcoal.

Composting Rotten Wood, Leaves, etc., with Liquid Manure.—"B.," Vegetable matter must be kept moist or it will not ferment and rot. The liquids should, therefore, be thrown over the pile, and, if the ammonia escapes, sods or earth may be thrown upon the heap. Pine-wood ashes contain so little potash that they would not injure a compost heap.

Sowing Clover-Seed on Wheat.—"G. A. B.," Prince Edward Co., Va., wants information about sowing clover-seed on wheat, and of laying down permanent pasture. Clover may be sown early in spring, on the last snow, which on melting carries the seed down into the soil; or later, by sowing on the soil when the ground is sufficiently dry to bear a harrow, and harrowing the wheat with a Thomas smoothing harrow, which covers the clover and benefits the wheat. Timothy may be sown at the same time as the clover; quantity, one peck of each.

Disease in Cattle.—"A Subscriber," Charlemont (no State), has some cattle suffering from a complaint which appears as sores, or raw places, mostly on the legs, which heal over, leaving bare spots. This is owing, doubtless, to low condition. Give good food, shelter, and pure water; also salt, in which some sulphur is mixed, for them to lick.

Mexican Ever-bearing Strawberry.—Who can tell us how the Mexican Ever-bearing Strawberry behaved itself during the year 1871? Will some of those pomological gentlemen who allowed their names to be used in its behalf, and those wise editors

who directly charged or mildly insinuated that we knew nothing about the subject, have the kindness to take the witness-stand? We received more abuse for opposition to this strawberry, and from persons of whom we had a right to expect better things, than ever fell to our lot before. We do not retort upon these gentlemen, but merely ask, How about that Mexican Ever-bearing Strawberry?

North Pacific Railroad.—Parties settling on the lands granted to the North Pacific Railroad Company along their line now constructing, can have the priority in purchasing their locations when the lands are brought into the market, and have their improvements thus secured to them. An immense territory of fertile lands is opened to settlement by this road.

Peanuts.—"E. R. P.," The crop requires good land and should form part of a rotation. We have no space now, but will try to give an article in season.

Stuffing Animals.—"J. W.," Billings, N. Y. The proper method of stuffing a quadruped can only be learned by practice. Careful measurements are to be taken of all the parts, and the size and natural position accurately preserved. The limbs and neck are strengthened by wires. Hemp, bran, and fine grass are used for stuffing, according to the size of the specimen. The skin is first poisoned with arsenic. Maynard's Naturalist's Guide is the best work on the subject. Price \$2.00.

Agave Virginica.—In an article in November last we expressed our doubts whether this plant would live after flowering. Mr. J. Williams, of Verona, Miss., writes that it flowers from year to year. We find that our plant has produced buds for another year.

Colorado Potato-Bug.—Some one asked through our columns, some months ago, if the Potato-Bug had, in its Eastern progress, left Colorado. Several have written to inform us that in Colorado it "still waves," but perhaps less troublesome last season than in previous years.

China-trees for a Hedge.—F. A. Looney, Bosque Co., Texas. By China-tree we suppose you mean what is commonly known in Texas as the "Wild China"—*Sopindus marginatus*. We have never heard of its being used as a hedge plant, and as it has no thorns we should not think it would make a very effective barrier. The late Mr. Affleck, who paid much attention to hedging in Texas, gave decided preference to the Cherokee Rose. The Pyracanth Thorn is also very useful. Almost any tree or shrub will make an ornamental hedge if kept properly cut back.

Raisins.—"T. L. N.," Winslow, La. The finest raisins are grapes merely dried in the sun. The Muscatel raisins have the stalk of the bunch partly cut through and are dried upon the vine, the leaves being removed to allow of full exposure. Commoner kinds are dried upon lines and afterwards dipped into a lye to which salt and oil are added. The effect of this is to give the raisins a brown, varnished appearance and to cause the exudation of sugar, seen on common raisins. Grapes that contain sugar enough will be gradually converted into raisins in an airy room, if not packed too closely.

Red-Root.—"C. S.," La Porte, Ind. We believe that the plant called Red-root by "Walks and Talks," is *Lithospermum arvense*, though we could never get him to send us a specimen. It is a most unfortunate name, as the weed is but a local one, while the widely-spread *Amaranthus retroflexus* is known as Red-root throughout the Western States. The common name of *Lithospermum* in England is Gromwell, and as we probably received the plant from there, we ought to take the name with it.

The Period of Incubation.—"B.," Ashland, Va., is positive that a hen of his hatched thirteen chickens from eggs that had been in process of incubation but fourteen days, instead of the normal period of twenty-one days. We would not question his veracity while disbelieving the account. Some person may have stolen the original eggs before they were spoiled, and substituted others that had been set upon for a week. Any reasonable theory whatever is preferable to one that involves a repeal or suspension of nature's laws.

Poultry Books.—"X.," no post-office given, asks us to name the best works on poultry. Our advertising columns afford a sufficient answer. A very modest but sound and reliable book is entitled Saunders's Domestic Poultry, and another, written by a gentleman who stands at the head in English poultry literature, is called Wright's Practical Poultry-Keeper. Both for sale at this office. The *Agriculturist* gives each month prac-

tical information concerning the management of fowls, and is in constant communication with some of the most extensive breeders in the country.

Degrees of Frost.—"J. W. F.," asks what is meant by ten or any other number of degrees of frost. We never heard any but an Englishman make use of the term, and it means the number of degrees below the freezing point. Ten degrees of frost would be 22°.

Citron.—"F. W. M.," Sacramento, Cal. The citron of commerce is the candied rind of a fruit resembling the lemon, but it is much larger and the rind very thick in proportion to the pulp. It will grow wherever the lemon and orange can be raised. The citron that "grows upon a vine" is a kind of watermelon, and can not be made into a substitute for the real thing.

Apples and Pears on Wet Land.—F. A. Looney, Texas. If your land can not be drained plant your trees upon the surface, put soil enough upon the roots to hold them in place, and then plow furrows towards the trees upon both sides. This will leave the trees upon ridges with trenches between the rows.

Mailing Seeds.—"C. S.," La Porte, Ind. If you wrote the labels upon the seeds, the postmaster might, by a very strict construction of the law, collect letter postage. A liberal view is generally taken of the law, and written labels are allowed by almost all postmasters. The label is regarded as a part of the seed.

Grafting.—"Subscriber," Dover, Del. The chestnut is very difficult to graft in the ordinary way. Success is most likely to follow grafting below the surface of the ground, as this would keep the cion and stock from drying. Peaches are seldom grafted; the wounds exude gum and are very difficult to heal.

Grafting Mineral Fertilizer.—This puzzles us. From the chemical analysis we should judge it to be nearly inert. Still those who have tried it, among them persons for whom we have respect, say that it is useful. Science and practice seem to be at variance in this case, and we allow it to be advertised with the distinct understanding that the analysis shall be given.

Minnesota and its Productions.

We lately inspected samples of grains and roots—potatoes, carrots, beets, turnips, and kohlrabi, with cabbages of enormous size, cranberries, and some fair-looking apples, all the product of the extreme northern part of Minnesota. Heretofore that country has had the character of being snow and ice-bound for the greater part of the year, and it seems to have been one of the special offices of the great railroad which is now constructing through our North-west territory, to remove from our minds the impression of the sterility of these vast tracts of land. Certainly the immense size of the roots and the plumpness of the wheat, barley, and oats, brought from near the western shores of Lake Superior, remove all doubts as to the agricultural capabilities of this part of Minnesota. Minnesota is but a young State, as yet; still with her fertile soil and enterprising population, aided by the various railroads now crossing her territory, and her very salubrious climate, she has made an excellent position among her sister States, which every year doubtless see improved.

Bee Notes for February.—By M. Quinby.

Hives that are out-doors should be raised when a warm day loosens them from the bottom, to see if the mice are nibbling the combs or destroying the bees, and all droppings swept off. Mice, if busy, should be trapped. Let such hives as are to have their location changed, be moved now, before the bees fly out. Give plenty of room between the hives—ten feet, if convenient, is none too much. Have a separate stand and roof for each hive. Bees are moved in a sleigh better than in any other way. Wagons with elliptical springs are next best. If bees are to be confined to the hive more than twenty-four hours, put over wire-cloth, instead of muslin. Shade the hives in bright sunny days, when there is a light snow on the ground. When it has thawed sufficiently to bear the weight of a bee, let them fly.

Bees that are housed should not be confined to the hive and removed to a distance, without first being set out on a warm day and allowed to fly. Those out-doors can be moved at any time. In purchasing bees, look out for foul brood, and be careful not to bring it into a neighborhood that is exempt from the disease. It is contagious and spreads rapidly. In twenty years we have learned nothing

new concerning this trouble. What I then said about it has only been confirmed, and what was recommended has been successful, with us at least. We rid ourselves of it by destroying the contents of every affected hive. Our near neighbors have not brought in any from abroad, and we expect to remain free from it until they do. Movable combs will allow close inspection of every comb. When every neighborhood is sufficiently informed, and will reject every diseased stock, foul brood will be among the things only heard of. Those expecting to make the most from their bees, must make themselves acquainted with the mel-extractor, its advantages, use, etc., and find another great advantage in the movable combs. Study the subject—Bee Culture—now, before work occupies the entire attention. The field for discoveries is extensive, and to a great extent unexplored.—[Mr. Quinby's "Mysteries of Bee-Keeping" still continues to be the standard work. See Book List.—Ed.]

Books Noticed.

Proceedings of the Pennsylvania Fruit-Growers' Society, 1871. A volume of less than 100 pages, but contains more than much larger reports often do. An address by President Hoopes, a paper on Pear Culture, by Mr. Satterthwaite, and one upon Insects Injurious to the Apple, by Mr. Rathvon, are among its contents.

Treatise on Ventilation. Comprising Seven Lectures, delivered before the Franklin Institute, Philadelphia, by Lewis W. Leeds. New York: John Wiley & Sons. This seems to be a thorough discussion of a most important subject and is copiously illustrated.

Smithsonian Report. The Annual Report of the Board of Regents of the Smithsonian Institution for 1869, with the moderation that becomes books printed at the Government office, has just reached us. The scientific papers attached to the report appear to be more than usually interesting.

American Home-Book of In-door Games, Amusements, and Occupations. By Mrs. Caroline L. Smith (Aunt Carrie). Illustrated. Boston: Lee & Shepard. This is, with one exception, a capital work for young people. It is full of games, new and old. The book would have been much better if the stuff about the Toilet, which is worse than useless, and the matter relating to sick-rooms, had been omitted.

Fireside Science. A Series of Popular Scientific Essays upon Subjects connected with Every-day Life. By James R. Nichols. New York: Hurd & Houghton.

The New York Observer Year-Book for 1872. Sidney E. Morse & Co., New York. \$1.

Independent Sixth Reader. By J. Madison Watson. New York: A. S. Barnes & Co. \$1.50. This seems to be a very judicious selection from the writings of authors from Shakespeare down to Greeley.

The Department of Agriculture—Report for 1871.

Mr. Capron resigned his position as Commissioner of Agriculture, to take office under the government of Japan, and Mr. Frederick Watts, of Pennsylvania, was appointed successor, and assumed the duties of Commissioner in August last. All that we know about Mr. Watts is, that he is highly esteemed in his own locality, as an excellent citizen and a good farmer; that he is over seventy years of age, and that he was President of the Board of Trustees of that much mismanaged institution, the Agricultural College of Pennsylvania. The appointment having been made and confirmed, nothing is to be said upon its fitness. The public acts of the officer and the official documents emanating from him are proper subjects of notice and criticism by the agricultural press.

In his first report Mr. Commissioner Watts labors under two difficulties: he has nothing to say, and he takes 14 pages to say it in. We do not often meet with so much commonplace, even in government reports.

Upon page 4 of the Report we find the following:

"It will be remembered, that by the act of the 2d of July, 1862, Congress donated to the States public lands to 'provide colleges for the benefit of agriculture and the mechanic arts.' This was a new and important era, and may be said to mark the beginning of scientific knowledge as it pertains to agriculture."

If this language means anything, it means that previous to the year 1862 there was no "scientific knowledge as it pertains to agriculture," but that this knowledge had its beginning in that year. Later in the report, the Commissioner, in speaking of the works in the Department library, says, "Many of them are not accessible in any other library in the country." It must have been from some of these remarkable books that the Commissioner

obtained this remarkable information in regard to "scientific knowledge as it pertains to agriculture."

Those who read only accessible books, suppose that Davy, Berzelius, Liebig, Boussingault, Way, Johnstone, Voelcker, Lawes, Gilbert, Pugh, and a host of others, long before 1862 contributed something to "scientific knowledge as it pertains to agriculture." But the head of our Department of Agriculture says differently, and he ought to know. We are informed that the various literary colleges spoil farmers' sons, while the agricultural colleges turn them out good boys, willing to stay upon their fathers' farms. Neither of these propositions is sufficiently established to make it safe to assert it in an official report. Detraction of "universities, colleges, and schools" seems to be a hobby with Mr. Watts. He was "down on them" in 1864, and is after them again in 1871.

In the report of the Board of Trustees of the Agricultural College of Pennsylvania to the Legislature, for the year 1864, and signed by Frederick Watts, President, we find Mr. Watts's views, and that they are unchanged in 1871, is shown in his report as Commissioner:

PRESIDENT WATTS IN 1864.

"The individual members of the Board of Trustees have labored assiduously for several years to establish a school, where an education may be obtained which will qualify farmers' sons intelligently to pursue their fathers' business. They have been influenced by the belief that this object can not be attained at any of the literary colleges of our State; that the knowledge and habits which they impart disqualify youth for such pursuits, and thereby defeat the object of the parent, and add nothing to the interests of agriculture. Our experience teaches us, that a farmer's son, graduated in such an institution, finds no place, ever after, in the domestic circle of his family; he is actually driven, by his education, into the necessity of resorting to some neighboring town, in pursuit of a learned profession, where he soon forms habits of idleness and intemperance; and the result is, that the father not only loses the expenses of his education, but the son himself."

Warmed-over dinners are often necessary and tolerable, but are not we entitled to something better than warmed-over reports?

We have not time to notice the Commissioner's peculiar views concerning Agricultural Colleges; but we think it will be long before they send the results of their experiments to Washington to be worked up, as he suggests they do.

The Commissioner thinks that the Annual Volume should not be published, in which we can only in part agree with him. In the main, the Annual Reports for the past few years have been creditable and useful, and if the Commissioner's suggestion that they be placed on sale at cost be adopted, the objection of free book distribution at Government expense would be removed. But the Commissioner proposes to run opposition to the agricultural journals by means of his monthly reports. In referring to the foreign journals received at the Department he says: "They furnish the results of the very latest investigations in entomology, botany, agricultural geology, and microscopy, as well as experiments in agriculture, which could be abridged and published in the monthly reports of the Department before they could be reproduced by the agricultural journals of the country." How do our brethren of the press like this?

The seed business is to be continued in its objectionable features, and, instead of pints and quarts, bushels and half-bushels of grains are recommended. We are in favor of a properly managed distribution of seeds. New varieties, not yet in commerce, may be obtained by the Department and distributed, but we do object—and so does every right-thinking man—to furnishing to Members of Congress, at public expense, innumerable packages of seeds with which to court favor with their constituents. These seed packages are a thorough fraud; they contain the seeds sold everywhere, of the commonest sorts. It is a flagrant injustice to the seedsmen, and no one can tell why Government should interfere with their business any more than with that of the druggist or grocer. If we

are to have a general free seed distribution, let us have one also of family pills and spices. Let us also have the hoes, and rakes, and all other implements necessary to cultivate the plants sent by mail with the seeds. The "Tabular Statement" of seeds sent out includes under "Cereals," 113 varieties of vegetables and 54 varieties of flowers. In the same table, under "Textiles," we have peanuts. We once knew a pompous man who spoke of a potato as an excellent condiment, but it takes an official report to call a peanut a textile. We might show up more of the weaknesses of this weak report, but we leave it with a feeling of melancholy that the official representative of American agriculture should make so poor a showing. We have no high hopes for the Department of Agriculture under its present administration. We await in patience further developments. It may be that one who makes a weak report with his pen may prove a good executive officer. One of these days the farmers will make themselves felt; then the Department of Agriculture will be quite different from what it ever has been.

Maple-Sugar Item.

BY W. I. CHAMBERLAIN, HUDSON, O.

Last spring, in painting a lot of new covers for sabbuckets, it occurred to me to make one side red and the other white. The object is this: in gathering sap where the trees are close together, and of course not in rows, it often puzzles a man to tell which trees he has visited. It is harder still, if two or three men gather to one team, or when you have to go and empty the barrels, or when night suspends the work unfinished until the next morning. The best local memory needs some help. Now, if when tapping you place all the covers red side up, for instance, and at the first gathering turn each cover white side up when you take the sap from its bucket, there never will be any uncertainty. You never will need run to a tree the second time, nor miss one. You can tell ten rods off, by the color of the cover, whether there is sap in the pail. Each gathering will change the color of all the covers. If one does not wish the expense of painting and painting both sides, a simple "dab" of red paint one side will answer the purpose. One stroke of the brush will do. Still, the covers ought to be planed and painted on both sides, to keep them from soaking water, and from warping in the sun; and they can just as easily be painted different colors on different sides. They ought to be turned over, too, at each gathering, or they will warp in time, even if painted. So this device makes no extra expense or work, and saves many steps and much leaving of sap. It is not patented, but saves more labor and loss than many devices that are. The more it is used by sugar-makers, the better I shall like it.

Another improvement I have lately made. Instead of the barrels for gathering sap, as given in the article and engraving (*Agriculturist*, Feb., 1870), I have a cask, six feet long and about 30 inches in diameter. It holds four barrels, and this full on a light stone-boat sled makes sufficient load for a team on bare ground. It tapers slightly towards the front end of the sled, so that when the top is level, the sap will drain completely from the bottom of the hind end. Here is a large iron faucet, and a tin conductor runs the sap down the side-hill into the store-troughs. This saves the time and labor of rolling the barrels up over the troughs to empty, and keeps all dirt and mud from falling into them from the outside of the barrels. With these improvements and the apparatus and methods described in the articles in February and March, 1870, and February, 1871, a man can make first-class syrup, rain or shine, cold or hot, through the entire season, and sell even that made late in the season at \$1.50 per gallon, when ordinary syrup will hardly bring \$1.00.

Sending Poultry to Exhibitions.

It has been customary in this country to send fowls and other poultry to the fairs in the same coops or cages in which they were to be displayed. Exhibitors have been expected to provide their own exhibition coops, and personally to attend to the wants of their poultry. Happily, we are now on the eve of a great change in this respect. The old system was fraught with danger to the poultry, and with both inconvenience and unnecessary expense. Before speaking of a better plan, we allude to some of these disadvantages. (1.) If the coops look well, are well made and strong, they will be quite costly. (2.) They will be liable to be broken and otherwise damaged by the careless handling of expressmen, railroad men, and car-

men. (3.) Unless they are lined with cambric muslin, the fowls are liable to be handled, poked at with sticks, and to have their feathers pulled

Fig. 1.—BOX FOR TRANSPORTING POULTRY.

out, etc., by mischievous boys or men. (4.) The poultry are in a constant state of excitement, seeing everything that goes on. (5.) They feel every draft, and are chilled by the constantly changing air. (6.) The coops are far too large for traveling boxes, and as they are carelessly tossed about, the fowls are thrown or

Fig. 2.—INSIDE OF BOX.

slide from one side to another, breaking their feathers, if not getting bruised. (7.) A large percentage usually arrives sick with colds, and the roup is almost sure to follow colds taken in this way. Colds pass into roup most rapidly and imperceptibly; especially if there be a roup fowl within a moderate distance. (8.)

Fig. 3.—HASP.

The coops of different breeders are recognized by persons familiar with our poultry shows quicker than the fowls, which effectually prevents that ignorance on the part of the judges as to the exhibitors which is considered so important. These are by no means all, but they are the principal disadvantages of the old system.

The N. Y. State Poultry Society, according to the prize schedule, rules, etc., before us, does much to abolish all this by providing exhibition coops, and not permitting exhibitors to use their own. This does away with the last objection (No. 8), and a very serious one it is. As for the other seven, the individual exhibitors are responsible for them; being no longer required to bring their own show-coops, they may place their poultry for the journey in as comfortable boxes or hampers as they please.

Fig. 4.

We describe some which are within the means of everybody. First, fig. 1 is a cubical box which, if intended for large Asiatic fowls, should be about 20 inches every way. The material may be five eighths to three quarters

inch spruce, larch, or pine, if lightness is a requisite, and it should be planed on the inside, and put together as close as possible. One entire side of the box is a door; in the door is a 5 by 5 window, covered by woven wire, nailed on upon the outside. Upon the door the feed and water holders are attached, as seen in fig. 2, so that the light from the window will fall full upon the water and the grain. In the middle of the top a hand-hole is cut of sufficient size to admit the fingers of a large man's hand. The door may be hung upon a pair of common butts, and the simplest and best fastening is made by taking a piece of stiff loop-iron and punching three holes in it, as shown in fig. 3. This is attached by "clout nails" or screws to the side of the box in such a way that the end containing the hole at the left hand will project through the door a little way from the edge; this hole is supposed to be large enough to receive a padlock.

The water-holder (fig. 4) is simply a common junk-bottle, inverted into a small tin-cup, and held suspended by wires, so that its mouth will not touch the bottom of the cup; both the cup and the bottle being attached to a piece of board which may be fastened by two screws in its place upon the door. There is little or no danger of the bottle breaking from frost, if a sound bottle is selected, the form of which is slightly conical. The water may freeze solid in such a bottle, provided it is inverted, and it will not break.

The feed-box (fig. 5) is made by taking a piece of board, 5 inches wide by 12 long, nailing a piece 3 inches wide, having the front corners rounded off, upon it at right angles, about an inch from one end; and then, first taking a sheet of tin, 9 inches long and 8 inches wide in the clear, that is, after allowing for the lap sufficient to nail in, say half an inch on each side, tack it upon the sides of the board, beginning half an inch from the top. It will form an arch or half-cylinder, extending to within an inch of the little board at the base, around which bottom tack a piece of tin, the upper edge of which has been turned over, extending a little higher than the bottom of the half-cylinder. This will hold

Fig. 5.

Fig. 6.—POULTRY HAMPER.

corn enough for a trio of well-fed fowls for three days upon a journey.

When the fowls are transported, the floor

should be covered with dried earth and clean straw, the birds well fed, sponged and cleaned, put in dry, and locked up. If care is taken in the construction to leave no slivers or rough edges of tin, ends of wire, or screw-heads, the feathers will not be harmed; the birds will be quiet, they will not catch cold, nor freeze their combs or feet in severe weather, and so all the objections from 1 to 7 may be avoided by this simple traveling box.

Fig. 6 represents a common hamper of willow-ware, easily made by any one familiar with the first principles of basket-making. When used for transporting fowls, it should be lined on the top and sides with cotton cloth, tacked in with strong thread. The water and feed vessels may be easily attached to the sides.

Fig. 7 is inserted as a suggestion. It represents one of the large baskets made for the use of paper-box manufacturers. It would be very easy to place in cross-pieces resting upon those strands which are woven in to strengthen the sides in the middle, and to lay upon these cross-pieces a movable floor made of thin wood or wicker-work, dividing thus the basket into two stories. Each of the stories might again be divided into two or three compartments by

Fig. 7.—PAPER-BOX-MAKERS' BASKET.

partitions of sacking or of strong cotton stuff, which should be carried also around the outside. With plenty of straw, feed, and water, several trios might thus be sent by express at a cost not exceeding that required to send one or two in exhibition coops.

Ogden Farm Papers.—No. 25.

When my autumn work was well advanced, and I could spare a little time away from home, I indulged in that most profitable of all pastimes for a farmer—a little foreign travel. Without much thought of "agriculture," only bent on having a good time, I went to visit some friends in Montreal, with an eye to the cheap clothing and French Catholic oddities for which that charming old town is noted. My friends thought to entertain me by showing me some of the farms in the neighborhood of the city. Not to seem rude, I made no objection, but I went, with some indifference, to see what the colonial agriculture was like. I came back a wiser man than I went, and, if the truth must be known, a sadder one; for I must frankly confess that I saw among the British settlers of Canada better farming than I had hitherto supposed to exist in America.

I might fill several columns with general observations as to the farming of Mr. Sheldon Stephens, Mr. Shedden, and other worthy examples, but I believe it will be more useful to my readers if I describe somewhat in detail a single instance of good agriculture, which seemed to be more strikingly suggestive than the others for an av-

erage American farmer, because it is an instance in which a laboring man, by the aid of the best processes, has worked out his own success without the aid of the large capital that, for our purposes, vitiates the experiment in so many instances of the more conspicuous farming in Canada as well as elsewhere.

The case to which I refer is that of Thomas Irving, the tenant of Logan's Farm, on the high ground immediately north of the city of Montreal. I was so much struck with his success as a farmer—I trust I shall not offend my patriotic readers by saying that he is a better farmer than I have seen elsewhere—that I have taken pains to investigate, so far as I could, the causes of his success; causes which may all be summed up in the one expression, Thoroughly good and faithful high farming. He came to Canada a healthy, stalwart young Scotch plowman in 1848, with his trade for his fortune. He soon became the manager of the farm, and in 1860 he commenced to carry it on on his own account as tenant. From that time until now he has had, so far as I could learn, no special advantage that any honest, industrious, thrifty, and intelligent laborer can not always command. That is, he was trusted by his landlord, and was given facilities for carrying on his business in a profitable way, even before he became, as he is now, a rich man. How rich he is, what rent he pays for his farm, what profit he makes year after year, I had no means of learning, nor would I have a right to report it if I knew. I did learn that he is an entirely satisfactory tenant, and that he is considered, even among the larger farmers of Canada, as more than "forehanded." The impression I received was that he has probably accumulated more money than falls to the lot of one farmer in a hundred thousand in the United States, and the only source of income that he has ever had has been the savings of his own wages while he was laborer or foreman, and his legitimate profits as a farmer since he became a tenant.

The exact amount of land under plow and in grass is 240 acres. Of this, 124 acres was last year in grass, and 116 acres under the following crops: Wheat, 20; barley, 10; oats, 40; corn, 3; horse-beans, 2; flax, 1; potatoes, 30; carrots, 3; mangolds, 4; turnips, 3. The grain-crops had not been thrashed at the time of my visit, but there had been stored 8,000 bushels of potatoes (besides 5 acres sold green in August), 2,400 bushels of carrots, 4,200 bushels of mangolds, and 2,100 bushels of turnips. The season for the latter was unfavorable. The stock on the farm consists of 15 horses and colts, 31 head of the choicest bred Ayrshire cattle, 20 Leicester sheep, and 15 swine. Of the horses, 11 are enormous thorough-bred Clydesdales, weighing some 1,500 pounds each. Three teams are kept for farm-work, and one for market. *The number of hands employed the year through is eight.* In spring, hay-time, and harvest, these are increased as the work may require, sometimes to twenty hands, including women.

Mr. Irving has imported on his own account five Clydesdales—three stallions and two mares; two Ayrshire bulls, "Robbie Burns" and "Lord Douglass;" and several heifers.

Being a good business man, Mr. Irving is a large exhibitor at agricultural shows, and he gave me a list of premiums taken at Kingston and Quebec in 1871. At Kingston he took seven first prizes on live-stock (including the herd premium for Ayrshires), and ten other premiums. At Quebec he took thirteen first premiums, and eleven others. He was also a large prize-taker at the Montreal Horticultural

Show. It is by no means to be understood that he is such an exceptional farmer in Canada that all these honors befell him as a matter of course. There are plenty of others as good as he, and the competition has always been so sharp as to give a real value to the prizes. Neither have I mentioned his case so particularly because it is a very unusual one in Canada; only because it is the one that seems to carry the plainest lesson for American farmers. Here is a man, brought up in the most laborious walks of his profession, full of practical shrewdness and dearly-bought experimental knowledge, who, on a farm of 240 acres—acres that are for five months of every year buried under the snow—keeps a much larger force of men and teams than any purely practical farmer in the United States with whom I am acquainted would dream of doing, who studies his *North British Agriculturist* as though he had never heard book-farming laughed at, and who devotes his money and time and skill and energy to working out in his own business every suggestion he receives, from whatever source, that commends itself to his judgment as worth trying. If ever there was a "book farmer" and a "high farmer," Mr. Irving is one; yet his fields, and his barns, and his stables, and his root-cellars, and—if the stories that are told of him are true—his "stocking-heel" especially, all mark him as a more thoroughly practical farmer, and a much more successful one, than we are accustomed here to see. I went more than once to his farm, and endeavored to find what "secret" might underlie all this success. For all that I could see, it is only the old, old secret of a good business well followed. The land is not very rich, and it lies so flat that, being heavy, it has all to be worked in narrow "lands" to keep it dry.

It is more a Scotch farm than an American one. Scotch horses, Scotch harness, Scotch plows, and Scotch plowmen turn the furrows with a precision and uniformity for which the farmers of North Britain have always been noted; and all of the details of the business, in the fields and about the buildings, had to me a very foreign look. There was everywhere the evidence of a large capital being employed, and of far greater attention being given to a workmanlike completeness of all farming operations, that is at least unusual with us. It was really a source of regret with me that I was not so situated that I could commence my farming life over again, and learn the art in so systematic a school.

The crops are all good, and uniformly good, but none of them very remarkable, except for the absence of very poor yields; the average is very high, because there are no poor crops to reduce it. The animals are well chosen, well bred, well cared for, and bountifully fed. The home-made manure is abundant, and purchased manure is easily accessible. If I were farming in Canada, on a similar soil and in a similar location, I should be glad to do as well as Mr. Irving does; yet I fail to see anything, either in the location or in the soil, any better than I have at home. It is true that labor costs him only half as much as it costs me, but the same products would bring nearly twice as much with me as with him. My buildings are as good as his, and I have as good facilities for obtaining manure. In applying his measure to my own results, I see no recourse but frankly to confess that he is a very much better farmer than I am. My only consolation is a conviction that if ever I shall become as good a farmer as he is, my success will be as great. Consequently, all that I saw and what I have tried to de-

tail for the benefit of my readers is entirely applicable to the circumstances of us all; and it is a not inappropriate end of my reflections to think that the best way "To Keep the Boys on the Farm" would be to have them realize that well-regulated and skillfully managed farming is here shown to possess every advantage that they can hope to gain from professions which are erroneously considered to be more learned, more worthy of an intelligent mind, and more profitable than good farming.

I came home from Canada late in November to find the winter closed in, in dead earnest, a month earlier than usual, and the work we are accustomed to leave in our moderate climate for December, all thrown at sixes and sevens. We have had a hard time in sowing some crops that we ordinarily gather at our leisure, after others, farther from the sea-shore, have gone into winter quarters. However, thanks to our facilities for steaming food, we have commenced our winter diet without much checking of our yield of butter, which, even in the coldest weather, did not fall below sixty pounds per week; and is now, as the cattle are eating their winter rations more eagerly, increasing week by week.

I have arranged to have my cows come in as far as possible in April and May, but some of them are always out of time, and three have calved since August. Two others are due in January, and although these are all young ones, and the better cows are fast going dry, I hope that copious feeding will enable us to keep up our full product.

I have found less trouble than I anticipated in curing my corn-fodder. It was bound in large stooks in the field, and we took pains to keep it up until winter feeding commenced. Then, in hauling in, we always took first that which stood the least securely and was in danger of being injured; never hauling in more than five loads at a time; but this quantity, stored ten feet deep in the mow, has shown no tendency to heat. At this writing (Christmas) we have a month's supply still standing in the field, where it has withstood many storms of snow and rain without the least injury, keeping in perfect condition.

This corn was cut when in full bloom, much of it ten feet high, and when the stalks were so hard that as green fodder only the leaves and tops were eaten. Now, the rind seems to have been softened in curing, the pith is almost as sweet as sugar-cane, and the cattle eat it greedily to the butts when it is given to them whole. Cut and steamed with bran, they eat it to the last particle, licking their mangers clean. For a month past they have had no hay whatever (as its price is inordinately high) only corn-stalks and cured oats cut up together as the basis of the steamed food. They were never in better condition.

An Egg Farm.

BY H. H. STODDARD.—Tenth Article.

When poultry are kept upon a large scale they can obtain but few insects, for the latter are attracted and supported by vegetation, of which there is next to none near the adult fowls, though care is taken to rear a part of the chickens among growing crops. The ample grounds around each station house, and the areas inclosed by the yards for sitters and for breeders, give space to secure cleanliness and

exercise, but that is all. As far as affording insect-foraging is concerned, a paved court in a

Fig. 1.—SOUTH ELEVATION.

city, or a continuous rock, would be about as good. Ground room out of doors, upon our farm, whether inclosed in yards or not, is solely for air, sun, and exercise. These secured, it matters not whether there is more or less space, so long as there are no insects to be procured. We hear much about the number of fowls proper to an acre of ground; some say 50, and others 100; but in order to give a 100 good forage they should have the range of no less than 4 or 5 acres, containing grass and a variety of other crops. Now, if we give up as impracticable, as we must, pasturage of this sort, and afford nothing but a field entirely bald, save for a few patches of clover and such other vegetables as may be plucked when young and tender by the birds, under such circumstances one acre is as good as four. We go further, and say that 15 or 20 rods of ground, and the grain for the fowls buried to induce exercise, will answer the purpose better than an acre without such an artificial provision of natural conditions. But the feed, which must be all brought to the fowls, costs in money if purchased, or in labor if raised upon the cultivated part of the farm. In fowl-keeping upon a small scale, where one flock has for a range as large a portion of a farm swarming with insects as they choose to travel over, food is obtained for nothing. The food for fowls is more expensive than that of any other live stock in proportion to the value of the animals themselves, necessitating economy in its choice. There are many things "good for" fowls, but we must use principally

Fig. 3.—GROUND PLAN.

those only which supply all the needful nutritive elements, and are at the same time the cheapest.

There are three classes of articles in which the natural and indispensable diet of fowls con-

sists; grains or seeds, green plants, and insects. Corn and wheat-shorts should be the main reliance to fill the first division; boiled potatoes and raw cabbage in winter, and newly-mown grass in summer, are the most suitable vegetables, and chandlers' scraps and butchers' waste, procured fresh, are the most economical animal food, excepting near the coast, where clams and various sorts of fish can be obtained at a trifling cost. While depending mostly upon the above, because they are the best and cheapest, a great many other things must be given occasionally for the sake of variety, such as oats and buckwheat, both ground; rye; barley; wheat; brewers' grains; various vegetables, such as carrots, beets, and yellow turnips, boiled and thickened with corn-meal or wheat-bran; raw onions, chopped fine; and for animal food sometimes young calves may be obtained from milkmen at a low price, and the carcasses boiled and fed. It must be an invariable rule to give every bird, whether young chicken, layer, sitter, or fattening for the table, a portion in each of the three divisions—grain, fresh vegetable, and animal food—every day in the year. It has been asserted by some that there is no

The south elevation of the granary and cooking-house, fig. 1, shows the manner of making a "side-hill barn" on nearly level ground, the object being to drive the wagon containing dry earth to as high a point in the building as possible. The drive-way is made of masonry and earth, excepting near the building, where a wooden bridge is substituted. A corresponding drive-way at the north end, shown in fig. 2, enables the team to pass out without backing. The dotted lines in figure 2 indicate the floors *A A*, which follow the inclination of the drive-ways till the level space *B* is gained at the center, where is a trap *C*, through which the earth falls into a hopper-shaped chamber, as mentioned in our third article. For filling the corners there are additional trap-doors at *D D*. This chamber or bin slopes at the bottom, the position of a part of which is shown by the dotted lines *E E*, which converge at the point *F*, where is a slide-door, through which the contents are discharged to be carried to the stations, the wagon being backed for the latter purpose through the doors *G G*. West of the room, where the dry earth is discharged into the wagon, is a bin for potatoes, etc., built of

Fig. 2.—EAST SIDE OF GRANARY AND COOKING-HOUSE.

substitute that can fill the place of insects for poultry. We say that beef and mutton are as much better, as oats are better than grass for horses of which much work is demanded. A partridge or a wild jungle fowl can produce her normal number of eggs from forest fare, but not such quantities as are laid by a White Leghorn or Houdan. Two thirds of the grain fed must be ground. The natural mill of a fowl's gizzard, containing hard gravel for mill-stones, is capable of grinding all sorts of grain perfectly, but at too great an expense of muscular exertion which, though involuntary, is severe, and employs force that had better be used for growing eggs or flesh. One half of the feed for both grown birds and chickens is cooked, because more easily digested, and because less is needed. We should cook it all only for the fact that a part raw is preferred by the fowls.

The building which contains the cook-room must also store the grain and vegetables where they will be handy, and dry earth is kept at the same place, because in connection with other apartments a receptacle may be most economically constructed, which shall admit of labor-saving in the unloading and reloading of so heavy an article.

thick stone walls, to prevent freezing. This bin is filled from above by driving a load of roots to the floor *B*, and allowing them to slide down an inclined plane. The cook-room, with which the window *H* communicates, occupies the north part of the lower story of which fig. 3 gives a ground plan. *I*, cook-room with its outside (north) door *J*. *K*, grain-bin entered at the door *L*. The root-bin is at *M*, and entered at the door *N*. The cook-room is used in winter as a place in which to dress fowls, and contains also a work-bench with tools. The cooking apparatus is at *O*. There is no chimney proper, but only a chimney-top supported by strong timbers near the peak. A brick flue rises from *O* perpendicularly as far as the eaves, terminated by an ordinary stove-pipe, which conducts the smoke to a large drum in the upper room, and from thence to the chimney-top. In this way the garret is warmed to accommodate in February a few of the early chickens. The south wall of this nursery apartment is well glazed—see fig. 1. Enough late fall chickens of the half-blood sitting variety are raised to tenant it during December and January. The dimensions of the building are 36 by 30 feet, with 18 foot posts.

Venus's Flower-Basket.

The beautiful object represented in the engraving was some years ago only known in rare collections, and it was a long time before its real nature was ascertained. To ordinary inspection, it appears like an exceedingly ingenious arrangement of spunglass, its fibers being, like that, brittle and transparent. Few would suspect it to be a product of the sea, and much less a sponge, or rather the framework or skeleton, so to speak, of a sponge. For a long time it was a matter of doubt whether sponges should be considered as animals or vegetables, but now their animal nature is well established. Sponges belong to the division of Zoöphytes, which includes so many obscure forms of

animal life. The living part of the sponge we seldom see; it is a gelatinous substance, which is supported and strengthened in several ways. The common sponge of commerce is the fibrous-horny skeleton of certain species of what are called horny sponges, the gelatinous portion having been removed in preparing it for market. In other sponges the gelatinous body is supported by spiculæ of lime of various forms. Others, again, have a skeleton of pure siliceous—the same material as quartz or flint; to this last class the Venus's Flower-basket belongs. Sponges may be multiplied by division; if cut in two the parts will grow, and each form a perfect sponge. Their usual way of propagation is by budding. Gemmules or buds sprout from the body of the sponge, and are finally detached; these young sponges are able to swim about by means of vibratory hairs, or ciliæ, and when they find a suitable place they attach themselves and commence to grow, never moving afterwards. The form of the Venus's Flower-basket is shown in the engraving, which is photographed from a specimen belonging to one of our associates. It is generally about a foot long, and two inches wide at the top. It is usually somewhat curved, and has been compared in shape to a cornucopia. In growing it stands as shown in the engraving. At the base the glassy threads are separate, and include sand and other extraneous matter, showing that the sponge was anchored at the bottom of the sea by this portion. From below the middle to the top there arise from the surface elegant ridges or "flounees," as they might be termed, arranged diagonally with the squares of the network of the body. They are of the same material as the rest of the structure, and appear to be for the purpose of strengthening it. The top of the "basket" is covered by a network of glassy threads, crossing in various directions, but leaving numerous openings,

so that it looks somewhat like the cover of a pepper-box. When we examine the body of the structure with the unassisted eye, we see bundles of glassy threads, running longitudinally about an eighth or three sixteenths of

MANTIS CRAB.—(*Squilla empusa*.)

an inch apart. These threads are crossed by similar horizontal ones, dividing the whole surface into more or less regular squares. Then smaller threads cross these square meshes at the corners, giving the whole—to compare a de-

given to show the structure more clearly. The individual threads appear precisely like spunglass, and like that can be bent to a certain degree. A chemical examination shows them to be pure siliceous. Moderately magnified, the threads are seen to be variously branched, the branches forming junctions with those from other threads. After exposure to heat, the threads when examined by a high power are found to consist of concentric layers, one deposited over another. Although the individual threads are transparent the structure that is formed from them is not so. In this, as with spunglass, the action upon light is such that transparency is lost, and the whole has a delicate satiny luster. The first specimens were brought from the Philippine Islands, but it is now said to be found in other localities, and it is occasionally offered for sale by dealers in curiosities. We believe that naturalists have not yet had the opportunity of examining this interesting sponge in its complete state. The scientific name is *Euplectella speciosa*. The generic name, Euplectella, is from the Greek words, meaning *well*, and *to plait*.

The Squillas or Mantis Crabs.

A rather rare member of the family of Crustaceans (to which the crab and lobster belong) was brought to us not long ago by a gentleman who lives upon the coast of Long Island. It is so curious in its structure that we give an engraving of the animal. At first sight it resembles a small lobster, four or six inches long, but differs from it in a number of important points. There are seven pairs of true feet. The first pair, as in the lobster, are much larger than the others, and serve the animal in seizing its food. The first lower joint is curiously bent back upon the next one, giving these legs much the appearance of those of the insect known as the Praying Mantis, on which account this animal and its relatives are called Mantis Crabs. The next three pairs of legs are much smaller, and with the first pair are placed close around the mouth of the animal, and beneath a broad loose shield, which in the drawing conceals them. There are three more pairs of true legs upon the joints of the thorax. Along the abdomen are five pairs of false feet, and near the tail are several strong paddles. One of the most curious things about these Mantis Crabs is, that, unlike the majority of crustaceans, its gills are not placed within the cavity of the body, but are attached to the appendages or false feet, under the abdomen, so that these crabs may be said to breathe through their feet! The animal being drawn as seen from above, these appendages are not shown, being completely hidden by the abdomen

VENUS'S FLOWER-BASKET.

licate structure with a coarse one—an appearance not unlike the open-work of a cane-seated chair. An enlarged portion of the network is

shown, being completely hidden by the abdomen

Walks and Talks on the Farm—No. 98.

John Johnston has just paid me another visit. He is in his eighty-first year, but is as much interested in everything pertaining to farming as ever. He is a genuine enthusiast, and has unbounded faith in underdraining, thorough cultivation, good stock, and rich manure. He approved highly of my plan of managing my manure. I have a basin in the yard gradually sloping to the center. I formerly threw all the manure into the basin and let it lie there until the following autumn. During the winter, being spread over such a wide space, each layer of manure froze as fast as it was thrown into the basin, and, consequently, little or no fermentation took place until spring. Now, instead of spreading it all over the basin, we commenced a small heap on one of the sloping sides of the basin; with a horse and cart we drew to this heap, just as winter set in, every bit of manure that could be found on the premises, and everything that would make manure. When got altogether it made a heap seven or eight feet wide, twenty feet long, and three or four feet high. We then laid plank on to the heap, and every day, as the pig-pens, cow and horse stables were cleaned out, the manure was wheeled on to the heap and shaken out and spread about. The heap soon commenced to ferment, and when the cold weather set in, although the sides and some parts of the top froze a little, the inside kept quite warm. Little chimneys formed in the heap, where the heat and steam escaped. Other parts of the heap would be covered with a thin crust of frozen manure. By taking a few forkfuls of the latter and placing them on the top of the "chimneys," they checked the escape of steam and had a tendency to distribute the heat to other parts of the heap. In this way the fermentation became more general throughout all the mass and not so violent at any one spot.

"But why be at all this trouble?"—For several reasons. First, it saves labor in the end. Two hours' work now, will save three hours' work in the spring. And three hours' work in the spring is worth more than four hours' work in the winter. So that we save half the expense of handling the manure. 2d. When manure is allowed to lie scattered about over a large surface, it is liable to have much of its value washed out by the rain. In a compact heap of this kind, the rain or snow that falls on it is not more than the manure needs to keep it moist enough for fermentation. 3d. There is as much fascination in this fermenting heap of manure as there is in having money in a savings bank. One is continually trying to add to it. Many a cart-load or wheelbarrowful of material will be deposited that would otherwise be allowed to run to waste. 4th. The manure, if turned over in February or March, will be in capital order for applying to root crops; or if your hay and straw contains weed-seeds, the manure will be in good condition to spread as a top-dressing on grass land early in the spring. This, I think, is better than keeping it in the yards all summer and then drawing it out on the grass land in September. You gain six months' or a year's time. You get a splendid growth of rick grass, and the red-root seeds will germinate next September just as well as if the manure was drawn out at that time. If the manure is drawn out early in the spring and spread out immediately, and then harrowed two or three times with Thomas's smoothing harrow, there is no danger of its imparting a rank flavor to the grass. I know from repeated trials that

when part of a pasture is top-dressed, cows and sheep will keep it much more closely cropped down than the part which has not been manured. The idea to the contrary originated from not spreading the manure evenly.

"But why ferment the manure at all? Why not draw it out fresh from the yards? Does fermentation increase the amount of plant-food in the manure?"—No. But it renders the plant-food in the manure more immediately available. It makes it more soluble. We ferment manure for the same reason that we decompose bone-dust or mineral phosphates with sulphuric acid and convert them into superphosphate, or for the same reason that we grind our corn and cook the meal. These processes add nothing to the amount of plant-food in the bones or the nutriment in the corn. They only increase its availability. So in fermenting manure. When the liquid and solid excrements from well-fed animals, with the straw necessary to absorb the liquid, are placed in a heap, fermentation sets in and soon effects very important changes in the nature and composition of the materials. The insoluble woody fiber of the straw is decomposed and converted into humic and ulmic acids. These are insoluble; and when manure consists almost wholly of straw or corn-stalks there would be little gained by fermenting it. But when there is a good proportion of manure from well-fed animals in the heap, carbonate of ammonia is formed from the nitrogenous compounds in the manure, and this ammonia unites with the humic and ulmic acids and forms humate and ulmate of ammonia. These ammoniacal salts are soluble in water—as the brown color of the drainings of a manure heap sufficiently indicate.

Properly fermented manure, therefore, of good quality, is a much more active and immediately useful fertilizer than fresh, unfermented manure. There need be no loss of ammonia from evaporation, and the manure is far less bulky and costs far less labor to draw out and spread. The only loss that is likely to occur is from leaching, and this must be specially guarded against. I have a barrel sunk down in a hole below the heap and pump back the drainings on to the heap.

Our winter wheat is in rather a precarious condition. The ground was so dry that it made very little growth, and winter set in unusually early. I put a ton of dried blood on ten acres of my wheat. There is a poor, sandy knoll in the field, out of which we have taken a great many stones. After we were through sowing the manure, we went over this knoll again, and thus gave it a double dose. Last fall we could distinctly perceive, from the darker color of the wheat, how far this extra dressing extended. The whole field was of a good color, though the growth was very small. I dug up some of the plants, and think I never saw such a great growth of roots with so little growth of top. To my view this is a very favorable indication.

Mr. Johnston says, in the fall of 1835 snow fell two feet deep on the 20th and 21st of October. It remained until near the end of December, when it thawed and all went off. On the 8th of January a great snow-storm set in. Snow fell three feet deep all over the country, and remained on the ground until the middle or end of April. Farmers were then in the habit of sowing their wheat even earlier than they do now. Mr. J. had been experimenting for some years as to the best time to sow wheat, and had found that from the 20th to the 25th of September gave the best results. And so he had sown all his wheat that year at about that time. It had made very little growth when the snow fell

on the 20th of October. Those farmers who had sown early, got a great growth in the fall, and the result was that it was smothered by the snow. Wheat was a general failure. Many farmers did not get their seed. Wheat had to be imported from England. Mr. Johnston had a good crop, averaging 36 bushels per acre. The next fall, while attending an auction sale in the neighborhood, a miller from Waterloo saw him in the crowd, and called out to him: "Scotch, Scotch! have you sold your wheat?" "No." "Have you thrashed?" "Yes." "How many bushels have you?" "I have about 1800 to sell." "What do you ask for it?" "They tell me," replied Mr. J., "that it is going to be worth \$2 per bushel. I will take that for it." Without speaking a word, the miller put his hand in his overcoat pocket and drew out a great roll of bills. "There," said he, "is a thousand dollars to bind the bargain." "It gave me," said Mr. Johnston, as he told the story, "it gave me a great lift, I can tell you."

A farmer in Virginia wants to know about our "Dog Law," and how it works. The Deacon, who is a "squire" as well as a deacon, says, the law in this county allows any person to keep one dog on the payment of 50 cents a year; if he keeps more than one, he has to pay \$1 for the second dog; for a female he must pay \$3 a year. The money so raised is kept as a fund from which to pay for sheep killed or injured by dogs. In this county the fund is increasing, the tax bringing in more money than the loss of sheep calls for. But if the dogs should attack a flock of thorough-bred sheep, it is not improbable that the fund might be used up in a single night. The law is a good one—the only difficulty is to get it enforced, and that depends a good deal on the vigilance of the neighborhood. In some other States, judging from a letter I have just received from Texas, the law might need to include other animals besides sheep. I sent two pair of choice thorough-bred pigs to Dr. Stiles and B. R. Townsend, of Austin, Texas. Mr. Townsend writes me that the pigs got there safe and they were much pleased with them; "but last evening, before midnight, one of the pigs was killed by a dog. It is needless to say," he adds, "that in common parlance I 'went for that dog.'"

A Maryland farmer writes me that he is tired of sending his grain to a mill and paying one seventh for grinding. He wants to get a cheap mill, that can be run by one horse. I presume there are such mills, but I do not happen to know of one. The only one I have is the "People's Mill," which consists of a number of vertical cast-iron plates. It grinds rapidly and well, but chokes so easily as to be practically useless. I think that if a farmer is within five or six miles of a mill, he can get his grain ground cheaper than he can grind it himself. It is not well for a farmer to try to do everything himself.

Col. Weld writes me in regard to an Essex boar, recently imported. He is about 18 months old. "Measures 4 ft. 10 in. from snout to root of tail, measured over the back. From snout to between the ears, eight to nine inches. It is rather an indefinite spot to stop at. The ears are about five inches long. I wish you would measure some of yours, and give me a chance to compare measurements."

I have just measured and weighed some of my pigs, with the following result:

"Gen. Grant," 16 months old; whole length from snout to root of tail, 5 ft. 1 in.; girth, just

back of the fore legs, 4 ft. 3½ in.; length of nose, 9 in.; weight, 307 lbs.

"Old Adam," 15½ months old; length, 5 ft. 5½ in.; girth, 4 ft. 1 in.; nose, 8 in.; weight, 285 lbs.

"Willie's Favorite," a boar pig, 4 months and 10 days old; length, 3 ft. 3 in.; girth, 2 ft. 8½ in.; nose, 7 in.; weight, 92½ lbs.

I also measured and weighed a couple of my breeding sows.

"Sunfish," the sow which took the first prize at the State Fair; length, 5 ft. 3 in.; girth, 5 ft. 4 in.; nose, 9 in.; weight, 348 lbs.

A four-year-old sow, that looks to have a far longer body than "Sunfish," was found to measure exactly the same length, or 5 ft. 3 in.; girth, 5 ft.; nose, 9 in.; weight, 391 lbs.

"Sunfish" has produced more litters of pigs than any other sow I have. She is as thin as I can keep her. Neither of these sows gets anything but coarse bran, and a short allowance at that. The two boars are merely in fair working order. They have nothing but bran, with a few peas occasionally to keep up their vigor. "Willie's Favorite" is a square, fine-boned, well-formed pig, inclined to fatten rather than to grow. There is no waste timber about him.

The Deacon claims that he has better pigs than any of mine. He had a part Chester White sow that he crossed with a thorough-bred Essex, and he had a litter of black-and-white pigs, that are certainly remarkably well formed, of good size, and almost as fine-boned as the Essex. One of my men gave the Deacon seven dollars for a pair of them when two months old. Common pigs at the time were selling at a mere nominal price; and a German who works for me had one given him for nothing. But as soon as he saw the pair bought from the Deacon, he concluded that his pig was dearer as a gift than the others were at \$3.50, and he immediately bought one from the Deacon. These are facts. And I think they prove all I have claimed. If a grade pig at weaning time is worth only one dollar more than an ordinary common pig of the same age, how much is a thorough-bred boar worth in any neighborhood where the farmers avail themselves of his service?

I do not say that the Essex is the best breed. I believe it will make comparatively little difference what breed is selected, provided the animals are pure-bred, highly refined, with small bone and offal, quiet disposition, with the hams, shoulders, and other valuable parts well developed in proportion to the rest of the body, and, above all, that the individual animal is healthy, and comes from a herd which has always received the best care and attention, and has neither in himself nor his ancestors ever been stinted in food when young. In other words, if he inherits the quality of converting all the food he eats into growth, and has not been taught by experience that he must "lay up something for a rainy day." If he has sufficient "prepotency" to impress his qualities, disposition, and characteristics on his offspring, such a pig, of whatever name or breed, can be used with great profit by any farmer who will bestow the necessary care on his stock.

Depend upon it, no discovery in science, or mechanical invention, or improvement in the breed of animals, will ever do away with the necessity of mental or physical labor. They may change the character of our work, but "in the sweat of thy face shalt thou eat bread" will

be the condition of man until the end of time. There is to-day, in this latter part of the glorious nineteenth century, as much need of care, patience, thought, energy, and perseverance, as in the darkest days of any preceding age. In fact, we probably work harder now than ever before. What, then, have we gained? It would take a far abler pen than mine to answer that question. It is perfectly clear, however, that a given amount of mental and physical labor now gives us more of the comforts, necessities, and luxuries of life than at any previous period with which we are acquainted.

But do not dream that when we get the steam-plow or any other mechanical invention, we shall have little or nothing to do. We shall need a higher class of workmen than such as can only use the spade or the plow. It has required years of patient thought and persevering endeavor to produce the steam-plow or any other valuable invention, and it will require an extra amount of intelligence to manage it. And so with improved breeds of animals. They are the result of no less energy, care, intelligence and perseverance, and they require a no less extra amount of intelligence to manage them. There are men who had better stick to the scythe and the cradle, than undertake to run a mowing-machine or a reaper; and there are farmers who had better keep only the common kind of cattle, sheep, and hogs, than to introduce improved blood into their stock.

But it is as great a loss for an intelligent farmer to keep nothing but common stock as it would be for him to stick to the flail in thrashing, or to the sickle in reaping his wheat. He is wasting his energy, skill, and intelligence. Such men as Thomas and Barry sometimes assert that it is just as easy to raise the choicest as the commonest variety of fruit. And in their grounds such is the case, for the simple reason that their usual treatment and cultivation are fully up to the requirements of the most improved sorts. For them to plant inferior varieties would be a great waste of good opportunities. But it will not do to assert that it is as easy to raise choice fruit as poor fruit. It is not true. There are many men who could raise the Choke-pear that could not raise the Sheldon. And it is equally true that there are farmers who can keep Texan or native cattle that could not keep Alderneys or Shorthorns. The aim of agricultural and horticultural writers should be, and I believe is, to elevate the general standard of management and cultivation to the point where it is "just as easy to raise good stock and good fruit, as poor stock and poor fruit." There is pleasure and profit in raising the best.

I am always pleased to hear from farmers in different sections of the country. But it is impossible for me to answer all the letters I receive; I should have to write a Cyclopaedia of Agriculture to answer some of them. I have letters from several Northern farmers who have gone South, asking how they had better proceed in renovating their farms. My plan would be to find the best and most experienced farmer in the neighborhood and ask his advice. There may be reasons for certain practices that you do not understand—such as the character of the labor, climate, soil, and market. It is not wise to attempt sweeping measures of reform at once, or on an extended scale. Feel your way. Renovating a farm is slow work at first. There is no royal road to improved agriculture. You must learn to labor and to wait. But with the right use of means the end is sure to be satisfactory. Study principles. These are the same

everywhere. It is their application only that varies. We must get rid of stagnant water, kill weeds, and develop or apply plant-food before we can get good crops of either corn, cotton, clover, grass, or wheat. This is true everywhere. The land may be of such a poor, sandy nature that it may be cheaper to buy phosphates, potash, and nitrogen, in the form of artificial manures, than to try to develop them from the soil. One farmer in the South asks me if it will pay him to apply gypsum at \$40 per ton. I think not. Superphosphate at \$50 would be far cheaper. There is a grand opportunity for some man or company, with sufficient capital, science, and honesty, to embark in the manufacture of artificial manures. Give us available phosphates, nitrogen, and potash, at the cheapest rates at which they can be produced, and hundreds of thousands of tons will be used.

I do not care for "testimonials" as to the value of this or that artificial manure. Give me the right kind of an analysis from some reliable chemist and tell me what the manure is made of, and, so far as the value of the manure is concerned, I do not care for a catalogue of testimonials from the best farmers in the world. Farmers must insist on having a guarantee of the condition and composition of the manures. Until this is done, testimonials are an impertinence.

Several farmers have written me that they intend to try white mustard. I think they will not regret it. But they must recollect that the soil must be made as mellow as possible. It will not do on rough, cloddy land. It is a renovating crop, and the soil must be thoroughly prepared for it. Plaster, ashes, superphosphate, or guano have a great effect in stimulating its growth. The crop must be fed while green and before it goes to seed. It can not be made into fodder—at least I have never heard of its being so used. It is generally fed off on the land where it grows, but I cut a good portion of mine with a reaper, and use it in the yards or on grass land as a soiling crop for cows, sheep, and pigs. If the land is in good condition, half a peck of seed, sown broadcast and harrowed in with a light harrow, is sufficient. It can be sown at any time after all danger of spring frost is past, and in this section will mature a crop, sown as late as the middle or end of July. The better way would be to sow it in succession. In the Southern States three or four crops might be grown on the same land in a season.

Brick-Making.

In brick-making the most important item is the clay. This should have a certain proportion of sand mingled with it, which, unless naturally mixed, must be supplied artificially. The clay should be of a dry, loose texture, rather than of a sticky, greasy character, and should break into fragments easily in the hands. The process of tempering reduces it to a plastic and adhesive state. This is performed in the mill, which is sometimes called a clay-mill, but more commonly a "pug"-mill, represented at figure 1. This is a cylindrical tub of planks, strongly bound with iron hoops, set upon a platform of timber. In the center of the tub is an upright shaft, armed with projecting knives or cutters. This is worked either by an arm or sweep, fixed to the top of the shaft and turned by a horse which travels round the mill, or by means of bevel wheels beneath the platform turned by a tumbling shaft from a horse-power placed on one side. The clay fed into the top of the mill

is cut and sliced by the knives, and as the flat blades are made to slope somewhat backwards the clay is gradually pressed downwards towards an opening on the platform, where it escapes ready to be molded. Generally there is water sufficient in the clay as it is fed into the mill to make it work easily. It is dug and moistened a few days previously, and this short

Fig. 1.—MILL FOR WORKING CLAY.

exposure very much assists in the tempering. As the soft clay comes from the mill it is taken in wheelbarrows to the molding-bench, or it might be molded at the mill if desired, if the yard is not a very large one. The barrows are dusted over with sand before the clay is put into them; it can then be dumped out without sticking. The molding is the next process. This is done very rapidly by an expert workman, seven bricks per minute being the usual quantity molded, but we have seen fourteen molded in that time. The molds are of wood. They are merely a box without top or bottom, the sides of which project about an inch beyond the ends for the purpose of lifting them up easily when filled, and are a little larger than the brick to be made, to allow for the shrinking of the clay in drying. The molds are dropped, by the boy who lays the brick on the floor, into a trough of water at the molder's right hand. He takes one from the trough, dashes a handful of sand over it, with both hands digs into the pile of clay before him, and, taking up a proper quantity, throws it into the mold with force enough to make it fill all the corners. He then presses the clay down to make it compact, scrapes off what is super-

Fig. 2.—MAKING BRICKS BY HAND.

fluous with a small, smooth stick, and pushes the mold to the boy at his left hand, who

turns it on its side and carries it in this position to the drying floor, where it is dropped out on to the smooth, hard, prepared ground to dry.

Feeding Lambs.

One of the greatest difficulties in raising early lambs, more especially with some breeds which are not naturally good mothers, is the disposition of the ewe to disown or neglect the lamb. When she has twin lambs this not seldom happens. Without great attention at yeaning time a farmer may lose some fine lambs which might easily be saved. We have experienced this ourselves and have saved many early lambs by feeding with cow's-milk. It has been said that cow's-milk is poisonous to a lamb. We never found it so, but have had very good success, even with that very tender breed, the Leicesters. The critical time with a lamb, more especially in cold weather, is the first day of its life. Often the ewe may be as good a nurse as possible, but the lamb may be weak and chilled. A mouthful of warm milk will often revive a lamb when it is not able to get up to suck. To feed a lamb that has been altogether disowned by the ewe, we used a tin can, a common kerosene-oil can (as in fig. 2), with a piece of sponge wound round the end of the spout and covered with a cotton bag, shaped like a teat, which was tied on. The milk was made warm and a little sugar dissolved in it. The teat being put in the lamb's mouth it will immediately suck eagerly, and will soon get accustomed to the strange method. When a ewe is weak and has but little milk, a few spoonfuls a day will help the lamb very much. When a ewe will not own her lamb, it is best to take her as shown in fig. 1, and with one hand hold up the wool so that the lamb can get to the teat. Let the sheep be held so that she can turn her head and smell the lamb, and if a little salt be sprinkled on it, she will commence to lick it and her unmotherly objections be soon removed. Such a ewe should be placed with her lamb in a small stall by herself. As soon as the lamb is strong enough, it will, by dint of perseverance—when the sheep can not escape—learn to help itself. In two or three days the ewe will have become friendly to it.

The sheep-pens should be visited several times a day, and the last thing at night and the

first in the morning, as soon as lambs begin to appear. The ewes should be removed a day or two previous to this event, into a pen by themselves, where more care and a little extra feed can be given them. It should be remembered that when a can or bottle is used to feed the lamb, it should be carefully rinsed with

Fig. 1.—MAKING AN EWE OWN HER LAMB.

scalding water immediately after using, lest any sourness should occur. Sour milk will kill lambs very quickly. In case diarrhea should occur from any neglect in this respect, it may be stopped at once by administering the follow-

Fig. 2.—FEEDING YOUNG LAMBS.

ing cordial: One pint of peppermint water with one ounce of prepared chalk, in doses of half a teaspoonful or more, according to the age of the lamb, three times a day. It is very rarely, however, that this will be needed if care is used. It is also very important that warm, dry quarters with clean straw bedding be furnished.

Tighteners for Fence Wires.

A proper method of tightening the wires is of great advantage where wire fences are used. One of our Kansas friends sends us a sketch of a plan he uses, which we illustrate. The straining post is firmly set in the ground, and has two braces to help support the strain. The wires to be tightened pass through holes bored through the post, and are attached to small rollers, which have holes bored in the ends to receive the stakes, by which the rollers are turned and the wires wound up. As the rollers are turned by the stakes the wires are drawn up and tightened, and when a sufficient

strain is secured a stick placed between the stakes and the post prevents the roller from

METHOD OF TIGHTENING FENCE WIRES.

turning backwards, and allowing the strain to become weakened. When it is desired to slacken the wires, the stick is removed and the wires are unwound. A mode of tightening wires in common use, but which may be new to a beginner in this business, is also shown. A stout rod has two iron pins (strong hickory pins will answer) passed through one end six inches apart. The wire to be drawn up is passed between these pins, and the rod is turned around until the wire is tight enough. A loop is then passed around the end of the rod and the wire, and it is secured.

Protecting Banks of Streams.

The spring is a time when freshets often do

Fig. 1.—PROTECTING BANKS OF STREAMS.

serious damage by washing away or undermining the banks of streams. Very often a point projects into a stream which throws the current with great violence against the opposite bank,

Fig. 2.—CRIB FOR PROTECTION.

and renders necessary a sufficient protection to sustain the point attacked, lest it should give way and a permanent change be made in the

bed of the stream. Very often the planting of willow-slips on such exposed banks makes a good protection, but we have seen banks and trees washed away, that might have been saved had a simple breakwater been built at the commencement. One method (shown in fig. 1) is to drive stakes into the ground, perpendicularly, at the edge of the stream, on to which planks should be spiked. A brace or two may extend backward against the bank and be pinned into the ground. The stones filled in behind will hold this brace tightly and prevent bulging outwards or pressure inwards. At the foot of the planks a few well-chosen flattish stones should be laid, over which the stream will flow, and washing of the bed will be prevented. The other method is to build up a crib with logs, or light timber, and fill it in with stone, as in figure 2. The logs should be pinned together so that the frame is tied. This should also be protected at the foot with stone. No bridge-pier should be built in a bank without such a protection as either of these on the upper side.

A BARN BASKET.—Little economies on the

BARN BASKET.

farm are worth considering. A reader sends us a description of a barn basket which costs nothing, and is as useful as one that costs a dollar. The ends of a flour barrel are cut off above the second row of hoops, and leather handles are nailed or lashed on with thongs. Here is a feed basket that is light, handy, and costs only a little labor.

Making Stone Drains.

A "Subscriber" has a piece of land which he wishes to drain; drain-tiles are not to be procured in his locality, but he has plenty of round stone: will they answer a good purpose?—It is probable that next to a tile drain, a well-made stone one is the best that can be laid. There are some rules to be observed in building them on which their permanency and efficiency depend. In making stone drains a double purpose is served; the secondary purpose, getting rid of the stone, being often quite an important one. Therefore, we can very well afford to make the drains wider than would be necessary with tiles. The first operation is to locate the drains. This should be done so that a regular fall can be had with the least digging. Then commence at the outlet and work upwards. With the level described elsewhere, there will be no difficulty in getting a proper grade, so that the stone may be laid and the drain finished as it goes along. The stone may be laid in three ways. Fig. 1 shows two stones supporting each other, and prevented from losing their position by bracing stones on top of them. Fig. 2 shows a stone in the center of the drain supporting two other stones which lean against the side of the ditch. Fig. 3 shows two stones supporting a flat one, which is laid on them. Where flat stones can be procured, this is the best mode, and we know of no reason that should prevent it from being as permanent as

the best tile drain. The writer laid a drain of this character sixteen years ago, and it is in as good condition to-day as when first made. The other two modes are subject only to injury

Fig. 1. STONE DRAINS. Fig. 2.

from the caving in of the sides of the drain. Where the soil is at all compact there is little danger of this, and it may be guarded against by packing the filling of the drains carefully against the walls. When the water channels are properly built, stones may be filled in to within a foot of the top, taking care that they be compactly laid and small pieces laid carefully over any holes that may be left. The earth may be then returned to the ditch, with care

Fig. 3.—DRAIN.

that the stones are not displaced and that no earth be permitted to fall down amongst them. It is advisable to dig the drains four feet deep, two and a half feet wide at top, and twelve or fourteen inches wide at bottom. With one horse and a light plow much of the work may be done more quickly than by hand.

A Cheap Deep-Can Creamery.

BY G. E. WARING, JR., OF OGDEN FARM.

The severely cold weather of December has added the only test necessary to convince one that the deep-can system for creaming milk is suitable not only for warm weather, but equally so in winter. We have had the thermometer

Fig. 1.—SECTION OF CREAMERY.

down to 6°, with a high wind blowing, forming a skin of ice in our water-tank—the water works having been frozen up by the sudden

cold; and even then there was no perceptible difference in the amount of cream raised, nor in the time required for it to rise.

Whenever the water is running in the tank it

Fig. 2.—GROUND PLAN OF CREAMERY.

remains at all seasons at about the same temperature (58°), and the milk in the cans is entirely immersed in the water, the cans being covered, with only a 1½-inch hole for ventilation. The influence of the air on the very small surface of the milk is not enough to make it materially colder—even if this would be a disadvantage, which I doubt. The result is that, so far as the rising of the cream is concerned, it makes little or no difference, whether we are working in the dog-days or in the dead of winter.

Being satisfied of this fact, and having noticed that the discussion of the merits of the deep-can system is being actively agitated in the agricultural papers, I propose to say nothing more about it unless some new and noteworthy fact presents itself; but assuming that there is no question as to the advantage of the system, shall proceed to devise the best means for carrying it out under different circumstances. The plan set forth in the accompanying engravings is the one which will probably be applicable to the greatest number of cases. It is intended for level land, where water can be obtained only from wells, and where there is no fall to carry away the drainage.

Fig. 2 is the ground plan of an underground tank, some 10 feet long and 8 feet wide, the

Fig. 3.—LONGITUDINAL SECTION.

water-tank at one side being 10 ft. long, 3 ft. wide, and 2½ ft. deep. This is separated from the passage way by a mason-work partition, the lower part of which is widened to form a step high enough to facilitate the handling of the cans in the tank. This tank is large enough for thirty cans 8 in. diameter and 25 in. deep. At the far end of the passage a well is dug deep enough to insure a good supply of water in the driest weather.

Fig. 3 shows a longitudinal section of the

house, with steps approaching it, windows for ventilation, etc. The window marked *e* need only be put in in cold weather. Double windows should be provided for three sides, none on the south. The door, which should be in the east end, need not be double. The ceiling should be plastered to inclose an air space under the roof—to keep out both heat and cold.

Fig. 1 shows the construction of the working parts more clearly. The building is mainly in the ground, and its walls of course must be built of stone or brick. The wind-mill (supported in a stout cross-timber) need not be large; the smallest size that is made of any good mill will answer for the work. All that is necessary is to have a slight stream running whenever the wind blows; but, of course, the more the better. This will be often enough to keep the water fresh. The water may be made to enter the tank at the end nearest the pump, and overflow at the other end, running along a gutter in the floor and back into the well. The drawings are made to a scale, and the dimensions given will indicate the other measurements.

A HALTER-KNOT.—Howard Hawes, Riverside, Ct., sends us a drawing of a knot which will not slip, and is perfectly safe for tying halters or fastenings for horses in the stable. It is one also that is very easily untied, which is not its least recommendation.

HALTER-KNOT.

We give an engraving from which the mode of making the knot may be learned. A little practice with a string will soon enable one to tie it.

Sugar-Beets for Cattle Feeding.

In October last we saw, on the farm of Mr. I. M. Mackie, at Great Barrington, Mass., a field of sugar-beets of remarkable size and uniformity. They were of a variety originally obtained from the Patent Office by the Hon. Henry Lane, of Cornwall, Vt., and by him brought by careful selection to their present perfection.

We were so much struck with the superiority of this beet that we applied to Mr. Lane for further information concerning its history. We gather the following from his letter on the subject, and from an address delivered by him before the Vermont Dairymen's Association. In 1858 he received from Washington three varieties of sugar beets. They were carefully grown, and the variety called "Imperial Sugar-Beet" was found to be much superior to the others, and to any other beet that had been seen in the region. It at once supplanted all other varieties in use among his neighbors, and it has been so much improved by Mr. Lane that he claims that it yields "with greater certainty, a greater amount of food per acre than any other root, at less cost, of better quality than the turnip, nearly as good as the carrot for young stock, and better for milk, ready to feed by the first or middle of October, and keeping sound through the winter until late in the spring." Our own observation of Mr. Mackie's crop, and his opinion of the feeding value of the root, lead us to accept Mr. Lane's estimate as a just one.

It is recommended that this beet be sown very early in the spring (if possible by the middle of

April)—as soon as the land is fit for work—on strong, heavy land, free from stagnant water. He claims that the amount of the crop is (in his latitude) just about double its amount on the first of September, and that all the growth we are able to secure by that time will be doubled between then and harvest time. Whether this idea is correct or not, there is no doubt of the profit of early sowing. The land should be rich and additional manure should be used in the drill. The drills should be 30 inches asunder, and the plants stand 18 inches apart in the row, being singled to this distance as soon as they have put forth the second pair of rough leaves. After this they are to be thoroughly worked with the horse-hoe, and once by hand, before the leaves begin to cover the ground. They will be ready for harvesting by the middle of October, and they should be well dried before being taken into the cellar or dumped on the ground.

The usual yield per acre, in Vermont, is from 28 to 32 tons, but 40 tons have been grown. Mr. Lane says, in his address: "Without going into details, I estimate the cost of labor after the manure is applied, at \$40 per acre; the use of the land and manure \$40 more, making a crop of 1,000 bushels per acre, cost 8 cents per bushel, which I think is a fair average cost." Forty tons of these beets would be equal, in feeding value, to ten tons of good hay, without allowing for their good effect on the appetite and health of the animals feeding on them.

Drain-Level.

A subscriber sends us a sketch of a drain-level, which we illustrate. It is a very useful implement, and easily constructed. It consists of a parallel-edged board, seven or eight feet long, with a **L** affixed near one end, which supports a pendulum. A scale is marked on the board at the foot of the pendulum, whereby its motions are noted. When the board is perfectly level the foot of the pendulum marks 0. When the board inclines either way it varies accordingly. A handle is fixed to the end of the level, which serves to hold it in position when in use. In case it is not wished to lay out the bottom of a ditch to a very accurate grade, the mere movement of the pendulum to the left, when looking at the scale or index, will show that the grade is downwards. But if accurate measurement is desired, it will be neces-

DRAIN-LEVEL.

sary to make the instrument in proportion, and mark the index carefully also with a proportionate scale. Thus, if the bottom of the level is six feet long, and the **L** two feet high, an elevation of the hinder end of the instrument of half an inch would be equal to a grade of one inch in 12 feet, or one in 144, or eight inches in 100 feet, and would cause a deviation from the perpendicular of the pendulum of one sixth of an inch; a grade of 16 inches in 100 feet would cause a deviation of one third of an inch. If such close measurement is desired the instrument will have to be carefully made. For or-

inary operations, it will only be necessary to take care that the **L** is set on quite square, and then the least movement forward of the pendulum will show the grade to be correct.

WATTLE SHELTERS.—A plan has been requested for making shelter for stock on the Western prairies, where timber is scarce and the winds are often so severe as to make some kind of protection necessary. Where small poles or brush can be cut, wattle shelters are easily built and very useful. Poles, six to eight feet long, are driven into the ground about a foot

WATTLE CATTLE-SHELTER.

apart and for such a distance in length as may be desirable; occasionally a forked pole is driven into the ground, about six or eight feet in front of this row, to sustain a roof, which is made also of poles. Small brush is woven amongst the poles and coarse swamp hay laid over the brush, the ends of the bunches of hay being wound in amongst the brush to hold it. If this is built in the shelter of some knoll, considerable protection is afforded, and with a little care a very comfortable hovel may thus be made to which stock, especially sheep, will run for shelter. If built in a semicircular shape it will be stronger, and a more complete shelter against the winds.

Can Farming Pay such Taxes?

We are not thinking, now, of the Internal Revenue tax—which so many manage to evade—nor of our "State, County, Town, and Road" taxes, which we can not avoid. These are comparatively moderate, and somehow or other they do get paid, and the world still moves on.

There is, however, another tax, though it is not called by that name, from which few of us can hope to escape, and which is entitled to the gravest consideration. It is cutting into our substance like a two-edged sword—on one side idleness, on the other extravagance. Worst of all, the sword is wielded by our own flesh and blood, by those who love us, and whom we love—by our own daughters.

The reader will please notice that we make no assertion in the heading of this article; we only ask a question. We are not, ourselves, prepared to give it a definite answer; but we think there is at least grave cause for anxiety in the habits and tastes of farmers' daughters. On our drive to town, this afternoon, we met three young women, daughters of three ordinary farmers—men who have the usual struggle to make both ends meet, and who practice the usual economies in their households and on their farms. These damsels were so dressed that at a little distance they looked like the daughters of the rich city people who board in our neighborhood,

in the summer. As they came nearer, it was plain to see that they had economized in material as much as they had squandered in form and color, and this marked a wide distance between their brighter exemplars. Yet, save as they might, there was not one of them who had not on her person—counting everything from "button-gaiters" to what Mr. Punch calls "Chig-nonsense," and hat-feathers—the value of a first-class mowing machine, with reaper attachment. If this were the end, it would not be so bad, but it is only the bad beginning. It is not the capital invested in finery that tells on our fortunes, but the awful interest in the shape of renewals. A first-class two-dollar "back-hair" we might stand, and done with it, but fashions change and back-hair wears out, and the next style is worse yet, and costs three dollars. And so it goes from the crown of the head to the soles of the feet; there is the same eternal grind that wears away clothing and finery alike. The more it cost the more must we spend in repairs; and your modern country miss, with her Harper's Bazar and Peterson's Magazine for the law and gospel of her attire, is very apt to be a sort of well-dressed mortgage-deed upon her father's farm, and to become a sort of ornamental mill-stone about the neck of the man who marries her.

Aside from all this we would call attention to the occupation of these girls. Too often we shall look in vain for the steady, cheerful industry of their mothers' times. If they work, they are half-ashamed to be seen at it, and they rarely accomplish, from one end of the year to the other, a tenth part of what they are easily capable of.

In the "good old times," when farmers were none too prosperous, when the land was richer than it now is, and when the cost of living was far less, our grandmothers and their sisters were cheaply clad, they wore their own hair, the renewal of their gear cost wonderfully little money, and they worked like little beavers. If we can trust our grandfathers' account of them, they were as sweet and attractive and as promising sweethearts as the more costly and less useful jewels of our own modern firesides.

We are not grumbling, and we are not blind to the great advantages that modern civilization offers to the young of both sexes, as compared with those who have gone before; we only express our anxiety, lest the extravagance that a perversion of our civilization has caused, end in the ruin of the hard-riden fathers.

If farming was but a moderately good business forty years ago, with the industry and economy of that time to help it, we fail to see how, with the high price of labor, the low price of produce (comparatively), and the necessity for buying manure (that is becoming so universal), the farming of the present day is going to support a houseful of girls who cost so very much more than they come to.

Spreading Manure in Winter.

We are asked what advantage there is in spreading manure on frozen ground. It depends much upon the condition of the ground. If it is covered with grass, either a pasture or meadow, there is a great advantage in more than one respect. The surface is protected from sudden changes during winter, and the first thaw carries the manure to the roots, where it causes a vigorous growth early in the spring. If the ground is plowed for a spring crop, it is

also benefited by having the manure ready to be absorbed by the soil whenever the ground thaws; the seed, as soon as it sprouts, finds what it needs close at hand. On sod ground to be plowed for corn in the spring, the same advantages are gained as in the case of grass lands, and the manure is on the spot in time, which in a late season it might not be, for want of time or improper condition of the ground. But after all, it is far better to get the manure upon the ground before it is frozen, if possible; the earlier in the fall, the better. Winter top-dressing of grain is only a poor substitute at best for a proper and timely preparation in the fall, and rarely pays for the trouble, unless it may be in the advantage gained by the spring-sown clover.

A Curb for Digging Wells through Quicksand.

A "Correspondent" from Illinois gives his experience in digging wells to procure water for stock in a part of the State where quicksand is found twelve feet beneath the surface for a depth of several feet, and which must be passed through before water is obtained.

He has used a curb of two-inch plank, bound by iron hoops, in the shape of a large tube, a few inches narrower at top than at the bottom. This is set on a circular frame, with a sharp edge, and securely fastened to it. The frame, as shown in the engraving, is wide

CURB FOR WELL-DIGGING.

enough to carry a row of brickwork, which is built up within the curb. The bricks are laid in cement; the brickwork, of course, being laid after the curb is placed in the well, which is done as soon as the sand is reached. When the cement is quite dry the digging is resumed. As the sand is removed the curb sinks down (being smaller at the top than below, it readily does this), and the curb resists the pressure of the quicksand, which is very considerable. When solid clay or gravel is reached beneath the quicksand, water is generally found; if not, and more curbing is needed, another length is built and connected with the previous one. Thus the well-sinking is done safely and permanently.

Calks on Horses' Shoes.

During winter, when the roads and yards about a farm are often covered with ice, sharpened calks on horses' shoes are a necessity. It is absolute cruelty to do without them, not only on account of the risk of damage to the animal, but on account of the painful terror to which some horses are subject. Sometimes they may be seen trembling with fear when trying to keep a footing on smooth ice. But when horses' feet are thus armed, they become dangerous to themselves and their fellows. They should be very carefully driven, especially when turning round, and the greatest care should be taken that they

[COPYRIGHT SECURED.]

AN ICE-BOAT REGATTA.—Drawn and Engraved for the American Agriculturist.

are not allowed to get loose in the stable or to frolic in the yard. Most of the blemishes which have injured horses either for use or in value have happened at this season, and from the above causes. In case a horse should be kicked with a sharpened shoe, a deep gash is made, which should be immediately stitched with a curved surgeon's needle, making one stitch in a place, and tying the ends of the thread, and cutting them off before passing to another. If swelling occurs, bathe with cold water to reduce it before putting in the stitches. Prevention will save much needless trouble and expense.

Ice-Boats.

Ice-boat sailing is the most delightful of outdoor sports in the winter season. It combines all the excitement derived from the rapid and easy-gliding motion of skating, without the severe muscular exercise incident to that sport, with the quieter but not less agreeable pleasure of a sleigh-ride. Wrapped in warm robes and muffled in furs, one can sail with a good ice-boat and on good ice, with plenty of *sea room*, at the rate of fifty miles an hour, with no resulting fatigue to detract from the pleasure.

Poughkeepsie, N. Y., on the Hudson River, is the head-quarters of a fleet of ice-boats, which are fitted up in most exquisite style. During the present season there are boats in use built of walnut and other polished and ornamental woods, with hollow masts and spars, built expressly for lightness and strength, with nickel-plated wire rigging and mountings. With warm rugs and cushioned seats, and all other possible comforts, these boats furnish the means of the most luxurious sailing. But we have enjoyed a sail on a boat built of pine scantlings and rough seats quite as much as we could possibly enjoy one with the most costly turn-out that could be devised. If built on correct principles, and with ordinary means of comfort, the plainest boat will sail as well and as pleasantly as the most finished. An ice-boat consists of a triangular frame of wood; plank or scantlings will answer equally well. The apex of the triangle is the head of the boat, and the base the stern. The base should have a sufficient spread to resist any tendency to capsize when sailing with a beam wind—about equal to half the length is a good proportion, eight feet in a sixteen-foot boat for instance. A floor is laid on this frame, on which seats may be built to

accommodate the passengers, who may be as numerous as possible, the "more the merrier" being the general rule in loading. Beneath the frame there are three runners, one at the head, which is fixed on a swivel, so that it can be turned by the steersman, who sits at the front and guides the boat by this movable runner, and one under each corner at the stern. A mast and bowsprit are rigged in a similar manner to those of a sloop, and the sails are a jib and a main-sail, either with or without a boom, to which the sheet is attached as is usual with such sails. Some experience in managing sails is necessary before very swift sailing should be attempted, as the velocity attained is so great that an upset might be dangerous. The steersman should be cautious and experienced, as on him depends in the greatest degree the safety of the passengers. It is well to have the runners grooved or bluntly angular on the under surface, to gain a hold on the ice that will resist lateral movement. A boy's boat may be made with a small frame mounted on three boys'-sleds, the one in front is so arranged that it can be turned with the feet or with two strings, as is seen in the picture. A mast and one small sail is all that is required.

The Horned-Poppies.

Here and there in waste places, especially near the sea-coast, is found, though rarely, the Horned-Poppy, *Glaucium luteum*. It forms a large tuft of bluish-green cut leaves, and bears yellow, poppy-like flowers which are succeeded by narrow pods six to ten inches long. The shape of these pods has suggested the popular name. The plant has a yellow juice. We do not recollect to have seen this plant in cultivation, but with the present taste for striking foliage, it would no doubt be admitted. Another species, from Southern Europe, *Glaucium corniculatum*, was introduced by Olm Brothers, of Springfield, Mass., a year or two ago. We had it last year, and certainly never saw anything finer in its way. It forms a dense tuft, over a foot across, of beautifully-cut Acanthus-like leaves, which are of a most charming silver-gray color. It is highly ornamental, whether grown as single specimens or as an edging-plant to a flower-bed. With this, as with many other plants grown for the beauty of their foliage only, the flower-stalks should be cut off as soon as they appear. In its wild state it is an annual, but by preventing it from flowering it may be made biennial, as it is perfectly hardy. There is no beauty in the flowers, and if the plant is allowed to bloom it becomes irregular and ragged. When used for edging, well-established plants should be employed, and these can only be had of a proper size by starting them early in the greenhouse or hot-bed.

The Willow-leaved Amaranth.
Amaranthus salicifolius.

Each season has its horticultural sensations, and the weather can not be more certainly forecast from the admirable Government reports, than can the aspect of the horticultural horizon for 1872 be foretold by the inspection of the advertisements in the English journals for the last months of 1871. The deluge of wonderful peas, marvelous turnips, and unheard of potatoes, comes as sure as the fall rains, and then we have a sprinkling here and there of new flowers. The latest sensation is the new Amaranth, *Amaranthus salicifolius*. A literal translation would be Wil-

low-leaved Pigweed, but as we call only the coarser Amaranth Pigweeds, we will not be too literal, especially as some of the Amaranths are highly ornamental. This new plant comes from the Philippine Islands, where it was dis-

lish papers, and it has attracted great attention and received prizes at several horticultural shows. The Gardeners' Chronicle expresses doubts as to its being an Amaranthus, but we can hardly suppose that such eminent plantmen as the Messrs. Vietch would send it out with this name unless they felt sure of its correctness.

How Varieties are Improved.

Mr. Lane, of Vermont, who has been so successful with his sugar-beet culture, sends us an account of his processes. He commenced 12 years ago, selecting for seed the best six beets of those that approached nearest to the particular type he wished to produce. From the crop raised from this seed the best six were again selected; and so on until the present time, when he claims to have produced his ideal "of a good beet to raise for the dairy—a beet that for uniformity of shape, color, solidity, quality, size, and yield is not excelled by any beet or mangold that is raised in this country. . . . The largest beets raised the past season in our vicinity weighed 19 to 21 lbs." The specimens exhibited by Mr. Lane at the time of delivering his address weighed respectively 6 lbs. and 10 lbs. Grown at 18 in. x 30 in. spaces, roots averaging 6 lbs. would make a crop of nearly thirty-five tons per acre; roots averaging 10 lbs. would make fifty-eight tons per acre.

Mr. Lane has also made experiments of the same character with onions; and he thinks that instead

of trying to get better vegetables by producing new varieties, if we would improve the best old varieties, we would attain more uniformity and better quality. He thinks he can take the Peachblow potato, and by selecting a few specimens for seed the nearest

the type he wishes to produce, continuing this selection for 10 or 12 years, "produce Peachblows either round or oblong, white or peachblow in color, and uniform in either of these characteristics." The same is true of other vegetables besides roots; tomatoes and Indian corn are examples in which we can most strikingly see the good results of selection. So with flowers. By choosing for seed those speci-

WILLOW-LEAVED AMARANTH.—(*Amaranthus salicifolius.*)

covered by the late J. G. Vietch. The plant is from two to three feet high, with leaves five to seven inches in length, and one fourth of an inch wide. The graceful fountain-like habit of the plant is shown in the engraving. The color of the leaves in the young state

HORNED POPPY.—(*Glaucium corniculatum.*)

is a bronzy green, which, as the plant grows older, turns to a bright orange-red color. This novelty is spoken of in high terms by the Eug-

mens only that present desirable characters we can each year improve upon their beauty. Many varieties will deteriorate without this care.

Greenhouses attached to Dwellings.

BY PETER HENDERSON.

Every now and then the inquiry is made: "How can I best attach a greenhouse to my dwelling?" Nothing is more simple, as far as the mere shell of the greenhouse is concerned, but the difficulty is to heat it. Many may not know that a greenhouse, even without any artificial means of heating, can be made very useful in the early spring months in this latitude, and all through the winter in those Southern

SECTION OF A CHEAP GREENHOUSE.

States where the thermometer does not fall lower than 20° or 25°.

In the diagram of an end section of a simple house here given, the sashes (*B* and *C*) are 3 feet wide by 6 long; the top one is so placed that it can be let down by weights and pulleys over the lower one, and thus secure ventilation. The front wall and ends are best built by using 4 × 6 inch chestnut or cedar posts. Upon the outside of the posts rough planking is nailed; against that a layer of tarred paper; and against the tarred paper the weather boarding is nailed, either overlapping or tongued and grooved, as may be desired. The outer walls of all greenhouses built of wood are now thus made with us, and it is found to be far preferable to the old and objectionable mode of filling in between the boards with sawdust or shavings. The tarred paper is a good non-conductor, and we find walls so constructed are equally as good a protection against frost as a nine-inch brick wall, which would cost twice as much. A greenhouse of this kind, 25 feet long by 11 wide, should not cost more than \$100 complete, if plainly built; that is, without heating. Heating is a difficult matter in greenhouses so attached to dwellings, unless in cases where there is a surplus heat at night from furnaces or stoves in the rooms adjoining. In such cases, the windows or doors, if low enough, could be opened, and enough heat be supplied from the rooms of the dwelling; or, better yet, if it were so arranged that a register from the furnace opened into the floor of the greenhouse. But when this supply of artificial heat can not be obtained, the greenhouse as it is will be sufficient to protect plants against any frost that is likely to occur in this latitude after April 1st, particularly if light wooden shutters are put over the lower tier of sashes. I have recommended this style of greenhouse to many dealers and retail florists in the different States. Those who are simply dealers in plants experi-

ence great difficulty and loss in keeping what they purchase for sale in stores or dwelling rooms; for if not sold at once, they quickly get injured. But this cheap and simple style of greenhouse not only by its appearance advertises their business as dealers in flowers, but it enables them to buy from the wholesale florists at an earlier season. Besides this, they can purchase in March and April at less than half what the same plants would cost in May, and it gives them time to repot into larger pots. Placing them in the greenhouse where they have sufficient space to grow, the plants that are bought for \$12 per 100 in March, with but little trouble in potting, airing, and watering, will freely retail for 50 cents each in May. These greenhouses are also economical and useful to the amateur who purchases for his flower-garden in spring. Bedding-plants, as they are called, can not be safely planted out in the Northern States until the middle of May, and if the amateur buys from the florist then, he generally pays quite double the price that he could purchase the same plants for in March or April, for the florist always wants room in his greenhouses, and can better afford to sell a dozen Geraniums in

March for \$1.50 than for \$3 in May. Besides, the plants if purchased in March, and shifted into larger pots, and allowed plenty of room to grow, would be far better than could be purchased at any price from the overcrowded tables of the florists in May. The care of such plants in the greenhouse is very simple. The board benches or tables *E* and *G* should be covered with two inches of sand, upon which to stand the pots; place them so far apart that the leaves will not touch; water *thoroughly* whenever the surface of the soil in the pot appears dry, which will be every day in hot weather. Ventilate by letting down the sashes, more or less, as the day is warm or cold, whenever the thermometer indicates 75° or 80°; in other words, keep the temperature in the day time as near as may be to 60° or 65°, as marked by a thermometer placed in the greenhouse where the sun will not strike it. Burn half a pound of *damp* tobacco stems on the floor of the greenhouse twice a week, to destroy the aphids. One dealer in Maine informed me that from a greenhouse so constructed, 30 feet long by 11 feet wide, placed against the south side of a high board fence, he sold last spring, in six weeks, sufficient bedding-plants that he had purchased, and vegetable plants that he had raised from seed, to afford him a profit of \$200, or nearly double the cost of his greenhouse.

The "Late Roses."

BY GEO. W. CAMPBELL, DELAWARE, OHIO.

Your correspondent from "The Pines" mentions a fact of which I was not before aware, namely, that there are *three* varieties of potatoes claiming to be new, and each called "Late Rose." This is certainly unfortunate; and unless the names can be yet changed, I see no better way of distinguishing them than by prefixing the originator's name to each sort.

As I am informed, two of these varieties are

claimed to be "sports," or accidental variations from the Early Rose. I have had no experience with *sporting* potatoes, but it seems to me questionable whether they would be reliable or permanent in their character; and if they might not be disposed to *sport* back again to their original type, or into other, and perhaps undesirable, variations.

The third variety mentioned was produced from a seed-ball of the Early Rose, and was selected from forty seedlings raised at the same time, and from the same source. This batch of seedlings was in many respects interesting; especially remarkable, however, for their extreme variability. Nearly every variety of form and shade of color known in potatoes was produced; and the difference in production was equally varied. More than half these seedlings produced, the first year, quite small potatoes—from two to a dozen tubers in a hill, in size from a filbert to that of a pullet's egg. Others yielded more and larger potatoes, the product varying, with one exception, from one pound to two and a half pounds to a plant. The exception mentioned is the variety which has been named "Late Rose," but which I propose hereafter to call "*Campbell's Late Rose*." This potato yielded the first year, from a single seed, *twenty* potatoes of marketable size, the largest tuber weighing twelve ounces, and ranging from this size down to that of a hen's egg, the entire product *six and a half pounds*.

This remarkable productiveness continues unabated; and tested with the Early Rose, its yield has been invariably at least four times greater from the same area. The past season a parallel row of the same length, and under precisely the same conditions, was planted beside Bresee's Peerless. The result was *four bushels* of Late Rose, to *one bushel* and three pecks of Peerless. Several parties, to whom I sent specimens for trial last spring, report from one to *three bushels* from single potatoes cut into eyes, and planted with common field culture.

Next to great productiveness, its late keeping in spring is, perhaps, its most desirable quality. In the same cellar, and under the same temperature and conditions, where Early Rose had sprouts two feet long, and was, consequently, shriveled and unfit for eating, the eyes of this seedling remained dormant, and the tuber sound and crisp as when first dug. It is emphatically a late potato, the tops remaining fresh and growing into October. In quality it is, as described by your correspondent from the Pines, "excellent," and has received almost universal commendation. I believe it to be fully equal to that of the Early Rose, or any other popular variety now grown. In form it is much like the parent Rose, in color a little deeper, or more rosy.

Parsons's White Mignonette.

BY W. C. STENO, BRIGHTON, MASS.

In the December *Agriculturist*, Parsons's White Mignonette is classed by Mr. Henderson with the numerous frauds in novelties which are annually sent from Europe. Certainly we have reason to be indignant that so many wonders with high-sounding titles should serve to illustrate "a distinction without a difference." Sometimes they prove even worse. But the very fact that we are so often deceived is a good reason why we should recognize and appreciate a real prize. I am quite sure Mr. Henderson is mistaken in his estimate of the value of this White Mignonette. Possibly its name may be an unfortunate one, as it leads the public to in-

fer that the general effect of the spike is that of a white Spiræa. Of course this is expecting quite too much. We are to compare it with that which we now have, and in doing this Parsons's Mignonette seems to me to be decidedly superior. In the common variety, the general effect of the flower is a dull red, the anthers being of this color, while the light shading of the crest-like petals is less prominent than the color of the anthers. In the Giant Crimson variety, so called, the dull color of the anthers is still more prominent, and though it seems to be very strong in growth it can not be considered desirable. As Mr. Henderson says, "no stretch of imagination could honestly call it crimson." But in the Parsons's White, while the anthers remain of the same size and color as in the old kind, the superior, crest-like petals are at least three times as large as in that, giving to the individual flowers and to the spike a decidedly lighter and more floriferous appearance. The habit of the variety is also excellent, and its bloom abundant and continuous. It may be true that a casual observation might not detect the superiority of this variety, but it must be that Mr. Henderson has a mixed or spurious seed. His good judgment would have noticed the improvement in the Parsons's "strain." It is proper to add that my opinion is formed by an examination of specimens of various kinds raised by Mr. Joseph Tailby from seed imported by Washburn & Co., and that other florists who have tried the same seed agree with Mr. Tailby in giving this variety a decided preference.

The Quinn Pear.

Fruits, like men, have their histories; these are often quite commonplace, but sometimes there is obscurity enough about them to make them interesting. It is not rare to meet men who are polished, and every way acceptable, about whose antecedents we know little or nothing. In this category we must place the Quinn Pear; it is very excellent, but when we would trace its history we must stop at a certain point. All that is known of the Quinn Pear is this: Many years ago the late Prof. J. J. Mapes imported a lot of pear-trees, among which was the one now called Quinn. It was simply labeled "Knight's Seedling." In planting, this tree was not put in the orchard with the rest, and when unsatisfactory trees were grafted over, this, though it bore nothing for twelve years, being in an out-of-the-way place, escaped. A few years ago the tree commenced to bear, and now produces good crops of a small pear, of the size and shape shown in the engraving. The skin is of a greenish russet, which in well-ripened specimens approaches to golden russet. There are no markings of any kind, but sometimes there is a slight ruddy tinge upon the sunny side. In its general appearance the fruit much resembles a well-grown Seckel. The flesh is gritty towards the core, sweet, juicy, and of a remarkably high musky flavor. The pear is in eating in December, and without any especial care readily keeps into January. In order to ascertain the name of the fruit, Mr. P. T. Quinn, who now has charge of the place upon which it grows, took it a few years ago to the Farmers' Club. None of the savans there knowing it, they of course concluded that it must be unknown, and named it the Quinn Pear. In this the Club was more fortunate than it sometimes is in the bestowal of names, as the best pomologists of the country have been unable to identify it, and it is

gratifying to know that in all probability Mr. Quinn's name will remain associated with this excellent variety. It is likely that it is a seedling that never was named by Mr. Knight, and that the original tree was lost by accident or destroyed as unpromising. The tree in question stands in an unfavorable place, and has received no care whatever, and it is probable that under good culture it would come into bearing earlier and produce larger fruit. The list of really good winter pears is so very small, that we gladly welcome an addition to it that possesses so many excellent qualities as does the Quinn Pear.

FROZEN PLANTS.—Some plants in a room where the fire went out, allowed some observations to be made upon the effects of cold, which in part compensated for their loss. Some Chinese Primroses, which were just coming into bloom, had every leaf completely killed, while the flowers and the flower-stems were not touched. One would suppose that the delicate tissues of the flowers would show the effects of frost sooner than the more robust leaves. It seems impossible to predict what will be the effects of cold upon different plants that are closely related. There were several Begonias; all those of the *Fuschoides* section were killed to the root, while *Begonia nitida* did not suffer at all. We naturally expect plants with very succulent leaves to be most liable to injury by sudden freezing, but succulence does not seem to have much to do with it. *Echeveria metallica* was badly cut; *Echeveria secunda* was not injured.

Rabbits and Snares.

In some localities rabbits amount to a nuisance, doing great mischief in gardens and to orchards. Everywhere, however, they are acceptable in a pot-pie or a savory stew, and the destruction of them by traps or snares has a twofold object. These animals will always run in an old or well-beaten trail or path, and when they have once made a run

Fig. 1.—SNARE.

they will use it in preference to making a new one. This peculiarity makes it very easy to snare them. Snares are made of fine brass or copper wire. A piece eighteen inches in length is taken, and a small loop made at one end; the other end is passed through the loop and a ring formed. The end of the wire is twisted around a twig which lies at the side of the rabbit's run, and the ring stretches across it in such a position that the rabbit as it runs along puts its head into it. The wire tightens around its neck, and the animal is caught. (See figures 1 and 2.) A snare may be placed in a hole in a fence, or in a brushy place, or even in the open ground, by driving a stake on each side of the run.

Fig. 2.—SNARE.

Rabbits are very fond of salt, and they may be captured by means of a salted string. A box

Fig. 3.—RABBIT TRAP.

with falling doors is made (fig. 3), each door is held open by means of a string dipped in salt water and dried; this passes through a hole in the top of the box and is tied to a peg in the floor of it. Another salted string is carried from the box and stretched across the run. The rabbit finds the string, and eats it up to the peg to which it is tied. As soon as the string is cut the door falls, and is held firmly by a hinged leg fastened to the top of the door, which prevents its being opened. The rabbit is trapped. The common steel traps are of little use for rabbits; their long and broad feet cover not only the pan, but the jaws also.

The Dyehouse Cherry-Tree.

BY H. T. HARRIS, LINCOLN CO., KY.

About thirty years ago, an old man by the name of Dyehouse found growing in his orchard, among some English Morellos, a small, bushy tree, which differed in form from the others, and also ripened its fruit some four weeks in advance of them. The fruit was

DYEHOUSE CHERRY-TREE.

about the same size of the Morello, but different in color and shape; and the tree was found to be much hardier than its supposed parent. It grew vigorously, and soon became a full bearer. The original tree is now dead, but its numerous progeny—gathered from sprouts—have been disseminated to a limited extent only over this (Lincoln) and a few adjoining counties. The old gentleman was not a fruit-grower. He lived out in our hill country, far removed from fruit regions, and no one, until recently, save a few neighbors, knew anything of this cherry. Eight years ago I planted fifty of the "sprouts," about five feet high and one inch in diameter, and they grew rapidly, and for the past four years I have gathered full crops from them. They have been in full bearing for three years, and have not wholly failed, even the present year (1871), when all other fruits, without ex-

ception, were totally destroyed by the severe cold of April 28th. The fruit ripens in this latitude with strawberries—say from the mid-

DYEHOUSE CHERRY.

dle to the last of May. The tree is a semi-dwarf, with pendent, willowy branches; something like a Kilmarnock willow, although not so leafy. My trees, now ten years old or more, can have nearly all the fruit picked from them by standing on a chair. The original tree, as well those from which mine were taken, grew upon soil almost too poor to produce anything else; a slaty, cold, bluish, yellow clay, with a sand-stone substratum. In rich soil, the trees grow somewhat larger and faster, but do not ripen the fruit so early. I believe this fruit is well adapted to rigid climates and sterile soils, and planted in such places, I should advise a heavy mulch during winter and summer. The fruit is a bright, pinkish scarlet, when fully ripe, and somewhat opaque. A tree in full bearing, when ripe, has the appearance at a short distance of being covered with a scarlet cloth, such is the abundance of the fruit. I sent over three hundred of these trees to different parts of the country for trial, and sent some of the fruit to different eminent horticulturists, among them F. R. Elliott, of Cleveland, O., who pronounced it the "Early May." In this he is certainly mistaken, for we have the Early May growing beside it, and while there is much resemblance in these fruits, a novice can tell the difference at a glance, when seen side by side, at any season. They differ in shape of tree and time of ripening, also in color and shape of fruit on my grounds; and as to hardness, there is no comparison; the Early May being killed while the Dyehouse yielded a full crop, as could have been seen the present season in several localities about here. The "*Cerise Indulle*" of Downing is not

this fruit. I verily believe that it is a *seedling*, and new. It is certainly very desirable. As a fruit for tarts, pies, and especially preserves, it has no near competitor in the Cherry kingdom. Persons who know the fruit often pay fifty cents per gallon for them to make preserves, rather than use the old Morellos when they could be had for the picking. The fruit is quite tart, but when fully ripe is, to my taste, perfectly delicious, having the most pleasant and agreeable acid. One never knows when to quit eating it. I send you a rude sketch of a fair sample of my orchard of fifty bearing trees, now eight years transplanted. I believe these trees would make a fine wind-break and ornamental hedge, if planted eight feet apart, and cut down at planting time to within a foot of the ground, and annually pruned. It will bear much hacking, with impunity. I saw a small orchard of them which had been repeatedly browsed by stock, and it grew finely. I cut one down to the ground, and it threw up a dozen vigorous stems, and grew into a beautiful bushy tree.

I am only an amateur cultivator for the love of horticulture and fruit, and have no "ax to grind," having no trees for sale at any price.

The Hop-Tree.—(*Ptelea trifoliata*.)

A few years ago there was very generally advertised a Hop-tree for which was claimed great advantages over the common hop; as, being once planted, it would go on and yield its yearly crop of fruit without further care. This Hop-tree, which in its wild state is only a shrub, is

HOP-TREE.—(*Ptelea trifoliata*.)

very common from Pennsylvania westward, and southward to Florida; we have seen it very abundant in Michigan, but do not know its northern limit. Its leaves are compound, and

made up of three leaflets, as shown in the engraving. We notice that it is the latest of all our shrubs to start in the spring. The flowers are

QUINN PEAR.—(See preceding page.)

small and greenish, and are borne in clusters at the ends of the new shoots. They have a most unpleasant odor, as do the leaves when bruised. The flowers are polygamous—i. e., there are male, female, and perfect ones upon the same plant. A magnified representation of a single perfect flower is given in the engraving. The fruit is a two-seeded capsule, and is surrounded by a broad ring; it very much resembles the fruit of the elm. As an ornamental shrub, the

Hop-tree has in its favor a very neat habit and freedom from insects, and when in fruit it is at least interesting if not showy. When kept to a single stem it grows quite large. There are in England specimens thirty and forty feet high. The fruit has a very strong and nauseously bitter taste, entirely without the aromatic quality of the bitter of the hop. The use of hops in making yeast and beer is to prevent the fermentation from proceeding too far. Were it not for these, acetous fermentation would set in and the liquid become sour. Before hops were introduced into England, various bitter herbs were used in brewing. It seems that many, if not all, vegetable bitters possess with hops the property of retarding or preventing the souring of fermenting liquids, and hops are only to be preferred for the reason that their bitter is more agreeable to the taste than that of most others. So far as effectiveness goes, we have no doubt that the fruit of the Hop-tree will answer as a substitute for hops, but we should be afraid that its exceedingly disgusting taste might be communicated to bread from yeast made with it. The engraving here given represents the leaves and fruit of about half the natural size.

THE HOUSEHOLD.

(For other Household Items, see "Basket" pages.)

Home Topics.

BY FAITH ROCHESTER.

WHERE TO PINCH.—No exact line can be drawn between the rich and the poor. They are poor who are discontented. There are persons who pity me, I suppose, because they think I am denied so many things that are essential to their comfort; while I consider my own lot greatly preferable to theirs, and really do not have to practice the self-denial they imagine, in doing without such things as it is evidently not best for me to have at present. In the mean time I rejoice over possessions and investments which they do not envy, because they are unable to appreciate their value as I do. Let us spare our pity, then, for only those who mourn over what is beyond their reach, instead of enjoying the best they have already. While we are contented with our present lot, it is entirely reasonable to be reaching out for the things that are beyond, trying steadily to better our condition. The two states of mind, contentment and dissatisfaction, are not incompatible.

"Can't afford it," is a frequent excuse. Neighbor A takes only the county paper this year—times are hard and he "can't afford" as many papers as he took last year; but he still smokes expensive cigars, and, to please his palate, his wife breaks her back over the pastry board—for he must have a piece of rich pie at nearly every meal, and doesn't relish his coffee without a ginger-snap or doughnut to eat with it. When he finds it necessary to economize, he begins to pinch his mind before his body—a small mind, of course, or this thing would not happen. His wife and children feel the pinch more than he does, and it is a real injury to them all.

The same kind of a mistake is made by Mrs. B., who is a widow with two nice little daughters. She earns enough to keep them all decently, but watches all expenditures with a jealous eye. She is often solicited to let her little girls join some class in penmanship, gymnastics, vocal music, or something of that kind, when competent instructors make up classes in the little village where they live. She

Fig. 1.—SUSPENDERS.

"can't afford" anything of that kind, and her bright little daughters take their chance under the changing instruction of the ungraded district school. Other children try in vain to get the name of Lizzie B. in their club for *Our Young Folks*, and both little girls earnestly begged their mother to put down her name for *Hearth and Home*, when a lady who was making up a club called there the other day. Mrs. B. refused, but, being fond of reading herself, she thought to satisfy the children by subscribing for another paper which, she says, is just about as good and a great deal cheaper. It costs less money, to be sure, but it is very poor stuff. Trashy, sensational stories make up the bulk of it, and it is unreliable when it professes to give facts and attempts to instruct.

If Lizzie and Alice B. learn to like such literature, as they probably will, the natural result will be to make them sentimental, extravagant young women, given up to novel-reading dissipation. While their mother "economizes" so closely in these matters that concern their intellectual and moral development, she strains every nerve to dress her little girls as finely as any children with whom they associate. They are not pinched for ribbons, nor feathers, nor artificial flowers, though they often shiver for lack of warm undergarments in winter.

When we feel the necessity for retrenchment, shall we not begin to cut down our expenses at some point where only a personal whim or fancy has led to the expenditure? Not until our dress is brought down to the actual requirements of comfort, neatness, and simple good taste; not until our tables are supplied only with a wholesome variety of plain, nourishing food, should we think of dispensing with a good supply of the best periodical literature, or refuse to add to our growing library an occasional well-selected volume. Not until we have actually begun to pinch ourselves where we can feel the pinch, should we refuse our mite to those in need of charity.

CLOTHING FOR LITTLE GIRLS.—The perfect ideal has not been attained, but here is an effort toward it:

The little girl in question wears a loose-sleeved waist, with drawers attached, made of her mother's old merino (or ribbed) wrapper. The sleeves reach to her wrists and the drawers to her ankles, going inside the warm, yarn stockings, and having a strap under the foot to hold them down. An inch from the top of the stocking, on the outside of the leg, is a button to which fastens an elastic strap, which buttons again at the waist. This strap answers the purpose of a garter—or answers a better purpose, holding the clothing in place without interfering with the circulation of the blood, as garters do. A pair of heavy red flannel drawers is worn over, gathered into bands at the bottoms of the legs. These bands button around the leg, a little below the knee, and a button-hole in each band, fastened to the button, for the elastic on the stocking keeps the drawers from shoving up or down too far. The drawers button at the top to the waist of the under-drawers, which has a facing of thick cloth to hold the buttons firmly. Next comes the flannel skirt, with its shoulder-strapped waist; then the lined flannel dress, then the high, sleeved apron.

The long legs of thick, cotton stockings of large size, could be made to answer well as under-drawers for a child two or three years old, cutting them over to fit the ankles, and ripping them down several inches at the top, where they join the waist. Sleeved waists of cotton flannel are worn by many children instead of chemises, and to these the drawers are buttoned.

It seems quite reasonable that additional clothing should be put upon the feet and legs when going out from a warm room into the cold. Arctic overshoes and long yarn leggings are good, but long yarn socks with thick bottoms (leather is best for the bottoms) are very comfortable. Old woolen stockings, considerably worn at the toes and heels, can be cut over for small children, and bottomed with leather or with thick cloth. If the legs are long enough to come above the knees, so much the better. The knees should always be well protected against cold. I have seen daughters of prosperous people out-doors with their knees bare, when the mercury was below zero, this very winter!

A LETTER ANSWERED.—A mother writes to me from Missouri. She wants Miss Peabody's Kindergarten Guide, but does not know where to send for it. Let her send \$1.25 to the office of the *Agriculturist*, and they will send her the book by mail.

The same mother asks my opinion about allowing her eldest child, her only daughter, to play and romp with her brothers. She is advised not to do so by older mothers. I presume these "older and wiser" mothers think that it is not "pretty" for little girls to be noisy and fond of active games. They think that "boys will be boys," and the best you can do to get rid of their noise is to keep them out of doors as much as possible. They have quite a different programme for their girls.

I don't know as much about all this as I wish I did, and I am not trying to give advice now—only

to talk the matter over a little. This Missouri sister wishes she could talk with me about these things. She can hardly desire it more earnestly than I, to talk with her and get her experience—the experience of any earnest, observing mother.

No two children are exactly alike. Some girls are boyish and some boys are girlish, but there is a general type of the boy nature and of the girl nature. As a general rule girls are more quiet than boys, inclining more to dolls and to domestic pursuits, but the exceptions to the rule are so numerous that great liberty should be allowed. Little girls almost always suffer from being kept in the house too much. If they take injury from outdoor life, it is usually on account of the barbarous exposure to cold their limbs get, because they are so imperfectly clothed. There is no reason why girls should not be dressed as warmly and as evenly as boys. It seems to me a fortunate thing for both boys and girls when they are put together in the same families as brothers and sisters, and I think it well for them to share each other's pursuits as far as possible. Good manners should be taught to both sexes alike. Rudeness should be checked; the stronger should be taught to help the weaker. We want gentle boys as well as gentle girls, and hearty, active, strong-limbed, wide-awake girls are quite as desirable as the same kind of boys. Modesty is equally desirable in both sexes. A mother must keep her eyes and ears open, always ready to ward off impending danger from the young minds about her. Little girls are not in as much danger of corruption from the evil communications of their own brothers as from their brothers' playfellows who have no sisters of their own.

No; let the little girls have a fair chance to learn to coast, and skate, and row a boat, and harness and drive a horse. Let them jump, and climb, and learn to hoe, and mow, and rake, and bind, if they like. And encourage the boys to emulate the girls in the arts of sewing, knitting, dish-washing, etc. None of these things will affect the real nature and make a boy less manly or a girl less womanly.

A Support for Quilting-Frames.

Here is a little contrivance which will do away with the usual and awkward way of supporting a quilting-frame upon the backs of chairs. A model was sent us by Mr. Edward Skinner, of Middletown, N. Y., from which we have had an engraving made. The cross-pieces, forming the foot, are 18 inches long, and the upright 31 inches high. A piece of stout wire is driven firmly into the top of the upright, and as it passes through the holes in both pieces of the frame, no pins are required.

SUPPORT FOR FRAME.

About Suspenders.

"W. H. B.," Oakwood, Kansas, sends a plan for arranging suspenders which obviates the inconvenience resulting from their slipping off the shoulders when one works in his shirt-sleeves. Sewing the suspenders together at the point where they cross each other does not entirely answer the purpose. So our correspondent uses a strip of elastic, sewn to the two suspenders just across the shoulders, as in fig. 1. The elastic should be of good quality, an inch broad, and long enough to allow one to slip off the suspenders at will, but not so loose as to allow them to fall from the shoulders without aid. Our correspondent's plan is somewhat like that of some of the "patent braces." We notice that the suspenders made of late, instead of being sewed together at the crossing, are fastened

as in fig. 2, where each suspender is bent back upon itself, and the two firmly sewed together. This gives a strong doubled edge to sew to. The single edges are stitched, as shown by the dotted lines.

Letter from a Housekeeper.

HINTS ABOUT CRUMPETS.—A Frenchman brings to the door a very nice article of crumpets, for which he charges twenty cents a dozen. My English friend says, "They are nothing but flour and water, and fearfully dear." I think she is mistaken about their being nothing but flour and water. I have often made them, but never to my satisfaction, unless the batter was mixed with pure sweet milk, and at least two eggs to the quart of batter. Any housekeeper trying my receipt, will, I think, be pleased with it. Use a tin pail with a closely fitting lid. Take a quart of new or perfectly sweet milk, and raise it to a bread-making temperature. Mix it with flour enough to make a stiff batter. Now stir in a teacup of lively yeast and let the pail stand in a warm place until the sponge is very light. A teaspoon of salt may now be added, and the well-beaten whites of two or three eggs. Mix very thoroughly and let them stand again until very light, when they are ready to bake. A moderate fire is best, and the cakes should not be turned until the holes on the upper side are formed and set. A sort of secret, and a very important part of good crumpet-making, is this: After the crumpets are baked, do not remove them to a plate, or place them one over the other while warm; do not put them on the table or any solid substance, but pass each crumpet as soon as done to a cloth, drawn over an empty barrel, or suspended in a similar manner. In this way they cool rapidly and remain perfectly light, which would not be the case if this precaution was not observed. After they are cold you may place them one over the other without affecting their lightness in the least. Rings of the proper size should be provided, but they are not indispensable, as the crumpets may be made without and taste just as good. In this case, however, after they are cold it is well to trim them to a uniform shape, using a large pair of scissors for the purpose. They will keep for a week or more. When wanted for the table, they must be toasted brown, generously buttered, cut into three triangular-shaped pieces, and served very hot. They must be piled from three to five on the plate before being cut. If the pieces are displaced in the least, you will gently push them into place. My English friend tells me that they are an indispensable addition to a tea-table in her country, especially if invited guests are present, and that they are very generally used for breakfast. Husband is very fond of buckwheat crumpets, which are much less difficult to make. The buckwheat flour cooks and sets much quicker than wheat flour, so that it is quite possible to have the crumpets light and nice without milk or the whites of eggs. I often make them for tea, using the batter left from the morning's breakfast. No matter how light they are, if you place them one over the other, or even on separate plates, while just hot from the stove, they will be heavy. To insure their excellence, you must place them on a suspended cloth as directed for the wheat crumpets.

I have met with individuals who preferred crumpets toasted so much that they were dry and hard. This I consider a perverted taste, as the nature of the cakes is, to be soft, tender, and delicate.

ROASTING OLD POULTRY.—It is quite a general idea (and I think an erroneous one) that old and mature poultry should invariably be boiled to insure its being tender. This may be a good general rule, but it is not always necessary to follow it. For instance, if I want a roast chicken for dinner, and the one provided is an old one, by merely cooking it a longer time and at an even temperature, it may be made as tender as though it had been boiled. My experience, although of course limited, has taught me this. My mother once suggested to a young housekeeper that the goose intended for the Sunday's dinner was old and would require considerable cooking, but gave no length of time re-

quired. The young person, who had had very little practice in the art of cooking, put it in the oven as soon as the fire was well lighted in the morning. At nine o'clock she took it out until church-time (a little after ten), when she gave directions to the girl to keep it in the oven till they returned to dine at one. It was so tender that it broke away before the edge of the sharp carving knife, and the meat was a dark walnut color throughout. I relate this to show that an old bird may be made tender by roasting. The orifice at the neck and apron should be securely sewed together, in order to confine the steam and keep it moist. Another young housekeeper of my acquaintance some years since gave a dinner party, and naturally enough her husband bought the largest turkey in market. An experienced neighbor told her, "It is an old gobbler, and you will have to steam it." So the day before the party she steamed it until it was as tender as a spring-chicken, and ready to fall to pieces. Then she roasted it until it was a fine brown. The next day, an hour before the dinner, it went in the oven to be warmed up. This also fell before the knife, and so far as eating roast turkey was concerned, was a complete failure. Now, if this turkey had been properly trussed, the knee joints pushed up to the side of the breast under the skin, and then roasted in a moderate oven for about three hours on the *very* day of the party, and been well basted, I have no doubt it would have been tender.

SWEET-BREADS, cooked properly, are very delicious and exceedingly nice for invalids. A little butter only should be allowed in the pan with them, and no seasoning of any kind. After they are a fine brown all over, a little salt may be sprinkled over, and they may be served. They need a moderate fire and at least thirty minutes' time. Some years since I was in the habit of soaking and blanching them, but I have since learned better. I merely wipe them clean and cut off any unpleasant-looking part. It is best to purchase only those that are white and free from blood.

BOILING CLOTHES.—By a little incident that happened under my own observation, I am reminded to suggest to the inexperienced that clothes to be boiled should be placed in cold water. I have seen washer-women put the clothes into a boiler of very hot water. It is a mistake, and will be certain to make the clothes yellow. It would be well to say just here in this winter-time, that unless considerable care is exercised while taking clothes from the lines, they will be badly torn. Instead of pulling at the goods, simply bend or lift the part immediately under the clothes-peg from the line. It will separate easily, and will not injure the fabric in the least. Do not try to bend the articles while frozen, but allow them to remain on a table or the clothes-horse until the frost is out. A few moments in a moderate temperature will be sufficient.

How we Live at Our House.

I was about to write this to your horticultural department, but, upon the whole, I think I will send it to the Household, provided anything from a masculine pen can be admitted there. We live in the country, and have more or less visitors. Those who stay a few days usually make a direct or implied compliment to the way in which we live. This has been done so often as to induce me to consider in what particulars our living differs from that of people in general, and I find it all sums itself up in—vegetables, and plenty of them. Our butcher's bill is unusually small for a family of its size, and we do not take much pains to procure delicacies or rarities in that line; but upon vegetables, as the slang phrase goes, "we throw ourselves." To one from the city the profusion and quality of our vegetables is naturally a surprise, and it is still more so to the average farmer who now and then makes us a visit. Farmers, as a general thing, have fewer vegetables than those who live in cities. Our rule is, three or four vegetables besides potatoes, according to the season. I know I shall be set down for a heretic, but I never could see why people must

always have potatoes for dinner. To the world in general a dinner without potatoes is no meal at all, and in deference to custom we always have potatoes, which "himself" seldom troubles. Of course the foundation of this abundance of vegetables is the garden. I need not tell you what the farmer's garden generally is, nor what it ought to be, for you have been preaching about it these many years. I have been North, South, East, and West as far as most people, and know how meager are the farmers' tables as far as vegetables are concerned. There are pies, puddings, cakes, pickles, and preserves in costly profusion, for these the good wife can manage without man's aid, but few women care to undertake a garden. Some few do it, and capitably too, but they are not numerous enough to serve for examples. Though I do say it, the head of this family looks out for the garden products as being next in importance to bread. From the time the departing frosts allow the winter-covered spinach to be cut until the ground closes the next November, there are fresh vegetables every day. In the one item of "greens," there is no day between these two periods when there is not a cutting of something: Spinach, New Zealand Spinach, Spinach Beet, Sorrel, and Kale, or Sprouts, one or the other, is at hand. It is not necessary to go through the catalogue of the varieties we enjoy, as it would include nearly everything edible in the vegetable line. Let us look at our present winter's supply; it consists of Savoys and common cabbages, beets, turnips, onions, carrots, salsify, parsnips, scorzonera, squashes, sweet potatoes, celery, horse-radish, common potatoes of course, and beans. So in winter even there is a chance for abundant variety. Having the winter's store of vegetables, there are two things essential to their full enjoyment—proper keeping and proper cooking. As to the keeping, that is not a matter belonging in the Household Department. It is sufficient to say that each is stored according to its requirements, and that especially the roots are kept in bins where they are stratified with earth.

My two favorite vegetables in the above list are carrots and celery, and they are both cooked in the same way. I know that some will hold up their hands in horror at the notion of cooking celery—but just try it. We have a plenty to eat raw, but we like it cooked besides—they are two different things, just as are raw and stewed tomatoes. Cooking is, besides, an economical way of using celery, as that which is not well blanched may be cooked. As to cooking, the celery is cut up into inch-pieces, and the carrots into dice about the same size. They are stewed in a little water until tender, and what water remains is poured off; milk enough to make a sauce is poured on, and a good lump of butter, previously rolled in flour, is added, and the whole boiled up again. This makes a rich creamy sauce for the vegetables, and one who has never tasted carrots other than plain-boiled, will be surprised at the difference cooking can make to a common vegetable. Those who have never tried celery treated as above, will find it a new culinary revelation. Mind, I never cooked them as described, but that is the way "the Missis" says it is done. Salsify, which people will call "Vegetable Oyster," when there is no oyster about it, but good enough without borrowing a name, and Scorzonera, which is like Salsify, only a little more so, are both cooked in the same way. The Savoys are cabbages glorified; don't profane them by boiling with meat, but cook in pure water, and when done, drain and cover with a nice drawn butter, as you would cauliflower. Don't, when you have done this, make common cabbage of it by drenching it with vinegar. If this letter was not already too long, I would like to say something about the use of vinegar and other condiments, but that must remain for another time. I am not a "vegetarian" in the accepted sense of the word; we have meat twice a day, but it is quite astonishing how little of it suffices when there is an abundance of nicely served vegetables. If those who live in the country would expend dimes on the garden, they would save dollars in the yearly expenditure for meat, and it may be that health and comfort would be greatly increased. THORSON.

BOYS & GIRLS' COLUMNS.

Those Map Prizes.

I suppose that many of you will be looking for the announcement of the decisions on the maps sent for prizes. But you must recollect that the time for receiving maps is not up until the first of this month, so nothing can be said about it until March. There is already a goodly heap of them, and if they continue to come in as they have for the past week or two, it will be no little task to go over them all. Let us all have patience, and we shall next month know who are the successful ones.

THE DOCTOR.

AGRICULTURIST AND HEARTH AND HOME.—A great many of our boys and girls see both these papers, but some only take the *Agriculturist*, and to these we must say, that Aunt Sue is such a puzzling woman, that she puzzles in both papers. She is sometimes troubled because some who write her, do not say which paper the writer refers to. The good lady has two sets of boy and girl correspondents, one belonging to the *Agriculturist*, and the other to *Hearth and Home*, and she loves them too much to wish to disappoint either, by replying to them in the wrong place. Again we must ask that all answers to puzzles and all letters relating to her department be sent to Box 111, Brooklyn, N. Y., and not to 245 Broadway.

Tricks of Parlor Magic.

Tricks of legerdemain, or slight of hand, as it is often called, can afford much amusement in the social circle. If done at all, they must be well done, and no one should undertake to exhibit a trick until he has practiced it sufficiently to be able to do it smoothly and without any mistake. The performer should be perfectly self-possessed, and be able to keep up a lively talk, which will occupy the attention of the spectators and prevent them from watching his trick too closely. Some of the feats done by experts in the line are truly wonderful and are the

Fig. 1.—THE BALL PREPARED.

result of much ingenious contrivance and careful preparation. We give now a simple trick, which does not require expensive preparation, and which, when cleverly done, will prove very wonderful to those not in the secret. We have some other tricks ready, but we have room for only one at the present time.

TO PASS A PIECE OF COIN INTO THE CENTER OF A WORSTED BALL.—To perform this trick, you want three or four skeins of worsted yarn and a flattened tin tube, as shown by A (fig. 1). This tube must be exactly wide enough for a nickel cent to pass through. You must, previous to performing the trick, wind the worsted on the end of the tube, in the form of a ball, getting it as round as possible, and so that the end of the tube reaches

Fig. 2.—UNWINDING THE BALL.

only to the center of the ball, as shown in D (fig. 1). When finished, place it in a room adjoining that in which you are going to perform the trick. The last thing required is a pocket handkerchief, in the center of which you fix a nickel cent in such a manner that it does not show on

the other side. To commence the trick, borrow from one of the company a cent, at the same time getting him to mark it, so that he will know it again. Produce the handkerchief, and holding it up by one corner, and in such a manner that the coin fixed in it can not be seen, say, "I am now going to place the coin in the handkerchief," at the same time place the hand in which you are holding the cent-piece, under it, but retain the coin in your hand. Wrap up the handkerchief, and, still holding it, let the company feel that it is there. (They, of course, feel the coin which has been fixed in the handkerchief.) Now place the handkerchief, just as it is, on a chair close to you; pretending to have forgotten the ball, go to fetch it. When out of the room, drop the marked cent-piece down the tube into the ball, then draw out the tube, and by pinching the ball, the hole made by the tube will close, at the same time keeping the coin in its place. You should have a long piece of the worsted left unwound, so as to cover the hole after you have dropped the coin in. Now bring in the ball, saying to the company that you propose to cause the coin to pass from the handkerchief into the center of the ball. Place the ball into a glass tumbler (fig. 2) upon the table, lift the handkerchief and shake it, showing that the coin is gone; then let any one of the company unwind the ball, and when it is undone nearly to the center, out will drop the coin.

Aunt Sue's Puzzle-Box.

The "Arithmorem" is a very interesting puzzle when understood: therefore let us understand it at once. It is based upon the Roman numerals, and as you can not find those numerals in all the dictionaries, I will give you a list of them here.

A = 500.	G = 400.	N = 900.	T = 160.
B = 300.	H = 200.	O = 11 & 0.	V = 5.
C = 100.	I = 1.	P = 100.	W = 55.
D = 500.	K = 250.	Q = 500.	X = 10.
E = 250.	L = 50.	R = 80.	Y = 150.
F = 40.	M = 1000.	S = 7.	Z = 2000.

These; the Romans used those letters for figures, all except the W, which we have made 55 (because it is two Vs), just for our own convenience.

Now let me show you how to ring some of the changes on them.

5110018. What word does that make?
 5 = V, 1 = I, 160 = T, 1 = I, and 8 stands in this case for ate: so there we have VITIATE.
 95250200 = Nineveh.
 10500100160 = Exact.
 120009 = Immix.

These are the simplest specimens, they may be made much more complicated.

Now I want all of you to find out the following, and then go to work, yourselves, and make some more, which you may send to Box 111, P. O., Brooklyn, N. Y.

NOTICE.

Those sending puzzles to AUNT SUE, Box 111, P. O. Brooklyn, N. Y., will please specify whether their contributions are intended for the *Agriculturist*, or for *Hearth and Home*.

AUNT SUE'S NOTICES TO CORRESPONDENTS.

BELLE R. I like to hear that "Ma and Pa both helped." I rather think you will have to call in the assistance of Uncle William, Aunt Mary, and Cousin John this month! Give my love to "Georgie."

A. F. G. says she is very fond of children—likes to have them about her, but does not know how to attract them, being shy, etc. I will tell you one of my secrets, *Addie*—wear a watch-chain and attach to that watch-chain a bunch of "charms," a cherry-stone or almond-shell cut into a little basket, a bead, a ring, almost anything; and the little ones will gather close to you and lean against you, that they may examine with their little eyes and fingers those charms; and their mothers will say, "My dear, don't lean on Miss Addie!" then you will pass your arm around them so that they can't help "leaning." That's the way I fix them.

Glad to hear from Chalmers, Otis A. G., John R. S., Richard White, J. E. Du B., Charlie D. S., and Mary A. E. Thanks for puzzles, etc., to Adolph M. N., Tempy (of course), R. S. Isbester, Ella E. F., Max, and A. F. G.

The Eagles and the Teal.

The Eagle is our national emblem, as we all know. "But what is an emblem?"—That is just the way with you matter-of-fact boys and girls. There might have been something very eloquent following that first sentence, if some one had not asked, "What is an emblem?" That is right, however, let us understand things as we go along, but it would spoil a great deal of what passes for fine speaking and fine writing, were the speaker or writer obliged to explain the meaning of the words he uses. Perhaps the simplest definition of an emblem would be, "a figure that stands for something." Thus a dove is the emblem of peace, a lamb the emblem of innocence, a crown that of royalty. Not only are emblems used to express ideas, but they are adopted by nations and by parties. The Crescent, or New Moon, is the emblem of Turkey; the Lion and the Unicorn that of England; and the Eagle is the emblem of America. Your fathers will tell you that years ago the political parties used the hickory-tree, the coon, and the log-cabin as emblems. The emblem net only stands for a nation, but for the leading ideas of its people. So the Eagle not only means America as a nation, but it represents things peculiar to America, such as a republican form of government, political equality, religious liberty, etc. Thus you see that the eagle has a great deal to answer for, and ought to be a very noble and dignified bird. We do not know the reasons that induced our government to choose the eagle as our national emblem, but those who are familiar with his habits do not think him a very

[COPYRIGHT SECURED.]

THE EAGLES AND THE TEAL.—*Drawn and Engraved for the American Agriculturist.*

noble bird, and that our early Congress made a mistake in selecting him. When he has on his company manners, the eagle is a very fine-looking bird. If he has had a good dinner and stands contentedly upon some elevated rock, or if he has his dinner to search for, and is soaring high up, sweeping majestically upon his broad wings, he presents so noble an appearance, that we are quite willing to adopt him as our national emblem. In his domestic habits, in his moral character, the eagle is not to be admired. Emperors and kings sometimes do very mean things, and very high dignitaries are often cross at home, especially when they are hungry and dinner is late. This being the case, we shall not be surprised to learn that our eagle will steal from and tyrannize over birds weaker than himself, and that he is very quarrelsome with his equals. His conduct towards his humble relative, the

Fish-Hawk, though it is not unlike that of some rulers towards their subjects, is not to be excused by the fact that he is called king of birds. The Fish-Hawk gets its food by fair hunting: it sails above a lake quietly and patiently until it discovers a fish, and then, with almost the rapidity of lightning, it descends and seizes it, and starts off with the prey to feed its young. The poor Fish-Hawk does not know that from some high point afar off the keen eye of an eagle has been watching its movements, but as soon as it is making off with its fish, down comes the eagle on broad and swift wing, and the poor hawk has nothing to do but give up its hard-earned dinner to the stronger bird. In fact, our noble eagle gets the greater part of his living by stealing. Our artist has made the quarrelsome character of the eagle serve him for a subject of a very spirited and beautiful picture. As

it is an equal match, it represents the eagle in a rather better light than he shows in when robbing a smaller bird. An eagle having caught a teal is met by another, who is hungry enough to fight for the possession of the bird. In the heat of the fight the poor captive struggles and regains its liberty with the loss of its tail feathers. Of course, our sympathies are all with the poor teal, and we are glad to see him escape. The eagles, though they make a fine picture, certainly do not look amiable. We hope that this picture does not convey any lesson to our boys and girls. We don't believe that any of them ever wrangled over the possession of a toy to such an extent that the mother took it away from both, and so, like the eagles, they lost in the quarrel the thing that caused the difficulty. Oh! no. Our boys and girls never do such things. If you don't believe it, ask their mothers.

ALL TAXES PAID

WARING'S

BOOKS FOR FARMERS.

DRAINING FOR PROFIT AND DRAINING FOR HEALTH.

By **GEO. E. WARING, JR.,**

Engineer of the Drainage of Central Park, New York.

CONTENTS.

LAND TO BE DRAINED; HOW DRAINS ACT; HOW TO MAKE DRAINS; HOW TO TAKE CARE OF DRAINS; WHAT DRAINING COSTS; WILL IT PAY? HOW TO MAKE TILES; RECLAIMING SALT MARSHES; HOUSE AND TOWN DRAINAGE.

EXTRACTS FROM NOTICES BY THE PRESS.

He (the author) describes the action of draining upon the soil, the construction of single drains and systems of drains, the cost and the profit of thorough drainage, the making of tiles, and the reclaiming of salt marshes, treats sensibly of malarial diseases, and closes with a chapter which should be widely read, on house drainage and town sewerage in their relations to the public health. [Portland (Me.) Press.]

Nowhere does this book merit a wider circulation than in the West. Every year adds to the thousands of dollars lost to this State from want of proper surface drainage, to say nothing of the added gain to result from a complete system of under-drainage. This book will prove an aid to any farmer who may consult it. [Chicago (Ill.) Republican.]

A Book that ought to be in the hands of every Farmer. SENT POST-PAID, - - - PRICE, \$1.50.

EARTH-CLOSETS

AND

EARTH-SEWAGE.

- THE MANURE QUESTION.
- SEWAGE AND CESS-POOL DISEASES.
- THE DRY-EARTH SYSTEM FOR CITIES AND TOWNS.
- THE DETAILS OF EARTH SEWAGE.
- THE PHILOSOPHY OF THE EARTH SYSTEM.

With Seventeen Illustrations.

Paper Covers, Price, Post-paid 50 cts.

ELEMENTS OF AGRICULTURE.

A BOOK FOR YOUNG FARMERS,

By **GEO. E. WARING, JR.,**

Formerly Agricultural Engineer of the Central Park, in New York.

CAREFULLY REVISED.

CONTENTS.

THE PLANT; THE SOIL; MANURES; MECHANICAL CULTIVATION; ANALYSIS.

The foregoing subjects are all discussed in plain and simple language, that any farmer's boy may understand. The book is written by a successful practical farmer, and is full of information, good advice, and sound doctrine.

HORACE GREELEY says of it: "Though dealing with facts unfamiliar to many, there is no obscure sentence, and scarcely a hard word in the book; its 254 fair, open pages may be read in the course of two evenings and thoroughly studied in the leisure hours of a week; and we pity the man or boy, however old or young, who can find it dull reading. Hardly any one is so wise that he will not learn something of value from its perusal; no one is so ignorant or undeveloped that he cannot generally understand it; and no farmer or farmer's son can study it thoughtfully without being a better and more successful cultivator than before." SENT POST-PAID, - - - PRICE, \$1.00.

ORIGINAL STOCK OF
Moore's Early Sweet Corn,
 The Largest, Earliest, and Best
 Sweet Corn in Cultivation.
 Silver Medal Awarded.

We are pleased to announce to our customers that we have again made arrangements with Captain Moore for his whole stock of this favorite variety, which we introduced last season. This corn has been thoroughly tested in every part of the United States and Canada the past year, and has proved all that was claimed for it.

The following extract from the report of the Vegetable Committee of the Massachusetts Horticultural Society for 1870 will give a full description:

"The past year has not been so prolific of novelties in the way of vegetables as some of its predecessors. In this age of progress, when so many are engaged in striving to improve our garden vegetables, it would seem strange indeed if, among them all, some real gain is not annually secured. Such a gain your committee feel confident the public will secure in Moore's New Sweet Corn, which, after another season's trial, proves a decided acquisition."

"To Capt. J. B. Moore, the well-known horticulturist of Concord, Mass., belongs the honor of originating this splendid variety. It is a cross between Crosby's Early and Barr's Improved—the former the most popular early, and the latter the best late variety we have. After several years of great care and labor, Mr. Moore has, at last, succeeded in bringing it to its present perfection. It is strong, stocky, and vigorous, growing from seven to seven and a half feet high; ears set rather low on the stalk, and having from twelve to sixteen usually and occasionally twenty rows on the ear. Color, when fit for the table, very white and handsome. Quality superior, not surpassed by any other variety. Size of ears large, considerably larger than the Crosby, and superior to any other variety, either for the market or family use, and very productive. It also matures earlier than any other variety of equal size, which will make it a very desirable variety for the market garden."

"The Society's Silver Medal was awarded by your committee."

CHARLES N. BRACKETT, Chairman.

The following extract is from the report of same committee, for 1871:

"Moore's Early Concord Corn, which was described in our report of last year, was again on exhibition, from Aug. 5th through the season. It deserves all the praise that has been given it in previous reports, and appears to succeed as well with other cultivators as in the hands of Capt. Moore. The first prize was awarded to James Conley, Aug. 13th, for this variety. It was also exhibited at the same date by Capt. Moore, W. C. Child, and others, in the condition. At the annual exhibition in September, the first and second prizes were awarded this variety."

(Signed) "CHARLES N. BRACKETT, Chairman."

We have purchased Mr. Moore's whole stock, and can guarantee it to be first-class in all respects.

We have received hundreds of testimonials, which will be found in a circular, to be had on application.

Price, per pkt., 25 cents; selected ears, 25 cents; post-paid; per quart, 75 cents; per peck, \$3.00; per bushel, \$10.00.

Address **WASHBURN & CO., 100 Tremont Street, Boston, Mass.**

We are pleased to announce that the 26th annual edition of this well-known work is now ready, enlarged and improved, and containing a magnificent new colored Lithograph, besides hundreds of Engravings, in addition to its full descriptive Price-list of 3,000 varieties of Flower and Vegetable Seeds, rare Gladioli, Lilies, Tuberoses, etc., with full directions for their culture. This is, without doubt, the most perfect work of the kind before the public.

Sent free to applicants on receipt of two stamps. Address

WASHBURN & CO., Boston, Mass.

The Premium Sanford Corn.

The very favorable reports received from nearly every section of the country confirm all that has been said in its favor, and place it at the head of all other varieties for field culture. Sample ear, by mail, post-paid, 25c.; one quart, post-paid, 60c.; two quarts, \$1.; one peck, by express, \$2.; one bushel, \$5. Send stamp for Circular, giving testimonials and full description. Address **S. B. FANNING, Jamesport, N. Y.**

EXCELSIOR OATS.—Best White for our climate, weighing 37 lbs. to bushel now—yield 70 to 100 bushels per acre. Single bushel, \$5. Three bushels for \$10. Chester Pigs a specialty. New "Early Shipping" Tomato, per pkt., 25 cents. A pkt. of each will be mailed, postage paid, on receipt of 50c. For pounds of the new Late Rose Potato will be sent by mail on receipt of \$1. All the seed I sell I warrant fresh and reliable, and to reach the purchaser in good order. On the receipt of a postage stamp I will send to any plain address my

NEW DESCRIPTIVE CATALOGUE of VEGETABLE and Flower Seeds FOR 1872.

The pleasantest part of the whole business is the favorable reports accompanying the orders I am now receiving from those I sold seed to last season. All orders, be they large or small, will be promptly attended to. Read my advt in Jan. No., page 60. Address **H. E. ACKER, Seed Grower, Woodbridge, N. J.**

NEW AND RARE VEGETABLES.

I make the seed of New and Rare Vegetables a specialty, besides raising all the common varieties. On the cover of my Catalogue will be found extracts from letters received from farmers and gardeners residing in over thirty different States and Territories who have used my seed from one to ten years. Catalogues sent free to all. My customers of last year will receive it without writing for it. **JAMES J. H. GREGORY, Marblehead, Mass.**

COLOSSAL ASPARAGUS ROOTS.

Herstine and other Raspberries. Best Strawberries, Blackberries, etc. Grown and for sale *low* by **JOHN S. COLLINS, Moorestown, N. J.**

CONOVER'S COLOSSAL ASPARAGUS SEED at \$2 per lb., by mail, post-paid. Raised from seed bought of Conover. **S. W. HOPE, Dover, Delaware.**

EARLY ROSE, EARLY MOHAWK, and PEELLESS POTATOES. Boyden's No. 30, Charles Downing, Kentucky, and Albany Seedling Strawberry Plants. **SAMUEL C. DE COU, Rocklesstown, Burlington Co., N. J.**

Having been the first to introduce to the public the Hubbard Squash, American Turban Squash, Marblehead Mummoth Cabbage, Mexican Sweet Corn, Phinney's Watermelon, Brown's New Dwarf Marrowfat Pea, Boston Curled Lettuce, and other

New and Valuable Vegetables,

with the return of another season I am again prepared to supply the public with Vegetable and Flower Seeds of the purest quality. My Annual Catalogue is now ready, and will be sent free to all. My customers of last year will receive it without writing for it. It abounds in fine engravings, many of which were taken from photographs of the vegetables themselves. It has not only all novelties, but the standard vegetables of the farm and garden (over one hundred of which are of my own growing), and a carefully selected list of Flower-Seeds. As stated in my Catalogue, all my seed is sold under three warrants—1st: That all money sent shall reach me. 2d: That all seed ordered shall reach the purchaser. 3d: That my seeds shall be fresh, and true to name. Catalogues free to all. **JAMES J. H. GREGORY, Marblehead, Mass.**

Pure Cane Seed.

VARIETIES—Regular Sorgo, Librarian, Neezania, and Onisciana. PRICES—By mail, postage paid, 50c. per lb.; by express, 25 lbs. or less, 50 cts. per lb.; over 25 lbs., 30 cts. per lb., package included. Two to three pounds required per acre. Money with order.

We are the only parties in the country who give any attention to preserving the purity of Cane Seed. The crops from which our seed has been taken have been grown especially for us. Their yield from year to year has ranged from 240 to 300 galls per acre. Our Regular Sorgo is from seed recently imported from the mouth of the YANG-TSE-KIANG, the best cane-growing section of China. Send for Circulars.

BLIMYER, NORTON & CO., Cincinnati, O., Manufacturers of the Victor Cane Mill, Cook's Sugar Evaporator, etc., etc.

Our Seed Catalogue FOR 1872,

Enlarged and improved, containing a complete list of all the best varieties of **VEGETABLE, FIELD, and FLOWER SEEDS,** is now ready, and will be sent to any address on receipt of postage stamp.

E. A. REEVES, P. O. Box 2660, 58 Cortlandt St., New York.

The Trophy Tomato.

HEAD-QUARTERS SEED. WHOLESALE AND RETAIL.

Single packets, 10 cents. Address **GEO. E. WARING, Jr., Ogden Farm, Newport, R. I.** Send for Circular. T. J. Hurd's seeds, 25 cents.

400,000 STANDARD Pear Trees at greatly reduced rates, and a complete assortment of Nursery Stock. Address **E. MOODY & SONS, Lockport, N. Y.**

All who Love Flowers,

Collections of Flower Seeds by Mail.

The following collections contain the most showy varieties in our large assortment, with full directions for culture. Each packet contains a mixture of the different colors and varieties of its species, so that a greater display can be made at a much less price than when ordered in separate packets. Those unacquainted with flowers, as well as the experienced cultivator, may order without fear of disappointment.

- Coll. No. 1—contains twenty choice varieties of Annuals, \$1.00
- Coll. No. 2—contains twenty choice varieties of Biennials and Perennials, \$1.00
- Coll. No. 3—contains ten extra fine varieties of Annuals and Perennials, \$1.00
- Coll. No. 4—contains five very choice varieties, selected from Prize Flowers, of English Pansies, German Carnation, and Picotee Pinks, Verbenas, Truffaut's French Asters, and Double Hollyhocks, \$1.00

Any one remitting \$3.00 will receive the four assortments postage free.

A GOOD THING

(YOUR OWN CHOICE OF 106)

WITHOUT MONEY,

AND WITH

Very Little Trouble

DURING

THIS MONTH

OF

February, 1872.

Over 13,500 Others

HAVE OBTAINED THESE

Free Articles

WITH PLEASURE AND PROFIT,

and

YOU may do the Same.

Read over the list of good articles in the Table, and descriptions on page 74. They are all new, first-class, reliable, valuable articles, just as good as money. The assortment is so large that every one will find something needed.

Any person who chooses may collect a small or large list of subscribers and receive the premium. It is only necessary to show copies of the papers, explain their value, and collect and forward names. [Specimens Free.]

It has been done largely at Stores, Shops, Post-offices, etc., and by private individuals. By Co-operation, Ministers, Teachers, Churches, Sunday and week-day Scholars, have obtained Melodeons, Libraries, Cyclopedias, Dictionaries, etc., also Sewing Machines, and the like, for poor widows and others. Many professional men have opened and made up good premium lists at their Offices. Clerks in stores and Post-offices have materially increased their salaries thus, while individuals in all classes have secured good things

for themselves or for presents to others, all without the use of working hours, and at no money cost.

As a constant Business Employment, some persons canvass all the time, receive the premium articles, and sell them for cash, and thus secure large salaries. One lady has averaged over \$3,000 a year for years past, and others are getting large pay for their time, often \$5 to \$20 a day. Some who did poorly at first have, by perseverance, acquired the art of canvassing, and become very successful. The work is honorable. The Journals are useful in every family—in City, Village, and Country.

The American Agriculturist is everywhere known and approved. HEARTH AND HOME is now without a superior in the world as a splendidly illustrated Weekly Newspaper, for real value, cheapness, and adaptability to every home in America. The papers are entirely different. Taken together, they supply over \$35,000 worth of fine engravings, and more good reading than can be found in 100 books costing one Dollar each.

Premium Clubs can be made up of subscribers to either paper, or partly of both, as noted over the Table. We call especial attention to the last column of figures, showing the small number of names required where both papers are taken, at the reduced price of \$4 a year.

You, Reader, can get a Premium. TRY IT.

Explanatory Notes.

Read and carefully Note the following Items:

- (a) All subscribers sent by one person count, though from one or a dozen different Post-offices. But... (b) Tell us with each name or list of names sent, that it is for a premium....
- (c) Send the names as fast as obtained, that the subscribers may begin to receive the paper at once. You can have any time, from one to four months, to fill up your list.... (d) Send the exact money with each list of names, so that there may be no confusion of money accounts.... (e) Old and new subscribers all count in premium clubs, but a portion, at least, should be new names; it is partly to get these that we offer premiums to canvassers....
- (f) Specimen Numbers, Cards, and Show-bills will be supplied free as needed by canvassers, but they should be used carefully and economically, as they are very costly.... (g) Remit money in Checks on New York Banks or Bankers, payable to order of Orange Judd & Co., or send Post-office Money Orders. If neither of these is obtainable, Register Money Letters, affixing stamps both for the postage and registry; put in the money and seal the letter in the presence of the Postmaster, and take his receipt for it. Money sent in any of the above ways is at our risk; otherwise it is not.

[In the following table is given the price of each article, and the number of subscribers required to get it. Free, at the regular rates, \$1.50 and \$5.00 a year, for the two papers; also at the club rates of \$1 and \$3.50; also at the rates of \$4 a year for both papers together.]

N. B.—In all Premium Clubs for either paper, TWO copies of American Agriculturist at \$1.50 each, and ONE copy of Hearth and Home at \$3.00, will count exactly the same. So also two copies of American Agriculturist at \$1 each, and one copy of Hearth and Home at \$2.50, will count exactly the same. In this way Premium Clubs can be made up from the 2nd and 4th columns, or from the 3d and 5th, or wholly from the 6th column.

107	Smoother Harrow (J.J. Thomas & Co.)	\$25 00	38	120	19	60	21	21

Every Premium article is new and of the very best manufacture. No charge is made for packing or boxing any article in our Premium List. The Premiums, Nos. 8 to 12, 23 to 28, 34, 35, 36, 68 to 91, and 94 to 106 inclusive, will each be delivered FREE of all charges, by mail or express (at the Post-office or express office nearest recipient), to any place in the United States or Territories.—(No. 33 mailed for 30 cents extra.) The other articles cost the recipient only the freight after leaving the manufactory of each, by any conveyance desired. See Descriptions of Premiums on Next

Full Descriptions

of all the Premiums are given in our last October number, which will be mailed free to applicants. Read over the descriptions, and you will find many desirable articles—indeed, all are desirable. We have room in this paper only for the following DESCRIPTIVE NOTES:

Nos. 1, 2, 3, 4, 5, 6.—American Table Cutlery.—We are glad to be able to offer really good articles of American manufacture, such as are competing successfully with the best foreign goods. Messrs. Patterson Bros., 27 Park Row, who supply us with these articles, are also importers of English goods. They recommend these Knives, manufactured by the Meriden Cutlery Co., as equal to any Cutlery in the market, and their recommendation is a guarantee, wherever they are known. We offer four kinds of Knives, and three sizes of each kind. No. 1 have Rubber Handles, which are actually boiling-water proof, so that, if they were accidentally to remain in it for several minutes, or even hours, they would not be injured. The Blades are of the best steel, and warranted. Dessert size, with Forks, sold at \$14. For 23 subscribers at \$1.50, or 73 at \$1, we will give either the medium size or the table size, sold at \$15.50. No. 2 have Ivory Handles, are selected with great care, have Steel Blades, and are beautiful goods. Dessert size, with Forks, sold at \$13.50. For 31 subscribers, at \$1.50, or 100 at \$1, we will send the medium size, sold at \$20.50. For 34 at \$1.50, or 112 at \$1, we will send the Table size, sold at \$22.50. No. 3 are made of Solid Steel and are triple-plated all over with pure silver, which will wear for a long time, while the Knife is actually indestructible by ordinary use. Dessert size with Forks, sold at \$23. For 37 subscribers at \$1.50, or 118 at \$1, we will give the medium size, sold at \$24.50. For 38 at \$1.50, or 120 at \$1, we will send the Table size, sold at \$25. No. 4 have Steel Blades, triple-plated with silver, and larger Ivory Handles, and are really splendid goods. Dessert size with Forks, sold at \$25.50. For 42 subscribers at \$1.50, or 123 at \$1, we will give the medium size, sold at \$28. For 45 subscribers at \$1.50, or 143 at \$1, we will give the Table size, sold at \$30.50. The Forks, which accompany these Premiums, Nos. 1, 2, 3, are made of genuine Alhata, and warranted double-plated with coin-silver. The Forks with No. 4 are warranted triple-plated with coin-silver. These Forks are also furnished to us by Messrs. Patterson Bros. The Carving-Knife and Fork and the Plated Steel are made by The Meriden Cutlery Co., with the best Ivory, balanced Handles.

Nos. 8, 9, 10, 11—Pocket Knives.—HERE'S FOR THE BOYS AND GIRLS!—These Premiums are among the most pleasing and useful that we have ever offered. Every boy, and girl too, wants a pocket knife. We give them an opportunity to obtain a most valuable one for merely a little effort. These knives are made by Messrs. Smith & Clark, Bronxville, N. Y., whose work is equal to any done in this country or Europe. No. 8 is a neat, substantial Knife, with three blades and buck-horn handle. No. 9 is a still finer article, with four blades and buck-horn handle. No. 10 is an elegant Knife, with four blades and shell handle. No. 11 is a Lady's Pocket Knife, a beautiful article, with four blades and shell handle.

No. 12.—Minitum in Parvo Pocket Knife.—This is a most attractive as well as useful Premium. It comprises, in one knife-handle, a large and a small blade, a screw-driver, a saw, a strong hook, a nut-cracker, a Brad-awl, a gimlet, a corkscrew, a pointer, a slim punch, and, in addition to this, it can be used for various other purposes which will at once suggest themselves to any smart boy or man. The knives will be sent anywhere in our country, post-paid.

No. 13.—Cake Basket.—A new pattern, oval-shaped, nicely chased—a very taking, useful, and beautiful table ornament. This, with other articles that follow, is made by the Lucius Hart Manufacturing Co., of Nos. 4 and 6 Burling Slip, New York City, and is warranted by them to be of the best triple plate. Mr. Hart, "the veteran Sunday-school man," was engaged in the same place and business for nearly a quarter of a century. We have known him and his work for many years, and have taken pleasure in commending and guaranteeing its value to be as represented. We believe the Company which bears his name is fully sustaining his reputation. The amount of silver upon plated ware depends wholly upon the will and integrity of the manufacturer. We could give nearly as good-looking plated ware for less than half the money.

No. 14.—Casters and Fruit or Cake Basket Combined.—This is a new pattern, both novel and beautiful. It can be used as large, showy Casters, with six cut-glass bottles, or be instantly changed into complete Casters, with Call-Bell, and a separate Cake or Fruit Basket, with a colored glass dish inside. Every one receiving it will be delighted. It is from the same makers and of equally good quality as the preceding.

No. 17.—Nut Picks and Crackers.

—Here are twelve nut-picks, elegantly chased, of medallion pattern, with two handsome nut-crackers, in a morocco-covered case. From the same house as No. 13.

No. 18.—Half-Dozen Napkin Rings.

—These rings are beautifully chased, and in a morocco-covered case. From the same house as No. 13.

No. 19.—One Dozen Teaspoons.

No. 20.—One Dozen Table-Spoons.—These are "figured tips," Olive-leaf Pattern, all of the same metal, plating, etc., and from the same makers as No. 13. They are far cheaper than anything we have found at half the price, and well worth working for.

No. 21.—One Dozen Table-Forks.

—The same description and remarks apply to these as to No. 20. We select as premiums only such articles as we can warrant in quality and price. All these articles come from the Lucius Hart Manufacturing Co.

No. 22.—Child's Cup.—A beautiful gift for the little one-year-old. It is made by the Lucius Hart Manufacturing Co. Triple-plated on the outside and gilded on the inside. It never breaks, and will last for many years—indeed, be a life keepsake.

Nos. 23, 24, 25.—Gold Pens: with ever-pointed Pencils, in extension, coin-silver cases.

—Premium No. 23 contains the best No. 4 Gold Pen; and No. 24 the best No. 6 Gold Pen, which is the same style, but larger. No. 25 contains No. 7 Gold Pen, in Gold-tipped Ebony Holder. Each pen will be sent in a neat leather case by mail, post-paid. These pens are made by Geo. F. Hawkes, No. 64 Nassau St., and have obtained an excellent reputation. We have known the maker and his goods for many years, and can recommend them.

No. 26.—Ladies' Fine Gold Pen,

In Rubber Case, Gold Mounted, with Screw Extension, and Gold Ever-pointed Pencil. A beautiful present for a lady teacher or friend. Same makers as above.

Nos. 27, 28.—Ludden's Patent

Magic Revolving Pencil.—This is a beautiful Pencil, which is extended or closed by pulling or pressing the head. They are made with great care, and every Pencil warranted to work perfectly. They are gold-plated, and will last for years. We offer two patterns, one for ladies, with ring for chain, at \$1.50 each, and one of heavier and firmer plate, at \$3.50. They are made by Ludden's Gold P. and P. C. Co., Wm. A. Ludden, Agent, 195 Broadway, who has been in the business thirty years.

No. 29.—Amusette.

—We believe in home entertainment for both young and old people. Our observation is, that the increase of entertaining home games is already doing much to keep not only the boys but their fathers away from drinking and gambling rooms, and other places of evening resort not conducive to good morals. This premium, the "Amusette," as it is called, will afford interest to the older as well as the younger members of the family, male and female. It only needs a smooth table of any kind covered with a cloth. The play with the balls will develop much of ingenuity and skill, and give a capital study of the laws of motion, force, etc. The price has been reduced from \$10 to \$6, and our premium will place it in the power of very many to secure this additional source of home amusements. The Amusette is supplied by E. I. Horsman, 100 William Street, N. Y., who will send any desired circulars giving information. It packs in small space and can be safely sent anywhere by express at small cost.

No. 30.—Baby's Chair.

—This beautiful Premium will delight mothers and babies everywhere. It is a chair, in combination with a limited spring, suspended from a hook in the ceiling of a room. It gives a young child such a variety of amusement, such varied and healthful exercise, allowing free motion and action for limb and muscle, that it becomes almost an indispensable article to the nursery. It is made of black walnut, nicely finished, upholstered in green, blue, or red, with cords to match, and sold, with the book, for \$4. L. O. Colvin, 94 Waverley Place, Newark, N. J.

No. 33.—Steam-Engine.

—This is a veritable steam-engine; one that will GO; and a capital, intensely interesting, and instructive article for boys, and grown-up people too. Our eleven-year-old boy ran his engine an average of an hour or more a day for six months; he has exhibited it in motion to many of his playmates; has hitched on various toy machinery, and it appears to go just as well as when first started.

No. 34.—Garden Seeds.

—A valuable selection of 49 varieties of the best seeds for a family garden, each parcel large enough for a garden of ordinary size. This premium and the next two are put up for us by Messrs. B. K. Bliss & Sons, Seed & Horticultural Warehouse, 23 Park Place and 20 Murray St.,

whose seed establishment is well known as one of the best in the country. This premium will be of great value and convenience to many, as we send the seeds post-paid.

No. 35.—Flower Seeds.

—Like No. 34 this is a valuable premium. It consists of 100 different kinds of beautiful flower seeds, all in separate papers, and includes the finer common varieties, and many of the newer and rarer kinds that are costly. Delivered free.

No. 107.—Thomas' Smoothing Harrow and Broadcast Weeder.

—We consider this so good an implement that we have made arrangements with the manufacturers to offer it as a premium. Mr. J. J. Thomas has so wide and so good a reputation, both as a writer on agricultural subjects, and as author of "Farm Implements and Farm Machinery," that his name alone would be a safe guarantee for the goodness of a farm tool or machine. This harrow has, however, been tested by other good judges, who agree that it is a really valuable article. It is a thorough pulverizer of the soil and good cultivator of growing crops. It is of easy draft, takes a sweep of nine feet, can harrow twenty acres a day, and it leaves the ground as fine and smooth as a garden-bed. For 33 subscribers to *American Agriculturist*, at \$1.50, or 120 do., at \$1, or for 19 subscribers to *Heath and Home*, at \$3, or 60 do., at \$2.50, or for 21 subscribers to both papers, at \$4 for the two, we will send the harrow, worth \$25. Send for descriptive list to J. J. Thomas & Co., Proprietors, Geneva, N. Y.

No. 42.—Doty's Improved Clothes Washer,

with the Metropolitan Balance Weight. Over sixty thousand families in the United States are now using the Doty Washing Machine, and we believe the improved machine has no superior. The "help" use it and like it. Send for descriptive circulars to B. C. Browning, 32 Cortlandt St., New York, or to Metropolitan Washing Machine Co., Middlefield, Ct. It goes cheaply by freight or Ex.

No. 43.—Universal Clothes Wringer.

—A very useful, time-saving, strength-saving, clothes-saving implement, that should be in every family. The wringing of clothes by hand is hard upon the hands, arms, and chest, and the twisting stretches and breaks the fibers with lever power. With the Wringer Machine, the garments are passed rapidly between elastic rollers, which press the water out better than hand wringing, and as fast as one can pick up the articles. We have given thousands of these premiums, with almost universal satisfaction. They are made by the Metropolitan Washing Machine Co., Middlefield, Ct.

No. 48.—A Good Watch.

—The Watches made by the American Watch Co., Waltham, Mass., have peculiarities of excellence which place them above all foreign rivalry. The substitution of machinery for hand labor has been followed not only by greater simplicity, but by a precision in detail, and accuracy and uniformity in their time-keeping qualities, which by the old method of manufacture are unattainable. A smoothness and certainty of movement are secured which proceed from the perfect adaptation of every piece to its place. The extent of the Waltham establishment, the combination of skilled labor, with machinery perfect and ample, enable them to offer watches at lower rates than any other manufacturers. Their annual manufacture is said to be double that of all other makers in this country combined, and much larger than the entire manufacture of England. The mechanical improvements and valuable inventions of the last fifteen years, whether home or foreign in their origin, have been brought to their aid, and the presence of over 400,000 Waltham Watches in the pockets of the people, is the best proof of the public approval. We offer a Silver watch, jeweled, with chronometer balance, warranted by this Company as made of the best materials in the best manner, and in pure coin-silver "hunting" case; weight 3 oz. This watch we offer as one of our Premiums, with the fullest confidence. Upon the movement of each of these watches will be engraved, "AMERICAN AGRICULTURIST. MADE BY THE AMERICAN WATCH CO., WALTHAM, MASS."

No. 87.—Farmer's Boy's Library.

—A few dollars' worth of books pertaining to the farm will give the boys new ideas, set them to thinking and observing, and thus enable them to make their heads help their hands. One such book will, in the end, be of far more value to a youth than to have an extra acre of land on coming to manhood. Any smart boy can easily secure this Premium, and he will have two sterling works by a well-known, practical farmer. They are Allen's New American Farm Book, and Allen's American Cattle.

No. 106.—General Book Premium.

—Any one sending 25 or more names, may select books from our list to the amount of 10 cents for each subscriber sent at \$1; or 30 cents for each name sent at \$1.20; or 60 cents for each name at \$1.50. This offer is only for clubs of 25 or more. The books will be sent by mail or express, prepaid through, by us.

TREES, FRUIT AND ORNAMENTAL, For SPRING of 1872.

ANDERSON'S AGRICULTURAL STEAMER, for Steaming Feed for Stock; Heating Cheese Vats, Tannery Vats, Conservatories, etc. This Steamer is made of Wrought Iron, thoroughly riveted and finished in good style. It has a reliable Automatic or Self-Regulating Water Feeder, Safety Valve, Vacuum Valve, Water Gauge Cocks, Whistles, etc., all complete. The boiler is peculiar in construction, being ONE COMPLETE DOUBLE BOILER WITHIN ANOTHER, the two communicating one with the other. It has an extraordinary amount of fire space for the size of the boiler; No. 3, a medium size, having 3,833 square inches of fire surface; consequently, it requires but little fuel to run it. Either wood or coal may be used for fuel.

It will cook more feed or heat more water in a given time than any other steamer of the same size or cost. It is more durable than any other, for the reason that the fire-box is made of wrought iron, and is entirely surrounded with water. We are also manufacturing

Anderson's Low Pressure Steam Heater, for heating Private Dwellings, Stores, Churches, Conservatories, etc. We manufacture for all the territory east of Illinois. For further particulars, address

P. P. MAST & CO.,
Springfield, Ohio.

CARHART'S
Patent Two-Horse
Pulverizing Cultivator

was awarded the First Premium at State and County Fairs in 1870 and '71.
It is superior to the best Wheel Cultivator.
The draft is reduced nearly one half.
The depth you wish it to run is regulated without the use of wheels.
It can be drawn close to a tree or plant without injuring it.
It is not disturbed by short undulations of earth like the Wheel Cultivator; but pulverizes, levels, and fits the ground for the Mowing Machine better than any Cultivator in use, and can be used for more purposes than any other implement on the farm. Price \$20.

CONTINENTAL
WASHING MACHINE.

At the great trial of Washing Machines at Utica, N. Y., under the auspices of the New York State Agricultural Society, on the 22d of September, 1870, the CONTINENTAL won the FIRST PREMIUM, and was awarded the Bronze Medal, also First Premium and Medal at N. Y. State Agricultural Society at Albany in 1871.
It will wash a single collar or any amount of small articles at once up to the hulk of two or three sheets. It will wash the collar or wristband of a shirt, the hem of a garment, the feet of stockings, or any part of any clothing that may require more washing than the rest, and it will wash them clean. For washing bedding, it can not be excelled. A half-grown boy or girl can operate the machine with ease. It does not rub the clothes a particle, and consequently does not wear them or tear off buttons, which alone makes it worth many times its cost. Its action upon clothes is to turn and squeeze, thereby forcing the water through them; the mass revolving in the same.
So rapid, easy, and thorough is it in its operation, that in every case those who have purchased and used it, say they no longer dread washing.

NEW YORK TRIBUNE OFFICE,
New York, Sept. 6th, 1870.
Gentlemen—I have examined your Washing Machine, and heard the testimony of others better qualified than I am to pronounce upon its merits, and I concur with them in regarding it a very good one. I know it will save clothes. I have no doubt it will save labor—while doing its work very thoroughly.
I commend it to the careful attention of all who believe that progress ought to visit the kitchen and laundry, and not be confined to the shop and the field.
Yours,
HORACE GREBLEY.
Messrs. BRINKERHOFF & Co., Auburn, N. Y.

[From Governor Seymour.]
UTICA, Aug. 29th, 1870.
Those who do the washing in my house are very much pleased with the Continental Washing Machine. They did not care to try it at first, but now they think highly of it. It is simple, strong, and easily kept in order. In my opinion, it will prove to be a valuable invention.
HORATIO SEYMOUR
[From S. Willard, M.D., President of Oswego Starch Factory, Auburn Savings Bank, etc.]
AUBURN, Oct. 15th, 1870.

Messrs. BRINKERHOFF & Co.:
After an ample trial of your Washing Machine in my family, it is found to combine all the valuable properties which can reasonably be hoped for from any machine used for that purpose. It is simple in structure, easy to operate, cleanses the fabric with very little labor in a very short time, by a process which neither wears nor tears the most tender clothes. It is truly a boon to the washing family.
Respectfully yours,
S. WILLARD.

All who feel the want of a machine that will fully sustain all the recommendations given, are invited to try the CONTINENTAL, which will be shipped as directed on receipt of the price, \$15.
If entire satisfaction is not given one after four weeks of fair trial, the money will be refunded to all who will thus notify us.
Agents wanted everywhere, to whom liberal inducements will be offered, and exclusive sale given.
Address
BRINKERHOFF MANUF'G CO.,
Auburn, N. Y.

SOUTHARD & CORLIES, Gen'l Agts.,
55 Beekman St., New York.

It consumes less Soap, less Time, and less Fuel than the usual method. It saves Labor, Wear and Tear, and the Annoyance of Wash Day.
It Requires no Attention while the Process of Cleaning Goes on.
It will do the washing of the Family while you are eating Breakfast and doing up Dishes.

(READ CIRCULAR.)

I respectfully ask all to read this circular carefully, and candidly consider what I propose as a matter of business. Before making known my terms, permit me to state that the matter of washing clothes is one of no small consideration; it is something which concerns every family and every individual. It is but recent since **Hand Washing** was in common use. Latterly, however, the inventive genius of the country has been directed to the invention of various devices by which much of the labor, drudgery, loss of time, and wear of material might be obviated. Ponderous as well as intricate WASHING MACHINES have been constructed—many of which are decided improvements over the old method of washing—and these machines have been very salable. People will continue to have Washing Machines; but let me ask you if the **STEAM WASHER** can be constructed for a few dollars (much less than any ordinary Washing Machine), and enable all to wash by STEAM without labor, loss of time, without wearing of clothing, etc., is it not reasonable to suppose that it will supersede, in a great measure, all Washing Machines now in common use? The sale of this WASHER is unparalleled, and must be so. There is nothing like it in use. It is new, and every family needs it, and will buy it. I wish to secure a few good men to sell rights for me, and in order to secure as many as I need immediately, I offer extra inducements.

If you will agree to sell for me, I will allow 66% per cent commission. You shall have the right to sell any County or State for me, and on application I will forward deed to any County or State which you have sold for me, provided I have not already disposed of it before receiving your order.

Many of my patrons have requested me to suggest the best method of selling the **Steam Washer**, in order to make the most money in the shortest time. In reply, I would say there are many methods which might be suggested, all of which seem to work well, but the most prominent of which I will suggest: In the first place, send for a sample and carefully test it. You will learn by a single trial how to wash with it most successfully. All you have to do now is to exhibit it to others. I will suggest that you make an engagement to wash at a certain place, at an appointed hour; manage to have as many present as possible. You will be astonished at the intense excitement it will produce after the water and steam have rushed through the tubes and foamed over the clothing, rushing back through the clothlag to the lower bottom to be suddenly returned again in the same manner—say for thirty minutes—you take out the clothing, rinse, and wring out, and find the clothing perfectly clean. You will find all perfectly delighted with it.

You can take orders from nine in ten present, to be filled afterwards, at prices ranging from \$8 to \$10 each. A single trial in this manner will satisfy you that the **Steam Washer** is a success and will sell. You should lose no time in ordering a deed for your County, to be sent by express, C. O. D., if not convenient to advance the money. You should continue to take orders, and by the time your deed would come to hand you might have a gross sale. You should arrange with a Tinner to make the WASHERS—the price will vary according to style and finish. I have known some agents to sell as many as twenty Washers in a day. After you have introduced it more or less in your County, you can take another County, and rest assured that wherever you get a single Washer into a neighborhood it will sell many more. Consequently, after you have sold a few hundred in a County, you can sell the right of your County for much more than at the start. You can calculate what your gains will be by buying a single County, but this is not a tenth part what you ought to make, for while you are traveling you will meet with many men who want to make money, to whom you can sell rights. There is no business you can engage in which offers such splendid inducements, besides it is a safe business, no loss, and pleasant because it renders perfect satisfaction. I can not see how I can propose better terms. Should I allow my patrons to make their own terms, I scarcely believe they could make better terms for themselves, and make more money.

On the receipt of five dollars I will ship you a complete Washer, extra copper-bottomed, as a sample, together with a Certificate of Agency, with full instructions how to conduct the business. And upon the receipt of the Washer you may have time to test it, and if you find it not as represented I will refund your money. The Washers retail at from \$8 to \$10. After I send you a sample I will hold your County a reasonable time for you to decide whether you wish to purchase or not. I will furnish blank deeds, and will do all I can to enable you to succeed in the business. Let me hear from you soon, or your choice of territory may be taken by some one else.

Address **J. C. TILTON, No. 10½ Sixth St., Pittsburgh, Pa.**

SILVER-TIPPED SHOES
WEAR TWICE AS LONG
as shoes without.

BOOK AGENTS WANTED.

We desire to secure the services of a few more experienced agents, school teachers, and energetic men to solicit for our new and popular work, which has proven to be one of the best selling books in the market. For particulars, address **BILL NICHOLS & CO., Publishers, Springfield, Mass.**

TRANSATLANTIC MAGAZINE. 1872. 1872.

With the number for January 1872 the TRANSATLANTIC entered upon the third year of its publication. The favor with which it has from the first been received, and the flattering success it has met, encourage the publishers to renewed efforts to make it still more acceptable to the public, and they feel justified in the expectation that it will continue to grow in favor as steadily as it has heretofore.

Its contents are selected from the leading magazines of Europe, and embrace the best of the stories, sketches, essays, and poems published abroad from month to month, most of which are not otherwise accessible to American readers, and it is the aim of the editors, while preserving its general character as a "magazine of light reading," to admit into its pages nothing that is "trashy" or of questionable morality—nothing, in a word, that could prevent its hearty welcome in every family circle.

The rapid increase of the subscription list has enabled the publishers to reduce the price of the magazine to the very low rate of \$2.00 per annum, so that it is now the cheapest as well as one of the most attractive of American periodicals. All subscriptions payable invariably in advance.

Remit in drafts or Post-Office money order if possible, and where neither of these can be procured send the money in a registered letter.

HAMERSLY & CO., Publishers,
701 Chestnut Street, Philadelphia, Pa.

PUBLIC OPINION

A WEEKLY COMPEND
OF THE
SPIRIT OF THE AMERICAN AND
FOREIGN PRESS.

Presents in a compact form the opinions of the leading journals of this country and Europe upon all subjects of general interest. Its contents embrace extracts from the editorial utterances of newspapers of every section and of every party, without bias.

To the professional man, to the busy merchant, to the farmer, mechanic, and tradesman—to all, in a word, who would keep themselves familiar with the active thought of the day, but who have neither the means to procure nor the time to read many different periodicals, its broad comprehensiveness will make it always welcome.

PUBLIC OPINION is an octavo sheet of sixteen pages, clearly printed from new types and upon heavy paper, and issued on Wednesday morning of each week. Terms, one year, 52 numbers, \$3.00. Invariably in advance.

G. WHARTON HAMERSLY, Publisher,
No. 701 Chestnut Street, Philadelphia, Pa.

A SPECIMEN COPY OF THE

POULTRY WORLD,

throughout the city and country, will find

Hearth and Home

the cheapest weekly paper for their use, because it pays the best, and costs the least in proportion to circulation. The value of advertising good articles largely in the best mediums is indicated by the following facts:

HEARTH AND HOME, which has been prominently advertised in the leading papers throughout the country during the past few months, has added to its circulation more than 20,000.

The editions of HEARTH AND HOME have increased week by week, running 28,000, 30,000, 35,000, and 40,000, until at the present time

45,000 to 50,000

Are Printed & Circulated to Subscribers.

The intelligent, thrifty, buying classes find it just what they want. It is adapted to the whole family, and is READ ALL THROUGH.

Advertisements of patent and quack medicines, deceptive schemes, swindling agencies, and unreliable parties, are more rigorously excluded than from any other journal except The American Agriculturist. The readers know this, and therefore readily patronize those who are admitted.

ORANGE JUDD & CO., Publishers, No. 245 Broadway, New York.

AMERICAN CATTLE:

THEIR

HISTORY, BREEDING,

AND

MANAGEMENT.

By LEWIS F. ALLEN,

Late President New York State Agricultural Society, editor "American Shorthorn Herd Book," author "Rural Architecture," etc., etc.

NOTICES BY THE PRESS.

We consider this the most valuable work that has recently been issued from the American press. It embraces all branches of the important subject, and fills a vacancy in our agricultural literature for which work the author by his many years' experience and observation was eminently fitted. It ought to be in the hands of every owner of cattle; and the country, as well as individuals, would soon be much richer for its teachings.

Journal of Agriculture (St. Louis).

The large experience of the author in improving the character of American herds adds to the weight of his observations, and has enabled him to produce a work which will at once make good its claims, as a standard authority on the subject. An excellent feature of this volume is its orderly, methodical arrangement; condensing a great variety of information into a comparatively small compass, and enabling the reader to find the point on which he is seeking light, without wasting his time in turning over the leaves.

N. Y. Tribune.

This will rank among the standard works of the country, and will be considered indispensable by every breeder of live-stock.

Practical Farmer (Phila).

We think it is the most complete work upon neat-stock that we have seen; embodying as it does a vast amount of research and careful study and observation.

Wisconsin Farmer.

His history of cattle in general and of the individual breeds in particular, which occupies the first 180 pages of the volume, is written with much of the grace and charm of an Allison or a Macaulay. His description of the leading breeds is illustrated by cuts of a bull, a cow, and a fat ox, of each race. The next one hundred pages are devoted to the subject of Breeding. This is followed by chapters on Beef Cattle, Working Oxen, Milch Cows, Cattle Food, Diseases, etc. The arrangement, illustrations, analytical index, etc., of the work are in the best style of modern book-making.

New England Farmer.

The work is one that has long been needed, as it takes the place of the foreign books of like nature to which our farmers have been obliged to refer, and furnishes in a compact and well-arranged volume all they desire upon this important subject.

Maine Farmer.

Whatever works the stock farmer may already have, he cannot afford to do without this.

Ohio Farmer.

It is one of the best treatises within our knowledge, and contains information sound and sensible, on every page.

The People, (Concord, N. H.)

The object of the work, as stated by the author in his preface, "is not only to give a historical account of the Bovine race, to suggest to our farmers and cattle breeders the best methods of their production and management, but to exalt and ennoble its pursuit to the dignity to which it is entitled, in the various departments of American agriculture." From the little examination we have been able to give it, we can not recommend it too highly.

Canada Farmer.

Considering that there are some ten millions milch cows in the United States, and nearly a thousand millions of dollars invested in cattle, the magnitude of this interest demands that the best skilled talent be devoted to the improvement of the various breeds, and the investigation of the best method of so caring for the animals, as to gain the greatest profit from them. This volume will give the farmer just the instruction which he wants.

N. Y. Independent.

SENT POST-PAID.....PRICE \$2.50.

ORANGE JUDD & COMPANY, 245 Broadway, New York.

NEW

American Farm Book.

ORIGINALLY BY

R. L. ALLEN,

Author of "Diseases of Domestic Animals," and formerly editor of the "American Agriculturist."

REVISED AND ENLARGED BY

LEWIS F. ALLEN,

Author of "American Cattle," editor of the "American Shorthorn Herd Book," etc.

NOTICES BY THE PRESS.

Everything connected with the business of farming finds a place in it; soils, manures of every kind, irrigation and draining, grasses, grain and root crops, fruits, cotton, hemp, fences, farm buildings, domestic cattle, sheep, poultry, and the like. The work has been written with great care by men qualified to discuss the subject, and it is really valuable. The chapter on soils should be read carefully by every farmer who desires to make the most of the land he cultivates. The chapter on fruits constitutes an important feature of the work; and there is nothing in it which is not well considered and useful.

Worcester Daily Spy.

Comprehensive and careful, telling, and telling specifically, just what the tillers of the soil need to know; it will prove of great advantage to all who faithfully follow its counsels in the spirit in which they are given.

Congregationalist & Recorder.

It intelligently and quite fully discusses the various operations of farm life, and is invaluable to all engaged in agriculture.

Farmer's Cabinet.

For the young man of rural tastes, but without a training at the plow-handles, who asks for a general guide and instructor that shall be to agriculture what the map of the world is to geography, it is the best manual in print. For the working farmer, who, in summer nooning and by the winter fireside, would refresh his convictions and reassure his knowledge by old definitions and well-considered summaries, it is the most convenient hand-book. From its double authorship one might expect some show of patch-work, the original statement of the author of 1846, annotated and qualified by the writer of this year. But this has been wisely avoided. The book is a unit, and shows no disparity of style nor contradiction in statement. Practically it is altogether a recent and timely volume. Only so much of the original Book of the Farm, by R. F. Allen, as time could not change, has been adopted by the reviser.

New York Tribune.

It is a volume of over five hundred pages, and in its present shape comprises all that can well be condensed into an available volume of its kind.

Hartford Daily Times.

It is almost as comprehensive as a cyclopaedia. We can safely recommend it as a valuable and standard work.

Salem Gazette.

It has a very wide range of subjects, taking up nearly all matters that are most important to farmers. Comprising the combined wisdom and experience of two eminent agriculturists, it must prove of great value to the class for whom it is prepared.

New York Observer.

It is crammed full of just the information that is wanted, which it is a pleasure to recommend. We know of no better encyclopaedia of farming.

New York Independent.

In its present revised and enlarged form, it is a work that every practical farmer may consult with advantage, and none can well afford to do without.

Christian Intelligencer.

It is something in favor of this work, that it has been before the public for many years. The original work was prepared with extraordinary care, and contained a vast amount of general truth that is as applicable now as it was then; it has therefore been made the basis of the present work, which, to all intents and purposes, is new, since it is adapted to the present improved state of agricultural knowledge. Every department is prepared with conscientious care, and with a view of making the work a reliable source of agricultural information.

Chicago Republican.

AMERICAN AGRICULTURIST.

NEW YORK, MARCH, 1872.

It is not easy for us, here at the North, to realize that spring has come. We sometimes have "six weeks sleighing in March," and at any rate it is seldom that much real spring work can be done before the middle of April.

In a well-regulated factory, the manager can often tell what the men will be doing each day, for a week or a month ahead. But it is not so on a farm. We know what work there is to be done, but are never certain as to the particular time when we can do it.

performance of the work he must throw off his coat and labor with his might. He must pay great attention to such important little things as he is inclined to overlook and neglect, and he must study his operations until he finds out what are the points of greatest importance.

Hints about Work.

The first work in the spring, on our own farm, when the snow begins to melt, is to let off any water that accumulates on the surface. No matter how carefully the dead furrows and outlets may have been made in the fall, there is always more or less to be done in the spring, to provide free egress for the water.

Spring is a Good Time to Underdrain.—Unless we can do the work in the winter, spring is the best time to dig underdrains. The land is full of water, and it is much easier digging than in the summer or autumn.

The Cost of Draining depends a good deal on the nature of the land and the depth of the drains. In sandy or mucky land a ditch 2 1/2 feet deep for tiles should be dug, with labor at \$1.50 per day, for 15 cents a rod; 3 feet deep, 20 cents a rod.

Spring Wheat is the first crop to be sown in the spring. We hope our readers will bestow extra pains in putting it in well, for we anticipate considerable demand for wheat next fall.

Barley, taking one year with another, is a well-paying crop on good land and in the hands of those who know how to manage it. But it is a poor crop on poor land. A careless, slovenly farmer, whose land is poor, wet, and foul, should not attempt to raise barley.

Peas for Plowing under.—"J. M.," Portage Co., O. The best pea for this purpose is one with a great amount of stalk and leaves, like the large Marrowfat. Two to three bushels of seed should be used, as the ground is richer or poorer.

vious winter, by sheep; but in this country our heaviest crops are raised on soil of a more loamy character. The essential point on these heavier soils is, to get them thoroughly fine and mellow the year or fall previous. Barley is sometimes sown on a clover sod, but unless it was plowed last fall, it is not a good plan. As a rule, barley is sown on corn stubble, and is followed by winter wheat.

Oats do not require as careful culture and nice judgment as barley, but they will well repay far better treatment than they generally receive. They will grow well on land too mucky for barley, and a great crop is sometimes obtained on heavy clays. We believe in thick seeding for this crop, and would drill in not less than 3 bushels per acre, or 3½ bushels, if sown broad-cast.

Peas should be sown early. If on sod-land, we should plow as soon as the frost was out of the ground, and drill in the seed, 3 bushels per acre, as fast as the land was plowed and harrowed. After drilling roll the land smooth. Two bushels of plaster per acre, sown before or after the peas come up, as most convenient, usually prove beneficial.

Oats and Peas sown together is a favorite crop with us. If the land is rich enough and in good order, and the crop is sown early, a great amount of valuable fodder and grain may be obtained per acre. We would sow 2½ bushels peas and 1½ bushel oats per acre. They can be sown together with an ordinary grain-drill, but it is necessary to see that they are well mixed in the drill. Roll the land after the drill, and pick off everything that would interfere with a mowing machine. On rough land they are a troublesome crop to harvest, but when the land is so smooth that the machine can be set to run as close as a mower, they can be cut and delivered in bundles with a self-raking reaper.

Potatoes.—We are inclined to think that farmers seldom plant their potatoes early enough. If planted earlier and deeper, and the land was harrowed repeatedly with Thomas's harrow before the potatoes came out of the ground, and afterwards, far less hoeing would be required, and we think a better yield would be obtained.

Harrowing Winter Wheat is a practice we would earnestly commend. Many farmers are afraid that the harrow will pull up the wheat, but such is not the case. If the land is dry, a good heavy, forty-toothed harrow will destroy many weeds, break the crust, stir the soil, and greatly benefit the wheat.

Clover Seed can be sown on the snow, or when the ground is frozen hard enough on the surface to make good walking. But when the wheat is to be harrowed, it is necessary to defer sowing clover and grass-seed until the land is dry. Harrow first, then sow the seed, and, if necessary, roll afterwards. If Thomas's smoothing harrow is used, sow the seed first, and then harrow it in. Our own practice is to sow eight quarts of clover-seed alone per acre. Six quarts clover and four quarts timothy is a good and liberal seeding. If the land is intended for pasture, we would add one quart of white clover and four quarts Kentucky Blue-grass. This is heavy seeding, but we think it will pay.

Harrowing Meadows and Pastures is often very beneficial, and we are surprised that the practice is so generally neglected. Put three horses to a harrow, and get on and ride. Harrow the field both ways, and lap, if necessary.

Horses that have had little to do during the winter, and have been kept principally on straw, should now be fed more liberally and gradually accustomed to work. Let them be well groomed. When brought in heated, rub them dry. Do not suffer them to be blanketed in the stable, unless very much exhausted from hard driving. In this case put on a blanket, and rub the legs, ears, etc. Nine tenths of all the complaints in horses are caused by indigestion and consequent derangement of the bowels. Overwork, improper feeding, exposure to a chilling wind when heated, ill-ventilated stables, and want of grooming are the chief causes of indigestion in farm-horses. For colic we know of nothing better than an injection of warm water and soap. If this does not afford relief, give two table-

spoonfuls of laudanum in warm water or ale or whisky. If the pain is very severe, give four table-spoonfuls of ether in addition to the laudanum. If this does not afford relief, repeat the ether every hour, and repeat the laudanum in four hours. Blanket the horse, and set three or four men to rub him vigorously—legs, ears, belly, etc. Fomentations of hot water on the belly are excellent.

Cows.—Treat them gently. Card freely, water regularly, and feed liberally. Nothing is better for a cow at calving than good hay and warm bran-mashes. Give all the water the cow will drink, but for a week after calving take the chill off it. See hints for last month.

Sheep will now require better feed and more care. Nothing tests the judgment of the sheep farmer more than thawing weather and cold rain-storms. The great enemy of sheep is dampness. No sheep will thrive in damp, close quarters, or with fermenting manure under them. Even young lambs will stand dry cold far better than moist warmth. As lambing time approaches, it is well to have the ewes in small flocks, and there should be convenient pens for putting the ewes and lambs by themselves for a few days. Keep close watch of the ewes, but do not be in haste to assist at lambing, until it is necessary. If a lamb get chilled, wrap him in flannel and take him to a stove. If nearly dead, put the lamb in a pail of warm water, as hot as you can bear your hands in. Many a lamb, apparently almost dead, has been saved in this way. See that the lambs get milk enough. A lamb will sometimes suck warm milk from a bottle, furnished with an India-rubber nipple, when it has not strength enough to suck the ewe. Give the ewes good hay and bran, and roots, if you have them. But it is very desirable to save a few roots for the lambs in April and May. Oats are better for the ewes than corn, and this year nearly as cheap.

Pigs.—The low price of pork has disgusted thousands of farmers with the pig business. They have disposed of everything that would sell. Spring pigs that were intended for wintering over, have been slaughtered, and the fresh-meat market has been flooded with last fall's pigs. Breeding sows have been fattened and killed, and the indications are that there will be a scarcity of hogs to fatten next fall. Or, at any rate, there is little probability that there will be an excess. Those who have farrowing sows, should take good care of them. Thousands of little pigs perish every spring for want of proper attention. Farmers have no one to blame but themselves for having sows that will not let them go into the pen, to bestow the necessary care. A savage sow, in a cold pen, with a litter of chilled pigs, on a stormy night in March, is a case not provided for in the books. But with a quiet sow there is little difficulty in saving the pigs, no matter how cold the weather is. The first thing to be done is to stop up every hole or crevice in the pen. Shut the door, and bank it up on the outside with straw or litter. If the pigs are chilled, it is better, as a rule, not to take them away from the sow as long as she will lie down. Cover sow and pigs with a horse-blanket, and tuck them in. The heat from the sow will revive the pigs, and they will begin to nurse. If the sow has plenty of milk, and the pigs take hold, all immediate danger is past. Give the sow plenty of warm slops, such as bran mash, and be sure that she has all the warm water she will drink. In a week feed her richer food.

Work in the Horticultural Departments.

The weather is usually so changeable this month, that it is difficult to give directions for out-door work. Though the winter may have been comparatively mild, March will probably furnish its usual amount of cold and disagreeable weather. Everything should be in perfect order, to commence operations as soon as it is warm enough. The aim of the horticulturist should be to keep in advance of his work, and not allow himself to be driven by it, for if once ahead of him, it necessitates a loss of both time and money. Many of the directions

given last month will apply for this in more northern latitudes. We write for the latitude of New York, where the season is several weeks earlier than in the New England States and northward.

Orchard and Nursery.

Planting.—Whenever the ground is in proper order, plow thoroughly and apply a good coating of manure, which should be harrowed or plowed under. The sooner the trees are planted, if the conditions are favorable, the better, though they may be safely planted two months later if properly heeled in last fall. If any of the trees in young orchards have been badly injured, set new trees in their places.

Manure.—Cart to the orchards as soon as convenient, in order to prevent delay in planting, etc., when the spring fairly opens. If there is snow, the manure may be hauled upon a sled, and save much labor in loading. Supply the stables with plenty of absorbents, in order to save all the manure possible. Fork over the manure-heap once a month, in order to facilitate decomposition.

Root-Grafting ought to be got out of the way as soon as possible, so that no delay will occur in grafting trees in the open ground.

Cions.—Cut when the tree is not frozen, and before the buds start, and if not needed at once, store in sawdust, moss, or sand, in the cellar.

Washing and Scraping.—When the weather is suitable, give the trees a thorough scraping, and afterwards apply a wash, made with soft-soap.

Stocks, budded last year, should be cut back to within three inches of the bud.

Fruit Garden.

It is better to have the fruit garden separate from the kitchen garden, if one is able to do so, if for no other reason that the trees and bushes are liable to be broken in cultivating among the garden crops.

Strawberries.—Prepare the ground for new plantations as soon as possible, and give the old beds a fresh supply of manure and work it in well between the rows. Set in rows two feet apart, with eighteen inches between the plants.

Blackberries.—Set out in rows six feet apart, and allow from four to six feet between the plants, according to the variety. Cut the plants back to six inches before planting. The old plants should have their canes cut back to four or five feet.

Raspberries.—Do not uncover too soon. Plant as soon as the weather will permit, setting the plants four feet apart each way.

Grape-Vines may be pruned at any time in March, when the vines are not frozen, though it is always better to prune in the fall when possible. There are so many different ways to train a grape-vine, that each one can select the style which pleases him best, or adopt several methods.

Cuttings of currants, gooseberries, etc., may be made now, and planted out in trenches prepared for them as soon as the weather permits.

Dwarf Trees only should be admitted to the fruit garden proper. This is a good time to prune.

Kitchen Garden.

As usual at this season of the year we enumerate a few of the sorts of garden vegetables which are known to be good. The seed catalogues of the present day enumerate such large lists, that it is often difficult for a novice to select such sorts as will prove satisfactory.

Hot-Beds.—Directions for making hot-beds have been given so often that it will not be necessary to repeat them here. They should be prepared this month, and when the heat has subsided to 90°, place two or three inches of soil over the manure; after this has warmed through, sow the seeds in rows 3 or 4 inches apart. Admit air every mild day, and water whenever the soil becomes dry. During very cold nights cover the frames with straw-mats or shutters, to exclude the frost.

Window-Boxes are very useful for starting a few early plants of tomatoes, cabbage, etc., where the expense and care of a hot-bed are inconvenient.

Artichoke.—This vegetable is seldom cultivated at the North, but often grown at the South. The seeds may be sown in the hot-bed, and the young plants set out as soon as large enough. Set out in rows three feet apart, with two feet between the rows. The fleshy scales of the flowers are the parts eaten. The Green Globe is best.

Asparagus.—Give the beds a good coating of manure, if not applied last fall; spread also a dressing of salt. Set out new beds of one-year-old plants, two by three feet, after the ground has been plowed and manured. Conover's Colossal is the best.

Beans.—Do not plant in the open ground until all danger of frost is over. Then sow in drills two feet apart. One of the earliest sorts is the Valentine; the Dwarf Wax is the best bush for snaps; the Asparagus is a pole variety, excellent for late snaps, as is Giant Wax. Large Lima is the best of all beans.

Beets may be sown as soon as the ground can be worked, and if there is snow or frost, a board placed over the rows will prevent freezing. The best early beet, the New Egyptian Blood, is from one to two weeks earlier than the Bassano and Early Blood Turnip, which are both good. Sow in drills, one foot apart.

Broccoli requires the same treatment as cabbage. Sow White or Purple Cape.

Cabbage Plants, wintered in a cold-frame, or started in early hot-beds, may be set out as soon as the ground opens, if well hardened off. For early sow Jersey Wakefield, or Winningstadt, and Marblehead, Drumhead, and Flat Dutch for winter.

Cauliflower.—Early Paris and Early Dwarf Erfurt are good early sorts. Treat the same as cabbage.

Carrots.—Sow Early Horn in drills, 12 inches apart.

Celery.—For early crops sow Dwarf White Solid, and Boston Market, in hot-beds.

Corn.—When the ground is warm, plant Crosby's Early, Mammoth Sweet, Mexican, and Stowell's Evergreen, in drills $2\frac{1}{2}$ feet apart.

Cress.—Sow at intervals of a week, in shallow drills one foot apart. Curled is the best.

Cucumbers.—A few seeds of Early Russian may be planted on pieces of sod, in a hot-bed, for early; for general crop, White Spine, and later Green Prickly for pickles.

Egg-Plant.—Sow Long Purple in hot-bed for early, and Purple or Black Pekin for later.

Horse-Radish.—Sets may be planted in well-manured trenches, two feet apart.

Kale sowed last fall should have the soil well worked around the plants, to prevent the growth of weeds.

Kohl-rabi.—Sow Early White in two-foot rows in the open ground.

Leek.—Sow Flag or Musselburgh, same as onions.

Lettuce sowed last fall should be uncovered, and the soil loosened between the rows. Sow seeds in the hot-bed or open ground. Curled Silesia and Tennis-Ball are valuable sorts.

Melons.—Treat the same as cucumbers. Ward's Nectar, Skillman's Netted, and Cassaba are best.

Onions.—Sow in drills 15 inches apart, as soon as the ground can be prepared. Early Red and Yellow Danvers are good for the general crop. Plant out set and potato and top onions for early crop.

Parsley.—Sow the Curled variety in drills one foot apart, after soaking the seeds.

Parsnips.—Dig those left in the ground. Sow Hollow Crown in drills 15 inches apart, early.

Peas.—Plant in double rows Carter's First Crop and Daniel O'Rourke for early, Champion of England for main crop, and for dwarfs McLean's Little Gem is best; the dwarfs should be sown in single rows, one foot apart, and do not require any brush.

Peppers.—Start in hot-bed; the Squash variety for pickles, and Sweet Mountain for stuffing.

Potatoes.—Start a few for early in the hot-bed; those for early planting in the open ground should

be cut and exposed to a warm atmosphere for a few days before planting. Early Rose is the best early.

Radishes.—Sow thickly in rows in the open ground, at intervals of a week or ten days for a succession. Early Scarlet Turnip, Olive-shaped, and French Breakfast are good varieties.

Rhubarb.—Dig in plenty of stable manure around the roots, and if wanted very early, take up a few plants and put them in half-barrels, nearly filled with manure, with sufficient earth on top, and place in a sheltered spot, watering it often with liquid manure.

Salsify which was left in the ground during the winter, should be dug, and seeds sown for the next crop, the same as recommended for parsnips.

Scorzonera is very similar to salsify, and requires the same treatment.

Spinach.—Uncover the beds planted last fall, and in a few days it will be ready to eat. Sow seed for spring and summer crops in drills one foot apart. Round-leaved is best. New Zealand, for summer use, is sown later.

Sorrel.—The French sorrel is excellent for greens, and its slightly acid taste renders it particularly pleasing to most persons.

Sweet Potatoes are started in hot-beds, with two or three inches of compost placed over them, and when the sprouts are large enough, they are replanted in ridges. Nansmond and Southern Queen are the best for northern latitudes.

Squashes.—Summer Crookneck for early, and Boston Marrow and Hubbard for late.

Tomato.—Sow seeds of Trophy and Early Smooth Red in the hot-bed or window-box.

Turnips.—Sow Flat Dutch for early use, and Red and White Strap-Leaf for later; White French and Yellow Stone for ruta-baga sorts for family use.

Seeds.—Where roots are to be planted for seeds, they should be set out early, and the earth drawn up around the crowns to prevent freezing; when all danger of frost is over, it may be removed.

Flower-Garden and Lawn.

Annuals.—Sow a few seeds for early flowering in window-boxes or a hot-bed. Hardier varieties may be sown in the open ground, in sheltered places.

Lawns.—Gather up all rubbish which has collected during the winter, and if there are any spots where the grass has been winter-killed, sow fresh seed, and rake it in with a steel garden-rake. Give a compost of well-decomposed manure.

Walks.—Have all walks properly rolled and cleared of leaves, etc., which may have collected, and keep the center of the walk a little raised, to allow the surface water to run away.

Shrubs.—Prune, where needed, and cut off all broken branches.

Edgings.—Where box is used, re-set as soon as the ground is dry enough.

Greenhouse and Window Plants.

The increasing heat of the sun will render fire-heat less necessary, though the fires should be kept up during the night, as a sudden change of temperature might do considerable damage. Admit air freely, whenever the weather is mild.

Propagation.—At this season the gardeners should prepare a large stock of plants for planting out.

Azaleas.—As the plants begin to flower, give more water, and see that they are sheltered from the drip, which soon spoils the flowers.

Camellias which are just starting into growth should be allowed a little more heat and water.

Dahlias.—Place a few tubers in the greenhouse, to secure plants for early flowering; when the sprouts are two or three inches long, pot into rich soil.

Climbers, such as Passion-Flowers, Wax-Plants, etc., should have their branches trained to the rafters of the greenhouse, and kept properly tied up.

Bulbs which have flowered must be gradually dried off and stored in a dry place, ready for another year.

Roses.—Give the bushes liquid manure occasionally.

AMERICAN AGRICULTURIST.

ORANGE JUDD & Co., Publishers, 245 Broadway, N. Y. City.

ANNUAL SUBSCRIPTION TERMS (always in advance): \$1.50 each for less than four copies; Four to nine copies, \$1.25 each; Ten to nineteen copies, \$1.00 each; Twenty copies and upward, \$1 each. Papers are addressed to each name.

Either English or German Edition, at these prices.

HEARTH AND HOME: \$3 a year for less than four. Four to nine copies, \$2.75 each; 10 or more copies, \$2.50 each.

Hearth and Home (weekly) with American Agriculturist sent to one address for \$4 a year.

N. B. - - - 1

Spring Work is coming on, and thousands of people will gladly avail themselves of the Hints and Suggestions given in the *Agriculturist*.

N. B. - - - 2

HEARTH AND HOME (weekly), with its 20 large pages, full of Good Things for old and young, including an average of \$500 worth of Instructive Engravings in each number, is the best journal for the family—for every Home. It is everywhere very popular.

N. B. - - - 3

Any one taking copies of the above two papers, (specimens free,) and showing them to his or her friends or neighbors, can quickly gather names enough to secure one or more of the very valuable articles on page 119, each one of which is fully worth the same as money.

N. B. - - - 4

Four Months' time yet remains to make up premium clubs, as they will remain open until June 30th. This month is a good time to begin a club, or to fill one up and start another. Every name sent in on account of a premium list is credited to the sender, and he can fill up the list at leisure.—See list of good articles on page 119. They are all *new, first-class, reliable, valuable—just as good as money*. The assortment is so large that every one will find something needed. See page 119.

Over 13,500 Others

HAVE OBTAINED THESE

Free Articles

WITH PLEASURE AND PROFIT,
and

YOU may do the Same.

It has been done largely at Stores, Shops, Post-offices, etc., and by private individuals. By Co-operation, Ministers, Teachers, Churches, Sunday and week-day Scholars, have obtained Melodeons, Libraries, Cyclopedias, Dictionaries, etc., also Sewing Machines, and the like, for poor widows and others. Many professional men have opened and made up good premium lists at their Offices. Clerks in stores and Post-offices have materially increased their salaries thus, while individuals in all classes have secured good things.

See Page 119.

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Remitting Money:—Checks on New York City Banks or Bankers are best for large sums; make payable to the order of **Orange Judd & Co.**.....**Post-Office Money Orders**, for \$50 or less, are cheap and safe also. When these are not obtainable, register letters, affixing stamps for postage and registry; put in the money and seal the letter in the presence of the postmaster, and take his receipt for it. Money sent in the above three methods is safe against loss.

Postage: On *American Agriculturist*, 3 cents a quarter, in advance; on *Hearth and Home*, 5 cents per quarter. Double rates if not paid in advance at the office where the papers are received. For subscribers in British America, the postage must be sent to this office for prepayment here.

Bound Copies of Volume Thirty are now ready. Price, \$2, at our office or \$2.50 each, if sent by mail. Any of the last fifteen volumes (16 to 30) will also be forwarded at same price. Sets of numbers sent to our office will be neatly bound in our regular style, at 75 cents per vol. (50 cents extra, if returned by mail.) Missing numbers supplied at 12 cents each.

Clubs can at any time be increased by remitting for each addition the price paid by the original members; or a small club may be increased to a larger one; thus: a person having sent 10 subscribers and \$12, may afterward send 10 more subscribers with only \$3; making a club of 20 at \$1 each; and so of the other club rates.

SOME YOUNG LADIES complain that our publishers have given premiums to men, to boys and girls, etc., but never offered any special premium for young ladies. They forget the pianos, and many other things in our general list, but even these complaints are now done away with, in part at least. The new \$10 Sewing Machine, offered on page 83, is of special value to young ladies. They can easily collect subscribers enough among their friends to secure a sewing machine all their own.

Manuring by Pasturing.—"A Subscriber" asks whether drove cattle pastured on grass land at ten cents per head, after the grass has been cut, would be as cheap a way of manuring the land as hauling manure six miles, and paying \$1.50 per one-horse load. If the cattle are mainly full-grown and in good condition, and the manure left by them is well broken up and spread, and the money received expended in bone-dust and applied to the land, it will be more cheaply managed than by purchasing manure as stated.

When to Spread Ashes.—"J. J. L.," Crisfield, Md., asks the best time to spread ashes, and are coal-ashes worth saving as manure?—Spread ashes early in spring on grass or wheat; for corn or potatoes throw a handful in the hill at planting. Coal-ashes are worth but little on light soil, and but little more on heavy soil, except to loosen the texture.

Price of Drain-Tile.—"J. M. Hubbard, Middletown, Ct.," thinks the cost of drain-tiles mentioned in January number, viz., 20 cents per rod, too low (his cost \$25 per thousand). The cost there given was that actually incurred by us about three years since. Tiles, 1½ and 2¼ inch, are quoted at \$15 per thousand by a dealer in New York, length 15 inches, which will bring our estimate about right.

Fish Manure.—"A. Hampton lives on the bank of a river swarming with fish, and wants to know how to use them on his land.—First catch them, then pile them in layers, with swamp muck or earth, until rotted, then turn over once, and when heated, once more; cart on to the land and spread broad-cast on grass, or plow in for corn, wheat, or roots. One cord of fish to six or eight of muck will make a rich manure, equal to the best stable-manure. It is excellent for all crops.

Mad Itch.—"K. K.," Caput, Mo., found one of his cows with swollen head and jaw, and one eye nearly closed. She rubbed her head violently against a post until the hair was taken off, and pawed the ground and appeared wild. He drenched her with salts and

sulphur, and bathed her head with salt and water, but ineffectually. She died in a few hours. Was the treatment correct?—Nothing more could have been done in the effort to cure. The disease was "mad itch," but possibly, had sulphur been fed regularly, an ounce once a week, the complaint might have been averted. The usual treatment is a dose of one pound of sulphur, followed in eight hours with a pound of Glauber salts.

A Batch of Questions.—"Geo. S. W.," Chatham, N. Y., asks if the articles on An Egg Farm are based on actual experience?—Yes. What is the best kind of millet for seed, average per acre, time to sow, and value of straw?—The true millet (*Panicum miliaceum*), sown early in spring, produces 25 to 30 bushels seed per acre, on good soil; hay, when ripe, is equal in value to oat straw. Will coppers injure night-soil?—No.

How to Use Muck.—"C. O. B.," Pike Co., Pa., asks how he shall use muck, and what is the best artificial manure to mix with it? Muck should be dug in the winter, and exposed to the weather. The frost will reduce it to a fine condition, the summer's heat will cause it to ferment, and then it will be in a fit state to spread upon grass lands. There are many tanneries in Pike Co., Pa., and the refuse from them would be valuable to compost with muck. Fish-guano or bone-dust might well be mixed at the rate of a barrel to a cord of muck.

Hungarian Grass.—"A. J. W.," Port Gibson, Miss. Hungarian grass, Hungarian and Cat-tail millet, are all different names for the same plant, *Setaria Germanica*, usually called Hungarian grass. For a fodder crop it would be better to sow rather thickly, say twelve quarts per acre, in a succession, rather than depend on repeated cutting of the same sowing. When the straw is ripe, it is coarse and harsh, and considered poor feed. If the soil is not rich, a good crop can not be expected.

Hand Thrashing-Machine.—"J. H. Z.," Lancaster Co., Pa., asks our opinion of the hand-power thrashing-machine. We have no confidence in what is claimed for it. No combination of machinery can increase the motive power of a machine, without decreasing, proportionately, the velocity; nor can the velocity be increased without an increased expenditure of power, so that any way a man's power is not added to: the only advantage there can be is in the better application of the power than with the flail.—J. H. Z.'s answers to pruzzles should be sent to Aunt Sue, P. O. Box 111, Brooklyn, N. Y.

To Dissolve Ground Bone.—"S. C. S.," Aiken, S. C., asks, What proportion of sulphuric acid is required to dissolve ground bone? Twenty-two pounds of acid will dissolve one hundred pounds of bone. But the Charleston phosphate is not bone, and contains no animal matter; and a larger proportion of acid is necessary to dissolve it; we do not know the exact quantity, but it can be easily determined on trial; probably 50 pounds.

Curing Clover.—"Subscriber," Richland Co., N. Y., asks the best way to cure clover. We cure by putting it in cocks, after lying in the swath until near sundown, and keeping it twenty-four hours in that condition. It heats during the night, but in the afternoon of the second day it is in good condition to put in the barn. The exposure in loading and unloading carries off all excess of dampness.

Shall He Go West?—"D. W. H.," River Styx, Ohio, has twenty-five acres of land, in a good locality for fruit and gardening, near three railroads, and asks: Can he better himself by going West?—He can get a larger farm, but with more land he will have less comfort, and in ten years may be no better off than he now is, and less than he may possibly be, if he should stay in Ohio. The landless are those who should go West.

Early-laying Pullets.—"J. W. P.," Goffstown Center, N. H., alludes to our statement in the February number respecting Brahmas laying when six months old, and has a story to beat it, and about the "common sort of fowls" too. He says some of his pullets laid last summer before they were five months old, and one commenced to sit before she was five and a half months of age. He adds, "It is care that brings the eggs along more than extra breeds." Our correspondent's case is not unexampled. Instances have been known where pullets have laid in fifteen weeks from the time they were hatched. It is pretty well agreed among poultry-keepers that the common fowls can not be as well relied upon to lay at the age of five or six months as the Brahmas. The normal time of commencing to lay is at the age of twelve months, and early maturity is possible only under highly artificial influences.

Breaking Oxen.—"Subscriber," Sandy Spring, Pa., wants to know something about breaking oxen. Any one who can drive oxen can break them, if he commences when they are yearlings. A light yoke and bows should be made, and at first the steers should be led around with a cord and taught to understand the words of command and the duties required of them. When this has been well learned, a light sled or cart may be made for them, and when three years old they will be found useful for light work. According to the skill and patience of the breaker, they will be docile and laud, or otherwise.

Shall He Improve his Common Stock?—"F. R." asks whether to improve the common stock would not lead to a higher system of farming?—Certainly, and this course is open to every farmer who wishes to rise in his profession and improve his condition. Improved stock comes through improved ideas, and they result in improvements all around.

Warbles.—"W. S. G.," San Diego, Cal., has discovered a number of small lumps along the back of one of his heifers, in which a grub is concealed. These are warbles, or the larvæ of the Cattle Bot-fly. If left alone, the grub will escape when it is mature, and no injury will result. But the grubs may be discharged by pressing the lump between the two thumb-nails. After this the opening will heal. The grub should not be destroyed in the skin, or suppuration will take place.

Pawlonia.—"L. D. Scott, Ohio. We notice that some journals are helping some speculators to revive this tree, which had its day years ago. It grows very rapidly when young, and is no harder than the Catalpa. Its merit is in its flowers, which around New-York escape winter-killing probably one winter in three. It will bloom regularly farther South, but then it has the insuperable objection to an ornamental tree that its large clusters of seed-pods remain on until beaten off by the winds. This much disfigures the tree, and in our eyes condemns it, except as a curiosity.

Harrowing Wheat in Spring.—"D. W.," Holton, Kansas, asks if it would be better to go through his fall wheat in the spring with a harrow, or with the drill. When wheat has been drilled, the drill may be run through in the spring with advantage, but a light harrow would more effectually stir the ground and not injure the plants. We use the Thomas harrow for wheat.

Produce of Fifteen Hens.—"An octogenarian writes that his flock of fifteen hens averaged one hundred eggs each from January 1st, 1871, to the 27th of the December following. They were the common breed, and were fed regularly twice a day with wheat bran and Indian meal, scalded with hot water or milk, a little pepper occasionally, and the scraps from the table, and a small allowance of wheat and corn in the kernel.

SUNDRY HUMBUGS.—Any man wishing to spend \$500 or \$600, or more, in a sacrifice to his vanity, can be accommodated by a "publishing firm" that professes to enroll ever so many distinguished men in a grand book, with a steel portrait and biography of each one—that is to say, each one who will "come down" handsomely with greenbacks to pay a big price for the steel plates, and half a dozen other big prices for as many of the big books. From the number and kind of men approached by said Publishing Company, we judge that the chief thing necessary to be done to become distinguished, is to raise the needed greenbacks. This is an age of progress and improvement. To be ranked alongside of the "eminent" men of the nineteenth century, one need not work, toil, study, and strive through a long series of years; a lucky strike in trade, or speculation in vacant lots, yielding a few hundred dollars, will do the thing. If the speculation yield \$1,000, we suppose it will secure a rank in this book as the most eminent man of the age, unless some richer, vainer speculator outbids you for the place. . . . Omaha, Neb., seems to be a kind of head-quarters for the gift enterprise operators. Nobody but quernhorns and very foolish people will bite at the several apparently tempting baits, issued in flaming circulars, extras of newspapers, etc., from Omaha, but not many of such people will read this journal, and we will not devote space to analyzing the schemes. These last remarks apply equally to the Magnolia, Iowa, gift enterprise, and sundry other like schemes in various parts of the country, especially West and South. One number (Vol. I., No. 1) of a paper is issued in the interest of these schemes. . . . Several "queer," or "sawdust," or pretended "good" counterfeit money operators are still at work. A majority of these now use Masonic or I. O. O. F. symbols as a blind. No member of these orders is ever allowed to use these

symbols for business purposes. Here are some of the new and old names assumed by these swindlers: Amos Wainwright, 170 Broadway, Trenton, N. J., and N. Y. City; Dennis Dunn, *alias* G. C. Peck, 16 South Fifth Avenue, N. Y. City; John Hood, Jr., Wilmington, Del., and at corner Broadway and 29th Street, N. Y.; Rowley & Son, 176 Broadway; Albert Todd, 79 Nassau Street, N. Y. . . . The jewelry prize scheme of Pardee & Co., at Binghamton, N. Y., has, we believe, been shut up by legal process; if not, it should be at once. . . . Reuben Graham, P. O. Box 153, Williamsburgh, N. Y., sends out circulars advertising obscene prints, pictures, etc., under the thinly disguised plea that they are exposures of tricks, etc. Parents and guardians should be careful that their children and wards do not receive these circulars by mail; and the post-master at Williamsburgh will of course stop all letters coming to such a demon, whose proper address is in the lower regions. Such operators usually pocket the money sent them, sending nothing in return; or if they do respond with their poisonous trash, it is done from some out-of-the-way point. Furthermore, their patrons are not likely to come forward as witnesses and expose their own shame; this is the reason why such swindlers so generally escape the State Prison. . . . **Operators in Maine.** Every month we have more or less complaints against the operations of two parties at two points in Maine, which indicate a good deal of sharp dealing, if not positive swindling. We will be obliged to our readers if they will send us positive, definite accounts of what they know of these operators in books, papers, sewing machines, recipes, agencies, and a host of implements, medicines, gin-cracks, etc. We only desire to get at the facts, in reliable, responsible form.

A Capital Story is the "Hoosier School-Master"—or Life in the West. It is now published in a fine bound volume, and is so highly prized that the printers can scarcely keep pace with the demand for it. Price, prepaid, by mail, \$1.25.

Which is the Best Stock?—"F. E. D.," Wayne Co., Pa., asks, Which is the best stock, for size, beauty, beef, and butter?—For size, beauty, and beef, the Shorthorn is pre-eminent, next the Hereford. Sometimes these breeds are good at the pail. For butter and beauty only, the Jersey or Guernsey (the name Alderney is dropped now, but it includes both these) are best. There is no one stock that can be said to be best in all points, under all circumstances. The Ayrshires are beautiful, make good beef, and are good milkers, but are of moderate size. Devons are good beef and workers, only.

Kidney-Worms in Hogs.—"I. L. L.," can probably cure his hogs affected by the kidney-worm, which causes paralysis in the hind parts, by giving half a teaspoonful of copperas daily in the feed, for a few days. Salt, ashes, charcoal, and sulphur, given occasionally in the feed, is a complete preventive.

Mink-Raising.—"W. J. McC.," Reid City, Mich. There is no difficulty about it. First catch the minks. Make a tight-boarded yard, with water-tanks, hiding places of rock-work and dark retreats, with separate apartments, where the breeding minks can make their nests and be shut up when necessary. Feed on livers and fresh fish. Keep clean with dry earth. Abundance of fresh water is required. Close observation is necessary to understand their wants, which must be attended to. We can not say if it has ever been made profitable, but doubt it.

A Good Fowl-House Needed.—The following explains itself. "Dear *Agriculturist*: I have been a reader of your paper for years and enjoy it much, but there is one thing I regret, it does not stir my husband to farming up to the times. I have been coaxing him for years to build a henery. I like raising fowls; my children delight in helping take care of them. We have over two hundred light Brahmas, besides dark ones, and other breeds, and my greatest grievance is that they will freeze their feet roosting in the trees this winter. Now, if you will print something to induce my husband to build a house for them, I will continue to subscribe to your excellent paper so long as I am an inhabitant of this planet." We give the above in full, because sensible that it is better than any argument that we can make. If repeated home admonitions have failed, and this in type does not take effect upon the lady's husband, then we give him up as incorrigible.

How to Feed a Heifer Coming in.—"F. M.," proposes to feed a heifer soon to come in as follows: Hay three times a day, with 6 quarts of potatoes and yellow turnips, daily, until three weeks of calving; then change the roots to two quarts of oats per day, until the time is up, when he will give her two quarts of meal

with four quarts of carrots. This will be good and judicious treatment. If she is a large milker, the quantity of meal may be doubled.

Navicular Disease.—"Subscriber" asks for the treatment of navicular disease of long standing. It will most likely be found past cure. The horse may be eased of the acute pain by dividing the nerve, an operation easily performed by a real veterinary surgeon.

Cure for Cribbing.—J. Teackle, Baltimore, sends a cure for cribbing, which is a basket of wire fixed on the nose by straps over the horse's head. This comes below the nose, so that the horse can not get hold of the crib, and the practice is prevented. We should like to see a drawing of this nose-basket.

Seeding a Marsh.—"E. M.," Hillsdale, wants to seed a marsh to grass; has got the ground harrowed, but too late to sow in the fall.—Sow early in spring. The mixture of timothy and red-top, half and half, is proper for this purpose. In time the red-top will crowd out the timothy, unless the ground is dry.

Manure from Straw and Grain.—"E. M.," II., asks which is of most value, the manure from cattle fed on hay, or that from those fed on straw and grain. Either will be poor enough, unless considerable grain is fed, when that from grain and straw will be the best.

Earache in Horses.—"W. E. G.," asks, "Do horses suffer from earache, and what is the cure?" Doubtless. Make a sack to fit the upper part of the head, and apply a warm fomentation to the base of the ear.

Depth of an Artesian Well.—"C. K. R.," Schuyler, Neb., asks how to tell the depth necessary to bore for water in an artesian well. If the geological character of the country is sufficiently well marked, a geologist might make an estimate which might turn out nearly correct. But there are very few localities where even a guess could be hazarded. In your position (Platte valley) it would be safest for your neighbors to join you in the expense of testing the depth of an underground stream, as they would be equally benefited with you.

Salt in the Garden.—"J. H.," Mayfield. Your waste salt may be used to advantage upon the asparagus-bed, at the rate of five bushels to the acre, applied before the plants start. Onions, when four or five inches high, are benefited by the application of about three bushels to the acre. It is useful, according to some, as a dressing in the cabbage field. There is but little positive knowledge as to the fertilizing value of salt, but several good cultivators agree as to its utility in the cases above named.

The Right Sort.—"R. M. T.," writes that "reading the *Agriculturist* induced me to buy a farm about two years ago, and the more trouble I have the more I seem to like it." That man don't loaf at the grocery and complain of hard times and bad luck.

Curenlio, Lady-Bugs, Borers.—"A. J.," Smyrna, Tenn. "The Curenlio" is a dark gray or blackish snout-beetle that deposits its eggs in plums and other fruit. There are hundreds of species of Curenlio, but the one called by fruit-growers "the curenlio," is the chap that makes such havoc with plums. All red and black lady-bugs are your friends. They are around your apple-trees in search of plant-lice. Apple and peach borers are insects; the sap-sucker, although it bores, is not a "borer" in the accepted term.

Now for those Peach-Buds.—This is the time when we look out for dead peach-buds. We don't know how peaches grow, but we are quite sure that the buds are all killed every year—at least by those who bull or bear (we don't exactly know which) the peach market. Peach-buds were badly killed last spring, but in September loads of peaches were thrown away, to save the baskets. This spring every bud is as dead as a door-nail, yet we shall probably get our Delawares at a dollar a basket, or less.

Northern Pacific Railway.—By the opening of the European markets to the Northern Pacific Railway loan, a new interest has been awakened in the Northern road that is now pushing out rapidly towards the Pacific. The mutual interests, commercial and political, existing between the East and West of our great country render it imperative that there be abundant, speedy, and uninterrupted railway communication. There will soon be business for several railways. The Northern and Southern routes are even more feasible than the central one; while, of

the former two, the Northern one will have the advantage of passing through a rich agricultural region, in nearly its whole course, that will furnish an immense local travel and traffic, instead of running through broad, arid plains. There is a popular error in regard to high latitude and cold climate of the country traversed by the Northern route. A glance at the map will show that in nearly all its course it runs on a latitude corresponding with the north of France, Austria, and Southern Russia in Europe. Minnesota is one of the finest wheat sections, and similarly fertile regions of country are found stretching away westward towards the Pacific. All the inhabitants of Sweden, Norway, and much more of Europe, would find a warmer climate, more generous soil, and abundant room between Minnesota and the Pacific coast. The wonderful natural scenery along the Yellowstone River, now coming into notice, will ere long attract immense throngs of visitors from all parts of the country and from the Old World, and these sight-seers will pass over this road. So much for the future of the Northern Pacific Railroad. In answer to numerous inquiries from our readers, we will add that we do not see how the Bonds of this road can fail to be a safe investment, with the large business the road must ere long enjoy, and with the fifty-seven million acres of land granted by Congress as an additional security. Other inquiries are answered in the advertisement of Messrs. Jay Cooke & Co., on last cover page.

The Trophy Tomato.—W. R. Woodard, of Chicago, to whom we sent, last spring, a packet of Trophy Tomato seeds as a premium, writes: "I was rather surprised to read the account of the competition on the Trophy Tomato in your last. I anticipated much larger things than are there recorded. A packet of seed, which I received in April, as a premium, and planted in a box in the kitchen window, produced plants that in August gave me better results than any you there mention, and that, too, without receiving anything like proper care. A dozen plants, which I took the last of April, when three inches high, to Mercer County, gave, under the very good care they received, the largest and best tomatoes I ever heard of, the largest weighing 36 ounces, and those weighing 25, 30, 34, being numerous. Without care it has done better than any sort I ever tried, while it seems to me to yield better returns for extra care than any other, and I have for years made it a rule to try every new tomato that I hear of."

To Preserve Trees from Rabbits.—"R. W. M.," Kent, Ohio, preserves his fruit trees from rabbits and sheep by washing them with a mixture of fresh cow-dung and water. This is always available, while blood is not. This will do for rabbits, but sheep or goats should never be permitted in an orchard.

Gray Squirrels and Maple-Trees.—"E. C. B.," wrote from Embarrass, Wis., last March, "Why do gray squirrels gnaw the bark from the branches of the sugar-maple? An army of them have lived in a sugar-bush belonging to my brother, the past winter, and on many of the trees the whole of the upper branches are completely denuded of their bark. Some small saplings are stripped from root to topmost twig. As late as two weeks ago he shot one in the act of gnawing off fresh bark. Did you ever hear of a like circumstance? There is even now a plenty of acorns near by, but they seemed to prefer the bark."—We never heard of this trick of the squirrels. They probably do it for a change of diet.

Cranberry Culture.—"S. K. K.," asks if it will pay to make a cranberry meadow, where the preparation will cost \$280 per acre, and where he can flow the land—but not at will—and where frost is liable to affect the vines.—We fear the experiment is a risky one. The time for extreme high prices for cranberries is past, and for the future calculations must be based on an average of five or six dollars a barrel, or even less.

Cuttings of Grapes and Currants.—J. F. Herrick, Ky. Autumn is much the best time for making these cuttings; with currants particularly, nearly a year is gained. They can be made now with a fair show of success. As soon as possible, when the plants are not frozen, make cuttings of the wood of last year's growth. Cut the currant wood into pieces of six inches and the grape into lengths of two or three buds each, as most convenient. Tie the grape-cuttings in bundles, tops all one way, and bury in the cellar, or in a place outdoors where water does not stand. If possible to work the ground, set the currants at once; if not, bury them and set at the earliest day. Set in a trench, leaving one bud above surface, and crowd the earth well against their lower ends. Put the cuttings four to six inches apart, keep free of weeds through the summer, mulch when dry weather comes, and in fall set where they are to grow. Put out the grapes when the soil is warm and mellow, in

the same way, one bud at the surface, mulch with leaves, and water if need be. Some varieties of grape can not be grown in this way, such as Delaware and Norton. Do not set cuttings where they are to grow, but give them their first year in a bed.

Pine-Wood Ashes.—“J. M. W. K.,” Morristown, finds that Dana in his “Muck Manual” states that pine-wood ashes contain four times as much potash as hard-wood ashes. Dana, on the authority of Berthier, certainly says this; and J. F. W. Johnson (Johnson’s Agricultural Chemistry), on the authority of Sprengel, says that beech-wood ashes contain ten times and oak seven times as much potash as pine ashes. Sprengel, and not Berthier, is correct; we never saw or heard of potash made from pine ashes, while it is largely made from those of hard wood. No backwoods house-keeper would think of using pine-ashes for her soap.

Value of Tanners’ Refuse.—“C. S. E.,” Peabody, Mass. Tanners’ refuse is composed of lime, hair, and some animal matter, and is useful as a top-dressing to grass lands, or for orchards. It can hardly be compared with stable-mannure, as it contains no potash or phosphoric acid, and is rich only in lime and nitrogen.

Value of Marl.—“G. A. P.,” Charlestown, W. Va., has a bed of marl, composed of the following: Organic matter, with traces of ammonia, and water, 15.60 per cent; carb. of lime, 54.60; peroxide of iron and alumina, 2.40; silica and insoluble silicates, 27.40. What is its value as a manure, and in what quantities should it be used?—This marl is of value only for the lime and ammonia; it would make a good material to compost with swamp-muck as a dressing for grass lands. Alone, three or four tons per acre would be a proper quantity to apply on a meadow. Its value is about one dollar per ton, but might be increased by burning.

Hen Manure.—Vindex, Long Island, has ten barrels of hen manure, and now the question occurs, “What will I do with it?” Poor man! we are sorry for you; head up the barrels tight and pay the freight to our place and it won’t trouble you anymore. When it arrives, we shall mix it with two or three times its bulk of the driest earth at hand, shovel it over and mix thoroughly, and put it in a heap, with a few inches of earth over that. If it does not heat in a few days, we shall make the heap over, and wet it as we go, and cover the new heap with earth. If any ammonia escapes, put more earth on the heap. It will soon disappear as hen-mannure and be incorporated with the earth, and we shan’t buy any guano this year. We shall use it for corn and all sorts of quick-growing crops, top-dress cabbages, and anything else for which we would use guano. As it is very strong, it will not do to put it in direct contact with the seed. If he chooses to take the trouble, “Vindex” can do this himself, but we should be glad to do it for him.

Swindled in Eggs.—A correspondent in Wisconsin wishes us to expose the manner in which an individual in Chambersburgh, Pa., swindled him in an egg trade. He ordered geese, duck, and hens’ eggs, and sent the money to pay for them. The hens’ eggs came, and not a single one hatched. No duck nor goose eggs were received, nor has our correspondent been able to get the money back. We are always ready to expose swindles when we have the documentary evidence to back us. While we have not the least doubt that the case is as our Wisconsin friend represents, we should be subjected to great inconvenience were we called into court to answer for publishing it in full. The Chambersburgh man has long been denied admission to our advertising columns.

Manufacturing Bone Manure.—C. H. Stoffers, Knox Co., Tenn., wants to engage in making bone manures in a small way, and asks what the machinery would cost. It will not pay to engage in this business in a small way; the mill for crushing bones alone would cost \$150 to \$600. The mill figured in the *Agriculturist*, November, 1871, p. 417, might be built for \$150, without the power. The vats for dissolving the bone, and machinery for pulverizing and preparing the superphosphate, might cost \$150 more for a small manufactory. A power of six to ten horses is necessary to grind so tough an article as bone.

Seeding Down Corn with Clover is sometimes adopted with excellent results. Cultivate the corn on the flat, and after the last cultivating, say in July, mount a horse, and with a Cahoon’s broad-cast sowing machine sow five quarts of clover seed per acre. If the ground has been thoroughly cultivated and is moist and mellow, the clover will soon start; and if it should not, go over the field again after the first rain, and sow six quarts of timothy seed per acre. We would suggest this plan to J. T. B., of Maryland. His five-field rota-

tions would then be: 1. corn, seeded with clover in July; 2. clover, pastured; 3. pasture or summer fallow, and sow with wheat in the fall; 4. wheat, seeded with clover; 5. clover for hay and seed, or pasture; 6. corn, etc. If clover seed is grown, sell it and buy manure, or bran, cotton-seed cake, or other food with the money, and keep a flock of mutton sheep.

Steam-Engine.—“Subscriber.” Why don’t you sign your name? Do you and a thousand others think we will answer matters of an entirely private nature in these columns? Your name and a stamp would have given you a reply.

Rotation of Crops in Maryland.—“J. T. B.,” a young Maryland farmer, whose soil is light but not sandy, wishes our opinion as to the best rotation for five fields. He has hitherto raised nothing but corn and wheat, but thinks this brings the land too frequently in wheat and corn. We suppose the present rotation to be—1. corn, 2. wheat, 3. clover, 4. clover, 5. clover, 6. corn, 7. wheat. If the corn-stalks, wheat-straw, and clover are all consumed on the farm, the above is not an exhaustive rotation. If the land is well cultivated when in corn and is clean, we do not see how to better the rotation. If the wheat crop will not average 30 bushels per acre, we should be inclined to use some artificial manure, say Peruvian guano, or nitrate of soda, and a phosphatic guano or superphosphate.

The Wild Onion.—A correspondent in Albemarle Co., Va., asks how to destroy the wild onion. If this onion is one which propagates by seed, putting the land in grass, and mowing, would certainly destroy it in time. If it propagates by offshoots from the roots, nothing but plowing, harrowing, and gathering the roots will avail, so far as we know. We have heard that trenching the ground and thus burying the roots deeply will kill them. As this is a serious trouble in some localities, we should be glad to hear from those who have had experience with it. Fortunately we have had none.

Branching Corn.—We have published testimony adverse to the “Branching Sweet Corn,” and we now give the only favorable report that has come to us. Mr. J. M. Beckwith, Norwich, Ct., who planted the corn and raised from two to five ears to the stalk. Some of the hills had from five to ten ears each.

Catalpas and Magnolias.—“L. D. S.,” Hudson, O., asks which are the best varieties. The common Catalpa is well known; it is barely hardy at New York. *C. Kaempferi* seems to be hardier. It is more dwarf, very leafy, and a free bloomer. *C. Bungei* is recommended, but we have not tried it. All the native Magnolias (except the Southern *M. grandiflora*) are hardy, and the Chinese varieties are likely to be so with you, though the spring frosts may catch the flowers. *M. conspicua*, white; *M. purpurea*, purple; and *M. Soudanqueana*, a hybrid between the two, are old sorts. *M. Lenei* is a newer variety, and the flucst, but scarce and dear yet.

Evergreens.—“L. D. S.” Both *Cupressus Lawsoniana* and *Thuyopsis borealis* are generally hardy in the Middle States. They sometimes get badly injured near New York.

Burned Swamp Land.—“E. G. H.,” Lake Co., Ind., asks how corn, oats, potatoes, or onions would grow on a tract of peaty soil, which has been burned over from six inches to two feet deep. Such soil, when plowed and mixed with the ashes, would grow corn or potatoes excellently; oats would probably lodge on it until two or three crops have been taken off.

Diseases of Cattle.—“S. C. B.,” Topeka, Kansas, asks for the best work on cattle diseases. “Dad’s Diseases of Cattle” is a useful work, and as good as any.

Colorado.—“G. E. S.” wants to know all about the climate, soil, etc., of Colorado. The climate is dry, healthy, and cool on cloudy days and at nights; during winter there are occasionally severe storms, during which cattle need feed and shelter. Crops need irrigating, and then yield about equal to a good farm in New York or Pennsylvania. There is a colony near Pike’s Peak—we do not know the name of it.

The Best Beef-Cattle.—“A Subscriber” wants to know which is the best breed of cattle for beef? For a hilly country with light pasture, the Devon; for a moderate pasture, the Hereford; and the Durham or Shorthorn is best for the richest pastures on level plains. Cotswold is the hardest and largest mutton sheep. South Down is the choicest quality, but medium weight.

Measuring Hay in the Stack.—“G. W. B.,” Lafayette, Ind.—Hay is measured in the stack by the same rule as hay in the mow. See *American Agriculturist* for January, 1872, page 7.

How to Feed Carrots.—“P. P.” says his horses will not eat carrots; how shall he feed them? Cut or chop them with a sharp spade in a box, and sprinkle a little salt and ground feed over them. Roots are often refused at first, when fed whole.

Lolling of the Tongue in Horses.—“O. W.,” Newfane, N. Y., asks for a remedy for the unsightly habit in a horse, of hanging the tongue out of the side of the mouth. A bunch of small links of chain fastened to the center of the bit is sometimes used to prevent this habit, by occupying the attention of the horse, and causing him to champ the bit; a strong bitter decoction, as of gentian root, rubbed on the outside of the mouth will sometimes make him withdraw his tongue.

Paint for Tools.—“Mechanic” says there is difficulty in procuring crude petroleum in some cases, and recommends Venetian red or French yellow and boiled linseed oil as cheap paints for implements.

Raising Roots.—V. Yannier has sandy, warm, black soil, and asks which would be the most suitable roots to raise. We would recommend him to raise a variety—carrots, sugar-beets, mangels, and rutabagas. They can be grown side by side, and cultivated together. Manure is needed for all roots, and bone-dust and guano are especially useful. Artichokes are not to be recommended as a farm crop, unless the land can be given up to them.

Are Twin Cattle Barren?—“Subscriber” has a valuable twin heifer, which has shown no inclination to change her condition, and asks if this is inevitable. Not always. Some believe twin animals are necessarily barren. We do not believe it, having had a cow which was twin-sister to a useful bull.

Buying Food for Hogs.—W. S. Payson, Ill., writes: “Ogden Farm Papers say that a man can afford to buy food for stock if he can afford to feed what he has raised. Is this always a safe rule? If so, would it pay to make a specialty of pig-raising, calculating to buy all or most of the corn for fattening? Could such a business be depended on as profitable through a series of years? Will hogs do well in warm sheds or houses without straw?”—To answer the first question, the rule is always a safe one. Whether it would pay to make a specialty of raising pork, is another proposition, but it is one that is not at all affected by the question of raising or buying corn. The profit of such an operation would be very much affected by the value of manure in the locality where it is carried on. The question is a purely commercial one, in which the prices of pork and of corn and the value of manure are the factors. It is, we think, fair to assume, that no staple article like pork will sell, one year with another, for less than the cost of producing it. It is from the profit made by the production of staple articles that the population of the world mainly gains its living. The chances of success would probably be very good, if the business were carried on on a large enough scale and with sufficient care as to details. Hogs should have some sort of dry bedding, either straw, dry earth, or something else, that will keep them out of the mire, especially in cold weather. If many are kept together, their quarters should be very thoroughly ventilated.

Cabbages for Fattening.—“G. B.,” Lodi, O., asks if cabbages are profitable to raise for fattening sheep and cattle. No. Ruta-bagas, with the manure needed to grow a good crop of cabbages, would make a heavy crop and would be a much more valuable feed for fattening.

Yorkshire Swine.

The modern improved Yorkshire hog is an instance of what may be done in improving a breed by care and judicious selection for a series of years. Originally, the Yorkshire breed was reputed to be the worst in England, but by crossing on another race, and by care in selecting, it has been brought up to be one of the best. They are good feeders and quick growers, and readily attain a weight of four hundred to five hundred pounds at twelve months old, and eight hundred pounds when full grown, and are very prolific. Prize animals have been fed up to 1100 and 1200 pounds. The specimens represented in the engraving on the first page, are the property of Brodie, Son & Co., of Rural Hill, N. Y., who took four prizes at the New York State Fair of last year, on their Yorkshires.

A Great Boon—A Good Cheap Sewing Machine, at Last.

The *American Agriculturist* was the first journal in the world to bring effectively before the public that great labor and clothes saver—the wringing machine. So, also, this journal prepared and published the first popular illustrated article showing, in a clear manner, "How Sewing is Done by Machinery." The illustrations used in that article have been taken up, copied, and printed many millions of times by the various manufacturers. And now we have the pleasure of bringing before the public a practically useful, low-priced sewing machine. While so often recommending the utility of Sewing Machines, we have been all the while earnestly looking for the appearance of something that would come within the reach of the large class that could not possibly buy a \$50 or \$60 implement. But though we have bought and tried a multitude of machines of all sorts, sizes, and prices, until a spacious lumber-room would be required to store all the samples, we have, until now, felt obliged to continually caution our readers against buying any of the low-priced machines. And we still say that for general use the sewing machines, sold for from \$45 to \$75 each are to be preferred when obtainable. But not one half of the families in our country have any useful sewing machine, simply because not half the people feel that they can possibly spare \$50, or more, in this direction, and so the everlasting "stitch, stitch, stitch," by slow hand-process, goes on, exhausting the strength and health of the toilworn and careworn mothers of the land—just that class who can not hire help and most need the aid of the sewing machine.

The new machine, now introduced, we have been watching for months, and trying to like it on account of its cheapness, and because it was well made (which we could not say of other low-priced machines we have seen); but this was unsatisfactory simply on account of the motion, or method of applying the power—by a vertical motion of the hand for every stitch. Happily this difficulty is at last obviated. A crank and multiplying wheel have been devised, and now we are prepared to indorse the \$10 Beckwith Sewing Machine as one worthy of being at once secured by all who can not purchase the expensive machines; and as will be seen below, many of those who have the larger machines will want this one in addition. Here are some of the advantages of the Beckwith Machine:

1st. It is well and strongly made, and thoroughly electro-plated with nickel throughout, by the new process, which is decidedly superior to the usual thin silver-plating, as it is far more durable, and does not tarnish. It is simple in its parts, and its use quickly learned, and it runs so easily that a child can work it.

2d. It is easily attached to any table or stand having a leaf or edge projecting an inch or so, and can thus be used in any part of the house, near a window, etc. It is so light and portable that a lady can carry it with her in a reticule when visiting, or on a journey, ready for use at any moment. It is so convenient in this respect that it will be a useful addition where other machines are used, either for carrying to different rooms, or when two wish to sew at the same time. It is applicable for almost all kinds of family sewing.

3d. It makes the elastic loop-stitch (the same as the Wilcox & Gibbs and some other good machines), which, with a little care in making the closing stitch, is abundantly strong for nearly all kinds of sewing, and less liable to break in washing and wearing, owing to its elasticity. It has the advantage that the stitch can be removed when desired. Those who have lock-stitch machines, will find this stitch more convenient for many kinds of sewing, for embroidering, etc. Many contend that the elastic loop-stitch is more durable.

4th. While we do not gainsay the merits of the "foot-pedal," many persons who are unable to use that, will

find no trouble with this crank-motion. This gives complete control of the needle and every movement, so that the operator can stop on every stitch if desired. The crank in this new machine is placed below the table, which is an advantage over all other previous attempts at low-priced machines. The work is fed from the table towards the operator, which is claimed as a merit.

But the great commendation of this new machine is, that while it is practically useful, it is sold at the low price of \$10, and this brings it within the reach of a hundred thousand families that want a sewing ma-

BECKWITH'S NEW \$10 SEWING-MACHINE.

DESCRIPTION.—c, clamp holding machine upon edge of table; H, shield over wheels, with an opening to show the wheels; z, the crank-bar or pinion-arm, by which b, the upper arm, is moved; a, the lower arm; f, cloth plate; n, needle; t, thumb-screw to hold the needle; d, presser foot-spring; r, tension screw and disks; s, spool of thread; m moves the stitch-maker, which can not be readily shown. It is very simple, in form, and sure.

chine and can not raise funds to buy higher-priced ones.

We have contracted with the Beckwith Sewing Machine Company for the first 1,000 of them to supply our own friends, and as *Premiums*. Each machine is put in a neat, compact box, with *hammer and guide, oil-can, bottle of oil, thread, different-sized needles, etc.*, with full Printed Directions for using, and delivered to any express office in this city, without extra charge above the \$10. As we buy the machines at wholesale price, we have decided to give our readers some advantage of this, and we therefore propose to make a present for himself or herself, or for any friend, of one copy of *Hearth and Home* or two copies of the *AMERICAN AGRICULTURIST* for the balance of this year (1872), to the first 800 persons who send us \$10 for one of the new machines.

The New Sewing Machine as a Premium without Money.

To enable those to get this machine, who can not raise even the \$10 to buy it, we make the following offer:

We will send the Machine free to any one who will collect and forward SIX subscribers for HEARTH AND HOME one year at \$3 each; or TWELVE subscribers to AMERICAN AGRICULTURIST for one year, at \$1.50 each.

Almost any lady can readily secure this small number of subscribers and get a machine free; or some friend can thus obtain it for her, as a present.

Cultivation of Corn in the South.

A correspondent, "J. C.," Savannah, Ga., asks some very pertinent questions about growing corn, which, as they are of general interest, we reply to in full. He asks: 1st, Is it best to plant in beds or on a level surface? 2d, Is nine square feet sufficient room for one stalk (hill?) of corn? 3d, Is white or yellow corn the most productive, and which is the best variety of either kind? 4th, Would Early Canada, King Philip, or Dutton be likely to succeed in the South, and have the branching varieties any advantage? 5th, Would it be safe to cut the crop entirely at that stage when fodder is usually pulled; if not, how early could it be safely cut?

ANSWERS.—1. Level cultivation is now considered preferable to the ridge or bed system. 2. Nine square feet is not sufficient for a hill of corn, except of the small varieties. For a single stalk, six square feet (4 ft. \times 1½) would be room enough. 3. The white Southern corn is doubtless the best for a Southern latitude; the large, yellow gourd-seed corn would be adapted to stronger soils. This corn in Southern Pennsylvania has yielded over 100 bushels of grain per acre. 4. These varieties are best suited to a Northern climate, where the season is short. They are not so prolific as the larger and later varieties. The branching field corn is a myth, to say the least of it. The branching sweet or popcorn is not always to be depended on—sometimes it don't branch. 5. The grain is not fit to harvest when fodder is generally pulled, and this practice is often condemned as injurious to the grain for this reason. It may be harvested as soon as glazed, when it will cure safely in the shock.

We shall be happy to hear from J. C. in the manner he intimates.

The Agriculturist's

Ice-Boats.

— We have received several communications from ice-boat men on the Hudson in reference to the ice-boats figured in February. The difference between their boats and ours is, that ours is built to carry passengers, and theirs for racing purposes or speed only. The steering apparatus, being placed in front, enables the steersman to give his attention to that alone; the captain is behind, and gives orders to the steersman when necessary. When we go ice-boating, we enjoy the company as much as or more than the swift motion; it is with us, in fact, an old-fashioned sleigh-ride, without the horses. We think, with one of our correspondents, that our form is an improvement, as giving opportunity for enjoying this sport socially.

The Map Prizes.

When the Boys and Girls' part of the paper went to press, I was unable, as stated on page 107, to make the decisions. It has taken me no little time to examine all the maps, and when it came to decide upon the best three out of a dozen or more very good ones, the matter became very difficult. I find that the prizes all fall to boys. There were some forty maps sent by girls, but none of them seem to have taken the pains with them that the boys did with theirs. The first prize—five dollars—goes to Edward Hickey, Athens, Bradford Co., Pa.

The second prize—*Hearth and Home* for 1872—to *Jasmin Bergeron*, St. Louis, Mo.

The third prize—the *Agriculturist* for 1872—to *Edmund D. Redd*, Buena Vista, Henrico Co., Va.

It does not look well to see the prizes all go to boys, and I have requested the publishers to give gratinities for the best two maps drawn by girls. Consequently the *Agriculturist* for 1872 will go to *Alice Stewart*, Beaver Dam, Wis., and *Ellen N. Phillips*, Bellville, O.

Miss Frances S., Princeton, Ky., and Andrew M. G., Peterboro, N. H., worked under peculiar disadvantages. Mary R., Scott Township, Iowa, deserves great credit for her perseverance, and Hugh V. W., Macon, Ga., should be encouraged. These and some others will hear from me by mail.

THE DOCTOR.

Improved Sugar-Beet.—In answer to inquiries concerning the sugar-beet mentioned last month on page 58, we would say that we have learned that the whole disposable stock of seed has been purchased by B. K. Bliss & Son, of this city, who will no doubt make the fact known in their advertisements.

Clevis for Three-Horse Evener.—E. Fisher, Carroll Co., Ill., writes us that parties are claiming a patent-right on a clevis for a three-horse evener, figured in *American Agriculturist*, Aug., 1869, p. 293. Unless these parties can show that they hold a patent issued previously to above date, their claim is illegal. No payments should be made unless they can show this.

Farmers Look Out.—There is a very taking humbug after you just now. We have just received a pamphlet, setting forth the merits of "*Saccharum officinarum*, or Saccharine Sugar-Cane," which attempts to make farmers believe that they can raise the true sugar-cane as far north as Wisconsin. This pamphlet cautions people against being humbugged, appeals to the clergy, and is up to the latest dodges of the most refined humbugger. If people do not believe what is said, they will "forward samples of the sugar to any post-office in the United States, by mail, on receipt of twenty-five cents in currency, which analysis will prove is no ordinary or adulterated sugar." That is, indeed, convincing proof, but not so good as the Dutchman's, who said, "Hans, if you don't believe that is goat whisky, schust schmell of the cork." Seriously: The price of this remarkable seed is \$3 a package, with all sorts of club and other inducements to purchase by wholesale. We hope that no reader of the *Agriculturist* is so stupid as not to know that the true Sugar-cane (*Saccharum officinarum*) is so much of a tropical plant, that it barely maintains itself in Louisiana, and that they can no more hope to grow it in the open air in the Northern States, than they can Pineapples or Bananas. Good things and new things don't come sneaking along in such a dubious way as this. Let this Sugar-Cane alone!

Bliss & Son Want to Know.—The well-known seed firm of B. K. Bliss & Son wish to know where their money goes to or where it comes from—we don't know which. At any rate, they say in their advertisement, "We will send a packet of choice flower seeds, gratis, to persons ordering catalogues, if they will state the name of the paper in which they saw this advertisement." Here is a chance for women as well as men, to vote. No repeating, no ballot-box stuffing, but let us have a square vote. Read advertisement and order your catalogues.

Dyehouse Cherry.—Notwithstanding that the gentleman who described this cherry in February stated he was only an amateur and had no trees for sale, we have applications by the dozen, asking for his full address. This we must decline to give, as we can only say what he has already said, that he has no trees to dispose of. If any of the Kentucky nurserymen have propagated the Dyehouse Cherry, they will do well to advertise the fact, as inquiries are numerous.

Four Months still Remain, during which any and all persons who wish them, can secure, without money, one or more of the splendid assortment of useful and desirable articles described on page 119. Multitudes of people, now planning the work of the year, need and will appreciate the hints and suggestions of such a journal as this. *Heath and Home* is rapidly advancing in value and in the public favor, and some very valuable things are in preparation for its pages during the summer. . . . One only needs to take copies of these journals and show them to his or her friends and neighbors, and explain their merits, to soon have subscribers enough to secure a valuable premium article, that will be quite as good as the money it would cost. See pages 84 and 119.

Spring Work is Coming on, and hints and suggestions are wanted. See "Four Months," above.

Barry's Fruit Garden.—The new edition of this work, which was long ago announced, but which, by unavoidable causes, has been delayed, is now on the press. The Fruit Garden has long filled a place which has been occupied by no other work. It is full enough upon all the processes of propagation to suit the nurseryman, and this part of the subject, as well as those of pruning, training, and cultivation, are exactly suited to the needs of the amateur. A carefully considered selection of fruits of all kinds makes the work a most useful one to those who plant in a large or a small way. While the same general plan of the work has been preserved, the new edition has been in some parts re-written, and in others so largely added to, that it is essentially a new

work. To those familiar with horticultural literature we need only announce a new and thoroughly revised edition of Barry's Fruit Garden. To the novice, we can say that he can have no better guide than this work, which embodies the ripe experience of the veteran nurseryman and pomologist, P. Barry. The illustrations, which are all re-engraved and much augmented, are numerous and instructive. Price \$3, post-paid.

Organs and Melodeons.—Several parties have within a few months supplied their churches with small organs by canvassing for our papers, and secured the premium by a few hours' labor. We have given L. A. Prince & Co.'s instruments for many years, and have never had a complaint from any who have received them.

The Death of Joseph B. Lyman.—The friends of Mr. Joseph B. Lyman were startled by the announcement of his death, which took place, after a

THOMAS'S SMOOTHING HARROW.—(See next Page.)

brief illness, on January 28th. Mr. Lyman was the Agricultural editor of the New-York *Tribune* and a prominent member of the New-York Farmers' Club. He was a fluent and ready speaker and writer upon agricultural and other topics, and was much esteemed by his many friends.

The Quinn Pear.—Several have asked where they could obtain trees of the Quinn Pear. Mr. Quinn informs us that no trees have been propagated, consequently there are none for sale.

The Bickford Knitting Machine, which we offer as a premium on page 119, is a good and reliable machine. A great variety of work can be done with it rapidly and well. Any lady can do good, and obtain a valuable household helper, by canvassing at odd times for this paper.

A Fine Truck Farm, near New York City, can be bought at a bargain. For particulars, address S. F. Gooding, at 245 Broadway.

A Fine "Spring Bazaar" for our Readers is presented in our advertising pages this month. It will pay well to read through every item, and see what is offered, and by whom. *Nowhere else* can one find so many good business announcements together, without being annoyed with the sight of medical and other swindling advertisements. We believe there is not among all these a man who has not the ability and intention to do what he promises in his card. When writing to any of these parties for circulars, on business, ordering, etc., please let them know where their business cards were seen. We want every business man to know when he is dealing with our readers.

Bee Notes for March.—By M. Quinby.

Be sure that every stock has a queen, for without one almost any swarm will run down at this season, and if diseased the calamity will probably be greater from contagion. See that they are strong, and unite weak ones if necessary. To feed box-hives at this season, lay sealed honey on the open holes at the top of hive, and cover closely. To examine such a hive, turn it over with care, and quiet

the bees with smoke if necessary. Let the sun shine directly between the combs, and if they are strong, the cluster of bees will be seen to extend nearly through them. If the stock is seen to be weak, close the entrance, allowing room for only one bee to pass at a time.

While the hive is inverted, look at the top of the outside combs for sealed honey, and, if that is to be seen, they will probably live two weeks, unless plundered. This inspection is better done, this month, in a warm room, with all the windows darkened, except the one before which you are operating. A stock is often saved by a little timely care now, and sometimes, when the bees are thought to be dead, they may be revived. If, after warming a few of them, they exhibit any signs of life, they may be saved. In such case, pour a little liquid honey or sugar directly among them on the combs. Confine them with a cloth and bring near the fire. After a little, they may be returned to the stand and fed as before directed. Should any desert, as they may do at this season, they will be quite likely to join some other stock and be destroyed.

If they cluster, return them to their own hive and feed

regularly. Stocks with movable frames may be fed by putting a frame containing honey in place of an empty one. Save with care all combs left from weak stocks, if in good condition. It takes a large amount of honey for the secretion of a little wax, hence never melt up good worker combs. Protect them from the moth by freezing, or fumigate with sulphur and use them for swarms.

If not already done, get some rye finely ground, without bolting, with which to feed the bees, beginning on the first warm day. We can not afford to lose any day in which bees can work, even before the flowers yield honey or pollen. We want to stimulate breeding now, by every means in our power. To induce them to take the ground rye, scatter it at first in several places. Put a very little honey on or near it, until it is found. It is unnecessary to attempt this after the flowers yield pollen.

Mr. Waite, at the Clevealand Convention, gave us a new plan of feeding. Instead of a large floor or platform, as before described, he made a shallow box, with a rather coarse wire-cloth bottom, and put the feed in this, and covered it, raising one side a little, so that the bees could work under the bottom. Another box under it may be needed to catch the coarser particles as they fall.

In taking bees from winter quarters, we should avoid doing it in unpleasant weather, as well as in that which is unusually warm, for the season. Take out a dozen hives at a time, and then rest for an hour; when those first removed are comparatively quiet, set out more. If each stock can occupy its old stand of last year, there is much less danger of their mixing in each other's hive, but if stands are to be changed in the home yard, now is the time to do it, as there is very much less loss than after the bees have had a fly. They should be looked to many times through the day to see that all is right. If the place they are in is a new one, the bees sometimes leave their own and join a neighboring hive, in so large numbers as to reduce, and often ruin, the one they have left. Sometimes, when they have no queen, they will desert entirely. If the weak condition is discovered by the strong ones, the honey will all be carried off in a few hours, and the bees left to starve. These things should be detected within the first few hours. It is not to be supposed that every indication can be given, but he who looks at his bees very frequently will soon learn if anything is wrong, and will feel paid for what some might call needless trouble by the knowledge he will gain.

The Thomas Smoothing Harrow.

In an article in the *Agriculturist* for August, 1871, we spoke of the Thomas Smoothing Harrow as an excellent implement; it is designed for a wider range of operations than any other harrow in use. It serves not only as an implement to bring the soil into a proper state to receive the seed, but to destroy the weeds which germinate immediately after sowing, and by harrowing the growing crop to stimulate its growth and keep it clean at the same time. All this is effected by using a large number of fine steel teeth, and sloping them backwards at an angle of 45 degrees. Thus the teeth do not

weeds and mellowing the ground, both of which are of very essential service. In a similar way the potato crop may be worked.

Thomas's harrow has been used by several of the editors of the *American Agriculturist*, and they unite in speaking favorably of it. A committee of the 'Farmers' Club of the American Institute reported unanimously in its favor. The inventor and manufacturer of this harrow is Mr. John J. Thomas, widely known as a farmer, editor, and author of valuable works on farm implements, fruit culture, etc., and in view of all the testimony in its favor, we have put this implement (figured on the preceding page) upon our premium list. See page 119.

Ogden Farm Papers.—No. 26.

It is very probable that my readers may be interested in the details of some other butter-making experience than my own. I have given in another article an account of a cow owned in Providence. I was satisfied that her performances were due not entirely to the fact that she is a good Jersey, but in very great measure to the treatment she receives. I knew that it would be easy to make wheel-grease butter from her milk. I have therefore endeavored to find out all I could about Mr. Perry's practice, and about Mrs. Perry's part of the work, too.

My letters of inquiry have brought the fol-

SPEAKMAN'S COMBINATION OR PRAIRIE FENCE.

penetrate the fine soil more than two inches, which is not sufficient to permit them to injure the sprouting seed or the young shoot, and by a dragging motion which presses downward at the same time, they are able to pass over the surface without tearing out the growing plants, but at the same time disturb the small growth of weeds sufficiently to destroy them. The large numbers of this harrow now in use amongst farmers all over the United States, and the increasing demand for them, show that it is what it claims to be—a practical and useful instrument. As a pulverizer of the ground, after plowing and previous to sowing, it is in our estimation a perfect harrow, leaving the ground smooth and mellow, and in the best condition for the drill. Besides this primary use, it has many others to which it adapts itself in the most satisfactory manner. It can not clog either with trash, sods, or coarse manure, but rides easily over all obstructions and forces them into the soil. In harrowing plowed sod-ground this peculiarity is especially valuable, as also in harrowing meadows in the spring, which have been top-dressed during winter. By its use the manure is broken up fine and evenly worked down into the grass. The draft is also much decreased, both by the small size and position of the teeth, and a field may be harrowed equally well in half the time required by a common harrow. But as a cultivator it is most valuable, for no other harrow can be used to cultivate growing crops. On winter wheat it has been used in the spring with the best effects, and assists very much in securing a successful stand of clover. On growing corn and potatoes it has also been successfully used until the crops are sufficiently advanced to resist the ill effects of weeds, and the ordinary cultivator comes into operation. The corn crop is the one which it is claimed is essentially benefited by the use of this harrow. It is necessary to plant the corn level with the surface to enable the harrow to ride over the crop without injury. By its use corn may be cultivated in drills, using the corn planter, which will easily plant and cover ten acres per day with the labor of one man and a horse, and a gain of one fifth in the quantity of the crop be made. The round, sloping teeth pass over or through the young corn without injury, destroying the

A Prairie Fence.

We give an engraving of a "Combination or Prairie Fence," invented and patented by Thomas Speakman, of Philadelphia, and designed specially for Western farms. The fence is of wire. As many strands may be used as may be needed for small or large stock. The posts may be eighteen feet apart if desired, and the stretching posts 500 to 1,000 feet, according to circumstances and the size of the wire.

Between the stationary fixed posts are placed intermediate slats, the object of which is to strengthen the fence and make it plainly visible to stock. These intermediate slats are four inches wide, and may be of any desired thickness. They are bored edgewise, and the wires pass through the holes; thus a flat, broad surface is presented to view, making the fence conspicuous. The stretchers consist of movable posts, working in slots sunk in the ground, and the wires are tightened by means of cross-bars passing through the posts; the ends of the cross-bars being mortised to receive wedge-shape pins which, on being driven home, draw the movable posts together and stretch the wires tight.

It is not necessary to stretch this fence as tight as in an ordinary wire fence, as the slats support the wires and prevent sagging; only tension sufficient to keep the fence in line is required.

The end posts are strongly braced, to resist the strain, as in an ordinary fence. The stretching bars may be removed when needed to afford a passageway into or out of the field.

This fence combines the advantages of the wire fence with those of the ordinary picket fence, and its cost is about eighty cents to a dollar per rod for a three-wire fence, and a dollar and a quarter per rod for a five-wire one.

If galvanized wire is used, this fence is very durable. The slats may be renewed at any time by using two pieces and cutting grooves in each to receive the wires, and fastening them together with wrought nails. In a similar manner the posts may be renewed, and the whole fence may be thus replaced, as needed, piecemeal.

The inventor thinks this fence meets all the requirements of cheapness, durability, and efficiency; and although we have not seen the fence in operation, it seems to us as though it had sufficient good points to make it worthy of trial.

lowing reply: "I unite grazing and soiling, because it is more convenient for me to do so. I feed as great variety of food as I can readily obtain at fair cost, and always intend to give my cows the kinds or kind which they appear to like best and *will eat the most of*; keeping in view the chief object which I have in feeding them, which is to get the *most* 'gilt-edged' butter I can, *at least cost*, without forcing the animals to their injury.

"In the season for grass my cows get from one quarter to one half their food grazing, and the remainder from soiling with the common kinds of soiling-plants in their season, such as clover, corn, millet, kale, cabbage, beet-leaves, etc. I then give them but little grain in any form. Though if the cows are extra good ones for butter, (and I endeavor to keep no other), they will fall off in flesh to such an extent that they are almost skeletons, and too poor to be in good working condition, or even to look healthy and wholesome. To prevent this I give from one to two quarts of Indian meal per day, generally dry, sometimes clear, and sometimes mixed with wheat bran. I do not like to feed much concentrated food to milch-cows, any way, for I think it has a tendency to fill up the carcass more than the cream-pail. In winter and spring I feed hay, made from grass cut quite green, and rowen, which is still better for cows in milk. For the nearer hay approaches green grass as animals get it in the fields, the handsomer and better the butter will be. In addition to all the good hay they will eat, I give from a quarter to a half bushel of roots, to each cow, according to age and size, every morning. I raise several kinds of beets, carrots, and turnips, and change them in feeding as I think they will do the most good. In the evening each cow has her ration of from four to six quarts mixed feed, composed of wheat-bran and Indian meal, in about the proportions of 100 lbs. bran to 50 lbs. meal, or, in bulk, from five to six times as much bran as meal. I sometimes feed corn and oats, ground together half and half, but always mixed with bran—say 100 lbs. of the latter to two bushels of the former. I do not use cotton-seed meal when making butter. I think I like well-cured fodder corn and stalks, for a change, and for making winter butter, about as well as hay."

"I have told you my present way of feeding

milk-cows kept exclusively for the purpose of making butter and to supply the wants of a large family with milk, etc. I have never kept more than three or four cows at a time, but have fed them in various other ways, though not to so good satisfaction. The way I have described may not be the best—indeed, I do not think it is, for, as I have occasionally made some change, which has been to advantage, so I trust I shall continue to make improvements in the manner of feeding. I have never tried the steaming process, but sometimes I think I will.”

This gentleman has also a Jersey heifer that has recently dropped her first calf. Of her he says: “She is giving between eight and nine quarts of milk and making over one pound of butter per day, and her flow of milk is on the increase. I will tell you how I have fed her. For two or three days after calving, on *air chiefly*, with a very little hay, bran, and water. The hay and bran have been gradually increased, with a few roots, until now (ten days after calving) she has all the good hay she will eat, a peck of beets in the morning, and five quarts of coarse shorts in the evening, with all the water she wants to drink, and nothing else, except a little salt for seasoning. If I had a hundred heifers, I should treat them all in a similar manner, until I learned a better way.”

So much for feeding. The lesson taught is one of which all good farmers will recognize the importance, namely: while avoiding concentrated food, to give as much variety as possible, studying the cow's appetite, and doing everything to induce her to eat the largest possible quantity. The reason for this is, that all profit in feeding, whether for flesh or for milk, comes from the excess of the food consumed over what is necessary to keep the animal in a healthy condition.

Concerning the making of butter, Mr. Perry says: “We set the milk in old-fashioned tin-pans, in the usual manner, and skim every day; or, in other words, let it stand twenty-four hours. We keep the cream in the cellar, which is well ventilated, and stir it thoroughly every time more cream is added. A few hours before churning we bring up the cream and place it where the temperature is considerably warmer. We churn twice a week as regularly as we conveniently can. The time required is, on an average, about ten minutes, occasionally fifteen, and sometimes less than five or even three minutes. The butter is immediately taken from the churn, worked over with a wooden paddle till most of the buttermilk is out. Salt is then worked in with the paddle, a little at a time, to the amount of just one ounce to the pound, which we have found, by experience, is the quantity which best suits our customers generally. After the mixing and salting process is over, the butter is put away for twenty-four hours, in the cellar in hot weather, and in the closet in winter, when it is again, the second and *last* time, worked over thoroughly with the paddle; but never, on any account, in *warm* weather with the *hands*; my wife considers that operation a mistake, fatal beyond redemption, as the natural heat of the hands is sufficient to melt some portion of the butter, and thus destroy its fine grain, delicate flavor and aroma.”

My observation leads me to believe, that the force of this last opinion depends very much on the temperature of the hands, which is different in different persons. One of the best butter-makers I have had, worked the butter by hand in the warmest weather, without the least bad result. A good two-handled white-oak paddle is, however, quite as effective as the hands, and

so far as I have yet discovered, it is the best butter-working machine. The notion that it is untidy to work butter with the hands, does not count for much. Any dairywoman who would not make her hands scrupulously clean for this duty, would not be fit to touch butter with a ten-foot pole. Unless she is a cleanly creature *at heart*, she has no business near the dairy.

A sensible farmer in Vermont writes: “You give some very good reasons why ‘gilt-edged butter’ is sold for a gilt-edged price, but you give the great reason only by allusion—that your man advertises ‘Ogden Farm’ butter. That I regard as being the true reason for selling ‘gilt-edged’ anything. The great secret is first, to establish a reputation, and second, to keep it good. How often have I heard men say, ‘That sheep, if such and such a man owned it, would sell for \$500.’ That is, if such a man had such a sheep, and knew that it would prove just what he represented it to be, and if his customer knew that he could depend on him, he would sell it. But on the other hand, if he did not know the sheep to be exactly what he should be (although no living man could tell by its looks) he would sooner take its pelt and bury the carcass in a dunghill, than to sell it and risk his reputation.”

There is no doubt that every breeder, every nurseryman, and every seedsman who has made a permanent success, has adhered to this policy. Whether the motive be honesty or self-interest, the result is the same. A good reputation is established and one sale breeds another. There is nothing more sensitive than the reputation of one whose customers are scattered all over the country, and who have no other means of judging him than by the degree to which his goods conform to his recommendation of them. The drawback is, that in selling an animal, a plant, or a seed, success depends very much on the treatment that is given it by the purchaser. Sufficient allowance is not always made for this, and whoever embarks in the business, however honest he may be, must expect to be considered a swindler by those who ignorantly maltreat that which they buy at a high price.

It is true that there are more buyers of good butter than the market can supply, but not so very many more as yet. Not one person in five thousand ever saw what I consider really good butter, or would consider it good if he did see it. Oleaginous salt is not the article—though it is good enough for those who like it.

Of home topics to write about, I have really none. The engine goes regularly, twice a week, the fodder is cut and moistened and steamed, and the little burr-stone mill grinds all our meal; the windmill runs almost incessantly, and keeps up a good supply of water in the barn and in the milk-tank, and Hinderk, who has grown to be seventeen years old, takes entire charge of the whole machinery like a little man, as he is. But all this has been told before, and as our dictatorial editor cautions me not to write when I have nothing to say, and actually forbids me ever to “preach,” I will stop here, only saying, in response to numerous inquiries, that my ice-house, of which I hoped so much, has proved, as I used it, a dead failure, the ice lasting only until the latter part of July. If I could have procured sawdust to pack with, the result would probably have been better, but I used salt-hay, with the above effect. I find, too, that it cost me as much to fill it as to buy what I need of a dealer near by—so my ice-house will be turned into a storehouse.

An Egg Farm.

BY H. H. STODDARD.—*Eleventh Article.*

In keeping poultry on a large scale, there is no one thing more important, or more difficult to manage, than the chicken department. A failure in the yearly supply of pullets, with which to recruit the stock of layers, would be fatal to the whole plan. It is quite an easy matter to raise nearly every chick of a hardy breed, when there are but a few upon an extensive range, but it is the reverse when we are desirous of rearing several hundreds upon an acre, and there is, practically, no insect forage at all. If there are persons who consider the occupation of a poulterer as “small potatoes,” believing that it needs less thought and skill than to manage a cotton-mill, or mercantile establishment, or horses and cattle even, let them try once to raise chickens by the thousand, without losing money, and find the need of keeping their wits as sharp as in more pretentious kinds of business. Yet, all difficulties may be surmounted by thorough management.

To have strong chickens it is necessary in the first place to avoid, in the main, breeding akin, and to keep the breeding stock in a condition as near to normal as possible, securing for them sun, air, and exercise, and avoiding a pampering diet. The greater the number of eggs produced by a fowl, the less vitality there will be in each, therefore the first only of a laying should be set. Early chickens are the most certain to live, and this is because force is stored up in the parent before laying commences, sufficient to endow the first eggs or chickens with plenty of vigor, while later the abnormal or artificial prolificness impairs the eggs. In spite of the ungenial weather, March-hatched chickens are stronger than those produced in April, and the latter in turn are reared with greater ease than those hatched in May. But after attending to the above considerations, the chickens being hatched and assigned quarters, their lives then depend chiefly upon their diet. Of course, they must be kept clean, dry, free from vermin, and protected from other enemies, quadruped and biped, and be allowed space for exercise in the sun and open air; but all these things will not suffice, unless animal food is artificially provided as a substitute for the insects they would obtain if there were but few chickens on the premises. Butchers' meat, such as calves' and sheep's plucks, are even better than insects, provided they are fed plentifully, yet only a very little at a time, and care is taken to alternate with grain and green vegetable food. Chandlers' greaves may be used for chickens if very nice and sweet—the article varies much in quality. They are very cheap feed, cheaper than the fresh bits from the butcher, but not as good for chickens as the latter. There must be constant vigilance in supplying animal food regularly and systematically. The young of birds in a wild state are given an animal diet, even in cases when, as they reach maturity, they live upon seeds. The young of our domestic birds can not thrive upon grain and vegetables alone, no matter how nicely prepared, because such things can not be digested and assimilated fast enough by them, to meet the great demands for nourishment caused by their rapid growth. Nature has provided that the young of all birds shall mature and become fledged with wonderful rapidity, in order that the period of their helplessness, when they are liable to be preyed upon by numerous enemies, shall be short. The formation of the coat of feathers which succeeds the downy covering with which they emerge from the shell,

demands a quick and certain supply of nutritive materials, and in the case of domesticated species the young are obliged at the same time

hard for a living. The sitters must be fed a stimulating diet in winter and a rather low one in summer, and the fowls of the main laying stock should be crowded all their lives without any intermission by plying them with a diet growing richer and more stimulating, because containing a greater proportion of chandlers' scraps, the older they become. Cayenne pepper is the cheapest and best stimulant, with ground mustard and ginger for a change. Begin with a very little, and increase the quantity gradually.

any change in its shape; and in its operative parts, the teeth, there has been none at all until lately. But within two or three years past an ingenious improvement in the shape of the teeth has been introduced, by which the cutting capacity of the saw is doubled or trebled. This improvement is the invention of Mr. E. M. Boynton, of 80 Beekman street, New York, and has been found of such utility that large num-

Fig. 1.—QUARTERS FOR EARLY CHICKENS.

to nourish the growth of bodies which, owing to the artificial treatment man has subjected their parents to for many generations, tend to an abnormal size. The fledging period is a critical one, and the feeding from the time of incubation until the wing and tail feathers are

The chickens of the classes of breeders and sitters, which should be reared under the most favorable auspices possible, are housed at scattered stations in the cellars vacated in early spring by the early-hatched pullets (p. 12, fig. 2), and so have the advantage of a wide range.

bers of these improved saws are now in use. These saws possess several great advantages over the old V-tooth saws, among which the most important are speed and ease of cutting, and perfect self-clearing from the sawdust. After an experience of two years in using one of these saws, we can speak confidently of their great value, both in cutting wood for household use, and in the heaviest lumbering. Not only is time saved, but the work is rendered easier, and a saving of wood is gained; and that nuisance

Fig. 1.—FORM OF SAW TEETH.

Fig. 2.—PEN FOR MOVING FOWLS.

fairly developed, should all be contrived with a view to assist the digestive organs in changing just as much easily assimilated material as possible, into an abundance of good, rich blood. It will not do to wait until the time of the most rapid feathering, and then begin to allow a generous diet, but the systems of the young chicks must be prepared in advance, by being stored with nutriment in every cell and tissue. For the first few days after incubation feed the yolks of eggs *slightly* cooked by being dropped in hot water, not spoiled by being hard-boiled. Mix these with an equal quantity of the crumbs of corn-cake, made by baking a dough of Indian meal and milk. As soon as the chicks are a week old, begin gradually to substitute boiled plucks and livers, run through a meat-cutter, in place of the egg-yolks, and the Indian meal may be cooked as a thick mush, and to stimulate appetite by variety, add sometimes wheat-bran and ground oats. Also, cracked corn and wheat screenings, raw, may be introduced. All they will eat of tender grass, chopped fine, and boiled potatoes, nicely mashed, should be given. The grass may, of course, be discontinued when the birds are strong enough to pluck it for themselves. Skimmed milk should be the sole drink until the birds are two months old, at least. There is nothing that will so promote thrift. It contains just the elements needed, and in a very available form.

The adult fowls designed for breeders should be fed sparingly, and forced to literally scratch

The cellars are covered by the earth platforms, a glazed sash being temporarily hinged to one, for a door. The platforms are laid two deep, to make sufficient pitch. When the chicks are old enough to run in and out of the underground passage, they are confined at first in a lath pen, until they have learned the way, and afterwards allowed to go where they choose, the hen being confined to the cellar. Figure 2 represents a pen used in moving fowls. When it is put in the place occupied by the feed-room at the end of the passage (see fig. 1, fourth article, and fig. 1, ninth article), the fowls are baited into it, the door *A* corresponding to an opening in the side of the end of the passage. The partitions in the pen separate the flock into squads, to prevent too many fowls huddling together and trampling each other during moving, at which time a covering should exclude the light. Chains may be passed around the ends of the cross-piece at *BB* for draught.

in many a farmer's yard—viz., the pile of chips which accumulates when an ax is used—is rendered unnecessary and impossible.

The form of the teeth in the Boynton saw is such that as much cutting is done in the back stroke as in the forward one; the cutting is more rapid, inasmuch as the cutting face of the tooth is at right angles, or perpendicular to the surface of the wood to be cut, while the old V-tooth is of such a shape that it has a tendency

Fig. 3.—SINGLE-HANDED CROSS-CUT SAW.

to rise and jump over it. A log of buttonwood, twelve inches in diameter, has been cut through with one of these saws in *eight seconds*, and two men with one saw, once filed, have cut 26 cords of hard wood—beech, maple, elm, and hickory—in eight hours. The illustrations given show the shape of the teeth (as in fig. 1), and some of the forms in which the improved saws are made. Fig. 2 is the common bucksaw. Fig. 3 is a sin-

Improved Saws.

There is probably no mechanical tool with which we could less easily dispense than the saw. It has been in use from the earliest ages. When we consider the ancient origin of this tool, it is rather surprising that it should not have been long before this greatly improved in form, as it has been in the material of which it is made. With the exception, however, of giving to it a circular form, there has been little if

gle-handed cross-cut, to be worked by one man in cutting down trees or sawing logs; and fig. 4 the ordinary double-handed cross-cut saw.

Fig. 4.—DOUBLE-HANDED CROSS-CUT SAW.

Something about Trapping and Furs.

For the comfort we derive from our furs we are indebted to a class of people whom most persons know little about. Trappers are sup-

a less permanent one of poles which lean against a ridge-pole supported by forked stakes, and are covered with bark. The only furniture needed is the bed of hemlock brush, his ax, gun, traps, and cooking utensils, which consist

him \$500, or, if fortunate, double that sum. These usually simple-minded and honest men are generally natives of the rougher portions of the New England States, as Vermont, Maine, parts of Connecticut or of Massachusetts. To

mainly of a small tin kettle and a tin plate. His provisions are pork, beans, hard-bread, sugar, and tea; the rest the woods provide for him, and his gun or traps secure. The camp is generally pitched on the edge of an extensive beaver meadow, from which, and the banks of the stream passing through it, part of his game is gathered. This consists of beaver, otter,

mink, muskrat, which are all taken near the water, and marten, fisher (which has nothing to do with fish, however), lynx, and fox, which inhabit the uplands. The traps are the New

rob each other's traps or caches (hiding-places for their traps or furs) is considered too mean to be thought of, and is very rarely known to occur. The Indians, however, bring in most of the furs, and their grounds extend to the utmost limits of possible existence towards the North Pole. The Hudson's Bay Company, an English fur-trading company, procures its furs in this way, but a great number of Indians bring in furs to the towns and villages bordering on the unsettled country, and trade them for sugar, tobacco, traps, and whisky with the various backwoods stores. The Canadian Government controls this trade by means of licenses given only to responsible parties, but our Indians are unmercifully fleeced by anybody who likes to undertake the rough life of an Indian trader. The Indians bring their furs from long distances in trains drawn by dogs. The trains are flat pieces of board split from a white-ash tree, and shaved down with great labor until no more than an inch thick. They are about 18 inches broad and six feet long, turned up in front as in figure 4, and are called by them "tobagans." Four or five or more dogs are hitched by rawhide traces to the train, one before the

Fig. 1.—A TRAPPER'S CAMP.

posed to be men who live outside the bounds of civilization, and who pass their lives in a sort of semi-savage, solitary manner. This is true to a very great extent, although settlements are now made far in advance of many still prolific trapping grounds. These tracts, however, being situated in rocky parts of the country or in extensive swamps, will doubtless for some years yet be permitted to remain in a state of nature, and still furnish employment for the trapper. The trapping grounds of the United States and Canada lie either north or west of the great lakes, and are solely peopled by Indians and a few white trappers. The great bulk of furs are taken by Indians, but there are some white men engaged in the business whose camps are often passed by the engineers and surveyors who are the pioneers of settlement into the vast forests and prairies of the great Northwest. Probably few others have an opportunity to visit the camps of the trappers, buried as they mostly are from twenty to a hundred miles away from a regular habitation. The trapper chooses a location for his camp, which is his base of operations, and from which he travels out in all directions, not so far, however, as to

Fig. 3.—MINK TRAP.

York steel-spring trap, and often a hundred of these are used by one trapper in a season. The old wooden trap or deadfall is fast going out of use. The steel trap is surer, and, saving time, enables the trapper to enlarge his operations. Thus situated, the trapper passes from October to March, exposed to all the storms and

Fig. 2.—MUSKRAT HOUSES.

Fig. 4.—INDIANS BRINGING IN FURS.

Fig. 5.—INDIANS AFTER SELLING THEIR FURS.

require him to be absent from home more than a few days at a time. In the center of his game he pitches his camp, which is often, if game is plentiful, a log-hut roofed with bark, which he will occupy two or three successive seasons, or

perils of a lonely life in the woods, and often without seeing a human face until he in the spring packs his furs to the nearest town or village for shipment to "York," when he may very probably have secured enough to return

other; a thong is fastened behind, which is held by the Indian, to hold back by when going down hill, and mounted on his snow-shoes the Indian starts on his long journey with his packs of furs. Generally the party consists of four or five, who

often encamp and hunt as they find occasion on their way. On their arrival at a post the trade occupies several days, as many "pow-wows" occur before it is finally concluded, when, with a few dollars' worth of articles, of which the greater part is whisky, they leave for their nearest camping place, having probably parted with one or two hundred dollars' worth of furs for the value of five or ten dollars. "Lo, the poor Indian!" At their camp, out comes the whisky, and no work is done until it is consumed and the effects slept off, when they return to their wigwams to be supported by their squaws until next trapping season.

The mink, otter, beaver, and muskrat are all trapped on the banks of streams, the bait for beaver being birch twigs, and that for otter and mink, fish. The muskrats, like the beavers, live in houses built of grass or rushes in the shallow parts of lakes or ponds, and colonies of many houses are generally found together. A beaver house is built of sticks covered with mud or earth, generally on the banks of their pond, and the entrance to these houses is below the surface of the water. The skins when stripped are carefully stretched on frames and dried. A piece of cedar board, two feet long and four inches wide or larger, is used to stretch mink, marten, and other skins. The beaver skin is split and stretched over a round hoop; the edges are sewn over the hoop to retain the shape until dry. Notwithstanding the seemingly irregular course of this business, it is permanently established, and several million dollars' worth of skins are taken yearly.

Walks and Talks on the Farm.—No. 99.

A farmer, formerly from Michigan, and now a resident of Henderson Co., Illinois, writes me a very interesting letter. He says: "I have been much interested in reading 'Walks and Talks' in the *Agriculturist*, and often feel that I would like to talk with such a farmer, and see how his farm looks, and how his stock is fed and cared for."

He would probably be disappointed. I have not a "show farm." I do things in a plain, ordinary way, using what little capital I have to improve the farm, and not to make a show. Any one who has plenty of money can put up a handsome house, erect a model barn, and have fences, gates, gravel walks, etc., all in perfect order. But, while no one likes to see a neat, handsome farm-standing better than I do, I have thought it best to first improve the land, and trust to the increased crops to enable me to put up new barns and "fix things up generally" by and by.

Hard as times have been for farmers the past season, I am not discouraged. We have done as well as the majority of those engaged in trade and manufactures. No one need expect to get rich suddenly by farming. If we get a living and our farms are steadily improving, we ought not to complain.

I do not know how my farm would look to my Illinois friend, but to me it looks better than when I bought it. There was not a field then that I could plow straight through in the spring without striking some parts where the water would stand in the furrow. In the summer these baked almost as hard as bricks. No one expected any corn on these "clay spots." All the cultivation expended on them was so much lost labor. By a little judicious draining these clay spots have disappeared, and are now the best and most productive parts of the farm.

Then again, the farm was full of weeds. They say "one year's seeding makes seven years weeding," and my farm had been seeded with weeds for thirty years. My chief object in cultivation has been to get these weed seeds to germinate, and then kill the plants. Nothing pleases me better than to see millions of little weed plants spring up on a summer-fallow when I can get a chance at them. Most of my neighbors take great pains to prevent weeds from growing. I want to make them grow, and then kill them. You can not kill them before they grow. After I have killed a hundred million weeds I believe there are a hundred million fewer weeds in the field. Very few people believe this. And no wonder, for it certainly is a hard matter to make land clean. What I have done in killing weeds has cost me far more than what I have done in the way of under-draining. But it is encouraging to know that stirring the soil not only kills the weeds but develops the plant-food lying latent in the soil, and thus greatly enriches the land. I have found this pre-eminently true in my own case. My land is getting cleaner and richer.

As to how my "stock is fed and cared for," I have only to say that I have not yet gone into any elaborate processes of cutting and steaming food. I have done something in the way of cutting up corn-stalks, straw, and hay by horse-power, but do not think it pays in *my case*. If my buildings were well adapted for the purpose I should certainly chaff all my fodder.

I have one of Prindle's steamers, and have occasionally steamed some damaged hay. The cows and sheep ate it greedily. Without steaming, they would not have eaten it unless compelled by hunger. In such a case, steaming is certainly profitable.

This winter I feed my farm horses on pea and oat straw, cut into chaff, and mixed with a little corn-meal; and they are fed nothing but straw in the racks. Towards spring I shall feed hay.

My Merino sheep are fed corn-stalks and straw, with half a pound of corn per day. This keeps them in extra condition—an essential point when Merino ewes are crossed with a large Cotswold ram. They need extra food and strength to nourish such large lambs. I have had a grade Cotswold lamb, from a common Merino ewe, that weighed 12 lbs. the day it was born. Of course the mother of such a lamb needs something more than straw.

I have now (Jan. 17th) over thirty lambs from Merino ewes. We give the ewes pea and oat-straw and one pound of bran per day, and three or four pounds of mangolds. The lambs are allowed all the bran and corn-meal or oats they will eat, placed in a little trough where the ewes can not get at it. These lambs are intended for the butcher. Whether it will pay or not depends on proximity to market, and on one's ability to find the right purchasers. My *forte* does not lie in this direction. Last year I should have done far better to have kept my lambs, and sold them fat after shearing this spring.

The Cotswold ewes, so far this winter, have run out nearly every day on the rape field. The exercise, the fresh air, and the green food seem to agree with them. They are in high health and capital condition, and I hope for a good crop of lambs. I do not give them a particle of grain or oil-cake, nothing but corn-stalks, pea-straw, and bran. My stalks and pea-straw will be used up in a few days, and then we shall feed wheat straw and clover hay.

This "pea and oat straw" has been a great help to me. You may recollect that I sowed

ten acres of wheat stubble, on which the clover had failed, with three bushels of peas and one bushel of oats per acre. The land was well manured, and I had a splendid crop, getting *eighty loads* from the ten acres. It was well cured, thrashed at the time it was drawn in, or a few days later, and proves most excellent fodder. I have never raised a crop that gave me so much satisfaction, and I propose to grow it more extensively this year.

I feed my cows principally on corn-stalks, as long as they last, and afterwards hay. I allow them two quarts of corn-meal each per day, wet with cold water. We have been making butter all winter. I have two or three farrow cows that I am fattening and milking at the same time.

You see that my methods of feeding are not at all "scientific." I have no doubt that soiling in summer and steaming in winter would enable me to keep a good deal more stock. But I have always contended that it is the food and not the stock that makes the manure. Tell me how much and what kind of wood you burn, and I can tell you pretty closely how much your ashes are worth. I will not ask how many and what kind of *stoves* you use. Tell me how much and what kind of food you have to feed out, and I can tell you how much your manure is worth. I will not ask how many and what kinds of animals you feed it to, or whether you cook it or feed it raw. The only question of any practical importance is whether you save your manure after you have got it.

I feed my breeding sows through the winter on bran soaked for twelve hours in water. They run out every day in the barn-yard, and pick up whatever they can find. I notice them frequently chewing the joints of corn-stalks. They will eat chaffed clover hay soaked for twenty-four hours in water and mixed with a little corn-meal. Corn at present prices is unquestionably the cheapest food for pigs. But in my case I want something to render it more bulky. I want to let the sows have enough to fill their stomachs. Corn alone is too nutritious for breeding sows that have got their full growth. Early cut clover hay, chaffed quite short, and soaked for twelve hours and then steamed and mixed with corn-meal, is readily eaten. But it is a good deal of work, and on the whole I prefer to buy bran. The manure from the bran is worth 75 per cent of the cost.

For the little pigs I cook corn-meal. My men prefer to boil the water in a kettle, and then stir in the meal and boil until it is thoroughly cooked, rather than to use the steamer. We mix more or less bran with the gruel, according to the age and condition of the pigs. Those pigs which are inclined to fatten rather than grow are put into a pen by themselves and fed more bran. The young, growing pigs are allowed cut mangolds, fed raw. They are very fond of them. For fattening pigs, the mangolds ought to be cooked and mashed up with corn-meal.

My Illinois correspondent says he thinks if I would adopt some of their Western customs and implements I could raise corn much cheaper than now. "We raise more corn than you do," he says, "but raise it cheaper because we have better tools to do it with and different modes of doing it, and not because we raise so much more to the acre." He has raised corn in Western New York, and thinks we can adopt the Western method. "I would plow the ground," he says, "with a good steel plow, and fit it thoroughly either before or after planting, ac-

ording to the time and condition of the land. If the ground was very foul, I would mark it off in rows forty inches apart with a two-horse marker. Then plant in hills with a check-planter. But if the land was clean I would drill in the corn; as I believe more corn can be raised per acre in drills than in hills, provided it is well worked and kept clean. If the ground is rich and in good heart, it will raise a stalk of eight-rowed corn every seven inches by forty inches. After the field was planted, if not done before, I would thoroughly harrow the ground, and if I had time I would do it in any case and also roll it. This may be done before the plants are up, or when they are two inches high, and until they get too large. Then I would plow with the best two-horse plow to be had, with which I could keep the ground clear of weeds until it was so large that the corn would break down—and no ordinary weeds would grow after that. I think you have a drill, but I doubt your having a good corn plow, as they have not been introduced in your State."

I have a check corn-planter—and a very good one of its kind—that plants two rows at a time. But I have never yet seen a check-planter that drops the corn so accurately that the rows are perfectly straight, both ways; and for this reason I plant in drills and cultivate only one way. I have a two-horse corn cultivator, which I suppose is the same thing as a two-horse corn-plow. But I have no man skillful enough to run it as close to the corn as we run our one-horse cultivators. It can be used to advantage, in connection with a single cultivator, for stirring the ground in the center of the rows, and then use the one-horse cultivator for killing the weeds close to the plants. If of the right sort, and the rows are absolutely straight, a cultivator may be run within one inch of the plants, and thus leave little for the hand-hoes to do.

Doubtless great improvements are yet to be made in our methods of planting and cultivating corn, and more especially in our modes of harvesting and husking it; but it seems to me that our chief aim at present should be to so enrich the land that we may have a reasonable prospect of getting 80 bushels of shelled corn per acre. In other words, we must aim rather to reduce the labor per bushel than the labor per acre. And this is true of all our crops.

People who let out and those who work farms "on shares" seldom understand this matter clearly. Last year I know a farmer who let out a field of good land that had been in corn the previous year to a man to sow it to barley, and afterwards to wheat on "the halves." Another part of the farm was taken by a man to plant corn and potatoes on similar terms, and another man put in several acres of cabbage, beets, carrots, and onions on halves. It never seemed to occur to either of them that the conditions were unequal. The expense of digging and harvesting the potato crop alone was greater than the whole cost of the barley crop; while, after the barley was off, the land was plowed once, harrowed, and sowed to winter wheat; and nothing more has to be done to it until next harvest. With the garden crops the difference is even still more striking. The labor expended on one acre of onions or carrots would put in and harvest a ten-acre field of barley. If the tenant gets pay for his labor, the landlord would get say \$5 an acre for his barley land and \$50 for his carrot and onion land. I am pretty sure the tenants did not see the matter in this light, nor the farmer either.

Crops which require a large amount of labor

can only be grown on very rich land. Our successful market-gardeners, seed-growers, and nurserymen understand this matter. They must get great crops or they can not pay their labor bill. And the principle is applicable to ordinary farm crops. Some of them require much more labor than others, and should never be grown unless the land is capable of producing a maximum yield per acre, or a close approximation to it. As a rule, the least-paying crops are those which require the least labor per acre. Farmers are afraid to expend the labor. They are wise in this, unless all the conditions are favorable. But when they have land in a high state of cultivation—drained, clean, mellow, and rich—it would usually pay them well to grow crops which require the most labor.

And it should never be forgotten that, as compared with nearly all other countries, our labor is expensive. No matter how cheap our land may be, we can not afford to waste our labor. It is too costly. If men would work for nothing, and board themselves, there are localities where we could perhaps afford to keep sheep that shear two pounds of wool a year; or cows that make 75 lbs. of butter. We might make a profit out of a wheat crop of 8 bushels per acre, or a corn crop of 15 bushels, or a potato crop of 50 bushels. But it can not be done with labor costing from \$1.25 to \$2.50 per day. And I do not believe labor will cost much less in our day. The only thing we can do is to employ it to the best advantage. Machinery will help us to some extent, but I can see no real escape from our difficulties in this matter except to raise larger crops per acre.

I see nothing in the Western plan of raising corn, as described by my correspondent, that differs essentially from my own practice. I plant with a drill, and do nearly all the work of cleaning the crop with the cultivator. The reason the Western farmers can raise corn cheaper than we can is because their land is cheaper, richer, cleaner, and more easily worked. But I imagine that even they find very little profit in growing a crop of corn that does not average 30 bushels per acre. They, like us, must aim to grow larger crops.

In ordinary farming, "larger crops per acre" means fewer acres planted or sown with grain. It means more summer fallow, more grass, clover, peas, mustard, colesseed, roots, and other crops that are consumed on the farm. It means more thorough cultivation. It means clean and rich land. It means husbanding the ammonia and nitric acid, which is brought to the soil, as well as that which is developed from the soil, or which the soil attracts from the atmosphere, and using it to grow a crop every second, third, or fourth year, instead of every year. If a piece of land will grow 25 bushels of corn every year, we should aim to so manage it, that it will grow 50 every other year, or 75 every third year, or, if the climate is capable of doing it, of raising 100 bushels per acre every fourth year.

Theoretically this can be done, and in one of Mr. Lawes's experiments he did it practically in the case of a summer-fallow for wheat, the one crop in two years giving a little more than two crops sown in succession. But on sandy land we should probably lose a portion of the liberated plant-food, unless we grew a crop of some kind every year. And the matter organized in the renovating crop could not be rendered completely available for the next crop. *In the end*, however, we ought to be able to get it with little or no loss. How best to accomplish this result, is one of the most interesting and import-

ant fields for scientific investigation and practical experiment. We know enough, however, to be sure that there is a great advantage in waiting until there is a sufficient accumulation of available plant-food in the soil, to produce a large yield before sowing a crop that requires much labor.

The rape or colesseed alluded to is a new crop with me. I sowed six or seven acres of it at the same time we sowed the mustard, say in July. It is a very common crop on the fen lands in England, and on other soils that are not adapted to turnips. It is a winter crop, and is fed off on the land by sheep. The severest frost does not hurt it. My Cotswold sheep are kept in the yards and sheds at night, but in the morning, after feeding, we open the doors, and, except during a severe storm, the sheep march off to the field of rape and come back again of their own accord in the afternoon, with their stomachs full of succulent food. The Deacen seems much interested in the experiment. The field is near his house, and he says it is curious to see the sheep march to the field so regularly every day, in single file, and then disperse over the field, and pick up the green leaves or stalks from under the snow. After they have got their fill, a few of them will start on their homeward journey, but will wait at the gate (which is left open) until the whole flock is ready to return, when they slowly and in a dignified manner march home in single file along the beaten track.

The crop is now (January 24th) nearly all eaten up, and the winter has been so remarkably free from heavy snows, that I have had no opportunity of judging of the value of the crop for ordinary seasons. At any rate, however, I propose to sow a few acres every year, and run my chance of feeding it off at times when the snow is not too deep for the sheep to walk about the field. Any green crop that will stand our winters is certainly worth trying. It has one great advantage over the turnip, in our climate—it costs very little to grow it, and *nothing* to gather it and feed it out. The only expense about the crop is in preparing the ground. The soil must be made as fine and mellow as for turnips. The plant closely resembles the Swede turnip or ruta-baga, except that it has no bulb. It is grown for its leaves and stalk. Several farmers who were looking at my farm last fall, thought it was a crop of ruta-bagas, sown very thick, and not hoed—and they were disposed to criticise my method of turnip-growing!

We are feeding our cows nothing but corn-stalks and a little corn-meal; no carrots, no mangolds, no steamed food, and no blooded cows, and yet the butter is as yellow, firm, and fine-flavored as one can desire. We have no trouble about the "butter not coming." It came yesterday in twenty minutes. The farrow cows that I am fattening and milking at the same time, give the richest of milk, and I suppose the yellow butter is due to the corn-meal. It seems to me that if I lived at the West, where corn is cheap, I should engage in winter butter-making. As I understand the matter, good winter butter would sell readily and at good prices in the cities.

How to make Concrete Buildings.

A very substantial and cheap building may be put up with concrete, which is a mixture of hydraulic lime, sand, and coarse gravel or broken stone. Common lime may be used for common farm buildings, or even for dwellings, but as it is not nearly so durable when exposed

to the weather, hydraulic lime should be used for a good building. It has also been found that broken limestone is better than any other stone to use in concretes, a more perfect adhesion being formed between the particles. The proper proportions to be mixed are 20 parts of hydraulic lime mixed to a paste with water, 30 parts of washed sand, and 50 parts of broken stone or gravel. The chips from limestone quarries make the very best material for concrete. No more should be mixed at once than can be used in a day, as it hardens very rapidly. To proceed to build, the foundation must be made, and the courses laid on it in a box or mold, shown in the engraving. This mold is laid in place; the cement already mixed is shoveled in and beaten down with a rammer even with the top of the mold, which is then moved into place for laying the next block. The mold, being open at one end, laps a few inches over the end of the first block, which holds it in place and

though so simple, of great use in this way. The cross-bars (two inches square) should be let

IMPROVED HOG-TROUGH.

down flush with the edge of the trough, when a teupenny nail at each end will hold it.

The Cost of Poor Stock.

Probably few farmers think of what it costs to keep a poor cow or a land-pike hog. They readily understand that a good cow, or a hog that will dress 200 lbs. at ten months old, is profitable stock to keep, but the fact that this gain is really the amount of loss on the poor stock, is rarely considered. If a cow yields 200 lbs. of butter in a year, which brings \$60, and another yields 75 lbs., which brings \$22.50, the loss on the poor cow is just \$37.50. The fact is, it would be a more profitable operation to give her away than to keep her, for she does not pay for her feed. The dairy business of this country is not on a satisfactory footing by any means, and solely on account of the multitude of poor cows, which are kept year after year. This is a matter which should be looked after by the County Agricultural Societies. Every one of these associations should introduce improved stock, by means of thorough-

A Filter for Cisterns.
The engraving here given represents a simple filter which should be attached to every cistern. Generally, the water from a roof has but little solid matter in suspension, but has acquired a dark color and strong taste from the smoke-stained roof, which if of shingles will give in addition a woody flavor. No filtering material but fresh charcoal will perfectly remove this color and taste. The water therefore must be made to pass through a quantity of it. This is best done by affixing at the side of the cistern a box of hemlock, oak, or chestnut planks, or of bricks, in which the pipe discharges through a **L** at the bottom into a layer of coarse gravel. Above the gravel is a layer of coarsely-powdered charcoal, and above that another layer of gravel which holds the charcoal in its place. Above the upper layer of gravel a piece of slate, perforated with a number of holes, may be placed, which will keep these strata in their proper position. The discharge-pipe is curved

MANNER OF CONSTRUCTING CONCRETE BUILDINGS.

permits a close joint to be made. When the first round is laid, two small sticks are laid across the blocks, and the mold rests on them until filled. These sticks, when the building is completed, are sawn off close to the wall, and if it is desired to nail anything to the wall they will furnish a hold for the nails. As the walls are carried up, the door and window frames are laid in their places. This process is so simple that any intelligent mason is competent to carry it out. The important point is to get the materials of the right sort and mix them properly. The size of the blocks may be as desired, and as the material is very strong and sets very quickly, eight to twelve inches is sufficient thickness for a wall of any ordinary dwelling-house. When common lime is used instead of hydraulic lime, more time must be given for the concrete to set.

AN IMPROVEMENT IN HOG-TROUGHS.—

While we can not cure the propensity of a hog to be hoggish, we can curb it somewhat. The trough here engraved will prevent the strongest animal from pushing his fellows away from the trough, and robbing them of their share. When a little one gets his nose between the cross-bars it is a difficult thing for his big brother to dislodge him, and while he is trying to do it another little brother on the other side of him is busy appropriating all he can get. We have used these troughs in our pens, and found them,

CISTERN WITH FILTER ATTACHED.

upward, which prevents the current from washing any sand or gravel into the cistern. This filter can be taken up at any time and be cleansed and replaced.

Churning by Means of a Weight.

“S. L. F.,” Rock Bluffs, Nebraska, asks us for a churn power to be moved by a weight. We give a cut of one made by us some years ago, which worked a small churn very well, but which was discarded as the work became too heavy for it. It will churn very well in a dairy of five or six cows, but for double that number requires a larger weight and heavier machinery, besides a regulator, either in the shape of a pendulum or a balance-wheel with an escapement. Without this, when the cream becomes thick, the weight must be increased and must be changed again as the work becomes easier. On this account we could not recommend it except for a small dairy, when it may be made a useful help to lighten the often tedious labor of churning which falls on the housekeeper.

The machine consists of a frame which supports the barrel on which the cord is wound and the clock-work which transfers and increases the motion. This barrel is turned by a crank, and moves on an interior axle, and carries at one end a ratchet-wheel. The interior axle carries a ratchet, which engages with this wheel as soon as the crank is released, and thus communicates the motion of the descending weight to the machinery. By a system of cog-wheels

bred male animals, into their localities. It is a good work to elevate the ideas of farmers and to foster a taste for improvements, but to the great majority of their clients the possession of such stock, or the use of it, is quite unattainable, on account of want of the necessary means. By making this a special branch of their operations, the usefulness of these societies would be much increased, and their importance greatly enhanced.

FARM GATE.—“I. M. B.,” Glen Brook, Del.,

FARM GATE THAT WILL NOT SAG.

sends a sketch of an improved farm gate, from which we make an engraving. The improvement consists in the attachment of the panel and brace, seen at *a* in the cut, to the gate-post, by which the gate is prevented from sagging. This is a simple contrivance, and though we have not seen it tested the plan seems very feasible and useful. It is necessary to pin the bars of the panel and the brace into the mortises of the post, at *b*, very firmly, as the strain comes altogether on to them.

the motion is increased until the crank-wheel to which the dasher of the churn is connected makes a hundred revolutions per minute. The dasher of course makes the same number of strokes. The motion depends on the weight attached to the cord, and may be lessened or increased by adding to or taking from that. About twenty-five to thirty pounds will give the requisite motion for a small churning. Some little

CHURNING BY WEIGHT-POWER.

experience is needed in this, but once learned it is easily kept regular. To get a hundred revolutions of the crank-wheel a motion of the weight of two feet per minute is needed, so that if the weight is suspended twenty feet above ground it must be wound up every few minutes. With an increased weight and a regulator, heavier work may be performed. There is no patent on this.

Where can Artesian Wells be made?

Several inquiries have been made in regard to Artesian wells—their cost, character, and the nature of the ground in which they may be sunk. As a reply to all these inquiries we have prepared the illustration here given, which will make plain the nature and mode of operation of these wells. In the great Western plains, as well as on some of the more central prairies, Artesian wells will be found, when practicable, of inestimable value. Not depending at all on the character of the surface, few regions of country

SECTION OF ARTESIAN WELL.

are so barren or arid but water in abundance may possibly be procured from deep-buried underground streams. Such wells have been sunk in the hot, arid deserts of Africa, and water has been brought to the surface and has rendered them habitable. The engraving represents the surface of a tract of country of indefinite extent—it may be ten, fifty, or hundreds of miles without in any way changing the principle on which these wells operate. Several distinct strata of

rock or earth are here represented. The depression in the surface of the highest ground, marked *R*, is supposed to represent the bed of a river, which lies on sandstone or limestone rock or gravel or any other porous material. Beneath this stratum and above it are others of impervious material, such as rock or clay, through which water can not pass. This bed of porous rock or earth is depressed into a valley, and is covered with beds of sand, clay, gravel, or rock, as the case may be, represented by the letters *a, b, c, d*. Thus it will be seen that the water escaping from the river bed or by natural rain-fall into this porous bed will follow it along its course, filling all its interstices, until it can escape in the shape of springs at some natural outlet, wherever that may be. But suppose wells are sunk at the spots marked *W, W*, as soon as they reach the porous stratum through which the water is passing the stream is tapped, and it rises to the surface, and as the surface is lower than the bed of the river or the ground whence the supply is first received, it overflows, or if confined may be carried up in pipes to a height equal to that of the original source. If the source furnishes a sufficient supply, an unlimited number of wells may be sunk

wherever they can reach this porous stratum, and the region capable of furnishing water in this way will be exactly equal in extent to that of the water-filled stratum beneath. Thus, there is needed before such wells can be sunk successfully the following conditions—viz.: Two impervious beds of rock or clay, inclosing between them a bed of gravel, sand, or rock containing pores or fissures, as sandstone or limestone, and a source superior in height to the location of the well. Sometimes also there are beds of gravel or sand above the water through which it would escape unless the well be tubed, but as wells are necessarily tubed, excepting when passing through rock, little difficulty occurs on this account.

The fine Artesian well at Chicago, which pours forth a continuous and very large amount of water, is supposed to derive its supply from the Rock River, over a hundred miles distant, the water passing through a bed of limestone containing extensive fissures or caverns. The town of Fond du Lac, in Wisconsin, called the Fountain City from its numerous flowing wells, also derives its supply of water from a bed of fissured limestone, and very probably from the same river, and in such a well-marked case as this, if the source is really the same, the whole country between these two cities could be depended on as a successful field for the sinking of wells. It will be thus seen that some acquaintance with the geography and geology of a country is necessary before it can be predicted that wells may be sunk with success. In the absence of any such knowledge, large amounts of money have been spent in sinking for water without success, both in the United States and in foreign countries. With proper tools and experience in the work, the cost of these wells

is very moderate—from one to three dollars per foot, as the nature of the earth or rock may cause the sinking to be easy or difficult.

It is probable that this very important question for the inhabitants of the Western plains will soon be completely solved, as Artesian wells are being sunk in many places by the various railroad companies, and a few experiments successfully made will locate the bounds of the water-bearing stratum of rock or gravel so that other parties may bore with some amount of certainty of procuring water.

A Farm Stable.

We present herewith illustrations of a farm

Fig. 1.—PERSPECTIVE VIEW OF BARN.

stable recently built on Dr. C. F. Heyward's farm at Newport, R. I., by our Ogden Farm correspondent, who has charge of the improvement of the estate.

It has stalls for twenty cows, four oxen, and two horses, and will stow about ten tons of hay in the bays, and, in an emergency, five more on the thrashing floor. It is intended to keep the main store of hay in a hay-barn already standing and in Dutch hay covers. On this place, there being a large amount of pasture land, it is not intended to "soil" the stock, and the object has been only to furnish comfortable quarters for the cattle, where they may be conveniently fed and milked with the least expense possible. Everything is built in the plainest manner, and as cheaply as permanent usefulness would

Fig. 2.—SECTION OF BARN.

allow. The cost of the building, including cellar, foundation wall, etc., has been about \$1,250.

The building stands sideways against a gentle slope, the fall being about five feet in the width of the barn (36 feet), a very little artificial grading having brought the cattle floor on one side and the manure cellar on the other, to the ground level. Under the cattle and horse stalls there is one large cellar for manure, with two wide entrances for carts. Under the thrashing

floor there is a root-cellar, and under the principal hay-bay a storage room for plows, harrows, etc. The general arrangement of the cattle floor and hay-room is shown in fig. 3. The ox and horse stables open into a small yard, separated from the cow-yard. The animals have access to the latter through the doors at the end of the building. The feeding passage is not wide enough for a cart, but it is wide

incloses the manger on this side. Eighteen inches in front of it is a board four inches high, nailed to beveled blocks at intervals of three or four feet. These blocks support a shutter, which may be turned back against them for putting in cut feed or meal; or turned up straight and closed with a button against a three-by-four timber which supports the hay-rack. This rack consists of strips of Georgia pine 2½ in. wide and

and she has not the "black points" of which we read so much in the agricultural papers and see so little in the best Jersey cows. She is of "the real old Tainter kind." If handsome is that handsome does, then "Theresa" is a beauty of the first order. She is eleven years old, and had her last calf Mareh 18th, 1871, and is to calve again Mareh 16th, 1872.

The account given below is made up to the last day of 1871—275 days from April 1st (13 days after calving). The family she supplies is a large one, and aside from the milk required for other purposes, much fresh milk is used in cooking. Mr. Perry estimates the value of the milk used in his family at \$50—say 17½ cents per day. Fresh milk and cream were sold to neighbors for \$12. Probably these items represent nearly 1,000 quarts of fresh milk that was not used for butter-making. In spite of this, there were made from this cow alone in the 275 days 301¾ lbs. of as fine butter as I have ever seen, which is sold to a gentleman in Newport for 75 cents per pound. The value of the butter at this price is \$226.31. Value of skimmed milk fed to pigs and poultry, \$20.

The product of butter averaged for May, her best month, 9¼ per week, a yield which many a common cow could beat under the same circumstances; but then she averaged about 7¾ lbs. per week for the whole 39 weeks—a feat that, so far as my information goes, has rarely been equaled.

The regularity of her production is surprising, especially when we remember that she was with calf for more than two thirds of the time, and that in December she was milked but once a day, in the hope of drying her off. She produced in April 38¾ lbs.; May, 44 lbs.; June, (all the milk being sold for three days), 32¾ lbs.; July, 34¼ lbs.; August, 34¾ lbs.; Sept., 35 lbs.; October, 33½ lbs.; November, 28¼ lbs.; December (milked but once a day), 20½ lbs. A better illustration of what is meant when it is said that a good Jersey is the best family cow I do not know where to find.

The total value of the produce of the 288 days after calving, supposing all the butter to have been sold (as it might have been) for 75 cents per pound, and including \$35 for which the calf was sold, was \$343.31—an average of \$1.19 per day. Allowing about \$20 for the remaining 2½ months, she will have produced one dollar per day the year round.

Caponizing.

The object of caponizing is to improve the quality and increase the quantity of the flesh of fowls. A capon will outgrow a cock of the same age, just as an ox will exceed a bull in weight, and for the same reasons, which are that castration makes an animal less restless and quarrelsome, and less of the nutriment it digests is diverted from flesh-forming.

The operation is not difficult, and is so quickly performed after a little practice, that operators earn high wages by caponizing cockerels at \$5 or \$6 per hundred. There are sets of instruments for the purpose, which are advertised by the "Poultry World" in our columns, and we believe are sold by several other parties. To save expense an ordinary pocket-knife and tweezers can be used instead of those made especially for the business, and the remaining instruments, which are illustrated in fig. 1, may be made to order by any jobber in metals. *a* is a tube with the end (*b*) flattened to an oval about one third of an inch in its greatest diameter.

Fig. 3.—PLAN OF FLOOR OF BARN.

enough for a team alone when unhitched from a loaded cart or wagon left standing upon the thrashing floor.

The features of this stable to which we especially wish to call attention, are the arched floor and the arrangements for tying and feeding. The main timbers supporting the floor are 28 ft. long, running across the building. There are two of them, one about one third the distance from either end of the cow-room. These are supported each by two 10-inch chestnut timbers, resting on foundation stones, and standing under the lines of the upright posts to which the cattle are tied. Before these were put in, and after the outside of the building was finished, the cross-timbers were screwed up in the middle as much as they would bear, having a "crown" of about six inches, giving an arch-like form to the floor, the middle of the feeding passage being six inches higher than the outside of the passage behind the cattle. The floor-joists were then notched in to these timbers and to the end sills to a uniform depth as far back as the rear of the floor on which the cattle stand. At this point a drop of four inches is given by spiking a scantling against the floor-joist. From this point the passage floor rises to the side of the building. This gives good drainage, great simplicity, and great strength. The construction of this floor and of the feeding apparatus is shown in fig. 2, the details being more clearly set forth in fig. 4.

There are no partitions between the cattle, save the bars which separate the oxen from the cows. At the left side of each cow's neck, on one side of the barn and at the right side on the other, stands a turned post of chestnut, three inches in diameter at the bottom and two inches at the top. To these the cows are tied, by ropes arranged with a running loop fastened around the posts, and with buttons and eyes to fasten around their necks. A board six inches high

one inch thick. In front of it there is a shutter 3 ft. wide, hinged at the bottom, which may be turned flat against the slats when hay is not being fed, or may be dropped back the length of the chain which supports it when necessary. Fig. 1 is a perspective view of this barn from the down-hill side.

The Story of a Good Cow.

BY GEORGE E. WARING, JR., OF OGDEN FARM.

She is a Jersey, of course—not that there are not good cows of other breeds, but then I am a Jersey man, and my interest in this breed leads me to learn more of the good qualities of this family than of others. Her sire and dam were imported from the island of Jersey by Col. Goddard, of Providence; and her name is "Theresa." She belongs to Mr. E. B. Perry, of Providence, and I had heard enough of her to induce me to pay her a visit. She lives on a little farm about two miles north of the city,

Fig. 4.—SECTION OF STALL.

and has all the care that it is possible for a man who is fond of her to give.

I have seen handsomer cows—indeed, she has few of what are known as "fancy points," being large, raw-boned, crumple-horned, and big-bellied. She is far from being solid-colored,

Through this tube is passed the horse-hair loop (*c*), *d* is a steel-rod with a spoon (*e*) at one end and a pointed hook (*f*) at the other, and *g* is a steel splint 6 inches long with a broad, flat hook (*h*) attached to each end by twine, three quarters of an inch slack being allowed.

The best way to hold the subject is to place a board, 14×24 in., in the lap of the operator, upon which the fowl is to rest upon its right side, while an assistant grasps its wings with one hand and its feet with the other, as represented in fig. 2.

Remove the feathers from a spot as large as a watch at the point *i*. Next pull the skin backwards, so that it may slip forward again after the operation is completed, and with the knife make an incision an inch and a half long, parallel with the last two ribs and between them, until the intestines are visible, taking care to not injure the latter. Now separate the ribs by attaching one of the hooks (*h*, *h*, fig. 1) to each, and allowing the ends of the splint to spread, as they will do when let go. The intestines may be

to the organs removed. The best age for cockerels to be operated upon is two months. In order that the intestines may not be distended, prepare the bird by shutting it up without food or drink for thirty-six hours. Capons continue to grow for a long time, and they should be kept until twenty months old, in order to gain the full advantages of the operation.

The Milk-Mirror in Cows.

A correspondent in Andover, Mass., asks us to explain the meaning of the term "milk-mirror." This is used to describe that portion of the animal's hide on and in the vicinity of the udder, on which the hair grows in the opposite direction from that of the adjoining parts. The line of demarcation between the two is generally quite distinct, and constitutes what is often called a "quirl," the up-growing and down-growing hair meeting sometimes quite abruptly. More often the change of direction is more

with advantage, but we are constantly applying the general principle in the purchase and sale of animals in our own herd. Although the system, applied with our imperfect knowledge, is not absolutely infallible, we would no more think of buying a cow with a very defective escutcheon, or of selling one (unless for an extra price) with a perfect escutcheon, no matter what their other qualities may be, than we would think of breeding from a second-class bull to save a few dollars in the cost of service.

We can not here give the space necessary for even a rough sketch of this method, but a translation of the original work is published at this office, which will be mailed, post-paid, on receipt of the price, 75 cents.

Cooking Food for Stock.

We would be glad to receive statements of the *practical results* of experiments in feeding stock—especially horned cattle—with steamed food. We want facts, *not opinions*. Most of the literature of this subject is made up of the notions of the writers, and of their conclusions, based on their own experience; and these notions and conclusions are hardly worth the paper they are written on, except to the man who forms them and others situated like him.

The hidden character of the processes of animal life, and the degree to which attending circumstances affect the result of any experiment in feeding, make opinions that are based on single experiments exceedingly untrustworthy. The most skillful physiologist would be uncertain as to the true bearing of any effect that he might observe, and surely even the most intelligent farmer is incompetent to give us a reliable theory of the experiment that has, in his case, brought a certain result. All he can do, that will be worthy of the world's attention, is to state the result, and so much as he can of the attending circumstances—that is, the kind of shelter, the amount of exercise, the temperature of the water, the breed, age, and condition of the animals fed, and all else that could in his opinion affect the result. Here he ought to stop, and allow the public to form its own conclusions as to the "why and wherefore," and as to the general applicability of the truths that a majority of the instances reported seem to point out. Should the reports that we ask point very generally in one direction or the other, we might venture to express an opinion as to their force, but we doubt whether the experience of the country is yet sufficient to justify a decision as to the propriety or impropriety of steaming under all circumstances.

We would especially suggest that our correspondents leave out of the consideration the question whether steaming fodder seems to them more or less "natural" than the common practice. Left to a state of nature, our domestic animals would soon cease to exist in a useful condition. They are the product of artificial treatment, and the real question is not what treatment is the most natural, but what artificial deviation from natural conditions promises still further artificial advantages.

Our Native Bats.

When a bat enters a dwelling room of an evening, flitting noiselessly about and searching for some avenue of escape, the whole household is aroused, and with brooms, towels, and other weapons the little creature is beaten to death, unless by some fortunate chance it escapes

Fig. 1.—INSTRUMENTS FOR CAPONIZING.

pushed away with a tea-spoon handle or other flat, smooth instrument, and when the testicles are found (attached to the back) the tissue which covers them must be held by the tweezers and torn open with the pointed hook (*f*). Next pass the horse-hair loop around one testicle, which cut off by pulling upon the ends of the horse-hair, so as to communicate a *sawing* mo-

Fig. 2.—HOLDING THE FOWL.

tion to the loop. The spoon (*e*) is now introduced to scoop out from the cavity the severed organ and the blood, when the operation is repeated upon the other testicle, the incision is closed (no sewing being necessary), the skin is allowed to resume its place, and the feathers which were removed are stuck on the outside and left to adhere by means of the blood, forming the only bandage necessary.

There need be no more than 6 or 8 per cent of the birds killed even by an indifferent operator, and as those die by bleeding to death they may be eaten as if they had been butchered in the regular way. To avoid bleeding take care to not rupture the large blood-vessels attached

gradual, but it is always clear enough to be seen at a glance, especially in summer, when the coat is clean and the hair is short. The significance of the mirror was discovered by a French cow-herd, named Guénon, who classified the different forms of mirrors, and established a system by which he claimed that he could tell, from an examination of the mirror alone, how much milk any individual cow would give (supposing her to be of average size and in good health), and what would be the quality of the milk, and how rapidly she would dry off after becoming impregnated again. This discovery was subjected to a very critical examination in 1837, by a committee of the Agricultural Society of Bordeaux. About sixty animals were submitted to Guénon's inspection, and his statement concerning them was recorded and afterwards compared with the statements of the owners of the cattle. They were found to agree in every instance. Other trials, in different parts of France, were equally successful, and high honors have been awarded to Mons. Guénon for his discovery. In other countries the success of the system has been no less marked. That it is a carefully arranged system is shown by the fact that others have attained an equal efficiency with its discoverer in applying its principles to practice, and although the minute classification that has been given by the discoverer may, perhaps, be questioned, there is no longer the least doubt of the fundamental soundness of the idea. In America, as well as in all countries of Europe, it is fast becoming a recognized standard by which to determine the milking qualities of cows, and to foretell the promise of calves and the probable breeding value of bulls.

We are not ourselves sufficiently familiar with the minutest details of Guénon's classification to determine how closely they may be followed

[COPYRIGHT SECURED.]

NORTH AMERICAN BATS.—Drawn by Herrick, and Engraved for the American Agriculturist.

through the open window. We have seen this bat-hunt many a time, and have strongly protested against it, for two reasons: The bat is perfectly harmless, and he is greatly useful. The structure of the bat is so remarkable that it is worthy of a moment's consideration. It belongs to the family of *Cheiroptera*, which is as much as to say, hand-winged animals. The bats are true mammals, producing their young alive and suckling them, but they differ from other mammals in being able to fly. Some Squirrels and Lemurs are called flying, but they are only able to make prolonged leaps by means of an extension of skin between their fore and hind legs. The bats, however, have real wings. Their fingers are much elongated, and by means of a membrane extended from the neck across the arm, fore-arm, and fingers, they can fly with all the rapidity, grace of movement, and sudden change of direction that birds are capable of. The fore-legs, being designed for flight, the animal makes but a poor figure at walking, and it is only able to shuffle about in a rather ludicrous manner. The eyes of bats are very small, and this has led to the saying, "As blind as a bat,"

but being provided with very large ears and wings of great sensitiveness, they do not depend upon their eyes as much as other animals. Some cruel experiments made some years ago in Europe, proved that bats, the eyes of which had been destroyed, could fly about, without striking against any object. The bats are all nocturnal; they remain concealed during the day in caves, old buildings, holes of trees, or other hiding places, and only venture forth at night. In some places, if undisturbed, they accumulate in great numbers. The writer has visited more than one abandoned church in Mexico, where the bats were in such numbers as to form clouds when disturbed, and their droppings formed a deposit upon the floor of two or three feet in thickness. The bats are divided into the fruit-eating and the insect-eating groups. The fruit-eaters are all natives of the East Indies and tropical Africa. If they eat much fruit, it is gratifying to know that they are eaten in return, and are said to be a choice delicacy. The Vampires are insect-eaters, and belong to tropical America. They have curious leaf-like appendages to their noses, and the bad reputation of

sucking blood from man and other animals. This quality of the Vampires has been regarded as a superstition, but late testimony goes to show that they do at least bleed horses. Our North American bats have, however, no appendages to their noses nor stain upon their characters! They all belong to the genus *Vespertilio*, and number a half-dozen or more species. The engraving presents three of these. The upper one is the Hoary Bat, which is over four and a half inches long, and has a spread of wings of over fifteen inches. It is grayish above, with a fawn-colored band at the throat. The one at the right-hand is the Carolina Bat; this is nearly four inches long, spreads twelve inches, and is of a chestnut color. The Little Brown Bat is shown on the wing at the left of the engraving; this is olive-brown above, grayish beneath, and has a spread of nine inches. All our bats are insect-eaters, and when we see them flitting about, we may be sure that they are foraging for night-flying moths and beetles. Instead of destroying the bats, let us preserve them, for they are among the few wild quadrupeds that may be classed as the farmer's friends.

The Balloon-Vine or Heart-Seed.

Among the annuals the Balloon-vine commends itself by its delicacy and the curious character of its fruit, rather than by the showiness of its flowers. The plant is a low climber; in its wild state it runs along the ground and over low bushes, and in cultivation it should

The Balloon-vine stands in the same family with the Bladder-nut, Horse-Chestnut, etc.

The Matrimony-Vine.

In old gardens we sometimes meet with a shrub that was formerly more common than it is at present—the Matrimony-vine. It is the

feet. It is a rapid grower, and is frequently used in Europe to cover walls, the sides of buildings, etc. In some places in this country it has become partly naturalized, and as it throws up a great abundance of suckers it is difficult to eradicate where it is well established. The name Lycium is from Lycia, the native country of one of the species. A native spe-

BALLOON VINE.—(*Cardiospermum Halicacabum*.)

MATRIMONY VINE.—(*Lycium vulgare*.)

have some support about four feet high. The engraving gives a portion of a plant slightly less than the natural size. The leaves, which are thin in texture, are handsomely cut. The flowers are in axillary clusters, very small, and with the parts in fours. Each flower cluster bears hooked tendrils, by means of which the plant climbs. The fruit is a large bladderly capsule, with a single seed in each of its three cells. Each seed is marked (shown in an enlarged seed, *a*, in the engraving) by a heart-shaped spot (*arid*), which suggested the generic name *Cardiospermum*, or Heart-seed. When filled with its curious fruit, the Balloon-vine is an interesting plant, and is sure to be a favorite with the young people, who find much amusement in exploding the inflated pods. It is found growing wild in Florida and Texas, and is widely distributed throughout the warmer portions of the world. It is said that in the Moluccas the foliage is cooked and eaten as a vegetable. Like other tender annuals, it does better if started in a hot-bed. The full name of this little vine is *Cardiospermum Halicacabum*. The meaning of the generic name has already been given. The specific name is the Greek one for another plant, and applied to this one by Linnaeus, for what reason we are unable to say.

Lycium vulgare, though in most botanical works it is called *Lycium Barbarum*, a name which belongs to a different plant. Other common names are Bastard Jasmine, Barbary Box-thorn, and the Duke of Argyll's Tea-tree. The last name was given to it from the fact that a plant of this and one of the true Tea were sent to the Duke of Argyll, and the labels having become exchanged this shrub was cultivated for a while under the belief that it was the Tea-plant. As generally seen, the shrub presents a mass of long, pendent branches, bearing leaves of a grayish green color. The flowers are produced in the axils of the leaves in small clusters, each upon a stalk about an inch long. The corolla has five lobes, and is of a pale greenish purple color. The oval berries are orange-red when ripe, and contain numerous seeds. Though the shrub can not be regarded as a showy one, it presents a neat appearance with its rather modest flowers and abundance of shining berries. It keeps in flower for a long time; as the stems elongate, new blossoms are developed, while the fruit from the earlier ones is already ripe. When left to itself, the shrub seldom grows more than six or eight feet high, but if the branches are trained to a wall or other support it will grow to the height of thirty or forty

feet. It is a rapid grower, and is frequently used in Europe to cover walls, the sides of buildings, etc. In some places in this country it has become partly naturalized, and as it throws up a great abundance of suckers it is difficult to eradicate where it is well established. The name Lycium is from Lycia, the native country of one of the species. A native spe-

Sowing Seeds of Tropical Annuals.

BY PETER HENDERSON.

Our climate is much more favorable than that of England for the growth of annuals of tropical origin. Not only do the plants with us attain a greater height and development, but those that are grown for the color of their foliage acquire a greater brilliancy under our clear sunlight than they do under the dull skies of the British Isles. Notwithstanding all this, the English gardeners and also the amateurs, as a general thing, meet with better success with these plants than do ours. This success is due to beginning properly with the seeds. Our amateurs are ready to buy at a high price all novelties that are offered, but their results are not in proportion to their liberality. Take for illustration the new Amaranth which is figured elsewhere; the seeds of it will be offered this spring in "homœopathic" packets at an "allopathic" price. Of those who purchase, a few

will succeed in raising fine plants, while many will fail, and pronounce the thing a humbug. There is no good reason why every one should not succeed, as all the Amaranths are easily raised from seed—the seeds never failing to germinate if the conditions are right. I will endeavor to state what these conditions should be. First, then, you may procure your seed as soon as you can get it, but don't think it imperative on you to sow it as soon as you get it, as I know is too often done with flower seed.

One half of all seeds purchased by amateurs perish from one or other of the following causes. A seed that should not be covered with more soil than $\frac{1}{16}$ or $\frac{1}{8}$ of an inch is covered often an inch or two in depth, and the delicate plant perishes from being unable to push through this weight of soil. Or a light seed is sown in the open border, at a proper depth perhaps, but a dashing rain sweeps it away, or a dry spell shrivels the delicate life in the tiny seed so that all possibility of germination is gone. But the most common error is to sow too early, for most of our annual flowers are tropical, and if they germinate at all, the chilly nights of April, and often of May in this latitude, are certain to destroy them. So for such seeds as this new *Amaranthus*, and the others named below, the following method is a safe one.

If you have a greenhouse or hot-bed, sow in this latitude (sooner or later, South or North) from the first to the tenth of May, in shallow boxes (two inches deep), covering say $\frac{1}{16}$ part of an inch with some light kind of soil, such as leaf-mold from the woods, sifted through a mosquito netting or a sieve of similar fineness of mesh; water daily with a very fine rose watering-pot, until the seed germinates; or, if you have not a suitable watering-pot, place porous paper so as to cover all the soil where the seeds are sown, pour water gently over the paper, and it will quickly pass through it, distributing itself evenly over the surface of the box without disturbing the seeds. When the seeds are up sufficient to show the rough leaf, which will be in about two weeks after sowing, take them up carefully, and replant in similar boxes and soil, one inch apart. By the first week in June they may be planted out-doors.

To those who have not the convenience of either hot-bed or greenhouse, a window exposed to the south or east in the dwelling-house would answer the purpose nearly as well if the same care in sowing is used. If wanted for exhibition at agricultural fairs in the autumn, it would be best to pot the plants in three or four inch flower-pots, setting the pots in the soil in the open ground level with the rim. As the plants grow, they should be shifted into larger pots, until the final shift, which would probably require a pot or box one foot in diameter. If not wanted for this purpose, plant in the open flower-border, but not in pots.

As this class of annuals is unsurpassed for decorative purposes, a fine effect might be produced by many of your readers at the agricultural fairs held in October. Below is a list of such kinds, in addition to the *Amaranth* already referred to, as can be easily raised from seeds, and would be suitable for this purpose:

<i>Amaranthus, bicolor, ruber.</i>	<i>Browallia alata, blue.</i>
<i>Amaranthus, tricolor (Joseph's Coat).</i>	<i>Globe Amaranthus, purple, yellow, or white.</i>
<i>Amaranthus, tricolor, giganteus.</i>	<i>Sensitive Plant.</i>
<i>Amaranthus sanguineus.</i>	<i>Petunia, striped and blotched.</i>
<i>Coxcombs, yellow and crimson.</i>	<i>Cypress Vine, scarlet or white.</i>
<i>Egg-plant, white and scarlet, fruited.</i>	<i>Lophospermum scandens.</i>
	<i>Thunbergias of sorts.</i>

The first four in the above list have brilliant

and highly ornamental foliage, and well-grown specimens of them are very attractive. A fine specimen of the Sensitive Plant is to most persons a great curiosity. The last three plants named above are climbers, and must be furnished with trellises, or some kind of supports, four to eight feet high. The Globe Amaranth and Cypress-vine germinate more readily if scalded before sowing.

Dwarf Fruits and Small Fruits in Kentucky.

BY HENRY T. HARRIS, LINCOLN CO., KY.

Horticulturists of the South are beginning to "wake up" from a long supineness on the proper culture of dwarf and small fruits in their respective localities. With rare exceptions, they have neglected their culture, and hence but few families, comparatively, have a supply of either, notwithstanding the great adaptability of the climate and soil to their production.

I know of but two or three dwarf fruit orchards in this county; and but few small-fruit gardens. A half-dozen knotty, ill-cared-for pear-trees, and a rod square of strawberry plants overrun with filth and weeds, a hedge-row of unpruned wild-raspberry bushes, make up the sum total of their fruits. Here and there an old standard pear-tree, loaded with luscious fruit, the result of some more thoughtful individual's labor half a century ago, rises up from beside the garden-gate, as if to upbraid the rising generation for their want of forethought, and to convince them that fruit-raising would be a success if they would only plant and tend the trees. Here and there a few time-worn apple-trees and worm-eaten peach-trees dot the landscape in the rear of the tumble-down barns, with weeds and "water-sprouts" contending for the mastery of the situation.

Now and then you will find a beautiful young orchard laden with its wealth of fruits—the Golden Pippin and blushing Ben Davis, the luscious Crawford's Early and Oldmixon Free peaches, the Bartlett and Louise Bonne of Jersey pears, the Green Gage and Jefferson plums, the Black Tartarian and American Amber cherries, and a host of others adapted to our climate and soil. Enter the garden, here we find the Wilson, Triomphe de Gand, Downer, Charles Downing, Green Prolific, and French strawberries, with perhaps a few choice plants of newer kinds on trial, including "President Wilder," in a clean, neat propagating bed. The fence rows are not filled with bushes, but these are planted in a square by themselves. The Doolittle, Thornless, Clarke, Seneca, Philadelphia, and Orange raspberries are neatly trimmed and tied to stakes.

We inquire for the owner, and find almost invariably that he is some "irrepressible Yankee," who, with an eye to business and profit, came amongst us during the unhappy war, and found that our climate and soil were the home of fruits. Let more of them come: we need their aid in rendering our lands fruitful.

But I have somewhat digressed, yet not without reason or aim. We find by our partial experience, that the dwarf fruits, especially the pear, do exceedingly well here. I know one orchard of three hundred trees, now ten years from the nursery, which have yielded splendid crops for six years, having failed only partially one year, and that from an unprecedented drouth, which continued from June first to the last of August. This orchard has ten varieties,

amongst the best and most prolific of which are Bartlett, Winter Nelis, Louise Bonne of Jersey, Vicar of Winkfield, Duchesse d'Angoulême, Bloodgood, and Seckel. Would not other dwarf fruits do as well?

The small fruits of all kinds, strawberries, raspberries, currants, cherries, gooseberries, blackberries, grapes, etc., flourish here with surpassing productiveness, and many of our best varieties of strawberries have had their origin in Kentucky soil. I refer to the Downer, Charles Downing, and Kentucky, the latter kind having, on my grounds this spring, produced a choice crop of superior fruit, after all other varieties had yielded the bulk of their crops.

The White and Crimson Mignonettes.

BY PETER HENDERSON.

Mr. W. C. Strong, of Brighton, Mass., takes me to task in last month's *Agriculturist* for denouncing these Mignonettes as frauds, and thinks I could not possibly have had the varieties genuine, or I would not have done so. That I had the true varieties there is no doubt, and that I did see a difference from the old variety I also acknowledged in my article in December, and a distinction also that I am willing to accept as a variety, and perhaps an improvement; but what I complained of as a fraud was the names "Crimson" and "White," given "the same with intent to deceive."

Mignonette is one of the best known of all cultivated annuals, and valued for its fragrance rather than the color of its flowers, but when it was heralded by hundreds of catalogues throughout the land that we had been blessed with a "Crimson" and a "White," every one interested in the old flower wished to possess the new. Surely Mr. Strong knows that not one in a dozen of those who purchased would be satisfied that they got the value of their money by the difference, and certainly none had credulity enough to believe that they had got either crimson or white. Mr. Strong says possibly the name *White* was an unfortunate one. It is not a "name," it is a "description," and it is worse than unfortunate—it is false.

We know that there are dozens of itinerant scoundrels peddling "blue" and "black" roses in the rural districts every spring and fall, and almost every spring one or more has the impudence to pitch his camp right in the business part of New York City, and unblushingly assure his gullible patrons that he has made them the possessors of these floral wonders.

Now, I claim that it is just as much a fraud to call Parsons's new Mignonette "White," as it would be for Mr. Strong or me to call the famous Tea-rose Bon Silene "blue," and that we would no more deservedly bring down censure on our heads by issuing the one so described than in issuing the other.

I am rather sensitive and suspicious, perhaps, in this matter of startling novelties in color, having once palmed off on my customers a certain yellow Verbena, which I had received in good faith—and with entire faith—from a London house. It was described as the great plant of the season, a bright, yellow-colored Verbena, which they named "Welcome." After many failures, I succeeded in getting a dozen plants alive, which we propagated rapidly, and sold just as rapidly, but without taking the precaution to prove it. One April morning developed the flower of the new Verbena, but to me the sight was far from "welcome," for instead of

bright yellow, it was simply a dubious white. But, worse yet, the plant arrayed in full dress revealed to me an old acquaintance of my boyhood—*Verbena sulphurea*—a half-hardy species cultivated in the botanical collections of Britain for possibly twenty years before. Some "enterprising" florist had come across it, saw in the name *Sulphurea* a "golden" tinge, and set it on its commercial travels, which, I am happy to say, were short, but to me, for one, far from satisfactory, for I have not yet heard the last of that Yellow Verbena, and from that time have been morbidly sensitive and skeptical until I have had evidence of the truth of descriptions. Whenever descriptions are no nearer truth than those of the Crimson and White Mignonettes, I shall not scruple to say they are fraudulent.

Venture a Little Seed.

The writer once lived on the Mexican border, where no crop could be depended upon, unless the land was irrigated. The best planters, after they had sown their crops upon all the land capable of artificial watering, would put in a field of greater or less extent, upon the upland. This they called planting *a Dios* (to God). If the rains came, which they did once in three or five years, a good crop was taken from these high lands; if not, it was only the loss of a little seed and labor. In something the same spirit we have been in the habit of putting in moderate quantities of some seeds just as soon as the frost was out of the ground, without reference to the promise of an early spring, or a late one. Sometimes we have received nothing for our labor, but more frequently we have enjoyed vegetables considerably in advance of the regular crop. We find it worth while to sow a few early peas, radishes, and beets, and plant some early potatoes long before our neighbors have thought of their gardens. The soil is manured and spaded in the fall, and a forking over in spring makes it ready for the seed. These early crops need not be tried in large quantities, and then, if they come up, they can be easily kept from injury, by having some bog hay or other litter to pull over them when frost is expected.

When to Prune.

Being a novice and an enthusiast about things rural, I have so faithfully followed your counsels regarding the study of the best books upon agricultural subjects, that, as my helpmeet truly says, poor Dickens, Thackeray, Irving, and a few lesser lights are being crowded from our shelves, or tumbled into rather familiar companionship with Miss Ingelow, Mrs. Browning, and Miss Mulock upon the library floor.

Whatever useless fiction is not denied shelf-room altogether, is packed ignominiously behind my all-important farm books.

Now, all this may evince an enthusiastic "pursuit of knowledge under difficulties," but I fear the wife doesn't altogether share and appreciate my zeal.

Last evening she inquired where I had put "The Vicar of Wakefield." I told her behind "Harris on the Pig," adding that I couldn't find Johnson's "How Crops Grow."

"Why," said the orderly little lady, "I put that among your poultry books, of course."

I smiled wisely—or rather unwisely—for she continued, somewhat excitedly: "Well, how can I tell where *any* of the books belong, after the changes and confusion you've made?

'Mother's Recompense' is cast aside for 'Dadd's Horse-Doctor,' and you have stuck 'Gregory on Squashes' directly in front of 'Jane Eyre.' 'The Marble Faun' and 'The Snow Image' are tucked away back of 'Youatt and Spooner on the Horse.' 'Agatha's Husband' and 'The Old-Fashioned Girl' are together in the big, gray chair, while 'Little Dorritt' and 'David Elginbrod' are on the floor under 'Bleak House,' with 'The Scarlet Letter.' Because you want to eradicate mosses from an old pasture is no reason why my precious 'Mosses from an Old Mans' should be cast aside."

My helpmeet stopping to take breath, I asked her to please hand me Thomas's "American Fruit Culturist," reminding her of her promise to help me "study up" on pruning.

She said a promise was a promise, and seated herself opposite me at the table, I with paper and pen to make a few notes in aid of a somewhat fickle memory, and she with "Fuller's Forest Tree Culturist," to compare authorities.

"Here it is," I exclaimed, "page 80 of Thomas's book: 'Pruning, after the tree has commenced growth, has a tendency, in nearly every instance, to check its vigor. For this reason . . . the work must be performed before the buds begin to swell.' I'm sure *that* is explicit enough, isn't it?"

"Well, yes," said my better half, "that *is* rather explicit; but hear what Fuller says on page 66: 'For this purpose, there is no better time [to prune] than after the leaves have become fully formed, and the tree has commenced to make a new growth.'"

I am afraid my wife read this extract rather exultantly. She supplemented it with: "There, my dear, now you know exactly what to do!"

What I did was to despondently put my books away, secretly resolving to imitate the Father of his Country, and hack away at my trees whenever my hatchet is sharp.

This is certainly the only correct "principle and practice of pruning," according to "the best authority," as nearly as I can strike an average. F. A. W.

REMARKS.—We publish the pleasant letter of our correspondent, in part because it is pleasant, and in part that it gives us an opportunity to answer a number of inquiries as to—"When shall I prune?" At the risk of incurring the displeasure of his "better half," we would advise our novice to do his own reading in future. Had he done so, he would have found, by reading the next paragraph to the one from which he quoted, that Mr. Fuller, in his *Forest Trees*, says: "Pruning may also be done any time in summer, fall, or early winter, but should not be performed in the latter part of winter or just as the spring approaches, for at this time there is more or less danger of the trees bleeding."

That is all that need to be said upon the time of pruning. There is one thing that our novice says nothing about—why does he prune at all? Some persons think that it is necessary to prune their trees every year, just as the more ignorant Irish think it is necessary to be bled every spring. No branch nor twig should ever be cut away but for some well-understood reason. We have not space to discuss the *why* of pruning; suffice it to say that it is sometimes necessary, though less frequently than is by some supposed. If it is to be done, the above direction as to time is a sufficient guide. The *how* is a matter of no little importance. If our correspondent is intending to "hack" his trees, he has read his books to little purpose. A good pruning saw and a

drawing knife are the most convenient tools. Saw off the branch neatly, taking care that no tearing of the bark takes place from the falling of the limb. Then with the drawing knife, or, if more convenient, a sharp pocket-knife, pare the wound to a smooth, sound, clean surface. If the wound be covered with some protecting material, it makes but little difference what time the pruning is done, though we would always except early spring, when the tissues are turgid with sap. The neatest and at the same time the most expensive material with which to cover the wounds is shellac varnish. Common shellac is covered with alcohol and set in a warm place. If stirred now and then, the solution will take place in a day or less. Thin with more alcohol, if necessary, until the varnish is of the consistence of paint. Keep in a bottle with a mouth wide enough to admit a brush, the handle of which should pass through the stopper, and thus prevent evaporation. For the amateur, nothing can be handier, cleaner, or more efficient than this. A single coat over the wound will in a few moments dry into a firmly-adhering water-proof film. When there is much work, melted grafting-wax may be applied with a brush, or common white-lead paint may be used. If the paint is mixed with a little lamp-black or umber it will be less conspicuous.

Greenhouses attached to Dwellings.

BY PETER HENDERSON.

I omitted to state in the article under this head in February that these greenhouses can be used for all the purposes of a hot-bed. Soil placed to the thickness of four inches on the benches will grow fine plants of all varieties of vegetables if the proper time in sowing the different kinds is attended to—presuming that the greenhouse has no artificial heat other than that produced by the sun's rays which pass through the glass. In this latitude, cabbage, cauliflower, and lettuce had better be sown about middle of March. By attention to ventilating and watering, fine plants may be had in five or six weeks from time of sowing, which will bring them just into the proper season for planting in open ground. Tomatoes, pepper, and egg-plant, and the tenderer kinds of flower seeds, should not be sown much sooner than end of April. True, they would not be as early as if sown a month sooner in a hot-bed and *replanted* into the greenhouse bench in May. But if no hot-bed is at hand, the protection of the greenhouse over these tender plants in May will give satisfactory results if earliness is not particularly wanted.

Shovel and Mole Plows in the Garden.

There are no cultivator teeth of any form that run so easily and do so efficient work in loosening the soil and putting weeds out of

Fig. 1.

Fig. 2.

sight as those called shovel plows at the West and South, and shaped as shown in fig. 1. The plates, when made of steel—as they always should be, and dished and set forward at the right angle—seour bright in any soil, and never clog with weeds unless these are very large.

All the corn cultivators used in the Western States for one or two horses, the most expensive and the cheapest, have teeth, with trifling variations, shaped like these. They are used to make single, double, and triple shovel plows for one horse, or with four shovels on wheels, for two horses, to cultivate both sides of the corn rows at once. With the two-horse implement, one man in Illinois tends 75 acres of corn.

The one-horse double-shovel plow is made with two shovels, one set to run deeper than the other, and about ten inches apart. The shorter plow is set about twelve inches forward of the other on the right-hand side, to run next the corn. By having the hind plow run deeper, and going twice between the rows, a handsome slightly-raised hill is made for the corn by leaving a small furrow in the center. A single-

shovel plow has a larger shovel, and runs but once between the rows, and makes a higher hill. The triple plow is made with the two shortest shovels set forward on opposite sides, and the longest shovel in the center in the rear. These plows are but little known in the Eastern States, but will be found to give much satisfaction wherever used on land free from stones.

The mole plow, which figure 2 represents, runs underground, and loosens the soil to let in air and rains to the roots without disturbing the plants. This is essential in heavy soils, or in those compacted by heavy rains. Similar to a subsoil plow, but not running so deep, it is es-

pecially adapted to the culture of rice after the first flooding has been drawn off, when the land is always left very close and heavy.

SEA-BEAN.—(*Entada*.)

pecially adapted to the culture of rice after the first flooding has been drawn off, when the land is always left very close and heavy.

Mole and shovel plows like those figured are made to fit Constock's Hand Cultivator and Onion Weeder, which we offer in our premium list. They are an important addition to that very useful implement. W. G. C.

The Great-flowered Thunbergia.

The Thunbergias are pretty well known through the annual climbing *Thunbergia alata*,

GREAT-FLOWERED THUNBERGIA.—(*Thunbergia grandiflora*.)

which is now much used as an ornamental vine in our gardens. We present here an engraving of a woody species, the Great-flowered Thunbergia—*T. grandiflora*. The leaves and flowers are represented about half the natural size. It makes an excellent climber for a warm greenhouse. The leaves are of a pleasing green, and the flowers, which are freely produced, are of an

Sea-Beans.—Entada.

exceedingly delicate blue color. The plant is a native of Hindostan, and has been in cultivation for many years, though we now seldom see it in collections. It is worthy the attention of those who have greenhouses, but we much doubt if it would succeed in apartments.

In January we gave a description and figures of the seeds of a *Mucuna*, which had been sent us from Florida, under the name of Sea-bean. Now a correspondent writes from Mayport, Fla., that that sea-bean is not the true Sea-bean, one of which he sends. He states that his sea-bean is washed upon the shore with the other, and says: "I am assured by some who ought to know that it is a true marine production." We give a figure of the seed sent by our correspondent; we have specimens from other sources both larger and smaller than the one here represented. The seed is the product of a Mimosa-like vine, the *Entada scandens*, which is found in the tropical portions of both hemispheres. The vine is chiefly remarkable for its large pods and seeds; the pods are often six or eight feet in length, are flat and woody, and divided up into numerous joints, each one of which contains a seed. The inhabitants of places where these seeds are found convert them into various trinkets; perfume-bottles, snuff-boxes, spoons, and other such things are fashioned from them. The exterior is of a fine dark brown or purplish color, very hard and polished. It is said that in some parts of India these seeds are used for weights. In the streets of London the seeds of the Entada are sometimes sold under the name of "West-Indian Filberts," though they are not eatable. The seeds found upon the coast of Florida have been borne there by the sea from other shores. The distance to which these seeds are carried by ocean currents is something remarkable. It is not rare to find them upon the western coast of Scotland, and they have occasionally been carried as far as the Lof-foden Islands, off the coast of Norway.

Turban Squashes.

A gentleman who called at our office some weeks ago mentioned a very fine squash, the seeds of which he obtained at Florence, Italy, from the palace garden of Victor Emanuel. We expressed a wish to see this squash, and sometime after received from Mr. Caywood, of Clarksburgh, W. Va., a specimen raised by him. We give an engraving of the one sent, which seems to be a highly exaggerated Turban squash. In the ordinary Turban variety the projection, at the blossom end is small in proportion to the body of the squash. In this Florentine one the main bulk consists of this projection while the body proper is small. In our specimen the projecting portion is very deeply three-lobed and the skin of a dull cream-color; the body part is dark orange, with green splashes.

We do not find any description that quite agrees with our specimen, though it is like the Turban squash of the French with the projecting portion much larger than ordinary. Mr. Gregory, in his work upon squashes, says in speaking of the French Turban, it is "the most worthless in quality of all the varieties of squash that have come to my notice." This remark certainly can not apply to our squash, as upon trial it proved very fine, and quite equal in quality to those we consider standard varieties. The "Improved Turban" is said by Burr to be probably an acclimated sub-variety of the French Turban, while Greg-

ITALIAN TURBAN SQUASH.

ory claims that the "American Turban," which is the same thing, is the result of hybridizing, owing its form only to the French Turban and all its excellent qualities to the Hubbard or other varieties with which it may have been mixed. In the American Turban the projection before referred to has been by selection so much reduced in size as not to be conspicuous. Perhaps in the squash we have figured the selections have been made with a view of securing the greatest amount of protuberance. At all events here is a squash quite as good as the American Turban, with the shape of the condemned French Turban intensified. We shall look with interest to the progeny of this squash.

THE HOUSEHOLD.

(For other Household Items, see "Basket" pages.)

Our New Flour-Box.

A correspondent at Buda, Ill., writes: Having recently made a few improvements in our pantry, the best of which is a flour-box, differing from any I have ever seen, and which is admired by all the

Fig. 1.—FLOUR-BOX AND ACCESSORIES.

ladies who have seen it, I send you a sketch of it. It is easily made, and there is no patent on it. It can be made without the four drawers, closet, and spice drawers, though these are all very handy. The top, *a*, I made of $1\frac{1}{2}$ -inch pine, 22 in. wide. The flour-box, *b*, is 16 in. wide inside at top, and 14 in. at bottom. Depth, 15 in. inside. Length of end boards, 30 in. Width of front, 19 in. Length, 24 in. outside. These dimensions may be varied, but the form of the ends, *c*, fig. 2, should be preserved. They rest on pieces of thick leather, fastened to them and to the floor when finished. A strip (*e*) is screwed under the top, for the box to shut and open against. The back should be screwed on firmly. The spice-drawers are made of tin, 6 in. by 6 in., with black-walnut fronts, 2 to 3 in. deep, and lettered. They set in a case made of $\frac{3}{4}$ -in. white-wood. The molding-board (*g*) is slid behind them when not in use. The drawers (*m* and *n*) are always useful for sugar, Graham or buckwheat, towels, baking tins, and a score of things; the closet (*k*) for syrups, lard, butter, eggs, etc., etc. Three shelves are in the corner, though only one (*j*) is shown. Now, if any husband is coaxed by his better half to get one made for her, he may lay the blame to

J. F. R.

Farmers' Daughters.

The *Agriculturist* is an old friend at our house, and I owe it a thousand thanks for its numberless good suggestions. I feel more regret at seeing in it such an article as that "Can Farming Pay such Taxes?" than if it had been published in another paper. The *Agriculturist* is an authority in many a farmer's home, and probably many a *pater-familias* will point out that very article, and say, "Here, daughter, that's the most sensible thing I've seen this long while;" and next time Mary or Lucy wants those buttoned shoes or that "love of a hat,"

which she has well earned, she will have to go without, or perform more than the usual amount of strategy to get him to open his pocket-book.

Your correspondent takes the position that our daughters are growing idle and extravagant—assertions that are impossible to sustain. I have no daughters, and am obliged to pay \$9 a month for hired help, very uncertain at that. My neighbors, who are more fortunate, do all their work, including all the sewing except the men's best clothes; and the clothes of any one of the young ladies do not cost any more, if as much, as the wages of my hired girl, but with the assistance of the condemned fashion-magazines they are made up at home so tastefully as to rival the dressmakers. The time spent at the machine busily and patiently stitching at those ruffles, or at the ironing table fluting them, is not lost. They deserve praise for their ingenuity.

Nor is this neighborhood isolated in respect to the industry and economy of the girls. My observation is that such is the rule, not the exception, among country lasses; about others I know little. Often, too often, is it that fathers are insensible to what their children are really worth to them in a pecuniary view. They do not note that those willing little feet save them a great many steps, and that those young hands are doing about all they ought. Of course, that reference to our grandmothers is necessary—I observe it always is in articles of this kind. To be sure, the old ladies did not wear chignons, for the reason that they were not yet invented. But they stuffed their hair full of rolls—look at the pictures of Lady Washington, or the fashion plates of that time. They wore high tortoise-shell combs that cost four or five dollars apiece, and gold beads, and scarlet cloaks, and all the other finery of the day. The fact is stubborn, that since the world has stood woman has loved personal adornment, and man has loved to grumble and refer to the past. Time will bring round its revenges, and a century hence the girls so censured now will be held up as patterns.

Your correspondent fails to notice the expensive clothing and habits of farmers' sons. Bless the boys! they are welcome to their stove-pipe hats and fine boots—but I protest it is not right to condemn one and not the other. If he has seen girls whose clothes cost as much as a mower and reaper, has he not as often seen boys whose clothes cost as much as a sewing-machine which their patient mothers were doing without? Our children should fairly know their parents' circumstances, and be allowed what can be afforded for their clothing, always being made to understand that something must be put by for the future. Then they will not repine when they are denied, if they feel sure father is not "stingy," but just as well as generous.

H. C. A.

Warm Plates.

A trifling thing can convert what would otherwise be an enjoyable meal into an uncomfortable one. The difference between a warm plate and a cold one often makes the difference between a good dinner and a bad one. During all the cooler weather the plates should be properly warmed. In no case is the necessity for this more strongly shown than when the meat is mutton. The fat of mutton melts at a higher temperature, and consequently solidifies more readily, than that of other meats, and it is exceedingly repulsive to see it harden upon the plate. To warm the plates is an easy matter, and may be accomplished in various ways. When the stove oven is not occupied, the plates may be set within that, or they may be set upon the cooler part of the top of the stove, taking care to change the bottom one before it becomes too warm. Some very fine plate-warmers are made of elegantly ornamented japanned ware. These are like a small closet, open towards the fire, with shelves within, upon which to set the plates. At the opposite side is a door. Warmers of this kind are intended to stand before the open fire of the dining-room. We recently saw in the store of J. H. Baldwin, in Murray street, a very simple plate-warmer, which is here figured.

It is a rack of galvanized iron-wire, which holds the plates and may be set upon a stove, or in front of a fire, or over a hot-air register. This sells at \$2. When one has to warm plates in a hurry, it

WIRE PLATE-WARMER.

may be very quickly done by placing them in the dish-pan and pouring boiling water over them. A few minutes suffice to warm them sufficiently.

Home Topics.

BY FAITH ROCHESTER.

CONVERSING WELL.—Somebody criticises me for not speaking of Conversation under the head of Accomplishments. I know there is a good deal said about the art of conversation, but I have not much relish myself for conversation that is the result of art, however "high and transcendental." It is a good thing to know how to speak one's native tongue correctly, and a good thing to have learned to listen well to our partners in conversation. In short, it is a good thing to be able to communicate our ideas to others without wearying or disgusting them either with ourselves or with our subjects of conversation. But it is a better thing to have good ideas and a kind heart. A few simple words from an honest heart, or looks of brotherly or sisterly sympathy, are far preferable, I think, to any amount of artistic discourse by one who is chiefly concerned about the *manner* of his conversation rather than about its *matter*.

I have no particular right to give advice upon the subject, but if any one should ask me how to go to work to learn to converse well, I should say, Get as good an education as you can, not only at school, but by general reading, and by keeping your eyes and ears open. Above all, keep your heart open, and remember the golden rule. That will make you a good listener when others are speaking. To write your thoughts carefully will help you to express yourself clearly. But try not to worry about yourself and the impression you are making.

Young people but slightly acquainted with each other sometimes have difficulty in finding anything to talk about, and silence seems very awkward to them. It is well enough for Miss Amanda, when invited to ride with Mr. Arthur for the first time, to think beforehand what she will talk about, and to prepare herself somewhat. But conversation which needs much especial preparation is never of the best kind. Out of it may grow, however, something fresh and worthy of the name. When among one's friends there is usually no lack of things to talk about. You may have to jot down beforehand the few very particular things that you *must* talk about, or they will get crowded out by the innumerable minor topics of mutual interest.

WASHING FLANNELS.—Wash white flannels in clean suds. Some washers put them into the "sudsing water," the water in which the suds has been washed from the white clothes after they have been taken from the boiler. This gives them a dingy appearance, quite different from the soft, fleecy whiteness they have when washed in bright clean suds. There is a difference of opinion among housekeepers about the proper temperature of the water in which flannels should be washed and rinsed. Some tell us to have both waters as warm as the hand can bear, or hotter if machines are used for washing and wringing. Others, of equally good authority, say use only cold water. I have been assured that the very nicest way is to soak them over night in cold suds, wash them out of this in the morning, and rinse in cold water. I do not practice this method, but think I would if

obliged to hang flannels where they would freeze before drying. I have tried it, but found it no better than my usual method of washing and rinsing in hot water. Less soap is needed to wash clothes clean with hot suds than with cold. The water used should not be boiling hot. I fancy that the secret of washing flannels without shrinking them is to wash and rinse them without too sudden changes in their temperature. Fullers try the opposite when they wish to full their cloth—from hot to cold, or from cold to hot. Rubbing also tends to "full up" or shrink flannels. The soap used should not be rubbed into the cloth, but made into a suds sufficiently strong to cleanse the garments without much rubbing.

A DANGEROUS PRACTICE.—A guest arrives. He appears well dressed and tidy. He stays over night, and occupies the regular "best chamber," with its clean sheets and pillow-slips. The mistress of the house does all of her own work, or she has a scant supply of bedding, and it seems hard work to enlarge her usual week's washing by those scarcely soiled sheets. So she puts them on the children's beds, thinking they will never know the difference, and it won't hurt them at all. In nine cases out of ten this may be true—but the tenth case! I do not care to mention to "ears polite" the diseases that may be communicated in this way, and sometimes by the most respectable persons, who have been contaminated in the same way perhaps.

SCALDED BREAD.—An excellent breakfast dish is made by pouring boiling water over pieces of stale bread—enough to soak them soft. Better than steamed bread, and preferred to toast by many.

CREAM (OR MILK) GRAVY.—I thought I would say a good word for "white gravy," as children often call it. With them it is a great favorite as a dressing for potato. It is better for them than butter or meat with warm potatoes. Pork fat can not be compared with it at all on the score of healthfulness. Those who use fat pork often make this gravy in the same spider where the pork has just been fried, thus seasoning it with pork. We make it of milk, thickened with flour, and seasoned with butter and salt. For a pint of gravy you want a large spoonful of flour, stirred smoothly into half a teacup of the cold milk. Let the milk be boiling when this is added, and kept constantly stirring, or the gravy will be lumpy. If cream is used instead of milk no butter is necessary. The milk should be stirred while coming to the boil to keep it from burning. It is less likely to burn if a little butter is melted in the spider before pouring in the milk.

RED STRINGS tied on tools used by children aid one to keep track of these implements. For instance, here is a small hammer with a string of scarlet cord through its handle. An old case-knife hangs by a string of red braid put through a gimlet hole in the handle. Two lead-pencils have red cord tied around one end. A knot of scarlet braid on one bow of the scissors makes it no difficult task to find them when lost. Children need "a place for everything," in order to learn to keep things in their places.

Cooking the Egg-Plant.

In the season of egg-plants we have numerous inquiries about cooking them. These usually come so late, that before the answer can reach our readers the season is over. To be in time we give the following, and housekeepers can just "stick a pin" in their memories to remind them to refer to this article when the proper season comes round. It will interest our housekeepers to know how wide their circle is. This letter comes from a very distant member, Mrs. H. C. Phillips, at Santipore, in India. We are always glad to hear from these far-away friends, and so we are sure are those housekeepers who live nearer to us. Mrs. P. writes:

I notice an inquiry as to the best method for cooking the Egg-plant—or *Bijou*, as it is called here. The *Bijou* should be used while the seeds

are quite tender and the vegetable will readily yield under the pressure of the fingers. Throughout this part of India, no vegetable is more highly prized or more generally used by all classes than the *Bijou*. It is served up in a variety of ways, some of which would not suit a Western palate.

The best way is to cut them in slices a half an inch thick, spread them on a plate, strew a little salt over them, and allow them to stand ten minutes for the sap to escape. Turn them over in a well-beaten egg, and then in flour, and fry them in very hot butter or lard, as you would fresh fish, which they resemble when thus cooked.

Another way: Roast them as our mothers used to roast potatoes, though it does not require half the time. Remove the skin while hot, mash, and season with butter, pepper, and salt. Many here, instead of butter, use mustard oil, and add uncooked onions, leeks, and cayenne peppers chopped fine, also a little roasted fish pounded fine.

Still another method: Cut the vegetable, stem and all, into halves. Boil them, and when quite soft, carefully scrape the inside from the skin; season to suit the taste, and return to the skins, filling them even full. Arrange them on a plate with the stem extending over the edge, then strew them with some nicely toasted bread-crumbs. The *Bijou* is also cut into pieces the size of an egg and put into curries.

Table Etiquette.

The following comes from a correspondent in Massachusetts, who signs herself "W.":

How often do we see a hostess overstep the bounds of true courtesy as she presides at her table by urging her food upon her guests! "Now do take a piece, it is very simple, it will not harm you in the least." "Why do you not eat?" "Isn't that good?" "You do not eat anything!" This latter remark is not unfrequently made when a visitor has eaten as much or even more than others, but as she does not choose to partake of all that is placed before her, the hostess seems to consider it incumbent on her to urge, and question her reasons, which oftentimes places the guest in a very unpleasant position. Now, are not visitors supposed to have common-sense? They are often treated as though they lacked all knowledge of their own appetites and desires. This continuous urging and discussing of food implies either that, or that they distrust the willingness of the hostess to have her food partaken of. This would be a decidedly uncomplimentary opinion for the visitor to possess, consequently very uncourteous in the hostess to insinuate the existence of such by her excessive importuning.

The food denominated very simple and harmless is frequently compounded of the most deleterious ingredients. Not that prevarication is intended, but there is often an unconscious ignorance of its harmful qualities, and the guest must either run the risk of being made uncomfortable for several hours, by giving her stomach food for which it is not capable of caring, or incur the evident displeasure of the hostess. This is no imagination or exaggeration, but fact. Even if it be a simple dish, who can tell better than ourselves whether we can eat it with impunity or whether we desire it? The questions "Is it not good?" and "Why do you not eat?" are such that if truthfully answered might sometimes occasion embarrassment to the visitor and deep mortification to the hostess. Supposing the visitor refuses food for sanitary reasons, she does not wish to solicit the commiseration of those around her by making a parade of her weaknesses. On the other hand, imagine the feelings of the hostess if the visitor replies to her questions, "Is it not good?" and "Do you not like it?": "No, I do not like the molasses sweetening in your pie; I prefer to eat this cookie instead;" or, "Your cake is not well baked, consequently is not palatable to me." Now, does the lady of the house expect or wish her visitors to criticise the food, or cavil to this or that because it does not

happen to suit their taste? If so, a more discretionary way would be to avoid the publicity of the table. If she desires praise, would it not be much pleasanter for her guests and more creditable to herself to dispense with her questions, and await the option of the guests for compliments? If desiring, they will generally be given by actions, if not in words. Not that the visitor should flatter, but when circumstances will admit, compliments may be bestowed, which will give a happy gratification to the hostess, and add not a little to her ease—for deserving praise helps wonderfully. Simply passing food, with a single invitation to partake, ought to be sufficient, without any urging. Of course, if one knows her visitor's peculiar taste, she will endeavor to cater to it; and if not, to ascertain it in the most delicate manner possible, and not because her food is refused demand an explanation, or express surprise by looks and exclamations if she discovers a palate that does not coincide with her own. Doubtless, a frequent cause of the many queries is an earnest desire to please, and out of it has grown this thoughtless habit. But it is one which should be overcome, for in the adherence to it a hostess can never become an adept in the presidency of her table; for she defeats her aims, torturing instead of entertaining. It should be the aim of the host and hostess to make each gathering at the table pleasant, that the mind may be diverted and digestion assisted. Do not make the current prices of the market the subject of your conversation, or find fault with the oven or the cook. If the result of your teachings or your own personal efforts does not equal your desires, resolve to try again; but defer until away from the table all conversation that may be necessary to effect the desired change. An excuse may sometimes be needful; if so, make it in the briefest and most pleasant manner possible, after which avoid further allusions to the subject. Avoid all unpleasant topics; choose those in which all can participate or be interested, and then make merry, tempering your solicitude for your friends' appetite by a little reasonable judgment—remembering the maxim, "Every one to his taste."

The Cost of Bones and of Cooking.

Somebody in England has been making a calculation of the wastes of meat as we usually buy it and cook it. He weighed a leg of mutton before cooking, 9 lbs. 10 oz. Then he roasted it and weighed it again, 6 lbs. 12 oz. Then he took out the bone and weighed it again, 4 lbs. 13 oz. This was the net result—exactly one half waste. The Warren Cooker would have saved much of the loss shown at the first weighing, but the bone is "a hard nut to crack," and makes the cost of a meat diet more than we at first suppose. By the above showing, a leg of mutton, at 25 cents per lb., gives us clear meat (including fat) at a cost of 50 cents per lb. This, when a pound of wheat flour, containing more nutriment, costs less than 4 cents.

Samp or Hominy.

"Thorson" writes as follows: "The names samp and hominy are differently applied in different localities. Both terms are given to a sort of coarse Indian meal or cracked corn, and to whole corn with the hull removed. This whole corn is the kind I refer to. It retains the shape of the grain, but the thin hull has been removed by beating. It has one great fault—it is cheap! It costs me by the bag six cents a pound, and I do not know where else the same amount of food can be had for the money. The samp is soaked for a day, and then cooked in a farina-boiler for some hours, or until quite soft. Served hot, dressed with butter, etc., like potatoes, it is fine at breakfast or dinner. Put when hot into a bowl or other mold, and allowed to cool, it may be turned out like blanc-mange, and like that eaten with sugar and cream. If it were only fifty cents a pound, how popular it would be!"

BOYS & GIRLS' COLUMNS.

The Map Prizes.

About two hundred and fifty pairs of eyes will look for this column with great interest. They will not see the award of prizes here, and will be much disappointed. To put your little minds at ease, I will tell you that the names of those who are to receive the prizes, are given in the "Basket" pages—which one I don't know, but you can find out by looking in the table of contents on the second page. After you have satisfied yourselves about that, turn back here, and I will tell you all about it. Such a lot of plans! within a few of two hundred and fifty; they filled a large basket. I did not open them until February 3d, in order to give a fair chance for all to get in, and as this page must be made up on the 5th, I shall have to put a part of the story on some page that is made up later. Most of the parcels have been opened, but the selection of those for the prizes has not been made at the time I write. What a nice lot of maps there are! I am glad that I thought of them for prizes, as it has done every one who has drawn a map quite as much good as if he or she had taken a premium. A large share of the

Fig. 1.—SEARCHING FOR THE KEY-HOLE.

senders say that this is their first attempt at drawing. Good! Go on and try again. It is a capital plan to learn to put things on paper, and you will find it useful all your life. If an Indian wishes to show you the way to a place, he smooths off a space on the ground and draws a map with his finger. Civilized boys and girls ought to be able to make a good map with pencil and paper.

Some funny things have turned up in this map business. One boy wrote to the office that he had sent money for his subscription and had not received his paper, and that the money was inclosed to "the Doctor." As I put away the letters as fast as they came and did not open any until the time was up, no wonder the young man's money was missing. Another youth addresses me as "Dear Aunt Sue." Now that is a little too much. It has been supposed that Aunt Sue was a man, but I was never before taken to be a woman. Aunt Sue and the Doctor are not the same, not by any means, though if I were to be a woman, I should like to be just such a one as Aunt Sue. Whether Aunt Sue can return the compliment I can not say. Some young men of 18 and 19 have sent in drawings, thinking that they can compete with "boys and girls." Just think of a young gentleman of nineteen—no doubt with whiskers and mustache—entering into competition with my youngsters of 12 and 14! No, all males over 16 are young gentlemen, and all females over that age are young ladies. I did not in the offer make this distinction, but everybody knows that "boys and girls" means—little folks. In some cases I have been puzzled to know whether the writer was a boy or a girl. If a letter is signed J. Smith, I can not tell whether it is Miss Jane Smith or Master John Smith. This in future correspondence should be avoided. One young man expresses his doubt if there is any such person as "the Doctor." If that incredulous youth will call at 245 Broadway any day, from 11 A.M. to 3 P.M., and ask the first person he meets, from the smallest shop-boy to Mr. Judd himself, to show him the

Doctor, he can be convinced that there is such a person, and that said person will be very glad to see him. Well, children, we have all had a good time over this trial, you in working at the maps, and I in studying them. I wish I could give every blessed one of you something, but as I can not, I have used my best judgment, with the help of the "young Doctor," as the neighbors call him. Those who have not been successful in one thing, may be more fortunate in another, and I am intending to have more trials during the year. There is one proposed in another place in this paper. Try again, children. You all have the best wishes of

THE DOCTOR.

Trying to Find the Key-Hole.

Here is a chance for fun, if you only know how to make it. We have seen an evening party made wild with laughter at seeing this little trick well done. Like many other things, its success depends upon the individual. The fewer there are in the secret, the greater will be the enjoyment. To do the thing properly, requires two boys. Let these go out quietly, so as not to attract notice. One of the boys is to be dressed, and the other boy is to dress him. Any common or even discarded clothing will do. A long skirt should be fastened around the neck, with the slit in front, to allow the hands to be used, or a cloak will serve all the better.

We might as well say here, that the trick, game, or performance, as we choose to term it, is called the "Old Woman finding her Key-hole." Well, the boy with the skirt or cloak around him is the foundation of the old woman. To complete her, we want a broom, a sun-bonnet, and another cloak, or a very large shawl. The bonnet is to be put upon the broom, adding a veil to hide the face; then the cloak or shawl is to be pinned or otherwise attached to the broom, beneath the bonnet, so as to look as much like the real thing as possible. The boy must now hold the broom so that the bonnet will appear as if upon his head, and the attached shawl or cloak will fall over him and the garment he already has on. The position of the boy in the clothing is shown by the light lines in fig. 1. When this "old woman" is properly rigged and understands her or his part, the other boy goes into the room where the company are, and contrives to draw them to one side, so as to leave a door free for the operations of the old woman. This he can do by mentioning an unfortunate old woman that he has just seen, who seems to be lost. At the proper time he lets the old woman into the room, who immediately turns her back to the company and begins to search for the key-hole. The boy who plays the old woman should make her as short as possible, by stooping and keeping the broom as low as he can.

The old lady looks from one side of the door to the other, and not finding the key-hole she looks a little higher, and keeps on higher and higher—the boy, of course, all the while lifting the broom, until she presents the ludicrous figure seen in fig. 2. As if disgusted with not finding what she is in search of, at the top of the door, she suddenly

tracting. A boy who enters into the spirit of the thing can make it exceedingly funny. It must be so arranged that the upper garment, or shawl, attached to the broom,

Fig. 2.—THE KEY-HOLE CAN'T BE SO HIGH.

shall not be lifted above the top of the lower one, and thus disclose the hidden boy and the simple "machinery."

Aunt Sue's Puzzle-Box.

NUMERICAL ENIGMAS.

- 1. I am composed of 39 letters.
 - My 4, 16, 6, 11, is used by soldiers.
 - My 10, 9, 7, is used by men for one purpose, and by ladies for another.
 - My 18, 14, 20, is a body of water.
 - My 13, 27, 15, 19, is an herb.
 - My 17, 24, 12, 28, 29, 22, is a girl.
 - My 23, 26, 14, 25, 5, 30, is worn on the head; so is my 1, 2, 8, 18.
 - My 3, 2, 21, 22, is a season.
 - My whole is a proverb. BAYARD W. PURCELL.

Fig. 3.—HAS THAT KEY-HOLE DROPPED UPON THE FLOOR?

shrinks—boy drops the broom—to the original stature of fig. 1, and begins the hunt again. After trying awhile the old lady thinks that the key-hole may have fallen to the floor, and she suddenly elongates herself in that direction, giving a sweeping glance as in fig. 3, and as quickly con-

- 2. I am composed of 19 letters.
 - My 16, 6, 7, 14, 4, is a river in Indiana.
 - My 3, 15, 10, 18, 2, 13, is a town in North Carolina.
 - My 9, 18, 13, 4, 8, is a bay in North America.
 - My 12, 17, 18, 19, is a town and a kind of bark.

My 19, 11, 10, 9, 1, 5, 15, 8, is a town in Tennessee.
My whole is something nice to work.

SHOE FLY.

BLANKS.

(Fill the following blanks with words pronounced alike but spelled differently.)

3. He _____ of them.
 4. Ask _____ to _____ that tree.
 5. An _____ man made an _____ of his cigar.
 6. The _____ did not lose a _____ of grain.
- THE ITALIAN BOY.

Boys' and Girls' Pictures—More Prizes.

It is very pleasant to think that a great many of the *Agriculturist's* boys and girls are at work upon the same thing. We had a grand time over the map prizes, and we wish to "keep the ball a-rolling." So I make some more propositions. Here are two pictures, one of which I call the Boys' Picture, and the other the Girls' Picture. Each picture tells a story. It may say one thing to you, and another to me. Let us see what stories we can get out of these pictures. Premiums for excellence will be offered below. Write out some little story that you think

ANSWERS TO PUZZLES IN THE JANUARY NUMBER.

CHARADE.—Turnkey.
OMISSIONS.—Boston.

PL.—Sloggards cause their own misfortunes.
REBUS.—Who aims by industrious efforts to live,
May make a character no one can give.
CATS.—Catalogue. Cat-o-nine-tails. Catacomb. Cat-echism.

AUNT SUE'S NOTICES TO CORRESPONDENTS.

JERE PLUMER. You are head of the class this month with your good long list of answers.

E. R. JACKMAN. Of course, I "like to get answers to the puzzles." How else should I know that my friends "enjoyed solving them"?

HARRY M. D. It is scarcely fair to make *pi* of "schmeacase" and "baughnaagbclaoghber;" our folks are not all insnred.

MARK W. You can write on both sides of your paper, as I re-write everything sent to the PUZZLE BOX. For rebuses it is only necessary to write the characters thus — Tooth hat B rye T world witch nose nose eye on fan C swings eye (long) 2 fly.

"To that bright world which knows no sigh,
On fancy's wings I long to fly."

Our artist will dress it up for you *secundum artem*. If your "straight line" be horizontal, where is the difficulty with the "perpendicular"?

J. M. S. The same "Aunt Sue," but not there now.

JESSIE D. You can get both *Hearth and Home* and *Agriculturist* for four dollars a year.

NOTICE.

Once more I must request puzzlers to refrain from sending enigmas constructed upon the names of our papers, or of any of the editors. Also, let me assure them, that as a groundwork for a puzzle of any kind "Honesty is the best policy" is entirely used up.

Glad to hear from Henry Mulford, F. W. Hall, Horace H., Mrs. H. J. N., O. A. G., E. R. J., Mary W. C., Ellie F. M., Sam J. F., and Collie.

Thanks for puzzles, etc., from Harry M. D., N. G. D., C. H. R., W. S. H., H. S., F. W. R.

the picture illustrates. Do it all yourself, the best you can, and do not let the story be longer than four pages of note paper, or two pages of letter paper. It may be as much shorter as you please. Let us see how many story-writers we have among our Boys and Girls. If I think any of them are so good that the rest of "the family" would like to read them, they will be published. Here are the premiums:

THE BOYS' PICTURE.

Boys of 12 and not over 16.

First Prize—Miltum-in-Parvo Knife.

Second Prize—A Book.

Third Prize—A Book.

Boys under 12.

Three prizes, each of a book.

THE GIRLS' PICTURE.

Girls of 12 and not over 16.

First Prize—Gold Pen.

Second Prize—A Book.

Third Prize—A Book.

Girls under 12.

Three prizes, a book each.

The premium articles will all be of the first quality. The knife and gold pen sell at \$3.50 each. The books shall be new, useful, and interesting, just such as any wide-awake boy or girl will be glad to have. *Mind these conditions:* It is not expected that the boys will write about the "Girls' Picture," nor the girls about the "Boys' Picture." This trial is to be boys against boys, and girls against girls. In the map trial it was an open field without regard to sex. The stories must be written upon one side of the paper only, and in black ink. I can not spend time in making out rubbed pencil-marks, and young folks should avoid the folly of red and other fancy inks. They must reach me on or before May 1st. They must be directed to "The Doctor," 245 Broadway, and not to Orange Judd & Co., or to any one else. Each one must give his or her full name and age. There! The publishers allow me to make these very generous offers, and now let us have a fine lot of responses.

THE DOCTOR.

American Organs!

THE SMITH AMERICAN ORGAN CO. have now completed their TWENTY-FIRST year of business, with a constant and still increasing growth. As the manufactory is one of the oldest, it also ranks among the highest in the country. During the long experience of the manufacturers, they have steadily added to the capacity of their instruments, and have availed themselves of every method to improve the quality of tone, and to increase the mechanical facilities for the performer. And though they expect to continue the course of improvement, they are abundantly satisfied with what has been done, and with the estimation in which their instruments are held by good judges of music.

As heretofore, they will use

THE BEST MATERIALS, without regard to cost, and give to every organ the Most Thorough Workmanship.

They especially invite comparisons as to the quality and volume of tone, and as to effective mechanical appliances. They call attention to the fact that their organs are sold AT EXTREMELY LOW PRICES, as low as is charged for many of an inferior sort. Having a large and thoroughly appointed manufactory, employing none but skilled workmen, and having made a minute division of labor, they are able to produce organs at less rates than most competitors.

They believe, also, that among other things they have earned a reputation for fair dealing, and they would assure distant purchasers that no organ will ever leave their warehouse, WITH THEIR KNOWLEDGE, that is not in every respect perfect of its class.

As they have before stated, they intend to secure

A Friend in Every Purchaser.

*. Their catalogue, with full descriptions and accurate engravings, will be sent free to any address upon application. All necessary information cheerfully furnished.

ARE YOU GOING TO PAINT?

MORE THAN

100,000 HOUSES

HAVE BEEN PAINTED WITH THE

AVERILL CHEMICAL PAINT

IT IS THE BEST

In the world for exterior work upon Cottages, Villas, or Buildings of any kind, whether built of brick, wood, or iron. It is a liquid, ready for use, and requires no oil thinning or drier. Purest white, and any desired shade can be had in packages from one gallon upwards.

Letter Received from Levi Shaw, Trustee of the United Society of Shakers.

MT. LEBANON, N. Y., Sept. 27th, 1871.

RESPECTED FRIENDS: In reply to your inquiry as to what we think of the Averill Chemical Paint, we have used in our Society at Mount Lebanon some 1,000 gallons. We are very much pleased with it, and until we are convinced that there is something better, shall give it the preference of all other paints. We have used heretofore the (—), (—), and most all other brands of white lead, neither of which have given us perfect satisfaction. Most of it would chalk off after being on some two or three years. This, after three years' experience, we do not find to be the case with the Averill Pure White Chemical Paint. Indeed, it appears just as well as when first put on. I will write you again on the subject when I am not in quite so much of a hurry.

Sample card of beautiful colors, and recommendations from owners of the finest residences in the country, furnished free by the

AVERILL CHEMICAL PAINT CO., 33 Burling Slip, New York, or 118 Superior Street, Cleveland, Ohio.

GEO. PARTRIDGE & CO., St. Louis, Mo.

P. S.—The superiority of these Paints has already brought numerous worthless imitations in the market. We caution the public against using them.

"Dooley's Yeast Powder."

The superiority of this Baking Powder has long been demonstrated by every housekeeper who has used it, and from the steadily increasing demand for a reliable article. The universal expression is that it is the best in the market, and its perfect purity and freedom from deleterious substances warrant the assertion. To those who have never used it, we say give it a trial, and your testimony to its worth will be added to the many thousands of others. Sold by Grocers generally. DOOLEY & BROTHER, 69 New Street, New York, Manufacturers.

IMPORTANT TO

ADVERTISERS.

The best mediums for shrewd advertisers are those which go to the largest number of intelligent, well-to-do readers. The

Christian Union,

EDITED BY

HENRY WARD BEECHER,

Already contains the advertisements of most of the prominent firms of the country; admits no medical, or doubtful, or "blind" advertisements; gives to every business card a conspicuous place in its compact, neat pages (all being either "outside" or "facing reading matter"); and goes to a regular weekly Subscription and Sales List of more than

80,000!

THIS

CIRCULATION

is growing by about 3,000 per week, and, at the usual reckoning, gives advertisers the benefit of more than

400,000 READERS.

The advantages of advertising in such a substantial and growing journal are plain. Apply to

J. B. FORD & CO., Publishers,

27 PARK PLACE,

Rare and Beautiful Flowers and Choice Vegetables

CAN ALWAYS BE OBTAINED BY SOWING

Collections of Flower Seeds by Mail.

The following collections contain the most showy varieties in our large assortment, with full directions for culture. Each packet contains a mixture of the different colors and varieties of its species, so that a greater display can be made at a much less price than when ordered in separate packets.

Collections of Kitchen-Garden Seeds.

A COMPLETE ASSORTMENT OF VEGETABLE SEEDS FOR ONE YEAR'S SUPPLY, FOR A LARGE OR SMALL GARDEN.

The following Collections are made up in the most liberal manner, care being taken to give a sufficient quantity of all the finest varieties and most useful sorts of Vegetables required in the Kitchen-Garden:

- Assortment No. 5 contains 60 varieties, \$3.50
No. 6 contains 40 varieties, 2.00
No. 7 contains 20 varieties, 1.00

For a list of the contents of each Collection, see the Eighteenth Annual Edition of their celebrated Seed Catalogue and Amateur's Guide to the Flower and Kitchen Garden, just published, which will be mailed to all applicants upon receipt of 25 cts.

This is without exception the largest and best Catalogue ever published in this or any other country. It contains 146 pages closely printed matter, besides several hundred finely executed engravings of favorite flowers and vegetables, and a beautifully colored Chromo of a group of twenty of the most popular flowers in cultivation.

We will send a packet of choice Flower Seeds gratis to persons sending us orders, if they will state the name of the paper in which they saw this advertisement.

Address B. K. BLISS & SONS, P. O. Box 5,712, New York City.

Genuine Wethersfield Onion Seed.

We have just received a fine stock of the above from one of the most reliable growers in Wethersfield, which we offer at prices greatly reduced from last year.

Table with 4 columns: Variety, Price per lb., Price per 1/2 lb., Price per 1/4 lb. Includes Extra Early Red, Wethersfield Large Red, Large Red Oval or Globe, Yellow Danvers (True), White Portugal, White Globe, and Early Cracker.

The above will be sent, post-paid, to any address upon receipt of price. Address B. K. BLISS & SONS, 23 Park Place, and 20 Murray St., New York.

The Best Cucumber for Forcing. GENERAL GRANT.

A superior variety, either for forcing or for culture in the open ground. It is perfect in form, solid, and crisp, and of a most agreeable flavor. Many specimens were grown the past season averaging thirty inches in length.

Moore's Early Concord Sweet Corn. Another year's trial has proved this to be the best Sweet Corn in cultivation.

Selected ears, 25c. each; packet, 25c.; quart, by mail, 90c. Address B. K. BLISS & SONS, P. O. Box 5712, New York.

LATE ROSE POTATO.

This valuable Potato, which is now for the first time offered for sale, differs from all other varieties so far introduced, inasmuch as it is not claimed to be a new seedling, but a sub-variety or sport of the well-known Early Rose, which it strongly resembles in quality, color, and form—but is three weeks later, hardier, and more productive, having yielded the past season 250 to 300 bushels to the acre.

Our Illustrated Potato Catalogue will be mailed to all applicants. Address B. K. BLISS & SONS, 23 Park Place, and 20 Murray St., New York.

LAWN GRASS SEED.

By the use of our improved mixture, a beautiful Lawn may be made in a very short time. For preparing a Lawn, and subsequent management, see our Seed Catalogue.

B. K. BLISS & SONS, Nos. 23 Park Place and 20 Murray St., New York.

PEERLESS POTATO.

Another season's trial confirms more fully than ever all that has been said heretofore in favor of this wonderful Potato. We have favorable reports from customers in every section of the country, whose crops have averaged from 100 to 150 BARRELS TO THE ACRE.

By mail, post-paid, four pounds for \$1. By express or otherwise, \$1 per peck; \$2 per bushel; \$5 per bbl.; 6 bbls., \$25. Early Rose, Climax, Early Goodrich, and others at market prices. For sale by

B. K. BLISS & SONS, P. O. Box 5,712, 23 Park Place and 20 Murray St., N. Y.

Lane's Improved IMPERIAL SUGAR BEET.

This superb variety is the result of a careful selection for several years past of the French Imperial Sugar Beet, by Mr. Henry Lane, an experienced farmer of Cornwall, Vt. After a satisfactory trial, we can recommend it with the greatest confidence, as being harder, more productive, and containing a greater percentage of sugar than the ordinary variety, and much better adapted for cultivation in this country, either for stock or the manufacture of sugar.

Four pounds is the amount usually required for one acre.

See remarks respecting this variety in the February No. of the Am. Agriculturist.

We have purchased the entire stock of Mr. Lane.

Price, 15 cents per ounce; 40 cents four ounces; \$1.25 per pound.

B. K. BLISS & SONS, No. 23 Park Place, and 20 Murray St., New York.

Bliss's Improved Long Orange Carrot.

This superior variety is the result of a careful selection, for successive years, of the best-formed, largest, and deepest-colored roots of the Imported Long Orange Carrot, by which it has attained a perfection hitherto unknown in this useful vegetable, being larger, better flavored, and of a deeper orange color, and more sure to produce a crop.

B. K. BLISS & SONS, P. O. Box 5,712, New York.

BRESEE'S Peerless Potatoes.

For sale by the originator. Excellent in quality, shape, and color, and a very large yielder. \$4 per barrel, delivered at R.R. depot.

Early Rose and Prolific at same price. ALBERT BRESEE, Hortonville, Vt.

Cabbage, Onion, Squashes.

I have written three works on the cultivation of each of these vegetables. They abound in engravings, and go into all the minute details so exceedingly valuable to a beginner. Each book 20 cents. Sent by mail. JAMES J. H. GREGORY, Marblehead, Mass.

The Premium Sanford Corn.

FIVE REASONS WHY it is superior to all other varieties: 1st, It ripens early—often from two to three weeks in advance of other kinds. 2d, Tested in many States in same field with other noted varieties having the same chance, it has produced from one third to double the quantity per acre. 3d, It has a small cob, deep, broad grain, capping over the ends. 4th, It will do better on all soils than any other. 5th, The great superiority in the quantity and quality of fodder it produces, North, South, East, and West, testifies to its great superiority.

SEED POTATOES.—Peerless.—The potato for the million. In size and productiveness unequalled, in quality not excelled. NEW DESCRIPTIVE CATALOGUE.

and flower seeds worthy of cultivation, and the seeds are offered at very favorable rates.

Seed in pkts. amounting to \$1.15 for \$1.00, and \$2.35 for \$2.00.

Read my advertisement in Jan. and Feb. Nos. Am. Agriculturist, pages 50 and 71.

Or, for 20 cents, my Catalogue and 20c. worth of Seeds, free by mail. It contains about all the varieties of vegetable and flower seeds worthy of cultivation, and the seeds are offered at very favorable rates. Seed in pkts. amounting to \$1.15 for \$1.00, and \$2.35 for \$2.00. Address H. E. ACKER, Seed Grower, Woodbridge, N. J.

Head-Quarters Mammoth Dent Corn.

This corn having proved superior to other varieties in the following respects, we think every farmer should have it. It is the largest early field variety in the country. It will yield more, shell more, weigh more, fill better at both ends of the ear, has greater depth of grain, and will do better on all kinds of soil, than any other variety.

Price of selected ears, by mail, 50 cents each. Two pounds, 75 cents; four pounds, \$1.00. One peck, by express, \$1.75; half-bushel, \$2.50; one bushel, \$4.00; two bushels, \$7.00; five bushels, \$15.00.

No corn sent C. O. D. Send stamp for circular. Address

ISAAC N. BALTHIS, Box 59, Corydon, Ind.

Choice Onion Seed

Every old onion-raiser knows that the difference in value of a crop of onions raised from seed of average quality, and one raised from onions that have been most carefully hand-picked each year for a long series of years, is from fifty to a hundred dollars. The seed I offer is of my own growing, and has had its reliability of yielding choice onions, free from scullions, as fully proved as are the traits in any of the purest bred animals. My catalogue has recommendations from twenty farmers who have used my seed, and so know all about it. Catalogues sent free to all.

JAMES J. H. GREGORY, Marblehead, Mass.

Peach Tomato.—New, and the handsomest and best shaped grown. 100 seeds, 25c. Eugene Winter Squash.—Said to be a variety of the Valparaiso. Very sweet and rich flavored. Pkt., 15c. Silver Maple Seed.—The best quick-growing tree for fuel, shade, or ornament. Oz., 10c.; lb., \$1. All by mail, post-paid. Send for descriptive circular to J. M. BENTHALL, Quasqueton, Iowa.

SEED POTATOES.

I will deliver Peerless, Early Rose, Prolific, or Climax Potatoes at the R.R. depot, as soon as the weather will admit, in the spring, for \$3 per bbl.; five bbls. or more, \$2.50 per bbl. All warranted genuine. FRANK QUA, North Granville, Washington Co., N. Y.

EARLY ROSE and Early Mohawk Potatoes, \$1 per bush. Peerless, \$1.25 per bush. Charles Downing Strawberry plants, \$2.50 per 1,000. Boyden's No. 30 and Kentucky, \$4 per 1,000. Albany Seedling, \$3 per 1,000. SAMUEL C. DE COU, Recklesstown, Burlington Co., N. J.

NANSEMOND SWEET POTATOES for seed! \$2 for 1/2 bushel—bottom prices on large lots. Plants in May \$2 per 1,000. Send for "Directions for Sprouting," etc. W. W. RATHBONE, Marietta, Ohio.

HOP PLANTS.—A specialty. For Circular and price, address E. FRANCE, Cobleskill, N. Y.

BOSTON MARKET MELON.

ASPARAGUS, Moore's Premium. This variety is now well known in Boston and vicinity as the largest and finest in every respect, without exception, in cultivation. Cant. Moore has taken first prizes for his celebrated Asparagus every season for the past ten years, at the Exhibition of the Massachusetts Horticultural Society. Per oz., 50c.; per pkt., 25c.

BEETS, Egyptian. Very fine. Per pkt., 10c.

Hatch's Early Extra Blood-Turnip. This is an improved variety, both in earliness, smoothness, and fine quality, for table use, and is a favorite with the growers of fine early vegetables for the Boston market. The seed we offer is from the stock which received the first premium awarded. Per lb., \$1.50; per oz., 20c.; per pkt., 10c.

Dewing's Early Turnip. This is a new and superior blood-beet, recently introduced. The roots are of a fine globular shape, uniformly smooth, with long, slender tap-root. Skin dark purplish black; flesh deep blood-red; very fine grained, tender, and sugary; very early. Excellent for the table. Per lb., \$1.50; per oz., 15c.; per pkt., 10c.

New Chilian (for decorative purposes). This striking novelty is specially adapted for bedding purposes, the foliage presenting a variety of color, from bright orange to purplish crimson; used extensively at the Battersea and other Metropolitan Parks. Per pkt., 25c.

Carter's Perfection Salad. Small-sized, short-top variety, of delicate texture, and sweet flavor, even growth, and dark foliage. The best variety for salad purposes. Per pkt., 25c.

BEANS, Australian Runners. This variety, introduced by Mr. Jos. Tully, has proved remarkably productive, and given the best of satisfaction. The pods are from nine to twelve inches in length, and about one inch in breadth. Very early, coming in with the early Six Weeks, stringless, and when cooked very delicious. Price per pkt., 25c.; per qt., \$1.

CAULIFLOWER, Boston Market. Very early. Produces uniformly large and fine solid flowers, or heads, of snowy whiteness and excellent flavor. Weight of specimen, seven and a half pounds; diameter, ten and a half inches; circumference, thirty-one inches; length of foliage, twenty-nine and a half inches. Per oz., \$1.50; per pkt., 25c.

CELERY, Boston Market. A favorite variety in the Boston market; remarkable for its tender, crisp, and excellent stems, and its peculiarly mild flavor. It is extensively cultivated by the market-gardeners around Boston, and surpasses any other variety for its great excellence. Per pkt., 10c.; per oz., 50c.

CORN, Moore's Early Concord. SILVER MEDAL AWARDED. This valuable variety of Corn, which we had the pleasure last season of introducing, we now bring before the public with renewed confidence. It has proved all and more than we recommended. We have received hundreds of testimonials, which will be found in a circular, to be had on application. Per pkt., 25c.; selected ears, 25c.

KALE, Acme. A very dwarf curled Kale, growing close on the ground, with glaucous green leaves intersected by a scarlet mid-rib. Really a superb thing, and combines every desideratum, being very hardy, very early, prolific, tender, mild, and a brilliant green when boiled. It is a hybrid between Dwarf Green Curled Borecole and Sea Kale. Per pkt., 25c.

LETTUCE, Bunney's Incomparable Hardy Green Cos. The raiser of this says: "I have tried it with all the leading kinds of lettuces; but none are equal to it. You may grow it for any time of the year, as it is very hardy, and has stood the drouth of the last season when other sorts 'bolted.'" A compact, large-growing, crisp variety, of fine flavor. Per pkt., 25c.

MELON, Boston Market. Persons wishing a fine melon will find this superior to any other in all respects, either for family or market purposes. Fruit nearly round, but flattened slightly at the ends; deeply, and very regularly ribbed; size medium; skin green, and thickly netted. When fully mature, the green becomes more soft and mellow, or of a yellowish shade. Flesh thick, very juicy, and of the richest and most sugary flavor. It is an abundant bearer, quite hardy, and remarkably uniform in its quality. Per oz., 50c.; per pkt., 15c.

SMILAX. A beautiful winter climbing plant, adapted alike to the greenhouse and conservatory. Nothing can excel this plant in beauty of foliage and orange fragrance of the flowers. It is extensively used for bouquets and floral decorations of every description. Large sized bulbs, 50c. each. Extra sized bulbs, \$1 each. Seed, per pkt., 25c.

NOTE.—This plant is grown and used most extensively as a decorative vine by every florist in the vicinity of Boston. No lady dressed for a party feels her toilet complete (if natural flowers are worn) without a spray of Smilax appended to her hair.

For further descriptions, see

AMATEUR CULTIVATOR'S GUIDE TO THE FLOWER AND KITCHEN GARDEN.

We are pleased to announce that the 26th Annual Edition of this well-known work is now ready, enlarged and improved, and containing a magnificent new colored Lithograph, besides hundreds of Engravings, in addition to its full descriptive Price-list of 3,000 varieties of choice Flower and Vegetable Seeds, Rare Gladiolus, Lilies, Tuberoses, etc., with full directions for their culture. This is, without doubt, the most perfect work of the kind before the public. Sent free to applicants upon receipt of two stamps. Address

WASHBURN & CO., Boston, Mass.

To Farmers and Gardeners.

I invite all who have been in the habit of buying their garden seed from boxes left at the stores to give my seed a trial, side by side, and mark the difference to their germination, and in the purity and quality of the vegetables raised from them. I have made it my mission for several years past to drive bad seed from the market, and so save farmers and gardeners the immense loss they annually suffer from the purchase of it.

The public have well appreciated my efforts, and I have now fifty thousand customers in the United States and Canada. I sell no seed I do not warrant, and what is the real pith of the matter I stand by my warranty. To enable me to do this I grow myself a large proportion of the seed I sell. Catalogues sent free to any applicant.

JAMES J. H. GREGORY, Marblehead, Mass.

GEN. GRANT CUCUMBER.—Grows from 25 to 30 inches long; enormous bearer; unsurpassed for table use or pickles; 20c. per packet. SANFORD COIN.—Yields 150 bushels per acre; 1 qt., 50c.; 4 qts., \$1.50, post free. PEERLESS POTATOES—1 lb., 60c., post free. G. W. WILSON, Auburn, Ohio.

NEW AND RARE VARIETIES OF VEGETABLE SEEDS.

WASHBURN & CO., 100 Tremont Street, Boston, Mass.,

Take pleasure in offering, post-paid, by mail, on receipt of prices annexed, the following choice varieties:

"CORN IS KING!"

COOLEY'S EARLY WHITE FIELD CORN!

The Earliest Large Corn in America! Corn planted in Ohio May 3d—crop gathered and ground into meal August 9th, only fourteen weeks from planting! In Minnesota, in thirteen weeks. Will yield as much per acre as the celebrated Chester County Corn (which is said to be the most productive corn in the U. S.), while it is two months earlier! thus escaping the drouth and early fall frosts. Send stamp for circular, giving testimonials from some of the best farmers in the Union. This Corn (shelled) weighs 62 lbs. per bushel.

PRICES.—One peck, by express or freight, \$2; one quart, by express or freight, 50c.; one quart, by mail, post-paid, 75c.

Address all orders to C. C. COOLEY, P. O. Box 95, Manchester, Adams Co., Ohio.

VAN SICKLEN COLOSSAL ASPARAGUS. THE LARGEST AND BEST.

Plants, \$1.50 per 100; \$10.00 per 1,000. Seed, \$4.00 per lb. For sale by JAMES THORNTON, Byberry, Philadelphia, Pa.

GARDENING MADE EASY FOR THE MILLION.

ONLY TEN CENTS! Really worth Ten Dollars! Inclose 10c., and 2c. stamp for postage. J. C. THOMPSON, Tompkinsville, N. Y. (Staten Island.)

CHOICE VEGETABLE SEEDS. NEW AND RARE FLOWER SEEDS.

Our LARGE ILLUSTRATED CATALOGUE, containing prices and full cultural directions, mailed to all applicants on receipt of 10 cents. Seeds mailed to any address in the United States, at Catalogue rates, postage free.

Mammoth Dent Corn. THE BEST IS NEVER TOO GOOD.

The Mammoth Dent Corn is the largest early field corn produced in America. For large ears, depth of grain, and well filled at both ends, it far surpasses any other. Bee Journal, Having been a partner of I. S. Balthus, in introducing this corn, I will supply the genuine article, owing to the pressure of the times, at the following rates: 100 lbs. by mail, post-paid, 85c.; one peck, by express, \$1.50; half-bush., \$2.25; one bush., \$3.50, or two bushels for \$6.00. Send stamp for circular. Address HENRY DENBO, Box 34, Corydon, Harrison Co., Ind.

HOVEY & CO.'S ILLUSTRATED

Seed Catalogue,

1872, 150 pages. Sent to customers free; to all others for ten cents, not half cost. The most extensive Seed Catalogue published. All seeds warranted to reach Purchasers. HOVEY & CO., 53 North Market St., Boston, Mass.

THE HANSON LETTUCE.

The above cut represents a sectional view, showing the inside of this truly superior Lettuce. The heads are remarkably large, deliciously sweet, tender, and crisp, even to the outer leaves. Price, per packet, 25c.

Bastian's Extra Early Beet.—The perfection of a Beet, being very early, of quick growth, fine turnip-rooted form, and good color, a profitable variety for the Market-Gardener, and one of the best for family use. Per lb., \$1.50; per oz., 20c.

Bastian's Half-Long Blood Beet, in color, shape, and size, is all that can be desired in a Beet. A valuable variety to follow after the preceding one. Per lb., \$1.50; per oz., 20c.

Dark Red Egyptian Beet.—A small, early variety. Flat, dark blood color. Per lb., \$3; per oz., 30c.

Philadelphia Flat Dutch Cabbage.—Extra selected. A profitable variety. Per lb., \$3; per oz., 30c.

Philadelphia Late Drumhead Cabbage.—Per lb., \$3; per oz., 30c.

Boston Market Celery.—A dwarf solid variety. Per oz., 50c.; per packet, 10c.

Conover's Colossal Asparagus.—Per lb., \$3.00; per oz., 30c.

Leshor's Mammoth Asparagus.—Per lb., \$1.00; per oz., 20c.

Early White Curled Endive.—Self-blanching; very fine, large, and extra curled. Per oz., 50c.

Cauliflower Le Normand.—The finest variety. Short-stemmed. Per oz., \$2.50; per packet, 25c.

Trophy Tomato.—Our own saving, from extra large selected fruit. Per oz., \$3; per packet, 20c.

Tomato.—The Cook's Favorite, Tilden, and Feejee Island. Per oz., 40c.; per packet, 10c.

Tomato.—Philadelphia Market and Gen. Grant. Per oz., 50c.; pkt., 10c.

Onion.—Yellow Danvers. \$3 per lb.; 30c. per oz. White or Silver Skin, \$3.50 per lb.; 30c. per oz.

The above Onion Seed are Philadelphia-grown, the best for sets.

The above are only a few of the many varieties we have for sale, all of which will be mailed free at prices quoted.

1872.

FLOWER SEEDS.

Our stock of flower seeds is unusually large and fine. We make a specialty of this department, and grow many of the leading kinds on our seed gardens and farm. The finest varieties of Asters, Balsams, Carnations, Calceolaria, Cineraria, Cyclamen, Dahlia, Diadem Pink, China Pink, Heart's-Ease or Pansy, Larkspurs, Lobelia, Minulus, Nasturtium, Phlox Drummondii, Petunia, Double Portulaca, Stock Gilly, Verbena, Double Zinnias, etc., etc., etc.

PLANTS, SHRUBS, BULBS, etc.

Every variety for the Garden, Window Garden, Conservatory, and Greenhouse.

DREER'S GARDEN CALENDAR FOR 1872,

With full descriptive lists of our stock, will be mailed to all upon receipt of a postage-stamp. Address

HENRY A. DREER,
Philadelphia, Pa.

Fottler's Improved Brunswick Cabbage.

This fine Cabbage, originally introduced by our Mr. Schlegel, and perfected in size and form by Mr. Fottler, father of the junior member of our firm, still maintains its superiority for general culture over all other cabbages at present known.

The accompanying cut was drawn and engraved from a fair average specimen of our seed stock crop of 1871, and is a faithful representation of the variety as sold by us. It is a rapid grower, and uniformly productive of large, handsome, solid heads, on short stems, with but few outside leaves. Early planted, it is ready for use in July and August. Later planted, it is in use throughout the winter. We offer seed of this fine variety, and a general assortment of other seeds, in quantities suited to the requirements of purchasers.

The specialty of our business is furnishing seeds of extra quality suited to the requirements of Market-Gardeners and others. Our seeds are grown from the choicest stocks and in the most careful manner, and we knowingly deal in no other.

Catalogues of varieties and prices sent free to all who apply for them.

Address

SCHLEGEL, EVERETT & CO., 16 S. Market St., Boston, Mass.

English Acorns, for Seed.—This variety of White Oak is celebrated throughout England for ornamental and useful purposes. The growth is pyramidal, instead of branching like other varieties of oak. Our stock is kept in the finest condition for planting. One quart of Acorns, by mail, post-paid, for 60 cents. Price per bushel on application. Address

CURTIS & COBB,
161 Tremont St., Boston, Mass.

Having been the first to introduce to the public the Hubbard Squash, American Turban Squash, Marblehead Mammoth Cabbage, Mexican Sweet Corn, Philney's Watermelon, Brown's New Dwarf Marrowfat Pea, Boston Curled Lettuce, and other

New and Valuable Vegetables,

with the return of another season I am again prepared to supply the public with Vegetable and Flower Seeds of the purest quality. My Annual Catalogue is now ready, and will be sent free to all. My customers of last year will receive it without writing for it. It abounds in fine engravings, many of which were taken from photographs of the vegetables themselves. It has not only all novelties, but the standard vegetables of the farm and garden (over one hundred of which are of my own growing), and a carefully selected list of Flower Seeds. As stated in my Catalogue, all my seed is sold under three warrants—1st: That all money sent shall reach me. 2d: That all seed ordered shall reach the purchaser. 3d: That my seeds shall be fresh, and true to name. Catalogues free to all.

ESSEX PIGS.

Last year, several readers of the *American Agriculturist* purchased Essex pigs from me.

So far as I have heard, they have given good satisfaction. I keep only pure Essex, and breed them with great care. Last spring, I could not fill all my orders, and, much to my own regret and the loss of the intending purchaser, was obliged to return the money.

This spring I expect to be able to furnish very superior pigs, and shall be glad if those wishing to buy pure Essex from me will order early.

Address **JOSEPH HARRIS,** Moreton Farm, Rochester, N. Y.

Essex Pigs. Blood of recent importations. Pigs of all ages. From my first premium herd.

White Leghorn fowls, bred with care for past 8 years. **G. W. FARLEE,** Cresskill, N. J.

Thorough - bred Stock.

L. A. CHASE, 245 Broadway, N. Y.

Valuable Premiums.

(See also page 84.)

Any person, anywhere, can obtain one or more of the valuable premium articles in this table, without money, by simply gathering a few names for one or both of the papers.

As a **constant Business Employment**, some persons canvass all the time, receive the premium articles, and sell them for cash, and thus secure large salaries. One lady has averaged over **\$3,000 a year** for years past, and others are getting large pay for their time, often **\$5 to \$20 a day**. Some who did poorly at first have, by perseverance, acquired the art of canvassing, and become very successful. The work is honorable. The Journals are useful in every family—in **City, Village, and Country**.

The *American Agriculturist* is everywhere known and approved. **HEARTH AND HOME** is now without a superior in the world as a splendidly illustrated Weekly Newspaper, for real value, cheapness, and adaptability to every home in America. The papers are entirely different. Taken together, they supply over **\$35,000** worth of fine engravings, and more good reading than can be found in **100** books costing one Dollar each.

Premium Clubs can be made up of subscribers to either paper, or partly of both, as noted over the Table. We call **especial attention** to the last column of figures, showing the small number of names required where both papers are taken, at the reduced price of \$4 a year.

You, Reader, can get a Premium. TRY IT.

Explanatory Notes.

Read and carefully

Note the following items:

- (a) All subscribers sent by one person count, though from one or a dozen different Post-offices. But... (b) Tell us with each name or list of names sent, that it is for a premium....
- (c) Send the names as fast as obtained, that the subscribers may begin to receive the paper at once. You can have any time, from one to four months, to fill up your list.... (d) Send the exact money with each list of names, so that there may be no confusion of money accounts.... (e) Old and new subscribers all count in premium clubs....
- (f) Specimen Numbers, Cards, and Show-bills will be supplied free as needed by canvassers, but they should be used carefully and economically, as they are very costly.... (g) Remit money in Checks on New York Banks or Bankers, payable to order of Orange Judd & Co., or send Post-office Money Orders. If neither of these is obtainable, Register Money Letters, affixing stamps both for the postage and registry; put in the money and seal the letter in the presence of the Post-master, and take his receipt for it. Money sent in any of the above ways is at our risk; otherwise it is not.

In the following table is given the price of each article, and the number of subscribers required to get it free, at the regular rates, \$1.50 and \$3.00 a year, for the two papers; also at the club rates of \$1 and \$2.50; also at the rates of \$4 a year for both papers together.]

N. B.—In all Premium Clubs for either paper, **TWO** copies of *American Agriculturist* at \$1.50 each, and **ONE** copy of *Hearth and Home* at \$3.00, will count exactly the same. So also **TWO** copies of *American Agriculturist* at \$1 each, and **one** copy of *Hearth and Home* at \$2.50, will count exactly the same. In this way Premium Clubs can be made up from the 2nd and 4th columns, or from the 3d and 5th, or wholly from the 6th column.

Table of Premiums and Terms,
For American Agriculturist,
and for Hearth and Home,
for the Year 1872.

Price \$35,000; one sixth cash, and balance in five equal annual installments, with interest. Send stamp for *Tennessee Land Register.* Large list of all kinds of property for sale, and interesting information about climate, etc. Address **MUNSON & BAILEY,** Real Estate Agents, Knoxville, Tennessee.

RHODODENDRONS.
 For prices of both seedling and grafted plants, apply to **PARSONS & CO.,** Flushing, N. Y.

The First Division of the
ST. PAUL & PACIFIC RAILROAD COMPANY

Offer for sale **1,500,000 Acres of Land**

Along their lines of Railroad. Also, **TOWN LOTS**

In twenty flourishing Towns and Railroad Stations.

ACTUAL SETTLERS can purchase on **long credit** with 7 per cent annual interest. *The Bonds of the Company taken at par on Cash Sales.* For Descriptive Pamphlets, Prices, and other information, apply to **HERMANN TROTT, Land Commissioner.**
General Office at St. Paul, Minnesota.
 Mem.—Attention is called to Government lands on the west end of the Main Line, which can be taken under the Homestead Law.

900,000 ACRES OF EXCELLENT FARMING AND SELENDID Michigan Pine Lands FOR SALE,

On which are **ONE THOUSAND MILLIONS OF PINE TIMBER,** and inexhaustible quantities of Maple, Beech, Elm, Ash, Hemlock, Oak, etc.

The grant of lands to the Grand Rapids and Indiana Railroad Company, to build their Road from Fort Wayne, Ind., to Traverse Bay and Mackinaw, Michigan, comprises in its farming lands every variety of soil, from the rich clay loam to the light sandy, and they are found in that section of Michigan, north of the city of Grand Rapids, and contiguous to the great fruit belt on the eastern shores of Lake Michigan, now being rapidly developed by railroad and other enterprises.

Farming Lands are sold to actual settlers, on credit, one quarter down, balance in yearly payments, interest 7 per cent. Persons desirous of locations for farms will, on application at the **Office in Grand Rapids,** be furnished with **Tickets over the Road,** entitling them to **Return of Fares,** in the event of purchasing any of the Company's farming land. For information about the lands, prices, location, etc., address

WM. A. HOWARD, Land Commissioner.
 TITLE PERFECT. Grand Rapids, Michigan.

For Sale, a Good Farm, Stock, etc.

My farm, estimated to contain fifteen hundred acres, lying in Cumberland Co., Va., in sight of the James River and Kanawha Canal, fifty miles above the city of Richmond, Va., good grain, grass, and tobacco land, good buildings, orchard, etc. Perfectly healthy. Price for land, crops, team, cattle, hogs, sheep, provisions, provender, and farming utensils, Twenty-eight Thousand Dollars. One half cash, and the balance in equal annual installments of one, two, three, and four years, with interest. Apply in person, or address me at Cartersville P. O., Cumberland Co., Va.
JAMES MILLER.

NO FREEZING—NO SNOWS—RIPE ORANGES AND GREEN VEGETABLES AT DAYTONA, FLORIDA.

For Cheap Lands and Homes, inquire of **M. DAY, Jr., Mansfield, Ohio.**

FOR SALE.—THE TROUT FARM of the subscriber, at Bristol, Ct. Six acres of land and water, two thousand adult fish, twelve thousand impregnated spawn, hatching-house, dwelling-house, and all necessary apparatus. Terms moderate. Address **F. C. CREVELING, Bristol, Ct.**

RUSTIC WORK.

Made from Natural Growth of Wood.

The most attractive, ornamental, and durable embellishment of the garden and portico in summer, and for window decorations in winter. Our manufactures include every style, as

- Rustic Vases,
- Hanging Baskets,
- Bird Cages,
- Rustic Chairs,
- Settees,
- Tables, etc., etc.

Having the most extensive manufactory in the United States, we are prepared to fill orders of every kind, from a single bird-cage, to the complete furnishing of a park with rustic work.

Send for Illustrated Circular and Price-lists. Address **JAMES KING, New Haven, Ct.**

DEAFNESS.—A newly-invented acoustic pocket instrument with which to hear public speaking or conversation. Recommended by thousands who use them. Address **H. MANSFIELD, Book Publisher, 43 Sachem St., New Haven, Ct.**

W. A. COVERT & CO., Produce Commission merchants, No. 63 Pearl Street, New York. "Quick sales and prompt returns." Send for our weekly Price-current and Marking Plate.

Calendar for April.

Table with columns for Day of Month, Day of Week, and Moon phases for Boston, N.Y., Wash'n., and Chicago. Includes sunrise, sunset, and moonrise data.

PHASES OF THE MOON. Table with columns for MOON, BOSTON, N. YORK, WASH'N., CHICAGO. Includes New Moon, 1st Quart., Full., 3d Quart. data.

AMERICAN AGRICULTURIST. NEW YORK, APRIL, 1872.

At the present writing, it is impossible to form any definite opinion as to the condition of the winter wheat crop. So far as our observations extend, the indications are generally unfavorable. Throughout a large extent of our country the soil last autumn was remarkably dry, and when winter set in the wheat looked small and thin on the ground. We are disposed to think, however, that the wheat had made a good root growth, and that the plants on good land were healthy, hardy, and vigorous. On our own farm the wheat is apparently uninjured. The weather-wise people are telling us to look out for a wet summer. Of course they know nothing about it. But we will unite with them in advising the farmer readers of the American Agriculturist to look out for wet weather—and prepare for it. We do not base this advice on the fact that we have had and are still having a great drouth, and therefore that it is reasonable to expect a great rain. There is something in this; but we urge our readers to prepare for wet weather simply because we know that farmers suffer much loss every spring from falling to expect and prepare for rainy days, muddy roads, and wet fields.

We fear this advice will not do much good. Good, prompt, energetic, thinking, sensible farmers prepare for all kinds of weather and for all emergencies; but there are thousands who are constitutionally indisposed to do anything to-day that can be put off until to-morrow. They never clean the leaves or other impediments from the gutters on the roof of the house until it rains; never plow until they are ready to plant, and never get or clean up the seed until the field is prepared and waiting for it. Such farmers rarely get a new plow-point until the old one is worn out, and never get the teeth of the harrows sharpened until the day they want to use them. But why multiply illustrations? Nothing that we can say will rouse such men. All that we can hope for is to persuade young farmers to cultivate the habit of promptness—of doing things at the best time, and especially of disciplining themselves to do first those things which they like to do least. Indolent people often busy themselves in doing something that they specially like to do. We have known a farmer's son too weak to sort potatoes or milk a cow, but quite strong enough to break a colt or feed a thrashing machine.

Hints about Work.

Start the Plow the moment the ground is dry enough, but not before; and where it can be done, harrow and sow as fast as you plow. Do not wait to finish the field. We know there is some loss of time in changing work so often, but it is nothing compared with the extra time and labor required to prepare plowed land that has been exposed to heavy rains, and then had to lie for several days until the surface was crusted over before it was dry enough to harrow. Our springs are so short, and the weather so uncertain, that our rule should be never to leave the field until all the land that has been plowed is harrowed and sown.

Sod Land can be plowed after a soaking rain earlier than fall-plowed or stubbles. And a steel plow will make a clean furrow slice where a cast-iron plow will clog. But it is doubtful whether it is or is not advisable to avail ourselves of these facts. Sod land is just as wet as the stubble land, and if one would be injured by plowing it is not easy to understand why the sod land would not be injured also. It is one of those points, however, on which we need more light. Our own practice is based on the practical fact that we have a good deal of plowing to do and little time to do it in, rather than on any theoretical considerations as to what is the absolutely best condition for the soil to be in when it is plowed. A farmer must not be a "one-idea" man. He has many things to take into consideration, and has need of experience and good judgment. A safe rule is to avoid running to extremes.

Barley is with us the first crop that we aim to sow in the spring. We say "aim," because, in point of fact, it not infrequently happens that we are able to plow a clover sod, and drill in peas or oats, before we can plow a corn-stubble and prepare it for barley. But when the weather is favorable we should get in the barley at the earliest time possible. So good a farmer as John Johnston, however, differs with us on this point. With him, later sown barley has frequently proved a heavier crop than that sown earlier. And in our own experience we have sown part of a field of barley the last day of March, and the remainder of the field a week or ten days later, and the one was as good as the other. But in this case both were "sown early." We have had two crops of barley in different years, one of which was over 50 bushels per acre, and the other 49 bushels, and one was sown two or three weeks earlier than the other; but both were sown as early as possible. We have never had a good crop of barley that was not sown early.

Oats can be sown on a great range of soils, from a black muck to the heaviest clays. Of all the small grains they will stand the greatest neglect, but will repay good cultivation. They are often sown on new plowed sod land, and occasionally do well enough to induce farmers to continue the practice, notwithstanding the fact that in nine cases out of ten the result is anything but satisfactory. Better plant corn on the sod land, and sow oats after the corn. We have seen great crops raised where the land is rich by fall-plowing a corn-stubble, and then sowing as early as the land could be harrowed in the spring, and when the frost was not sufficiently out of the ground to plow. Sod land plowed late in the fall may be got into fair condition for oats by the use of a Shares or Nishwitz harrow, when the sod is not sufficiently rotted in the spring to admit of cross-plowing. When the sod was plowed early, say in August or September, and the land was what we call "fall-fallowed," the sod should be well-rotted, and when plowed in the spring would be in excellent condition for oats, and if the land is rich enough a great crop may be expected. From 2 1/2 to 3 1/2 bushels per acre is the proper quantity of seed, according to the condition and fertility of the soil—the richer the soil, the less seed is required. As a rule, we do not sow oats thick enough, or make the soil sufficiently fine and mellow. When sown with a drill, which is by far the better plan, harrow the land thoroughly, and then roll before drilling, and if there are still any clods roll again after the drill.

Peas in many sections are so much affected by

the pea-beetle, or what is improperly called "the bug," that their culture is almost entirely abandoned. There is at present no known remedy. Getting seed entirely free from bugs, or dipping the seed for a minute in boiling water, are popular remedies, but are not based on any satisfactory reason. Late sowing is to a certain extent a remedy, but the crop is almost invariably a poor one. Better sow as early as possible, and try to raise a great crop, and feed out the crop to pigs before the bug eats out much of the substance of the peas. This is killing the bugs and converting them into pork at the same time. If generally adopted, and our seed obtained from sections free from this insect, we should in time get rid of the trouble. We drill in the peas at the rate of 3 bushels per acre, or $2\frac{1}{2}$ of peas and $1\frac{1}{2}$ bushel of oats. See Hints for March.

Potatoes with the writer do better on a rich clover sod than on stubble land. It is time we paid more attention to enriching the soil for this crop. The labor of digging an acre yielding only 90 bushels, is nearly or quite as great as digging an acre that will yield 280 bushels, and if the soil is in good condition, the latter yield can safely be calculated on, with a good variety, and good cultivation. At average prices, few farm crops pay better than potatoes, provided a maximum yield is obtained. Manure, if thoroughly rotted and well worked into the soil, does not increase the disease. Planting in hills, three feet apart each way, saves seed and labor in planting, hoeing, and digging, and where land is cheap, is undoubtedly the better plan; but planting in drills, three feet one way, and sets dropped from 12 to 15 inches in the row, will, provided the land is rich enough, produce a greater crop per acre.

Clover Seed on winter wheat should be sown early. But we have sown it as late as the middle of May, and had a good catch. Much depends on the season and the condition of the land. We prefer to delay sowing until the ground is dry enough to harrow. A Thomas smoothing harrow is best for harrowing the wheat immediately after the seed is sown, but an ordinary heavy harrow may safely be used to break the crust on the soil before the seed is sown. The most thorough harrowing with a common forty-tooth harrow, early in the spring, provided the soil is dry, will not pull up the wheat to any injurious extent. Such a harrow may be used before sowing the seed, and a Thomas harrow after sowing, with excellent effect.

Grass and Clover Seeds should not be covered more than half an inch deep. Far more seed is lost from covering too deep than from being left wholly exposed on the surface. A fine mellow soil is the great essential condition.

The *Roller* is not used as much as it should be in the spring, though it is sometimes used where it does more harm than good. It is easier to break clods when wet than when dry, but if you can break them when dry, the pulverizing effect is far greater. Clayey land rolled when wet, forms a hard crust. Sandy soil that needs compression, may be rolled when quite moist. No amount of rolling will injuriously pack or consolidate a perfectly dry soil.

See *Hints for last Month*.—We hope every reader of the *American Agriculturist* preserves the numbers. Many of the hints given last month may be found useful now.

Horses, after their winter's rest, should be worked only moderately at first. Look to their shoulders, and wash them frequently with cold water. Poor-fitting collars are the chief source of galls.

Working-Oxen should be well carded every day, and be liberally fed. They have a much larger stomach than a horse, and do not need as concentrated food, but they require more time to eat. Cut the hay into chaff, moisten it, and mix a little corn-meal with it—say one quart of meal to a bushel of chaff. Horses may have two quarts (and at noon three quarts) of meal to a bushel.

Cows need much care and extra feed this month. They are longing for green grass, and he is a fortunate farmer who has plenty of mangolds for them. But bran and good hay, with a good card-

ing every day, to keep open the pores, will keep a milch-cow in good condition, and prepare her for giving a large mess of milk when grass comes.

Raise your own Calves, and let them have good care, nutritious food, and plenty of it, with the kindest treatment. Cows will be high again in a year or two. Good cows are always scarce.

Poultry.—Clean the house, sprinkle with crude carbolic acid and water. Carbolic soap, rubbed on to the roosts, finds its way on to the feathers, and kills the lice. Whitewash all the woodwork, and if a little carbolic acid is added, so much the better. Absolute cleanliness is one great secret of success in keeping poultry. At this season of the year farmers should see that their fowls are regularly fed. There is not much for them to pick up, and it is impossible for them to furnish an abundant supply of eggs without food enough to manufacture them. When the ground is frozen, so that they can not get worms, they should have fresh meat, bones, etc. See that they have plenty of fresh water.

Sheep.—See Hints for last month. Nothing is better for sheep than clover hay. Let the breeding ewes have all they can eat. And those with their lambs at their side should have a pound of bran each per day, in addition, and a few roots, if they can be spared. Make a small pen in the yard, with slats about ten inches apart, or just wide enough to allow the lambs to go through, and put in a few small troughs, and keep the lambs supplied with oats, corn-meal, bran, and sliced roots. This is one secret of raising good lambs. See that the ewes and lambs also have an abundant supply of fresh water. The ewes will drink nearly twice as much water when giving milk as before lambing.

Pigs.—Last fall's pigs should have a liberal allowance of corn-meal and mangolds, to keep them growing rapidly till they can get clover. Breeding sows should be kept in good thriving condition. Succulent food, and bran or fine middlings, are better than corn. It is desirable to keep the bowels somewhat relaxed. Daily exercise is very desirable. The young pigs should be taught to eat from a small trough, separate from the sow, as early as possible, or at any rate when three weeks old.

Rainy Days are usually numerous this month, and there is also abundance of work to be done indoors, such as oiling harness, picking over potatoes, painting implements, machines, wagons, etc.

Clean out the Cellar.—As health is the greatest of earthly blessings, cleaning the cellar from all decaying vegetables and other impurities is the most important work to be done in the spring. Give not sleep to your eyelids until it is done.

Whitewash the cellar walls, pig-pens, sheep-sheds, horse and cow stables.

Pick up the old Iron.—There has been a great advance in the price of iron, and it is a good time to dispose of all the old plow-points, horseshoes, etc.

Make the whole Premises clean.—We have "house-cleaning" every spring; let us have stable, barn, and barn-yard cleaning also. Leave not a particle of manure scattered about the yards. Either apply it to the land at once, or pile it in a heap.

Work in the Horticultural Departments.

In most of the Northern States April will be the earliest month for out-door work, and all gardeners will find plenty to do in preparing the soil and sowing seeds for early crops. If seeds and tools have been provided and everything prepared for early work, no delay need occur. Work should always be planned before actual operations commence, so that if a rainy day comes once or twice a week, the work need not be behindhand. Some in-door labor should be arranged for the workmen during rainy days, such as mending tools, making labels, etc. Procure tools of the best description, as men take more interest in their work when provided with suitable tools. A stock of duplicate handles for hoes, rakes, etc., will often save trouble when work presses, and every gardener ought to have a supply of these ready for an emergency.

Orchard and Nursery.

We will take it for granted that the ground has been properly plowed and prepared for early spring planting, and that trees have been ordered in time.

Planting can be performed as soon as the trees arrive, but if this is not done at once, see that the roots are properly protected from winds and sun. When the trees are set, trim the mutilated roots, shorten the branches, and remove all useless ones. Take care not to plant the trees too deep, but make a broad opening and spread the roots in a natural position, then cover with fine soil, well pressed down. When trees arrive in poor order, resulting from improper packing, and the bark appears shriveled, bury entirely in the soil, and in a few days they will look fresh and plump if not too far gone. Trees that have started into growth during their journey must be cut back severely.

Grafting.—As soon as the buds commence to swell grafting may be done, but do not commence too early.

Cions.—Cut at any time before the buds start, and preserve in sawdust or earth until needed.

Root-grafts.—Plant in nursery rows as soon as the ground is in proper order.

Seeds of fruit and ornamental trees may be planted in nursery rows or in beds, but it is better to wait until next month before planting any tree seeds, except nuts, peach-stones, etc., which were buried last fall.

Insects.—Continue to destroy all injurious insects wherever found, both in the egg and larva or grub state. If the trees have not been washed with soapsuds, they should be gone over with a moderately stiff brush as soon as convenient.

Transplanting.—Transplant trees from the nursery rows and set where they are to grow, or else make them into rows where they will have sufficient room to grow for several years.

Fruit Garden.

Almonds.—In some parts of the country considerable attention is being paid to the cultivation of this fruit, and it will thrive wherever the peach will, and the culture is the same.

Figs.—This fruit is not cultivated profitably in the open ground north of Maryland, but a few trees may be grown for the sake of variety, and during the winter may be taken up and stored in the cellar, or laid down and covered with earth.

Quinces.—Most persons fail to secure a good form for their quince-bushes, and instead of a handsome pyramid is usually seen a long-branched, unshapely tree, which is far from being ornamental. If properly pruned, they may be trained into very handsome pyramids.

Currants.—A good supply of currant-bushes ought to be found in every fruit garden, and if given proper care, they may be made to yield large crops of fine fruit. The Versailles and White Grape are the best varieties. Cuttings ought to be planted in rows two feet apart, and the cuttings six inches in the row, and in two or three years these will produce bearing bushes.

Gooseberries.—Houghton and American Seedling are two valuable varieties, and are quite free from mildew. Give thorough cultivation and plenty of manure between the rows.

Grapes.—Plant one-year-old vines in well-drained soil, enriched by ashes and bones; heating manures are not proper for a vineyard. A good selection of varieties, combining the early and late sorts, should be set out for home use.

Raspberries and Blackberries.—Set out new plants of these valuable fruits, allowing four feet each way for raspberries and six by eight feet for the blackberries.

Strawberries.—Set out new beds as soon as the ground will allow and give the rows a good mulch. Hill culture is the neatest, and the plants ought to be set out in rows eighteen inches apart, and the rows two feet apart. No fruit should be allowed to set the season the vines are planted.

Kitchen Garden.

Some of the hints given last month will answer for this in many parts of the North. Hot-beds will need constant attention to prevent the young plants suffering from the want of water or air.

Asparagus.—Remove the coarse litter and fork in the fine manure. Make new beds.

Beans.—A few rows of Snaps and Bush beans may be planted for early use, but pole beans and Limas should be left until the soil is well warmed.

Beets.—Sow early sorts in drills 15 inches apart.

Cabbages and Cauliflowers.—Plants may be set out from the cold-frame in rows twenty-four by twenty-eight, and lettuces planted between. Sow seeds for second early in open ground, and gradually harden off the hot-bed plants.

Carrots.—Sow a few rows for early use in fifteen-inch drills, taking care to use plenty of seed to insure a good start.

Celery.—Plant in a seed-bed, in drills eight inches apart, and cover lightly with fine soil.

Chives.—Make new plantings by taking up the old clumps, and after dividing, set in rows six inches apart.

Cress.—Sow in one-foot rows every week.

Cucumbers do better if not planted until next month, though a few may be started on inverted sods in a hot-bed for early use.

Egg-Plants.—Sow in hot-bed and give plenty of heat; do not let the young plants get chilled.

Garlic.—Break up the bulbs into sets, and plant six inches apart, in rows twelve inches apart.

Horseradish.—Plant the sets which were saved last fall at digging, and plant in well-manured rows two feet apart and fifteen inches in the row.

Herbs.—Have a good supply of sweet or pot herbs for flavoring soups, stews, etc. Thyme, Sage, Summer Savory, and Sweet Marjoram are the ones usually planted. Sow in rows four inches apart; keep free of weeds until ready to transplant.

Leeks.—Plant early in fifteen-inch rows, and when up thin to six inches in the row.

Lettuce.—Set out plants from the cold-frame and hot-bed. Seeds may be sown in the open ground in drills eight inches apart.

Onions.—Plant out sets and top and potato onions as early as the ground is suitable. Seeds should be sown early, in rows fifteen inches apart, and if a few radish seeds are mixed with them they will serve as a guide to show where the rows are.

Parsley.—Sow seeds in hot-bed or open ground. Parsnips need to be sown early in very deep, rich soil, to get a good start; sow in fifteen-inch rows.

Peas.—The earlier these can be planted after the frost is out of the ground the better, as they will bear cold weather very well. Sow the dwarfs in rows a foot apart and the taller sorts two or three feet apart.

Peppers.—Treat the same as egg-plants.

Potatoes.—Plant in well-manured soil in rows three feet apart. Cut the potatoes into sets and plant these one foot apart in the rows. The sprouts may be started earlier if the potatoes are placed in a warm room for a week or ten days before cutting.

Radishes.—Sow in hot-bed and in open ground once a week for a succession.

Salsify and Scorzoneria are both excellent vegetables, and need the same culture as carrots.

Spinach.—Hoe over the beds sown last fall, and sow seeds in drills fifteen inches apart.

Seeds.—Set out roots, bulbs, etc., for producing seeds, selecting only the finest specimens.

Tomatoes.—Sow seeds under glass, and transplant those already up into pots or boxes where they will have plenty of room, and so that the plants can be turned out without injuring the roots.

Turnips.—Sow a few rows for early use, and as soon as up dust with plaster, to prevent insects.

Flower-Garden and Lawn.

Ornamental Trees.—Use as much care in planting these as in setting fruit-trees. In ornamenting a lawn do not plant the trees and shrubs in regular

order, but endeavor to give it a natural appearance. Trees that have been bent by winds during the winter should be righted or reset.

Hedges.—Where a protection is needed near the house, a living fence of Arbor Vitae or Norway Spruce is quite ornamental.

Climbers.—Plant a good variety of climbers for covering trellises, arbors, etc. Clematises, Wistarias, Honeysuckles, etc., are all very handsome and rapid growers.

Herbaceous Perennials that have been set several years, ought to be taken up and divided before they have started into growth.

Biennials, such as Hollyhocks and Sweet Williams, should be transplanted to the border.

Annuals.—The hardy sorts may be sown as early as the frost leaves the ground. Sow tender varieties in a hot-bed or in window-boxes.

Bulbs.—Hardy bulbs should be uncovered and the ground kept free of weeds.

Greenhouses and Window-Boxes.

As the time for bedding out plants is so near at hand, proper care should be taken to give them plenty of air, so that the change will not be sudden. This may be done by opening the ventilators, shutting off most of the fire heat, and on warm, pleasant days by opening the doors.

Camellias.—As they are making their growth they should have plenty of water and a little more heat. Keep clear of insects.

Pelargoniums coming into flower will need plenty of water and light.

Propagating.—Continue to propagate bedding-plants as fast as possible, in order that a large stock may be prepared for sale or planting out.

Seeds of annuals that are small ought to be planted in boxes or pans, and instead of covering with earth, press the seeds into the soil and then sprinkle from a fine-rose watering-pot.

Dahlias.—Bring the tubers into a warm place where they will sprout.

Cannas.—Start in the greenhouse, and set out in the open ground when warm.

Tuberoses do best if started in the greenhouse and then turned into the open ground next month.

Window-Boxes.—The plants ought not to be allowed to become drawn, but should have plenty of light and air, and free exposure on mild days.

Beef Cattle.—Receipts are usually lighter at this season of the year, farmers arranging to increase their stock for grazing. Besides this, it is evident that so many cattle perished at the West during the unusually severe winter, we shall have a light run this spring, and it is feared the stock will be poor. Trade has been somewhat uniform during the past month, the market closing at a trifling decline. There is a great falling off in arrivals of Texans, only 494 coming forward during the past month. At the last general market there were 130 carloads of cattle on sale at Communipaw, 95 cars at Hunderdth Street, and 40 at Weehavken, all these places comprising the New York market. Good cattle commanded 12c. $\frac{7}{8}$ b., and were in fair demand, though the opening of the shed season, with abundance of cheap eggs, and veals coming in freely, somewhat lessen the demand for beef.

Below we give the range of prices, average price, and figures at which large lots were sold:

Feb. 19th, ranged 9 @ 13 c.	Large sales 10 $\frac{1}{2}$ @ 12 c.	Av. 11 $\frac{1}{2}$
Feb. 26th, do. 9 @ 12 $\frac{1}{2}$ c.	do. do. 10 $\frac{1}{2}$ @ 11 $\frac{1}{2}$ c.	do. 11 $\frac{1}{2}$
March 4th, do. 8 $\frac{1}{2}$ @ 12 $\frac{1}{2}$ c.	do. do. 10 $\frac{1}{2}$ @ 11 $\frac{1}{2}$ c.	do. 11 $\frac{1}{2}$
March 11th, do. 9 $\frac{1}{2}$ @ 13 c.	do. do. 11 @ 12 c.	do. 11 $\frac{1}{2}$

Milk Cows.—The spring of the year is always looked upon as the best time in which to sell cows. The present time proves an exception, made so by the large

numbers of milkers sent here for sale. Poor quality has also contributed to the general dullness. So ghted have our markets been with hard lots of old cows, that they were sold at \$25 @ \$30 each by the car-load. Recent sales of two cars rather ordinary cows were made at \$55 each. The decline for the month is about \$10 per head. Very many of those now sent here for sale are springers. Fresh cows vary from \$30 to \$50 each for poor, \$55 to \$70 for medium to good, with a few choice at \$75 to \$80.....

Calves.—The figures show only a moderate increase in numbers, but the markets to-day are perfectly glutted with dressed veals, and overstocked with live. Trade is slow, and prices much lower. There are fully three times as many dead calves sent in as are reported above among the live-stock. It now takes a fat calf to bring 10c. $\frac{7}{8}$ b., alive, or over 13c., dressed. Good to prime milk-fed live calves are worth 9c. @ 10c. $\frac{7}{8}$ b.; common to fair sell at 7c. @ 8 $\frac{1}{2}$ c.; mixed lots, at 5c. @ 6 $\frac{1}{2}$ c. Hog-dressed are worth 10c. @ 14c. for milk-fed, and 6c. @ 9c. for grassers.

.....**Sheep and Lambs.**—These show quite a falling off in arrivals, the approach of shearing time and the season of spring lambs inducing farmers to keep stock back. Already we have a few spring lambs, which sell too high to be taken as regular quotations, for they will rapidly decline. By the pound they are worth about 20c., though some of 41 lbs. each went at 22c. Sheep have advanced a full cent $\frac{7}{8}$ b. during the month. Three cars fine-wool Ohio, 115 lbs. average, just sold at 10 $\frac{1}{2}$ c. $\frac{7}{8}$ b. Poor to medium sheep are quoted at 7 $\frac{1}{2}$ c. @ 8 $\frac{1}{2}$ c. $\frac{7}{8}$ b.; fair to good at 8 $\frac{1}{2}$ c. @ 9 $\frac{1}{2}$ c.; and prime to best selections at 10c. @ 10 $\frac{1}{2}$ c.**Swine.**—In addition to the live hogs reported above there were 39,232 dressed received during the month. Prices are scarcely as firm as they were four weeks ago, the packing season approaching its close, while receipts are still quite liberal. Live are worth 5 $\frac{1}{2}$ c. @ 5 $\frac{3}{4}$ c.; city-dressed Western, 6 $\frac{1}{2}$ c. @ 6 $\frac{3}{4}$ c.; Western dressed, 5 $\frac{1}{2}$ c. @ 5 $\frac{3}{4}$ c.

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Remitting Money: — Checks on New York City Banks or Bankers are best for large sums; make payable to the order of **Orange Judd & Co. Post-Office Money Orders**, for \$50 or less, are cheap and safe also. When these are not obtainable, register letters, affixing stamps for postage and registry; put in the money and seal the letter in the presence of the postmaster, and take his receipt for it. Money sent in the above three methods is safe against loss.

Postage: On *American Agriculturist*, 3 cents a quarter, in advance; on *Hearth and Home*, 5 cents per quarter. Double rates if not paid in advance at the office where the papers are received. For subscribers in British America, the postage must be sent to this office for prepayment here.

Bound Copies of Volume Thirty are now ready. Price, \$2, at our office; or \$2.50 each, if sent by mail. Any of the last fifteen volumes (16 to 30) will also be forwarded at same price. Sets of numbers sent to our office will be neatly bound in our regular style, at 75 cents per vol. (50 cents extra, if returned by mail.) Missing numbers supplied at 12 cents each.

Clubs can at any time be increased by remitting for each addition the price paid by the original members; or a small club may be increased to a larger one; thus: a person having sent 10 subscribers and \$12, may afterward send 10 more subscribers with only \$8; making a club of 20 at \$1 each; and so of the other club rates.

Our Basket.—We try to answer each month as many questions as possible, but we find that we usually have many items for which room can not be made. Notwithstanding the many answered in the paper each month, and as many or more answered by mail, we find it difficult to keep up with this department. We regard "The Basket" as one of the most important parts of the paper, and there is none upon which more care is bestowed. The longer articles often answer many correspondents at once; for instance, those in this issue upon Irrigation and upon Cattle Stanchions serve as a reply to a score or two of letters. With every desire to make the contents of the paper meet all wants, we must ask the patience of some who are unanswered. We will try to get to them in time.

Useless Letters.—Some persons ask us questions which are beyond the power of any one to answer. We have letters asking: How much will a given sum return if invested in stock, market-garden, or orchard? It is as impossible to reply to these as to tell what kind of cake a woman whom we never saw will make, provided she has plenty of flour, sugar, etc. The probable success in enterprises of this kind depends upon many local considerations, not the least of which is the character of the man who undertakes them.

To numbers of Eastern people who have written to ask our advice as to whether they had better go West, we say, No! The person who in such a matter will seek and act upon the advice of a total stranger is not of the kind needed to populate the West. He will be much safer if he remains where he is.

Moreover, we must repeat that we can not procure places on farms, in the city or elsewhere, for any one. If we wished to find a place for our own brother we should advertise, and we advise all others to do the same.

Manure Advertisement.—"L. A. W.," Woonsocket, R. I. The advertisement you send about "chemicalizing manure" is a humbug shown up several years ago in our columns. The advertiser threatened to prosecute us, but we have not yet been called into court.

O Dear!—In the Western Pomologist and Gardener is an article by F. R. Elliott, of Cleveland, Ohio, in which he says: "Not a single journal emanating from New York City, to-day, has in it, aside from its Western correspondence, a single writer whose brains can grasp our great country, or who can see aught of value outside of the New York, Boston, or Philadelphia market." Mr. Elliott was employed on a New York paper, is not now, hence the rest of us catch it in the extract above quoted.

The Northern Pacific R.R.—Those who are seeking for chances to invest will not overlook the 7.30s of the Northern Pacific, a road which is making satisfactory progress. We learn that during the month of February over a million of the bonds were sold, and a million and a half were taken during January.

Barry's Fruit Garden.—Those who have been long looking for the appearance of this work, will be glad to know that it is now ready for delivery. It contains nearly 500 pages, is printed on heavy paper, abundantly and handsomely illustrated, and bound in beveled boards. Sent by mail for \$2.50—not \$2.00, as was inadvertently stated in a notice last month.

Non-explosive Lamps.—S. M. Herr, Lancaster Co., Pa. We know of no lamp that will make it safe to burn bad oil, and do not believe one can be made. The danger is not altogether in the lamp. It is not safe to have very volatile oils in the house, at any rate. No safety lamp will guard against accidents in filling and at other times. Get oil that will not flash at a lower heat than 110°, and you may use any lamp you please. Those who do not choose to buy good oil, should use candles or go to bed at dark. As you value your own life and that of others, use no cheap oil in any lamp whatever.

See the "Items."—This month we have adopted a plan of giving matters of news and of general interest in a very condensed form, which will be placed wherever we happen to find room for it. In the present issue it is upon page 158, and though not as full as we intend to make it, will give an idea of our plan. This will give us more room in the "Basket" proper, to answer our increasing number of correspondents.

Inverted Cuttings.—"C. B. S.," Excelsior, Minn., writes that he has seen it stated that if fruits, as apples, grapes, currants, etc., are grown from grafts and cuttings that are inserted in the stocks or in the ground with the small or top end down, they will have few or no seeds or cores. Is there any truth in this statement?—[None, please.—Ed.]

Raspberry Leaves Scalding.—"I. F.," Floyd Co., Ind. The cause of your raspberry and strawberry leaves scalding and dropping off may be the lack of a mulch around the roots, to prevent the too rapid evaporation of moisture from the soil. It may be rust. It is impossible to tell without seeing them.

Chinese Yam.—"A. M.," Erie Co., Pa. The Chinese Yam is usually raised from small tubers, which are planted in the spring in a rich soil, in rows two and one half feet apart, and plants one foot apart in the rows. Small tubers may be had of most of the seedsmen at about 25 cents per dozen. Your compost of ½ sods and earth, ¼ leached ashes, and ¼ hen manure should be thoroughly mixed, and when the sods are well

rotted, the compost may be applied to corn; a handful around each hill is sufficient.

Liquorice.—"W. S. K.," Washington, D. C. This root will probably succeed south of latitude 32°, though we do not know of any experiments made with it in the Southern States. It requires a rich, loamy soil, and should be planted early in spring in rows three feet apart, and eighteen inches in the row. The sets are made from the small roots thrown off by the main root, and cut into lengths of 5 or 6 inches. All weeds must be kept down, and the field top-dressed in the fall, and three years after planting the roots will be fit to dig. We do not know where sets for planting can be procured.

Chinese Yam for Stock.—W. A. Moore, Iowa. We do not believe that any one ever dug enough Chinese Yams to be able to try their value as food for stock. We have no doubt that they would be as valuable, at least, as potatoes; they are perfectly hardy, but they run so far towards the center of the Earth, that one has to dig a small well in order to get out a root.

Ash-leaved Maple, or Box Elder.—"A. G.," Monticello, Wis. The seeds of this tree ripen at the end of summer or in early autumn. A tree upon our lawn was last year filled with seeds, but upon long examination we failed to find one with a perfect germ. In gathering seed examine them carefully. Sow in shallow drills as early as the ground can be prepared, and thin to about four inches. Thornburn & Co., New York, keep a large assortment of tree seeds, as does Thomas Meehan, Germantown, Pa.

Euclavian Grape.—"A.," Newbury, Vt. The quality of this grape is most excellent. It has the fault of not making handsome bunches, but this may disappear as the vines get older. We can not advise you about planting more. If in your place, we should wait and ascertain how those you already have turn out. Every fruit does not suit all localities.

Insect on House Plants.—Mrs. H. F. B., Brooklyn, N. Y. Thrips, one of the worst pests to exterminate of all that infest house plants. The air and soil have probably been too dry. Remove the affected plants from those that are free from the trouble. Give frequent syringings with tobacco-water over the foliage, washing it off after a while with clean water.

Plowden Peach.—C. Norris, Mich. We have seen nothing about this peach of late. It has been claimed as a distinct and early variety, while others assert it to be only Hale's Early. Write to John Saal, Washington, D. C., who will know all about it.

Vineyard.—"F. M.," Seabrook, Me. We advise you to go and see for yourself, and not trust the advertisements of this or any other similar enterprise.

Gooseberries.—Geo. Chivers, Alleghany Co., Pa., had the foliage of 3,000 Houghton Gooseberry plants destroyed by "some unseen enemy," and wishes to know what to do. How can we at this distance see the "unseen enemy"? Look more closely. If worms, they will be found on the under side of the leaves. Sprinkle White Hellebore. If mildew, there will be white patches. Dust with sulphur. If neither, send us some leaves for examination. It is difficult to prescribe without seeing the patient.

Honey.—"A. C.," Orleans, Ontario. Honey in the comb has a higher market value than strained honey. The retail price of honey in the comb varies from 20 to 40 cents per pound, according to the season and quality, and the wholesale price is about two thirds of this.

Gouk's Patent Earth-Closet.—We wish to call attention to this very useful application of the dry-earth system. It combines a tub or receptacle for the earth, and a mold with which a basin is formed. Six inches of earth is thrown into the tub, to form the bottom, the mold is placed on it, and earth placed around the mold and packed firmly, so as to retain the shape when the mold is withdrawn. There is then a basin of absorbent earth as a receptacle, into which the deposit is received, and an immediate covering of dry earth or other deodorizer effectually prevents any unpleasant consequences. When the basin becomes filled, the tub is emptied of its contents into a covered shed, where the matter is allowed to accumulate until it is needed as a fertilizer. As such its value is very great, and although we know many farmers have an objection to using night-soil on vegetables or grains, yet, if they can not overcome the objection to use it in this way, it will be found a most excellent application to grass or clover crops. The great convenience of this method makes it very desirable for

all those who have material on hand to use with it. Dry sifted coal ashes would make a good substitute for earth, in towns and cities, where it can not easily be procured, and powdered coppers makes an excellent deodorizer. The absolute necessity for disposing of our waste matter in a manner which is not prejudicial to health, make it imperative to use a dry-earth closet in some shape, and this one has many advantages to recommend it.

Hog Swindler.—"T. J.," La Crosse Co., Wis., wants to know all about hog swindlers, and whether they will prevent rooting. No method of cutting the snout short of cutting it off will prevent hogs rooting as soon as the wound is healed. The old-fashioned ring is the best thing yet. A horse-shoe nail passed through the "rooter," with the point twisted around the head, makes a good ring.

Bones, Hen-Manure, and Ashes.—"A. J.," Baltimore Co., asks the oft-repeated question whether it is injurious to mix ashes with manures containing ammonia. It is, except when the compost is to be used immediately, and then plaster or fine dry earth should be mixed; if the materials are perfectly dry, and kept so, very little ammonia will then escape.

Tiles, where procured.—"T.," Bangor, Wis., wants to know where he can procure drain-tiles. Doubtless in Milwaukee; certainly in Chicago.

What to Do with Cloverseed Straw.—"P.," Lodi, Wis., writes: "I have 140 acres of straw and corn-stalks, and that is about as much as I can work into manure. My clover straw is out in the field where it was thrashed. Would it be of any service to spread it on the land as it is, and plow it under without being converted into manure?"—Certainly, it would. A ton of clover straw is worth at least twice as much for manure as a ton of wheat straw. Spread it out on the land, and let it be exposed to the rain as much and as long as possible before plowing under. It will rot all the sooner, and have a greater effect on the first crop. Or it may be spread on a pasture. It will act as a mulch, and as manure also, and increase the growth of grass.

SUNDRY HUMBUGS.

We can not possibly find time to answer by letter the multitude of individual inquiries about this and that humbug, or the merits or demerits of advertisements, medicines, doctors, instruments, etc., etc. All doctors advertising positive cures are humbugs; no reputable, reliable, regular physician ever advertises thus; the rules of all reputable medical associations forbid it. No man can safely give medical advice to a patient upon his own written description of his case, or without seeing him. So much depends upon individual peculiarities, condition, and local circumstances, that, in fact, what is one person's meat (or medicine) is another's poison. There is no getting around this, and it sweeps away at one brush the whole class of patent or specific medicines. There is but one "medical specific," good in all cases for the same difficulty, and that is "Sulphur for the Itch." Some important suggestions on this subject were brought out during our recent libel suit, noticed elsewhere. . . . All cases of general swindling that we get hold of are exposed in these columns as early as we can collect proofs sufficient to warrant us in doing so. The unsupported statement by letter of one person, not personally known to us, that he has been cheated, is not enough to warrant us in publicly denouncing a party. Swindling parties have themselves often tried to entrap us by giving false statements concerning themselves, sent from distant localities under assumed names, written apparently by some of our own subscribers. After following up swindlers for a score of years, we have become somewhat skillful in their arts and wiles, yet we are surprised at not having been caught napping in a single instance in all these years. We are glad to hear from all our readers in regard to swindling operations, for a number of single well-authenticated cases from different individuals, pointing in any one direction, generally serve to bring to light the nefarious operations of parties previously supposed to be trustworthy. We invite all to promptly forward to us all suspicious circulars, advertisements, and the like. . . . An Advertiser informs us that he received a letter from a Boston party offering him a list of good names for addressing with business circulars. He forwarded \$3 for the list, and received a letter saying the list would soon come. After waiting a month, and writing for information, a letter came from (apparently) another person of the same name, saying there was some mistake, for he had never received any money or asked any for any such purpose, and he could find no one else of the same name in the Boston Directory. This looks like a "sell." Have any of our other advertisers had a similar experience? . . . The Albany "Dr. Andrews,"

or some other nuisance using the real or assumed name of "Dr. Andrews," is now sending out circulars, "Good Samaritans," etc., from 360 Lexington avenue, New York, promising impossibilities, and offering a great variety of medicines, instruments, books, etc. A person must be very ignorant and very foolish to patronize such a charlatan, yet there must be such persons, or he would not spend so much in printing and mailing these numerous advertisements. . . . Humbug seeds and plants are in order at this season, and it is well to be on the lookout for fraud. A Ciacianati chap has a marvelous corn from "Hungaria" (where's that?), of which he received three seeds two years ago, planted them in a garden corner, got 3 stalks and 13 ears "as large as can be found," planted it on less than an acre, and with only ordinary culture got 290 bushels! half of which he wants to sell *pro bono publico* at \$123 a bushel (\$2 a pint), but won't sell over five pints in a county. The absurdity of the claims ought to prevent farmers investing in this corn seed. . . . We have often cautioned our readers respecting sundry advertisements emanating from Maine, offering great wages to agents, and other brilliant business promises. Two of these were from Saco, Me., and Alfred, Me. We are glad to find the Young Men's Christian Association of Portland taking up the subject and exposing the swindlers. We suggest that other branches of this noble association, both in Maine and elsewhere, can do a good work by following the example of the Portland young men. There are local swindles, specially directed to young men, in various parts of the country, which need like attention. Some of the religious papers unwittingly or carelessly (and therefore criminally) help on the swindlers by inserting their advertisements. (Some other Maine swindlers are under special investigation.) . . . D— & Co., to be addressed at Malden, Mass., send out circulars offering a vilely attractive book, according to their own description. Any party willing to debauch morals and steal one's chastity would steal money, and if we wanted such a book we should not trust our money to such a fellow. The Malden postmaster or other good citizens of Malden should see to it that their post-office be not used by swindlers or vendors of obscene books. . . . "Sunlight Oil," so often shown up by us, is still offered to agents by Michigan operators. We suppose, therefore, that customers and victims are still found in dark corners where the sunlight of this journal does not penetrate. . . . What! not dead yet? Pardee & Co.'s Prize Sale of Watches, etc., etc., at Binghamton, N. Y.! Can it be that there are fools enough alive to keep this concern going, with its promises of \$250 gold watches for \$2.24? . . . A wonderful magnetic comb for curling the hair is advertised out West. Every editor who advertises this small swindle ought to have his hair combed with a flax-hatchel, and be made to pay \$1.21 to each of his readers who has lost that amount by patronizing the advertisement. . . . The Merchants and Bankers Association—great daily distribution of cash gifts—is a pure swindle; ditto the "National Exchange Co.," 107 Fourth ave. . . . James Stewart & Co. is the assumed name of some swindler who seems to be professedly operating in "fancy" cattle, sheep, swine, etc., ostensibly at Kennett Square, West Chester, Coatesville, Downingtown, Lancaster, and other places in Pennsylvania. Any one hearing of him under the above or any other name should report him promptly (privately) to H. M. Worth & Co., publishers of the *Weekly Leader*, at Kennett Square, Pa. . . . We have circulars of W. H. Chichester, and many other humbages already shown up. . . . The "Queer," or pretended counterfeit-money operators, still practice their swindles upon other would-be swindlers. A fellow at 16 South 5th avenue, New York, works under all the following names: Geo. Parker, *alias* S. S. Flint, *alias* J. T. Wildman, *alias* Dr. Thos. Walkins, *alias* Geo. W. Bates, *alias* E. D. Robinson, *alias* Edwin Carter, etc., etc. Wonder if the letters of his real name would spell E-I-I-a-s? Then we have Geo. Harrington, 173 Broadway; Chas. W. Lawson, 81 Canal st.; J. T. Spencer & Co., 10 S. st., Philadelphia; Amos Wainwright, Trenton, N. J.; John Hood, Jr., Wilmington, Del., and New York City, etc. . . . We began investigations upon the "Great Bankrupt Watch Sale" at 763 Broadway, but the Tribune and Post are giving a brisk ventilation of the concern, and save us the trouble. We will only add, that we recently spent some time in Geneva, Switzerland, visited the various watch manufacturers, and we are sure there was no "Great Geneva Watch Company" known there.

Variegated Japanese Honey-suckle.—"R. Z. S.," Laclede, Mo. This is perfectly hardy and is a capital climber. It is also a very useful plant for edgings to flower-beds.

Plaster on Oak Openings.—"R.," Woodworth, Wis., asks if plaster will benefit tame meadow on what are called "burr oak openings." Yes. We have seen one barrel per acre applied on such land with the best effects, though in other places a less quantity is

generally used. It should be sown early in May, when the dew is on the grass, or immediately after a shower. It is of little benefit to spring wheat.

Sanerkrant.—"W. M.," Battle Ground, wishes to know if kraut can be made of cabbages that mature in August. In our vicinity it is only prepared from hard, late-heading cabbages in cold, frosty weather. Who can tell him about summer making?

Catching Owls.—W. Emery, Champaign Co., Ohio, plants a ten foot 4x4 scantling "near the trees the chickens roost on," and on the top of this puts a wolf-trap, which catches the marauding owls. Query: Would it not be quite as easy to build a chicken-house?

Wood-eating Cattle.—E. Everett, Auburn, Me., wants a remedy to prevent his cattle eating their stanchions and boards off the barn, and any other wood they can reach. Give them some bones, burnt and powdered, with some wood ashes and salt, to lick; when they have enough, they will eat no more boards.

Spaying Cows.—"C.," Dale, Ky., wishes to spay an Alderney cow, if the operation will not injure her for producing milk. Cows, when spayed, continue to give a somewhat reduced quantity of richer milk for some years, when they gradually fatten and dry up.

Draining by Subsoil Plow.—"Farmer," Dane Co., Wis., has a piece of land with clay subsoil, which he can not afford to underdrain, and asks if there is any subsoil plow by which the clay can be opened sufficiently to permit the water to pass off, and how far apart under ground the furrows should be made. The best plow for this purpose is the Miner subsoil plow, made by R. H. Allen & Co., Water street, New York. It can be drawn by two horses, at a depth of fourteen inches beneath the surface, and costs \$8. It leaves what is called a mole track, and at twelve to twenty-four inches apart these tracks permit the water to escape.

To Tan Buckskin for Mittens.—"M. P. B.," Minnesota. The best method is the Indian mode. Remove the hair by means of a lye of ashes, and then rub them with brains and smoke them. We have forgotten the details of the process, but probably some of our Western readers can give it to us in full. Indian-tanned skins do not harden after being wetted.

Blue Lice.—"W. D.," Sevasapol, Ia., wants a remedy against blue lice on cattle. See *Hints about Work* for February, page 43. If crude petroleum can not be got, a mixture of lard and kerosene oil will answer as a substitute. Kerosene alone is too strong. If carbolic acid can not be got, sulphur, ground up with the lard, will answer, but not so well.

Feed for Calves and Colts.—"N. W.," Pottstown, Pa., asks what is the best feed for young calves after weaning, and should yearling colts be fed grain?—The best calves we have raised were fed on early-cut clover, hay cut, wetted, and sprinkled with a handful of coarse middlings or mill-stuff and some oil-cake meal to each feed. They also got the skimmed milk until six months old. Yearling colts should have a quart of bruised oats per day—it is well repaid.

Kansas.—"H. R.," Alleghany Co., Md., with some friends, are going to Kansas, to take up homestead lands, and wants a book which gives information about farming there. The Kansas Immigration Society, Leavenworth, Kansas, will give all information respecting lands and locations of homesteads. The methods of farming there are not much different from those elsewhere, and will soon become plain and easy to any smart man.

Esparecette, or Saintfoin.—"P. D.," Atlantic Co., N. J., asks where Saintfoin seed can be purchased. At almost any of the seed-stores in New York, at 50 cents per pound (see advertisements). The best grass for a "mucky" soil is Red-top.

Jerusalem Artichoke.—A. Meyer, Dubuque Co., Iowa. Plant as early in spring as the ground can be worked, the same as potatoes, in rows far enough apart to cultivate between them. The tubers may be dug in fall, or be wintered in the ground and fed in spring.

Spurry.—A. Richardson, Wilmington, Del., wants to know all about Spurry. Spurry is a small annual plant, and useful only on poor, sandy soils, where no other forage plant will grow. If there are such poor, sandy soils in Delaware or Maryland, Spurry may be grown on them as a commencement for improvement by sowing twenty-four pounds of seed per acre in March, again in May and July, thus growing and plowing under

three crops in one year; afterwards it may be sown and eaten off, the ground plowed, sowed, and eaten again, until the soil is sufficiently strengthened to grow clover. Spurry is said, in the Agricultural Department report of 1864, to be a native of this country, which is incorrect. It has been introduced from Europe, and has become sparingly naturalized in some States.

The Best Oil for Harness.—A. Jones, Smyrna, Tenn., wants the best oil for harness and other leather. A non-drying oil is needed. Tanner's oil is the best. Fish oils are non-drying oils. A mixture of bees-wax, lamp-black, and tallow is a good application, well rubbed into the leather when damp.

Fruit Trees.—"J. T. B.," West Redding, Ct. It does not make any difference whether you procure your trees from a nursery near home or far away, provided the trees are well grown and the wood properly ripened.

Hay-Caps.—"R. P.," wants a composition to make hay-caps water-tight. Two coats of lincseed oil will do it, but when dry, the cloth is apt to crack. A good quality of sheeting will turn water for 21 hours, without any coating, if the hay-cock is made pointed at the top.

Humbugged.—"H.," Ashley, Mass., has bought a right to use a secret method of chemicalizing manure for \$5, and fears he has been humbugged. His fears are well founded, doubtless. A mixture of salt, plaster, lime, and ashes, in itself, is of very doubtful value to mix with manure, to treble its fertilizing properties, and \$5 is too much to pay for the knowledge. As an honorable man he will respect the obligation he has voluntarily entered into, but \$5 would pay for the *Agriculturist* for four years, and one can learn more than five dollars' worth from its pages in less than that time.

Spring-Wheat Sections.—W. F. Atkinson, Boon Hill, N. C., referring to the advice in February *Agriculturist* to farmers in "spring-wheat sections" to sow largely, asks what are spring-wheat sections, and if North Carolina is one. It is not. Spring wheat succeeds best in colder climates, as Northern Illinois, Iowa, Wisconsin, and Minnesota. It should be sowed as early as possible in the spring.

Heeling in.—G. C. Brown. This is a gardener's term for laying plants in a trench and covering the roots with earth. In the case of Osage Orange, the year-old seedlings, if left in the seed-bed, will get badly drawn by the frost. If taken up in the fall and heeled in, they may be kept in safety.

Cranberries on Hills.—C. Blakeslee. The berries you saw upon the hills in Labrador were the Cowberry (*Vaccinium Vitis-Idaea*), a close relative of the true Cranberry, and common in the northern parts of both hemispheres. They are much liked by Norwegians and other natives of Northern Europe, but they are too bitter to be popular. It would probably grow on any not over-rich upland, and we have grown it in common garden soil.

The U. S. Signal Service.—The Farmers' Club of Middlesex Co., N. J., recently passed a resolution of confidence in the Signal Service Bureau, and approving "of the efforts made by that Bureau to benefit the agriculture of the country in a practical manner." Everybody will agree with the Middlesex Club; the Bureau is so well established in popular favor that it hardly seems to need resolutions in its favor any more than does the law of gravitation.

Cranberries.—"W. H. B.," Plainfield, Ct. We can not give a treatise on Cranberry culture in a basket item. If you intend to engage in the business on either a large or a small scale, the very best investment you can make will be to put \$1.25 in White's Cranberry Culturist.

Cure for Ringbone.—Baxter White, Sherborn, Mass.—Poment with warm water for half an hour, and then apply a blister of ointment of biniodide of mercury or lead; which must be repeated until an active blistering is effected. Another remedy is firing, but this should not be attempted but by a skillful veterinary surgeon. An old ringbone is incurable, and a better left alone and rest given to the horse.

New Corn.—"W. A. S.," Will Co., Ill., sends us a circular of a new corn, and asks what we think of it. As the circular says that the corn in ordinary culture produced 300 bushels to the acre, we think it very fishy. If you touch it at all, do it gently. Do not spend any money on this corn unless you can afford to lose it. A small investment will enable you to test the truth of the statement, and give you seed enough for another year.

How many Horses make a Team?

—Two or more. It is generally understood that a farm "team" means two horses, and if more is intended, it is so stated, as a "three-horse team," etc.

Colorado.—S. & T. write: "G. E. S." can learn about the soil, climate, etc., of Colorado by writing to A. K. Baker, Secretary Chicago Colorado Colony, Longmont, Col. The Colony lands are at the foot of "Long Peak."

Deep Cans for Creaming.—"P. S. D.,"

of Saratoga Co., N. Y., says that when their cheese factory shut up for the winter, he procured some deep cans, and fixed up an old box so that it would hold water, and commenced a trial of the new system as described in our *Ogden Farm Papers*. After four months' trial in cold weather, his success has been "highly gratifying." He has had "less work, better butter and more of it." He asks: 1. How to keep the cans from rusting along the seams? 2. Must the caps be covered? 3. Are the covers to be kept on at all seasons? 4. Should the animal heat be withdrawn before the covers are put on? 5. Are cans eight inches in diameter better than those eleven inches in diameter?—To which we answer: 1. Have the seams well covered with solder. 2. The covers are an advantage as excluding dust, and lessening the drying of the surface of the cream. They have each a one-inch hole in the middle, which allows sufficient ventilation. 3. We use the covers at all seasons, as a protection against the changing temperature of the air. 4. No; put the covers on at once, and set the cans in the cold water, which will soon withdraw the heat. 5. The colder the water, the larger the cans may be. No rule can be given; probably eight inches would be best for a temperature of from 58° to 60°, and eleven inches would do as well at 52° or less.

Grapes in Michigan.—A. W. Ingraham,

Lamont, writes: I have been testing several varieties of grapes. The Iona bids fair to prove a failure. The most of the fruit is attacked with black rot, and the three years that it has borne, it has ripened but once (in 1871). The Israella is of poor quality, the Adirondack nearly worthless, the Creveling extra good and very early, the Eumelan not yet fruited but a rapid grower, the Delaware unexceptionable.

Spring Wheat.—We have received a great

many inquiries as to the possibility of growing spring wheat in the Middle and Southern States, to all of which we reply that this crop can not be profitably grown in Pennsylvania or in the States south of it, nor in the southern part of Ohio and Illinois. It is suited to localities further north than those mentioned.

Berkshires.—Mr. F. H. Hall, of Aurora, Ill.,

asks, "Is a small white spot on the side of a Berkshire an indication of impurity?"—Such a spot would suggest an impurity, but it would not prove it. It would be better not to breed from the animal, for although in a composite breed like the Berkshire the color of remote ancestors will sometimes crop out without any apparent cause, there is a so much simpler way for the spot to have been produced, that it is best to keep on the safe side.

Spawn of Trout and other Fish.—

"I. A. S.," Buena Vista, S. C. The spawn of trout and of all the Salmonidae can be sent to any part of the country, where there are express offices, without much danger of loss, if they have fair treatment. But it is of little use to attempt to raise them in the extreme Southern States, unless the supply of spring-water is copious. They would not thrive in the common brooks. The spawn of the black bass is not yet in the market, and probably never will be. The best way to stock ponds is, to introduce yearling fish. These can be sent by messenger to any part of the country. The Northern black bass (*Grystes nigricans*) does well in Pennsylvania and in all the northern States, and probably would flourish in any part of the South, as it is a very hardy fish. We are not aware that it has gone south of Philadelphia. The Southern black bass (*Grystes salmoides*) is already distributed in the South and in the Mississippi Valley. There is much more demand for the Northern fish, and probably there is a foundation for this in its superior excellence. There are now some 250 trout-hatching establishments in the country, from whom spawn may be obtained.

Corn Fodder.—We have a number of letters

asking full directions for the preparation of the ground for this crop and for the planting, cultivation, harvesting, curing, and storing. To answer all these questions would take a longer article than our readers would enjoy, and we propose to take up one point at a time, keeping in advance of the dates when the work need be done. To begin with, then, it is now late to begin the preparation of the soil. This had better have been done in the autumn,

but if still to be undertaken, no time should be lost, and no other work except the getting in of the oat crop should be allowed to interfere with it. All the preparation needed until just before planting time in May, is to be done with the manure-cart and dung-fork. The result, under any fair treatment, will be in proportion to the amount of manure that is used. Make the land rich, doubly rich, trebly rich, if you would succeed and would realize the real profit of growing corn-fodder. If you have enough manure to make an acre of land produce fifty bushels of shelled corn, put it on a half-acre, or even on less; you can not make it too rich, and within reasonable limits, the richer you make it, the greater will be the profit realized. Of course, the land should be good, well drained (naturally or artificially), and in a good state of cultivation—what we know as "good corn land." If you have such a soil, especially if now in grass, so that the manure can be applied to a good sod, you can ask nothing more—except more manure.

Ashes Wanted.—A good example for farmers is shown by the Agricultural Association of Roanoke, N. Y., which buys guano and similar manures in large quantities for its members at a great reduction on retail prices. H. W. Young, the Secretary (address, Roanoke, N. Y.), now wants 40,000 bushels of ashes.

Onion Sets—Correction.—In Mr. Henderson's article on page 143, it is stated that the seed should be covered with two inches of sand. It should be one inch.

To Prevent Milk from Souring.—

A "Subscriber," Saginaw City, Mich., wants to keep his milk sweet for twenty-four hours or more in some perfectly harmless way. The most harmless way we know is to scald and wash perfectly clean all the pails and pans used in milking and setting milk, and to use tin ones. By doing this, milk may be kept sweet for twenty-four hours at any time in the year in any clean, cool cellar.

Hollow-Horn.—"T. G. C." Because the

horns are cold it is not safe to conclude that hollow-horn is what's the matter with your cow. It is often the case that the circulation may become torpid temporarily, or otherwise deranged by constipation or bilious disturbance, and the horns will then be cold. If a warm bran mash, given for a few days, does not improve the cow, and her eyes are yellow, give half a pound of glauber-salts. The oil-cake you have been feeding has made her bilious probably.

Packing Hams in Ashes.—Tetzell,

Greenwood, Miss., asks if it is safe to pack smoked hams in ashes during summer. If the ashes are kept perfectly dry it will be safe enough, but we would prefer clean wheat bran, which is just as good.

Grade Durhams as Milkers.—"J. C.,"

Pine Grove, Ohio, purchased some grade Durham calves, which he fed well and allowed to come in at three years old, but he is disappointed in their milking qualities. Will they improve?—It is most likely they will, with their second calf, but such a disappointment is not rare with this stock; they are eminently beef cattle, and not often excellent dairy stock.

Grubs in Horses.—"G.,"

Granville Co., N. C., asks if, when warm from work, his horse turns his head to his side, it is a sign of grubs. We suppose he means what are called bots. No; it is a sign doubtless that he feels some discomfort, probably colic. The remedy in this case is not to feed or water him when warm or exhausted with work. Give some ginger and powdered gentian root in his feed, and some wood-ashes occasionally to lick.

Sal-Soda.—C. J. List, Richland, O., asks what

is the soda mentioned in the article on utilizing bones, page 457, 1871. Sal-soda is the common washing-soda, sold at every grocery store in the country. It is sold in coarse lumps, not in a powder.

To Destroy Wild Onions.—J. W.,

Pickering, Norfolk Co., Va., says he has succeeded in destroying this pest by putting the field in a hoed crop, and about June, just before the onions go to seed, turning in and pulling them and destroying them. Thoroughness in this process alone is effectual.

Scab in Sheep.—G. Claxton, Andrew Co.,

Mo., has some sheep infected with scab and wants a remedy. Take one pound of plug tobacco, boil it in four gallons of water, and add to it four gallons of the clear water in which some lime has been slaked, and a pint of spirits of turpentine. With this wash the parts affected daily for a few days. Keep affected sheep by themselves.

Rats and Mice.—A correspondent at Annapolis, Md., gives the following: I have tried, in vain, for weeks to catch some mice that were undermining the bricks in the hearth. The little fellows were shy of the trap, eating the bait up to the very door, but the most tempting morsel of roasted cheese could not tempt them to venture under the fatal spring. After revolving the matter over in my mind, I hit upon a plan which proved a perfect success. I took a wooden box about a foot and a half high, and two feet long (any size would do) and placed it over the trap, which could only catch one at a time, but in four days I had caught nine—all there were in the hole. The philosophy of the box is, that it gives the mice a feeling of security while they are taking the bait. Rats will frequently enter a wire trap and eat up all the bait on the bottom without touching that on the hook. I have frequently outwitted them by putting, in addition to the bait on the hook, a piece of cheese on the bottom, and connecting it with the hook by a piece of black thread. Traps should frequently be shifted from one part of the house to the other, as seldom more than one or perhaps two rats are caught in the same place within a short time.

Jersey Cow.—Mr. Hall, Aurora, Ill., makes

the following statement: "I have one full-blood Jersey cow and two high grades. In December we churned the cream from (37) thirty-seven (heer) quarts of the milk of these three cows, and had therefrom (8¼) eight and three quarter pounds of butter." This is less than 4¼ quarts of milk to the pound of butter. The statement is remarkable, but by no means incredible, relating to Jersey cows in the winter season, and at a time when they were probably nearly dry—the milk being always much richer at such time.

The Breaking up of the Ice.

While we are all glad to know that the ice is breaking up and the winter is gone, yet there are some people to whom this gladness comes mingled with apprehension for the safety of their property. Such an occasion is represented by our artist on the first page of our present number. Here is represented the breaking up of the ice in the lumbering country, where all through the winter which has just passed, logs have been cut and drawn either on the ice or on the roads along the banks of the stream. Much waste necessarily accumulates in the shape of refuse logs and tops of trees, which, when the ice breaks up, comes down the stream with the fragments, and often forms "jams," which cause the water to back up and sometimes overflow the bank, and wash away mills, logs, and lumber altogether. Such seems to be the fear of the men shown in the picture, who are striving with "pike-poles" to break the jam and allow the accumulated ice to float away, and so save their mill.

Special Notice.

The Book of the Season—"Farm-Gardening and Seed-Raising."—A few years ago we made a revolution in horticultural literature by bringing out "Gardening for Profit," by Peter Henderson. This practical book, by a practical man, stands as the authority in its department. We now announce a work which we predict will make quite as much stir among farmers as did Mr. Henderson's among gardeners. There are thousands of farms near cities where land is too valuable for the raising of grain and for grazing, which the owners wish to make the most of. They can only make cultivation pay by following farm-gardening, which is half-way between market-gardening and regular farming. It is that kind of farming that will pay wherever manure can be bought, and such crops as potatoes, onions, carrots, etc., will sell. Market-gardening proper deals with perishable articles, that must be rushed into market at once; farm-gardening raises such crops as will bear transportation by the ordinary channels. The work, the title of which is given above, is by Francis Brill, a practical cultivator of long experience in raising such crops, and as a seed grower. In the present work he gives full directions for raising and caring for all kinds of seeds. It contains information to be found in no other work, and although the seed-growing is made a sub-title it is not the least important part of it. The work is of about 150 pages, and in order to put it within the reach of all, it is put at the low price of \$1, post-paid. It is a book that every farmer will want. We feel no little pride in being able to present three standard works covering the whole field of farming and gardening—namely: Allen's *American Farm-Book*, Brill's *Farm-Gardening and Seed-Raising*, and Henderson's *Gardening for Profit*. These form a library in themselves for every cultivator of much or little soil.

To Measure Corn in the Crib.

W. F. Mallow, New Holland, Ohio, wants a rule for measuring corn in the crib. Add the width of the bottom of the crib in inches to the width across the corn in the upper part, also in inches; divide the sum by two, and multiply it by the height and length of the corn in the crib, also in inches, and divide the product by 2,750. The result will give the heaped bushels of ears, two of which will make a bushel of shelled corn. By multiplying the average width, height, and length, in inches, together, the cubic contents in inches is found, and 2,750 cubic inches make a heaped bushel.

Green Crops for Manure.

John Iseman, Armstrong Co., Pa., wants to grow two green crops to plow under for manure before next September—what shall he sow? Probably peas would make the best crop for this purpose. First plow and spread some lime—as peas need lime—and harrow; then sow three bushels of peas (an early sort) in April, plow them in with a light furrow with one horse; in June they may be plowed under and another crop sown, which will be ready to turn under by 1st September.

Canada Thistles.

“O. K.,” East Smithfield, Is in trouble. His tenant harvested a large patch of Canada thistles, drew them to the barn with the grain crop, and thrashed all together, so that the seed is mixed through the manure. What shall he do?—This oversight will cost years of annoyance, without doubt. There is no remedy but to watch for the thistles, and pull them while young. As a warning, good may however result.

Analyzing Soils.

A reader sends us an advertisement of a man who offers to analyze for a certain sum the “soil of a farm,” and asks what we think of it. We think it a fraud; and even though a correct analysis of a soil be made, it is good only for that particular sample, and no criterion to judge accurately of a farm. Money had better be spent in adding manure to the land, rather than in paying for a chemical analysis, however perfect it might be.

Tonzelle Wheat.

D. B. Alexander, Culpeper, Va., sends us a sample of Tonzelle white wheat, which he says last year yielded with him 50 bushels per acre, weighing 66 pounds per bushel. Sowed 25th September, it was ripe on the 1st June. It stands the winter well, is stiff in the straw, and stools thickly. He has no seed for sale. He would like to hear the experience of others with this variety.

How to Churn.

—A “raw hand at the business” asks how to churn, how rapid a motion of the dasher is needed, should the dasher be lifted out of the cream, and the proper temperature of the cream. The cream should be sour, but not bitter; temperature about sixty degrees; the dasher should be lifted out of the cream at each stroke, and make about 100 strokes per minute. The rotary churns, such as the Blanchard, are quicker in operation than the upright dash.

Manure for Grass on Drained Swamp-Lands.

—“A Reader,” Potsdam Junction, N. Y., has raised a crop of oats on newly cleared and drained swamp-land, and has it now well stocked with timothy and red-top. What manure would keep the grass in good condition? A dressing of 25 or 30 bushels per acre of finely-slaked fresh lime would no doubt be of good service for a few years, and would bring in clover. An occasional dressing of three or four bushels of salt or 200 pounds of bone-flour or Peruvian guano per acre would keep the meadow in good heart, but timothy has a tendency to run out on such land, and fresh seed would be needed when this occurs.

Western Interests.

—“H. M. M.” wants “more practical hints on Western farming, and not so much about peat, bone-dust, etc.” We do not lose sight of our Western friends: in a few years peat, bone-dust, etc., will be as interesting to them as to anybody.

Hollow-Horn.

—“M. T. P.,” Abingdon, Va., has an ailing cow, which his neighbors say has hollow-horn. What is this disease, and the remedy?—The symptoms of what is called hollow-horn, are, eyes dull and sunken, horns cold, eyes and head swollen, the animal standing with the head low down against the barn or fence, staring coat, and sometimes bloody urine. It is the result of exposure to cold and low condition, and affects the sinuses of the head at the base of the horns. Turpentine rubbed on the top of the head and around the horns, and warm fomentations, with hot wet cloths wrapped around the horns, are useful. Carbonate of ammonia, with warm stimulating drinks, should be given, and nourishing food, and the patient should be kept warm.

3

MONTHS

3 MONTHS

Three Months

THREE MONTHS

THREE MONTHS

THREE MONTHS

yet remain, during which any person, anywhere, who desires one or more of the 106 most excellent articles catalogued on page 157 can easily get them **without money**. This is no idle or deceptive statement. Nearly 14,000 persons have tried it with success and great satisfaction. Letters are constantly coming from all parts of the country for these articles, saying, “I found it much easier to raise a club than I anticipated. It really cost me but little time when I set about it in earnest.”..... One says:

“.....I took your papers, read them through so as to be posted, and then went to my neighbors, evenings, and talked plainly about the many useful things found in them, showed the pictures, and explained that half a cent for each week day would pay for the *Agriculturist*, or one cent a day for *HEARTH AND HOME*, and less than one and a half cent a day would give them and their families the entire reading of BOTH of these journals, and I found very few who, when they really looked into the matter, did not see how greatly it would benefit them, and they soon contrived a way to save the small amount required. For some who had not the money on hand I have advanced it. So here are your subscribers, some for one paper, some for the other, and some for both, as you find them marked on the list. These entitle me to Premium 40.”

A Clergyman writes:

“I needed the American Cyclopaedia for my library, and told my people so. On going around among them I found them quite ready to help me (and I know the paper will greatly benefit them), and it took only four days to get the enclosed club for the Cyclopaedia.”

Another Clergyman writes:

“Our Sunday-School wanted a Melodeon very much. Seeing your Premium List, I set children and teachers to work, and helped them, and we found no difficulty in speedily getting subscribers enough to secure it. Many outside of the church took the paper to help on the object, and I know they have killed two birds with one stone; for, besides helping the school, they will get many times their money's worth in reading the papers.”

A Merchant writes:

“I opened a list at my store for your papers, and we soon made up the enclosed club for the Premium Watch, which I intend to present to a faithful clerk.”

Another Merchant writes:

“They were discussing the case of a poor soldier's Widow at my store last week, and some one proposed a subscription to buy her a sewing machine. Another (one of your subscribers) proposed a premium club for your papers, and all agreed to help. The list was opened at my store, and on Saturday night we had the full list of names brought in. Please send Premium No. 38,” etc.

Many Boys and Girls, and especially many **Post-office Clerks**, and others, forward us Premium Clubs for various articles, with interesting letters, but we have no room for more.

The New \$10 Sewing Machine, offered last month, is awakening great attention, and hundreds are getting it.

Well, what the above persons have done, can be done just as well by thousands of others in all parts of the country. Human nature, human wants, and human capabilities are about the same everywhere. We invite **all** our subscribers to take a hand in the enterprise, and secure one or more of these Premium Articles this month. Full descriptions of the Premiums will be sent whenever desired, and specimen copies of both papers when needed.

See Page 157.**The Proposed Cattle Show at**

Boston.—The trustees of the Massachusetts Society for promoting Agriculture propose to hold in Boston, in September next, a four-days exhibition of thorough-bred stock and dairy produce, with prizes amounting to \$14,000. From the circular received they evidently mean what they say. Their intention is clearly to work for the “promotion of agriculture,” for of the very large amount appropriated for premiums only \$925 in all is applied to other horses than stallions and mares for strictly agricultural purposes. When we remember that it is to these trustees, or their predecessors, that we owe the introduction of the Percheron horse, and very largely that of Jersey cattle as well, we are justified in expecting a really thorough and honest effort to organize the most extensive and the most useful exhibition of live-stock ever held in this country. The trustees ask the cordial co-operation of all breeders in the United States and in Canada; and we are glad of an opportunity of saying, from our own knowledge of the men, that the personal character of the committee charged with the management of this exhibition is such as to insure thorough fairness in the awards, and the most impartial treatment of all exhibitors. It is a case in which, if ever, the best man will win. Circulars, giving full information, will be sent to any address, on application to Mr. Charles S. Sargent, Brookline, Mass.

Woolly Taste in Mutton.

—Rev. D. Mills, Hamonton, N. J., says this flavor called woolly is owing to the absorption of gases from the stomach and intestines, consequent on the cooling of the carcass. If the sheep is cleaned rapidly, it is prevented. But he further says, if the sheep is not killed at all, it would be better, for animal food is improper. He does not say what we should do with the old sheep, when they accumulate on our hands.

Peaches and Frost.

—“East Tennessee Farmer.” Fires in the orchards are not expected to keep off the frost by the heat they give out, but by means of the smoke, which prevents radiation, just as a cloud does. The fires should be made of material that will produce the heaviest smoke, and in such places as the direction of the wind may require. To both the other questions—Probably not.

Apple-Tree Borers.

—A correspondent in Pa. writes: “Dig the sod away from the tree, and put sulphate of iron or dust from anvils about it. This will save the tree every time.”—We give this as one of the singular remedies proposed for borers; such absurd notions could not prevail, if the habits of the borer were understood. Let our friend go through his orchard and repeat the multiplication table backwards. It will not be half the trouble and quite as efficacious as his remedy.

Egg-Plants.

—“Aunt Aggie,” Latrobe, Pa., raises egg plants in the following manner: “We raise the plants in a box in the house. Plant out in the garden in May, as soon as the ground is warm enough. If there be danger of frost, cover with boards, supported at the ends with bricks; let the air pass under the boards. As soon as the plants begin to grow, or get the least start, we wet the ground around them with liquid manure, keeping a vessel with it in the garden, by putting manure in the vessel and filling it with water. We water with it every evening until the plants are large. By this treatment we have raised as fine egg-plants here in Western Pennsylvania, as I ever saw in an Eastern market. The Long Purple is most productive, but the Improved New York Purple is decidedly the best.”

What Beets to Raise.

—J. P. Landen, Harrison Co., Ind., wishes to know what beets to raise for cattle. His soil is a shallow upland, in which no beet will do its best. It must be deepened and enriched as much as practicable. On such soil the best beet for common cultivation is the Long Red Mangel. The Orange Globe is very good but does not yield quite so largely; it grows mainly above ground, but there must be a good range for feeding roots, whatever sort is grown. Lane's Sugar Beet is better than any Mangel, but the seed is not yet in the general market.

Norway Oats.

—A correspondent in Minn. thinks he has a good joke on our friend Gregory, the eminent seedsman of Marblehead, Mass. “Speaking of Ramsdell's Norway Oats, Gregory, in his catalogue for 1871, p. 27, says: ‘These oats in some localities have yielded over one hundred varieties to the acre.’ This statement, so much nearer the truth than seedsmen usually get, entitles him to credit. Send James to the head; let it be recorded.” Having “recorded” this typographical error, we add that one of the best farmers in N. Y. State informs us that he prefers the Norway Oats to all others, provided the grain is ground before feeding.

Our Great Libel Suit.

**End of a Four-Year Litigation—
Patent Medicines, Quack Nos-
trums, Doctors, and our Hum-
bug Columns, in Court—Import-
ant Legal Opinion by Judge
Brady, of the Supreme Court—
Manufacturers and Venders of
Patent or Specific Medicines
responsible for the Positive and
Negative Results of their Use—
Interesting to all Physicians,
to Lawyers, to Newspapers, to
Dealers in Medicines, and to
Buyers and Users of Medicines.**

The *American Agriculturist* has for many years published exposures of various humbugs, and warned its readers against the operations of a great multitude of ingenious swindlers. While this has been of great benefit to the country, and saved millions of dollars from going into the pockets of sharpers, it has cost a world of work and investigation, and much legal expense. Libel suits have been frequently begun for intimidation, or to obtain notoriety. Our readers well know how little the intimidation has benefited the operators, and the silence we have maintained about the lawsuits has deprived them of the notoriety they thus sought. Though preparation for defense has been expensive, in no case has a cent been awarded against us for damages or costs, as we have always been ready to prove our charges, and, with a single exception, every suit has been dropped before final trial, and this, too, without a word of concession or taking back on our part. We have been ready to "face the music," every time.

The exception referred to is the libel suit begun against us by Dr. M. L. Byrn, in the spring of 1868, which has been in Court ever since, and has recently occupied a week and a half before Judge Brady, of the Supreme Court, and a jury—ending in a complete verdict in our favor. We depart from our usual course of silence, in this case, because the legal opinions brought out and the testimony introduced, are of very general interest. Though this suit has been a long one, and taking into account our own expenses for legal fees, analyses, investigations, interruption to business, loss of time, etc., it has cost us more than Two Thousand Dollars, we think the sum would have been well expended, had it only brought out the authoritative opinions of the court, and the testimony given by the highest medical authority. During some of the interlocutory proceedings Judge Brady gave an opinion, which will be hereafter quoted as authority, that in effect makes the manufacturers and venders of nearly all advertised medicines responsible in damages, not only for any direct ill effects produced by their use, but also for the indirect injury resulting from delay in the use of proper medicines by those who trust to the claims put forth for these nostrums.

There were many other interesting points brought out, of general interest. We regret not having space in this journal to give a full report. (We can not insert extra pages without increasing the weight beyond $\frac{1}{4}$ lb., and doubling the cost of postage for the entire paper.) We have decided, however, to use several pages in our weekly journal, *Hearth and Home*, and give a pretty full report of the more important features, rulings, and testimony.

This will be given in the number of *Hearth and Home* for April 20th (Vol. IV, No. 16), which will be ready by Friday, April 12. It can be had for a dime of any newsdealer. Those remote from newsmen can have a copy forwarded post-paid by sending 10 cents to this office, giving their post-office address plainly. We hope every reader will manage to see a copy of that number and read the account of the trial. *The information should be read by every person in the country.* It will be a favor to every Physician, Surgeon, and Druggist, to call their special attention to it.

Draining a Flat on High Land.—Mr. J. H. Cook, of Knox Co., Ill., says he has read the *American Agriculturist* till he has caught the draining fever. He wishes "to lay a drain on land that has a fall of about one foot in sixteen for half or two thirds the distance, and the rest of the way is quite flat and wet." "Will it do," he asks, "to lay the tiles according to the lay of the land, or must I dig down where the flat and sloping lands meet, so as to make a uniform grade from end to end of the drain?"—This is not at all necessary. The writer has drained just such a piece of land on his own farm. The only point to be observed is that the drain is cut deep enough through the brow of the hill to afford sufficient fall to drain the flat perfectly. As the flat is wet, there will be sufficient water in the drains to enable you to level by. If the water runs off freely in the drains before the tiles are laid, and the tiles are laid properly, you may be sure you are all right. A little practice in laying the tiles will teach you more than a long article. If you meet with any difficulty, write us, and we will reply immediately.

Measurement of Poland-China Hogs.—J. M. Tubbs, of Ohio, sends us the dimensions, but not the weight, of a pair of Poland-China or Magie hogs. Boar, nine months old, measures from snout to root of tail 5 feet 5 $\frac{1}{2}$ inches, and girth, just back of the shoulder, 4 feet 1 inch. Sow, one week older, 5 feet 1 inch in length, and girth 4 feet 4 inches.

Essex or Berkshire Pigs.—Lewis Owen writes: "I have the White Chester hogs. Wish to cross with Essex or Berkshire. Which would you prefer? Where can I get a genuine 4 or 6 months old pig, and at what price? I am willing to pay for what I get, but do not always get what I pay for, except in grass and clover seed, then I get more than I want—weed seed."—We must refer you to our advertising columns. Either the Essex or Berkshire, if pure, will refine the ordinary Chester Whites. You should read "Harris on the Pig," where this subject is fully and fairly discussed.

Roup or Cholera?—A correspondent in Onarga, Ill., says: "I am losing about two fowls per day out of a flock of sixty Light Brahmas. The discharges become yellow and watery, the chicken droops and soon dies, and just before or soon after death a large quantity of a yellow fluid is discharged from the beak. What is the matter?"—Ans. The description is not sufficiently full to enable us to determine whether the disease is roup or chicken cholera, but the latter is probable. Our object in mentioning the case is to show the importance of thoroughness and minuteness when ailments of live-stock are described by mail. Some symptoms are common to several disorders, and it will not do to base judgment upon a few facts only.

Berkshire and Essex Pigs.—"J. G. B., of Wisconsin, asks: "Do you regard the Essex a good breed to cross with Berkshire, Chester, and Poland-China sows for fattening, and are the Essex enough better than the Berkshire, to make them preferable for a farmer to raise?"—The most distinguishing characteristic of the Essex, when well-bred, is its remarkable docility of disposition. It is also highly refined. Some of the modern Berkshires approximate closely to it in the latter respect, and are in every way a very superior breed. But we think, as a general rule, the Berkshires are, as compared with the Essex, much more active and restless. If a farmer intends to keep a pure-bred race of pigs for raising pork, we think the Berkshire better than the Essex, as they are not so refined, and can stand rough treatment with less injury. But for crossing with common sows, or with Chesters, or China-Polands, we prefer the Essex. You will get a most marked and decided improvement at once. But recollect, that no breed will afford good satisfaction without good care. The better the breed, the better must be the treatment. For some farmers the worst breed is the best.

City Boys that Want to Learn Farming.—We are constantly in receipt of letters from boys who want to go on to a farm, to study agriculture and work at the same time. In England, farmers advertise to take boys and teach them farming, but expect from \$500 to \$1,000 a year with them. Occasionally, there are farmers in this country who do the same thing. But this is not what our American boys want. They very properly expect to work and pay their way. There is work enough for such boys on the farm, if they could only find the right kind of farmers. As a rule the better plan for such boys is to go to some of their relatives or friends who are farmers, rather than to strangers. They will learn more and fare better with some plain farmer, who feels an interest in them, than with that class of farmers whose names frequently appear in the papers.

A New Story Coming.

EDWARD EGGLESTON'S story of the "Hoosier School-Master," first published in *Hearth and Home*, has achieved an extraordinary success. The leading journals and magazines have devoted whole columns to reviewing it, and are almost unanimously enthusiastic in their praises of it, several of them pronouncing it one of the most remarkable American stories ever written. The Pittsburgh Christian Advocate says:

"Since Unele Tom's Cabin, we have seen no tale that so entirely absorbed us.... It is American throughout, and full of quaint humor and most delightful character sketches. The author (Dr. Eggleston) is a superior limner of character, and makes all his sketches with a flowing pen." The *New York Independent*, in a column review, says: "This story shows the author to be a keen observer, a hearty lover of the things that are true and honest, and a skillful story-teller.... Indeed, we have rarely read any story whose truthfulness as a picture of life was more apparent." The *N. Y. Tribune* devotes over a column to "Hoosier School-Master," awarding it a very high meed of praise; and the same may be said of the press generally, including those of all shades of opinion.

Though copied more widely by the press of this country than any previous story, the demand for it has been so great that it has been issued in book form, and is having an immense sale. It is also republished in London, and is meeting with the most commendatory notices from the English press.

We take pleasure in announcing that Mr. EGGLESTON has nearly completed another Story, which will excite even more interest than the "Hoosier School-Master." It is entitled

"The End of the World,"

A LOVE STORY,

and will be illustrative of *Life in the West* thirty years ago. "THE END OF THE WORLD" will begin to appear in *Hearth and Home* the middle of April.

This Story will alone be worth far more than the subscription price of the paper, but *Hearth and Home* contains besides a large amount of excellent reading matter, articles, editorial and contributed, on the greatest variety of topics, and from the best pens of the country. One of the most eminent of American critics pronounces it, as it is now, "Number I among the weeklies." It has an admirable Household Department, and a Children's Department, profusely illustrated, of surpassing interest both to the little people and to children of a larger growth. The News Department gives a full and capital digest of current events throughout the world, enabling busy men and women to keep up with the times—to be intelligent, without having to wade through a large amount of printed matter.

Very great improvements have been recently made in *Hearth and Home*, and it is now doubtless the best *Illustrated Home Journal* in the world. Though each weekly number contains 20 pages as large as the largest illustrated weeklies, and averaging over \$500 worth of fine Engravings per week, *Hearth and Home* is supplied to subscribers for only \$3 a year, or with the *American Agriculturist* for \$4 a year. Subscriptions may begin with any week.

Special.—*Hearth and Home* will be sent from the beginning of Mr. Eggleston's new story to the end of 1872 (over eight months) for \$2, but only to those who order it during April.

Mr. Bresee and S. J. Parker, M.D.—In the Western Pomologist and Gardener for February, Mr. S. J. Parker, M.D., has an article on the Peerless Potato, in which he says: "One of the most remarkable seed-balls of the potato plant was that which has given the Early Rose and the Peerless. I have requested Mr. Bresee, who lives in New England, to give a full account of how that potato ball was had by him. He has been so *unkind* as to never reply to my request. This silence of any originator casts in my own mind a great doubt over all the early history of a plant, as on more than one occasion I have found a letter or two unanswered on a grape or plant, covered facts that would not bear investigation. We can only say that our letters to Mr. Bresee are unanswered, which is very ungentlemanly in him, and we therefore can not rouch for anything connected with him."—Here is a case in which a private gentleman, not choosing to answer the demands of an unknown correspondent, is most unwarrantably arraigned in a public print, and an attempt is made (which no editor should have published) to throw doubts upon his reputation for honesty. We will not stop to inquire who this S. J. Parker, M.D., is, who thus takes upon him the office of censor, the quotation we have given from his published article being sufficient testimony as to what he is. Having the pleasure of knowing Mr. Bresee, we are able to say that he is one of the most modest gentlemen we have ever met. Though he has in the introduction of his potatoes placed the whole country under great obligations, he shrinks from all notoriety, and has a strong dislike to appearing in print. These are qualities that S. J. Parker, M.D., may not be able to appreciate, but there are others who can. As to the case in point, the "remarkable seed-ball" that produced both the Early Rose and the Peerless potato, Mr. Bresee has never withheld anything concerning it. There is very little to tell, but what little there is should be known to any one who attempts to write upon the potato. We will relieve the anxious Parker's mind to the extent of stating "how that potato ball was had by him" (Mr. Bresee). It was had honestly.

Potato Sports—Late Roses.—The question of the permanence of sports in potatoes is just now of interest. One of our friends thinks us to blame for publishing Mr. Campbell's *opinion* that sports are not likely to be permanent. Where a point is a mere matter of opinion, the fair way would seem to be to hear different opinions, and then judge which carries the most weight with it. We published Mr. Campbell's view of the matter without indorsing it—indeed, we quite dissent from it; still, that is no reason why Mr. C. should not have a hearing, or that we are right. We base our opinion that the varieties of potatoes obtained as sports will be permanent upon the fact that sports in other plants are generally so. Sports, producing leaves, flowers, and fruit, differing in a marked degree from the typical plant, are well known to horticulturists. Indeed, some of our most valued varieties were obtained in this way. The sporting branch, severed from its parent and propagated, may continue the peculiarity indefinitely. The potato is an underground branch, and subject to the same laws of growth as a branch growing above ground; and there seems to us to be no reason for believing that a well-marked sport of a tuber may not be as permanent as any other sport. So far from a sport indicating a degeneracy of the original stock, we should sooner expect great vigor of growth to result in departures from the typical form than we should look for it in a degenerate stock.

Sulphur to Kill Vermin in Nests.

Now that the season has arrived for raising chickens, it is well to know that the powdered sulphur of the druggists is the cheapest, handiest, and best thing yet discovered for killing parasites that infest sitting hens, and find their way to fresh pastures upon the chickens as soon as the latter are hatched. Many times people complain that when their chickens are a week or two old, they droop and die from the attacks of large lice, which literally cover the heads of the birds. If examination is made earlier, it will be found that the insects have taken up their abode upon the chickens' heads while still in the nest, for they forsake the hen, preferring the chickens. It is bad business to have to catch the chickens and hen for treatment after they have left the nest, when the remedy can be applied with so little trouble before hatching begins. A week or so after the hen has been given her clutch of eggs, sprinkle them and the whole of the nest and the straw for a little distance around it, with the sulphur when the hen is off. The night following attend to the hen herself, by lantern-light. Disturb her just enough to make her bristle her feathers, and then dust sulphur well down to their roots. Go over her whole body thoroughly, excepting the parts in contact with the nest, and lift each wing and scatter a pinch, and attend to head, neck, and tail. It will not injure the hen in the

least, nor the chickens when they are hatched. We repeat the operation at an interval of a week (though perhaps one application is sufficient), and have never found the slightest trace of vermin upon hen or chicks afterwards. Use two small handfuls. It costs little either in money or trouble. Tobacco, snuff, grease, carbolic powder, etc., are not to be compared with sulphur for this particular purpose, and the best dust-bath privileges for the hen are not to be relied upon alone.

Bee Notes for April.—By M. Quinby.

This month is a good time to take the first lessons in bee culture. One of the most important things is to learn how to avoid stings. The greatest difficulty in bee culture is the fear of being stung. Among the higher animals it is believed that qualities resulting from education and training are transmitted to the offspring. When we see how much the Italians are in advance of the black bees, we may suppose bees are also capable of improvement. The Italians will allow us to take liberties with them, that the black bees would highly resent. They have become accustomed to our presence, and seem to consider it a matter of course. The black bees have never been approached, except for pillage and murder, and they seem to fully comprehend it. They are either indignant at the first familiarity, or yield with the most abject submission. To educate or train the bees, and ourselves as well, in order to feel absolutely certain that we shall not be troubled with stings, we want a good veil. To readily detect anything wrong in the interior of the hive, we must become familiar with its condition when everything is right. To do this we must frequently have access to the interior for observation, and do not want the annoyance of fear, to make us forget any important item. The bees are quieted when irritable, by means of some mild smoke. That made by hard wood just rotten enough to hold together, when sawed or split into pieces two inches square, is good enough. The veil, that important appendage, consists of about a yard of tarlatan or millinet, sewed together like a bag, open at both ends; one end is gathered on a string, that will allow it to slip down over the crown of the hat, which should be of a light color. In the part that comes before the face, insert a piece of fine wire cloth, 6 x 8 inches square. Opposite the mouth put in a pipe, ten or twelve inches long, to be held by the teeth. When ready to operate, light one end of the rotten stick, adjust the veil on the hat, and go to the hive—it is movable comb, of course—and take off the top. There are different methods of removing this, according to the skill of the operator. One will get hold of the top that, if in cold weather, is firmly held by bee-glue, and with a sudden jerk bring it off with a snap, that will be but little less than thunder to the bees. These will sometimes come out to reconnoiter, before the smoke can be brought to bear. Another will use something to raise the top more moderately; a chisel or heavy jack-knife will be slipped under, to pry it loose, often without a jar, and sometimes without alarming a bee. Before removing the top, after it is loose, and raised just a little, he will listen to the notes within. If a sharp, angry buzzing is heard, instead of letting the top fall to crush and pinch a few, and make all still more angry, he simply holds it still, and holds the smoking wood as near as possible, and with the pipe held by the teeth directs smoke exactly among the bees. Almost immediately they will go down among the combs. By raising the top gradually, any bees not yet down, may be seen and smoke directed to them specially, until all retreat. In the same easy way the frames are loosened, and some are separated until one can be lifted out, without crushing a single bee. Any angry demonstrations should be quieted at once with smoke. When a comb is once lifted out, and bees exposed to open day, the greatest danger is over. The bees seem to be so astonished at the change, that they forget about resenting any insult. The gloves that are often called for, are not often needed. The anger of the bees ought not to be allowed to rise until they will sting a person's hands. Shall I say that any wanting gloves for their hands, are not yet thoroughly skilled in bee management? Some of us have not stopped here, but have looked a little further, and found as we became acquainted, that under some conditions we can do much more. In a warm day, when the bees are bringing stores, the propolis that holds everything fast, is softened and comes off without a jar or snap, the bees engaged in work do not notice what is being done. We can often open the hive, look over the combs, and empty out the honey if we wish to, and return them to the hive, without having an angry bee. This is because we do it at the right time and in the right way. There is the value of two millions of dollars in this State wasted annually—20,000,000 lbs. of honey. The people must be educated to save it. This dreadful fear of stings must be overcome. When we come to find it can be avoided—and if a sting does happen, it would not be so very bad, had we not been taught to

so regard it—we shall have advanced some. Let us begin now to educate our bees, and ourselves as well.

The Report of the Department of Agriculture.

Dear Mr. Editor—I think it is hardly quite fair in you to complain of the U. S. Commissioner of Agriculture for "doing over" some bits of his old reports. Take for instance those parallel extracts, which you have paraded in your February number. Don't you see that Judge Watts wished to improve a good opportunity of qualifying some statements which he had rather rashly advanced in 1864, and to render others more perspicuous?

For instance, in the report for 1864 Judge Watts states as the result of his experience and that of his fellow-trustees, that a farmer's son, educated in college, is thereby "actually driven by his education into the necessity of resorting to some neighboring town, in pursuance of a learned profession, where he forms habits of idleness and intemperance," etc. Now, upon reflection it has evidently occurred to the Commissioner's mind, that a goodly proportion of the ministers, lawyers, and physicians of the country, and even the most eminent of them, have been farmers' sons, and that a fair share of them have led reputable and moral lives. So he now qualifies his original sweeping assertion, with a "perhaps" to be led into the haunts of intemperance and vice; and you must allow that the qualification was called for.

In the Report of 1871, I see that he still gives a deplorable account of the prospects of a farmer's son who has had the ill fortune to receive a college education; insisting, that "he is driven to the nearest country town, to prepare himself to make a poor figure in professional life." But here perhaps the judge is speaking only for himself. The experience of others might be different. And I really do not see why a farmer's son is more likely to fall into intemperance and vice, or to make a poor figure in professional life, than any one else's son, nor why a professional career should not be as freely open to him as to others.

Moreover, in the original report the contemplated "result is, that the father not only loses the expenses of his education, but the son himself." Certainly not a perspicuous sentence, as it leaves us in doubt whether it is the son who also loses the expenses of his education, or whether it is the father who loses his son. Now, you perceive that this riddle is solved in the amended edition of 1871. It is the father, who "realizes the loss of the son himself."

In his next Report, perhaps, the Commissioner will try his hand upon a short paragraph of his, which has lately attracted attention: "If science and learning be useful at all, where can it tell with so potent an influence as where it deals with the operations of a farm, which embrace a great number of mechanical and chemical forces, and involve the necessity for searching after philosophical truth?"

If "it" refers to "science and learning," all is so far more intelligible than grammatical: but the "operations," "which embrace mechanical and chemical forces and involve the necessity for searching after philosophical truth," involve an all-embracing obscurity of statement, which needs some elucidation, in order to be quite clear to the simple apprehension of your humble correspondent.

A FARMER'S SON.

Ogden Farm Papers.—No. 27.

I suppose that suspicion is a necessary consequence of publicity, and, while I trust I shall not seem discourteous, I beg to say, in my own behalf, that I really have not the time—even if I had the inclination—to write personal letters in vindication of my truthfulness. My statements must rest on the simple fact of their being made. If they are disbelieved by some of my readers, I am sorry for it, but not so sorry as to induce me to take steps to verify them. If any of the readers of these papers desire practical information that can be given in few words, I shall always try to find a moment to give it, but even this is a severe tax on a busy man's time, and I certainly shall not add the further labor of insisting that I tell the truth in what I write. Those who doubt whether I sell my butter for 75c. per lb., or whether Mr. Sargent sells his for \$1.15, must apply elsewhere for the proof. I have made the statement, and there I rest my

case. I am led to make this personal explanation to save the doubting Thomases the trouble of writing letters which it costs me valuable time to read.

I have lately revived my old lecturing experience, in an afternoon talk to a farmers' meeting at Ogdensburg, N. Y., and I was surprised to note the change that has come over such meetings during the seventeen years that have passed since lecturing to farmers was my business. Then, in no matter what part of the country, an average farmer, no matter how intelligent and liberal in other things, came to such a meeting with very much the air with which a dog puts his nose to a hornet's nest, doubting, but curious; afraid of what he shall find; and very conscious as to the impression he makes on those who are watching him. Every statement was received with suspicion, and if, by good fortune, the new idea—that science has something to do with agriculture—began to dawn upon him, it was received with the greatest slowness and distrust. If he were of the other sort—an enthusiastic believer of new things—he came to the meeting almost by stealth, and evidently dreaded the gibes and jeers of the neighbors to whom he should return. Even so short a time ago as that of which I write, there were but few agricultural papers, and they were struggling for a feeble subsistence. It was rare to find in any country neighborhood two men who took a purely agricultural paper. The *Agriculturist* has hundreds of subscribers now to one that it had then, and it was already an old and well-known paper. I was never treated with rudeness or incivility, but I was generally looked upon with undisguised pity—the sort of pity that is not far removed from contempt. But for the handful of enthusiasts who were ready to believe all I had to say, and more, the position would have been almost unbearable. No one who has not had such experience, would realize the change that has now taken place. During all these years the press has been doing its constant work, and I believe that in the better farming communities it would now be as rare to find an intelligent farmer who does not take or read a paper that is wholly or partly agricultural, as it then was to find one who did. It is not easy to describe the change that the spirit of the recent meeting indicated. It is precisely the change that has come over the better class of farmers in their conversations with each other. Without becoming less conservative they have lost their "old fogysm," and have begun to realize that the truly conservative course is that which allows no opportunity for valuable improvement to escape. Men who have seen the mowing machine drive to the wall the old slow-going, back-breaking scythe, with its gang of hungry mowers and their jug of sun-warmed grog, and who have witnessed within a few years a greater revolution in the work of the harvest than has been effected within the same time in any other branch of human industry, have become eager for still further advances in their art. As a consequence, we had a meeting that it was a real satisfaction to attend. In the course of a two-hours talk, matters were intelligently discussed, which in the old times would hardly have found place in the minds of those present. The subject of underdraining engaged more attention than would have been thought possible, and the treatment of manure and other branches of farm economy attracted an earnest consideration, that showed how real an advance had been made. Indeed, we may congratulate

ourselves that the wedge is fairly entered; that the minds of farmers are awakened to the importance of an improvement in their practices, and that the chief remaining obstacle to the rapid improvement of American agriculture lies less with the indifference of farmers than with the extravagance, the ill-considered advice, and the want of judgment of those whose business it is to spread a knowledge of agricultural improvement. This throws a weighty responsibility upon agricultural writers, who should have a constant watch over the soundness of their teachings and the avoidance of false premises. A better audience could not be asked than that which is addressed by the agricultural press, and if its instruction is well considered and wisely given, the greatest good will flow from its influence, while unsound advice and the encouragement of mistaken practices will seriously weaken its effect.

In my northern journey (in February), I have had occasion to see several herds of Ayrshire cattle, notably those of Mr. Morgan, of Ogdensburg, and of Mr. Irving, of Montreal, from whom Mr. Morgan obtained his foundation stock. The more I see and hear of them, the better I like them. They are evidently no competitors of the Jerseys for the butter dairy, either in quality, or, as compared with the amount of food consumed, in quantity. But for all other purely agricultural uses they are evidently better. Their milk seems richer in caseine, and during the flush of their milking their flow is much larger. They are docile, intelligent, and motherly, and when they cease milking they take on fat very readily. In short, for all purposes, except butter-making, I believe they are the best farmer's cows. It filled me with envy to see these herds so bountifully bedded in clean straw, and to think of my own, in a country where the little straw that is grown is held at enormous prices for the bedding of carriage-horses, obliged to content themselves with beach sand, which, so far as comfort goes, is a poor substitute, good as it undoubtedly is as a manure for our heavy land.

Mr. Irving, buried in the snow of a Canadian winter, is no less impressive as a good farmer than when his ground was open for fall work. His large stock is comfortably housed and cared for, and the accumulation of manure which was being hauled to the fields, ready for spring work, showed that he unlocks his success with a very large key. In some respects I thought that his stock showed a tendency to run too much to "big things." I am not prepared to say, though I suspect it, that his enormous Clydesdale horses are less economical for work than our animals of more medium size; but he had an amount of pork on four legs that I should much prefer, if it were my own case, to put upon eight. It has a bountiful look to see the large Yorkshires rolling up fat to the tune of 700 lbs. dressed weight, but three natty Essex shoats, weighing 230 lbs. apiece, would be more to my fancy. However, it would probably be modest in me to confine my criticisms to men who have less to show than Irving has for their work and their wits.

A farmer in Asliby, Mass., writes that he got a tin pan large enough to hold one milking from ten cows, but got less butter from it than he did from the same amount of milk in smaller pans. He asks whether he should have set the pan in water, the temperature of the air being 63° to 65°. Certainly he should have done so. The great secret of successful dairying, or one of the

great secrets, is to withdraw the animal heat from the milk as soon as possible. A *pan*, such as is described, seems to me much less suitable for the purpose than a deep and narrow can, set to its neck in the water. The latter is more conveniently skimmed and more easily handled, cools more rapidly, and exposes a larger proportion of the milk to the influence of the water and less to that of the air; this is better, as the temperature of the water is uniform. To answer further questions of the same correspondent: We let our milk stand 24 hours (all the time in the water); and we prefer to keep it lower than 62°. I fancy that 50° would be better, if so cold a spring could be had, and Mr. Swartz in Sweden uses ice-water, at about 40°. The colder the water, the larger the diameter of the can may be. If the water stands at 60°, then a diameter of 8 inches is large enough. The point is to have the mass of milk cooled as soon as practicable. If it were first passed through a cooler, then the can might be of any size that would not expose too much surface to the air.

We hear a great deal about the "animal heat" of milk, and we do not always stop to think that animal heat is exactly the same as any other heat. It is produced by the combustion of a different fuel in a different sort of stove, but as heat it is the same as though it came from an anthracite fire. Fresh, cooled milk, raised again to blood-heat, by being set over a fire, would be as badly off as though it still retained its "animal" heat.

An Egg Farm.

BY H. H. STODDARD.—*Concluding Article.*

Two buildings remain to be described. Fig. 1 represents a hospital, that is, a building that can be used as such in an emergency. It is 14 feet wide, 60 feet long, and 8 feet high at the peak. There is a passage 2½ feet wide, running its whole length the north side, which communicates with the twelve rooms into which the building is divided by wire partitions. The glazed roof is upon the south side. There is an outside door (not shown in the figure) in the north wall, opposite the chimney, for convenience in attending the fire. The building is warmed by coal, a fire-chamber of brick, and a boiler and hot-water pipes being used. It is injurious to animals to breathe the fumes that will escape when it is attempted to warm a room by passing a smoke-pipe through it, leading from a coal-fire, unless the chimney is quite high, causing a strong draft, which is one reason for preferring hot water, and another is that the risk of overheating is not so great (for water can not be heated above a certain temperature), and a third reason is that less fuel is needed with hot water than without. The original cost of hot-water fixtures is double, it is true, but they are kept in repair with hardly the expense of a cent, and cause a saving of full half the fuel. The ventilator at the top of the building has immovable blinds at its sides; and horizontal doors at its bottom, opening upwards, and closing by their own weight, moved by means of cords and pulleys, regulate the egress of air. At the north side of the building are a number of small windows, covered with ordinary adjustable blinds, for the admission of fresh air, and in summer the doors at both ends of the structure may be opened, as in the illustration, and the windows in the roof should be partly curtained. This building is used for early chickens and numerous other purposes, it not being expected to have much occasion to take care of sick fowls, for the

true plan is to prevent disease by inducing constant exercise by scratching, by allowing sun, air, good food, and breeding from vigorous stock.

The office and "watch-house" (fig. 2) contains a room below for a business desk, and above are sleeping apartments. Lights should be kept burning all night, to show thieves that vigilance is maintained. Dogs, small and great (in-doors and out), are valuable aids (accounting for the kennels in the figure), but in the day time they should be yarded in a strong inclosure made on purpose, or chained where they can not frighten the fowls. The eggs designed for hatching are kept in a closet on the first floor, so situated with respect to the fire (maintained day and night in a small base-burner coal stove

during cold weather), as to be kept at a constant and even temperature of about 50 degrees.

[NOTE.—In the January article, p. 12, the types made us say 10° instead of 20° as the difference between the inside and outside temperature of our fowl-houses.—In the description of the house for sitters in our fifth article it should have been mentioned that about one third of the south roof is glazed, the windows being partially darkened as warm weather approaches.—In the eighth article, fig. 1 should be denominated "Nests for Sitters," not "House for Sitters."]

A tract of land, 100 × 100 rods = 62½ acres, will contain ten rows of houses for the laying stock, arranged on the quincunx plan, ten in a row, as stated in the initial article. These one hundred buildings will each contain 50 birds, or 5,000 in all. In addition there must be 500 of the sitting stock, and 500 at the breeding and experimental yards, or a total of 6,000. The 5,000 layers comprise 3,000 yearlings, and the rest are two-year-olds. To replenish the laying stock, there must be raised 7,500 chickens yearly (for three out of five are cocks and inferior pullets to be rejected). To replenish the sitters and also the breeders—in the latter class much "weeding out" being necessary—2,500 chickens more must be raised. That is, about 10,000 chickens must be reared annually.

Now, when fowls are kept under the ordinary system pursued by the family living in a village—by which we mean that there is a fowl-house and yard to accommodate a flock, and then, if the number is to be increased, another yard is made, and so on—one man can take care of 600 fowls without the aid of a team. He can take off all the produce in the cars, and distribute to his city customers from a basket carried upon his arm; can spade up the ground in the yards, keep the fowls out of mischief by setting them at work scratching, clean the houses regularly, prepare the food, build a fire, and cook for his charge every day, giving a variety, meat, vegetables, pounded shells, etc., and keep his stock young by raising enough chickens, so as to have on hand 400 pullets every autumn, after killing the supernumerary cocks and inferior pullets. But one man can not take care of more than this, and do it well, under the ordinary domestic or small-scale plan. If he attempt to manage

1,000 or 1,500, market their produce, raise the needful number of chickens, etc., he will slight the work, and so sure as it is slighted, there will be loss. He can keep 600 adult fowls, and make \$600, and no more. If he is not skillful, vigilant, patient, and persevering, he will not make that. We mean reckoning ordinary market

Fig. 1.—HOSPITAL FOR EGG FARM.

rates for produce (not selling live fowls, or eggs for hatching, at high rates, and supposing that he raises some early chickens, but only as many as may be while distributing his labor evenly throughout the year, and allowing the value of the manure to exactly offset the interest upon the land and buildings, and the repairs and depreciation in value of the latter.

We have kept accurate accounts for five years, and though we have in one year cleared \$2 per head on an average, and sometimes on single flocks as high as \$2.75 per head, yet it is unsafe to count on more than \$1 per head profit upon each adult fowl, all losses and expenses considered. Now let it be remembered that the skill and incessant care and industry necessary to clear \$600 in the case supposed above would, employed at some other business, earn \$800 or \$900, for a bungler can not keep fowls as a business, and we see why it is that during the past fifteen years so many persons who have tried to enlarge their poultry business on the ordinary "family fowl-house and yard" plan have failed and quit in disgust. What is needed is the reduction of the amount of labor. This must be accomplished by employing a team in every operation where it can be done, and by using movable buildings. The movable houses and no yards (necessitating the system of indirect feeding) are the central features relied upon in our "egg-farming" to crowd down labor to the minimum. All the other features are subordinate.

Five hands (with two horses) can attend to the whole establishment of 6,000 adult fowls, and the excess of produce over feed will be \$5,000 for the laying stock of 5,000 birds. Nothing is said about any income from the breeders and sitters, they are supposed to be as much a necessary evil as anything; or about income from crops or manure, that being an offset, and a fair offset, as our experience and laborious accounts show, against the interest on land and buildings. The help can come of it be of the cheaper sort—boys of fifteen, if intelligent and steady. One hand worth \$800 at the top of the scale (there's no use in reckoning a princely salary at any rural occupation), the "right-hand man" at \$700, No. 3 at \$600, and two apprentices at \$350 each, and there is \$2,800 for labor, to which \$400 must be added

for the maintenance of team, including wear and tear of vehicles and harness, and sundries. As our eggs are only partly hatched, we can't count all the chickens, but our readers have a right to figures enough to get a fair understanding of our enterprise.

There are only three systems of fowl-keeping possible. There are many modifications of these, it is true, but to one genus or another of the three following they may all be referred.

One is the highly artificial or bird-cage plan of Mr. Geyelin as detailed in his "Poultry-Keeping in a Commercial Point of View," a book which is, after all, one of the most valuable repositories of information for fowl-keepers ever written. But the cage plan fails, because there is not enough exercise for the birds, and altogether too much for the attendant.

Another is the ordinary plan of the villager or the fancier, given in poultry books and agricultural papers in endless variations of one tune, and that tune a "house and yard adjoining." A good plan for the family who make no account of the labor involved, and who have odd bits to spare from their table, or for those expecting to sell blooded fowls or early chickens at high prices (minor branches in which a few can and do make fortunes), and a good plan too for getting a start in operations on a large scale, but a money-losing plan if it is attempted to supply city markets with table fowls and eggs at ordinary market rates.

The remaining one is that pursued by nature before fowls were domesticated, and the one under which they have been mainly kept since, during a period antedating history and continuing to the present; by giving them their freedom in the daytime and a shelter by night. Nature gave a thicket for a roost; the farmer, from the barbarian down, gave a shed—that is about all the difference. Spite of neglect, the farmer's poultry at large is more free from disease than that kept yarded under average management. As the wild fowls need no attendant at all, so by arrangements as near like theirs as possible the least labor is demanded. Fend off storms and wind and the summer sun by the simplest shelter that can be made, dodge the labor of house-cleaning by plowing and moving buildings, and make the mutual antagonisms of neighboring flocks take the

Fig. 2.—OFFICE AND WATCH-HOUSE.

place of yard fences just as among wild jungle fowls, and the maximum of thrift and the minimum of labor and expense will be secured.

Our ambition has been and is to demonstrate, not how to raise blooded fowls nor mainly early chickens, capons, or any other article with a view to high prices, but to change one staple, grain, into another, eggs, by the most economical method possible. The industrial problems which concern the masses are the most important.

The Mandarin Duck.

Almost any one upon seeing the Mandarin Duck, or rather the Drake, would guess that it was a native of China. There is an oddity about many of the animal and vegetable productions of that country, not less striking than that presented by its people. Our artist was afforded a rare opportunity of sketching these birds from life, by the Hon. Caleb Lyon, formerly Governor of Montana. Mr. L. has at Rossmere, his residence on Staten Island, N. Y., a pond in which he has many rare and interesting aquatic birds, but none more beautiful than the Mandarin Ducks. These birds are known in China as Li-chi-ki, and highly prized by the wealthy Chinese, who are quite unwilling that they should be allowed to leave the country. An Englishman wrote some years ago to a correspondent to send him a pair of these birds. The reply came that it would be easier to send a pair of Mandarins than it would a pair of Mandarin Ducks. The first pair that was imported into the United States cost, in England, \$375. The drake is quaint in appearance and gorgeous in plumage, while the duck is modest in her dress and makes but little show. One of the striking features of the Drake is its wing-fans, which stand erect and look much like the wings of a butterfly; these are of a chestnut color, edged with the deepest green. The crest is varied green and purple upon the top of the head, the long crest-feathers being chestnut and green. From the eye to the beak is a warm fawn color, and a stripe of cream-color extends from the eye to the back of the neck. The sides of the neck are bright russet, and the front and breast a rich, shining purple. Upon the shoulders are two bands of black and two of white, alternating. The lower part of the bird is white. The bill is crimson and the legs are pink. The plumage of the female is a mottled brown. The drake wears his fine clothing only a portion of the year. In May he lays aside his crest and wing-fans and takes on the brown color of the female, and remains in this inconspicuous clothing until August.

The birds are able to perch, and are very fond of sitting upon branches overhanging the water. Though very attentive to his mate and a model husband, the drake has the reputation of being very quarrelsome, and will tyrannize over much larger and more peaceable birds.

MANDARIN DUCKS.

Silver-spangled Polish Fowls.

There are a number of varieties of Polish fowls, all of which possess the characteristic crests, or top-knots, and U-shaped combs, suggesting a deer's antlers, and prominent nostrils. The principal breeds are the black, with white crests, and two others, named from their respective markings of gold or silver spangles upon a black ground color. The relationship of all these to each other is indicated in the fact, that by culling from the last two mentioned, birds with but faint markings of yellow bay (gold)

Polish fowls possess some economic merits; they are plump, small-boned, and moderate eaters, lay freely when their constitution has not been excessively weakened by repeated in-breeding (as is too often the case with a breed that is represented by only comparatively few stocks), and they are quite as hardy as any other fine-bred fowls, the Asiatic races excepted, so long as they are kept out of the rain. The reason why they can not endure wet is, that the crest absorbs so much water, and the bones of the skull are so thin, and spread apart on account of the development of a fleshy knob, serving as the base of the crest, that the head is exposed to cold. Their strong points are however not so much utility as good looks and an attractive disposition. They are about the

most graceful in outline and carriage and showy in plumage of any fowls we have, and they are naturally as tame as the Leghorns are wild.

Walks and Talks on the Farm.—No. 100.

I do not know of anything that has pleased me more than the numerous letters that have come to me from farmers, fruit-growers, and nurserymen in all parts of the country asking for more information in regard to my experiment with white mustard. Let no one call farmers "clod-hopping old fogies;" for while as a class we are somewhat suspicious of new things, and are inclined to hold on to that which is good, it is very evident that there are thousands and tens of thousands of active, intelligent, enterprising men engaged in agricultural pursuits who are studying everything pertaining to their business. I have sometimes felt annoyed at the disposition manifested by some of my neighbors to criticise unjustly

SILVER-SPANGLED POLAND FOWLS.

and white (silver), and breeding in this way for some generations, a black breed with white crests may be formed, from which, by reversing the process, and seizing upon pied variations or "sports" in the progeny of black fowls, beautiful gold or silver strains may be again produced.

my own farming operations. I have thought they were rather pleased than otherwise when any of my experiments failed. But, on the whole, I believe I have judged them unjustly. At any rate, they seem interested and pleased whenever I get a large crop or raise a good animal. At first, they

my own farming operations. I have thought they were rather pleased than otherwise when any of my experiments failed. But, on the whole, I believe I have judged them unjustly. At any rate, they seem interested and pleased whenever I get a large crop or raise a good animal. At first, they

seemed to think that I intended to "show them how to farm," and they very properly resented such an assumption. Of course I had no such idea. I have devoted my life to the study and practice of agriculture. I have a great love for country life. Few things give me greater pleasure than to see good crops and clean land. I like to see good animals. I like to be among them. I do not find farm life dull, stupid, monotonous, and lonely. And yet there is not one farmer in a thousand that is more isolated. Perhaps it is this very isolation that makes me feel such an interest in the letters I receive from my brother farmers in all parts of the land. Their letters are always friendly and sensible, and are well calculated to give one a high estimate of the enterprise, good feeling, and intelligence of American agriculturists.

In regard to white mustard, it should be understood that I have tried it only one season, and of course I am only warranted in saying that it "promises well." I shall sow it more largely this year, and at different times. Last year I sowed three acres, July 26th. The land was an oat stubble that was seeded down the previous year and failed to catch. We plowed the land three times. But, to please an English friend, the land was neither harrowed, cultivated, nor rolled, until after the last plowing. I think this was a mistake in our climate. If the soil had been thoroughly harrowed and rolled after the first plowing, and then cultivated occasionally to kill the weeds, and then plowed just before sowing the seed, I think the fallow would have been in better condition, and the soil finer and moister. As it was, the clay spots were quite rough, and the seed failed to germinate. No plaster or other manure was sown on the mustard. This was also a mistake. Still, on nine tenths of the land, where the soil was fine and moist, the seed germinated, and the crop grew finely, and gave us a large quantity of succulent food. The crop will do to turn on to in from six to eight weeks after sowing. By the first of October the plants on the average were about two feet high; and on the moist, alluvial land it grew from four to five feet high. I estimated the yield on this rich alluvial land at 20 tons per acre, and on the whole field at 12 tons per acre.

The composition of white mustard in the green state, according to Dr. Voelcker, is as follows:

Composition of white mustard in its fresh state, as compared with clover, Swede turnip leaves, rape, cabbage, and red clover.

	Mustard.	Swede turnip leaves.	Rape or cole-seed.	Cabbage.	Red clover.	Green-corn fodder.
Nitrogenous compounds, albumen, etc.	2.87	2.08	3.13	1.50	3.30	0.90
Non-nitrogenous matter, gum, sugar, etc.,	4.40	1.61	4.65	6.70	8.40	9.30
Non-nitrogenous matter, vegetable fiber, etc.,	4.39	5.64	3.56	2.90	4.50	5.00
Ash or mineral matter,	2.04	2.29	1.61	1.20	1.50	1.10
Water,	86.30	83.37	87.05	89.00	83.00	84.30

It will be seen that mustard is rich in nitrogen and mineral matter. It is wonderful how a plant can take up and organize such a large amount of these important substances in so short a time. Prof. Johnson, in his masterly and invaluable work on "How Crops Grow," gives a figure of a seedling mustard plant, showing its root to be thickly covered with an innumerable number of minute hairs. "These root-hairs," he says, "consist always of tubular

elongations of the external root-cells, and through them the actual root-surface exposed to the soil becomes something almost incalculable."

A crop of winter wheat yielding 40 bushels per acre organizes in grain and straw 353 lbs. of nitrogenous matter per acre. And the plants are in the ground about ten months.

A crop of mustard, on land rich enough to produce 40 bushels of wheat per acre, would probably yield 20 tons of green food; and this would contain 1,148 lbs. of nitrogenous matter. In other words, an acre of mustard plants can take up and organize from the soil in about two months more than three times as much nitrogen as an acre of wheat.

Now, we know that on the greater number of our wheat-growing soils the element of manure that we most need to give us a large crop of wheat is available nitrogen. All our approved processes in agriculture tend to this one object of furnishing available nitrogen for wheat and other grain crops. If I have a field of wheat sown on the dry upland portions of my farm without manure, that will yield 15 bushels per acre, I should expect that 100 lbs. of available nitrogen per acre would cause it to produce from 35 to 40 bushels per acre.

This is precisely what we want. We are now getting about 15 bushels of wheat per acre, and other crops in proportion. We want 35 bushels; and if our climate will give us 40, 45, and 50 bushels, we want such crops. We have to pay so much for labor, implements, etc., that we must have large crops if we are to obtain a fair compensation for our capital, care, and labor.

That we can make our land rich enough to produce from 30 to 50 bushels of wheat per acre, according to the season, is unquestionable. We must make our land dry and clean, and at the same time accumulate in the soil from 150 to 200 lbs. of available nitrogen per acre, and other plant-food in proportion. And we can not get this nitrogen from natural sources without at the same time getting a full sufficiency of all other elements of plant-food.

All our so-called renovating crops are rich in nitrogen. It will be seen from the above table that clover, rape, and mustard all contain more than three times as much nitrogen as Indian corn. All the cereals, such as wheat, barley, oats, rye, Indian corn, and the grasses proper, such as timothy, red-top, etc., are comparatively poor in nitrogen. The cereals contain but a comparatively small proportion of nitrogen, and their roots are not provided with the power or means of taking it up in large quantity from weak solutions of nitrogen in the soil. Clover, peas, beans, vetches, turnips, rape, mustard, and other renovating plants contain, as compared with other ingredients, a large proportion of nitrogen, and are provided with the means of taking it up from a soil relatively poor in nitrogen. I do not know that I make my meaning clear. But I am very anxious that the matter should be understood. I do not believe that clover and other renovating plants take nitrogen from the atmosphere through their leaves. There is no proof of it. The facts all point the other way. And yet these plants do get a large amount of nitrogen from a soil that will only produce 15 bushels of wheat per acre; and from a soil that when supplied with 75 to 100 lbs. more nitrogen per acre will produce, without any other additional plant-food, 35 to 50 bushels of wheat per acre.

Whatever the scientific explanation of these facts may be, one thing is clear: If we want to raise large crops of wheat, barley, oats, rye, Indian corn, and timothy hay, we must devote

a considerable area of our farms to the growth of clover and other renovating crops. And, contrary to the teaching of some writers, for whom I have great respect, I say emphatically, these renovating crops must be retained on the farm. We must not sell a pound of them. Sell the cereals; sell timothy hay if need be; sell straw if you must; sell anything rather than clover and other renovating crops. The object of raising these crops is to take up the nitrogen that is diffused through the soil, and concentrate it sufficiently for wheat and other cereals to get hold of it. It is as poor economy to grow wheat and other cereals without rotating them with clover and other renovating crops, as it would be to gather a light crop of hay with nothing but a fork. We first concentrate the hay into windrows with a steel-toothed rake, and then use the fork for putting the hay on to the wagon. Clover is the steel-toothed rake. It does not create the hay, nor fetch it from another field; it merely gathers it into heaps for the fork—or, in other words, for the wheat. The nitrogen is in the ground, but the wheat can not get hold of a good forkful until the clover has gathered it into heaps.

But to return to the mustard. It is a far inferior crop to clover. Red clover is and always will be the grand renovating crop of American agriculture in all sections and soils where it flourishes as well as it does in Western New York, Pennsylvania, Michigan, Ohio, Indiana, Wisconsin, Minnesota, and other wheat-growing sections. But this is no reason why we should not grow other renovating crops when convenient. There is no danger of our growing too much of them, no danger of getting our farms too rich to grow mangolds and Indian corn.

Until we get hurdles or a good portable fence, and adopt the system of folding sheep on land, mustard will not be extensively grown here except for plowing under as manure. For the latter purpose its composition shows it excellent. A medium crop of say 10 tons per acre would contain about 90 lbs. of nitrogen gathered from the soil, and when plowed under it would be more or less available for the next crop. On sandy soils, that are not specially enriched by summer-fallowing, mustard could undoubtedly be used to advantage as a green manure for winter wheat or for Indian corn the next spring. For wheat, I would plow the land in the spring, cultivate, harrow, and roll, until it was as fine as possible, and sow four or five quarts of mustard broadcast per acre the middle of June. By the last of August it would be ready to plow under.

I fear my readers will be tired of the subject, and I will conclude with a few extracts from an English writer in Morton's Cyclopaedia: "Mustard is considered obnoxious to the wire-worms. . . . We know that an abundant crop of mustard if plowed into the ground when just coming into blossom is an excellent preparation for barley or oats. The mustard is best plowed in during the month of October or November. The land gets the winter's frost, and may be worked into excellent tilth in the spring, merely by the use of the scarifier."

The experience of the heavy-land farmers of Suffolk is in favor of sowing about a peck of white mustard on the long fallows in August or early in September, and plowing in the herbage about six or eight weeks from the time of sowing. The effect upon the barley crop is considered by practical farmers as equal to half a coat of farm-yard dung, obtained at a cost of

2s. 6d. for the seed, and the additional trouble of sowing and harrowing in the seed.

Mr. Kimball, of Buxhall, gives the following as his experience upon a clay loam: "The mustard being sown after peas, and plowed in for wheat, the difference in the crop was visible to the eye at a considerable distance from the field. At harvest, the wheat where the mustard had been plowed in was six inches higher, and ripened ten days sooner than wheat on adjoining lands where no mustard had been sown, but otherwise treated in a similar manner."

This is a remarkable case. Winter wheat in England is sown much later than with us, and there was time after a crop of peas had been harvested to grow a crop of mustard to turn under for the wheat. In Maryland, Virginia, and further South, the same thing might be done in this country. In fact, I am inclined to think mustard and rape will prove more generally useful in the Southern States than with us. The Charleston phosphates when treated with sulphuric acid would make a manure well adapted for these crops, and when the mustard and rape are consumed on the land or plowed under, a considerable amount of available plant-food would be provided for cotton, corn, wheat, or whatever crop it is thought best to raise. Superphosphate has seldom any direct effect on wheat, but will greatly stimulate the growth of mustard, rape, and turnips, and the manure left from the consumption of these crops is precisely what wheat and other cereals need.

One of my neighbors has just sold twenty acres of his farm to a German for over \$200 per acre. The land is on a cross-road, seven miles from the center of the city, and has been so much neglected that it will cost at least fifty dollars an acre and two years' time to get it clean and in good condition. The farmer who sold this land does not make three per cent on \$100 an acre from his farm, and if the German can make it pay at \$250 per acre it will be another illustration of what industry, thrift, and enterprise can accomplish. It seems to me, however, that such a man would have done better to have gone West. He certainly would if he intends to raise ordinary farm crops. But these thrifty Germans seem to have a knack of paying for land, and bid fair to become the principal land-owners in the older portions of the country. Their great forte is saving. I have a German neighbor, a well-to-do farmer, who always has money in the bank. But if he owes you anything, he never thinks of giving you a check—not he. He knows a trick worth two of that. He sells something from the farm. After he has done his day's work, in the evening, he picks up a few apples, or potatoes, or squashes, or a few heads of cabbage, a basket of eggs, and a little butter or lard, or perhaps a bushel or two of nice hand-picked beans. These he puts in a spring-wagon, and the next morning before I am up he is half-way to the city, and by the time I am through breakfast he is back with the money. It is far easier to give a check on the bank. But that man would run in debt for a hundred-acre farm at \$150 an acre and pay for it. I couldn't. I can raise as good crops as he does—perhaps better—and the receipts from my farm per acre are larger than his, but he and his family do all their own work, and when one of his bright, active boys wants to get married, there is money in the bank to make the first payment on a small farm and give him a start in life.

He is withal a capital farmer, keeps his land clean, and works it thoroughly. He is a good

neighbor—not inclined to borrow, and willing to lend; and if he *does* borrow anything for a few hours he returns it promptly. He is as cheerful as the day, minds his own business, and is always beforehand with his work. He keeps a good span of rather gay young horses that he bred himself, and which are always well groomed and full of spirit; a nice carriage that is always clean, and a good harness that is in perfect repair and well oiled and blackened, and he drives to church every Sunday in a style that many a German baron might envy. That man commenced life with nothing but good health, good habits, a pair of good hands, and a good head, with indomitable energy and perseverance. There are thousands of such cases, and in view of them it seems unnecessary to ask the question, "Does farming pay?"

The only question that such farmers as you and I, who depend a good deal on hired help, need ask is, "Can we compete with such men as this German and his family?" If we can get our men to do as much work for the same pay as he gets, less the interest on his capital, we can. If not, no. Our profit or loss depends a good deal on the kind of men we hire, and on our ability to plan work and to see that it is executed without loss of time and labor. Whether we had better take hold with our own hands depends a good deal on the character of the work and on the number of men employed. A farmer who knows how to do all kinds of farm-work, and knows what a good day's work is, if he has a large farm to manage will seldom find it profitable to take a team and plow all day or follow the harrows. He will do better to attend to the little details of the work and keep an eye on everything that is going on. He should be able to detect the weak spot and lend a hand there. For instance, if you are drawing manure with three teams, there will be one wagon at the heap with a man besides the driver to fill, another wagon unloading in the field, and one going back and forth. The rapidity of the whole work will be determined at one point, just as the strength of a whole chain is determined by the weakest link. If you see that the empty wagon gets to the heap before the other is loaded, take hold and help to fill a load, and put a little spirit in the men. If, on the other hand, the load is ready before the wagon returns, the weak spot is in the field. Take hold and help to pull off a load or two. In drawing hay or grain with three wagons, I have doubled the speed of the whole force by getting on to the wagon and helping to unload. We unloaded in half the time, and yet the next wagon-load was there in time for us. Sometimes it will be the pitcher that can not keep up—then help him. You will accomplish far more by looking out for the weak spots than by doing steady work. If a man has a hard row to hoe, none of the others will help him. They will keep up with him, or if they should by any mischance go ahead, will wait for him at the end. That row is the weak spot. Take hold and help. And so with every operation on the farm. We must study how to economize labor.

Railroad men are studying how to lessen the "dead-weight" on their roads—in other words, how they can reduce the weight of their cars in proportion to the load they have to carry. American plows, harness, wagons, and implements, and machines generally, are the lightest in the world. So much we have accomplished. Still there is too much "dead-weight" on the farm. Look at that man weighing 160 pounds carrying a pail of water. He has to move 160 pounds

of dead weight to carry 25 pounds of water, or, seeing that he has to go empty one way, he moves 320 pounds of dead-weight to carry 25 pounds. A sensible man who has much water to carry would either put in a pipe and save the labor of carrying, or he would get pails holding forty pounds and carry a pail in each hand.

I have never before been able to carry my stock through the winter on so little hay, and never had them do better. The season was so favorable for curing corn-stalks that they are eaten greedily by the cows and sheep. My corn was on low land, and knowing that if we should have a heavy rain it would be a difficult matter to harvest it, I cut it early and drew it in as soon as it was thoroughly cured, without stopping to husk it. We tied it in bundles and stowed it away in the barn and sheds. We did not get through husking the whole of it until the middle of February. The ears were damp, but soon dried out in the corn-house, and the stalks were never so good.

It may be, as some say, that corn-stalks are not injured by being left out in the field until wanted in the winter. But I do not believe it. They may be better than stalks left out during weeks of rainy weather in the fall, and then drawn in just before winter, and put in the barn with mud and snow attached to them. But if cut early and drawn in when well cured, with not a drop of external moisture on them, it is clear to my mind that they must be sweeter and more nutritious than when exposed to our heavy fall rains. Hereafter I mean to raise more corn, and take pains in curing and preserving the stalks.

I have sold some timothy hay this winter, and propose to do so whenever the price suits. But some of my neighbors, who do not hesitate to sell their own hay, think I ought not to do so, because I "write for the papers"! It ought to satisfy them to know that I bring back 30 cwt. of bran for every ton of hay I sell. My rule is to sell nothing but wheat, barley, beans, potatoes, clover-seed, apples, wool, mutton, beef, pork, and butter. Everything else is consumed on the farm—corn, peas, oats, mustard, rape, mangolds, clover, straw, stalks, etc. Let us make a rough estimate of how much is sold and how much retained on a hundred-acre farm, leaving out the potatoes, beans, and live-stock. We have say:

Sold.	
15 acres wheat, @ 40 bus. per acre.....	18 tons.
5 " " barley, @ 50 " " " " " "	6 " "
15 " " clover seed, @ 4 bus. per acre.....	1½ ton.
Total sold..... 25½ tons.	
Retained on the farm.	
15 acres corn, @ 80 bus. per acre.....	33½ tons.
Corn stalks from do.....	40 " "
5 acres barley straw.....	8 " "
10 " " oats and peas equal, 80 bus. oats.....	12½ " "
Straw from do.....	20 " "
15 acres wheat-straw.....	25 " "
15 " " clover hay.....	25 " "
Clover seed straw.....	10 " "
15 acres pasture and meadow equal 40 tons hay	40 " "
5 acres mustard, equal 10 tons hay.....	10 " "
5 " " rape.....	10 " "
5 " " mangolds, 25 tons per acre, equal to 3 tons dry.....	15 " "
Leaves from do.....	3 " "
Total retained on the farm..... 252¼ tons.	

It would take a good many years to exhaust any ordinary soil by such a course of cropping. Except perhaps the sandy knolls, I think there is not an acre on my farm that would be exhausted in ten thousand years, and as some portions of the low alluvial soil will grow crops without manure, there will be an opportunity to give the poor, sandy knolls more than their share of plant-food. In this way, notwithstanding the

fact that we sell produce and bring nothing back, I believe the whole farm will gradually increase in productiveness. The plant-food annually rendered available from the decomposition and disintegration of the inert organic and mineral matter in the soil will be more than equal to that exported from the farm. If the soil becomes deficient in anything, it is likely that it will be in phosphates, and a little superphosphate or bone-dust might at any rate be profitably used on the rape, mustard, and turnips.

The point in good farming is to develop from the latent stores in the soil and to accumulate enough available plant-food for the production of the largest possible yield of those crops which we sell. In other words, we want enough available plant-food in the soil to grow 40 bushels of wheat and 50 bushels of barley. I think the farmer who raises 10 tons for every ton he sells

Fig. 1.—BURNING A KILN OF BRICKS.

will soon reach this point, and when once reached it is easy to maintain this degree of fertility.

Brick-Making.

When bricks have been molded, they are carried by boys from the molding-table in the molds to the drying-floor. This is a floor of clay and sand, beaten hard with rammers, and made perfectly level and smooth. It is dusted with fine sand, and the bricks, in their soft state, are turned carefully out of the mold on to it (see fig. 2), and allowed to remain for a few days

Fig. 2.—STACKING BRICKS IN THE DRYING YARD.

until they are partially dry and can be handled safely. As soon as this happens, they are removed and piled up into long narrow heaps, similar to low walls (see fig. 2), open spaces be-

ing left between the bricks to admit the air and permit rapid drying. When nearly dry, those

Fig. 3.—ARCHED FLUE OF BRICKS.

intended for pressed brick are selected and carried to the press, which is a machine operated generally by one man; sometimes, in large manufactories, the press is worked by steam. The brick is received on a table, the bottom of which is of polished metal; polished metal sides also surround it. The table is carried beneath a die, also of polished metal. The table is brought upwards by means of a cam or eccentric, or a combined lever acting with great force, and the inclosed brick pressed until the remaining water is squeezed from the partially dried clay, and it is compressed so much that even the sides take a smooth face from the polished surfaces brought into contact with it, and the edges are rendered sharp and perfectly square. These bricks when burned are known as Philadelphia fronts, or pressed brick, and bear a much higher price on account of their improved appearance. The common bricks undergo no process further than drying until they are ready for burning. They are then piled into a kiln, which is a large square heap, holding generally a hundred thousand or even three or four times that quantity, piled up loosely, so that the heat from the flues can pass through the interstices and burn the bricks evenly and thoroughly. It is important that the flues be built up properly. Fig. 3 shows the method of building the flues, which pass through the kiln from side to side, and in which the fires are placed. When the kiln is finished, it is plastered over with clay to retain the heat, and is generally covered over with a

rough shed, as a protection against the weather. This mode of building is adapted for burning with wood, forty cords of which, generally dry yellow pine or hemlock, is needed for a kiln of a

hundred thousand. If coal is used, the flues are mere draft-holes, sufficient to hold only enough wood to kindle the kiln, and fine slack coal is spread in layers between the bricks, and sometimes mixed in the clay of which the bricks are made. Three weeks' constant burning is needed to complete the bricks, when they are ready for use. Bricks may be made for from four to six dollars per thousand, if in a quantity not less than a hundred thousand, and we have known of farmers who, intending to build, have made a kiln of brick, and sold the residue after supplying their own wants for as much as the cost of the whole. Of course, the services of an experienced brick-maker will have to be secured.

A Wooden Bridge.

Country bridges are always useful, but rarely ornamental. Designed for strength, appearance is sacrificed to utility. It is often the case, however, that the ornamental may be combined with the useful with advantage. In bridges of a certain character this is essentially the case. A simple timber laid across a stream as a foundation for a bridge, although the simplest and plainest form of structure, is far from being the strongest. The truss of lighter materials is stronger than a single heavy beam, while the arch may be made lighter yet than the truss, with a still further gain in strength. We give a cut of a wooden arch, to be made of boards fastened together with nails and bolts, which may be built readily of materials always at hand, and needs no piece longer than twelve feet, even for an arch of forty feet span or over. Nor is it necessary even to lay a center on which to build this arch. It may be built up on the ground, a foundation of stakes or posts being made on a level place on which to commence; or it may be built on a barn-floor, if of sufficient size, and when complete moved to its place and set up.

BRIDGE WITH WOODEN ARCHES.

The mode of proceeding is as follows: We will suppose a bridge of twenty-four feet span is needed. The first necessity is to make the foundations for the arches. These should be built firmly of stone or timber, and well backed, and steps made to receive the feet of the arches. If the bridge is to be twelve feet wide, three arches will be necessary. These are made of spruce boards, preferable as being elastic and tough, or, wanting them, pine or hemlock will answer, and twelve inches wide and one inch thick. The form of the arch is laid out on say the barn-floor, and a scantling tacked down for the base, with studs reaching from it to the line of the arch. A board is then tacked to the end of the scantling, and bent round on to the ends of the studs, and tacked to them to hold it into its place; another board is put to the end of this, until the other end of the scantling is reached, and the figure of the arch is complete. Other boards are then placed over the first ones, and wrought-nails driven through and clinched. The joints must in all cases be broken. Boards are nailed on in succession until a sufficient thickness is secured—twelve to twenty inches, as may be needed for a bridge

to bear less or greater weight. Nails must be plentifully used, to make the arch solid, and when complete a few screw-bolts should be put

Fig. 1.—IRRIGATING BY MEANS OF A DAM.

through, and the nuts, protected with broad washers, screwed up tight. There will then be a solid rigid arch of timber, twelve inches wide, and as thick as may be. Three or four of these are made and set up on the foundation, and stayed with cross-stays. Cross-beams are placed on them, on which the roadway is built. These arched beams are much stronger than straight ones, and are of much more desirable form. For an ornamental bridge they are especially desirable, as they are susceptible of any amount of improvement in shape that may be wished. Where long, heavy timbers are difficult to procure, these arches will be found much cheaper, as the materials are at hand everywhere. A coating of hot tar to each board before the next one is laid on, and then an extra coating over all when finished, will help to preserve the timber for many years.

Irrigating Meadows.

The practice of irrigating or watering meadows is one of great antiquity. In Europe meadows are to be seen, in which the banks and ditches are several centuries old. For all

Fig. 2.—IRRIGATING A HILL-SIDE.

this long space of time these fields have been yielding large crops of grass, and those we have seen certainly show no symptoms of wearing out, but are as prolific as ever. Streams of considerable size and smaller brooks and creeks are embanked or dammed, and in time of freshet the water is permitted to flow over the fields, carrying much suspended matter, which is soon deposited and forms a rich dressing of fertilizing material; or the water flowed back by the dams is led in channels around the meadow, and permitted to run through sluices over the grass. By this last method there is no necessity for waiting for a natural rise of the stream, and a watering can be given whenever desired. It is necessary that the field should be flat and somewhat level, with a small and gradual rise from the banks of the stream. The space overflowed, of course, depends on the amount of this rise, as it is not practicable, without much expense, to dam the water to a greater height than two or three feet. Where the ground has

but a very small declivity, or is very nearly level, the water may be backed up and made to overflow as much as possible, and a succession of dams and low embankments will then form a succession of meadows down the stream. Where the ground has a greater slope, the stream is dammed and the water led around the meadow (as in fig. 1), and discharged in sluices as it may be desired. The ditches are made only deep enough to carry the water, and the earth thrown out forms the bank of the canal. A suc-

cession of these may be made down the stream, more or less in number, as the slope of the ground may necessitate. Another and very common mode in use in many parts of this country where springs are plentiful, is shown in fig. 2, and is well adapted to flowing hillsides as well as level ground, in the absence of a stream. A spring is led by a small ditch, often a mere furrow made by the plow, in as level a direction as possible across the field, when it is turned at a sharp angle (the angle should be protected by a large stone, to prevent wearing of the bank by the current), and brought back at a lower level until it is exhausted, or the field has been passed over. This little stream is tapped here and there, and the water distributed where it is wanted and as it is needed, until the whole field is watered as far as possible. Before cutting

for hay, the water is diverted from the channels, so that the ground may become quite dry. After the hay is removed, the water is let on again, and a good watering given. To keep a meadow in good order, it is necessary to keep all stock from it (pasturing is completely destructive), and to occasionally scatter seed, where the desired grasses run out, with

a little guano, wood-ashes, plaster, or other fertilizer, and avoid watering during the winter.

By judicious and careful treatment a meadow may be kept in timothy, red-top, and clover for several years, without re-seeding. It is necessary, in this case, to give waterings of short duration, and only at times when the rains are not sufficiently copious. Meadows of red-top and common meadow-grasses may have the water running during the season. A good water-meadow, well cared for, may be depended on for two cuttings equal to three or four tons of hay per acre in the season. Such crops will pay good interest on the

outlay, which in favorable localities is but trifling, if properly directed.

Stanchions and Stalls.

We have many inquiries from readers desirous of building stables about inside arrangements of stalls and fastenings for the stock. Fig. 1 shows an arrangement for an ordinary cow-stable in which stanchions are used. The stalls may be made single or double, or the stable may be without stalls. But this latter mode permits the cows too much lateral movement, and tends to keep the stable dirty. Stalls are to be recommended if only for the purpose of cleanliness, to keep the cows in their proper position so that the droppings may fall into the gutter behind them. A double stall should be six feet wide, a single one four feet, and eight

Fig. 1.—CATTLE STANCHIONS.

feet is about the proper depth. These proportions will vary according to the kind of stock kept, whether large or small.

The stanchions are a row of posts, every alternate one being movable, so that the top may be thrown sideways (as shown by the dotted lines in fig. 3), and when the animal's head is placed between them, brought back and secured by a pin (a). The cow has no motion allowed to her head, except up and down, and she is kept from moving backwards or forwards. Thus stanchions, while they are or may be uncomfortable for the cow, are very convenient for her owner, and the stable and the animals themselves may be kept very neat and clean.

Fig. 2 shows another stall in which the cows are fastened by chain ties, which slide up and down on the rod (b). The feed-trough is ap-

Fig. 2.—STALLS FOR CATTLE.

proached by the feeder from a passage-way at the front of the stall, where a drop-door is fixed

through which the feed is placed in the trough. A cord prevents the door from opening further than needed, and a button holds it in place when closed. The advantages of this stall and

Fig. 3.—STANCHIONS.

mode of fastening are, greater freedom of movement for the cattle, and a closer and warmer arrangement of the stable. The disadvantage is want of cleanliness, which may be to some extent obviated by plenty of litter.

It is often very desirable to have a close stall, in which an animal such as a bull, feeding ox, or an incoming cow or sick animal may be loosely confined without any fastening. Such a one is shown in fig. 4. It is built similarly

to fig. 2, but has no chains, or if it should have they are not needed. A door is made to close the passage-way, and shut each stall from the next, if more than one is needed. This door may be swung round so as to close in the stall, and then the passage-way is open. Thus the passage-way may be made a part of each stall if desired. The trough, shown by dotted lines, may be divided for water and feed. A fattening animal may remain in its stall for weeks or months. Kept thus solitary, it will feed better and fatten more readily than if at liberty. Plentiful littering will keep the animal clean, and as the manure (and straw) accumulates it is trodden down hard and tight, and does not need removal until the animal is taken away.

The New Rules of the American Jersey Cattle Club.

After an experience of three years with the pedigrees of Jersey cattle, the above-named association (which now numbers about one hundred, including most of the best and most reliable breeders in the country) has adopted the following rules for the admission of pedigrees into its Herd Register:

1. All animals imported from the Island of Jersey up to the date of the last meeting of the Club (January 24th, 1871) are eligible for entry.
2. No animals imported after the above date will be admitted to entry, unless they—or their sires and dams—are already entered in the Herd Book of the Royal Jersey Agricultural Society.
3. No animals imported after the above date by a dealer will under any circumstances be admitted to entry, whether reputed to be pedigree stock or not.
4. Until the end of the year 1872, the execu-

tive committee of the association will be allowed to admit to entry animals bred in this country whose record may not be entirely complete, but which there is every reason to believe pure. Such entries must be accompanied by an explanatory note, stating the precise character of the defect in the record.

The third rule bears rather harshly on those who have made a lucrative business of the importation of Jerseys, but after a full discussion it was decided that the true interests of the breed could not be faithfully guarded, except by such an absolute prohibition. The Executive Committee is to decide whether any individual importer is to be considered a dealer. The second rule is of the utmost importance. The rage for Jerseys has been so great, that there was danger that, under the high prices now ruling, all the poor cheap animals on the Island of Jersey would find their way to this country. The entry in the Herd-Book of the Island Society is based on an examination of each animal, and if we take only such as have passed this examination, we shall stand a fair chance of improving our stock instead of debasing it.

Applications for entry should be made to Col. Geo. E. Waring, Jr., of Ogden Farm, Newport, R. I., who is the Secretary of the Club, and the editor of its Herd-Register, who will furnish the

Fig. 4.—BOX-STALL.

requisite information to those who wish to have pedigrees recorded.

Our Forests—Great Waste.

The annual products drawn by the people of the United States from the forests exceed one thousand millions of dollars, or eight times the interest on the national debt! This being the case, the preservation of our forests, and the right method of cutting timber, is a matter of general interest and of national importance.

To save our timber, we must not only cut no more than is necessary, but cut it in a proper and economical manner. We must stop the merciless waste and primitive method of chopping with axes, and use saws scientifically. The forests of Europe are protected by law, and the removal of their timber is carefully and economically performed.

Not to speak of the decrease of moisture and other climatic changes superinduced by removing trees, let us look at the matter in a lower aspect, and compute the profit and loss.

Probably not less than thirty millions of the people of America are warmed by wood fuel, consuming more than one hundred million cords per annum, as any one knowing the prodigal use in our newer timber districts, will certify. If mills, railroads, and steamboats consume one third as much, reckoning the cost at \$3 per cord, we have four hundred million dollars annually

for fuel alone. An equal consumption of timber for fencing, and a like amount for wooden buildings of all kinds, give the enormous aggregate of one thousand two hundred millions of dollars annually, produced by our forests for consumption.

When we consider the fencing and farm-buildings required by our more than four million farms, if reckoned at one hundred and fifty dollars, *annually*, to each farm, making six hundred millions of dollars, and when all the uses of wood are considered, few men who have traveled widely, and observed and estimated closely, will deny that more than one thousand million dollars in products is derived from our forests annually—five times the value of our largest cotton crop, ten times the production of our pig-iron, twelve times our production of gold and silver, and four times our wheat crop. Indeed, few single interests exceed in value the enormous production of our forests.

How to cut timber with saws scientifically may be treated of in another article, and I will only at this time point out some of the advantages over the wasteful and primitive ax. First, saw the trees down; they can be cut closer and with greater economy than by chopping, and by the use of wedges felled in any desired direction. They can be cut with less labor, if the operator knows how, and uses the most improved saw. If the tree be designed for fuel, the saving by sawing it the length desired on the ground in the forest is manifest. If for stove-wood, the blocks may be carted without splitting, and when thus sawed, trees that any chopper would leave to rot in the forest, become instantly available; for who does not know that a one-foot block may be split easier than one of four feet, besides saving the immense waste of a chip a foot in width? From one third to one quarter of the trees in many forests are what woodmen regard as "culls," and tough timber; this, added to the saving of the chips, makes fully one third of the forests available for fuel that might otherwise be wasted and remain an obstruction and incumbrance. Those who, like the writer, are conversant with this matter, will appreciate this statement, made from actual experience.

Saw-logs and dimension-timber, fencing, posts, etc., in the Northern States are now usually sawed, but in a recent trip through all the Southern States (except Texas) I noticed in mill and lumber-yards the splintered ends of saw-logs cut with axes; indeed, this is the general method of country mills there, but improved methods will soon prevail everywhere in all wood-cutting.

Now let us consider the time and labor saved by sawing, instead of chopping. To cut one hundred million cords of wood with the ax requires as many days' labor, and as many dollars; if the use of hand cross-cut saws be substituted, and only one half the labor be saved, the fifty millions now thrown away are gained, besides the immense waste of fuel, making in the two items an annual saving of an amount equal to the interest of the national debt. B.

Raising Hay for Market.

"A. J.," Smyrna, Tenn., writes us that he intends to try and raise hay for market, and wants information as to manures, implements, presses, best modes of storing the hay, etc., etc.

First, as to manures for the land. It is not absolutely necessary to keep stock to raise hay, as it has been abundantly demonstrated that commercial manures, with occasional dressings

of lime and swamp-muck, will make a substitute. To get a good stand, the ground should be well plowed as deeply as possible without injury, reduced to a fine tilth, and sown to whatever grass is most suitable, directly, without the intervention of a grain crop. Bone-dust, guano, and plaster, alternately every two or three years, may be used as fertilizers, at the rate of two hundred pounds of the former and one hundred pounds of the last per acre. Only one crop should be cut, and the aftermath should be encouraged to grow and allowed to fall down and rot. No pasturing should be permitted.

SECOND, as to implements. The mowing machine, hay-tedder, and horse-rake in the field, and the horse-fork at the sheds, are all that can be profitably used at present. Of the mowers, there are a great variety. We have a preference for the Buckeye, and we have cut ten acres per day with it without trouble or weariness. At the same time, there are other machines which others prize as much as we do this. The tedder is not adapted to clover hay, but for timothy, blue grass, or red-top is a labor-saver. The spring-tooth hay-rake is an absolute necessity in the hay-field, and as there are several very much alike in construction, there is not much choice between well-made ones by different makers. Hay-loaders are not yet brought to that perfection which makes them desirable, as there are many contingencies which interfere with their successful operation.

THIRD, as to pressing and baling. Hay-presses are made which, worked by two-horse power with two men, will bale ten tons per day. It is not at all difficult to construct one with which two men can bale four tons in a day, by means of a screw. With such a press, costing about twenty dollars, the writer at one time prepared 100 tons of hay for shipment. Our bales weighed about 200 pounds, were what is called loose pressed, and were tied with three bands of coarse hempen cord. There were no corner laths used, and consequently no tare was deducted when the bales were sold.

FOURTH, as to storage. It will be found more economical to erect cheap sheds or barracks than to stack the hay. The amount lost by stacking will in five years pay for a shed, which if built properly and taken care of, may last forty

BARRACK FOR HAY OR GRAIN.

years. We give a sketch of a hay barrack we have used, which answered equally well for hay, grain, or corn-stalks. Built of hemlock timber, and boards tongued and grooved for the roof, the cost is about forty to fifty dollars for one sixteen feet square and sixteen feet high, holding five tons of loose hay. It is much more economical to build them larger than this one. Twenty-four feet square and sixteen feet high

may be built for one third more, and will contain over twice as much. On a large scale, one long shed would be found more economical in cost, but the smaller ones may be scattered about, and thus be found more convenient. When these barracks are to be used for grain or stalks, they should have caps over the foundation posts, to render them rat-proof, as shown in the engraving. Very cheap hay-sheds may be made by setting four posts in the ground and covering with a roof of straw thatch, but they are not durable.

JERSEY COWS FOR BUTTER. — "Thirteen cows and heifers made in January 282 lbs. 12 oz. of butter—all sold at 75 cents per lb." So writes Mr. J. Milton Mackie, of Great Barrington, Mass., of his herd of pure Jerseys. Perhaps somebody's "natives," or somebody's "grades" can beat this; if so, we would be very glad to know it. \$16.30 per month as the average product of thirteen animals, not forced in any way—only kept in good breeding condition—and in mid-winter, is a product with which any farmer might be satisfied. Of course, at this season some of the cows were nearly dry, and some were two-year-olds with their first calves, yet the average weekly yield of butter was nearly 5 lbs. per week all around. The "moral" is that Jersey cows are good to have on a butter-maker's farm, and the natural inference is that if you can not afford thorough-breds, you will do well to breed to pure Jersey bulls, and raise a herd in which there shall be a strong and a constantly increasing infusion of Jersey blood.

The Uneven Pulling of Teams.

We have received many communications on the subject of the uneven pulling of horses, and it seems not to be well understood. It appears to be a general idea that when one horse of a team is pulling ahead of the other, either one or the other (some say one and some the other) is pulling a greater share of the load. Now, it is a matter of fact that however uneven the double-tree may be, if the whipple-trees are free from entanglement with any part of the wagon, the draft is not in any way changed; each horse is exerting exactly the same power on the load—if the bolt is exactly in the middle of the double-tree, as it should be—as it would if the double-tree were exactly level. This is to be proved by a simple problem in mechanics. The double-tree is a lever, the fulcrum of which is the bolt by which it is attached to the wagon tongue. If the arms of the lever are of the same length, the power expended on each of them in drawing the wagon is necessarily the same. Now, however far from level the double-tree may get, the lengths of the arms or the distances from each hook to the center bolt remains the same, and straight lines drawn from the bolt to other straight lines parallel to the tongue drawn from each hook will be equal. The dotted lines in the engraving are intended to show this more plainly. The distance between the points *a a* is exactly divided by the line *A* which passes through the draw-bolt, and the draft from these points is equal on either side. These distances, which alone can change the amount of force exerted, remaining the same, the force exerted is the same.

There is no relation between a double-tree and a balance or the beam of a scale, which is apposed by one correspondent. If a greater weight is placed in one scale than in the other, the beam oscillates, and it will not stop until

one weight is completely suspended by the other, or the beam rests against something which stops the motion. So if one horse pulls more than the other he will draw him back until the whipple-tree comes against the wagon and presses against it, when the amount of

pressure will be exactly equal to the excess of force, exerted by one horse. But while there is no pressure against the wagon and the whipple-tree is free each horse draws equally. But it must not be understood that we do not deprecate the practice. It is un-

DIAGRAM OF PULLING.

pleasant to see, unworkmanlike, and slovenly, and a farmer that permits it can not be looked upon as a neat farmer. To prevent it, take a strap with a buckle at one end and a snap-hook at the other; buckle one end to the check-rein of the quick horse, and hook the other to the inside trace-chain of the other horse so far back as to prevent his mate from getting ahead of him. They can then be kept even.

GATE HINGE.—David Ruble, Eula, Oregon, sends us a drawing of a new gate-hinge, which is calculated to obviate the inconvenience of splitting of the post when the timber is bored for the insertion of the bolt of the ordinary heavy gate-hinge. It is made of strap iron, $1\frac{1}{4} \times \frac{1}{4}$ in., and requires a bar about 15 inches in length. The extremities of the bar are fashioned into screws, which pass through holes in the back strap, and are fastened with nuts, which enable the gate-post to be firmly clasped. An eye is formed to receive the other part of the hinge, which is of ordinary construction, or may be made on the same principle as this. The illustration here given will explain the peculiar construction of this improved hinge.

HINGE.

Rack for Shoeing Unruly Animals.

The rack of which we give an engraving is one suited to use for shoeing vicious animals. It is often found necessary in shoeing a vicious mule to have the aid of several men with ropes. With this rack the operation can be done with much greater ease. The animal is led into the frame, and secured by hooking the harness to the hooks. A forefoot is taken up and secured by the strap to the post seen at the front. Bars, with bands passing beneath the horse, are placed on each side, which may be elevated until the beast is lifted off its feet and rendered perfectly helpless, if needed. The hind-feet may be fastened to the hind-posts by straps, in case of a very vicious animal, and the shoes nailed on while the blacksmith is protected against any attempts at kicking, and the beast can not throw himself, being supported by the frame and belly-bands. The rack should be made with stout sills and posts, about 4 inches square, or sufficiently strong to resist the struggling of any animal that may be put into it, and mortised into them. The size of the frame should be adapted to the animals for which it is provided—about 8 ft. in length and 2 ft. in width.

Sheep Washing and Shearing.

Washing and shearing sheep may be made easy or troublesome, as more or less attention and skill are applied to the business. All the discomfords sometimes attendant on it, may be avoided by proper preparation and judicious management. Where there is no stream, washing may be done in a tank, into which water may be pumped with a force-pump and hose. If a stream is at hand which affords three feet of fall, a spout may be arranged as in figure 1. By either method there is no necessity for the operator to enter the water. If not more than a dozen or twenty sheep are to be washed, a sufficiently large tank is not a costly affair, and the water left after the washing will in the shape of liquid manure pay for the trouble of making it. The water in which sheep have been washed contains much potash, and, if possible, should be scattered over a meadow. Where a large flock is to be handled, it will pay to make a dam in a stream, and use the apparatus shown in fig. 1. It consists of a spout from the edge of the dam, which conveys a stream of water under which the sheep are washed. A floor of planks laid loosely to permit the water to escape between them, is placed across the stream, and a pen to confine the waiting sheep is built near it. The sheep, having been previously tagged and freed from all lumps of adhering dirt, are brought one by one beneath the spout, and the fleece well washed. It is a great help to the washing, if the sheep can be exposed the day previously to a warm rain, which will loosen and soften the dirt on the wool. When the fleece is washed, the excess of water is squeezed out of the wool and the sheep permitted to escape at the opposite side of the stream, if possible into a clean pasture-field or meadow. It is better to have

by a pair of rubber boots, and a rubber apron will protect the body from splashes of water.

When all is ready for shearing, the sheep should be put into a clean and well-littered barn-yard; the barn-floor, or the floor of a shed specially provided, should be swept perfectly

restrain its motion. Then the side of the sheep is shorn completely, the clipping always being in lines from the belly towards the back. When the left side is completed, the fleece is gathered up closely towards the sheep's back, and the animal is turned over on to the shorn side, the

head being still kept quiet by one foot resting on the neck. The right side is then shorn similarly to the left, and the sheep is released. Before allowing it to go, however, the cuts, which will in all cases be made more or less, should be dressed with a mixture of tar, hog's-lard, and a few drops of turpentine, to prevent flies from depositing their eggs, which would in a very short time, if neglected, hatch and seriously injure the sheep. The fleece should now be cared for. It should be taken up and spread on a table (see fig. 2), or on a clean part of the floor, all dirt picked off from it, any loose tags placed in the center, and the sides folded towards the middle, when it may be rolled up into a compact bundle twelve to sixteen inches in length, and secured by two strings of twine tied tightly around at equal distances from the end. We think it hardly necessary to caution farmers against the practice of putting soiled tag-locks into their fleeces. It is sometimes done however, but really such a caution should be as unnecessary as one against stealing. A farmer should never be ashamed to look a wool-buyer in the face after selling his fleeces to him. When the fleeces are tied up, they had better

PLATFORM AND SPOUT FOR WASHING SHEEP.

clean, and kept so during the operation. As the sheep are brought in one at a time, the animal to be shorn is placed on its rump, with its side against the operator's knees, and its back towards his left hand as he stands in an upright position. Stooping slightly, he is able with the shears to cut the wool from the sheep's neck all round, down as low as the shoulders, by turning the sheep a little now and then. Then stoop-

be bagged at once and kept in a dark room, neither dry nor damp, until sold. If very dry, the wool becomes harsh; if damp, the first touch reveals the fact, and a lower bid is the consequence. A moderate dampness is no injury, and gives softness to the wool. Proper preparation for market and neatness in packing always pays with all sorts of produce, by securing an advanced price or a readier sale. Finally, it is economy

FOLDING FLEECES.

RACK FOR SHOEING HORSES.—(See preceding page.)

them kept a few days in such a clean pasture before shearing, to permit the fleece to recover the natural softness which results from the oil or grease absorbed from the skin. By this plan of washing there is no necessity of wetting even the operator's feet, which may be kept quite dry

ing, he is able to cut half-way down its body, in lines from the belly towards the back, from which the wool is cut as far as the back-bone. The sheep is then permitted to fall gently on its right side, and the shearer, kneeling on one knee, holds his other on the sheep's neck, lightly, to

to shear close—the wool near the skin being heavier, because it contains a greater portion of yolk. If the buyer complains of the uneven strength or texture of the wool, it is due to want of care or neglect in feeding, which has affected the growth or health of the sheep.

The White Lady's-Slipper.

Among our wild-flowers, none are more attractive than those belonging to the Orchis Family. The singular structure of their flowers, and the beauty of their coloring in most

WHITE LADY'S-SLIPPER.

species, are sure to attract attention, and the rarity and very local character of many of them make them great favorites with plant collectors. The Lady's-Slippers, as the species of *Cypripedium* are popularly called, are among the most noticeable of our native orchids. There are six species in the Northern States, one of the rarest of which is the White Lady's-Slipper, *Cypripedium candidum*, which we have figured of the natural size. The lip, which is the conspicuous portion of the flower, is of a pure white, the rest of the flower being greenish. This rare little plant is found in bogs from Central New York westward.

All the *Cypripediums* are worthy of cultivation, but they can only be grown successfully by imitating their natural conditions. They require a peaty, sandy soil and a shady situation, and under these circumstances their cultivation is not difficult. They are all perfectly hardy as far as enduring cold is concerned, but they will soon die if continually exposed to a hot sun. The finest of our species is *C. spectabile*, which has a large white and crimson flower, is quite common in some of the Western States, and is justly prized in Europe as one of the most beautiful of herbaceous plants.

The Wild-Yam.—(*Dioscorea villosa*.)

One of our commonest climbers, the Wild-Yam, seems to be among the least noticed and the least known, as we very frequently have

specimens sent to us for determination. Our plant belongs to the same genus with the edible Yam of tropical countries, and the more northern Chinese Yam (*Dioscorea Batatas*). The root of these is very large, fleshy, and edible, while that of our wild plant is knotty and medicinal, rather than nutritious. The stems of the Wild-Yam are slender and herbaceous, and climb to the height of eight feet or more. The shape of the leaves is given in the engraving, which is about half the natural size. The staminate and pistillate flowers are borne upon different plants, the staminate ones being in loose clusters, as shown in the engraving. A small raceme of pistillate flowers is shown at the right-hand side of the engraving. These are quite different in appearance from the staminate ones. The fruit is a dry, three-winged capsule, which is conspicuous in winter when the foliage is gone. A single fruit is given in the engraving. This yam grows nearly all over the United States, being much more abundant southward. It makes a very good and quick-growing climber for covering low screens and trellises, and is sometimes cultivated for that purpose.

The botanical name of our species is *Dioscorea villosa*; the specific name is not a descriptive one, as the plant is far from being villose (having long hairs), but the leaves are nearly smooth, or at most downy on the lower surface. The generic name was given in honor of the Greek Dioscorides.

Flower-Garden Plans.

BY AL FRESCO.

In a late issue of your paper, I noticed a plan for flower-beds by a contributor; and as I am opposed to beds of complicated forms and nu-

PLAN OF FLOWER-BEDS CUT IN A LAWN.

merous angles, I inclose a simple arrangement of beds which has given me much pleasure. In planting, numerous angles present difficul-

ties; and when the owner of a garden prides himself upon a well-kept lawn, he should so design his beds as to enable him to use the

WILD-YAM.—(*Dioscorea villosa*.)

mowing machine or grass-hook to advantage. Nothing, in my opinion, is so attractive as well-defined masses of color in appropriate beds surrounded by luxuriant and well-kept turf.

The accompanying plan is cut out of my lawn in front of my library window, and the effect from both the house and street is satisfactory. The center bed is four feet in diameter; then there are two feet six inches of grass, beyond which are outside beds three feet wide. At present the beds are filled with Hyacinths, and as soon as these can be removed they will be planted as follows: No. 1. Scarlet Geranium. No. 2. Variegated-leaved Geranium "Bijou." No. 3. Achyrantes Lindenii. No. 4. Colens. No. 5. Striped Petunia. No. 6. Phlox Drummondii. No. 7. Tropæolum Tom Thumb.

Some of your readers will exclaim: "Oh! what nonsense! I can not afford to purchase such expensive plants." For the benefit of such persons, we will point out what can be accomplished by the expenditure of fifty cents—an amount that can be spared by any one who is desirous to make home cheerful and attractive. To such I would say: Prepare the ground by deep digging and pulverizing, and send to a responsible seedsman for the seeds referred to below—costing from five to ten cents per packet. At the proper time plant them as follows:

- No. 1. Crimson Petunia. No. 2. White Phlox Drummondii. No. 3. Crimson Phlox Drummondii. No. 4. Tropæolum Tom Thumb. No. 5. Petunia, Countess of Ellesmere. No. 6.

White or Striped Petunia—latter preferred. No. 7. Dwarf Convolvulus.

Sow the seeds in rows, and when large enough thin out to about eight inches to one foot apart. These inexpensive plants will continue in bloom until destroyed by frosts, and will present a marked feature in any garden. The plants recommended are free growers, constant bloomers, easily cultivated, and produce a fine effect when planted in masses. The primary expenditure of fifty cents will prove the last outlay, for the cultivator can secure an ample supply of seed for the next season.

Grafting the Chestnut.

[A correspondent, "D. A.," at Washington, D. C., gives the following valuable experience in grafting the Chestnut. Some time ago we stated that grafting at or below the surface had been found successful with hickories, and suggested that it be tried with the Chestnut. We are glad to learn that the method had already been tried, and with good results.—Ed.]

In the spring of '56 I engrafted near Annapolis, Md., some 200 trees with grafts imported, and in excellent condition, from Leroy, of Angers, France.

I placed the grafts, as they do in France, on young, thrifty stocks of from one to three inches in diameter, at a height of four feet from the ground, when the peach-trees blossomed. Perhaps 130 grew satisfactorily; the following spring I found nine tenths of these killed, and, as I had afterwards reason to believe, they died from the different expansion on freezing of the stock and the growth on the graft, the one being comparatively solid and fibrous, the other sappy.

I had a compulsory absence for three years; on my return I engrafted in the spring of '60 about 1,000 trees, half of them growing satisfactorily; they died out as before.

The civil war again absented me. On its conclusion I engrafted a number on a level with the ground, with the usual success as to growth. In November, the earth was heaped up around them, a foot or more, to prevent their freezing. It was effective; a few of them, that were passed over or neglected in covering, died out as before.

There was a difference in the growth of the ten varieties employed, the "Black Prince" the least satisfactory, and the "Lyons Marrow" as good as any. The culture of the European Chestnuts in this manner is quite practicable, as far north at least as Philadelphia.

Thorburn's Late Rose Potato.

BY EDWARD L. COY, WEST HEBRON, N. Y.

In the autumn of 1869, when digging a large field of Early Rose, which had been entirely ripe for several weeks, a few hills were discovered, the stalks of which were green, and the yield of tubers enormous—in fact, outyielding the neighboring hills of Early Rose at least three to one. At first I supposed some fertilizer or some other local cause had forced an unnatural growth and kept the stalks green. But a closer examination proved that such was not the case. The tubers were a lighter red at the seed-end than the Early Rose, and the stalks more "stocky" and more upright in growth. The leaves were also thicker and more pointed, but narrower. The next spring these potatoes were cut in pieces of one eye each, and planted one piece in a hill; making three rows through

the center of a large field of Early Rose. They did not come up quite as quick, but made a far larger growth than the Early Rose, although the latter had two to three eyes planted in each hill. The difference in growth was so marked that it could be seen at a great distance. When the tops of the Early Rose were entirely dead and ripe, these were as green and thrifty as ever. They ripened about with the Jackson White, thus having nearly the whole season to grow in. When dug, the three rows yielded more than nine rows of the others.

I had now enough to test their keeping qualities, which I find are unsurpassed. In the same cellar, at planting time, when the Early Rose were so badly sprouted and wilted as to be totally unfit for table use, these had not started, and were as crisp and solid as when first dug. A few that were reserved for the purpose of testing them, kept in good condition for cooking until the new crop of Early Rose came upon the table.

Last season I planted $4\frac{3}{4}$ acres on a piece of ordinary clay-loam soil. It was on a side-hill, so steep that it had to be plowed with a side-hill plow. It was lightly manured, before plowing, with barn-yard manure. No other fertilizer was used, except a light top-dressing of plaster, when they first came up. The field was finished out with Early Rose. The Late Rose maintained the same marked difference in growth, time of ripening, and yield, as before. I harvested on that field 1,280 bushels. On the same soil, and under the same treatment, the Early Rose yielded only 80 bushels per acre. In table quality they are not surpassed by any. They cook very dry and mealy, and have a peculiar rich and delicate flavor. They grew very compactly in the hill, making them easy to dig.

The valuable characteristics of this Late Rose are so distinctly marked, and have proved of so permanent a character for three years, that I do not hesitate to pronounce them positive and fixed. It is not, as Mr. Campbell has asserted, "a sport of a single season whereof the producer can give no history or support as to its reliable permanency." But it is a thoroughly tested and invaluable variety of the Early Rose. I had a few of them planted last year in different sections, and in every case with the same result. I have no Late Rose to sell. One of the seed firm of J. M. Thorburn & Co., 15 John st., New York, made me a visit about the 1st of last October, and after thoroughly testing their table quality, and examining them on my grounds, bought all the potatoes I had to spare. I would here earnestly caution the public against purchasing Late Rose from irresponsible parties. They are being offered under that name of all colors, shapes, and sizes. The comparatively low price at which the Messrs. Thorburn & Co. offer them, places this variety within the reach of all.

Thomas Wier's Apple-Worm Trap.

BY C. V. RILEY.

Mr. Thomas Wier, of Lacon, Ill., has hit upon a very simple device for alluring apple-worms, which is destined to play an important role in counterworking their injuries.

In conjunction with his cousin, Mr. D. B. Wier, he has patented the trap, and though I do not think that the patenting of such simple devices is quite in accordance with a progressive horticultural spirit, or that the patentees will

find it a very profitable undertaking, they have a perfect right to think otherwise.

It was too late in the season when the trap was brought to my notice to give it a thorough trial, but I was at once favorably impressed with its usefulness, and what little I have seen of its work has not altered that impression.

The trap (see figure—A closed, B open) consists of two, three, or more thin pieces of board, 12 to 20 inches in length, and 2 to 4 inches wide, with a screw (a) through their center. The screw must be long enough to be firmly driven into the trunk of the tree, so as to hold the boards in position. The boards are cut out on each side of the screw, as at c, to facilitate their separation when fastened together by the silken threads of the worms, and to better expose the latter when the trap is opened.

The advantages of this trap so far outbalance the disadvantages that it may be considered the best we yet have. These advantages may be stated as follows: It is cheap, accessible to all, easily placed on the tree and removed again; wood forms, perhaps, the most natural covert for the worms; the traps may be collected with little trouble, by the barrowful, submitted to a killing heat, in one way or another, and replaced again; they may be used on the ground as well as on the tree. Its disadvantages are few. One it has, in common with all other snares or traps for this insect, namely, that it can never exterminate the Codling-moth, for many reasons that will suggest themselves to all who have any acquaintance with the insect. Another is, that where one trap only is used it can be attached to but one side of the tree, and in this single respect, notwithstanding all the theories of my friend Wier, it must always be inferior to any trap that encircles the tree.

The worms will spin their cocoons between the inner shingle and the tree as freely as between the shingles themselves, and I suspect that it will be found less tedious and cheaper to detach the traps and kill the worms by wholesale, than to open them on the tree. Those who prefer

WIER'S APPLE-WORM TRAP.

the latter method, will be pleased to learn of the means described by Mr. Wier, who says: "The quickest and best way to do this is to have a large tin pan bent in on one side, so as to fit closely to the trunk of the tree. When you reach the tree, drop upon your knees, place the depression in the pan against the trunk of the tree, hold it there by pressing your body against it, and you have both hands free to open the trap. When opening it, many of the pupæ or chrysalids will fall into the pan, and some of the worms. Kill the rest or scrape them into the pan. The trap must be turned clear around, as many will be found between it and the bark

of the tree. A person will open and kill the worms in from 400 to 800 traps in a day." I have known one of these traps to be so thoroughly torn to pieces by the Downy Woodpecker, that if they are to be preserved from year to year, it would be dangerous to leave them on the tree during winter.

The inventor informed me that he believes his trap is more apt to come into general use by being patented, than if offered without price to the public. If, in his hope to realize a fortune from it, he sends out agents among the fruit-growers of the country, I am not sure but he is correct; especially if such agents are enabled, by proper circulars, giving a true and condensed history of the Codling-moth, to disseminate important information. But the danger is, that patentees are sure to claim too much for their pet creations. This fact is well exemplified in the present instance, for the label pasted on such of the traps as have been so far sent out, commences as follows:

THOMAS WIER'S
APPLE-WORM
AND
CURCULIO TRAP;

Which catches Apple-Worms, Curculio, and every Species of Insects infesting Fruit. [!!!]

The love of gain obscures the light of truth; and this wonderful power of a pair of shingles to catch "every species of insect infesting fruit" is altogether too much like Mr. Quackenbosh's patent universal, never-failing Elixir, which cures all diseases that possess mankind! It would not deceive the well-informed, but the glittering of its panaceal power may lure the ignorant.

Other evils will likewise result from the sale of this trap under such spurious claims, and without some explanation of the insects' habits. One of them may be illustrated by the following dialogue, which is not altogether imaginary, but is founded on an actual occurrence. Agent Gaingreedy—his desire to sell rights being stronger than his love of accuracy—meets farmer Glauball, and straightway expatiates upon the merits of the patent trap. He shows how the worms gnaw their way in between the shingles, and how easily they may be destroyed. "Ach!" cries the credulous German, "und is it true das de worm rader eat de schindel dan de apfel?" "O yes!" says Gaingreedy, "screw one of the traps on to this tree, and in a week I will come back, and we will examine it." At the expiration of the week the trap is opened, and upon viewing with wonder the worms that have secreted in it, Glauball rapturously exclaims, "Ist es möglich? das ist debest ting I yet see," and purchases the right to use much quicker than he would if he knew that the worms had already been in his apples.

It may be claimed that so long as men can be induced to use the trap, and kill the worms regularly, it matters little whether or not they understand the philosophy of its use; but barring the principle at stake, the spread of error can never be fraught with any continued good; and when, by carelessness or oversight, some of the very priests of horticulture spread through the columns of prominent journals the absurd idea that the moth deposits her eggs between the "face of the trap," it becomes patent that it is not the credulous German alone who needs correct rather than bogus information.

I have thus indicated the mischief that may be done by overestimating the value of this trap, in order that the patentees may strip it of all

appearance of sham, and present it to the fruit-grower for what it is—a very useful and important device—and not extol it as a sure Codling-moth exterminator.

Onion Sets—A New Plan of Raising.

BY PETER HENDERSON.

Mr. Wm. C. Pelham, of Maysville, Ky., writes requesting me to try his method of raising onion sets the coming season, and give the result of the experiment to the readers of the *Agriculturist*. But his method is so simple, so valuable, and so certain to be successful, that I deem it advisable to give it to the readers of the *Agriculturist* at once, so that many may avail themselves of it the present season.

Mr. Pelham says that his method for the past three years has been to select a level and dry piece of ground. His ground is rich alluvial loam, but the character of the soil is of no special importance. Beds are formed two feet wide, with a path of one foot between. The "beds" are excavated to the depth of two inches—or, in other words, the path or alley between is two inches higher than the beds; the bottom of the beds is nicely smoothed with the back of a spade, so as to present a level surface whereon to sow the seed. The seed is sown so that from fifteen to twenty seeds will cover a square inch. If the surface of the beds was sprinkled with plaster or white sand, the seeds, which are black, could be sown more evenly. After sowing, the seeds are covered with two inches of pure clean sand, which brings the beds and paths to the same level. The whole is then rolled with a light roller or patted down with a spade. The advantages of this plan are, that there being no seeds of weeds in the sand, the labor of weeding is entirely saved, and the sets when matured are far more easily harvested from the clean, soft sand than from the hard-baked surface which most soils present after a season's rains and sun on a surface that can not be stirred.

I consider this plan of raising onion sets most valuable to the market-gardener, as a very little space devoted to this purpose will save him a heavy expense in the purchasing of onion sets. Few market-gardeners can grow them in the ordinary manner, unless at an expense greater than they can be purchased for from those who make a business of growing them. But the price paid for sets the past six or eight years has been so high that many market-gardeners have abandoned growing them. Last year I paid about \$150 for sets sufficient to plant an acre. By Mr. Pelham's method, I think the same quantity may be grown at an expense of from \$30 to \$50.

Every now and then we find practical gardeners and farmers grumbling that there is nothing new for them to learn from our agricultural papers. True, they may not learn something valuable from every number, but there are very few who will carefully read the columns of the *Agriculturist* for a year without gaining some information. I consider that this simple plan of Mr. Pelham's is alone worth twenty years' subscription to any market-gardener cultivating five acres of land, and who makes onion sets one item of his crop.

HOT-BEDS are more likely to suffer this month than at an earlier time. Though the weather may be cold, the sun has now great power, and a short neglect of the tender plants in the beds may ruin them past recovery. Give air before

the sun gets too hot in the morning, and cover early in the afternoon. Be prepared with mats or shutters for a cold night. The sudden changes must be watched, and their ill effects provided against.

Hints about Tree-Planting.

BY AN ILLINOIS CORRESPONDENT.

There is a prevalent idea, that trees if grown from seed in any particular locality, will be especially adapted to its soil and climate. I regard this as all humbug. It can not be expected or looked for any more than that an elephant born at the North Pole should be adapted to the climate and food of the white bear.

Many men buy apple and pear seed, and plant them with the expectation that the trees will be adapted to their climate and soil, which is no more apt to be the case than were they grown in any other country. It will be a hard matter to find two trees in one thousand that are exactly alike.

The first thing for any man to do, if he wants to plant an orchard, is to make a survey of his own town and county, investigate the different orchards, varieties, and locations, no matter what he may have seen away from home, or how well he may like certain varieties. All that he has observed elsewhere is of but little use until he determines its adaptability to his own locality.

Could we have things done as they should be, there would not be such a loss in apple, pear, and cherry trees, in the West and South-west. We plant so many trees that are not adapted to soil and climate, and our management is so bad, that we lose thousands of trees yearly by what is called by some of our wise men "root-rot." A thorough investigation of the matter proved to me that there was no such complaint or disease among trees, notwithstanding it is kept before the people, like many other humbugs, not for the utility of the theory, but for want of something better.

The cause of this complaint is banking trees above the collar. In the months of July and August a canker sets in just below the surface, and continues until it eats the bark to the wood; then the trees die immediately.

The only way to avoid this is to keep the crown of the tree exposed to the weather all summer, or by double-working the tree. It has been claimed by some that root-grafting was the cause, but experience has shown different. Take any sort that will throw out new roots when the tree is too deeply set, and you may root-graft all you please, without any bad results, except an overgrowth of some varieties. Then you can top-graft, and you have the whole thing, and just such a thing as you want, without any interference of soil or climate.

The best time to plant trees is in the spring. If we take trees from New York to a colder climate in the fall, and set them out in the field, the chances are that many sorts will die. But if set in spring, they have a chance to become acclimated, and will stand the succeeding winter far better. I am very much opposed to planting trees in the fall for that reason. If trees are grown in crowded nursery rows, the bark and wood are tender, and if taken to the cold bleak fields, many will die, and, especially where the ground freezes and thaws, the roots will be injured. If planted in spring, the trees take root and become acclimated. Always keep one thing in view—do not set trees *too deep*; let the collar be above the ground; then, with decent cultivation, the tree will grow and do well.

ZACK.

Chinese Primroses.

There is no plant that will give more satisfaction in window culture than the Chinese Primrose in its different varieties. If we go to the florists in December, and purchase plants

with the buds ready formed and just about to open, the chances are that we shall not get a flower. The change from the atmosphere of the greenhouse to that of our living rooms is too great, and the buds will blast. If we procure the plants in September or October, and let their change from open air to our closed dwellings be gradual, they will succeed finely. There are now many varieties of the Chinese Primrose, double and single, and of colors varying from pure white to deep crimson. Besides, there is a great difference in the foliage, and the flowers of some are beautifully crimped or fringed. The Double White variety is now quite common, and is one of the most prized plants by those who grow flowers for the bouquet-makers. The double sorts bloom less freely than the single ones in house culture, but if the atmosphere of the room is not "killing dry," they will give very satisfactory returns. The double colored sorts were a few years ago more rare than the white

ones, but of late several very fine varieties have appeared. We have seen nothing finer in the way of Primroses than one sent us by John Saul, the well-known florist of Washington, D. C. We present an engraving of a small plant of this, the *Grandiflora rubra*. Of course, an uncolored engraving can only give form, and we are obliged to leave its rich crimson to the imagination. These choice varieties can only be perpetuated by cuttings. The plants, after flowering, throw up offsets from the base, which are removed and treated like other cuttings. If one wishes fine double Primroses, he must obtain them from the florists. Still, the single ones are very fine, and can be readily raised

from the seed, provided that be fresh; and if the seed be of a "good strain," as the florists say, there is a chance of obtaining some very handsome varieties. The seeds should be sown in June or July in a box or pan of very light soil, in a shady place. When the plants are

It may seem untimely to bring window plants to notice at this season, but the chief cause of ill-success with house plants is in not beginning far enough ahead. Most people do not think of house plants until frost comes, while we ought to be preparing them all summer.

We can not have plants bloom satisfactorily in the house unless they have had proper treatment beforehand.

Strawberries in Missouri.

A correspondent in Audrain Co., Mo., writes: "I planted in my garden the Mexican Ever-bearing Strawberry, the *Agriculturist*, the *Jucunda*, and a seedling I had raised from Longworth's Prolific; they all grew well. The Mexican Ever-bearing bloomed and bore fruit until the ground was covered with snow, but the berries were small and tasteless, and I could get about two a week. I suppose if I had planted an acre, I could never have gathered a saucerful at a time, so I cut up the vines and threw them over the fence. My seedling was a strong, thrifty plant, and the fruit was fine, but it was not abundant, so it followed the Mexican humbug over the fence. The *Agriculturist* and the *Jucunda* are all the varieties that I want. These far surpass all others that I have raised or tasted, and they

DOUBLE CHINESE PRIMROSE.—(*Primula Sincensis*—var. *Grandiflora rubra*.)

large enough to handle, they may be transplanted to another box, and when still larger, put in the pots in which they are to bloom. The roots are very fine, and the soil should be rich, open, and light. A mixture of peaty soil, cow-dung, and sand suits them best. Seedling plants will bloom the next winter. They should at the approach of cold weather be taken in-doors, placed in a room without fire, and given air every mild day. By gradually inuring them to house culture they will go on and bloom abundantly. Plants that have bloomed in-doors should be set out in a shady place for the summer, and kept properly watered; if they show flower-buds, pinch them off.

are not few. The *Agriculturist* is a remarkably hardy and thrifty plant, and it yields abundantly; it is sweet and of good flavor, and of large size. The *Jucunda* is more tender, and does not stand the long dry summers nor the cold of winter so well as the *Agriculturist*. I measured some berries of the *Jucunda*, which were from five to six inches in circumference, and they had had no extra cultivation. We did not require a third as much sugar for the *Jucunda* and *Agriculturist* as for the *Wilson's Albany*. I would not cultivate the *Wilson's Albany* for my own use, it is too sour." Our correspondent's experience with the "Mexican Everbearing" is similar to our own.

THE HOUSEHOLD.

(For other Household Items, see "Basket" pages.)

Hints on House-Cleaning.

BY "NOMAD."

A house-cleaning of the most thorough character at least once a year, is very essential, in a sanitary point of view, for the accumulated dust beneath the carpets and with which everything becomes in time interpenetrated, is not the innocent thing

A SAFE STEP-LADDER.

some consider it. Dust is a curious compound of minute fragments of almost everything in creation, mixed with spores and germs of vegetable and animal life, which need only favoring circumstances to bring them into activity, and they may produce effects injurious or destructive to human life. Therefore the first necessity in house-cleaning is not to raise a dust, but to gather it together in such a manner that it can be quietly removed and got rid of. Before the carpets are taken up, they should be sprinkled with a good coating of dampened material. The old-fashioned tea-leaves are good in their way, but can seldom be had in sufficient quantities. Clean sawdust, chaff, finely-cut hay or straw, or coarse bran washed free from flour and dust, are all good substitutes for the tea-leaves. A liberal coating of such matter, well dampened, but not wet, spread upon a carpet and brushed smartly over it, will keep dust from rising, and at any time will improve its appearance. The water used to dampen this material would be made a disinfectant by dissolving in it a small quantity of carbolic acid; one part in two or three hundred is sufficient. The damp material may, when used for the carpets, be swept into one corner and afterwards spread over the bare floor, more water being sprinkled over it, and used to gather the thick dust generally found beneath the carpets.

House-cleaning should commence at the top of the house and work downwards. In this case it may be undertaken by spells, with intervening rests.

After the floors are cleared, the walls and ceilings claim attention. If no special cleaning is needed, a brush of soft hair is the best to use on them to remove dust. Here I will describe an improvement on the common step-ladder. This is usually made with legs of equal length, and therefore a person, when using a long one, can not get quite so close to the wall as may be desired, and is obliged to reach over and run the risk of falling. A step-ladder should be made with the back legs shorter than the front ones, so that the back will stand almost perpendicularly, as shown in the engraving. It may then be placed as close to a wall as may be desired. Any step-ladder may be altered by sawing off an inch or two of the back legs. A ladder should never be mounted unless the iron hook or cord to keep it from spreading is used.

A very beautiful whitening for walls and ceilings may be made by slaking the best lime in hot water, covering up to keep in the steam, and straining the milk of lime through a fine sieve; add to a pailful half a pound of common alum, two pounds of

sugar, three pints of rice-flour made into a thin, well-boiled paste, and one pound of white glue dissolved slowly over the fire. It should be applied with a paint-brush when warm.

Paint should be cleaned by using only a little water at a time and changing often; a soft flannel cloth or sponge is better than cotton or a brush; a piece of pine wood with a sharp point should be used for the corners. Where the paint is stained with smoke, some ashes or potash-lyc may be used. A soft linen towel should be used for wiping dry. Glass should not be cleaned with soap; a little paste of whiting and water should be rubbed over, and with another cloth it should be rinsed off, and the glass polished with a soft linen or old silk handkerchief. Alcohol or benzine is a good thing to clean glass, and clean paper is probably better than any cloth, sponge, or towel; dry paper leaves an excellent polish. Marble may be cleaned with a mixture of two parts of common soda, one part of pumice-stone, and one of chalk, finely powdered, and tied up in a fine muslin rag; the marble is wetted with water, the powder shaken over it, and it is rubbed with a soft cloth until clean, then washed in clean water and dried with a soft linen or silk handkerchief. No soap or potash should be allowed on marble. A good furniture polish is made by melting two ounces of beeswax, one ounce of turpentine, and one dram of powdered rosin together, with a gentle heat, and rubbing on when cold, with a soft flannel cloth, and polishing with a soft linen or silk cloth. If for mahogany, a little Indian-red may be mixed in. Cracks in furniture may be filled with putty, mixed with Indian-red or burnt umber, to get the desired shade. When dry it will take an equal polish with the wood.

How to Paper a Room.

Old paper may be removed by wetting thoroughly with water, and when soaked, it will easily strip off. If lime-wash has been used on a wall on which it is desired to paper, the paper may be made to stick by washing the wall with vinegar, or water which has

thin, creamy liquid is made; it should then be boiled, when it will thicken; if too thick, it may be thinned by adding boiling water. A little carbolic acid in the paste will keep it sweet and prevent mold. The paper should be cut to proper lengths, sufficient in quantity to finish the room, before pasting is commenced. Enough spare paper should be

Fig. 1.—PASTE-PAIL AND BRUSH.

left at top or bottom, to match the pattern evenly. These lengths should be laid evenly one over another, and the bench should be a little longer than the lengths of paper. The paste should be applied with a broad brush similar to the white-wash brushes, and should be laid on quickly, or the paper will soon become tender. If a piece of tin be fastened to the brush it can be hooked to the side of the pail and prevent much "mussing" with the paste (see figs. 1 and 2.) The cheap sorts of wall paper should be avoided, if possible. They contain generally twenty-five to forty per cent of clay, and a very common material for the pulp is cow-dung; only a very small proportion consists of fiber of rope, matting, or other coarse material of any strength, and in putting it on a wall it will often fall to pieces in the hands. Two persons are required to lay

Fig. 2.—PASTE-BRUSH.

on paper with rapidity, one to paste and one to apply the paper. When the paper is pasted it should be handed to the person on the ladder, who holds it about a foot from the top end,

Fig. 3.—PASTING AND PUTTING ON WALL-PAPER.

been made sour by the admixture of sulphuric acid (oil of vitriol). Papering is very easily done by making a bench on which to paste, of boards placed on two empty flour-barrels. Common flour-paste is made by mixing smoothly in cold water wheat or rye flour (rye makes the strongest paste) until a

and lays it evenly against the wall at the top, allowing the upper end to hang over on the backs of the hands (fig. 3). By looking down the wall it may be seen when it matches the previously-laid length, and should then be brought gently to the wall, the backs of the hands then pressed against the wall

and passed upwards towards the ceiling, spreading them out towards the corners of the length of paper. The scissors are then run along at the junction of the wall and ceiling, making a mark which can be easily seen, when the top of the paper is removed for a little distance, and it is cut off even and replaced. Then a soft cloth is gently passed downwards and the paper pressed against the wall to the bottom, where it is cut off as at the top. After a few lengths are laid, the operation will become easy, and if a room where the work is not very particular is commenced with, the best rooms may be attacked next.

A Pot, Pan, and Kettle Scraper.

A curious thing came by mail. It was a piece of galvanized iron, of about the size shown in the engraving, and had attached to it a label which read: "Pot, Pan, and Kettle Scraper. Please accept, with the compliments of the season, from John Furbish, dealer in kitchen furnishing goods, stoves, etc., Main street, Brunswick, Me. Decem-

POT AND PAN SCRAPER.

ber 25th, 1871." It seems that the John aforesaid did not, as many stupid people do, go and patent a simple thing. He had tried the little scraper, found it good, had a lot made, and gave one to every holiday customer. The piece of sheet-iron is so shaped that it will meet all possible angles, and save no end of knives and spoons. If John does not scrape himself into the good graces of the people of Brunswick, it will not be his fault. Any one can make this scraper, and the lady who directs the kitchen destinies of the writer hereof says: "First-rate; I wish I had had it before."

Home Topics.

BY FAITH ROCHESTER.

"A HOUSEFUL OF GIRLS WHO COST SO VERY MUCH MORE THAN THEY COME TO."—My text may be found in the February number of the *Agriculturist*, at the end of an article entitled, "Can Farming Pay such Taxes?" Girls of the description given in that article do not read the Household columns of this paper, I suppose. So we (sensible ones) may talk the matter over among ourselves.

It is doubtful whether the silly girls are most to blame for their general good-for-nothingness. They never deliberately consented to be born and bred to such a disgraceful state of things. They have been unfortunate indeed in their inheritance of mental and moral traits, and in their bringing up, if, having reached adult years, reasonable persuasion will not induce them to be reasonable in their conduct. Perhaps they are unfortunate in being born and brought up before general society—of which you and I are members—has grown sensible in its opinions and practices.

I don't profess to know what taxes *farming* can afford; but I think we can none of us afford to have the complaint about the extravagance and indolence of the "girl of the period" kept up much longer. What can we do toward putting an end to it?

Our children, of both sexes, should be diligently trained to take care of themselves, and to make themselves useful to others. Taking care of themselves means earning their own living, and it means

more. It means a practical acquaintance with household labor, and the ability to take care of one's own clothing. It is absurd for each person in a family to do the cooking, washing, and sewing for herself or himself apart from the general cooking and washing. A division of labor is best for pleasure and for profit; but no boy or girl gets a complete outfit for life who does not get some good domestic training. Such knowledge may prove very useful in an emergency, though not made of daily use by the circumstances of one's life.

More important than any actual knowledge of the details of labor, is the *habit of industry, and a disposition to be of use*. So all that we do to encourage healthy activity and kind regard for others in our children, tends to prevent their growing up to be idle spendthrifts. Let the little girls be active as children, if you would have them become active women. Play as well as work—and sometimes more than work—tends to this end. Anything but to make children "keep still" long at a time.

Our boys and girls should be ashamed to be dependent upon their parents after they are able to support themselves. But it is our duty, as their guardians, to give them as thorough and broad an education as we can; and this should include a knowledge of some business which may serve, in an emergency, as a plank between themselves and starvation. It is not the duty of every able-bodied person to earn money, but every one should find some way of being so useful to others as to gain right to the bread and butter that person eats.

If little girls are dressed for show rather than for comfort, will they not be likely to grow up vain? If their mothers sit up late to tuck and braid their little frocks, why should they not continue to toil early and late in order that their grown-up daughters may "shine"?

Let fathers take the whole family into their confidence as far as possible, and then the daughters will know the comparative value to the whole family of a silk dress with "two hundred and twenty-five yards of trimming" for one of the girls, or a mowing machine for the father. Fathers who only draw their purse-strings tight and growl when asked for money, with no kind explanations of their motives for refusal, get the name of being "stingy" and "unkind."

It is idle to talk about our grandmothers, for we do not live in their day. It is natural enough for our girls to wish to wear such garments as seem to them the most admired. So here comes in our duty as members of society, whether we have daughters or not, to use our influence toward making simplicity and common sense fashionable.

STOVE-CLOTHS.—I read a "premium essay" on housekeeping the other day, and then I went straight and made me some stove-cloths. Common holders have never given me much satisfaction for use about the stove and its furniture. These stove-cloths are long enough to reach from one end of the gas-pans to the other. "My aunt's" were made of an old grain bag, and were finished with lems and loops or rings. As soon as one was soiled so as to be uncleanly to the touch, it was put with the dirty clothes, and a clean one put in its place. Such a cloth, hung conveniently near the stove, saves the cook's apron some scorching and soiling, also some desecration of the dish-towels.

A TERRESTRIAL GLOBE.—The jolly St. Nick did a good thing by our family last Christmas. The wish for a good globe for the sake of the bairns had been breathed by the "united head" of this family, more than once, but we did not know as our wish had been overheard, and we were utterly surprised when one of Schoedler's beautiful twelve-inch terrestrial globes actually found its way into our family circle in holiday week. With all our wishing we had never dreamed what a treasure it would really be. I believe we old folks have learned more geography since that globe came than we ever learned before. As for the little ones, they have probably learned more than they would in many months of study of geography in the old memorizing way, and their first ideas will not be so erroneous as mine were. I had been almost through

Peter Parley's First Geography, when I learned, to my astonishment, that I lived on the *outside* of the round world pictured in the book, and not shut up in the inside. I wonder what proportion of the readers of this page have a clear idea of the motions of the earth; and their effects.

The globe is full of suggestions for stories of the most profitable kind, and it provokes one to historical and scientific reading. The children's most natural questions lead one on indefinitely— all about Columbus, the mariner's compass. But it's of no use to begin enumerating the topics suggested by the globe, for they seem endless.

It is a beautiful ornament, too, and it strikes me that no parlor-library is quite furnished without one. Such globes should be used in all our common schools. There is no other method of teaching the most important part of geography with success. The maps are excellent, and of course they are much more correct in their proportions than any flat representation of the earth can be.

Butter Molds and Stamps.

H. M. Taylor, Kansas, asks whether there are any molds made by which butter may be put up in pound or half-pound cakes for the market. We give on this page cuts of the usual forms of molds for this purpose. They are made of soft wood, as white-ash or soft maple, and are generally kept for sale at all country stores where willow-ware is sold.

Fig. 1.—BUTTER-STAMP.

The manner of using them is as follows: When the butter is ready for making up, it is weighed out into the proper quantities, and each piece is worked in the butter-dish with the ladle into flat round cakes. These cakes are either pressed with the mold shown in fig. 1, or are made to go into the cup of the mold shown at fig. 2. Inside of the cup (fig. 2) is a mold with a handle which works through a hole in the upper part of

Fig. 2.—BUTTER-MOLD.

the cup. The cup is inverted on to the table, and when this handle is pressed down it forces the mold on to the butter, which is squeezed into a very neat ornamented cake. By pushing the handle and lifting the cup, the cake of butter is pushed out of the mold. This makes a very favorite mode of putting up fine butter for market, and is also well adapted for preparing butter for the table in houses where neatness of appearance is studied. The molds when in use should be kept wetted in cold water to prevent the butter from sticking.

BOYS & GIRLS' COLUMNS.

Something about Rebuses.

Aunt Sue has full control of the Puzzle-Box, and all things thereunto belonging, and though she has supplied us with a plenty of rebuses (not *rebi*, miss who is just beginning her Latin), we have been so crowded with other things that we have not been able to give them room. We like rebuses, for they call for ingenuity in those who make them, and demand a corresponding amount of the same quality in those who make them out. As they are mostly furnished by boys and girls, and are always guessed by boys and girls, there is a good deal of ingenuity exercised somewhere. So let us have answers

424—Illustrated rebus, which gives, as usual, good mystical advice.

425—Illustrated Rebus.—A true saying, whoever made it.

426—Geographical Rebus.—A cape.

to these, and let our ingenious youngsters make new ones. And mind this—send them all to Aunt Sue, Box 111, Brooklyn, N. Y. Nowhere else. Aunt Sue is as well known at the Brooklyn P. O. as—well, better than the Postmaster-General, for she brings more business there.

About those Picture Stories.

All our boys and girls have read about the prizes which the publishers offered last month through "The Doctor." We learn that he has already received a goodly number. The time for closing was put off until May first, in order to allow the far-off youngsters in California, Oregon, and all those distant parts to have a chance. Now send on the stories, you who compete for prizes, and recollect that on the first day of May—slap—the door will be shut, and none come in after that time. Please note the conditions carefully. Some have already sent in stories without giving their ages and names in full. We can not always guess from the handwriting whether it is that of a boy or girl, and where initials only are given the matter becomes puzzling. Tell your story first, and if you have any remarks to make put them on a separate paper, and do not mix the two. It is not necessary to make any apologies for bad writing, as we presume every one does the best he or she can. We do not expect our little folks to be perfect penmen; indeed, we have known some old people whose handwriting might be improved. We have other things to bring on after this contest is settled, and if we mistake not, this is going to be a pretty lively year with our large and growing *Agriculturist* family.

What shall we Learn?—For our Older Boys and Girls.

The question at the head of this article does not refer to what we shall learn at school. All buildings, whether small or large, have pretty much the same kind of foundations, and all that we learn at school is but the foundation of our real education, and we all need to learn, as far as school goes, very much the same things. One of the most important things for a boy (or girl either) to learn is how much and how little they can do, to be convinced that "you can't put a quart into a pint measure," or, to put it in other words, "you can not lift yourself by pulling at your boot-straps." These sayings have passed into proverbs, and like many proverbs, which old people are very fond of repeating and which young ones are very apt to dislike, they contain much common-sense. It is a brief and rude way of telling one that he must learn something about things, about his relations to the objects around him, about his own possibilities. There is an education that every boy and girl gets outside of the school-house. It begins when we are very young, and teaches that hot iron will burn, and that we can't have the moon, no matter how loudly we may cry for it, and continues or should continue to the end of life. "Pshaw!" says some bright boy, "I'll never be such a gooney as to try to lift myself by my boot-straps." But many men have spent fortunes in doing the same thing. Some day you may read the history of the attempts at producing perpetual motion, which is just the same thing as lifting one's self by the boot-straps. Many people who did not understand simple principles have hopelessly tried to devise means to increase power by multiplying machinery. The history of inventions is full of people who have failed in, so to speak, endeavoring to lift themselves by their boot-straps.

"But about the quart in the pint measure?" you will say. "No one can be so foolish as that." It is only another caution against believing in impossibilities. Good Father S. puts it in another way, "Out of nothing nothing comes. When you see an advertisement of watches worth \$25, sold for \$5, before you try to raise that \$5 to send for a watch, just recollect that "you can't put a quart into a pint measure." In other words, that the person making the offer can not perform an impossibility, and that there is a wrong somewhere. Either the man will cheat you in the watch, or he has stolen the watches that he sells. When some one offers to sell a secret for a dollar, by which you can readily make a large sum of money, just stop and think of the nature of the offer. If this secret is so valuable, why don't the man use it and get rich himself? A great many of our older boys are attracted by these tempting offers, and we get frequent letters from them, concerning this or that project. When grown-up men and women are caught by such chaff, we think they learn a lesson that is worth what it cost them. Young people are enthusiastic, and do not stop to consider that no result is to be gained without expending force, whether in throwing a stone or moving a steamer; that there is no honest gain in money to be made without expending something; it may be labor, time, talent, or learning, but something must be given for whatever we honestly receive. When tempted by these offers of great returns from little outlay, remember that "Out of nothing nothing comes"—"You can't put a quart into a pint measure"—"You can't lift yourself by pulling at your boot-straps."

Aunt Sue's Puzzle-Box.

Well, we have had a glorious time with the arithmorems from "grandfather" down to "little Jimmy," and I am very glad you have enjoyed them so much. Now, let's

have some fun with "square words." You will be surprised to find how many words there are, of four letters, in the dictionary, that you never dreamed of. A. B. Leach sends the word "CARE" squared thirteen times, but in one square he has an obsolete word ("reit"), and in three others he has proper names ("Adam," "Ella" and "Etta"). Now, who will send me the greatest number of squares on the word "CARE," using no obsolete nor foreign word, and no names of persons nor places ("Eden" excepted)?

PUZZLE.

Bird, beast, and man, my whole—for food—
Will use, and count it very good:
Take off my head, and yours may be
Uncomfortable made by me.
I can not always thus remain,
So please put on a head again;
Oh! dear, how stupid you would be,
If you were now bereft of me.
Behold me twice, and then is shown
What Scottish laddies claim *their own*.
If I again beheld be
A preposition you will see;
Now change my head and turn me round
A much-used Latin word I'm found.

A. H.

ANAGRAMS.

- 1. Nat's score.
- 2. See her cars.
- 3. Eden contract.
- 4. Electing line.
- 5. I scent rue.
- 6. Cram a cut soul.
- 7. Enchain serf.
- 8. Slender pence.
- 9. Oh! idle surf.
- 10. Sit erect, Dr.

CROSS-WORD ENIGMAS.

- 1. My first is in ounce but not in dram.
My next is in Harry but not in Sam.
My third is in ant but not in bee.
My fourth is in ocean but not in sea.
My fifth is in young but not in old.
My sixth is in silver but not in gold.
And now my whole I prithee tell—
'Tis a tropical fruit, you know it well.
- 2. My first is in spectacles, not in eyes.
My second in owl but not in wise.
My third is in picture, not in sketch.
My fourth is in villain, not in wretch.
My fifth is in entry, not in hall.
My sixth is in cricket, not in ball.
My seventh is in you but not in thee.
My whole is a place where some like to be.

CYRUS R. II.

AGNES LEE.

SQUARE WORDS.

NUMERICAL ENIGMA.

I am composed of 22 letters.
 My 16, 17, 18, 10, is an article of clothing.
 My 19, 8, 9, 13, is a number.
 My 14, 15, 12, is a boy's nickname.
 My 3, 11, 21, 22, is a spike.
 My 7, 20, 2, 5, is an interjection.
 My 12, 1, 6, 17 is much used in cooking.
 My 4, 5, is a pronoun.
 My whole is a well-known proverb.

B. W. PURCELL.

AUNT SUE'S NOTICES TO CORRESPONDENTS.

ADDIE L. B. It grieves me to be unable to reply personally to hundreds of just such charming letters as yours, but I feel none the less grateful for such kind interest, and can not have "too many correspondents."

Glad to hear from O. A. Gage, M. M. L., James McA., F. W. H., Cora F. B., Chs. De L., A. B. Leach, M. F. D., and S. L. Y.

Thanks for puzzles, etc., to Gustavus M., Harry H. D., O. O. Y. S., Clayton C., St. Johns, "Scientific," M. L. E., and John Bright.

In sending contributions for the puzzle department, please specify whether they are intended for the *Agriculturist*, or for *Hearth and Home*.

How Came He to Pull her Nose?

A SENSATIONAL STORY BY "THE DOCTOR."

The characters in my story are three, and I might as well introduce them to you at once. They are Will, Nell, and little Caoutchouc. To save the trouble of de-

HOW CAME HE TO PULL HER NOSE?

F. L. S.—Is the "trick" you send, original? Is it not already published in the books on "parlor magic"?

O. O. Y. S. ("One of your Subscribers").—If "the boys come in from their sledding" "to puzzle over the arithmorems," my mission is surely fulfilled.

DAISY.—As you have numbered your questions, I may reply briefly. 1. No. 2. The value depends entirely upon the merit of the article, or the fame of the author. 3. A *nom de plume* is sufficient.

M. L. E.—No, thank you; I have more "cross-word" and "numerical enigmas" now on hand than I ever expect to use during my natural life, and I belong to a long-lived race.

scribing them, I refer you to the picture. Caoutchouc is not such a very pretty name, particularly when you pronounce it ko-chuk. If you look in the dictionary, you will find that Caoutchouc is an Indian name for India-rubber, and before we go on with our story I wish to ask, What do you boys and girls know about India-rubber? For that matter, what do the old folks? "What has this got to do with it?"—Didn't I say this was a sensational story, and you never can tell how these stories will come out. Well! I am not a very old fellow—at least I didn't think so until the other day, when I entered a crowded street-car, and a bright-looking youth got up and said, "Take my seat, old gentleman." How an India-rubber story does stretch, to be sure! To get back! I am not

a very old fellow, but I can recollect many things that you can not. When I was a youngster like you—never mind the date—I had a great fancy for learning to draw. I had the run of a fine large library, and you may be sure that I hunted up all the books that told anything about drawing. There was one book, I have forgotten the name of it now, that I liked very much. It said that no false marks should be made upon the paper, but if any were made, they could be taken out by carefully rubbing them with a piece of stale bread. Just here in the book was an *, which referred to a foot-note, where it was stated that the author had seen a peculiar substance, brought from the Indies, and went on to describe it so that any one might know it was India-rubber, and stated where and at what price a small piece could be bought for rubbing out pencil-marks. Now, how different! We wipe our feet upon an India-rubber mat, and dress our hair with an India-rubber comb. To enumerate all the forms in which we are familiar with this article, would require a long catalogue. So far from being a rarity, a curiosa thing with which to rub out pencil-marks, it has become one of the necessary things of our lives. . . . How did I first become acquainted with it?—In my first pair of India-rubber shoes—Philadelphians used to call them "gums," and people who wished to be very elegant in their speech, used to call them "elastics." We matter-of-fact people called them India-rubber over-shoes, and if we were in a hurry and wished to be very economical, we would abbreviate to "rubbers," but never "gums" nor "elastics." But before I tell you about my first "rubbers," let me say something about rubber in general. There are several trees in tropical countries that have a milky juice, and this juice, when dried, is the very thing we are talking about—India-rubber. If I were to tell you that an Euphorbiaceous plant, *Siphonia Elastica*, produces the most and the best, I don't think you would be much the wiser for it. So we will content ourselves with the fact, that a South American tree, which grows in the greatest abundance, is always ready to yield its juice, if properly treated. A notch is hacked in the trunk of the tree, and below this cut a little basin of clay is molded. You will say that "hacking" is not the best way to make a tree "give down," but the tree does, and lets at least a teacupful of milk run into the little clay basin each day. If you were to dip a stick into this milk, and let it dry, you would find a thin film of India-rubber on your stick—and that is the whole story of India-rubber making, only the natives, while they follow the principle, put in many variations. "Milk?" you say.—Yes, it looks like milk, and tastes not so very unlike it, for I have seen and tasted it. Some one discovered that if a little ammonia (which you perhaps know as hartshorn) be added to the milky juice of this tree, it can be kept for a long time without change. Some one sent a lot of this preserved milk to Boston (Boston, you know, children, is "the hub," where everything that is worth knowing is to be found), and there is where I saw this wonderful liquid. The South American Indians make molds of clay, dip them in the milk of the India-rubber tree, and then hold the mold over a fire to dry it; then they dip again, dry again, and thus the mold gets covered with rubber as thick as they please. When the coat is thick enough, they break the clay mold, shake out the broken clay, and have a bottle, a bird, or a shoe, of just the shape of the mold.

This brings me to my first rubber shoes. They were made in this way. Clay molds were gradually coated with the milk, and dried, and the rude shoes sent to market. The shoes had no particular shape, but they were wonderfully elastic, and would adapt themselves to the boot or shoe over which they were worn. You would be puzzled to find now a pair of rubbers like my first ones, and, as I believe I told you before, I am not such a very old fellow, either. Just look at our "Aretics" now! How unlike the shoes of — years ago! This change all comes of an inquisitive American by the name of Goodyear. He found that in cold weather our rubbers would be as hard as iron. If put in a warm place, they would become sticky. He wished to have a rubber that would be soft in the coldest weather, and not be too soft with any moderate amount of heat. So he began to ask the rubber questions. . . . "Questions?"—Yes, all experimenting is asking questions. So he mixed a little of this thing with the rubber, and said, "How now?"—then he put some of that thing with it, and said, "How now?" again. Then he used "other thing" and cooked the rubber, and when he said "How now?" this time, the rubber yielded and said, "All right! Sulphur and cooking did it, and all our nice rubber things are based on that discovery. Now we have rubber that will make boots to go to the North Pole, or water-bags to go to the Equator, and it is not changed by heat or cold. We have our splendid shoes, our capes, elastic material of all sorts, our balloons, our dolls and other toys, and even our jewellery, made out of that curious substance that was first used to remove pencil-marks from paper. I began this as a sensational story, entitled "How came he to pull her nose?" The introduction has been so long, that I am obliged to make the story very short—Because it was an India-rubber doll!

It has been stated that

40,000 ORGANS

(presumably "Cabinet Organs") are sold annually—some where; which we think is nearly the whole number of all sorts of reed organs made in the United States. But over

40,000 AMERICAN ORGANS

are in use, and we are constantly extending our facilities for manufacture. THE SMITH AMERICAN ORGAN CO. is the oldest among New England makers, having been in business over twenty-one years. Our organs are distributed over the civilized world, and are everywhere recognized as

The Leading Instruments.

English manufacturers, wishing to commend their wares, advertise them in large type as

AMERICAN ORGANS!

While we believe in BRAINS, MUSICAL FEELING, and CULTIVATED TASTE, and think that such a combination will not be beaten, in the production of artistic works, by any quantity of planers, borers, and jig-saws, we nevertheless avail ourselves of every practical expedient to save labor, by employing machinery to do such work as does not require intellect for its perfection. There is no establishment that uses so many

INGENIOUS LABOR-SAVING MACHINES.

Our large capital—equal in amount to that of any competing company—enables us to purchase ample supplies of

THE BEST MATERIALS,

and to give thorough workmanship and completeness to every part of our instruments. And for this end we mean to secure the most

Intelligent Supervision

in every department, and especially to produce the most

BRILLIANT AND MELODIOUS TONE.

Our prices are as low as those of any instruments that pretend to a comparison in quality.

We shall be glad to send our new

RED-LINE CATALOGUE

to any address upon application.

ARE YOU GOING TO PAINT?

MORE THAN

100,000 HOUSES

HAVE BEEN PAINTED WITH THE

AVERILL CHEMICAL PAINT

IT IS THE BEST

In the world for exterior work upon Cottages, Villas, or Buildings of any kind, whether built of brick, wood, or iron. It is a liquid, ready for use, and requires no oil thinning or drier. Purest white, and any desired shade can be had in packages from one gallon upwards.

Letter Received from Levi Shaw, Trustee of the United Society of Shakers.

MR. LEBANON, N. Y., Sept. 27th, 1871.

RESPECTED FRIENDS: In reply to your inquiry as to what we think of the Averill Chemical Paint, we have used in our Society at Mount Lebanon some 1,000 gallons. We are very much pleased with it, and until we are convinced that there is something better, shall give it the preference of all other paints. We have used heretofore the (—), (—), and most all other brands of white lead, neither of which have given us perfect satisfaction. Most of it would chalk off after being on some two or three years. This, after three years' experience, we do not find to be the case with the Averill Pure White Chemical Paint. Indeed, it appears just as well as when first put on. I will write you again on the subject when I am not in quite so much of a hurry.

Sample card of beautiful colors, and recommendations from owners of the finest residences in the country, furnished free by the

AVERILL CHEMICAL PAINT CO., 32 Burling Slip, New York, or 118 Superior Street, Cleveland, Ohio.

L. HATFIELD, AGENT, 131 Portland Street, Boston, Mass.

CHARLES OSGOOD & CO., Norwich, Ct.

ROBERT SHOEMAKER & CO., N. E. corner 4th and Race Streets, Philadelphia, Pa.

R. & W. H. CATHCART, 113 Thames Street, Baltimore, Md.

LAWRENCE & CO., 52 Main Street, Cincinnati, Ohio.

GEO. W. PITKIN, 120½ Michigan Avenue, Chicago, Ill.

GEO. PARTRIDGE & CO., St. Louis, Mo.

P. S.—The superiority of these Paints has already brought numerous worthless imitations in the market. We caution the public against using them.

DOTY'S CLOTHES WASHER.

"We believe the improved machine has no superior. The 'help' use it, and like it."—American Agriculturist. (See premium-list description, Feb. number, page 74.)

METROPOLITAN WASHING MACHINE CO., 32 Cortlandt st., New York.

PRATT'S ASTRAL OIL

has now the established reputation of being in every respect the safest, purest, and most reliable oil made.

OIL HOUSE OF CHAS. PRATT,

Established 1770. 108 Fulton st., New York.

We do not consider the success of the Blanchard Churn to be wondered at. Everybody knows that "the best" will always win.

WHY NOT WRITE AT ONCE!

We are trying to distribute information in regard to Waltham Watches. We know the better they are understood the more they will be sold. Hence, we have prepared an interesting pamphlet, illustrated with fine engravings, which gives a full and correct account of their manufacture; also a Descriptive Catalogue, with prices of every size and grade. We send this free to any one. From it you will learn the prices, also our plan of sending them by Express; the Watch not to be paid for till you have handled and examined it. Address HOWARD & CO., 865 Broadway, New York.

Mention that you saw this in the American Agriculturist.

No stamps required for return postage.

Residents of California, Oregon, and the Territories will find special advantages in writing to us, as we make the extra heavy cases adapted to these localities.

EXCELLENT FARMING AND SPLENDID

Michigan Pine Lands

FOR SALE,

On which are ONE THOUSAND MILLIONS OF PINE TIMBER, and inexhaustible quantities of Maple, Beech, Elm, Ash, Hemlock, Oak, etc.

The grant of lands to the Grand Rapids and Indiana Railroad Company to build their Road from Fort Wayne, Ind., to Traverse Bay and Mackinaw, Michigan, comprises in its farming lands every variety of soil, from the rich clay loam to the light sandy, and they are found in that section of Michigan, north of the city of Grand Rapids, and contiguous to the great fruit belt on the eastern shores of Lake Michigan, now being rapidly developed by railroad and other enterprises.

Farming Lands are sold to actual settlers, on credit, one quarter down, balance in yearly payments, interest 7 per cent. Persons desirous of locations for farms will, on application at the Office in Grand Rapids, be furnished with Tickets over the Road, entitling them to Return of Fare, in the event of purchasing any of the Company's farming land. For information about the lands, prices, location, etc., etc., address

WM. A. HOWARD, Land Commissioner, Grand Rapids, Michigan. TITLE PERFECT.

Best No. 1 Peruvian Guano. Best Ground Bone. Best Land Plaster. Sold in lots to suit, to either the farmer or dealer, by GRIFFING & CO., Send for Circular. 60 Cortlandt St., New York.

SEED CORN!

"CORN IS KING."

Cooley's Early Field Corn.

MILLIONS OF BUSHELS OF CORN are lost annually by the early fall frosts; and other millions are not developed, by the failure of the young stalks to push forward before the dry and hot weather of July and August dwarfs their growth.

Mr. C. C. Cooley, of Manchester Island, in the Ohio River, during the past twelve years has developed a White Field Corn that is at once VERY PROLIFIC, and

Matures in Fourteen Weeks.

Of this corn the New York Herald says: "The ears of corn received of Mr. Cooley are certainly a novelty. Only think of new corn, raised in Ohio, ripe enough to shell and sell in the New York market on the 15th of August."

The N. Y. Tribune says: "This corn is extraordinary."

The Prairie Farmer says: "The ears average eleven inches in length. The kernels . . . are matured enough to withstand injury from the frost. As the stalks of this corn are not so tall as those of other varieties, it can be planted nearer together."

FREE DISTRIBUTION OF SEED.

The seed of this very desirable Corn is only this spring first presented to the public. For the purpose of extending its benefits as widely as possible, the publishers of the

CINCINNATI WEEKLY TIMES

Have devised a method of distributing

TEN THOUSAND SACKS FREE,

To the farmers of the North, North-west, West, and South-west.

For further information address, with stamp,

PUBLISHERS WEEKLY TIMES,

No. 63 West Third St., Cincinnati, O.

The Premium Sanford Corn.

It has received the highest premiums at every State and County Fair wherever exhibited. 150 Farmers, in different States, who have tested it the past season, testify to its superiority over all other varieties. M. W. Stone, of Hamden, O., reports a yield of 203 bushels from one and one sixth of an acre without extra culture. J. J. Abernethy, New Village, N. Y., says: I have raised 55 bushels from one half-acre. J. D. Edgar, Yankton, Dakota Terr., writes: It matures much earlier than any corn we have ever had here. It is the corn for this country. I propose to give it a more extended trial. Ship me by freight 40 bushels selected seed. From Chamberlain & Chaffin, Garrotte, Ill.: The Sanford corn produced of an average two ears to a stalk. Planted 1st of June, harvested middle of September (100 days from planting). Have found none to equal it. J. W. Miller, Graham Lake, Minn., writes: I planted May 14th. The season being very dry, it did not sprout in three weeks. My neighbors said I was sold, but changed their tune at picking time. I harvested 14 bushels of the finest corn I ever saw from the plant of seed planted. I shall plant the whole, and want no better corn. Dr. N. S. Smith, Janesville, Wis., reports: I raised 110 bushels of same, ripe corn per acre, white and Yellow Dent did not exceed 65 per acre.

Beware of bogus and impure seed. Send to head-quarters and get the genuine. Those who order, and state the name of the paper in which they saw this advertisement will receive gratis one pound of the famous Late Rose Potato. One quart, post-paid, 60c.; two, \$1; peck, by ex. or freight, \$2; 1/2 bushel, \$3; bushel, \$5.

SEED POTATOES.—Peerless—4 lbs., post-paid, 75c.; one bushel, by freight or express, \$1.50; one bbl., \$3.50; five or more, \$3 per bbl. Late Rose (genuine)—4 lbs., post-paid, 75c.; 1 bushel, by freight or express, \$3.50; one bbl., \$8. Early Rose, \$2.50 per bbl.

SEED OATS.—For two stamps, to pay postage, I will send three samples, sufficient for trial, the best from ten varieties tested for two seasons.

Send stamp for Circular, giving full description and list of choice Field and Garden Seeds. Address

S. B. FANNING, Jamesport, N. Y.

MAMMOTH DENT CORN.—Raised 500 bushels, seed obtained from I. N. Balthis. Enormously productive. Price by mail, 4 lbs., 50c. By express, 1 pk., \$1.75; 1/2 bu., \$2.50; 1 bush., \$2.75; 2 bushels, \$5. Address RICH LECHNER, Sheridan, Pa.

CHOICE SANFORD CORN, saved from selected ears. Price per qt., post-paid, 50c.; two qts., 80c.; one pk., by ex., \$1.75; 1/2 bu., \$2.50; per bu., \$4. Address CHARLES L. SCHMUCKER, P. O. Box 1392, Fort Wayne, Ind.

MOORE'S EARLY CONCORD SWEET CORN.—Every one should plant this, the earliest and best in cultivation. 15c. per pkt., 4 pkts. for 50c., by mail, post-paid. JULIUS L. BROWNING, Chatham Village, N. Y.

CAMPBELL'S 60 Days Sugar Corn.—New. Believed to be the earliest sweet corn grown. Long ears, large grains, and exquisite flavor. Packet, 25c., post-paid. GEO. W. CAMPBELL, Delaware, Ohio.

JOHN S. COLLINS sells good genuine plants as low as any other responsible person offers.

Great Reduction in Prices.

As we have reduced the prices of our CELEBRATED BONE FERTILIZERS for the spring trade, we invite all interested in agriculture to send for Circulars. Address LISTER BROTHERS, Newark, N. J.

Having been the first to introduce to the public the Hubbard Squash, American Turban Squash, Marblehead Mammoth Cabbage, Mexican Sweet Corn, Phioney's Watermelon, Brown's New Dwarf Marrowleaf Pea, Boston Curled Lettuce, and other

New and Valuable Vegetables,

with the return of another season I am again prepared to supply the public with Vegetable and Flower Seeds of the purest quality. My Annual Catalogue is now ready, and will be sent free to all. My customers of last year will receive it without writing for it. It abounds in fine engravings, many of which were taken from photographs of the vegetables themselves. It has not only all novelties, but the standard vegetables of the farm and garden (over one hundred of which are of my own growing), and a carefully selected list of Flower Seeds. As stated in my Catalogue, all my seeds are sold under three warranties—1st: That all money sent shall reach me; 2d: That all seed ordered shall reach the purchaser; 3d: That my seeds shall be fresh, and true to name. Catalogues free to all.

JAMES J. H. GREGORY Marblehead, Mass.

One sent free for a club of five.

Catalogue of Flower and Garden Seeds sent free. W. B. DIMON, JR., & CO., Brooklyn, N. Y.

Choice Onion Seed

Every old onion-raiser knows that the difference in value of a crop of onions raised from seed of average quality, and one raised from onions that have been most carefully hand-picked each year for a long series of years, is from fifty to a hundred dollars. The seed I offer is of my own growing, and has had its reliability of yielding choice onions, free from scullions, as fully inbred as are the traits in any of the purest bred animals. My catalogue has recommendations from twenty farmers who have used my seed, and so know all about it. Catalogues sent free to all.

JAMES J. H. GREGORY, Marblehead, Mass.

Fall Meadow Oat-Grass Seed.

Last year we were unable to supply the demand for this article. We have now a limited quantity (all we could obtain from Europe) of this variety, so valuable for pasture or hay. It is fully described and figured in the American Agriculturist of March, 1871, page 104. Price one bushel of 14 lbs., \$4.00. Sample packets, by mail, of two pounds, for one dollar. We also offer the following:

- English or Perennial Ryegrass Seed, per bush., \$4.00
Kentucky Blue Grass, extra clean, " 4.50
Lawn Grass, finest mixture, " 5.00
Sweet-scented Vernal Grass, per lb., .80
White Dutch Clover, " .50
Alsike or Hybrid Clover, " .50
Lucern or French Clover (Alfalfa), " .50

With all other Grass, Garden, and Flower Seeds, for which see Dreer's Garden Calendar for 1872, mailed to all applicants.

HENRY A. DREER, Seed Warehouse 714 Chestnut st., Philadelphia, Pa.

Three New Melons.

My Catalogue contains a description, with engravings, of three new melons, which are well worthy the attention of all who love choice melons. Catalogue free to all.

JAMES J. H. GREGORY, Marblehead, Mass.

RUSSEL COE'S

Ammoniated Bone Superphosphate Lime, The most valuable commercial fertilizer now in use, at a reduced price.

Quality guaranteed equal to any heretofore manufactured. Prof. Samuel W. Johnson, of Yale College, and Chemist for the State of Connecticut, in his report on commercial fertilizers, makes it worth fifteen dollars per ton, in gold, more than any of the sixteen kinds of fertilizers analyzed, most of them superphosphates, as will be seen by reference to his pamphlets.

Manufacture and Post-Office at Linden, Union Co., N. J. CLUB TOGETHER. SAVE WHEN YOU CAN. Small Fruit Plants given away. \$7 worth for \$5. \$10 worth for \$10. \$45 worth for \$25, ordered at dozen or 100 rates. See pag. 153. THOS. C. ANDREWS, Moorestown, N. J.

**Rare and Beautiful Flowers
and Choice Vegetables**

CAN ALWAYS BE OBTAINED BY SOWING

Collections of Flower Seeds by Mail.

The following collections contain the most showy varieties in our large assortment, with full directions for culture. Each packet contains a mixture of the different colors and varieties of its species, so that a greater display can be made at a much less price than when ordered in separate packets. Those unacquainted with flowers, as well as the experienced cultivator, may order without fear of disappointment.

- Coll. A—contains twenty choice varieties of Annuals. \$1.00
 - Coll. B—contains twenty choice varieties of Biennials and Perennials. 1.00
 - Coll. C—contains ten extra varieties of Annuals and Perennials, embracing many of the new and choicest in cultivation. 1.00
 - Coll. D—contains five very choice varieties, selected from *Prize Flowers*, of English Fancies, German, Carnation, and Picotee Plinks, Verbenas, Truffant's French Asters, Double Hollyhocks. 1.00
- Any one remitting \$3.00 will receive the four assortments, postage free.

Collections of Kitchen-Garden Seeds.

A COMPLETE ASSORTMENT OF VEGETABLE SEEDS FOR ONE YEAR'S SUPPLY, FOR A LARGE OR SMALL GARDEN.

The following Collections are made up in the most liberal manner, care being taken to give a sufficient quantity of all the finest varieties and most useful sorts of Vegetables required in the Kitchen-Garden:

- Assortment No. 5 contains 60 varieties, \$3.50
 - " " No. 6 contains 40 varieties, 2.00
 - " " No. 7 contains 20 varieties, 1.00
- The above are prepared expressly for sending by mail, and will be sent post-paid upon receipt of prices annexed. Larger Collections, which can be safely sent by express (freight paid by purchaser), to any part of the country, as follows:

No. 1, \$20; No. 2, \$15; No. 3, \$10; No. 4, \$5.

For a list of the contents of each Collection, see the Eighteenth Annual Edition of their celebrated Seed Catalogue and Amateur's Guide to the Flower and Kitchen Garden.

just published, which will be mailed to all applicants upon receipt of 25 cts.; an edition beautifully bound in cloth, 75 cts. Regular customers supplied gratis.

This is without exception the largest and best Catalogue ever published in this or any other country. It contains 146 pages closely printed matter, besides several hundred finely executed engravings of favorite flowers and vegetables, and a beautifully colored Chromo of a group of twenty of the most popular flowers in cultivation. Also a descriptive list of 2,500 species and varieties of flower and vegetable seeds, including all the novelties of the past season, with full directions for culture.

We will send a packet of choice Flower Seeds gratis to persons sending us orders for catalogues and inclosing 25 cents (price of catalogue), if they will state that they saw this advertisement in the *American Agriculturist*.

Address **B. K. BLISS & SONS,**
P. O. Box 5712, New York City.

The Earliest and Handsomest Beet.

Early Dark Red Egyptian Turnip Beet.
A trial of this variety for the past three years authorizes us in recommending it as a week or ten days earlier than any other variety—which makes it invaluable to the Market-Gardener as well as to all lovers of Early Vegetables. 30c. per ounce; \$1.00 per 4 ounces; \$3 per pound.

B. K. BLISS & SONS,
23 Park Place, and 20 Murray St., New York.

To Farmers and Gardeners.

I invite all who have been in the habit of buying their garden seed from boxes left at the stores to give my seed a trial, side by side, and mark the difference in their germinating, and in the purity and quality of the vegetables raised from them. I have made it my mission for several years past to drive bad seed from the market, and so save farmers and gardeners the immense loss they annually suffer from the purchase of it.

The public have well appreciated my efforts, and I have now fifty thousand customers in the United States and Canada. I sell no seed I do not warrant, and what is the real pith of the matter I stand by my warranty. To enable me to do this I grow myself a large proportion of the seed I sell. Catalogues sent free to any applicant.

JAMES J. H. GREGORY, Marblehead, Mass.

GEN. GRANT CUCUMBER—Grows from 25 to 30 inches long; enormous bearer; unsurpassed for table use or pickles; 20c. per packet. **SANFORD CORN**—Yields 150 bushels per acre; 1 qt., 50c.; 4 qts., \$1.50, post free. **PEERLESS POTATOES**—1 lbs., 60c., post free.

G. W. WILSON, Auburn, Ohio.

IMPROVED White-spined Cucumber Seed.—The result of a careful selection for several years of the most perfect-shaped cucumbers, from vines that have uniformly produced them, in my own frames. Price 25 cts., post-paid. **C. THOMPSON ADAMS, Florist and Horticulturist, West Medway, Mass.**

Choice English Peas.

The following varieties have been fully tested both in Europe and this country for the past two years, and can be confidently recommended as superior to any other varieties in cultivation. Mailed, post-paid, at prices affixed.

Laxton's Alpha Pea.
THE EARLIEST WRINKLED PEA IN CULTIVATION.—A blue, wrinkled pea, of exquisite flavor, remarkable for its earliness and prolific bearing. This pea was raised by Mr. Laxton; it is very early as first crop, beating in this respect *McLean's Advance* and *Little Gem*; its beans pods well filled and of good size down to the bottom of the haulm. The Royal Horticultural Society awarded a first-class certificate to this variety.

One-half pint packets, 35 cents; \$1.40 per quart.
Laxton's Prolific Early Long Pod.
This valuable variety has created a great sensation among market-gardeners and seed growers. Pods in a green state were exhibited in London averaging eleven to twelve peas in a pod, and were pronounced an exceedingly fine variety. For a second early pea, there is none of a similar class in cultivation equal to it, and we feel very confident that it will soon come into general cultivation. 1/2 pint pts, 50c., per quart, 56c.

Laxton's Supreme.
The earliest blue pea in cultivation, with enormous well-filled pods. This pea has been exhibited all over the country, and has taken innumerable prizes, and was included among the twenty-four sorts of vegetables which won the Fifty-Guinea Cup, which was presented by the editors of the *Gardener's Chronicle* at the Royal Horticultural Show at Manchester. Per 1/2 pint packet, 35c.; per qt., 90c.

Also many other new varieties introduced the past season, for which see our Catalogue.

SUPREME PEA.—(LAXTON'S.)

B. K. BLISS & SONS,
Nos. 23 Park place & 20 Murray st., New York.

LATE ROSE POTATO.

This valuable Potato, which is now for the first time offered for sale, differs from all other varieties so far introduced, inasmuch as it is not claimed to be a new seedling, but a sub-variety or sport of the well-known *Early Rose*, which it strongly resembles in quality, color, and form—but is three weeks later, hardier, and more productive, having yielded the past season 250 to 300 bushels to the acre.
\$12.00 per bbl., \$5.00 per bush., \$3.00 per 1/2 bush., \$2.00 per peck, 4 lbs., by mail, \$1.00.

Our Illustrated Potato Catalogue will be mailed to all applicants. Address **B. K. BLISS & SONS,**
23 Park Place, and 20 Murray St., New York.

Moore's Early Concord Sweet Corn.

Another year's trial has proved this to be the best Sweet Corn in cultivation.
Selected ears, 25c. each; packet, 25c.; quart, by mail, 90c. Address **B. K. BLISS & SONS, P. O. Box 5712, New York.**

LAWN GRASS SEED.

By the use of our improved mixture, a beautiful Lawn may be made in a very short time. For preparing a Lawn, and subsequent management, see our Seed Catalogue. Packages of one qt., 30c., mailed to any address, post-paid. By express, per peck, \$1.75; per bushel, \$6.00.

B. K. BLISS & SONS,
Nos. 23 Park Place and 20 Murray St., New York.

Reserve Potato.

NONE better. Satisfaction or no pay. Send for Circulars. **Peerless at Bottom Prices.** Largest stock west of N. Y. Half sold. Central and Western buyers save freight in purchasing of us.
L. D. SCOTT & CO., Huron, Erie Co., Ohio.

PEERLESS POTATOES.

Get the GENUINE, delivered at R.R. depot, \$3 per bbl., \$1.50 per bush., \$1 per 1/2 bush., 75c. per peck; or 4 lbs. by mail, post-paid, 75c.

JULIUS L. BROWNING, Chatham Village, N. Y.

SKY FARM PEERLESS.—Best because unmixd. Mountain-grown, selected seed. 4 lbs., 60c.; peck, 60c.; bush, \$1.25; in quantity, \$1 per bush. All varieties furnished. **H. S. GOODALE, S. Egremont, Mass.**

PEERLESS POTATOES.—Delivered on cars at \$3 per bbl. No charge for bbl. **HARVEY BROTHERS, Growers and Importers of Select Garden and Flower Seeds, Buffalo, N. Y.**

PEERLESS POTATOES, \$3.50 per bbl. Early Rose, \$3.
W. S. CARPENTER & SON, Rye, Westchester Co., N. Y.

Lane's Improved

IMPERIAL SUGAR BEET.

This superb variety is the result of a careful selection for several years past of the French Imperial Sugar Beet, by Mr. Henry Lane, an experienced farmer of Cornwall, Vt. After a satisfactory trial, we can recommend it with the greatest confidence, as being hardier, more productive, and containing a greater percentage of sugar than the ordinary variety; and much better adapted for cultivation in this country, either for stock or the manufacture of sugar. We hear the most favorable reports from those who have tested it in various sections of the country, all of whom are satisfied of its superiority. It is the best beet raised for feeding cows or young stock. From thirty to forty tons raised to the acre, at a cost of from five to eight cents per bushel, the cheapness with which they can be raised, the large amount of healthy, nutritious food raised to the acre, and its great value as food for cattle, sheep, and swine, make this the most profitable root to raise.

Four pounds is the amount usually required for one acre.

See remarks respecting this variety in the February No. of the *Am. Agriculturist*.

We have purchased the entire stock of Mr. Lane.

Price, 15 cents per ounce; 40 cents four ounces; \$1.25 per pound.

B. K. BLISS & SONS,
No. 23 Park Place, and 20 Murray St., New York.

Bliss's Improved Long Orange Carrot.

This superior variety is the result of a careful selection, for successive years, of the best-formed, largest, and deepest-colored roots of the Imported Long Orange Carrot, by which it has attained a perfection hitherto unknown in this useful vegetable, being larger, better flavored, and of a deeper orange color, and more sure to produce a crop. Butter-makers will find this variety very useful in giving to their butter a rich, deep yellow color. We unhesitatingly pronounce it the best variety in the market, and one which will not fail to give satisfaction to the purchaser. One oz., 15c.; four ounces, 50c.; one lb., \$1.50, by mail, post-paid.

B. K. BLISS & SONS,
Nos. 23 Park place & 20 Murray st., New York.

Genuine Wethersfield Onion Seed.

We have just received a fine stock of the above from one of the most reliable growers in Wethersfield, which we offer at prices greatly reduced from last year.

	oz.	1/2 lb.	lb.
Extra Early Red, very early and productive.	25c.	\$0.75	\$2.50
Wethersfield Large Red, for main crop.	15c.	50	1.50
Large Red Oval or Globe.	30c.	1.00	3.00
Yellow Danvers (True).	25c.	75	2.50
White Portugal, very mild.	30c.	1.00	3.00
White Globe, an excellent market sort.	40c.	1.25	4.00
Early Cracker, a flat yellow variety.	40c.	1.25	4.00

The above will be sent, post-paid, to any address upon receipt of price. Address **B. K. BLISS & SONS,**
P. O. Box 5712, New York.

SILVER-HULL BUCKWHEAT.

This extraordinary variety, originated abroad and carefully tested here for two years, is now offered as a very great improvement upon the ordinary black or gray Buckwheat. Sown at the same time as the common Buckwheat, it continues in bloom longer, matures a few days sooner, and yields nearly or quite double under the same conditions. The grain is of a beautiful light gray color, varying slightly in shade, and the corners are much less prominent than in the ordinary variety, while the husk is thinner, thereby saving from 15 to 20 per cent waste in the mill. It is manufactured into flour, which flour is whiter and more nutritious. Price per bushel, \$5.00; half-bushel, \$3.00; peck, \$2.00; four pounds by mail, \$1.00.

B. K. BLISS & SONS,
23 Park Place, and 20 Murray St., New York.

NEW AND RARE VEGETABLES.

I make the seed of New and Rare Vegetables a specialty, besides raising all the common varieties. On the cover of my Catalogue will be found extracts from letters received from farmers and gardeners residing in over thirty different States and Territories who have used my seed from one to ten years. Catalogues sent free to all my customers of last year will receive it without writing for it.

JAMES J. H. GREGORY, Marblehead, Mass.

ESSEX PIGS. Last year, several readers of the *American Agriculturist* purchased Essex pigs from me. So far as I have heard, they have given good satisfaction. I keep only pure Essex, and breed them with great care. Last spring, I could not fill all my orders, and, much to my own regret and the loss of the intending purchaser, was obliged to return the money. This spring I expect to be able to furnish very superior pigs, and shall be glad if those wishing to buy pure Essex from me will order early. Address **JOSEPH HARRIS,** Moreton Farm, Rochester, N. Y.

OHIO IMPROVED HOGS take most premiums. Send for Price-list. And imported fowls. **L. D. SILVER**, Salem, Ohio.

ESSEX PIGS.

It gives me great pleasure to state that my spring pigs are very fine—I think the best I have ever raised. I shall be happy to receive orders from any readers of the *American Agriculturist*, as I feel sure the pigs will give good satisfaction.

The Essex, when thorough-bred and of the right kind, will, in my judgment, improve any breed with which they may be crossed.

For further information, address

JOSEPH HARRIS,
Moreton Farm, Rochester, N. Y.

Essex Pigs. Blood of recent importations. Pigs of all ages.

Jersey Cattle. From my first premium herd.

White Leghorn fowls, bred with care for past 8 years.

THE "LIGHT RUNNING" "DOMESTIC"

"BEST TO USE." "EASIEST TO SELL."

S. M. Agents: It don't pay you to fight the best machine. Prove our claims. Get the agency and sell it.

"DOMESTIC" S. M. Co., 96 Chambers St., N. Y.

BETTER STILL for 1872.

PAGE'S PORTABLE PUMP, Patent Syringe, and Fire Extinguisher, with metal boxes, and otherwise improved, for \$3. Send for Circular. N. PAGE, JR., Danvers, Mass.

The uniform success of the Clipper Mowers in the field, the testimony of every farmer who has used them, that they are the lightest in draft, the most durable, and the most economical machine for the farmer to buy, fully substantiates what the proprietors have always claimed—that the Clipper is the Best Mower in the World. To the No. 4 size is attached the Dropper (cutting 5/8 feet, with separate Finger-Bar for reaping), constructed with great improvements—in fact perfected; and in point of efficiency, strength, lightness of draft, and symmetry of proportions, it is, as a Reaper, also unequalled. Farmers! see it before you buy. Pass your own judgment upon it. Look at its many improvements possessed by no other machine. Remember, it is fully warranted. Send for Pamphlet. THE CLIPPER MOWER & REAPER CO., P. O. Box 6,173, 151 Chambers st., New York.

ANDERSON'S AGRICULTURAL STEAMER, for Steaming Feed for Stock; Heating Cheese Vats, Tannery Vats, Conservatories, etc. This Steamer is made of Wrought Iron, thoroughly riveted and finished in good style. It has a reliable Automatic or Self-Regulating Water Feeder, Safety Valve, Vacuum Valve, Water Gauge Cocks, Whistles, etc., all complete. The boiler is peculiar in construction, being ONE COMPLETE DOUBLE BOILER WITH ANOTHER, the two communicating one with the other. It has an extraordinary amount of fire space for the size of the boiler; No. 8, a medium size, having 3,853 square inches of fire surface; consequently, it requires but little fuel to run it. Either wood or coal may be used for fuel. It will cook more feed or heat more water in a given time than any other steamer of the same size of cost. It is more durable than any other, for the reason that the fire-box is made of wrought iron, and is entirely surrounded with water. We are also manufacturing

Anderson's Low Pressure Steam Heater, for heating Private Dwellings, Stores, Churches, Conservatories, etc. We manufacture for all the territory east of Illinois. For further particulars, address

P. P. MAST & CO.,

Having no use of the hands, any child of five years can push a grown person about. Invalids' Carriages to order. **PATENT SEDAN CARRYING CHAIRS.** State your case and send stamp for circular. **STEPHEN W. SMITH,** 90 William St., New York.

A Great Boon—A Good Cheap Sewing Machine, at Last.

The *American Agriculturist* was the first journal in the world to bring effectively before the public that great labor and clothes saver—the wringing machine. So, also, this journal prepared and published the first popular illustrated article showing, in a clear manner, "How Sewing is Done by Machinery." The illustrations used in that article have been taken up, copied, and printed many millions of times by the various manufacturers. And now we have the pleasure of bringing before the public a practically useful, *low-priced* sewing machine. While so often recommending the utility of Sewing Machines, we have been all the while earnestly looking for the appearance of something that would come within the reach of the large class that could not possibly buy a \$50 or \$60 implement. But though we have bought and tried a multitude of machines of all sorts, sizes, and prices, until a spacious lumber-room would be required to store all the samples, we have, until now, felt obliged to continually caution our readers against buying any of the low-priced machines. And we still say that for general use the sewing machines sold for from \$45 to \$75 each are to be

which is decidedly superior to the usual thin silver-plating, as it is far more durable, and does not tarnish. It is simple in its parts, and its use quickly learned, and it runs so easily that a child can work it.

2d. It is easily attached to any table or stand having a leaf or edge projecting an inch or so, and can thus be used in any part of the house, near a window, etc. It is so light and portable that a lady can carry it with her in a reticule when visiting, or on a journey, ready for use at any moment. It is so convenient in this respect that it will be a useful addition where other machines are used, either for carrying to different rooms, or when two wish to sew at the same time. It is applicable for almost all kinds of family sewing.

3d. It makes the *elastic loop-stitch* (the same as the Wilcox & Gibbs and some other good machines), which, with a little care in making the closing stitch, is abundantly strong for nearly all kinds of sewing, and less liable to break in washing and wearing, owing to its elasticity. It has the advantage that the stitch can be removed when desired. Those who have lock-stitch machines, will find this stitch more convenient for many kinds of sewing, for embroidering, etc. Many contend that the elastic loop-stitch is more durable.

4th. While we do not gainsay the merits of the "foot-

herself, or for any friend, of one copy of *Hearth and Home* or two copies of the *AMERICAN AGRICULTURIST* for the balance of this year (1872), to the first 800 persons who send us \$10 for one of the new machines.

The New Sewing Machine as a Premium without Money.

To enable those to get this machine, who can not raise even the \$10 to buy it, we make the following offer:

We will send the Machine free to any one who will collect and forward SIX subscribers for HEARTH AND HOME one year at \$3 each; or TWELVE subscribers to AMERICAN AGRICULTURIST for one year, at \$1.50 each.

Almost any lady can readily secure this small number of subscribers and get a machine free; or some friend can thus obtain it for her, as a present.

Full Descriptions

of all the Premiums are given in an extra sheet, which will be mailed *free* to applicants. Read over the descriptions, and you will find many desirable articles—indeed, all are desirable. We have room in this paper only for the following DESCRIPTIVE NOTES:

Nos. 8, 9, 10, 11—Pocket Knives.—HERE'S FOR THE BOYS AND GIRLS!—These Premiums are among the most pleasing and useful that we have ever offered. Every boy, and girl too, wants a pocket knife. We give them an opportunity to obtain a most valuable one for merely a little effort. These knives are made by Messrs. Smith & Clark, Bronxville, N. Y., whose work is equal to any done in this country or Europe. No. 8 is a neat, substantial Knife, with three blades and buck-horn handle. No. 9 is a still finer article, with four blades and buck-horn handle. No. 10 is an elegant Knife, with four blades and shell handle. No. 11 is a Lady's Pocket Knife, a beautiful article, with four blades and shell handle.

No. 12.—Multum in Parvo Pocket Knife.—This is a most attractive as well as useful Premium. It comprises, in one knife-handle, a large and a small blade, a screw-driver, a saw, a strong hook, a nut-cracker, a brad-awl, a gimlet, a corkscrew, a pointer, a slim punch, and, in addition to this, it can be used for various other purposes which will at once suggest themselves to any smart boy or man. The knives will be sent anywhere in our country, post-paid.

No. 14.—Casters and Fruit or Cake Basket Combined.—This is a new pattern, both novel and beautiful. It can be used as large, showy Casters, with six cut-glass bottles, or be instantly changed into complete Casters, with Call-Bell, and a separate Cake or Fruit Basket, with a colored glass dish inside. Every one receiving it will be delighted. It is from the same makers and of equally good quality as the preceding.

No. 33.—Steam-Engine.—This is a veritable steam-engine; one that will GO; and a capital, intensely interesting, and instructive article for boys, and grown-up people too. Our eleven-year-old boy ran his engine an average of an hour or more a day for six months; he has exhibited it in motion to many of his play-mates; has hitched on various toy machinery, and it appears to go just as well as when first started.

No. 34.—Garden Seeds.—A valuable selection of 40 varieties of the best seeds for a family garden, each parcel large enough for a garden of ordinary size. This premium and the next two are put up for us by Messrs. B. K. Bliss & Sons, Seed & Horticultural Warehouse, 23 Park Place and 20 Murray St., whose seed establishment is well known as one of the best in the country. This premium will be of great value and convenience to many, as we send the seeds post-paid.

No. 43.—Universal Clothes Wringing Machine.—A very useful, time-saving, strength-saving, clothes-saving implement, that should be in every family. The wringing of clothes by hand is hard upon the hands, arms, and chest, and the twisting stretches and breaks the fibers with lever power. With the Wringing Machine, the garments are passed rapidly between elastic rollers, which press the water out better than hand wringing, and as fast as one can pick up the articles. We have given thousands of these premiums, with almost universal satisfaction. They are made by the Metropolitan Washing Machine Co., Middlefield, Ct.

No. 48.—A Good Watch.—The Watches made by the American Watch Co., Waltham,

BECKWITH'S NEW \$10 SEWING MACHINE.

DESCRIPTION.—c, clamp holding machine upon edge of table; W, shield over wheels, with an opening to show the wheels; e, the crank-bar or pinion-arm, by which b, the upper arm, is moved; a, the lower arm; f, cloth plate; n, needle; l, thumb-screw to hold the needle; d, presser foot spring; r, tension screw and disks; s, spool of thread; m moves the stitch-maker which can not be readily shown. It is very simple in form and use.

preferred when obtainable. But not one half of the families in our country have any useful sewing machine, simply because not half the people feel that they can possibly spare \$50, or more, in this direction, and so the everlasting "stitch, stitch, stitch," by slow hand-process, goes on, exhausting the strength and health of the toil-worn and care-worn mothers of the land—just that class who can not hire help and most need the aid of the sewing machine.

The new machine, now introduced, we have been watching for months, and trying to like it on account of its cheapness, and because it was well made (which we could not say of other low-priced machines we have seen); but this was unsatisfactory simply on account of the motion, or method of applying the power—by a vertical motion of the hand for every stitch. Happily this difficulty is at last obviated. A crank and multiplying wheel have been devised, and now we are prepared to indorse the \$10 Beckwith Sewing Machine as one worthy of being at once secured by all who can not purchase the expensive machines; and as will be seen below, many of those who have the larger machines will want this one in addition. Here are some of the advantages of the Beckwith Machine:

1st. It is well and strongly made, and thoroughly electro-plated with nickel throughout, by the new process,

pedal," many persons who are unable to use that, will find no trouble with this crank-motion. This gives complete control of the needle at any and every movement, so that the operator can stop on every stitch if desired. The crank in this new machine is placed below the table, which is an advantage over all other previous attempts at low-priced machines. The work is fed from the table towards the operator, which is claimed as a merit.

But the great commendation of this new machine is, that while it is practically useful, it is sold at the low price of \$10, and thus brings it within the reach of a hundred thousand families that want a sewing machine and can not raise funds to buy higher-priced ones.

We have contracted with the Beck with Sewing Machine Company for the first 1,000 of them to supply our own friends, and as Premiums. Each machine is put in a neat, compact box, with hemmer and guide, oil-can, bottle of oil, thread, different-sized needles, etc., with full Printed Directions for using, and delivered to any express office in this city, without extra charge above the \$10. As we buy the machines at wholesale price, we have decided to give our readers some advantage of this, and we therefore propose to make a present for himself or

Mass., have peculiarities of excellence which place them above all foreign rivalry. The substitution of machinery for hand labor has been followed not only by greater simplicity, but by a precision in detail, and accuracy and uniformity in their time-keeping qualities, which by the old method of manufacture are unattainable. A smoothness and certainty of movement are secured which proceed from the perfect adaptation of every piece to its place. The extent of the Waltham establishment, the combination of skilled labor, with machinery perfect and ample, enable them to offer watches at lower rates than any other manufacturers. Their annual manufacture is said to be double that of all other makers in this country combined, and much larger than the entire manufacture of England. The mechanical improvements and valuable inventions of the last fifteen years, whether home or foreign in their origin, have been brought to their aid, and the presence of over 400,000 Waltham Watches in the pockets of the people, is the best proof of the public approval. We offer a Silver watch, jeweled, with chronometer balance, warranted by this Company as made of the best materials in the best manner, and in pure coin-silver "hunting" case; weight 3 oz. This watch we offer as one of our Premiums, with the fullest confidence. Upon the movement of each of these watches will be engraved, "AMERICAN AGRICULTURIST, MADE BY THE AMERICAN WATCH CO., WALTHAM, MASS."

No. 87.—Farmer's Boy's Library.—A few dollars' worth of books pertaining to the farm will give the boys new ideas, set them to thinking and observing, and thus enable them to make their heads help their hands. One such book will, in the end, be of far more value to a youth than to have an extra acre of land on coming to manhood. Any smart boy can easily secure this Premium, and he will have two sterling works by a well-known, practical farmer. They are Allen's New American Farm Book, and Allen's American Cattle.

No. 106.—General Book Premium.—Any one sending 25 or more names, may select books from our list to the amount of 10 cents for each subscriber sent at \$1; or 30 cents for each name sent at \$1.20; or 60 cents for each name at \$1.50. This offer is only for clubs of 25 or more. The books will be sent by mail or express, prepaid through, by us.

No. 107.—Thomas' Smoothing Harrow and Broadcast Weeder.—We consider this so good an implement that we have made arrangements with the manufacturers to offer it as a premium. Mr. J. J. Thomas has so wide and so good a reputation, both as a writer on agricultural subjects, and as author of "Farm Implements and Farm Machinery," that his name alone would be a safe guarantee for the goodness of a farm tool or machine. This harrow has, however, been tested by other good judges, who agree that it is a really valuable article. It is a thorough pulverizer of the soil and good cultivator of growing crops. It is of easy draft, takes a sweep of nine feet, can harrow twenty acres a day, and it leaves the ground as fine and smooth as a garden-bed. For 38 subscribers to *American Agriculturist*, at \$1.50, or 120 do., at \$1, or for 19 subscribers to *Health and Home*, at \$3, or 60 do., at \$2.50, or for 21 subscribers to both papers, at \$4 for the two, we will send the harrow, worth \$25. Send for descriptive list to J. J. Thomas & Co., Proprietors, Geneva, N. Y.

Agricultural News and Items.

Twenty-two head of cattle, lately shipped from Illinois to New York, weighed over sixty-one thousand pounds, an average of over twenty-eight hundred; ten of them averaged over thirty hundred. They were grazed on the open prairie. . . . A Shorthorn cow, *Rosedale*, now owned by Col. King, of Minnesota, brought her former owner, in three years, the amount of \$2,500 in prizes, besides three calves. . . . The prize Merino ram at the Ohio State Fair has been sold to a Maryland breeder for \$500. . . . Twenty-five Merino ewes were lately sold in Vermont for \$1,000. . . . Five hundred dollars was paid for a pair of Poland-China hogs which took the premium at the Michigan State Fair. . . . A collection of two hundred and three Poland-China swine were exhibited by a single breeder in Fulton Co., Illinois, at the fair of 1871; a building expressly for their accommodation was erected by the owner at his own expense. . . . A Wisconsin farmer, in 1871, from fifteen cows, made 5,530 pounds of cheese and 900 pounds of butter, which brought him \$730 in cash. . . . A California sheep raiser owns 90,000 sheep, from which he realizes an income of \$100,000 yearly; he commenced twenty years ago with a flock of 800. . . . Mutton carcasses are shipped from the Rocky Mountains to New York for \$1.75 per head. . . . It was stated at the N. Y. Dairymen's Association that a grade Ayrshire cow owned by J. H. McMillan, of Erie Co., in that State, had given during twenty-three weeks an average of forty-three pounds of milk per day, from which 322 pounds of butter had been made in that time, equal to fourteen pounds per week. She was six years old. . . . The ma-

chine for extracting honey from the comb, called the Mel Extractor, is now largely used in this country and Canada; one bee-keeper, during the past season, took from one hundred and twenty-five hives and their swarms ten tons of honey by the use of this machine. . . . In California there is a single apiary of two thousand hives; the Italian bees are there considered the most productive honey-makers. . . . A Canadian breeder has sold a Shorthorn bull, which has taken many important premiums, to an American farmer of Wythe Co., West Virginia. . . . A cattle sale in California, made by the executor of the estate of J. R. Walsh, realized \$40,000; unbroken horses brought from \$24 to \$120; bulls, from \$5 to \$100, and cows from \$18 to \$100. . . . Butter is being packed in Washington Territory, for want of tubs and jars, in cylindrical bags of white muslin; these are again packed in barrels which are filled up with brine; in this manner the butter is said to keep excellently, and the packages are cheaper and cleaner than tubs or jars. . . . The scarcity of hay in Canada has caused great activity in the demand for fodder or straw-cutters, and from motives of economy and to prevent sacrificing their stock, Canadian farmers are cutting, steaming, and feeding straw with crushed grain. . . . The Silver-beet is being raised in Canada as a crop for plowing under as manure; it produces a mass of leaves thirty inches high, which furnishes a large quantity of green manure. . . . A New York farmer has realized \$700 from fourteen acres of clover in the shape of hay and seed. . . . Tobacco has been a very profitable crop in the New England States the past year; one farmer grew on half an acre a crop which sold for \$163; another, on five acres, to the value of \$2,863, and another on two acres \$841. Some of the choicest leaf sold for \$1 per pound, and several farmers sold at 22 to 30 cents a pound all through. One farmer in Massachusetts had twenty-eight acres. . . . In Connecticut a worn-out field was fifty years ago planted in timber. The timber has yielded ten cords per year and fencing for the farm for twenty years past, and when cleared last year produced fifty cords per acre, and is now new land again. . . . In the San Joaquin valley, California, one man owns 350,000 acres of land, and twelve others in all own 2,735,000 acres; one man's pasture field has sixty-five miles of fence around it, and his farm is forty-five miles long. . . . O. Barnhardt, Fairport, N. Y., lately sold a steer of his own raising for \$234.73; it was forty-four months old and weighed 2,890 pounds; during summer he was fed on pasture and some meal daily, and in winter on hay, roots, and meal. . . . C. W. Wadsworth sold at auction at Geneseo, N. Y., the following Shorthorn stock at the prices named, viz.: a roan cow, "Music," \$195; white cow, "Mollie," \$66; red cow, "Honey," \$71; roan cow, "Melody," \$120; others from \$95 to \$130, and bull-calves and bulls from \$35 to \$105; \$1,500 was refused for five choice heifers. . . . Mr. Alexander, of Ky., has sold two Shorthorn heifers to an English purchaser for \$12,000. . . . Irrigated land in some parts of Europe sells for \$50 per acre, while adjoining land, not thus improved, will sell for \$50 per acre. An owner of land having a surplus of water from his works often sells it to his neighbors for large sums, or rents it yearly to them. . . . Orendorf Bros., of McLean Co., Ill., lately had at Chicago eighty-one hogs fed by themselves, which averaged 513 pounds. The hogs were of the Poland-China variety. . . . Ex-Commissioner of Agriculture Capron has purchased a large quantity of agricultural implements in this country, mainly from Western manufacturers, for shipment to Japan. . . . A Pennsylvania farmer planted one acre in pumpkins in hills six feet apart, which yielded fifty double wagon-loads, estimated at over forty tons, besides which two hundred quarts of seed were saved, which brought \$50 in cash. . . . A Western farmer has saved his corn fodder by placing it in pits dug in the ground, salting it, and covering with straw and earth; in this same manner clover is cured and preserved in parts of Belgium. . . . An Ayrshire cow imported by Mr. Peters, of Massachusetts, is said to have given in one hundred and fourteen days an average of 49 pounds 3 ounces of milk per day, and three days' milk gave 6 pounds 3 ounces of butter; the weight of this cow was 967 pounds. An Ayrshire cow, also owned by Mr. Peters, when slaughtered, gave 882 pounds of beef and 111 pounds of tallow; the beef was fine-grained, well-marbled, and of the very best quality. . . . It is estimated that the cattle in the United States number 25,145,240, valued at \$1,000,000,000. . . . The herd of Ayrshire cows owned by J. H. Morgan, of Ogdensburg, N. Y., number thirty-seven bulls and fifty heifers and cows. . . . At the Kansas Agricultural College farm the crop of wheat yielded forty-three and a half bushels per acre. . . . A Michigan farmer experimenting with Alsike clover found it to fail on dry soils, but on wet, mucky lands it yielded well. It stood exposure to the weather well, was free from dust, and was agreeable to the stock, and mated with the timothy. The after-growth amounted, however, to nothing. . . . Amasa Scott, of Orleans Co., Vt., has a pair of steers, twenty months old, which weigh 2,500 pounds. . . . Fifteen companies, with a capi-

tal of \$2,000,000, are engaged in mining and manufacturing the Charleston phosphates. . . . An Englishman once appeared at dinner in a coat which was made from cloth woven from wool which was on the sheep's backs on the morning of the same day; and now a California farmer has breakfasted on bread which was made from flour ground from wheat cut, thrashed, and taken to mill the same morning, four hours only being occupied in the whole process. . . . M. L. Sullivan, an Illinois farmer, keeps two hundred and twenty-five plows, one hundred and forty-two cultivators, three hundred and fifty mules, fifty horses, and fifty oxen at work, and the result is that he needs a corn-crib eight feet high and five miles long, and a hay-shed that holds 2,500 tons of hay. . . . The condition of winter wheat is unpromising generally throughout the country; exposure to severe cold has injured the grain which unfavorable weather in the fall left in a very weak condition. . . . In Indiana, the State Board of Agriculture elected John S. Sutherland as President, J. D. G. Nelson Vice-President, A. Herron Secretary, Carlos Dickson Treasurer, and H. W. Caldwell Superintendent. . . . Two townships of land on the North Pacific Railroad have been purchased for the settlement of a colony of Scotch farmers, who are now arriving with a choice selection of thorough-bred stock. . . . Ten thousand acres of land in Maine have been purchased for a party of Swedish immigrants. . . . J. Bridgeford, Paris, Ky., has sold for \$300 a Shorthorn bull-calf, 8 months old, to J. H. Talbot, of Missouri; the calf weighed 760 pounds. . . . N. P. Neely, Ottawa, Ill., sold in January the following stock to Theodore Willson, Osage, Iowa: Shorthorn bulls "2d Duke of Greenbush," \$500; "Young Primrose," \$300; "Young Beauty," \$300; heifer calf "Golden Age," \$300; "Last Rose of Summer," \$300. To D. V. Perrin, Grant Co., Wis., "5th Duke of Greenbush," \$500; also one Essex sow, \$60; three Essex pigs, \$60; one Berkshire sow, \$50. Mr. Neely has fed his stock the past winter on Hungarian hay cut before the seed was ripe, and found it good feed; he also raised 6,000 bushels of mangels on five acres.

PEAR CULTURE

FOR PROFIT.

By P. T. QUINN,

PRACTICAL HORTICULTURIST.

ILLUSTRATED.

If one wishes to raise pears intelligently, and with the best results, he must know first the character of his soil, the best mode of preparing it, the best varieties to select under existing conditions, the best mode of planting, pruning, fertilizing, grafting, and utilizing the ground before the trees come into bearing, and finally, of gathering and packing for market.

The hope of furnishing practical information on all these points has induced the author to endeavor to draw for others the same lessons which years of practical experience have afforded him.

Contents:

Chap. I. Varieties.	Chap. IX. Varieties to Plant.

Eureka Butter-Worker.

A lever-ladle works in all parts of com-
mon bowls, which are held firm; revolved
easy; drained by the strength of one finger;
very simple, strong, light, convenient
to carry, detached, and washed readily as
any bowl and ladle. It enables a person
to wash, salt, press, cut, turn, and work
soft or hard butter in every manner de-
sired, exactly on the hand-ladle principle,
three times easier and faster, and not as
liable to injure butter. It received the
highest honors at the following Fairs:

Working Position
N. Y. State; Pa. State; Western N. Y.;
American Institute; Buffalo International; and very highly
commended by thousands of dairymen; and all sold give
entire satisfaction as far as heard from.
Three sizes, \$7, \$7.50, \$8, with bowls. Liberal discount at
wholesale. Send plain shipping directions. Circulars and
information sent on application.

Gardening for Profit

In the Market and Family Garden.

By Peter Henderson.

ILLUSTRATED.

NOTICES BY THE PRESS.

All the vegetables that thrive in the open air in our
latitude are described, together with the best methods
for growing them. The author also imparts practical
instructions on the subjects of drainage, and the forma-
tion and management of hot-beds. Numerous well-ex-
ecuted wood-cuts tend to make clearer the instructions of
the author.—*Philadelphia Inquirer*.

The author of this treatise is one of the best known
and most successful of these gardeners who supply New
York with green vegetables; and as he writes from long
and dear-bought experience, the positive, dogmatic tone
he often assumes is by no means unbecoming. The book
itself is intended to be a guide for beginners embarking
in the author's business, and gives full and explicit di-
rections about all the operations connected with market-
gardening, lists of varieties of the most profitable vege-
tables, and much sound advice on kindred topics. Though
designed for a special class, it can not fail to be valuable
to the amateur and private gardener, and unlucky experi-
ence has taught us that the information contained in a
single chapter would have been worth to us the price of
the book.—*Daily Mercury* (New Bedford).

It is unquestionably the most thorough and the best
work of its kind we have yet had from the pen of an
American author. It is written in a clear, concise style,
and thus made more comprehensive than works which
smack more of the office than the farm or garden.
[*Daily Evening Times* (Bangor, Me.).

Mr. Henderson writes from knowledge, and is not one
of those amateur cultivators whose potatoes cost them
ten dollars a bushel, and whose eggs ought to be as
valuable as those of that other member of their family—
the goose of golden-egg-laying memory—for they are all
but priceless. No; he is a practical man, and he has the
art of imparting the knowledge he possesses in a very
agreeable manner; and he has brought together an ex-
traordinary amount of useful matter in a small volume,
which those who would "garden for profit" ought to
study carefully.—*Evening Traveller* (Boston).

There are marvels of transformation and rapid repro-
duction recorded therein, which might well shame the
dull fancy of the author of Aladdin or of Kaloolah.
There is no theory about it; a man who has made him-
self rich by market-gardening plainly tells our young
men how they can get rich as easily as he did, and with-
out wandering to California or Montana for it either.
[HORACE GREELEY in the *N. Y. Tribune*.

We have devoted more space to this little work than
we usually do to tomes much more pretentious. We have
done so because of the rare merits of the book in its
fund of information, useful to the farmer and market-
gardener, and because of the dearth of that kind of
knowledge. We earnestly advise that fraternity, for
whom this work was written, to buy it and study it. If
any among them have never yet read a book, let this be
their primer, and we will vouch for the excellence and
endurance of the priming. The work is profusely illus-
trated with wood-cuts.—*Louisville Daily Journal*.

AMERICAN AGRICULTURIST.

NEW YORK, MAY, 1872.

The busy season is upon us. On our own farm we find more work to do in May and October than any other two months in the year. May is emphatically the "seed-time," October the "harvest." As we sow so shall we reap. Much of our success for the year will depend on our labor this month; and the amount, character, efficiency, and the economy of our labor this month will depend very much on the care, forethought, and wisdom with which we have laid our plans and prepared for their prompt execution. This is a lesson which every farmer of experience has had abundant opportunities to learn. He is the wise man who takes the lesson to heart. We can not now fully atone for past negligence or mistakes, but this fact should not discourage us. We should forget the things that are behind, and press forward. The man who never makes a mistake is to be pitied. The growing man, the man who is learning, the man who is destined to do something in the world, is the man who makes mistakes and profits by them. He tumbles down, but gets up and pushes onward. It is better to stumble than to stand still.

Hints about Work.

Take Care of your Health.—Few people realize what health is worth until they lose it. It is easier to prevent disease than to cure it. The character of our farming is undergoing great changes. We are using more machinery, keeping better stock, raising choicer varieties of fruit, grains, potatoes, roots, and grasses; are buying more or making better manure. Now, all this requires brains. We are aware that there is a great deal of nonsense written on this subject. But it is undoubtedly a fact that a man can not long use his brain as an intelligent, enterprising American farmer is now compelled to do, and work and worry at the same time, without abundance of nutritious food. If he undertakes to do it on fat pork, potatoes, bread, and cake, his health will certainly give way. The American farmer of to-day needs and must have more fresh meat. Better patronize the butcher than the doctor; better sell fewer eggs and buy less medicine. We have heard a farmer say: "Food

that is good enough for my men is good enough for me." He may have been right. But the farmer who thinks and works too, needs better food and cooking than he who merely works with his hands.

Don't Take down the Stoves.—Keep a fire in the living room night and morning. If you have a good old-fashioned hearth, so much the better. Keep a good fire on it. Nothing is more pleasant or healthy. But do not think because you have a fire you must shut the doors. In most localities, until the land is better drained, people will suffer more or less from malaria. Hard work before breakfast should be avoided as much as possible.

Let the Children Sleep.—Our bright, active, intelligent American boys and girls need a good deal of sleep. Make them go to bed early, and then if they can sleep until breakfast-time let them.

Do not Work the Boys too Hard.—Ever since boys were, men have been inclined to abuse them. And the better the boy and the worse the man, the more likely is the boy to be "put upon." The poorest tools are given to him and the most disagreeable work. Did you ever know an average man who selected the hardest cows to milk and gave the boy the easiest? Did you ever know a man who would go for water and let the boy sit down and rest in the field while he was gone?

Live-Stock.—The animals on the farm need extra care and attention this month, and yet, owing to the pressure of other work, they are very apt to be neglected. Recollect that a farmer's success depends very much on the judgment with which he manages his live-stock. Almost any farmer can raise corn and potatoes, but not one farmer in ten has the qualities necessary to manage horses, cows, sheep, and pigs to the best advantage. It requires good judgment, a kind disposition, promptness, systematic regularity, a keen eye to detect the first symptoms of lameness, indigestion, want of appetite, sluggishness, want of vigor, etc. When one animal is taken sick, it should be taken for granted that, as a general rule, there is some defect or neglect in the food or management, not only of this one, but of all the others. At any rate, the matter should be investigated.

Indigestion.—In nine cases out of ten, especially with horses, sickness in animals is caused by indigestion. Want of grooming, dirty, ill-ventilated stables, starving one week and over-feeding the next, not feeding at the regular time when on the road and then giving too much grain when the horses are exhausted by fasting and labor, giving too much food at noon and too little time to eat it in, feeding immature grain and musty hay—these are among the causes of indigestion.

Sheep.—Do not turn out to grass too soon; and as long as the grass is succulent give a little hay.

Milk Cows.—At this season grass is often too succulent. There is not nutriment enough in it in proportion to bulk. And it will generally pay to give the cows in the yard some hay to eat during the night, and a little "cut feed"—say one peck of hay and two quarts of fine middlings—the first thing in the morning. A good cow at this season gives a generous flow of milk, and it is unwise not to supply her all the food she can digest.

Horses.—When horses have been fed grain all winter, and have not worked regularly, it not unfrequently happens that they have little appetite as warm weather approaches, and when put to hard work on the farm lose flesh rapidly. They need a change of food. If it is possible, give them a few carrots, or, in the absence of these, a bran-mash, sufficient to relax the bowels. If oats have been fed in the winter, give a little corn in the ear by way of change, varied with "cut feed," consisting of chaffed hay and corn-meal or fine bran, or, better still, oatmeal. As a rule, nothing is so good as oats—and this year oats are nearly as cheap as corn. Barley is also cheap, and by way of a change there is nothing better for farm horses than boiled barley. Boil it until it bursts open, and add a little salt and mix it with chaffed hay. There is nothing that will fatten a horse so soon as boiled barley.

Three-horse Teams should be used wherever pos-

sible. There is economy in it. One man can drive three horses as well as two. The "dead weight" of the implement is the same in either case, and as it not unfrequently happens that the power of one horse is expended in drawing the empty machine, wagon, or implement, three horses can do *as much again* real work as two. It is a great mistake to do heavy plowing or harrowing with two horses, and be compelled to let them rest frequently. Put on three, and keep them steadily at work. In harrowing, especially, a rapid gait is much more effective than a slow, dragging pace. Brisk, steady work, and fewer hours in the field, with better grooming in the stable, would accomplish more work with less fatigue to man and horse.

Swine.—The system of feeding should be adapted to the breed. No pig can grow rapidly on poor food. A well-bred pig will grow rapidly on good food—a poor-bred pig will not; and this is the real essential difference between them. If you starve both, the well-bred pig is no better than the other. Let young pigs have all they will eat and digest. The younger the pig, the more it will eat in proportion to live-weight, and the more it will gain in proportion to the food consumed. We commence to feed our pigs when two weeks old, placing a little trough where the sow can not get at it. The pigs are specially fond of boiled beets or mangels, mixed with cooked corn-meal or fine wheat-bran. Wean gradually, at from six to eight weeks old. Until from three to four months old, the pigs can hardly be fed too liberally. After that, and when running out at pasture, if they are unmistakably getting too fat, ease off on the grain. As a rule, however, all young well-bred pigs should have a little grain in addition to pasture, and the slops of the house and dairy. See that the pigs have access to fresh water. They may not drink much, but it should always be provided for them, no matter how sloppy their food may be. Provide ashes, salt, sulphur, and charcoal. Keep the pens and troughs clean.

Poultry.—Provide plenty of nest-eggs for the hens, and see that two do not lay in one nest or in the same nest with a sitting hen. See that everything is kept clean in the poultry-house, and that it is well ventilated. Whitewash frequently. Nothing is better for young chickens than mud, or bread soaked in hot water, placed outside the coop, where the hen can not get at it. Move the coops frequently, so as to keep the ground or grass clean. This is particularly necessary with turkeys. Avoid the common mistake of having the coops too small, and see that they are well ventilated. The great secret of raising ducks is to feed them all they will eat, half a dozen times a day, or more!

Corn.—Nothing is more important in raising corn than to secure a "good start." It is half the race. A fine, mellow soil is of the first importance. The best way to secure this depends on circumstances. Every farmer must determine this matter for himself. As a rule, we seldom harrow the land sufficiently. Corn can not thrive among clods. Our own practice, when planted in hills, is to soak the corn from twelve to twenty-four hours in warm soft water, and dry it with plaster. By exercising due precautions, the same thing may be done when sowing with a drill.

Corn-Fodder.—It is a great mistake to sow corn broadcast. Sow in drills $3\frac{1}{2}$ feet apart, say four bushels of seed per acre, or a kernel about every inch in the row. The land must be as rich and mellow as possible. Use the cultivator frequently.

Potatoes.—Peachblows and other late varieties should be planted early. If you are late, plant the Early Rose or some other variety that ripens early. We have had a good crop of Flukes planted the first week in June. The Early Rose has a tendency to grow out of the ground, and should be planted deep, or else be well hilled up.

Mangel-Wurzel.—All things considered, we regard this as the best root crop for our climate. If the land is rich enough, and the plants get a good start, the severest drouth seldom hurts the crop. Sow in drills three feet apart, and thin out twelve to fifteen inches in the rows. It requires about

four pounds of seed per acre. The earlier the seed is sown this month the better, provided the soil can be got in good condition. But it is better to wait until June, or substitute ruta-bagas, rather than to sow on poorly-prepared land.

Work in the Horticultural Departments.

The spring has been so backward that many of the operations which ought to have been finished last month, will have to be done in this. Many plants that have usually survived the winter with a little protection, will probably be found to be injured and perhaps in some cases destroyed. It will often be necessary to replant, and preparations ought to be made as early as possible, so that the trees may be set before they have started to grow.

Orchard and Nursery.

Planting.—If trees were properly heeled in last fall, they may be set several weeks later than they could, if taken from the nursery rows. The planting should be forwarded as fast as possible, so that the present season's growth may ripen properly.

Grafting, if done after the trees have started to grow, will require considerable care, as the bark slips so easily, that there is danger of injuring the trees by peeling.

Cultivating.—An orchard needs to be kept plowed and thoroughly cultivated, in order to produce the best results, and during the first few years after planting some crop may be raised between the rows; potatoes or carrots are good crops for a young orchard.

Mulching.—Too much can not be said about properly mulching young trees, especially the first season after they are set: it saves a great deal of work in destroying weeds, and during a dry season will often prevent trees dying.

Nursery Trees.—Those budded or grafted last summer, will be disposed to throw out suckers from the stock. These should be rubbed off, and not be allowed to get large enough to require cutting.

Seeds.—Plant all seeds as soon as possible, and keep the beds free from weeds. Young seedlings should be shaded as soon as up, taking care to use some kind of shelter that will allow a free circulation of air around the plants; a screen of laths is much used by nurserymen.

Insects.—War must still be kept up against all injurious insects, plans for destroying which have been given heretofore.

Fruit Garden.

As the fruit garden is only an orchard on a small scale, the directions for planting and general cultivation will be the same.

Strawberries.—Finish setting new plantations, and fork under the manure applied last fall.

Cuttings of currants, gooseberries, etc., may be set out in rows three feet apart, with six inches between the cuttings. After one season's growth they may be planted where they are to grow.

Currant bushes which have become sickly and unsightly from the want of care, ought to have the old wood cut back, so as to give light and air.

Raspberries and Blackberries.—Tie up the canes of last year's growth and cut away the old bearing canes, if not attended to last fall. Plenty of manure should be spaded under between the rows.

Grape-Vines.—If grape-vines have been left down until now, on account of frosts, and the shoots have pushed, great care must be used not to injure them. When vines are trained according to the arm system, the arms should be bent in the form of a curve, to allow the buds to start equally. Young vines, set out this season, should be allowed to grow only one cane.

Layers may be made by laying the canes in trenches until the buds start, when they should be gradually covered with soil, as the shoots grow.

Kitchen Garden.

In the warmer parts of the country, the early crops of hardy vegetables will be ready to gather this month, while in the more northern States the ground will not be ready to plant sooner than the first week in May. It is best to wait until the ground is warm and dry, before sowing, as a few days can not make a great difference in the harvest.

Asparagus may be cut from established beds, taking care not to injure the roots. If it is sent to market, it should be put up in bunches six to eight inches in diameter, according to the season, taking care to have the tops even, and when bunched, to cut the butts off square.

Beans.—Do not plant the pole and Lima beans until all danger from frost is over. A few rows of bush beans may be planted early this month.

Beets.—Sow a few rows very early, as they will stand considerable frost. The seed may be sown thickly, and afterwards the plants may be thinned and used for greens.

Cabbage and Cauliflowers.—Set out plants from the hot-bed and cold-frame, and sow seed for second early. As soon as the seed is up, sprinkle the plants with air-slaked lime, to keep off the fly. Plants that were set last month must be kept hoed, and liquid manure applied occasionally.

Carrots.—Sow a few rows for early, and put in plenty of seed, as it often comes poorly. Keep the soil between the rows stirred often, to prevent the growth of weeds.

Corn is a tender plant, and is easily injured by frost; therefore it should not be planted until all danger from frost is past. In garden culture plant in drills, allowing one foot between the plants.

Cucumbers, started under glass, may be set out as soon as the ground is warm; give them a little protection from the sun, during the day, by means of a newspaper, or pieces of board set around the hills. Sow for pickles next month.

Egg-Plants require more heat than most other vegetables, and ought not to be planted out until settled warm weather.

Herbs.—Sow seeds of Sage, Sweet Marjoram, Summer Savory, and Thyme, etc.

Leeks ought to be sown early, so as to get a good start before the dry weather comes on. Stir the soil between the rows, and thin if too thick.

Lettuce.—Sow seed for a succession, and set out plants from the hot-bed.

Martynias make one of the finest pickles we have, and if once tried, will always be grown. Sow when the ground is warm, and when large enough, transplant into rows, two feet apart, allowing eighteen inches between the plants.

Melons.—Treat as recommended for cucumbers.

Mustard.—Sow for salad in rows, 15 inches apart.

Nasturtiums.—Plant and give them the support of brush.

Okra.—Sow the latter part of the month where it is to be grown.

Onions.—Keep the beds sown last month clear of weeds, and loosen the soil often.

Peas.—Brush the tall varieties and keep them properly hoed. Plant more seed for a succession.

Peppers should be treated the same as egg-plants.

Potatoes.—Hoe as soon as up; plant for the second early crop. A great deal of labor may be saved, if the garden is large enough to allow of horse cultivation.

Radishes.—Sow for a succession, and sprinkle with air-slaked lime as soon as up, if insects trouble.

Salsify.—Sow thickly in drills, fifteen inches apart, and when up, thin to three or four inches in the row.

Spinach.—There ought to be several sowings of spinach for a succession. New Zealand Spinach should be sown in drills, and afterwards transplanted into rows, three feet apart each way; this is preferable to Spinach during the summer, as it is not so liable to run to seed.

Tomatoes.—Transplant as soon as the weather will permit, three or four feet apart each way, according to the richness of the soil. The plants

in neat gardens are trained to some sort of a trellis, and the vines pruned, to secure the best results.

Turnips.—Sow in well-manured soil, and as soon as up, sprinkle with ashes or air-slaked lime, to prevent the insects from destroying them.

Flower-Garden and Lawn.

Evergreens do best if planted this month, as this is the season when they commence their annual growth. In transplanting do not expose the roots to the sun and air, but keep wet and protect with hay or blankets, and set out as soon as possible.

Margins.—Cut the edges of beds, walks, and drives smoothly with an edging-knife.

Annuals.—Transplant from the hot-bed or window-boxes the young seedlings as soon as the weather becomes mild.

Perennials may be sown in a bed by themselves, and kept free from weeds. Sow seeds of those coming into flower as soon as ripe.

Bulbs.—Plant out Gladioluses, lilies, etc., as soon as possible. Tuberoses should be started in pots in the greenhouse or hot-bed.

Climbers.—Provide supports for climbing vines, such as Sweet Pea, Cypress-vine, and Morning Glory.

Dahlias.—Start in the hot-bed, and set out the plants as soon as the ground is warm.

Lawns.—Mow often, in order to induce a thick growth of grass, and to keep down all weeds. Use the roller after a rain.

Greenhouse and Window Plants.

The latter part of this month will be early enough to put out house plants into the borders, and in order that the plants may not be put back in their growth, the ventilators should be opened, and during mild days the doors, so that the plants may be gradually hardened. Plants stored in the cellar during the winter may now be brought out, potted, and placed in the borders.

Camellias, when put out of doors during the season, should be shaded, or else placed where they will not be injured by storms.

Fuchsias seldom do well when planted in the borders, unless they have some protection from the sun; if planted out, they should be well staked.

Cuttings of shrubs may be made from the green wood as soon as it becomes a little firm.

Hanging Baskets make very pretty ornaments for a piazza, if they do not get the strong rays of the sun. They should be so arranged as to be moved up and down, to allow them to be watered easily.

Commercial Matters—Market Prices.

The following condensed, comprehensive tables, carefully prepared specially for the *American Agriculturist*, show at a glance the transactions for the month ending April 15, 1872, and for the corresponding month last year.

1. TRANSACTIONS AT THE NEW YORK MARKETS.

Table with columns: Receipts, Flour, Wheat, Corn, Rye, Barley, Oats. Rows for 26th of this month, 25th of last month, and sales.

2. Comparison with same period at this time last year.

Table with columns: Receipts, Flour, Wheat, Corn, Rye, Barley, Oats. Rows for 26 days 1872 and 26 days 1871.

3. Exports from New York, Jan. 1 to April 15.

Table with columns: Flour, Wheat, Corn, Rye, Barley, Oats. Rows for 1872, 1871, 1870, 1869, 1868.

4. Stock of grain in store at New York.

Table with columns: Wheat, Corn, Rye, Barley, Oats, Malt. Rows for 1872, 1871, 1870.

Gold has been variable in price, having advanced to 109 1/2 and advanced to 110 1/2. The closing quotation, April 13th, was 110 1/2. Bread-stuffs have been moderately active. Flour has been in reduced stock, and decidedly firmer, particularly winter wheat extras, which have been offered

with unusual reserve. Spring wheat has been without material changes in values, but closed weak. Winter wheat, on the contrary, has been much dearer and in quite urgent request, especially the better grades of red and amber, which have been purchased more freely by millers, in good part for use at the South. Corn has been in fair request, and closed stronger in price, shippers buying moderately. Rye and Barley have been depressed and lower. Oats have been quoted cheaper, leading to more extensive dealings, mostly in mixed Western. Wool has attracted less attention, and prices have been quoted lower, though holders had not been willing to make important concessions. Manufacturers have been buying only to meet urgent wants. Provisions have been in rather more demand, particularly hog products, which closed more steadily. Cotton has been more active, and quoted higher. Hay has been in demand at former rates. Hops and Tobacco, in request within our range. Grass Seeds have been dull and irregular.

CURRENT WHOLESALE PRICES.

Table with columns: Item, March 16, April 15. Rows include Price of Gold, Flour, Extra Western, Wheat, Corn, Barley, Straw, Hops, Feathers, Seed, Timothy, Sugar, Molasses, Coffee, Tobacco, Wool, Domestic, California, Oil-Cake, Pork, Beef, Lard, Butter, Cheese, Peas, Potatoes, Turnips, Onions, Cranberries, Broom-Corn, Apples.

New York Live-Stock Markets.

Table with columns: Week Ending, Beesves, Cows, Calves, Sheep, Steine, Totl. Rows for March 18th, 25th, April 1st, 8th, Total in 4 Weeks, do. for prev. 4 Weeks.

Table with columns: Average per Week, do. last Month, do. do. prev's Month, Average per Week, 1871. Rows for Beesves, Cows, Calves, Sheep, Steine.

Beef Cattle.—Notwithstanding an average increase of about 400 cattle per week during the past month, there is a little improvement in price. The rates remained unchanged for three weeks, when drovers combined for a rise, as they had been losing money. After holding lots for several days in the yards, hoping for an improvement, owners were forced to sell at just about what the cattle cost in Chicago. Having eaten beef freely all winter, people are ready to turn to something else in the spring, and they now find substitutes in the abundant supplies of veal, eggs, fish, etc. Just now, with a strong holding back on the part of shippers, the rates are advanced 1/2 c. per lb., and stock is in demand again. Texan "Jong-horns" are coming forward more freely, some of them from Ohio distilleries, where they have taken kindly to slop-feed. The fat cattle have been exhausted in Kentucky. Our main supplies now arrive from Illinois, with fair supplies from Ohio and Missouri.

Below we give the range of prices, average price, and figures at which large lots were sold: March 18, ranged 10 @ 14 c. Large sales 11 @ 12 1/2 c. Av. 11 1/2 c. March 23th, do. 10 1/2 @ 14 c. do. do. 11 1/2 @ 13 c. do. 12 c. April 1st, do. 10 1/2 @ 11 c. do. do. 11 1/2 @ 12 c. do. 11 1/2 c. April 8th, do. 10 @ 13 1/2 c. do. do. 11 @ 12 c. do. 11 1/2 c.

Milk Cows.—The fresh-cow trade does not improve in the least, though receipts have been lighter. Milk is abundant and low, cow beef hard to sell, and

cows themselves too plenty for the demand. The greatest difficulty is found in selling poor cows, and, judging from the stock sent here, one would suppose the farmers had all combined to dispose of their worthless trash. A pen of this kind of stock—genuine scallawags—was just sold at \$15 per head. Other poor cows sold at \$25 @ \$40; fair, at \$50 @ \$60; and good to prime at \$65 @ \$80. Calves.—We have seldom seen the calf trade so completely demoralized. Not that the supply of live calves has been so very large, but because dressed have come forward so freely, while soft weather rendered it imperatively necessary to sell them at once. When a butcher was offered fat dressed calves at 10c. per lb., he was not inclined to pay above 8c. for live. One large lot of dressed was sold at 5c. per lb. A pen of 280 choice Bucks Co., Pa., live calves, 135 lbs., was sold at 8c. It is now too late in the season to send in dressed calves from any distance. Good to prime milk-fed live calves are worth 7c. @ 8c. per lb.; common to fair sell at 4c. @ 6 1/2 c. Hog-dressed are worth 8c. @ 10 1/2 c. for milk-fed, and 4c. @ 6c. for small and thin veals. Sheep and Lambs.—Sheep are coming forward sparingly, and are now improving. They ran down about 1/2 c. soon after last report, and trade dragged heavily. This was owing to a dullness in wool, which led skin-buyers to reduce the prices of pelts about 75c. each. The skins had formerly been the chief recommendation for selling sheep, so quick did the pelc-buyers pick them up at \$1.50 @ \$5, each. Now it takes a fine lot of skins to reach \$1. Lambs come forward sparingly this backward spring. They are worth \$1 @ \$9.50, each, on 10c. @ 12c. per lb., live weight. Poor to medium sheep are quoted at 7 1/2 c. @ 8 1/2 c. per lb.; fair to good at 8 1/2 c. @ 9 1/2 c.; and prime to best selections at 10c. @ 10 1/2 c. Swine.—No hogs are now arriving dressed, and live come forward less freely. And still there is a decline of 1/2 c. on live. Just at the close there is a scarcity, and prices of city dressed are 1/2 c. higher than they were a few days ago. The consumptive demand lessens as warm weather comes on. Live are worth 4 1/2 c. @ 5c.; city-dressed Western, 6 1/2 c. @ 6 3/4 c.

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Remitting Money:—Checks on New York City Banks or Bankers are best for large sums; make payable to the order of **Orange Jud & Co. Post-Office Money Orders**, for \$50 or less, are cheap and safe also. When these are not obtainable, register letters, affixing stamps for postage and registry; put in the money and seal the letter in the presence of the postmaster, and take his receipt for it. Money sent in the above three methods is safe against loss.

Postage: On American Agriculturist, 3 cents a quarter, in advance; on *Hearth and Home*, 5 cents per quarter. Double rates if not paid in advance at the office where the papers are received. For subscribers in British America, the postage must be sent to this office for prepayment here.

Bound Copies of Volume Thirty are now ready. Price, \$3, at our office; or \$2.50 each, if sent by mail. Any of the last fifteen volumes (16 to 30) will also be forwarded at same price. Sets of numbers sent to our office will be neatly bound in our regular style, at 75 cents per vol. (50 cents extra, if returned by mail.) Missing numbers supplied at 12 cents each.

Clubs can at any time be increased by remitting for each addition the price paid by the original members; or a small club may be increased to a larger one; thus: a person having sent 10 subscribers and \$12, may afterward send 10 more subscribers with only \$8; making a club of 20 at \$1 each; and so of the other club rates.

Castor Pomace.—"H. S.," St. Louis, wants to know the value of Castor Pomace as a fertilizer. The only analysis of this substance we know of was made by Prof. Johnson, and is as follows: Water, 9 per cent; oil, 18; fiber and mealage, 33; nitrogenous bodies, 29 1/2 ash, 6 (the ash consists of one third phosphoric acid, and one third potash, magnesia, sulphuric and carbonic acids). As the pomace contains one third as much phosphoric acid and ammonia as ordinary guano, its value as a manure or as an article of commerce is proportionate. It is stimulating and rapid in its action, and therefore would be valuable as an article to enrich composts, or as an application for stimulating the early growth of plants.

Be Sure and Read the number of *Hearth and Home* for April 20. The information about medicines, humbugs, etc., is alone worth ten times the cost of the paper.

The "Lightning" Saw. — "Jas. J. D., Sberbrooke, P. Q., Canada, asks if the saw described lately in the *American Agriculturist* is really what it is represented to be, or half as good.

Culture of Beans. — "Vermont" wants to grow beans, and asks what manure shall be put on, how shall he put in and how harvest the crop.

Averill Co. Paint. — E. Evans, Somerset Co., N. J., asks what we know of the Averill Co. Paint. We know that it is put up in cans, all ready for use, and of any desired color; that it spreads easily, has good body, and a very beautiful appearance; that we have used it on inside and outside work, and found it so convenient and excellent, that we would not again go to the trouble of mixing up ordinary paints for any purpose, even at a much less price than the Averill paint can be procured for; and therefore we recommend those who are going to paint, to use it.

Section Roller. — "A Subscriber," Denver City, Col., sends us a cut of a roller, furnished with several flanges, which not only rolls the ground, but leaves a number of parallel channels, which serve to conduct water used in irrigation, over the land, and asks our opinion of it.

Charcoal-Dust. — "A Subscriber," Pine Bash, N. Y., asks if the charcoal-dust from old pit-bottoms will help a poor soil, in which nothing grows but sorrel. Charcoal-dust has no fertilizing property. It is not uncommon to see old pit-bottoms, twenty years old, as bare as the day on which the pit was burned. It would therefore do little good to spread the stuff over a field; it would be better to grow and plow under two crops of buckwheat. Lime would help this land, especially after the buckwheat was plowed in.

Purchasing Improved Stock. — "J. B. R.," Wayne Co., Ill., asks us if we would advise him to buy an inferior bull of thorough-bred stock at a low price, or if it would be cheaper in the end to procure a good one at a higher price. It would be best to get the most perfect animal that can be procured, consistent with the depth of the purse.

Broom-Corn. — "Farmer," Somerset Co., N. J., wants to know all about growing broom-corn and the best kind to plant. Broom-corn needs the same cultivation as Indian corn. It is often grown in the same field with corn by farmers who make their own brooms, and cultivated with it. Two quarts of seed are required per acre. Plants should be thinned to five or six to a hill; rich soil is needed to get a good yield.

Valuable Premiums.

(See also page 168.)

Any person, anywhere, can obtain one or more of the valuable premium articles in this table, without money, by simply gathering a few names for one or both of the papers.

As a constant Business Employment, some persons canvass all the time, receive the premium articles, and sell them for cash, and thus secure large salaries. One lady has averaged over \$3,000 a year for years past, and others are getting large pay for their time, often \$5 to \$20 a day.

The American Agriculturist is everywhere known and approved. HEARTH AND HOME is now without a superior in the world as a splendidly illustrated Weekly Newspaper, for real value, cheapness, and adaptability to every home in America.

Premium Clubs can be made up of subscribers to either paper, or partly of both, as noted over the Table. We call especial attention to the last column of figures, showing the small number of names required where both papers are taken, at the reduced price of \$4 a year.

You, Reader, can get a Premium. TRY IT.

Explanatory Notes.

Read and carefully Note the following Items: (a) All subscribers sent by one person count, though from one or a dozen different Post-offices. But... (b) Tell us with each name or list of names sent, that it is for a premium.... (c) Send the names as fast as obtained, that the subscribers may begin to receive the paper at once. You can have any time, from one to two months, to fill up your list.... (d) Send the exact money with each list of names, so that there may be no confusion of money accounts.... (e) Old and new subscribers all count in premium clubs.... (f) Specimen Numbers, Cards, and Show-bills will be supplied free as needed by canvassers, but they should be used carefully and economically, as they are very costly.... (g) Remit money in Checks on New York Banks or Bankers, payable to order of Orange Judd & Co., or send Post-office Money Orders. If neither of these is obtainable, Register Money Letters, affixing stamps both for the postage and registry; put in the money and seal the letter in the presence of the Postmaster, and take his receipt for it. Money sent in any of the above ways is at our risk; otherwise it is not.

In the following table is given the price of each article, and the number of subscribers required to get it free, at the regular rates, \$3 and \$3.00 a year, for the two papers; also at the club rates of \$1 and \$2.50; also at the rates of \$4 a year for both papers together.] N. B.—In all Premium Clubs for either paper, TWO copies of American Agriculturist at \$1.50 each, and ONE copy of *Hearth and Home* at \$3.00, will count exactly the same. So also two copies of *American Agriculturist* at \$1 each, and one copy of *Hearth and Home* at \$2.50, will count exactly the same. In this way Premium Clubs can be made up on the 2nd and 4th columns, or from the 3rd and 5th, or wholly from the 6th column.

Table of Premiums and Terms, For American Agriculturist, and for *Hearth and Home*, for the Year 1872. Open to all—No Competition. Columns include Name of Premium Article, Price of Premium, and Number of Subscribers required at various rates (\$1.50, \$3, \$4, etc.).

Every Premium article is new and of the very best manufacture. No charge is made for packing or boxing any article in our Premium List. The Premiums, Nos. 8 to 12, 23 to 28, 31, 35, 36, 68 to 91, and 94 to 106 inclusive, will each be delivered FREE of all charges, by mail or express (at the Post-office or express office nearest recipient), to any place in the United States or Territories.—(No. 33 mailed for 30 cents extra.) The other articles cost the recipient only the freight after leaving the manufactory of each, by any conveyance desired. Full Description of each Premium sent free.

Roofing Material.—"Inquirer" wants a roofing material in place of shingles, one which is fire-proof and durable. H. W. Johns's Asbestos Roofing is probably as good as any, where the roof is flat or of low pitch. It is easily applied—any farmer or workman of ordinary intelligence can put it on.

Manure for Quinces.—A Germantown, Pa., correspondent obtains good results from hog manure spaded in and a top-dressing of salt.

Average Crop of Beans per Acre.—"D. H. P.," Leavenworth, Kan., wants to know how many beans can be raised per acre, on the average. We have generally raised twenty to twenty-five bushels, but the average is probably not over fifteen. Few farmers do justice to this crop.

An Imperfect Ice-House.—"L. L. S.," Newburgh, finds the ice in his ice-house has begun to melt rapidly. He states there is a ditch communicating with the bottom of the house which probably admits air, and if so, it is doubtless the cause of the trouble. If any current of air is permitted to enter the bottom of the house, it rapidly raises the temperature and the ice melts. There should be a trap in all drains from ice-houses to prevent air from entering.

Sowing Plaster.—"D. B.," Manalapan, N. J., wants to know how much plaster should be applied per acre on clover, and when. One bushel should be spread evenly early in May, or when the clover has got a good start. Guano will be found a better application to strawberries than flour of bone, spread about the roots and raked in as early as possible.

Clark's Compost.—"Subscriber" asks for our opinion about Clark's compost from Manchester, N. H. We advise him to keep his five dollars and lay it out in ashes and plaster nearer home.

Horseradish.—"Ignoramus" is referred to article on page 153. As to land, rich light loam and plenty of manure will give the best returns. At the distances given in the article, it will take 14,496 sets to the acre. The roots are dug the fall after planting. Under the best cultivation, the yield is about five tons to the acre. Grinding is done upon revolving graters. R. H. Allen & Co., New York, make them. We can not tell about price—it is very variable.

Alsike Clover.—Wm. H. Joy, Muscatine, Iowa, wishes to sow some Alsike clover (*Trifolium hybridum*) for forage and as food for bees, and wants to know something about it. It is said to be adapted to moist soils, to grow rapidly, make good hay, and to be relished by cattle, but as far as we can speak from actual experience in one season it has no especial advantage over red clover as a forage crop, except that it will grow on moist soils, where red clover is subject to be heaved out by the frost. As bee pasture, it is recommended by some who have tried it; others again do not think much of it. The seed may be purchased at the seed stores, at 80 cents per pound, and four or five pounds are sufficient for an acre. It should be sown similarly to red clover.

A Tasteless Pump.—"P." asks what sort of a pump he shall use to avoid the unpleasant taste often given to the water. Cucumber wood (*Magnolia*) gives no taste, hemlock gives little or none, iron pipes, even when rusty, only flavor the water which stands in them; if that is pumped out, the fresh water is tasteless.

Where the Fashions come from.—Wherever the court of Fashion may be, her prime ministers are E. Butterick & Co., of New York, who "receive" in a fine structure at 555 Broadway. The building is 200 feet long and seven stories high, and is all occupied by their subordinates. Messrs. Butterick & Co. deserve the thanks of the community for demonstrating that in dress, as in other things, simplicity and utility are first principles in aesthetics. In the sanctum where the fashions are made, are a number of women intently studying the outlines of magnificent garments of—tissue-paper. They imagine and then embody new effects in form, style, color, and arrangement. The fashion of a garment having been decided on by the designer, the conception finds form in paper, and if accepted, a duplicate is made in cloth and fitted to a living model, and its merit proved by actual trial.

Other departments are devoted to different branches of the business, such as sketching and drawing, engraving for publication, editing, making up, and printing the "Metropolitan," the fashion magazine published by this house. The mechanical part of the work is completed in Brooklyn, in a separate factory, a building 50 x 100

feet, three stories high, and all occupied with the peculiar details of grading, cutting, arranging, folding, and preparing the patterns for the salesrooms. One hundred and fifty persons find constant employment in this department, but the total number of employes of the house is about 300.

The whole is completely systematized, and so confident are the proprietors of the exactness of their work that, though they cheerfully pay for all material spoiled in cutting through fault of the pattern, they have had but two such cases occur in the many millions of patterns they have sent out. Their arrangements enable ladies in all parts of the country to obtain, at very moderate cost, patterns for any garment, in the best styles, which may be relied on. It gives us pleasure to say that the cardinal principles which form the groundwork of the fashions of this house are neatness, feasibility, cheapness, and, above all, harmony; and as a consequence they have become the dictators of the modes for our country.

To Improve a Meadow.—"J. W. S." has a field in pasture, which needs renovation; he proposes to plow it and sow to rye, and seed with timothy, and pasture the rye with sheep, early next spring. This may do, if the field is plowed and harrowed twice during the summer, but it would be preferable to dress the field with manure, sow six quarts of timothy and clover, and harrow it well, without plowing.

Grubs in Cattle.—"A. M. K.," Mansfield, Ohio, can expel the grubs from his cattle by pressing the lumps on their backs between the finger and thumb, when the grubs will be forced out. They should not be killed in the skin, or they will make sores. Turpentine will have no effect but to irritate the cattle.

Harrowing Winter Grain.—"R. W. B.," Victor, N. Y., asks if harrowing his winter wheat will injure the young grass (timothy), and whether once harrowing is sufficient. One harrowing is sufficient; we have for several years harrowed our winter grain in the spring, and never found the timothy injured by it. Spread plaster about May 1st; it should be kept on the surface.

Lime for Corn in the Hill.—"J. P. Johnston, Wilmington, Pa., asks if it will pay to put lime in the hill when planting corn. No. The great benefit of lime is to help decompose the sod, and it needs to be applied as soon as the ground is plowed, and as long before the corn is planted as possible. A more stimulating manure would be preferable at planting time, as hen or hog manure, superphosphate or guano.

Tobacco Stems.—"J. B. Schneider, Kankakee, Ill., asks if it will pay to use tobacco stems for manure. In New England the stems are carefully collected, and composted as manure, and if it pays there, it ought to in Illinois.

Cost of Fence Wire.—"E. D. C.," North Star, Pa., wants to ascertain the cost of a wire fence. As he does not state what sort of a fence he proposes to build, we give him the price of the wire, when he can figure out the cost of the fence he needs. No. 9 wire is 10 cents per pound, and weighs one pound per rod. Staples are about 12 cents a pound.

Buckwheat Fallow.—"H. B. Cameron, Bealton, Va., asks if it would benefit "their cornland" to plow in two crops of buckwheat before seeding to wheat. Yes, the effect would be to add some fertilizing matter—although it is not very much—clean the land, and improve its texture.

Cotton-seed Meal.—"Mrs. "W. B. K.," Ilawara, La., writes her experience about cotton-seed meal for cows. She has used it for one year, and finds it makes rich milk and sweet, yellow butter. Mixed with wheat-bran the cows will eat more of it than alone.

Buffalo Bull-Calf.—"P. B. B." wishes to procure a buffalo bull-calf, if he knew where to get one. Unfortunately we can not help him, and, except as a curiosity, would not advise him to go to much trouble or expense to get one.

Plowing New Ground.—"S. B. S.," Patterson, Mo., asks if he should plow newly cleared ground before growing grass seed. By all means, get the ground into as mellow a state as possible, if you desire the grass to succeed well.

Devon Cattle.—"C. B. S.," Wayne Co., Mo., asks the price of Devon cattle. The general price is about \$400 per head for young stock, and \$250 to \$300 for mature animals, unless of superior character, when

the value is dictated by the estimation in which the owner holds them. For prices of fowls write to any of those who advertise in our columns.

Efflorescence on Bricks.—"M. A. H.," Little York, Washington Co., Ind., sends a sample of a substance with which in that vicinity bricks made of clay become incrustated. The sample sent is an impure nitrate of potash, and is doubtless due to the presence of potash and some organic matter in the clay. Clay, when produced from feldspathic rocks, often contains free soda or potash, and the efflorescence sometimes seen on bricks is thus occasioned.

Leached Ashes and Hen-Manure.—"W. H. W.," Evansville, Ill., has thrown leached ashes into his chicken-house, where they have become well mixed with the manure; he asks, if the mixture will be good for cabbages. Yes, or for any other crop.

How much Manure to the Acre?—"S. J." asks how much stable manure, at \$1.50 per load, he shall apply to the acre. It depends on the crop. Twenty loads for grain or potatoes, while corn, turnips, grass, or cabbages will bear double that quantity. Manure in too great abundance often causes grain crops to lodge or rust, and potatoes or peas to run to stalks.

Plaster on a Meadow.—"F." asks if it would benefit his meadow to sow plaster on it, enough to pay him for drawing the plaster twenty miles. If the time can be spared as well as not, the advantage gained would repay for the trouble. A bushel of plaster per acre has sometimes doubled the crop of hay, and almost always has proved very useful.

Cure for Cribbing.—"W. E. H.," Dunleith, N. Y., sends the following cure for cribbing—viz.: Take one pound of common soap when soft, and work it up with the hands with two ounces of cayenne pepper, and rub the manger, neck-yoke, etc., with the mixture. This cured his horses.

SUNDRY HUMBUGS.—The "Electro-Magnetic Curling Comb" swindle, denounced in these columns twice before this, has had an extensive run, and multitudes have been cheated out of \$1.25 each—because religious and other respectable journals have given it the use of their columns, often in editorial items. False engravings and false statements have been widely issued, and the rascal, hailing from Garrettsville, Ohio, has by these means coined money rapidly. Samples of these combs are before us—cheap little common horn combs, 3 inches long, worth a few cents only, having a bit of zinc and copper bonded upon the sides with a small copper wire, and of no utility whatever. A line at the end of the "directions for use" says: "The Electro-Magnetic Curling Comb must be used ONLY on FALSE hair," though nothing of this is hinted in the showy, talking advertisements. Those journals which have unwittingly or carelessly (and therefore reprehensibly) helped on this swindle, should make all amends possible by promptly denouncing the cheat—*stalling* is the proper word—and thus help stop it. . . . A standing caution: Beware of "Sault Oil," "French Burning Oil," and of "rights" to make them, and of the other things advertised along with them. This caution applies to all cheaply manufactured, so-called burning oils or compounds. You will be burned if you touch them. . . . Wood & Co., Mt. Vernon, N. J., ought to be avoided by everybody having an ounce of brains. There must be a good many having less than this amount, or he would not continue to get money enough from his offered vile and nonsensical wares, to keep him going as he does. . . . J. H. Reeves, 78 Nassau street, is trying the confession and affectionate dodge, and pretended exposure of other humbugs, to work himself into the confidence of nervous people and get their money. He changes his operations and tactics often, but clings to his old name, that was long since synonymous with humbug. . . . The "College of Health" is a name adopted by a swindler. . . . Only poor deluded people will trust their health and lives to the medicines of "Dr. F. E. Andrews, 300 Lexington avenue, N. Y.," "Edward P. Hynlar, M.D., Thompson street, N. Y.," "Dr. Abel King, Broadway, N. Y.," or any single one of the advertising "doctors" and medicine-makers whose circulars, advertisements, 20 to 50-page pamphlets, etc., with pretended recommendations of high personages, have been sent to us by the score, with inquiries as to their reliability. They are to be avoided *without exception*. . . . Is it cheap? A nice-looking paper sent a whole year for ten cents, and to large clubs for five cents! The big hand-bill says so. An examination reveals the fact that it is published once a quarter, and that it is really an advertisement of a plaster that will cure all the ills that flesh is "air to. . . . The "Dollar Stores," when not swindles, as are most of

them, especially those that receive orders by express or mail, are just like any other stores, only they put a lot of showy articles together that they will sell for \$1, and they are seldom cheap at that price. . . . All the "cheap watches" for \$1 to \$5, by tickets or otherwise, the magnetic time-keepers, etc., are humbings. Never buy a watch except of a known party, whom you can reach readily, and compel him to make good all he promises for it. . . . It is strange that some very respectable people should write to us asking about reliable agents for the Havana and other lotteries. Every lottery, even if genuine, is a cheat. It takes a great number of people's money, pockets half or more, and then gives these people a chance to cast lots for what is left. All gift enterprises are similar in character and results. St. Joseph, Mich., has a flaming one (on paper); Boston has a lottery called the "Women's Homestead League," ostensibly managed by a "goddess of the morning," Aurora C. Phelps. We have a lot of presented tickets, between the numbers 42,000 and 4,000, for sale cheap! We can't impose on our friends by giving them away. . . . Among other lotteries to be let alone, is the sale of the "Mount Florence Estate," to be sold in 35,000 dollar shares. Wonder how many of these "shares" are to be given to editors to advertise it? . . . The Sawdust operators are getting thick again, with the new dodge of receiving letters "for safety" in some other city (where Mr. Gaylor can't watch them so closely they think), but still claiming that their head-quarters is in New York. They are all similar. Among them are Turner & Wells, 220 Chestnut st., and J. T. Spencer & Co., 10 South st., Philadelphia; D. H. Dayton and R. S. Turner, Williamsburgh, N. Y.; Sidney Messenger, cor. Broadway and John street, New York; Noah Judson & Co., 109 William st.; C. E. Penn, 28 Bowerly; J. P. Gurney, *alias* J. P. Strange, *alias* Austin Chipman, *alias* Dr. Wm. S. Cody, *alias* M. O. Doane, all of 16 S. 5th ave., New York; G. M. Washburn, 3 Beckman st., etc., etc. (A gentleman of Barre, Vt., in sending this last, says, "Go on in your good work of exposing humbings; for although you may not think it needed, it is saving thousands of dollars to the laboring class of our country"—yes, hundreds of thousands!). . . . To "Subscriber": Yes! you might cut out a thousand just such advertisements, and 999 of them would be humbings.

Seeding to Grass after Corn.—"A Subscriber" asks if he can get a crop of corn off from the ground in time to seed down to grass in the fall, and cut hay the next season. Not under ordinary circumstances; but if the ground is very rich, clean, and made mellow, and the grass seed sown not later than the middle of September, it may be done. Grass and clover have been sown on such land in the spring, and mowed for hay the same season.

Twin Cattle.—F. F. Vasey, Dunn Co., Wis., corroborates the assertion that twin cattle are not necessarily barren, he having twin cows seven years old which have had five calves each.

Lime and Salt Mixture.—"D. V. H.," Washington Co., Ill., asks how lime and salt should be mixed for applying to wheat, and when it should be applied. Slake the lime with a quantity of water in which salt has been dissolved until it can take up no more, sufficient to reduce the lime to a fine dry powder. Five or six bushels per acre of this mixture may be spread early in spring over the wheat. Its effect is generally to stiffen the straw.

Price of Chemical Manures.—"A Reader" is informed that the following articles can be purchased in New York at the prices mentioned—viz.: Nitrate of Soda \$10, Nit. Potash \$15, Sulph. Potash \$12, Sulph. Ammonia \$10—per 100 pounds; Superphosphate of Lime \$45 to \$60, Ground Bone \$35 to \$45, per ton. For dealers' names, see advertising columns.

Cotswold Sheep.—John Irwin, Buchanan, Mich., has purchased a Cotswold buck, but he is not satisfied with his appearance; his wool is long and grows on his forehead, but his legs are of a brownish color. This answers to the description of the Cotswold, excepting the color of the legs, which may be due to his having been kept in a dirty pen, which at this season often causes the wool to be stained.

Concrete Buildings.—"L.," Eastwood, Lucas Co., O., asks if the walls of concrete buildings need to be lathed before plastering. No; these walls are absorbent, and do not condense moisture on the surface.

Washing Fruit-Trees with Lye.—"T. W. S." asks when is the best time to wash apple-trees with lye, and whether it is good for peach-trees.—The object is to kill moss, lichens, and other parasites, as

well as the eggs of insects, and the best time is early in the spring, and repeat as often as is necessary to effect the object. It is a very old remedy. Carbolic soap added to the lye is a great improvement. We have this spring gone over all our apple-trees with it, using say half a pound of the soap to a gallon of lye. It is as beneficial on peach-trees as on apple-trees.

Which Stock?—"A Subscriber," Adams Co., Pa., wants to improve his stock; he wants that breed which will grow large and quickly, and be pretty good milkers; he does not like the Jerseys or Devons, as they are too small. The Durham or Short-horn would suit him. In his county there should be pasture sufficient to raise this stock, which grows quickly to a large size, but needs correspondingly good feed.

"Quack" Grass.—M. J. Hughes, St. Lawrence Co., N. Y. There is no way of getting rid of "Quack" grass but plowing and harrowing, and picking up the roots and destroying them; mere plowing and harrowing tends to increase the evil.

A Six-Acre Farm.—"J. C. S." has six acres of land, twenty-five miles from market in Central Ohio, and wants to know what he had best do with it; land is dry and rolling. Market-gardening would doubtless be better than poultry-raising. Get Peter Henderson's Gardening for Profit for \$1.50, and follow his directions.

Mulching with Wheat-Chaff.—"I. F." asks if wheat-chaff will compact so closely when used as a mulch for fruit-trees, as to injure them. There can be no danger of this; chaff is a good material for a mulch.

Share's Horse-Hoe.—"F. R. K.," Gallia Co., Ohio. Share's Horse-hoe and Perry's Scarifier are both excellent implements; the first is suitable to a greater variety of uses than the second—for that reason we prefer it.

Brittany Cattle.—A few months ago it was stated in these columns that we knew of no herd of Brittany cattle in the country. We have since learned that the Hon. Charles L. Flint, Secretary of the Massachusetts State Board of Agriculture, has for some years been breeding the Brittany cattle, but we are not informed if he has them for sale.

Wood Ashes.—"C. L. J.," Saybrook, O., has 100 bushels of unleached wood ashes; can he use them to most profit on clay land, or on sandy land to be seeded to clover?—The effect of wood ashes in considerable quantities, as 50 to 100 bushels per acre, is to make clay lands looser in texture, and sandy lands more compact. In small quantities these effects would not be very apparent. In any other way, either soil would be equally benefited, though probably the light soil may need them most, on account of the seeding to clover. Ten bushels per acre, sown in spring, would be a proper quantity under above circumstances.

Potatoes after Corn.—A friend, whose garden consists of a heavy clay soil, says he "forks up his corn-stubble into ridges in the fall, burying all the stalks and leaves in the trenches, to make the soil mellow for potatoes as the next crop. I cut the stalks into pieces about eight inches long, so that they will rot and supply potash to the potatoes." Corn-stalks do contain about three times as much potash as wheat straw; but we apprehend the advantage of the above plan is due to rldging and mellowing the soil rather than to potash.

Artesian Wells.—J. F. Smith, Sand Point, Texas. It is impossible to tell the cost of an Artesian well, or of the implements necessary to bore it, unless the depth is known. This can only be ascertained by an experiment, which after all may be a failure, but if successful, is a guide for others in the same locality. The experiment, therefore, should be a joint affair.

Grub in the Head.—"D. M.," Ulster Co., N. Y., has lost some sheep by grub in the head, and wants a remedy. Tobacco-smoke blown up the nostrils of the sheep has sometimes been effectual in dislodging the grubs; it is not often that sheep die with grubs, though they are often annoyed by them. To prevent them, keep the sheep's noses smeared with tar during the warm summer months, when the fly abounds.

Preventing Hill-Sides from Washing.—"J. T. J.," La Crescent, Minn., asks, if a hill-side is sowed to clover, whether the clover roots will prevent washing of the surface?—No; clover roots have no binding influence on the soil; the spreading surface roots of a close sod, in which white clover is plentiful, tend to pre-

vent washing; such land should be laid down with grass instead of clover, and when plowed the furrows should run diagonally up and down the hill.

Fits, or Megrimms.—"F. D.," Tom's River, N. J., has a pony, which is sometimes taken with fits, or blind-stagers (?), and asks what he should do for a cure. There is no remedy that can be depended on, if the disease is what is often called megrims, and causes the horse to fall in convulsions or insensibility. If merely a temporary giddiness, it may be relieved by avoiding rapid or heavy work requiring great exertion, and administering tonics, with the best of food, but not stimulating, and securing perfect ventilation of the stable. If the disease is the more serious one, it is not safe to use the horse, and very wrong to sell him, as one fit is only a precursor of others, which will follow until death occurs suddenly in one of them.

Fowls eating Feathers.—"Subscriber" asks if there is any remedy for fowls eating each other's feathers, when they have abundance of fresh meat fed to them. We know of none but the effectual one of "Off with her head."

Saltpeter for Cows.—"Subscriber," McKeysport, has been told that a handful of saltpeter, given twice a week to cows, will prevent the milk turning sour rapidly in hot weather, and asks, "How is it?"—We think it would be a somewhat questionable and dangerous remedy. Saltpeter is poisonous in large quantities; half an ounce has been known to kill a man, and a handful given to a cow, unless for some good reason, as medicine, would or might be hurtful. As it operates on the kidneys, it would probably reduce the flow of milk. With perfect cleanliness, and cooling the milk before starting, it ought to be carried 100 miles without souring.

To Seed down Wet Land.—"E. A. B.," asks how he shall get a piece of wet land into grass. We have succeeded in getting a good stand of red-top on such land by burning the stubble of the coarse growth in spring, harrowing, and sowing red-top thickly, or about a bushel and a half per acre, with a few quarts of timothy intermixed. Red-top will finally crowd out all the rest.

\$1, or \$2, or \$3.—One dollar will pay for the *American Agriculturist* from May 1, to the end of 1872. Two dollars will pay for the weekly *Hearth and Home* from April 20 to the end of 1872 (including all of Edward Eggleston's great story, "The End of the World"). Three dollars will pay for *Hearth and Home* and *American Agriculturist* for the same time.

Earth-Closets.

While farmers enjoy especial advantages for the preservation of their own health and that of their families, it is nevertheless true that in one very important essential they are careless and inattentive. We allude to the necessary appendage to a household, the closet; with which is generally connected a cesspool. This cesspool receives, for a number of years, the aggregate waste of a family, which is absorbed by the ground and soon saturates all the soil contiguous to it. The well often receives the drainage which finds its way through the soil, and the water, becoming contaminated, conveys, as it is consumed by the family, the deadliest poison. This peculiar poisonous matter, in quantities so small as to be undetected by taste or smell, produces dysentery, cholera, and typhoid fevers. Here exists an alarming danger to which a great proportion of unsuspecting country residents are subjected. The earth-closet system at once does away with this unpleasant and serious evil. Dry earth is an absorbent and a disinfectant, and it needs only to become generally known, and that there be a satisfactory means of applying it, to have it introduced into use in every country household. The Goux Earth-Closet is one of the simplest and most convenient of several modes of using dry earth. The tub or vessel used is not contaminated, being lined with a thick layer of earth, which is made compact by being compressed or beaten in around a mold. This lining forms a receptacle which receives or absorbs all solid or liquid matter, and a scoopful of dry earth, thrown in, completes the method. When the tub is filled it may be removed and emptied upon a heap, under cover, where it may be preserved in a perfectly inodorous condition until needed as a fertilizer. In this shape it will be found equal to guano, and spread on meadows or on fodder and other crops, it will represent a considerable money value, which now is utterly wasted, and worse than wasted, rendered injurious. In place of dry earth, sifted coal-ashes may be used.

Read the Story.

On page 196, the Publishers give the first chapters of a Remarkable Story, by EDWARD EGGLESTON, author of the "Hoosier School-Master." It is entitled a "Love Story," but it will be found to differ very widely from the sensational novels or love stories that fill up flash newspapers, and form the staple of "yellow-covered literature." It illustrates life in the West thirty years ago, and though following a historical chain of occurrences in the eventful lives of a group of persons, which will render the story attractive, there is a constant dropping in of the philosophy of human actions, so to speak, which is full of instruction and food for thought. The author has a wonderful power of observation, and delineates character and conduct with a master-hand. Having read many chapters of the story in advance, we can assure all who follow it that they will enjoy a rich repast, affording great pleasure and profit. It will doubtless have a success unsurpassed by any American story that has ever yet been written.

The small portion given in this paper hardly takes the reader into the merits of the narrative, but will suffice to give some idea of the style and character of the whole. Its earlier chapters read like a Western Idyl; but Mr. Eggleston soon gets us into the grotesque scenes which he draws so strongly, and Gottlieb Wehle, the Backwoods Philosopher, the Millerite Preacher, the Steam Doctor, Cynthy Ann, the "Hawk," and, above all, Jonas Harrison, one of the most effective Western characters ever drawn, make a rare gallery of original portraits. The speeches of Gottlieb Wehle, Jonas, Cynthy Ann, and the Philosopher, the Night Adventure of August, the Mob Scene, the life-like description of gambling in the saloon of a Mississippi steamboat, are drawn most vividly.

. The weekly numbers of HEARTH AND HOME are supplied by all News-dealers. Single copies are mailed, post-paid, from this office, for 10 cents each.

EXTRA.

. The subscription to *Hearth and Home* is only \$3 for a whole year, but when specially desired, subscriptions will be received from the beginning of this Story (April 20th) to the end of this year (over 8 months) for Two Dollars.

XXTRA.

. *Hearth and Home* and *American Agriculturist* are sent together for \$4 a year; or \$3 will pay for both from April 20th to the end of 1872.

N. B.—In making up Premium Clubs, referred to elsewhere (pages 165 and 168), Three subscribers for either paper, or both, from April 20th to the end of 1872, may be counted as Two full-year subscriptions in Premium Clubs.

Percheron Horses.—H. E. Fisk, New York, asks the price of a pair of Percheron horses, or the cost of importing a pair. The Percheron horses are very scarce since the late war in France, and would probably be difficult to procure. Imported horses are held at high prices on their arrival here on account of the risk incurred on the voyage. Clydesdale horses possess every good quality of the Percherons, and probably more. One might cost \$2,000 to import. Some were lately sold in England for work-horses (geldings) at \$1,500 per head.

Winter in the North-West.

On April 10th we received by mail a cluster of peach-blossoms, plucked on March 18th, at Olympia, Washington Territory. Coming at a date when our own peach-trees were still enjoying their winter's rest, it occurred to us to say a word about the climate of the North-west, when most opportunely a friend handed us a slip from the Philadelphia Inquirer, in which the required data were already collated, and of which we here present the substance. There is a general impression that Oregon, Washington Territory, and Montana must be very cold, as they are so far north, forgetting that isothermal lines (lines of the same temperature) do not correspond with parallels of latitude. A comparison of the monthly mean temperatures as well as the mean of four months will show this in a striking manner. Most of the figures in the following table are furnished by the United States Signal Office at Washington, and represent three daily quotations of the thermometer at each place—morning, noon, and evening:

	Dec. '71.	Jan. '72.	Feb. '72.	Mar. '72.	Mean.
Louisville, Ky.	35°	33°	33°	35°	34
St. Louis, Mo.	31	28	32	36	31½
Chicago.	23	27	26	29	26
Baltimore.	30	35	36	33	33½
Philadelphia.	30	29	32	29	30
Washington.	33	33	34	33	33
New York.	30	30	30	29	29½
Helena, Montana 18	26	36	42	—	30
Kalama, W. T.	31	32	44	—	36

The temperature at Helena, Montana, may properly be taken as a fair average for the territory. It is on the general route of the Northern Pacific Railroad, directly in the mountains, and but a few hundred feet below the highest point on the line. Notwithstanding the past winter has been the coldest ever known in Montana, it will be observed that the average temperature at Helena (latitude 46½°) for the four months was the same as that of Philadelphia, although the latter city is 4,200 feet lower and 450 miles further south. Similar comparisons may be made with Chicago and other cities.

The average winter temperature at Kalama, Washington Territory, on the finished portion of the Northern Pacific road (in latitude 46°), was several degrees warmer than at Louisville or Baltimore, in latitude 39°. The greatest cold of the past winter at Kalama was 14° above zero.

Letters from members of the Montana territorial government, dated March 6th, state that for three weeks previous to that time (beginning about the middle of February) the weather had been so mild that all signs of winter had disappeared; farmers had put in their spring grain crops, and new grass was three inches high.

As we write near New York, April 10th, we can see the first plow afield that we have observed this spring, though of course the past has been an exceptional season.

The question of the climate of the North-west is now an important one, as a railroad through Montana and Washington Territories will open a vast region to settlers, who, as well as the projectors of the road, are interested in knowing what obstacles the climate may present.

What is a "Jointer" Plow?—"M. F. C.," of Somerset Co., N. J., asks what is the jointer plow mentioned by "Walks and Talks'?" It is simply an ordinary plow with another small point and mold-board attached to the beam in the place or just in front of the coulter. It cuts a small furrow an inch or so deep, and two or three inches wide, and turns it to the bottom of the previous furrow, where it is covered by the regular furrow slice. It is sometimes called the Michigan double-plow or Michigan subsoil plow. The word "jointer" refers to the small plow on the beam. This plow was first brought to general notice at the New York State Trial of Plows in 1850, and has been very extensively used ever since. It is a favorite plow with all that class of farmers whose great object is to check the growth of weeds rather than to kill them.

Drain-Tile or Stone?—"C. C. W." asks whether he should sell stone at 60 cents a perch, with only a few hundred yards to haul them, and buy tile, or use the stone in drains, and whether it would pay, after covering the tile with some earth, to put in six inches of small stone on top of it?—We would sell the stone and buy tile. The small stone would be quite useless where C. C. W. proposes to put it.

AMERICAN AGRICULTURIST.

ORANGE JUDD & Co., Publishers, 245 Broadway, N. Y. City.

ANNUAL SUBSCRIPTION TERMS (always in advance): \$1.50 each for less than four copies; Four to nine copies, \$1.25 each; Ten to nineteen copies, \$1.20 each; Twenty copies and upward, \$1 each. Papers are addressed to each name.  Either English or German Edition, at these prices.

HEARTH AND HOME: \$3 a year for less than four. Four to nine copies, \$2.75 each; 10 or more copies, \$2.50 each.

 *Hearth and Home* (weekly) with *American Agriculturist* sent to one address for \$4 a year.

Large Pay for Little Work,

and that, too, for rainy days, evenings, odd spells, or for a constant occupation—for MEN, WOMEN, and CHILDREN—anywhere, and everywhere.... Over 14,000 Persons have found it so; and here is how it is: The Publishers offer 107 Premiums, every one of them a first-rate article—just as good as so much money—for use or for sale. (See list on page 165, and send for a free, full description, if not having one.) Now, to get one of these articles without money, it is only necessary to solicit and forward a few subscribers for the *American Agriculturist* or HEARTH AND HOME, or for both of them.

The number required is given against each premium.

It is easily done. Show a copy of the papers, explain their value and cheapness—the cost being only a few cents a week. Few Post-Offices have around them less than twenty-five families, and many have hundreds, that would be profited in mind and pocket by reading one or both of these journals. They only need to have this shown to them. Any enterprising person, old or young, can do this just as easily as it has been done by the 14,000 who have already secured the premiums. Human nature and human wants are similar everywhere. Read page 165. These premium offers will remain open two months yet (to June 30), and May and June are good months for getting them. Partly filled premium lists can be completed, and new ones be begun and completed. A subscriber a day will get a large premium. Many can get several each day or week. Begin to-day. Any one taking hold with a will, determined to succeed, will succeed. The Premiums are open to all.

Value of Manure from different Animals.

A discussion was recently had at Lodi, Wis., on the relative value of the different kinds of manure. "The debate drifted on to the value of different animals to produce the best manure, consuming the same kind of food, and not being able to agree, it was decided to submit the matter to the *American Agriculturist*. Of course, you will understand that the question is whether with horse, ox, cow, sheep, or any other animal, consuming the same food, the quantity and quality of the manure will be the same." There is considerable difference in the bulk of manure made from different animals, as well as in the amount of water which it contains. But the intrinsic value of the manure made from a given quantity of food is practically the same, whether the food is consumed by a horse, ox, cow, or sheep. We say practically, because there are certain hypothetical cases in which there might be a difference in the value of the manure, but it is in all cases so slight that it is useless to discuss them. The manure from an animal that lost weight during the consumption of a given amount of food would contain a little more plant-food, and consequently be a little more valuable than from an animal, eating the same amount of food, that gained in weight. The flesh, wool, hair, feathers, hide, horn, and bone produced, take something from the manure. He is a very unwise farmer, however, that starves his animals for the sake of making his manure a trifle richer in nitrogen. It is generally said that a horse doing hard work will not make as rich manure as a horse lying idle. But if both have the same amount of food, the idle horse, if he gains in weight, would be less valuable than the working horse, that gained nothing or lost weight. But these are merely theoretical refinements

that a practical farmer, whose object is to make good manure, need not take into consideration. His only question need be, *What food* contains the greatest amount of valuable fertilizing elements? The animal has, practically, no more to do with making rich or poor manure, than a stove has to do with making rich or poor ashes. It depends entirely on the food.

Bee Notes for May. — By M. Quinby.

Surplus honey is the first consideration in bee-keeping. All boxes intended for use, should be ready now. One hive in a hundred may store surplus, in a good season, during apple-blossoms. It is not always economy to put on the boxes at this time, because Dandelion blossom new, and the abundant pollen that the bees get from them, will stain the combs yellow, and give an unpleasant flavor to the honey. Notwithstanding a yellow color is preferred for cheese and butter, the honey for market, to be nice, must be purely white. Manage to have the bees use all this honey to rear their brood, and get a strong force ready for clover-time.

Those who expect to increase their colonies this season should, if they have not already done so, prepare their empty hives at once. I am greatly in favor of Averill paint for hives; some light tint is preferable to the clear dazzling white. Hives of two or three colors, alternated with each other, seem to assist the bees to distinguish their own from their neighbors' hive. I do not assert that this is better than oil-paint. I only say it seems better, as there is no smell of the oil which appears to be offensive to the bees. When new swarms are lived in oil-painted hives, a greater percentage desert and go to the woods than in those unpainted.

Establish this rule at the beginning of the season, that is, to allow no bees to cluster outside for want of room inside. Extreme hot weather should be the only excuse hereafter for idle bees outside. Any one expecting the best results from his farm, garden, orchard, dairy, or apiary, without effort or knowledge on his part, will be likely to reap a short crop, and soon prefer some other pursuit. To know how to obtain the best results from a hive of bees, one must either learn by experiment himself, or adopt the experience of others. It seems now to be pretty well understood that the best results can not be obtained with the old box-hive. Another year's experience proves that transferring from box to movable-comb hives—of the right kind, of course—pays for all trouble. For directions see Bee Notes for May, 1871. After transferring, the hive is in condition to be controlled. Being able to reject all drone combs, and thereby preventing a useless horde of consumers, is of itself sufficient to remunerate all trouble. Eggs laid in drone cells, hatch out drones; the same eggs, if laid in worker cells, produce workers. Swarming is not always—may I not say, seldom?—satisfactory in box hives, when the bees manage it themselves. The bees have been brought up in ignorance of what we can do for them, for the very good reason that we did not know ourselves, and they suppose that it is necessary to provide a successor for the mother to the hive, before taking the old one away. As a rule, natural swarming does not take place short of a week or ten days' preparation. Quite often, at the commencement, there are abundant bees to spare a swarm—bees live but a short time, and often die as fast as they hatch out, when the hive is full—but at the time they get ready, they have not increased, have been idle during the preparation, and a whole swarm has lost several days right in harvest-time. Could a swarm have been taken out as soon as there were bees enough, and put into empty combs, ample winter stores would have been secured. Suppose that, just at this time, when they have prepared to leave, a change in the atmosphere prevents the secretion of honey in the flowers, and your swarm has an empty hive to fill, and no means to do it with. Have no combs in which to rear brood; the old bees are dying every day, and it is possible, before the next yield of honey, there are too few bees left to accomplish much. This can be avoided, if you understand it. When you have decided to take this matter into your own hands, you should become familiar with the appearance of the hive that has bees to spare a swarm. The next thing is to know when the flowers are secreting honey in abundance. When bees and honey are right, then is the time to make the swarm, regardless of any preparation of theirs. Every day that a colony is without a laying queen, in summer-time, reduces the profit of keeping it. The old queen goes, or ought to go, with the first swarm, whether natural, or artificially made. In natural swarms, they usually leave sealed cells with young queens, to supply her place in the old hive. It would be profitable to have a queen, fully mature, artificially reared, to supply her place, whether cells are left or not. At the end of a week the hive should be opened, and all queen-cells removed, when the laying queen may be safely introduced. If no mature queen is on hand, the next best thing is a

finished cell, ready to hatch, to introduce the next day. If no such cell is to be had, leave one, and but one, of the first made by the old hive. You will, of course, see that there are drones in some of the hives, at such times.

As long as good colonies, in the box-hives, can be purchased under ten dollars, it is doubtful if economy would dictate making artificial swarms, or having others. I would like to have you feel indifferent about it. I would suggest that you provide an empty hive for each old stock, in case they were disposed to swarm; but otherwise do just as if all the bees that hatched in a hive were going to stay home the whole season and wanted room for stores. Give room inside the hive for surplus boxes that will hold from 150 to 200 pounds. The chances are, that such hive will make no preparation for swarming. If they do not, the *extra* amount of surplus that they will store, will purchase two or three stocks for winter. Should they swarm, you will have the new stock and some surplus, and no anxiety in the matter. Give room inside, and have the boxes in close proximity to the body of the hive, and all will be likely to go well. Before there are many bees in the way, early in the month, open the hive, find the queen, and clip one wing; the swarm will not go off in such case, if they issue.

The hive may be so arranged that the room for surplus boxes can be occupied with frames; and as soon as combs, ready made, can be furnished, and the honey extracted, the quantity that we are now getting may be trebled. Any one having lost a hive of bees this winter, will find a great advantage in saving all the combs, unless drone-cells, or diseased; put them in frames, as in transferring. These are what we want when we come to extracting our honey, instead of compelling the bees to lose time constructing combs. I will make an estimate of the cost of comb, in honey, describe an extractor, and give instructions in rearing queens, etc., soon.

Holstein or Dutch Cattle.

Holland has long been famed for its dairy products and its milch cows. About twenty years ago a Dutch cow was imported into the United States, and her excellent qualities led to further importations, until the stock has become somewhat distributed, and has achieved a good reputation as heavy milkers and large beef-cattle. The cattle which are the subject of the illustration on our first page, are the property of Mr. J. T. Ellis, Flemington, N. J. Prof. Geo. H. Cook, Geologist of the State of New Jersey, in a recent visit to Europe was much interested in the Dutch cattle, and favorably impressed with their excellence as producers of both milk and beef. Prof. C. has examined the animals from which our engraving is taken, and pronounces them very good specimens of the breed. It will be seen that their milking qualities are largely developed, and that their general character stamps them as eminently a dairy stock. A cow of this breed has yielded 35½ quarts of milk per day, from which nearly 3 pounds of butter have been made. Heifers of two years old have reached a weight of 1,200 pounds. It is not uncommon for bulls to attain a weight of 2,400 pounds, and working oxen of 4,500 pounds the pair. They are large feeders, and need the best pasture and care to bring about these results.

Moles and Mole-Traps.

Moles are a nuisance. Whatever use they may perform in the economy of nature, in gardens and meadows they must be got rid of. The traps so far in use, are not efficient. They fail in many ways. What is wanted, is a trap which will not deter the mole from entering it, and which, as soon as the mole goes in, suddenly and unfailingly destroys it. The trap figured on this page seems well adapted to these joint purposes. It is set as follows: The earth over the run is pressed down with the foot, which closes the passage. The trap, set as in the cut, is forced down into the soft earth, until the pan

(a) is in such a position that the mole, in repairing its burrow, which it will be sure to do, presses it upwards as it passes beneath it, and

THE MERRIMAN RAT AND MOLE TRAP.

springs the trap. The jaws (b, b) close with force enough to instantly kill the mole.

We have tried this trap for catching rats, and have found it to be very efficient.

How they make Watches at Marion.

BY GEORGE CARY EGLESTON.

Pocket time-pieces were first used about the year 1600. They were then known as Nuremberg animated eggs, a rather long and clumsy designation, that soon gave place to the name watch, from the old division of the solar day into equal parts known as watches. They were made, for about two centuries, wholly by hand, each workman manufacturing the entire watch.

As a matter of course, they were of clumsy construction so far as the running apparatus was concerned, and exceedingly inaccurate as time-keepers, and for a considerable period the inventive faculty of watch-makers was directed wholly to the production of queer casings, or the devising of ingenious attachments, which impaired the value of the watches, and served only to make them curious and costly toys, of hardly any real use. They were encased in all sorts of things. Some were placed in heavy gold crosses, to be suspended from the neck. Others were made in the form of skulls and cross-bones, and watches appeared in all sorts of fantastic shapes. Their dials peeped out of snuff-boxes, bracelets, shirt-bufftons, and finger-rings, and some were even set in saddle-pommels. There were some of them as large as the crown of a hat, while others were so small as to fit in the end of a pencil-case. One of these is still preserved in Switzerland, the diameter of which is but three sixteenths of an inch, and yet it marked on its little dial the day of the month, the hour, the minute, and the second.

But, large or small, plain or curiously wrought, the watches of the olden time all failed in the one only excellence a watch can have—accurate time-keeping. There is nothing better calculated, however, to make people wish for a perfect thing than the possession of a very imperfect one; and so after a while there began to be a demand for something more accurate in the way of time-pieces, and out of that demand has grown the almost perfect watches now made in America, whose manufacturers are disposed to think them defective if they vary more than a few seconds a year from absolute mean time.

To trace the history of the improvements made would be pleasant enough, but the limits of an article are altogether too narrow for

such an attempt, and after all the real era from which the world must hereafter date the history of satisfactory watch-making, began when American mechanics conceived the idea of doing by machinery that which could never be adequately done by hand, and so making perfect the parts of a whole which, as a whole, is expected to do something like perfect work. When they did this, people derided their work, and sneered at it as "machine-made," forgetting that automatic machinery is of necessity much more accurate in its operations than any human hand can possibly be.

Then, again, it was said that these manufacturers had discarded *three fourths of the pieces* belonging to the works of a watch; and so they had, to the great improvement of the time-keeper, because, other things being equal, the simpler a machine is the better it is.

The jeerings went on, but little by little people learned two facts: first, that these machine-made watches kept better time than any others; and secondly, that they would last longer than any other time-pieces ever made, and when these two points were once fully established, the watches made in this country took the leading place that they hold to-day.

Ever since the first of these factories was started, there has been a steady improvement of the product, and now, under sharp competition, each of the great establishments is constantly adding to its machinery new devices for bringing the delicate wheels, and cogs, and pinions, and screws, and springs nearer and nearer to a mathematical perfection of form, for the one purpose of making their watches more and more nearly perfect in their marking of the time.

It was but a few years ago that half a dozen gentlemen got off a train of cars in the Jersey meadows a few miles out from New York. The place was bald and dreary enough then, but the visit of these gentlemen was the forerunner of a great industry that has grown up there. They went there to select a site for the United States Watch Company's works, and now they have quite a goodly little town around their great towering factory, wherein hundreds of happy, industrious men and women sit every day, each attending a quiet little automatic machine, that does its appointed work with the utmost precision, and helps to swell the daily shipment of nearly perfect Marion watches.

I saw these people and their machinery at work the other day, and truly wonderful work they do too.

In one room there are great punches, each cutting the rough metal into bits of convenient shape, or stamping the bits into a proper degree of density and hardness. Each punch has its own work to do, and nothing else, and each man confines his attention to his own machine. Here, as everywhere in the factory, the intelligence employed lies largely in the machinery, its attendants having nothing to do but to supply it with its proper material. In other rooms, hundreds of girls sit in long rows, each attending a machine which does its work silently, turning out screws, cutting screw-heads, cutting teeth in wheels, punching holes, or doing whatever else its function is, with unfiring industry and unerring precision. There are, in all, one hundred and seventy-six pieces, large and small, in every watch made at this factory, and each watch is the workmanship of one hundred and forty-one persons, and one hundred and fifty-two separate and distinct machines.

To catalogue all these machines, many of which were invented in this factory and can be

used nowhere else, and to tell their several uses, would of itself require more space than I can occupy with this article. I can only speak now of some of the curious parts of the great subdivided industry.

One girl sits in a corner running a little piece of mechanism that whittles steel wire up into shavings. Of what use are these little shavings, so small that they stick together in the box? My guide answers a question to this effect by putting a powerful magnifying glass into my hand, and asking me to examine them through that. I then discover that they are not shavings at all, but screws—perfect screws, all precisely of a size, and all precisely alike, with a fixed number of threads on each. These are used to fasten the jewels into their proper places. And so we went next to the girls who were cutting the jewels up into proper sizes and shapes. The jewels used are rubies, garnets, and sapphires. They are sawed first into thin slices, by means of circular bits of tin charged with diamond powder. Then these slices are cemented together and sawed transversely. This finishes the work of getting them out in the rough. The tiny bits are then cemented to a metallic disc and ground to an even thickness, the accuracy of which is tested by means of an instrument having a long indicating needle, which marks the thousandth part of an inch. As the stone is placed at the inner end of the needle, the minutest conceivable variation from its proper thickness will be shown, exaggeratedly of course, by the tell-tale point.

When exactitude of thickness is secured, the stones are cut to proper angles for their several uses, and the accuracy of these is tested by another indicator. A somewhat similar contrivance, too, is used to determine the exact thickness of the hair-springs, but with even greater attention to minute accuracy, the needle marking variations of $\frac{1}{15,000}$ part of an inch.

Every part of the watch, large or small, is made in the same way. Nothing is left to judgment, eye, or hand. Every shape is determined beforehand, and every result measured unerringly by instruments of almost marvelous delicacy. And so exactly is all this done, that the various pieces in the different watches are freely interchangeable.

When a "train," as a complete set of the working parts is called, has been finished, it goes to the regulator to be adjusted before being made into a movement. This regulator is a plate containing a perfect watch movement made to work a small hand marking a minute part of a second by each revolution, each revolution being divided into four separate motions. The newly-made train is placed in position by the side of this, and made to move a similar little hand. The man attending the regulator keeps the two in motion before him, adjusting the new one from time to time, until the two little hands revolve precisely together, and then he knows that all the parts are of proper size, proper shape, proper polish, and proper adjustment to make a watch that will run correctly. This much must be secured before any train is put into a movement, as the works of a watch set up, ready for the case, are called. The company wants to make correct time-keepers, and will tolerate no measurable variation from accuracy of motion.

When this is done the superintendent knows that the works are properly made, and without any further experiment he might safely sell the watch under a guarantee that it is vastly better as a time-keeper than any hand-made watch ever was or ever can be—namely, that it is very much better than any European watch yet

manufactured. But *perfection* is what the Marion watches aim at, and no possible means of securing it are spared. Besides defects of construction, there are two other causes of inaccuracy to be guarded against. One of these is change of position, and the other difference of temperature. When the movement is set up, therefore, it is kept running for a considerable time in a frame which holds it at different times in a variety of positions, and the slightest variation from mean time is sufficient to call for its readjustment. When it is so perfect as to stand this test, it is placed in an oven heated to 100° Fah., where it is kept for several days, after which it is removed and packed away in ice for a like period. If it shows no variation under this severest of all tests, it is sent out for sale.

And that is how they make watches at Marion, like the one Mr. Chittenden carries, that varies but two seconds in fourteen months.

Ogden Farm Papers.—No. 28

I sometimes wish I had never said a word about "gilt-edged" butter. For, since the publication of the article describing it, I have been run down with applications for detailed information. Knowing how ungracious it must seem to a farmer who writes a careful letter earnestly seeking information not to give it, I answered these letters at some length, until I found that my time and attention were being taken from imperative duties. Since then, at the disagreeable risk of giving offense, I have had to refer correspondents to this number of the Ogden Farm Papers for a statement of the whole case. I wish to premise that I do not pretend to know the best way to make butter; that my experience in dairy matters has not been very extensive; and that I hold up my practices as an example with much misgiving as to the judgment that may be formed of them by those who have more knowledge and experience in the business. I can only say that I do the best I know, and that I have found the result in my own business reasonably satisfactory.

First, to describe the utensils required: (1.) A water-tank holding at least two feet (or better two and a half feet) of water, having a superficial area of not less than four square feet for each ten cows in the dairy. This tank should stand in a room where it will not freeze in the coldest weather. It had better be partly or entirely below the level of the ground, that it may be reasonably cool in summer, and it must be fresh and well ventilated, its bottom free from stagnant moisture, and its sides not exposed to foul exudations from adjacent sink-drains, etc. The tank should be supplied with fresh water from a well or spring by a natural or artificial stream. The larger the flow the better, but it will suffice for a dairy of 40 cows to use a half-inch stream. The fresh water should have a temperature not higher than 58°. It would of course be better that the stream should be a constant one, but it will often be necessary, as in our case, to use a windmill, and we find in practice that it is never dead calm long enough together for the water to become stagnant or too warm. (2.) A set of cans, 8 in. in diameter and 25 in. deep, such as are made by the Iron-clad Can Co. of New York City, and called "Orange County Creamery Cans." These have heavy iron bands at the bottom, which serve the double purpose of strengthening them and of so ballasting them that they float upright in the water. They have common iron bails at the top for handling (fig. 1). Each can

should have a light tin cover (fig. 2), not wired at the edge, and furnished with three studs sitting inside the can to hold it in place. In the center there should be a hole, one inch in diameter, for ventilation. With a dairy of ordinarily good cows, three cans will be required for ten cows.

(3.) A conical skimming dipper (fig. 3), four or five inches in diameter at the top and pointed at the bottom, the top not wired, and the handle, which rises vertically from the dipper, attached a little below the top on the inside.

(4.) Larger cans, with tightly-fitting covers, for holding the cream.

(5.) A churn of whatever form may be considered best.

(6.) A butter-worker, of which there are several good varieties, none better in my opinion than a white-oak table, sloping a little, with a groove around the edge, to convey the buttermilk to one point, whence it drips into a pail; and a two-handled white-oak paddle for manipulating the mass.

(7.) A sponge, five or six inches in diameter, of the soft coarse-grained variety sold by druggists as bathing sponges. (8.) A suitable mold for making the butter into pats. (9.) Square pieces of the cheapest and thinnest bleached muslin, large enough to inclose the pats. (10.) A Philadelphia butter-tub, figured in a previous number of the *Agriculturist*, which is a high oval tub containing a tin case, of which the ends are partitioned off for ice, and the center furnished with studs to support light wooden shelves to hold the layers of butter.

These utensils being provided, the process is as follows: The milk is taken immediately from the stable to the milk-room (not allowed to stand and absorb the odor of the stable), and is strained into the cans, filling them to within about two inches of the top. As soon as a can is filled it is set into the tank and the cover placed upon it. It will often happen that the last can is not sufficiently filled to sink deep enough to float erect, and there should be one or more strings pendent from the ceiling to be made fast to its bail and keep it straight. At the next milking this can should not be disturbed, but the entire mess should be put into fresh cans. Just before the third milking time (after 24 hours' sitting), the first lot of cans should be carefully lifted out of the tank and skimmed with the conical dipper, the cream being put into the cream can. Just before the fourth milking time the second lot of cans should be skimmed in like manner. If necessary, toward evening of the day before churning, the cream-cans should be taken out of the water and placed in a warmer room, so that the temperature of the cream will rise to from 60° to 62°. If it is cold weather, and it is necessary to stand the cream in a room with a fire, the cans should be set on a table, as the air toward the floor, even in a heated room, is often too cold. We find it best to have two butter days a week—Tuesday and Friday. Early in the morning, the churn, which has stood uncovered and in a well-ventilated place since its last use, is thoroughly scalded, and then rinsed out with lukewarm water in winter, and cold

water fresh from the well in summer. Cream is then poured in, and the churn kept in motion, without interruption, until the butter comes. When the butter has all formed, it is gathered by a slow, rocking motion of the paddles, the plug is removed, and the buttermilk withdrawn. It is sometimes, but not always, necessary to rinse down the paddles before the butter gathers. The buttermilk having run off as well as it will, the plug is returned to its place, and two or three dipperfuls of water of suitable temperature, according to the season, are thrown in, and the paddles are worked slowly back and forth for a moment, when this water is drawn off and a second supply is added in like manner. If this water is quite milky a third supply is added. This is the only washing that the butter receives. It tends to consolidate the mass, and to remove the most of the buttermilk.

The butter is then taken out, about 10 lbs. at a time, and placed upon the working table, which, as well as the paddle, has been previously scalded, and washed with cold water. The butter is then flattened out with the paddle, its surface being gashed and checked (but not cut entirely through) in both directions by its blunt edge. When it is thoroughly cut over, the paddle is laid aside, and the sponge, well wrung out of cold water, is firmly patted over the whole surface, and over so much of the table as may contain buttermilk from the working. It is then returned to its vessel of water, and with the paddle the butter is turned over, rolled together, flattened out, and again manipulated with the blunt edge, and the sponge, wrung out clean and dry, is again used. This process is repeated until the butter is thoroughly dry, no globules of water (or perspiration) being perceptible when it is manipulated with the paddle.

Then the requisite quantity of salt (Onondaga Dairy salt being in our opinion the best) is sprinkled over it, and thoroughly incorporated with it by a short but rapid working. The butter is then packed in the bottom of a cream-can and covered up. Another mass is taken from the churn, similarly prepared, and packed closely upon it. The can is then set in a place neither too cold nor too warm, and allowed to remain until the next working, either from morning until toward evening, or from evening until morning. The butter is then worked again, and if necessary, though it generally is not, the sponge is used to remove any brine that may appear. Immediately after this working the butter is molded into pats, and each pat is turned from the mold with its lower side placed on the center of one of the squares of muslin, which has been freshly wrung out of clear cold water. Any inequality of the edge of the pat is smoothed over, two opposite corners of the cloth are turned over the top, and with the other two the pat is lifted into its place in the butter-box and completely covered over.

In winter-time this butter may be transported to any distance without ice, but as soon as the weather becomes warm the compartments at the ends of the box should be filled with broken ice, which will keep it cool, with proper care,

for twenty-four hours. When the butter and ice are ready for market, the top should be fitted on to the box and secured in its place by the stick which passes through the handles of the tub, and fastened with a lock if to be transported by public conveyance. If carried in an open wagon, the box should be covered with a blanket to shelter it from the sun.

Concerning the quantity of salt to be used, it is impossible to give directions to suit all tastes. We use about one ounce of salt to two pounds of butter. Most markets would require one ounce of salt to one pound of butter, or even more than this.

The butter being dispatched, one of the most important labors of the dairy remains to be performed—that is, the thorough scalding, and cleansing, and sunning, and airing of every utensil that has been used in its manufacture. The sun and air are great purifiers, and will remove any tendency to taint, provided all extraneous matter has first been carefully removed, but not otherwise. After the utensils have been put out to air, the room itself should be thoroughly cleansed and ventilated, and at least once in a month the walls should be lime-washed.

The question of artificial coloring is important to be understood. Unless one has a profusion of colored roots or of early cut hay or rowan, the butter will be at some time during the winter too white to be attractive. We have tried a great variety of processes for coloring, but until recently have had great difficulty in securing perfect uniformity. Carrot-juice put in the churn is often very good, but sometimes a bitter root will escape detection, and its juices will seriously affect the flavor of the butter; the color will also vary in intensity. Annatto and annattoine, as ordinarily used, require more judgment to secure uniformity than can always be commanded. We have now been using for some time a preparation of annattoine made according to Burrell's recipe, and find it as nearly perfect as could be hoped for. The recipe is as follows: Put 1 lb. of annattoine in 2 gals. of clear spring water, and let it stand 24 hours, stirring frequently. Put 1 lb. of potash and $\frac{1}{2}$ lb. sal-soda in $1\frac{1}{2}$ gal. cold water. When these are all dissolved, settled, and skimmed, pour the clear liquor into the solution of annatto. Let the compound stand some days, stirring occasionally. Keep the preparation in stone jugs or in bottles in a dark place. Shake before using, and put into the churn one tablespoonful for each five quarts of cream—more or less, according to the depth of color desired. By using always the same proportion, the same shade will always be produced.

I believe that an adherence to the foregoing directions will secure as good a result as the character of the cows in the dairy is capable of. With Jersey cows or grade Jerseys, there is no doubt that a much finer quality of butter can be made than with any other breed; and in the long run, the best utensil for making "Gilt-edged Butter" will be found to be a thoroughbred Jersey bull.

The butter being made, half the battle is fought. The other half will be to make a market for it. The secret in doing this is to make it known, by whatever means may be available, that the butter bearing your stamp is good—and always good. No matter about price at first, secure at the outset a good class of customers, at half-price if necessary, and make your butter a necessity to them. You will secure, as soon as you deserve it, a demand for your whole product at more than the usual market price.

About Harrows.

BY GEORGE E. WARING, JR., OGDEN FARM.

Last spring the makers of Thomas's smoothing harrow complained that the account given in "Ogden Farm Papers" of my experience with their implement had resulted to their disadvantage, and they asked me to try this year one of a new form, but working on the same principle. Another maker asked me to try a Bussell harrow (a cousin of the Nishwitz). A friend had sent me an English "Flexible" or chain harrow. I had already a large "Shares."

The latter, which is now well known, I consider the best harrow for rough cultivation that I have ever seen. It cuts up a newly-turned sod furrow to perfection, and gives one or two inches of perfect covering, while it tends rather to press the furrow into its place than to tear it up, as the common tooth-harrow does. I have

and the ground is very finely pulverized and leveled. By repeated use, it may be made to do the work of both roller and bush; and I have found it, for all work for which it is adapted, as nearly perfect as any implement can be. But it is *not* adapted for the cultivation of corn on Ogden Farm. I gave it a fair trial, with the row and across the row, and it tore up or covered up too much of the crop for my taste. On light soils it may answer—I can not tell without trying—but on my soil it will never do until I can get control of sun and rain, and keep the ground light and mellow from planting time until the corn is up, and I very much doubt whether it would do even then. It is, however, to my mind, no argument against a plow that you can't mow grass with it. I am entirely satisfied with the Thomas harrow, as a harrow; for hoeing corn I must still recommend "the good old way." If I could have only one, I would dispense with the Shares rather

ENGLISH FLEXIBLE OR CHAIN-HARROW.

not had a common harrow on the place for two years, nor do I care to have one so long as I can get a Shares.

The Bussell harrow is intended to do the same work with the foregoing—that is, the rough handling of newly-plowed land—but to do it in a very different way. The frame is A-shaped, like the Shares, and it has the everlasting spring seat on it by which manufacturers hope to catch the fancy of the lazier class of farmers. (I shall not be surprised to see some day a churn with a spring-seat for the man who is to turn the crank.) The frame is supported on about a dozen wheels set along its edge, wheels with sharp edges and very much dished, and about 14 inches in diameter. They are set at an angle with the line of march, so as to cut into the ground and throw the dirt (a little outward) as fine as sawdust. I gave this machine a fair trial, and found its wheels not suited to my heavy soil, its draught not suited to my very heavy mule team, and its seat not suited to my heavy style of riding. In short, I did not like it, either as an agricultural implement or as a pleasure vehicle. I have, however, good accounts of it in some other quarters. I return to my Shares harrow, quite content.

Thomas's smoother is mainly for finishing work. It has been very much improved from its original form, being now made in three sections, each about three feet square, hinged together in such a way as to cover a width of nine feet, and hung to run with one end a little further back than the other, so that the teeth shall not "track" with each other. The teeth are made of $\frac{5}{8}$ steel rods, and are a little inclined to the rear, so that their action is smoothing rather than scratching, something after the manner of a bush. When properly regulated, the tracks of the teeth are about one inch apart,

than with the Thomas. Both together make the most complete work.

The English flexible harrow (fig. 1) is quite an old affair—so old that the patent has run out, making it public property—which our implement-makers would do well to adopt. The teeth are of chilled iron, and they are fastened together with steel links. It is perfectly flexible, and every tooth is bound to descend until it touches the ground. This makes it the "s'archin'est" harrow that can be found. The top of every hummock and the bottom of every dead furrow is sure to receive its due share of the scratching. The teeth are longer on one side than the other, and at one edge they are vertical, while at the other they are oblique, so that the harrow may be used either side up or either end first. Drawn as it is shown in the cut, it is an effective harrow to follow the plow; drawn the other side up, and with the draught-bar hooked to the opposite end, it is a fine smoothing-harrow, almost equal to a chain-mat drawn over the ground.

I have found this a good implement for all work, and so much better than anything else I have ever seen for fining manure that has been spread from a cart, or for beating up the manure on a pasture (loosening up the grass at the same time), that I believe its use will add at least ten per cent to the effect of manure, spread and beaten in the ordinary way, simply by causing a more even distribution of the fertilizing matter over the whole surface.

JERSEYS IN NOVA SCOTIA.—The testimony of our Mobile correspondent is no more favorable to this breed for the far South than is that of Mr. Chas. C. Brown, of Yarmouth, Nova Scotia, for the far North. He says: "My $\frac{3}{4}$ Alderney gave Nov. 21st 23 lbs. 7 oz. milk,

dropped calf March 26th, and will come in again March 10th; gives now (Jan. 5th) 10 to 12 lbs. in the morning, fed on good hay (cut in June), with half a bushel of turnips per day, and is good beef notwithstanding the usual gauntness of the breed. We think our climate especially adapted to the Alaerney. When I had but one cow and a family of eleven, with five children, using milk freely, and cream always three times daily, we made as high as 7 lbs. butter from one week's milk. This season, with a second cow ($\frac{3}{4}$ Alderney), a daughter of the first, but with six children, we made up to 23 $\frac{1}{2}$ lbs. Surely we are not wrong when we think this breed suits our country."

How to Dress a Sheep.

The "woolly taste" in mutton is not derived from the wool. The peculiar flavor of ill-dressed mutton has nothing to do with the coat of the sheep, but arises from the absorption by the meat of the gases from the intestines, which, as the outside of the carcass cools, can not escape, and are therefore absorbed by the flesh. There is a simple remedy. As soon as the animal is dead, let the hide be slit up from the brisket to the tail, and to the knees, by a quick motion of a sharp-pointed knife, inserted beneath the skin. Strip the skin from the belly and the ribs and legs, so that it will be out of the way of the intestines. Then open the sheep immediately, and disembowel it. All this ought to be the work of about one minute or two, or if it occupies five, there will not be sufficient time for the carcass to cool sufficiently to cause any unpleasant taste. Then proceed to strip the skin from the back of the carcass. A sheep should be killed by thrusting a sharp knife through the neck, back of the wind-pipe, without touching it however, but cutting the arteries; and as soon as the knife is inserted,

DRESSING A SHEEP.

it should be twisted around as if to make a round hole; there will then be no mistake made in cutting the arteries, and the death of the animal will be comparatively painless and rapid. As mutton should be made the chief meat diet of a farmer during the summer, it is well that every one should know how to slaughter and dress a sheep in the best manner. Among other trades, a farmer ought to be a fair if not a good butcher. He will not then complain of woolly mutton.

The Abyssinian Wart-Hog.

Those who saw Barnum's Menagerie after the additions were made to it last autumn, will recognize in the engraving here given portraits of two of the most interesting ugly beasts in the collection—the Wart-hogs of Abyssinia. These animals belong to the genus *Phacochærus*, and though in the same family with our domesticated swine, differ from them sufficiently to be placed in a separate genus. The Wart-hogs have the same general appearance as the domesticated ones, but differ in the number and arrangement of their teeth. They have a very heavy look, and their uncouth appearance is enhanced by the small size of their eyes and their very large ears.

A marked characteristic, and one which gives them their common name—the scientific name being the same thing turned into Greek—is a warty appendage or tubercle attached below each eye. There are some four species known, all natives of Africa, and all having these peculiar appendages upon each side of the head. The species here figured has remarkably long bristles along the upper part of the neck and back, which serve to increase the wild aspect of the animal. In their native state the Wart-hogs are exceedingly ferocious, and we do not know of any attempts at domesticating them. It may be that if placed where their wants were provided for, they would, like the wild hog of Europe, lose their intractability and become useful. When we compare the hogs of the wilder parts of the South and West, where they are known as "sub-soilers," "ridge-backs," "jumping alligators," and "land-pikes," with a high-bred Yorkshire or Essex, the difference is very wide. Perhaps this wild hog of Africa is not so far below the "land-pike" as that is beneath the best specimens of our best breeders.

We do not know that these African animals possess any desirable qualities that should lead to their domestication, but this case is no more unpromising than was that of the originals of our valued breeds. It can not be supposed that all the animals likely to be useful to man have yet been brought under domestication. We

hope to see some day in this country a Society of Acclimation, which shall test under domestication all animals that promise usefulness, whether for their flesh or their coverings. Such a society existed in Paris, but the animals were eaten during the siege.

rocks, with peat bogs in the intervalles. On the stunted but nutritious pastures afforded by such a country, a race of hardy cattle have been bred for centuries without any admixture from other races. They have, therefore, as may be expected from all these conditions, and from the

fact that they have been bred for the especial purpose of supplying the English cities with beef, become a breed of active, hardy, comparatively small, but exceedingly vigorous cattle, of but little account for the dairy, but carrying on their fine frame a proportionately large amount of good, well-flavored meat. The vigor of the race is understood when it is known that a Galloway bull will perpetuate his qualities and marks thoroughly on the produce of even a pure

ABYSSINIAN WART-HOGS.

Polled Cattle.

Not long since, a Western "stock journal" stated that there was no established breed of hornless cattle. Hornless or polled cows and oxen are not at all uncommon in some of the Western States, more especially in Illinois and Missouri, but still, in the United States, it is true we have no stock-breeders who make a specialty of this species. In Western Canada there is at least one breeder who possesses a herd of pure-bred Galloways, of which race the cattle figured in the engraving is a true repre-

Shorthorn cow. This peculiarity gives him an especial value to those breeders who desire to cross their stock with Galloway blood. The usual method of raising the young cattle in Galloway is to let them suck the cows; or if the cows are milked it is only at such times as when the calf has possession of one side of the cow and the milkmaid the other. Under these circumstances, it can not be expected that the breed is fitted for the dairy. But for certain districts in the United States they would be found valuable, as they have all the hardiness of the Texan, with strength and activity sufficient to

GALLOWAY POLLED CATTLE.

sentation. Galloway is a district on the west coast of Scotland, which owing to the influence of the sea-breezes possesses a moist, warm climate, so much so that figs are sometimes ripened in sheltered gardens when trained on walls having a south aspect. The soil, however, is poor, and the surface mainly composed of granite

consequence a race of polled cattle has become established in those countries. But there the stock is generally of a red color, and more fitted for dairy purposes. An attempt is being made to import these Norfolk polled cattle into this country, and we think that it is a design worthy of being thoroughly carried out.

enable them to travel hundreds of miles in droves without falling off in condition. It has been customary for the Galloway cattle to be driven in large herds to the London market, a distance of five hundred miles, stopping nights to get a feed on pastures kept specially for them. Very often droves of lean stock have been retained on some of the rich meadows of the midland counties of England to be fattened. The breed has thus become crossed on the native stocks of Norfolk and Leicester, and in

Horns are frightful weapons amongst a drove of half-wild irritated and alarmed cattle, and so far as our beef stock is concerned may be very profitably dispensed with. There is no doubt but that the introduction of these hornless breeds, with all the other advantages they possess, would be of benefit to our Western and much of our Eastern country. They arrive at an early maturity, at three years old will make 600 to 800 pounds of beef, which is well flavored, tender, and with fat and lean well mixed together, and, in short, are a favorite breed with the feeder, drover, butcher, and consumer.

Walks and Talks on the Farm.—No. 101.

I have been reading Miss Howard's translation of Prof. Vile's lectures on chemical manures. His fundamental idea is that by the use of nitrogen, phosphates, and potash we can dispense with ordinary barn-yard manure. Within certain limits this is undoubtedly true. But it was Lawes and Gilbert, and not Prof. Vile, that proved the fact. The lectures are a strange compound of truth and error. That which is true is not new, and that which is new is not true—or at any rate, as the Scotch say, "not proven."

These lectures, as translated by Miss Howard of Georgia, and published in pamphlet form, are having a considerable circulation in the Southern States. And, notwithstanding their innumerable errors and doubtful statements, they are well calculated to attract attention to the advantages of using artificial fertilizers, and thus do much good.

Throughout the whole length and breadth of the large area known as the Atlantic slope, artificial manures, if of good quality and sold at a reasonable price, might be used to an enormous extent with great benefit to the individual farmers and planters and to the commercial interests of the country. If my memory serves me, as much as 145,000 tons of guano was used in a single year, and principally in the Southern States, before the war. Since then, Peruvian guano has deteriorated greatly, and what is even worse, it varies very much in quality, some cargoes being worth nearly twice as much per ton as others, while, as I understand, it is all sold by the Peruvian agent at the same price.

Our manufactured fertilizers, as a rule, are even still more unsatisfactory. A few are good, many are inferior, and some are not worth the freight. Prof. S. W. Johnson has done a noble work in determining the value of many of our commercial manures. In his last report on the subject, he has placed a higher value on the different ingredients of manure than formerly, and the manufacturers whose manures will not stand the test of such an estimate should know that there is something wrong in their processes. And there is one point that they should understand. This method of estimating the value of manures can not do the manufacturers injustice, but it may mislead the farmer. The manure can not be worth *more* than the ingredients it contains indicate; but it may be worth *less*, because some of the ingredients may be in an unavailable condition. For instance, a mixture of leather, hair, wool, and ground undissolved Charleston phosphates would not be worth half what the analysis indicates. The nitrogen and phosphoric acid are there, but in such an unavailable condition that the manure would have comparatively little effect on the crop to which it was applied. The analysis, therefore,

may represent the manure as more valuable than it is; but a manure is never more valuable than the analysis indicates.

Prof. Johnson, after a very careful consideration of the whole subject, estimates the values of the ingredients of manures as follows:

Potash.....	7	cents per lb.
Nitrogen.....	30	" "
Soluble phosphoric acid.....	10 $\frac{1}{4}$	" "
Insoluble ".....	6	" "

The Manhattan Manufacturing and Fertilizing Company, whose manures I have considerable faith in, send me an analysis of their Phosphatic Blood Manure, made by Prof. S. W. Johnson. It contains:

	Per cent.	Value per ton.
Water.....	21.40	
Soluble phosphoric acid.....	5.66	\$18.39
Insoluble ".....	8.03	9.63
Potash.....	1.40	1.96
Soda.....	2.60	
Nitrogen.....	3.32	19.92
Value per ton of 2,000 lbs.....		\$49.90

In the present condition of the artificial manure market, this is not a bad showing. The manure is not as good as it should be—not as good as the ingredients used in its manufacture are capable of producing. The fact is, it is not an easy matter to decompose bone-dust, and if I were the manufacturers I should employ mineral phosphates instead. I know there is an unfounded prejudice against them, but the soluble phosphoric acid obtained from them is just as valuable as that obtained from bones.

But can we afford to use artificial manures at these prices? On poor, sandy land, and where the products can be sent to the cities on the Atlantic coast, I think we can. And even here in the interior the market-gardener, seed-grower, and nurseryman may sometimes use them with considerable profit. Even farmers in the interior, on poor, sandy land, may use them for the purpose of "getting a start," but not as a steady thing. We can do better—at least I think so—by making more manure on our own farms.

Taking Prof. Johnson's figures, the potash, phosphoric acid, and nitrogen in a ton of clover hay would make it worth \$17.57 for manure. Bran would be worth \$22.10; peas, \$22.84; malt-dust ("combs"), \$31.30; linseed oil-cake, \$33.76, and decorticated cotton-seed cake, \$47.56 per ton for manure.

When fed to animals, there is a loss of about five per cent of nitrogen and a very insignificant amount of potash and phosphoric acid. If we deduct five per cent from the above figures, it will be safe to assume that they represent the value of the manure made by an animal consuming a ton of the foods named, as compared with the theoretical value of artificial manures. On the same basis, a ton of ordinary barn-yard manure would be worth \$3.25.

To a farmer who buys as much bran and other food to feed to sheep and pigs as I do, there must be encouragement in the above figures. I think they are too high, but it seems that artificial manures can not be obtained in this country at a cheaper rate. And if our Eastern and Southern friends can afford to buy these manures we certainly ought to be able to make considerable profit from feeding stock and making manure on our farms.

A Pennsylvania farmer writes: "During the winter I have been looking over old files of the *American Agriculturist*," which is certainly a very sensible thing to do. "You seem in Walks and Talks," he says, "to hold out the idea that

summer-fallow and thorough cultivation will exterminate the weeds. Do you really believe it?" I believe that weeds do not spring spontaneously from the earth. They are produced from roots and seeds. If we could kill all the roots, and get all the seeds to germinate and then kill the plants, the soil would then be free from weeds. This is a simple truism. But I do not believe that there is any practicable method of making a soil absolutely free from weeds. I think it is possible to cause all the weeds to germinate in say eight inches of the surface soil; but if when this was attained the plow should run half an inch deeper, we should probably the next season have a plentiful crop of weeds. Let these go to seed, and relax all efforts to kill the plants for a few years, and the land would soon be overrun with weeds. But what of all this? The only sensible plan for a farmer to adopt is to fight the weeds, and keep fighting them.

In England, where most of the land is rented, it is a great question how much the landlord or in-coming tenant shall pay the out-going tenant for unexhausted improvements. Mr. Lawes, in one of the ablest papers ever written on an agricultural subject, advocates allowing the tenant farmer a greater liberty in regard to the kind of crops he may raise than is common in most leases. But he says: "The tenant should be required to keep the land free from weeds; and, in default, to pay compensation to the landlord or in-coming tenant for the cost of cleaning; such cost to be assessed by competent persons." And he adds: "The cost of cleaning foul land which is in high condition is much greater than that of putting land which is poor in condition, but free from weeds, into good condition."

This is emphatically true, as I have found to my cost. I have had a hard fight with the weeds, but am steadily getting the upper hand of them. I feel savage on the subject, and have little patience with a farmer who looks upon a weed as something to be checked or kept back for the time being, and not killed.

"You say in March Walks and Talks," writes a young farmer at Cassville, Wis., "that soiling in summer and steaming in winter would enable me to keep more stock, but I have always contended it is the food and not the stock that makes the manure. From that we are to understand that the ultimate end and aim of farming is the manufacture of manure." This is pretty much so. It is quite certain that where manure is not one of the principal objects of feeding, soiling and steaming will not pay. In a section where land is cheap and rich, and where feed is abundant and manure is little needed, the mere saving of food will not pay for the labor of soiling and steaming. It is only where land is high and feed expensive that there is any chance of profitably adopting these processes. And on such land and in such circumstances manure is a great object. All I intended to show by my remark (and I must admit that it was rather an unfortunate one) was that even admitting that you could keep one third more stock on the same food you would not make one third more profit, less the expense of steaming, because you would not make any more manure. I buy a good deal of bran and grain to feed out on my farm, and I should think I was doing well if the stock would pay me the market price of the food that I raise and that which I buy, and leave me the manure for profit. Ordinary farm stock will not do this. But I have not time now to discuss this matter

as fully as its importance demands, and I have no wish to get into a controversy with the advocates of steaming. My sympathies are all with them, and with every farmer who is trying to improve our processes of agriculture. I have sometimes thought, however, that it is a pity so many of our ablest agricultural writers spend so much of their energy in advocating deep plowing, soiling, and steaming, when there are so many other subjects of far greater importance on which we need line upon line and precept upon precept.

A man at Reading, Pa., whose name I suppress, wrote me as follows: "I can increase your net profit on sales of live-stock *twenty thousand dollars per annum*. What arrangement can I make with you in reference to payment for such services? I am willing to do this either on commission or salary. It will require no addition to the capital you already have invested in that branch of your business. There is no risk; all operations being cash. I sincerely hope you will not consider the above assertion an exaggeration, or the product of an excited imagination of an unfledged novice, as I can assure you I am no child in operations of this character, and am accustomed to dealing in facts only." I wrote to ask him to tell me how I could raise and keep such an amount of stock on my farm as would afford a profit of \$20,000 a year. I told him I had no trouble in selling stock. But if he could tell me how to keep it more economically, and to raise it in such numbers and of such high quality as to afford such splendid results, I should be glad to hear from him. To this I have received no reply.

We have had capital luck with our lambs this spring. The weather has been very dry, and the sheep were strong, healthy, and in good condition, and this is the great secret of having "luck" with lambs. It is a curious fact that the lambs from Merino ewes sired by a thorough-bred Cotswold are generally as large and sometimes larger than the lambs from Cotswold ewes. And yet many of my Cotswold ewes weigh three times as much, and all of them twice as much, as the Merino ewes. One of the Cotswold-Merino lambs weighed at birth 14 lbs.

I notice a statement of a well-known Merino breeder in the West to the effect that he tried a cross with fifty good-sized "roomy" Merino ewes and a full-blood Cotswold. No difficulty was experienced at yearning time, and the lambs looked vigorous and healthy for several days, but after that seemed to want more milk than their mothers were able to furnish them, and though on good tame pasture, before the end of summer a few lank, living specimens and more dried pelts were all he had to show as the result of the experiment. "It may be," he says, "that the fault was not in the cross, but in the treatment before and subsequent to lambing. We treated the flock precisely as we treated our other stock." That tells the whole story. Though a sensible man and an experienced breeder, he thought he could bring into existence a lot of large lambs, and have them grow rapidly on the same amount of food required by the small, slow-growing Merino lambs. He "treated them precisely the same;" and consequently it is certain that either the small Merino lambs got more milk than they needed, or the grade Cotswolds got less.

Since writing the above, we have weighed (March 22d) a grade Cotswold ewe, that is about a year old. I can not tell her exact age. I had

74 lambs last spring from 60 Merino ewes. I sold 70 to the butcher, and this ewe is one of the four he left me, and he certainly did not leave me the best. I killed two for the table when from eight to nine months old, and never ate tenderer or more juicy mutton. But I thought it rather deficient in flavor. This ewe we have just weighed is covered with a heavy fleece of long wool that will answer for combing purposes. In fact it is nearly as long as that of the full-blooded Cotswolds. The ewe weighs to-day 121 lbs. Her mother at four years old did not weigh over 80 lbs. This is what these cross-bred lambs are capable of doing. This quality of rapid growth on the part of the Cotswolds is the result of years of careful breeding and liberal feeding. Now take such a flock of lambs and starve them, and what does any sensible man think would be the result? Is it not reasonable to expect "lank, living specimens and dried pelts"?

The grade lamb I have spoken of as weighing 14 lbs. was born March 3d. On March 1st we had one that weighed when born 12½ lbs. We have just weighed them again (March 22d). Both of them weigh exactly 25 lbs. each. I allow all my lambs a few oats, fine middlings, bran, sliced mangels, or anything that they will eat, placed in small troughs separate from the ewes; but it is not probable that these two young lambs, only three weeks old, have eaten very much. They have derived their nourishment from the Merino ewe. The milk seems to be very rich, and the secret of it is simply this: The ewes had good pasture last summer and autumn, and have been liberally fed all winter, and before and after lambing have abundance of milk-forming food—such as good clover hay, bran, and a few mangels.

My own opinion is that a farmer who has been accustomed to Merino sheep, and who does not expect to raise more than 75 lambs from 100 ewes, had better have nothing to do with Cotswold, Leicester, or South Down sheep. The poorest Merino sheep he can find, provided they are healthy, will be best adapted to his mode of treatment. When he is prepared to give better feed and more care he should get some improved Merinos; and if he keeps on improving in his general system of management he will in time be prepared to keep a still more artificial breed of sheep, and will at length succeed with Cotswolds or Leicesters. Whether it will pay to keep sheep that require so much more care and better feed will depend entirely on the demand for mutton, lambs, &c.

Some of the Cotswold breeders are disposed to expel me from the party for entertaining such notions—or rather for publishing them. I am not afraid of the truth hurting this splendid breed of sheep. To me it is encouraging rather than otherwise that these high-bred sheep are not adapted to "roughing it" on the cheap lands and vast prairies and plains and mountain-sides of the far West. If such was the case, the best thing we could do would be to pull up stakes and take our flocks out there. But depend upon it that Merino sheep will do better in such sections. Our Merino wool will be raised on these cheap lands, and the long-combing wool, good mutton, and early lambs will be raised in the better farmed and more highly cultivated parts of the country. In fact, I do not see how those of us who live in the older settled wheat-growing sections of the country can keep up the fertility of our farms without keeping more stock. And we have to

decide between dairying, or beef, pork, or sheep growing. I think we shall feel the competition from the West in the production of pork, beef, and fine wool, for some years, more than in early lambs, good mutton, and combing-wool. To raise the latter to the best advantage, we need clean, dry, highly cultivated land—or precisely what is needed to produce remunerative crops of winter wheat. The more mutton we produce the more wheat shall we grow per acre.

So far, my mangel-wurzel have kept perfectly. I raised about 3,000 bushels on three acres, and as I had no cellar room to spare, we pitted them on a dry, sandy slope near the barn, and found it far less trouble every way than I expected. It would of course be far more convenient to have a good cellar, but the want of it need deter no one from growing roots.

I have never been a strenuous advocate for raising roots extensively in this country. They probably act as a tonic, and stimulate the appetite, and improve digestion, and regulate the bowels. They are very useful to the farmer who keeps improved stock and feeds liberally. But for ordinary farm stock, fed as most farmers feed, I doubt whether roots can compete with Indian-corn. In England it is customary, especially on sandy farms, to sow one fourth of all the arable land every year with turnips—the rotation being clover, wheat, turnips, barley. The latter crop is seeded with clover. This is pastured with sheep until the next fall, or sometimes for two years, and is then plowed rather shallow and sown with wheat. The land is not plowed until it is time to sow the wheat.

It has been said, and with much truth, that turnip culture is the sheet-anchor of British agriculture. Turnips must have very rich and very clean, mellow land. It is a crop that is all consumed on the farm, and on light sandy soils it is generally eaten on the field where it grew by sheep. The crop needed a heavy dressing of manure, the land was kept very clean, and where the crop was eaten off, and the droppings of the sheep left on the land, and especially with the sheep allowed oil-cake, it is easy to understand that the land would be in high condition for barley and clover, and when the latter crop is also eaten on the land the prospects would be good for a great crop of wheat. It is easy to see, therefore, why the turnip crop has proved so exceedingly profitable to the English light-land farmer.

It is a great mistake, however, to suppose that it is the turnip crop that makes the land rich. This would be mistaking cause for effect. The turnip requires rich land, and its growth and consumption on the farm husband the manurial elements already in the soil, and render them available for grain crops.

Mr. Lawes, in a recent address, after giving an account of his experiments, remarked: "We may learn from these results that the growth of the root crop did not of itself contribute anything to the fertility of the land."

He further said, speaking of his own farm: "I am disposed to give up the growth of turnips altogether, growing no other roots but mangolds, and these probably to the extent of not more than one fifteenth or one twentieth of the arable land of the farm."

Coming from the highest living authority on scientific farming, these remarks are certainly worthy of consideration. They are quite in accordance with some statements I have repeatedly made in the *Agriculturist*. But I have not time to say more on the subject at present.

A Western Cattle-Barn.

Several requests have been made for a plan of cattle-yard, barn, and sheds for a stock farm. We visited a farm in Illinois last season where we saw a barn and sheds very well adapted to this purpose. The barn was appropriated wholly to hay and grain; the yard was spacious, and

Larger stumps, up to 8 inches, may all be pulled out by using a block and tackle. Blocks of three sheaves should be used, and a rope sufficiently strong for the purpose. A hitch should be taken upon the largest stump, and all those around it drawn out, when another large stump may be chosen to hitch to. In the *Agriculturist* for Sept. 1871, page 338, is a cut of a stump-puller

bars reaching from it to the sides, made of light laths, are fixed to the top of the trough to prevent the sheep from jumping into it. Its light is regulated by the size of the sheep.

A WESTERN CATTLE-BARN.

surrounded on three sides with sheds, either closed or open, in which the stock was kept. A neat fence closed in the front. The barn was raised three feet from the ground and rested on posts of brick-work. The space thus gained was used as a shelter for those hogs which had the run of the yard. The yards were well littered with straw and the remains of the corn-fodder which had been fed to the stock, by which means a large quantity of manure had been accumulated. Eighty head of stock—cows and steers—had been fed the previous winter in this yard, and the sheds were occupied when we visited the place with several head of cattle just taken off the pastures to fatten. The plan here given is equally well adapted to a large or small farm, as it may be extended at will to accommodate any required number of cattle.

which is powerful enough to take out stumps two feet in diameter, but the method here figured will be found effectual for smaller stumps.

Sheep-Rack for the Field.

We have heretofore spoken of the benefit of pasturing fields with sheep. Often a poor field

A PORTABLE SHEEP-RACK.

may be much improved by turning in a few sheep and feeding them therein. In this case some supply of grain is necessary for the sheep, and useful to the land. We give a cut of a movable trough adapted to this purpose, which may be taken to any part of the farm or wheeled to any poor spot in the field where it is desired

Fodder-Corn—Planting.

The time for planting corn for fodder (for the main crop) is the same as for the grain crop. The land, enriched and prepared as directed in an item on page 127, in April, should now be made thoroughly fine, clean, and smooth. One plowing, and repeated harrowings just before planting, will leave the soil fresh and loose, and will give the crop a fair start with the weeds.

The rows should be marked out 3 feet apart (if possible north and south). Abundant light and air are necessary to the perfect development of the plant. We were once advised by a farmer friend to plant our crop in drills, 10 inches apart, because this would cause the corn to shade the ground completely, and obviate necessity for weeding. At the end of that season the friend who had advised it, said he was satisfied that "fodder-corn was a humbug, and not fit to feed to a decent cow." The advice had come to us after we had already planted at three feet, and the reply to our friend was, that we considered the corn-fodder we were then using the best butter-making food we had ever had. Later experience and observation have confirmed the belief that the *quality* of corn-fodder depends more on ventilation and light to the very ground

than even on the richness of the soil. Probably a heavier weight of crop is produced at three-foot intervals than at anything less, owing to the greater height and

better development of the plants. No doubt the best variety of corn for this use is some rank-growing sweet corn, but as the seed of this is costly and often difficult to procure, we have settled on what is known in the market as "Western mixed," a yellow, dented, "horse-tooth" corn, which produces a large crop, and develops a good proportion of saccharine matter in the stalk.

We use about four bushels of seed to the acre. This may be sown along the row by hand, or, better, planted by an Emery drill planter, set to discharge at its fullest capacity. If the land is tolerably free from stones, our advice would be to plant fully two inches deep, and then run a Thomas smoothing harrow over the field, just as the corn first begins to break ground. This will make the surface light and fine, and will destroy an immense number of weeds that would soon give trouble. An acre of corn planted in this way on thoroughly rich ground may, if the cutting is commenced early enough for a second growth to follow, be depended on for the chief support of ten cows during the two driest months.

Digging Post-Holes.

The labor of digging post-holes is the chief cost of setting up a fence. This can be economized by using the proper tools. Fig. 2 is a post-auger (shown without handle) which is an improvement on any we have seen. We procured one from B. K. Bliss & Sons, N. Y., and found it on trial to be excellently adapted for the work. It penetrates the ground easily, working its way as a common auger does in

How to Pull Small Stumps.

A subscriber writes: "How shall I go to work to pull the stumps on 15 acres of land? They are from two to eight inches in diameter. What machine do I require?"—No machine.

METHOD OF PULLING SMALL STUMPS.

Stumps of two to four inches may be pulled out by a yoke of oxen, by hitching the chain at the top of the stump, and taking two or three turns around it, so as to get a twisting pull upon it.

to get a quantity of manure. It is a common trough of boards, mounted on a pair of wheels at one end, and furnished with legs and a pair of handles at the other end. A bar, with cross-

wood, and when the pan surrounding the auger is filled with earth it may be drawn out and emptied. But where many stones are in the soil other tools are necessary. Then the bar

Fig. 1.—USE OF POST-HOLE SPOON.

and post-spoon (fig. 1) are needed. The bar is a common iron bar, with a sharp steel point, with which the hard gravel is loosened. The spoon is inserted in the hole and the stones and earth taken out. This post-spoon is made by R. H. Allen & Co., Water street, New York. We have found it a very handy tool in use. With these tools, post-holes may be made so small that the post will fit tightly in them, requiring little

Fig. 2.—POST-HOLE BORER.

filling, and making a firm, solid setting. A great saving is gained over the common method of digging with pick and shovel, whereby a hole is needed to be made as broad as it is deep.

In setting posts, it is an excellent plan to fill the hole around them with stones, which do not retain water while they admit air, thus preventing the posts from rotting for many years.

How to Manage Manure.

The value of liquid manures is not sufficiently realized. One cow voids in the course of a year 8,000 pounds of liquid, which undiluted and fermented would be too strong to apply even to grass. It is safe to say that not one thousandth part of this is ever saved for use, but

nearly the whole is allowed to go to waste. Further than this, the construction of barn-yards is so imperfect that much of the valuable part of the solid manure is washed away and wasted, or it is permitted to ferment and heat in such a manner that its value is much lessened. Struck with these views, we once went to work to economize all these wastes. A square pit was dug in the center of the barn-yard, four feet deep. The sides and bottom were planked. The bottom sloped to the rear about six inches. Blocks were laid on the sloping bottom (a) and a quantity of rails and poles were laid across, to make a false bottom, on which the manure was thrown as it came from the stable. Drains from the stables and sheds carried all the liquids into this pit, where it escaped to the rear into the cistern (d), together with all the water which filtered through the manure pile after rain had fallen on it. The cistern was lined with hemlock plank, which after three years was still perfectly sound, and was ten feet deep and eight feet square. A pump of wood (c) similar to that figured on page 339 in our volume for 1871 (fig. 1) was set in the cistern, and when necessary the rain-water from the barn roof was turned into it to dilute it. In this way a large quantity of liquid manure was procured, which was found of the greatest service both in the garden and in the field. Spread on a piece of clover it enabled four cuttings to be made during the season, which was estimated as equal to five tons of hay to the acre, and which otherwise on account of the dry season could have been cut but once, with but a fourth of this yield.

For hand-use the wheel-tank (fig. 2) was made with joints dovetailed and put together with strips of brown paper smeared with tar placed between them. This made them water-tight. The tank was three feet square and deep, and scattered the liquid over six feet wide, or over three rows of fodder-corn, which in this way, while young, could be easily watered with this cart at the rate of an acre an hour, and thus its early growth could be rapidly forced. Of all the economies of the farm it is safe to say that there is none in which greater improvement and saving may be made than in that of the management of manure, and the saving and utilizing of all the liquids. Here is a simple and inexpensive plan, which may, however, be improved upon after experience of its usefulness and possible defects. The pump by being turned could either discharge the water from the cistern on the manure-heap to prevent too much heating, or directly into the small tank or any other spreading apparatus.

Windmills for Farm Work.

Many of our readers are interested in the question of the applicability of the power of the wind to the light work on the farm. Before the introduction of steam, wind and water powers were the motive agents of machinery, and even now water powers are found to be of such value in respect of cheapness that they are very seldom idle, even in presence of facilities for the use of steam. In the same way wind powers are still largely used in old-settled countries, and steam has not driven them out of use. In the

northern parts of Europe—Germany, Holland, Belgium, France, and England, for instance—windmills are in constant work, some of which are over a century old, and are doing good and

Fig. 1.—MANURE PILE AND CISTERN.

cheap service. There is no doubt of the fact that wind-power might be largely used in the United States with great advantage; but many patents having been taken out for improvements on windmills, and all of them being persistently forced upon the notice of the public, and many

Fig. 2.—LIQUID-MANURE TANK.

of these being found not efficient or cheap in practice, a prejudice seems to have arisen against them. But the old-fashioned mill remains unaffected by patent rights, is just as useful as

A SIMPLE WINDMILL.

ever, and so simple that a mechanic who can construct a simple water-wheel or wagon-wheel is competent to make one. We figure such a windmill, which is in every-day use, which costs very little, and which may be constructed to do

light or heavy work, as desired. The frame on which to mount it may be of timber, as in the cut, or it may be a stone or brick building if desired for a substantial machine for heavier work. The power is constructed in the shape of arms—shorter or longer, according to the power needed—fixed to a center-wheel or hub, which is mounted and keyed on to an axle. Sails are carried on these arms, of sail-cloth or heavy sheeting, of a triangular shape, as shown in the engraving, which are fastened closely to one arm and by a cord at the corner (shown at *a*) a foot or less in length to another. This gives sufficient inclination backward to the sail to gain the motion required with a front wind. On the axle is a crank-wheel (*b*), which moves the rod to be connected with the pump, or it may be connected by means of pulleys and bands to get an upright rotary motion needed for grinding, or a pair of miter-wheels will give a horizontal rotary movement. A frame (*c*), is carried on a circular table, on which it may be revolved so as to enable the sails to be presented fairly to the breeze; a box (*d*) at the rear end of the frame is weighted with stone, to balance the weight of the arms and sails. A pin passed through holes in the circular table retains the frame in the position needed, and keeps the sails faced to the wind.

The construction of this mill is so simple, and it is so easily managed, that all those of our correspondents who of late have anxiously inquired for a cheap power for churning, pumping water, and irrigating land will do well to study it out. A mill with arms six feet long may be made to do work equal to one fourth of a horse-power, if all the working parts are well fitted and kept well lubricated, as all machinery should be. When out of use, the sails are untied and removed, or they may be furled and clewed to the arms until again required.

Implements for Cultivating Corn.

The corn crop is one which requires more hard labor than any other grain crop on the farm. Generally it is planted, covered, cut up, husked, and shelled by hand, rendering necessary at least ten days' labor for every acre before everything is completed. A great saving may be made by using machines as far as possible. There are many planters in use, more or less

Fig. 1.—SIMPLE CORN-PLANTER.

costly, but a very cheap and useful one may be made for a few dollars by any wheelwright, which will plant two or three rows at a time, and thus make it possible to get in twelve or twenty acres of corn in a day. It consists (see fig. 1) of a frame mounted on a wheel similar to a wheelbarrow frame, with handles to push or guide it. A box to contain the seed is mounted on the frame, which tapers toward the bottom, and thus obliges the seed to fall upon the revolving cup which distributes it. This is a cylindrical block of wood which fits closely to the bottom. An axle passes through it which is connected with a pulley outside of the box. This pulley is turned by means of a band or cord fitting into another pulley fixed to the driving-wheel, and every revolution of the wheel

causes one revolution of the pulley and likewise of the cylinder inside the feed-box. A cup or receptacle made by boring a hole with an auger or bit, large enough to hold three or four grains of corn, is made in the cylinder, which in passing around is filled with seed. The seed is carried on until it passes out through the open

Fig. 2.—CORN-COVERER.

bottom of the box in which the cylinder is made to fit closely, and is dropped into a tube which conducts it into the furrow made by the small plow in front; a semicircular scraper carried behind covers the seed. It is obvious that by adding to the width of the machine it may be made to drop two or three rows at the same time.

When corn is dropped by hand after the field has been furrowed out in squares, it may be covered, two rows at a time, by a simple contrivance shown at fig. 2. It is simply a triangular implement, made of narrow boards six inches wide and six feet long, nailed together by their edges in the form of troughs, and fitted into a V-shape, with a spread of five feet between the ends. A cross-piece is nailed on to hold it together, and a hook placed at the point, by which it is drawn along the furrows and the loose earth drawn over the seed. If it should not be found heavy enough, stones or some earth is thrown into it until the weight is right. It covers two rows at a time and may be drawn by one horse. For cultivating corn we have used a harrow shaped like that shown in fig. 3. It is made wide enough to work two rows at a time, passing over the young corn in the intermediate row by reason of the vacant space left in the front where the teeth are not put in. A pair of handles enables it to be guided and managed with facility. Two horses are required to draw this harrow, and if the ground is moderately clean no other tool is required. Hilling up corn with the plow is unnecessary, and flat cultivation with the harrow or horse-hoc is considered to be preferable.

How to Use SAWDUST.—Some years ago we had the control of a large supply of sawdust, which we used as bedding for horses and cattle. We used it through two years, and had a good opportunity of testing its value in the stable and in the manure pile as well as on the soil. The main bulk of the sawdust was from pine. When spread on the stable a few inches in depth, it

absorbed completely all the liquid from the animals, and their coats were consequently kept perfectly clean, and very little labor was needed to keep oxen and cows free from dirt, even during the winter. When thrown out into the heap, this litter fermented and rotted very readily, without fire-fanging, and soon became a homogeneous mass, not to be distinguished from clear fermented horse-manure. It was used with the very best effect as a dressing on meadows, and as an application for potatoes and oats. It was readily harrowed into the plowed soil, and the harrow spread it very evenly over the grass-land. Our experience was so favorable, that we should be glad to use it again.

Ridge and Furrow Plowing.

It is a common practice amongst English farmers to plow those fields which they intend to put into spring crops, in the early winter, on what they call the ridge and furrow plan. By this method the subsoil is exposed to the repeated frosts and thaws of the winter, and is mellowed and sweetened. Besides this the frost is enabled to penetrate several inches deeper than otherwise, lifting the compact subsoil and expanding it so that when it thaws in the spring it is loosened and rendered of an open texture. The mode of working is as follows: The plowman commences at one side of the field, and plows a furrow towards the outside. He returns in the same furrow, plowing up the subsoil and throwing it out on the unplowed land. He then plows another furrow parallel with the first, throwing the soil towards the subsoil last thrown out, and thus completes a ridge. He thus progresses throughout the field, which presents, when finished, a series of these ridges, separated by deep furrows, in which the subsoil is exposed. In spring these ridges are either split or the field is cross-plowed.

Fig. 3.—HARROW-CULTIVATOR.

It is thus evident that one such plowing deepens the soil over half the field just as many inches as the plow has penetrated into the subsoil, and another similar plowing may be made to complete the strips left in the first operation. This operation has the advantage of bringing to the surface a portion only of the subsoil at one time, and thoroughly mingling it with the surface soil, after exposing it in a most complete manner to the beneficial action of the atmosphere for some months. It would be a valuable experiment to make on a portion of a field to thus prepare a piece of corn stubble for oats next spring, and test the value of the process. We have no doubt it would be so satisfactory that the plan would be regularly adopted in future by every experimenter. Three acres a day may

be thus plowed, and if the ridges are split in the spring, the same quantity of work may be done, so that really a saving of work will be made, as one and a half acre per day will on the whole have been plowed; and the land can be worked earlier, and is in excellent condition for spring crops. In preparing for roots the manure may be thrown into the furrows and covered when the ridges are split, when it will be in fine order to cross-plow in the spring.

A Good Wool-Box.

Mr. F. M. Bugbee, Ohio, sends us the accompanying sketch of his wool-box. It is composed of three boards, each three feet long,

Fig. 1.—WOOL-BOX OPEN.

one inch thick, and twelve inches wide. The center one (fig. 1) is divided at equal distances at *a, a*, and connected with hinges opening upwards. The two outside boards are joined to the center square by hinges at *b, b, b*, also opening upwards. At *c, c, c, c*, screw on the springs, cutting away the wood underneath so that they may lie flush with the boards when pressed down. At *d, d, d, d*, make a cut one inch deep with a thin saw, to hold the ends of the strings. Make a hook (*e*, fig. 2) of hard wood, one inch thick and fourteen inches between the jaws, and the box is done.

To use it, first fix the strings from the cuts *d, d, d, d*, in the direction of the dotted lines

Fig. 2.—WOOL-BOX CLOSED.

on fig. 1. Lay the fleece with the clipped side downwards on the boards, bring up the sides, which secure by placing across them the hook, as in fig. 2; then close the ends, which the springs will keep in their places; tie the ends of each string tightly over the wool; then remove the hook, and the box will fall back, leaving the fleece tightly packed and tied.

Our correspondent claims the substitution of the springs instead of using pegs as a great improvement. And such is the case. But it is not new, as we have used a similar box for several years. It may, however, be new to some of our readers, and we present it accordingly. The use of some such contrivance in packing wool is always to be recommended, as it leaves

the fleeces in a more presentable shape, and enables them to be packed more closely in the sacks. With wool, as with all farmers' produce when sent to market, the best price is gained for that which not alone is good but looks well.

Disease in Calves.

Several have inquired about a disease to which young stock, particularly calves, have been lately subject. The symptoms are, falling off from feed, rough coat, bloodshot eyes, dry nose, a cough, and a highly fevered condition. On examination after death, small thread-like worms are found in the air-passages. It is often supposed that these worms are the cause of the trouble. This is a mistaken idea. This complaint is undoubtedly influenza, and the consequence of exposure to damp and cold, with an enfeebled state of the system. It is not necessarily fatal, if proper attention be given. Warm gruel of bran, middlings, or oatmeal is of service, a warm stable is necessary, and generally a careful restorative treatment will bring about a cure. The worms seem to be one of the last results of the disease, and are found not only in the air-passages, but also in the lungs. This complaint prevailed amongst the lambs last spring, and some of ours were attacked, but recovered by the administration of a little warm gruel, with a few drops of peppermint-water added, fed to them with a spoon. We notice that it has also been very prevalent amongst young stock in England, of late, but readily yielded to treatment similar to that we have suggested above. Prevention would be by means of warm shelter and generous feeding.

THE VALUE OF SOOT AS A MANURE.—As soft or bituminous coal becomes more extensively used west of the Alleghanies, it will be of great importance to farmers of the Western coal districts to understand the value of the soot which is left in large quantities as a deposit in the chimneys where this coal is consumed. Soot accumulates in chimneys so rapidly that it is necessary to remove it very often, and it is far too valuable to be allowed to be lost or wasted. A French chemist has made an analysis of coal-soot, by which we ascertain that in 1,000 pounds the following quantities of valuable ingredients as fertilizers are contained, viz.:

A substance resembling vegetable matter, soluble in caustic potash.....	302 pounds
A substance, soluble in water, containing ni-	
trogen.....	200 "
Carbonate of lime and magnesia.....	150 "
Sulphate and acetate of lime and magnesia.....	112 "
Phosphate of lime.....	15 "
Chloride and acetate of potash.....	45 "
Acetate of ammonia.....	2 "
Charcoal powder (carbon).....	38 "
Water and sand.....	136 "

A glance at these constituents will readily show that soot contains valuable fertilizing properties, while its very fine state of division renders it most easily and effectively applicable to crops. In Europe it has been used for years as a top-dressing to all crops, but with notably most effect on grass, wheat, and oats. Its pungent character and very bitter taste make it desirable as a preventive against the turnip-fly and the cut-worm and caterpillars, which injure cabbages. As it is a new article of use to American farmers, it would be of interest to experiment with it on various crops, and note its effects, with the precaution to be observed, that in quantities greater than ten bushels per acre it is apt to burn the crops in dry seasons. It should therefore be

applied previously to the rains of spring or fall, or in small quantities of say four bushels per acre, repeatedly.

COOKING FOOD FOR PIGS.—H. J. Fisher, Preble Co., Ohio, asks the following questions: "Do you feed cooked food to your pigs? What steamer do you use? and do you think it pays?"

—We are now feeding our *young pigs* cooked corn-meal and fine middlings, all they will eat, and give them sliced raw mangolds in addition. They are very fond of the mangolds, and we think them cooling and healthy. The breeding sows have only uncooked food—bran and a little corn-meal soaked in water for twelve hours. We have a Prindle steamer, but when cooking only a small quantity of corn-meal, etc., we take off the top and use it as a kettle. We think cooking food for young pigs that we wish to push rapidly forward pays well. Our aim is to get them to eat and digest as much food as they can assimilate. For old breeding pigs that can digest all the food we allow them and more, cooking or grinding is a mere waste of labor and fuel.

The Culture of Peanuts.

The best soil for peanuts is a light loam, light both in texture and color. The plant needs the mellow soil for its peculiar habit of growth, and a red or dark clay soil gives an undesirable color to the nuts, which depreciates their market value. The soil should be prepared by one or two plowings, so that a perfectly mellow bed be prepared for the seed. A shallow furrow is considered the best, for the reason that the harvesting of the nuts is rendered easier when they are nearer the surface; if the soil is deep they will penetrate further than is convenient in gathering them. When the ground is prepared in a proper manner, furrows are to be laid off twenty-seven to thirty-six inches apart, as the land may be poorer or richer. Cross-furrows are made at the same distances apart. In each check a handful of guano or superphosphate is to be dropped, at the rate of 150 pounds per acre. If the land is deficient in lime, a dressing of 50 bushels per acre should be given after the first plowing, and harrowed in. This is a crop that needs lime for its successful growth. The seed should be shelled very carefully by hand; the skin must not be broken. Two nuts are dropped in each hill and covered very lightly, not more than two inches, or three at the most. Directly after planting, cultivation with the plow commences, to be followed with the hoe and hand-weeding. The crop must be kept perfectly free from weeds and grass, and the soil be kept loose and mellow. Constant cultivation is necessary; as many as seven plowings being generally given until the vines spread and are in the way, when hand-weeding is to be resorted to. No hilling up is necessary. The stems which produce the fruit enter the ground without being covered with the soil artificially. Generally the crop is ready to harvest early in October. The harvesting should be done before frost if possible, as a hard frost destroys the vines and detaches them from the nuts. A plow with a broad, sharp share attached to a bar or coulter, so that no furrow is turned, is run up and down the rows, cutting beneath the plants and severing the tap-roots, or the vines are dug up with prong-hoes or forks. Hands follow the plow, who pull up the loosened vines and shake off the adhering earth, and lay them in rows to

[COPYRIGHT SECURED.]

SHEARING COTSWOLDS AT HERDSDALE.—Drawn and Engraved for the American Agriculturist.

dry. Two days' exposure is necessary before they are ready for stacking for final curing. A stake, pointed at both ends, and seven feet long, is thrust into the ground, rails are laid on the surface to prevent contact with the earth, and the vines are heaped around the stake in a tall, narrow stack, so that the air can easily penetrate and cure the vines. Straw is placed over the top to shed rain, and two weeks are required to thoroughly cure the crop. Mold or dampness, which would injure the color, is to be carefully avoided. On the brightness and lightness of the color the value in a great measure depends. When cured, the nuts are separated by hand generally, but this is a slow process, two to four bushels daily being the work of an experienced hand. A thrashing machine is used by large growers in North Carolina, which thrashes with two horses 100 to 200 bushels in a day. The vines make a very excellent fodder, but when spread on the ground and plowed in, and a dressing of lime given annually, with some fertilizer at planting, the crop may be grown successively for several years. It is not probable that this crop would retain its present market price if its production was materially

increased, the demand being but limited; and, in view of its comparatively costly culture, the average yield of 30 to 50 bushels per acre does not seem to make it a very enticing crop. The season required for perfect ripening is long, and it is very doubtful if the nuts could be matured further north than Virginia in the East and Kansas in the West. Nuts of excellent quality were grown in Kansas last season, but the bulk of the crop is raised in East Virginia and North Carolina, in the localities adjacent to tide-water. Our correspondents in Wisconsin, Michigan, and other Northern States will see that this crop is not suited to their climate.

Shearing Cotswolds.

Our illustration represents the shearing of a flock of Cotswolds at Herdsdale, the farm of our Mr. L. A. Chase, at Florence, Mass. The operation of shearing, although it looks a somewhat rough one, may be made by a careful hand very easy to the sheep. General directions for shearing were given last month on page 140. Some care is necessary in handling heavy sheep,

especially the ewes which have not yet had their lambs. The patience and docility of the sheep beneath the operation of shearing is proverbial, but still we have seen very unnecessarily rough usage given to them. Possibly no better shears can be found than the old-fashioned ones, and a skillful shearer will make as few cuts with them as with any of the new-fangled ones with patent guards and other preventives against cutting, which when used are found to be no guards at all. The operation is commenced at the neck of the sheep, the shearer standing behind it, as shown in the illustration. The remainder of the work is better described by the picture than it could be by a page of description. It is therefore only necessary that the positions of the figures be studied, and they will tell their own story. Long-wooled sheep have a rather tender skin, and if the weather after shearing should be wet and cold, it would be advisable that they be kept up until they become used to the loss of their coats. If any signs of cold or running at the nose appear after clipping, it is well to smear their noses with pine-tar, which they will lick off, and thus take sufficient internally to have a remedial effect.

Ivies—Plain and Variegated.

But few north of Delaware can grow Ivy as a climber and be sure of it. We have seen in favored situations in New England the side of a stone house covered with it, and in the city of New York it will often flourish for several successive winters. At last comes an unfavorable winter, and away goes the work of years. Through many of the Southern States the ivies do splendidly, but their success there is far eclipsed by that upon the Pacific coast. A few days ago we saw ivy leaves from Washington Territory, that would cover one's

our nurserymen and florists offer a dozen or more varieties at 25c. to \$1 each, according to size and rarity. Ivy roots readily from cuttings set in moist soil in a shady place, or if a

plain these names a little, *Cissus* is one applied to some beautiful green and hot-house climbers of the grape family; *Vitis* is the grape proper, and *Ampelopsis* we best know as the Virginia Creeper or American Woodbine. As the later botanists have been unable to find any points in these three genera which seem of sufficient importance to keep them separate, the three are by some united into one — *Vitis*, the grape. This helps us with the plant in question, which has been so banded about under different names that

VARIEGATED JAPANESE IVY.

branch be layered, it will root at every joint, and produce as many plants as there are joints.

A Variegated Grape-Vine.

We sometimes come across plants in cultivation which are puzzles. That which we call the Variegated Grape-vine is one of these. We find it in some catalogues as a *Cissus*, and in

we are well content to call it a variegated grape-vine, even if the fruit does not come up to our idea of what a grape should be. In foliage this vine is much like that of the grape in shape, very irregular at the extremities of the shoots, and beautifully mottled with white and green. The berries when ripe are of the most charming blue, about the size of pepper-corns, and upon bright crimson foot-stalks. This vine is one which will either give great satisfaction or produce disappointment, according to the position in which it is grown. If planted in a place where it is shaded the greater portion of the day, it will produce handsomely-marked leaves, but if exposed to full sun the foliage will be dull and unsatisfactory. This variegated grape is not a new plant, as we grew it some twelve years ago. Our specimen was unfortunately placed in an open exposure, and it made so poor a show that we were quite disgusted with it. Since then we have seen it in the grounds of others, grown in the shade, with the markings quite as distinct as those shown in the engraving.

VARIEGATED GRAPE.

hand, palm, fingers, and all. Still, in all places not excessively inclement, ivy can be grown as an edging, or to make a bed by itself. A slightly raised bed covered with ivy looks well upon a lawn, the darker green of its foliage making a pleasing contrast with the lighter shade of the grass. A well-kept edging of ivy is particularly elegant, and though it may take a full year to establish it, the result is well worth the trouble. As to the different species of ivy, we frankly confess that we know nothing positive about them. Several years ago the late Berthold Seemann "did up" the ivies, and told us that what we had been calling Irish ivy was *Hedera Canariense*, and made us unlearn many other things we thought we knew. A few years later came Shirley Hibbard with his classification of ivies. He not only knocked Seemann's arrangement into "smithereens," but that of every one else, and came out with an original renaming of old things made out of whole cloth. Between Seemann the botanist and Hibbard the egotist the nurserymen are in a poor case as to names. The variegated ivies, as a general thing, have a hard time of it during our hot summers. They are beautiful in house culture, but lose their markings under our summer suns. Some years ago Mr. George Such, of South Amboy, N. J., gave us a bit of what was then a new Japanese Ivy, and is now called in the catalogues *Hedera Japonica versicolor*. It has been subjected to all the slights and exposures that any plant should meet with, and yet year after year it has grown freely, and put out its beautifully variegated leaves as cheerfully as if it had received the best of care. The form of the leaves in this plant is so changeable, that it is difficult to say what the normal shape is. The coloring is no less whimsical. Some leaves are merely edged with white, others are half white and half green; sometimes one will come all white, and again a tinge of purple will be pleasingly intermingled with the white and green. We give an engraving of a small branch of this variety of the natural size. We think it probable that in even very cold localities the hardier Ivies can be grown as edgings or as beds, provided a good covering of leaves be given to protect them during the winter. The catalogues of most of

another as a *Vitis*, while an esteemed friend insisted last summer that we should come and see his beautiful variegated *Ampelopsis*. To ex-

which the pollen is taken than like that which received the pollen and bore the seed. It is likely that this holds true with other plants. The

Crossing and Hybridizing.

Dr. Denney has given in the Florist and Pomologist (London) some interesting articles upon cross-breeding Pelargoniums. His accounts of his experiments and their results are of great value to those concerned in producing new seedling Pelargoniums and other florists' plants, but are not of sufficient general interest for us to reproduce them. There are two points made by Dr. D. which should be kept in mind by those who aim at raising new varieties of fruits and flowers by hybridizing or cross-fertilizing. He finds that, provided the two parent plants are of equal health and vigor, the male plant exercises the greater influence upon the progeny. That is, the resulting seedlings will be in more respects like the parent from

Croton and Senasqua grapes are vastly more like their pollen-bearing exotic parents than the native Delaware and Concord which served as the mother-plants. Another point of interest to those who work at improvement of flowers is the infrequency of any really remunerative results. In flowering Pelargoniums, Dr. D. is satisfied if he gets on an average one good variety out of four hundred seedlings, and five or six others that are fair improvements over their parents. He is satisfied, nevertheless, that the only way that even slow progress can be made is by cross-fertilization, and states that out of a bed of several seedlings in flower, raised from seed from the best varieties, but which had been produced without artificial fertilization, there was not in the whole bed a single plant worth selecting for propagation.

Will Evergreen Screens Protect Fruit-Trees?

Mr. J. Day, of Dayton, Ohio, writes an article to show that shelters and wind-breaks of evergreens and other trees will not, as commonly believed, afford protection to orchards. His argument rests upon observations made upon peach and cherry trees. On the cold New Year of 1864 the thermometer fell about 50° in a few hours, and in the morning stood at 14° below zero. Our correspondent found that the buds and twigs of peach and cherry trees were as thoroughly killed in orchards surrounded by dense forest of miles in extent, as they were in the open country. Several other instances are cited, in which the buds were killed by extreme cold, notwithstanding the trees were surrounded by forests. The drift of Mr. D.'s argument is, that forests and evergreen belts are of "no protection against the severe freezing of fruit-buds." As we never claimed that they were, we can not spare space for a long article to show that they are not. We never knew any one to assume, as Mr. D. seems to think has been done, that it was possible to fence out the cold by means of evergreen or any other trees. Mr. D. will admit that a board fence or a screen of trees of any kind will break the force of the wind more or less, as the shelter is close and high or otherwise. This is all we have ever claimed or have ever known to be claimed for a protecting belt around an orchard. We are ready to admit that no amount of shelter will protect the fruit-buds, when the thermometer is 20° below zero. Our correspondent makes the mistake of supposing that it is only the severe cold that injures fruit trees. When the mercury falls to a certain point, we are quite sure that peach-buds will be killed, but this severe freezing is not the only thing that interferes with the productiveness of the trees. The winds of early spring are often very dry winds, and if they have an unobstructed sweep over the trees, the vitality of which has just awakened, they can produce great injury, simply in drying out the just swelling buds and young twigs. A wind carries away the heat from a body very rapidly. A still day, with the thermometer at 32°, is not uncomfortable, but if the wind is violent, we find it very inconvenient, even while the thermometer remains the same. We have known persons to perish from cold in a Texas "norther," when the temperature was above freezing. The constant wind cooled the person so rapidly, that they sank from the effects of cold, without being frozen. If the buds escape death from severe cold, we are not sure of a crop of fruit. The critical period of blossoming must be passed

before we can feel safe, and it is well known that long-continued rains and violent wind storms can seriously affect the fertilization of the flowers and the setting of the fruit. At this time a long cold wind has a most untoward effect, and it is then that the shelter is of great use. If our friend will leave extremely low temperatures out of the question, and observe protected and unprotected orchards without reference to exceptional winters, he may modify his views. At all events we can point him out places where fruit-trees have not only been benefited by shelter belts, but where their existence was actually impossible until the tree belts were planted.

The Matthews Apple.

BY DR. J. STAYMAN, LEAVENWORTH, KANSAS.

This is an apple of great promise, being very beautiful and perfect.

It originated in Nelson Co., Virginia, on the farm of Mr. Matthews, and was first introduced to the public by Tyree Dollins, of Albemarle Co., Va., from whom we received specimens at the meeting of the American Pomological Society at Richmond, Va., September last.

Tree a stout, upright grower, with light-colored bark.

Fruit medium to average; weight from 6 to 10 ounces; form round, slightly conic; skin smooth, rich waxen yellow; dots, large, scattered, whitish or gray; stem medium, slender; cavity wide, deep, green; eye small, closed; basin rather narrow and shallow, furrowed; core large, round, open; carpels large, hollow; seeds medium, ovate, plump, dark; flesh yellowish, very tender, juicy, pleasant sub-acid; quality good to very good; season October to February. (See outline on page 184.)

Raising Garden Seeds—Carrots.

With the multiplicity of books upon gardening, we have had none that gave any satisfactory directions for growing seeds. This gap in our horticultural literature is now well filled by Mr. Francis Brill's "Farm-Gardening and Seed-Growing," just issued by Orange Judd & Company. To give a specimen of the work as well as to answer several inquiries about carrot seed, we quote what Mr. Brill says upon raising it. Presuming that at the digging in the fall, a selection has been made of the finest roots for the purpose of growing seed, and that these have been successfully wintered in a pit or cellar, the work to be done this spring is thus described by Mr. Brill:

"The seed does best in a rather strong loam, moderately rich. After plowing and harrowing, make rows three feet apart with the marker, along which with a crowbar make holes eighteen inches apart; place the roots therein, the crowns level with the surface, fastening the earth firmly against them with a dibble. They should be set out about the middle of April or as soon as all danger of severe freezing is past.

"The after-culture is the same as for beets, except that ridging is unnecessary. Planting every fifth row with potatoes will facilitate the gathering of the seed. The seeds are produced in heads or clusters at the extremities of the branches, and ripen unevenly, hence they require repeated cuttings. When ripe, which may be known by the seed changing to a brown color and the branches commencing to dry, the heads must be cut with shears, gathered into a barrel, carried to the loft, and spread over the floor. When the crop has all been gathered

and the whole become thoroughly dry, the heads can be removed to the thrashing floor, and thrashed with a flail, only hard enough to separate the seed from the small sticks which support them, and avoid as much as possible breaking these sticks, in order to make the cleaning more easy. When thrashed, separate the coarser sticks from the seed with a No. 4, and again with a No. 6 sieve, rubbing the larger seeds through with the hand; place the seed thinly on a large cloth, exposed to the sun, and after it has lain so for five or six hours, set a barrel in the center; on this place a No. 8 sieve, through which pass the seed by rubbing with the hand, throwing out the sticks as they accumulate in the sieve. Repeat this operation the following day, this time using No. 10 sieve, which will remove the furze or beard, when it may be finally cleaned by passing twice through the fan-mill, and finished by No. 24 sieve. But a very few years ago it was believed that the removal of the furze injured the seed, and it was carefully picked out by hand, but experience has proved to the contrary, and now not a pound of seed is sold in any seed-store in this country but that which is rubbed clean, in which condition it is more easily handled and can be more easily and evenly sown."

Notes from the Pines.

In the natural course of events I should have been able to report progress, but now the first week of April has gone, and we are about where we were the first week in December. What a winter the past has been! and what a spring this is!! Winter shut down so suddenly, that my next neighbor had a large share of his potatoes and cabbages frozen fast in the field, with never a thaw to loosen them until April. I was so fortunate as to get everything up in time except a single row of cabbages. For the past week thawing has gone on during the day, making the soil too soft to tread upon, and each night it has frozen hard enough to form a firm crust.

CONIFEROUS EVERGREENS have had a most trying time of it. I shall lose a large number of rare species. Some sorts ordinarily hardy now present a sad array of dead and whitening leaves. It is too early yet to know the precise extent of the damage. All those evergreens which have passed the winter unscathed may be set down as perfectly hardy.

THE GOLDEN YEW.—I have before said a word in favor of this tree, and this spring I am more than ever impressed with its merits. It not only has shown no signs of winter-killing, but with the first bright days the tips of its branches begin to turn yellow, and give promise of that golden glow which shall shortly make this a conspicuous object upon the lawn.

BROAD-LEAVED EVERGREENS.—If the conifers have fared badly, it has gone much worse with the broad-leaved evergreens. The evergreen barberries, Mahonias as they are called, show no signs of life. Their leaves are of the color of sole-leather, and appear to be past resuscitation. But the rhododendrons! These all through the winter have been interesting objects, as their leaves have served as rude indicators of the temperature. In extreme cold weather the leaves would curl into a roll and hang pendent by their stalks. When the weather was less severe, they would assume a more or less horizontal position, and when there was any approach to mildness the leaves would uncurl and assume nearly their summer appearance. During the winter we daily watched these changes

as we passed the clump on going to and returning from the city. But those fatal days of March! No matter about the date, but it was when plants froze in a room where there was a fire. This finished them, and the browned leaves hang in mournful helplessness. I fear that the flower-buds are killed also. Still, a rhododendron is hard to kill, and I shall not give up until I find them dead to the root.

BULBS.—It seems strange to have no *Bulbocodiums*, *Snow-drops*, nor *Crocuses* in the first week in April. I have had the beds uncovered, and found that underneath the leaves the plants had just poked their noses above the surface, but when the soil freezes hard every night we can not expect that the flowers will unfold.

COVERED THINGS.—The past winter has shown the great benefit of a slight covering of marsh hay or litter. Spinach and the like that was covered is bright and ready to grow, while a few things that were overlooked are frozen to the very heart. It may look like a small economy to rake up the leaves in autumn and put them over the beds, but we do not know of anything that pays better.

HERBACEOUS PERENNIALS.—I have a very large bed of these, but did not cover it. The soil is too soft yet to walk upon, but from the paths I can see that some things have fared badly. It pleased me greatly to see that the most beautiful—I had almost said of herbaceous plants, and I will say—of all *Columbines*, *Aquilegia carolia*, was one of the first things to show signs of life. I think that the first notice, I am sure that the first engraving of this charming plant in this country was published in the Horticultural Annual for 1867. If I can make this plant as popular as it deserves to be, and make people feel that no garden, not even the smallest, is "complete without it," I shall feel that I have done something to benefit floriculture.

TRIAL THINGS.—As spring comes on, or rather as time progresses, new seeds and the like come in for trial. It is very interesting work, this testing of novelties, but horribly time-consuming. The whole work from planting to testing the product requires personal attention, and can not well be delegated. There are very few men who can take ten varieties of potatoes, and give you at the end of the season the returns from each variety separate. Somehow they will get mixed, the labels will get knocked over, or something will happen, to make the experiments valueless. Thorburn & Co. have sent that remarkable collection of Laxton's new peas, which came out from England this year. The trial packet contains five varieties of less than a hundred peas each, and sells for five dollars. If I get a single pod as large as the one figured on the packet as "Laxton's Superlative, average size," I shall sing *peculiar pæans* to Thorburn and Laxton, and wish them great *pecuniary* reward. Dreer has sent beans, warranted to be of the snappiest sort. Henderson & Co. put me under obligation to *try* more new tomatoes, when I thought the Trophy indicated the end of the fight. R. H. Allen & Co., among other seeds, wish me to see what I can get out of—goodness gracious—a yellow-fleshed watermelon. Can a watermelon be good if it is not of the richest crimson? We'll see. Then Bliss & Sons have new revelations in the potato line, and Richardson & Gould send

COLOCASIA ESCULENTA, or **CALADIUM ESCULENTUM**, as some have it. These bulbs or rather tubers are so much out of the usual way, that they deserve a separate paragraph. Such bulbs! We think ourselves lucky if our home-grown

ones are as large as a turkey's egg, but these are as big as cocoanuts, which, as they came from South Carolina, shows what climate will do. We have not reached the end of the sweet-corn business, for here comes Nicholas Cole, of Pella, Iowa, with "General Grant" sweet corn, claimed to be "larger and sweeter" than any other. But I can not take space to enumerate all, and results of things tried will be of more interest than a list of things to be tried.

How many Strawberries to the Acre?

BY "NOVICE," ATHENS, TENN.

The yield of strawberries is a subject concerning which I am much in doubt. Of experience I have but little other than prospective, and the authorities within my reach "agree not together."

What is a reasonable yield per acre? All the evidence I can find is the following:

Andrew S. Fuller in his *Strawberry Culturist* says: "An acre of the best varieties of strawberries, properly cultivated on ordinary sandy loam, will in four years produce something like the following results: Three crops of 300 bushels each, 900 bushels," etc.

From the catalogue of Wm. Parry, of Cinnamon, N. J., I quote as follows: "We have grown on one third of an acre seventy bushels of strawberries, which was at the rate of two hundred and ten bushels or 6,720 quarts per acre, . . . and the premium crop of this country was at the rate of 263 bushels."

From a paper read before the Farmers' Club by Henry T. Williams I also quote: "On the light lands south of us the average number of quarts per acre is about one thousand. Very few fields average over 1,500."

This certainly is diversity, but I can not see the unity. Are these gentlemen correct in their statements? Mr. Fuller's imaginary results are 30 per cent greater than Mr. Parry's best actual results, and nearly 15 per cent better than the best known results as recorded by Mr. Parry—viz., "the premium crop of this country." And Mr. Williams's statement of the average yield of a large berry-growing district is only about one tenth of Mr. Fuller's imaginary crop, viz., 30½ bushels; while "very few fields average over" about one sixth of the same, viz., 47 bushels.

With this evidence before me, I can not well guess what a novice, with average common-sense and a disposition to do everything in the best possible manner, may expect as the result of his labors in the cultivation of strawberries.

REMARKS.—"Novice" does not seem to have taken into consideration the facts that there is great difference in the productiveness of different varieties of strawberries, and that the same variety may be very fruitful in one soil and climate and worthless in another. We have no doubt that all three of the gentlemen quoted are right. Mr. Fuller's estimate was probably made from the yield in the grounds he then occupied, a naturally strong soil in high cultivation; Mr. Parry shows what can be done in the light warm soils of Southern New Jersey; while Mr. Williams probably tells what he has seen in Delaware, where strawberry culture on the large scale is yet a new thing. Belmont, near Boston, is a great strawberry-growing place, and there from four to five thousand quarts to the acre is considered a fair average crop, but this is obtained with varieties which would probably not grow at all with our Tennessee friend. Fruit culture of all kinds is a matter of local experience, and one in which large sums have been lost by a premature counting of chickens.

If "Novice" has no near fruit-growing neighbor by whose experience he can profit, he must learn by experiment what varieties are adapted to his locality, and will give him the best results.

Growing Horseradish.

To answer many letters, we give in brief the following directions:

Around the City of New York the gardeners usually grow it as a second crop. The ground is very plentifully manured, and then marked off into rows one foot apart. Every alternate row is then planted with early cabbages, and after the plants are all set out the horseradish sets are planted in the intermediate rows at the distance of eighteen inches apart. If the horseradish starts too soon it is cut off in hoeing the cabbages, which does not injure the horseradish roots in the least. In July the cabbages are harvested and sold, and the ground is left entirely to the horseradish. Such, in short, is the method practiced around New York. As the farmer is supposed to produce only one crop from his land each year, he can manage the crop without so much labor. The soil must be deep, so as to allow the roots to penetrate a foot or more if possible. The sets which are planted consist of the small roots taken from the large ones, and are from four to six inches in length. In order to distinguish the bottom from the top end of the sets, a slanting cut is made across the lower end, while the top is cut off square. When planted upside down they will grow, but the roots are apt to be irregular and branching. These sets are planted in May, in rows two feet apart and eighteen inches between the plants. During the summer it is only necessary to keep the weeds down and the soil loose. Horseradish is not injured by frost, and may remain in the ground until quite late. Just before the ground closes up the roots are dug, and after trimming off the small rootlets for sets for planting the next season, the large roots are either stored in pits in the open ground, or preserved in sand in a cool, dry cellar. The small rootlets are preserved in sand, taking care not to make the layers of roots so large that they will heat.

Lawns and Grass-Plots.

There is no horticultural operation more likely to prove unsatisfactory to the amateur gardener than the making of a lawn. The uncertainty of the seasons, and the unreliable character of much of the seed, are against his success, and if his operations are upon old soil a host of weeds will take possession of the ground before the grass is visible. Perseverance will command success in lawn-making as in other matters, but we wish to advise the novice that establishing a lawn is not so easy as some represent it to be. In view of the difficulties of the case, we advise those who have small plots which they wish to convert into lawns to lay turf wherever it can be obtained of good quality and at not too great an expense. The soil which is to be sodded should be well enriched before the turf is laid, and the job well finished by beating or rolling, so as to bring the grass roots in close contact with the soil. In England a method of grassing lawns is successfully practiced which we have never tried, but which looks as if it might be useful. Sod is cut or broken into pieces three or four inches square and scattered over the surface, seed is then sown in the usual manner, and afterwards the surface is made even by rolling or beating.

Fuchsia Culture.

Whoever first recommended Fuchsias as bedding plants did them great injustice. There are few plants less fitted for the purpose—in our climate at least. They often become miserable-looking objects under our hot sun, refusing to flower, and often losing their foliage. Even where Fuchsias will flourish and bloom, it is a great mistake to use them as bedding plants, as their flowers have their beauty concealed by the foliage and their own pendent position. Fuchsias to be properly appreciated should stand well up, and if they can be placed as high as the level of the eye, or even higher, the better will they show. We advise our readers, instead of planting out the little specimens offered by florists, to give them larger pots, and to continue to grow them in pots or boxes. They grow rapidly, and yield readily to cutting and pinching, so they may be trained in any form that pleases the fancy. The majority of Fuchsias are summer-blooming, and should be kept dormant in a cellar during the winter. They are especially useful plants for the ornamentation of verandas, balconies, and like places. Large, well-grown plants placed at an entrance that is approached by a number of steps produce a fine effect, as here the flowers can be seen from below as one ascends the steps. The engraving represents the variety "Elm City," which, though not new, is one of the best.

DOUBLE FUCHSIA "ELM CITY."

Transplanting Beets and Ruta-Bagas.

Another year's experience makes us confident

BEET FOR TRANSPLANTING.

that the recommendation to grow mangolds, beets, and ruta-baga turnips by transplanting is

worthy of general adoption. The great labor of growing these crops is confined to their care while young. Single plants should be left finally from 12 to 15 inches apart in the row. By the

ordinary process, not only these plants but the great number that grow between them, must be carefully weeded and cultivated. By the transplanting process, the plants are grown in a seed-bed, where they are all preserved to repay the cost of their care. The seed is sown early in May, and while these plants are growing to the proper size for transplanting, the harrow is keeping the field free from weeds at a very cheap rate, and the setting out will require less labor and cost less money than would a single one of the three hand-hoings required in the other system. The transplanting is done late in June or early in July, according to the state of the plants in the seed-bed. As the plants are pulled the tap-root is cut off and the leaves shortened to four or six inches. The engraving shows by cross-lines how the plants are prepared for setting. The planting is done by means of a dibble. Furthermore, the plant is benefited rather than injured by being removed and trimmed, all the imperfectly developed plants are rejected, and the final result will be a much better crop than can be grown in any other way.

Expert Garden Workmen.

BY PETER HENDERSON.

In my long experience with workmen I have observed that, other things being equal, the man who could move his hands quickest, was almost certain to be the man most successful in life. Rapid movement of the hands in such light operations as writing or type-setting argue quick mental decision, and if such a mind is well balanced, its possessor is more likely to distinguish himself than he who moves more sluggishly. Now, two thirds of all garden operations—particularly those of flower-gardening—are as light as either writing or type-setting, and for many years I have taken great pains to stimulate my workmen to rapidity of movement in all our light work, and it is astonishing what the gain in labor has been in this particular. For example, the average work of a man planting cabbage or lettuce plants, when we began market-gardening, did not exceed 2,000 a day; now, and for many years past, a man, with a boy to drop the plants, will set 6,000 a day, and one of my old foremen, Jelu Scarry, now gardener to Dr. Thos. Vail, of Troy, N. Y., has repeatedly planted 10,000 in a day. And John Rielly, mention of whose wonderful success as a market-gardener has been before made in these columns, can tie up 1,200 bunches of celery in a day, while the average workman scarcely reaches 400. In the lighter work of our green-houses rapid movement is even of more importance, and the rivalry among our workmen for distinction in this matter is of great benefit to themselves as well as to us. The acknowledged champion, at present, of our whole force of forty men is a young Irishman, named James Markey. Jim, though not yet 25, has been with me a dozen years or more, and from the first has distinguished himself for doing all light operations quicker and better than any boy of his years, and probably to-day can make more cuttings, or pot more plants, in the same space of time, than any other man in America. It is very good average work for one man to pot off in 2 1/2-inch pots 2,000 cuttings in ten hours. Jim potted off one day of ten hours, this spring, 7,000, while his average work of this kind is 5,000 a day. Of course, such ability

THE MATTHEWS APPLE.—(See page 182.)

commands its price, and Jim is paid quite twice that of most of his fellows, and is much valued by me as an example well worthy of imitation.

THE HOUSEHOLD.

(For other Household Items, see "Basket" pages.)

Support for a Quilting-Frame.

In February we gave a simple device for supporting a quilting-frame, and this has reminded "A. K.," of Tullahoma, Tenn., of another. The engraving shows one of the two supports required. It is made of any light wood, three feet wide and four feet high. The poles to which the quilt is attached are round, seven feet long, or the desired length. In the cross-bars of the support, holes (*a*, *b*) are bored to receive the ends of these poles, which are inserted in them. Gimlet-holes are made at *c*,

SUPPORT FOR QUILTING-FRAME.

down through the support and into the poles. The quilt is fastened to the poles in the usual manner, and rolled up upon one of them, except so much as is required to allow the ends of the poles to go into their places in the supports. The quilt as the work progresses can be readily rolled from one pole upon the other, and by boring a few holes in the ends of the poles at *a*, *b*, it may be stretched and held in place by the insertion of wooden pegs or nails.

Hints for the Household.

BY MRS. N. W.

Washing.—Housekeepers will find it a great convenience to have two wash-boilers on washing day, one for re-heating the suds, while the other and larger one contains the boiled clothes. It is as handy as plenty of flat-irons on ironing day. Let the readers of the *Agriculturist* try it and see.

Potatoes.—Always add salt to the water while potatoes are boiling; boil moderately, not violently, and let them be only well covered with water.

Buckwheat Cakes.—Never make buckwheat cakes of buckwheat alone; make one part of corn-meal, two of wheat-flour, and three parts of buckwheat. They are then spongy, instead of being *flabby*.

Bread-Making.—In making bread always use potatoes or nice corn-meal. I do not feel as though I were doing the correct thing if I use only flour. The corn-meal need not be made into mush; scald it first in the mixing pan before adding the flour, then set in the usual manner. The most prejudiced person can not detect by the taste any corn in the bread, but there is an increased sweetness, and it keeps moist much longer. Of course, the best corn-meal must be used, not that rank chicken-feed kind. Besides the improvement in the bread, the flour-barrel holds out *much* longer, and health is promoted. I put about one part of corn to three parts of flour, when setting the sponge.

Odds and Ends.

We now and then look through the stock of our neighbor, W. H. Baldwin, No. 38 Murray st., to see what new devices are offered to facilitate household operations. There seem to be but few novelties this spring, but then there are scores of old things that are not generally known, but are most useful. In the time of spring cleaning and moving, carpets are to be taken up and put down again. The pro-

per putting down is much facilitated by a carpet-stretcher. In cities, those who make a business of putting down carpets, would as soon think of going to a job without a hammer, as without a stretcher.

A *stretcher* (fig. 1) is a blade of steel, about five inches long, with blunt teeth like saw-teeth. By means of a socket it is attached to a handle of convenient length. In use the teeth are pushed into the carpet several inches from the edge, and the carpet is stretched by a pushing motion, and held in place until the edge is tacked. One person can stretch while another

Fig. 1.—STRETCHER.

tack, or the handle of the stretcher may have a broad end and be held against the shoulder of the one who tacks. An implement to answer equally well with the one here figured may be made from an old saw-plate, screwed to a properly-shaped wooden handle. A carpet looks better and wears longer when properly stretched.

The Potato-Muddler, shown in fig. 2, is made of galvanized iron. Being heavier than the ordinary wooden one, it is claimed to do better execution.

Back-saving Dust-Pan. Some one has got out a "Patent Back-Saver," which consists of a dust-pan with high sides and a long handle, as shown in fig. 3. By resting the handle against a table or other piece of furniture, the dust may be swept into it, without the sweeper being obliged to stoop.

Home Topics.

BY FAITH ROCHESTER.

WHAT SHALL I GET FOR DINNER?—This question sometimes haunts me all the forenoon, until the moment arrives when it must be answered without delay. So long as it is an unsettled question, it interferes with any permanent peace of mind.

"Why not settle it at once, and have done with it?" asks Paterfamilias.

"Sure enough!" I answer. "Well, what would you like for dinner to-day?"

"Oh! most anything good to eat," he says. But when I press for more definite suggestions, I am asked, "What have you got in the house?"

A most sensible question. It is surprising to find how large the list is, even when we seem to be "out" of many things we like to keep on hand. I must write out a list again, as I have sometimes done before. A glance at this, once or twice a day, will help much toward that refreshing variety in our meals that I so much believe in. It jogs one's memory about putting asoak over night mackerel and such things as are seldom cooked because we forget to prepare them until it is too late.

One should always have on hand a variety of flour and meal—corn-meal, Graham, fine flour, cracked wheat (or wheaten grits), hominy, oat-meal, buckwheat flour. Then there are the various starch preparations. Two or three kinds should be kept in the house—rice, corn-starch, tapioca, sago, arrow-root, farina, Irish moss, etc. Of vegetables there should be plenty, and a large variety, and this is the proper time of year to look after that matter. The kitchen or vegetable garden greatly concerns the housekeeper's interests, and should be thought of in season. In May it ought to be yielding, as a result of last year's forethought, spinach, early beet tops, asparagus, parsnips, salsify (these last two out of the ground and in the cellar before they begin to sprout, of course), lettuce, radishes, horseradish. If proper care has been taken, we have still on hand potatoes, turnips, onions, carrots, cabbage, beans, dried sweet corn.

Fig. 2.—MUDDLER.

Fruit, of course, every day, and at nearly every meal, in some shape. Canned tomatoes should come in very often. With plenty of good milk and eggs, in addition to the above-named articles of diet, how bountifully we may live!

Concerning meats I will say little, knowing how much depends upon one's nearness to a good market, and not caring to say a single word in favor of the eternal and abominable pork that is such a staple in most farmers' families. Fish, poultry, and dried beef have their place, and may be prepared in various ways.

It is well to make out a list, each season, of the kinds of food available and suitable for that season. A weekly programme for the season, in addition to this, would simplify matters—good deal sometimes, especially where one has a good servant who likes to work without asking questions. It is not necessary to fill out the programme entirely, but there are some things we could have regularly once or twice a week, on definite days, and we should be almost sure of a better variety in our meals, if we adopted the programme-system. Some persons have this method in regard to the dessert only.

HELP FOR MOTHERS.—Was I going to suggest some helps for mothers who have their "hands and hearts full"? Oh! if mothers could only have a chance to be mothers to their children, in a large

human (as opposed to merely animal) sense! So far in the world's history extremely few women have had the proper culture and the requisite leisure for the highest duties of motherhood. With most of us, the necessary care for our children's physical needs comes about all our time and strength. Looking at the matter in a general way, it seems a very cruel thing that mothers should be so burdened, as most of them are, with housekeeping and social labors and duties, while their children are young and need a mother's constant vigilance and loving guidance. But when I look at specific cases—my own, for instance—I see that it can not well be helped, in the present condition of human affairs, and we must just do the best we can in the midst of our common difficulties.

Fig. 3.—DUST-PAN.

Good household helpers are scarce in the labor market, and sometimes the family purse is too slender to pay for all the help that is really needed.

I suppose there are indolent women enough, sweeping the city pavements with their costly garments, to justify a good deal of the talk we see in the papers about the extravagance and indolence of fashionable women, but farmers' wives generally need to be exhorted to rest more, rather than to do more work. Especially is this true of mothers. Good health is a foundation for that which goes by the name of "good nature." A half-sick woman will usually be irritable. When a loving and well-meaning mother finds herself "cross," she needs to pray for grace and something else—to pray in the most practical manner for plenty of help and plenty of rest—and for good diet and pure air, too.

When children are well the care of them is much easier and pleasanter than when they are nervous and peevish, because of physical disorder. A plain, wholesome diet, with plenty of pure air, bathing enough to keep their bodies clean, and a comfortable degree of warmth—these are the essentials for a child's good health, and consequent good nature.

We want to give our little children such advantages for mental cultivation as their tender years require. Very few of us are within reach of kin-

dergartens, but if we have caught something of the kindergarten spirit, it will be a help to us in any situation as mothers or teachers. To educate by means of play, or to turn a child's pleasures into its discipline—that is the secret. We should encourage our children to do *well* whatever they undertake to do. Slow and careful, rather than quick and careless. We should encourage or awaken in them a desire to know all about the materials they use and see around them.

Country children have a great advantage over city children, during the summer months at least. While quite young, they may become familiar with the names and uses of the trees, shrubs, herbs, birds, beasts, fishes, insects, etc., of their own vicinity. Good illustrated works on scientific subjects may be great helps to mothers. A microscope is much to be desired, especially for use in examining flowers and insects. I mentioned a globe last month.

Of children's playthings I have written before, and nothing new on that subject occurs to me at this time. Pictures are great educators, and care should be exercised in the selection of picture books. Most of the large primers with colored pictures are very poor trash. There are packs of fine cards to be found at most book-stores, representing animals, birds, flowers, and foreign people.

THE DISTRICT SCHOOL.—Whether our children attend this school or not, it is our business (yes, women, *ours*) to look after the interests of the public school—the swarms of little children there are going to rule the country, by and by. Our children, even if they do not belong to their number—as most of them do, no doubt—must associate with them in many ways.

But why do I appeal to such selfish motives? Are not all children "ours," in a large Christian sense? Are we not, each and all, parts of the society which ought to see that a fair chance is provided for every child to get a good education? There is no law to keep women away from the school meetings. Mothers would not be out of their sphere there, and certainly not in the school itself. We ought to make our teachers feel that we are interested and anxious about their performance of the very serious duties intrusted to them. No week of the school session should pass without a visit to the school from some woman in the district. If this were expected and likely to occur at any hour, the effect upon teacher and pupils would be excellent. It would benefit the whole neighborhood. Each one of us should use some influence in favor of genial, well-qualified teachers (with as little change as possible from one session to another) and pleasant, well-ventilated school-rooms, with tasteful and convenient grounds and out-buildings. The teacher should be one among us. A frank association between parents and teachers would be mutually beneficial. None of us have any more important business—no, not priests nor potentates—than the education of little boys and girls into a noble manhood and womanhood. It is business that everybody can engage in, for the little children we have always with us; and all that they see and hear helps to educate them.

GRAHAM BREAD.—One woman wishes to know how to make good Graham bread. It is never made successfully after the usual recipes for bread of fine flour. To all who have thoroughly tried the Graham *gems*, I think that form of Graham bread is most acceptable. The method of making these is very simple. The *essentials* are patty-pans, buttered and well heated, and a hot oven. Nothing else but the meal and water. Inexperienced persons will probably make the batter too stiff, and it may take them some time to learn that the gems seem lighter and *sweeter* if made without salt. I am no vegetarian, and use salt daily in my food, but I think it a mere superstition and a gastronomic mistake to put salt into some forms of bread.

Our inquirer may have no patty-pans (the iron clusters are best), or she may wish especially to learn how to make Graham bread with yeast.

In an August number of *Hearth and Home* for 1871, "Mrs. Hammond" gave a recipe, which is the best I have found. She always sifts Graham flour,

to make it light, but mixes the bran again thoroughly with the flour. This is an improvement, certainly. For one quart of flour thus prepared, use half a cup of good yeast and a little more than half a pint of warm water. Stir this well together at night, and set in a warm place. In the morning add more flour, but not too much to stir with a spoon—for Graham bread should not be kneaded. Stir it well, pour it into the pan, and let it rise an hour. Some prefer to steam Graham loaves, as well as those of corn-meal, before baking. This prevents the formation of the thick hard crust so dreaded by poor teeth. Many suppose that molasses is essential to good Graham bread, but some of the best cooks do not use it.

A KANSAS MOTHER ANSWERED.—A good letter comes to me from a woman in Kansas, who has four little children under seven years of age. She says, "I have my hands and heart full, and need all the helps in the way of instruction and amusement that I can get. If the Kindergarten gifts are not beyond my limited means, I shall have them sooner or later." She asks me to state in the *Agriculturist* where they can be obtained and what is their cost.

I am unable to give their precise cost. I think \$10 would purchase the whole set. Through the agency of a friend I obtained Weibe's Guide, or "Paradise of Childhood," and all the gifts except Nos. 12, 13, 16, 17, 18, and 20, for that sum. The American manufacturer is Milton Bradley, Springfield, Mass., where they can always be found. The express charges from Massachusetts to Kansas would amount to nearly three dollars.

I can not conscientiously *advise* this mother to procure these gifts and attempt to give her little ones the Kindergarten culture. She does indeed need "helps," and I know of no help so great, for mothers and children also, as the Kindergarten. But for the Kindergarten proper, we *must* have qualified gartners (or teachers), and there should be a group of children of the same age. Very few mothers are smart enough and wise enough to use the Kindergarten gifts successfully, without having had especial training for it. I could not, even during the few months after I first obtained them, while I had the care of only one four-year-old child. But I could make *some* use of them, and enough to make me feel more than paid for the trouble and expense they had cost. After grandma and annie gave back our younger child, it became extremely difficult to use the Kindergarten gifts for *lessons*. The little blocks are very small (cubic inches and their halves and quarters), and dimpled hands of less than two years' growth were capable of making sad havoc among them, unless there was close watching. Now another "wee one" claims her share of mamma's time and toil, and the Kindergarten gifts are seldom brought into use, except for what the children call "Kindergarten *plays*"—when they build whatever they choose of the blocks or tablets, sitting in high chairs beside the table. The perforating and weaving have given a good deal of pleasure and some good exercise to the eldest child, but he is such a woodsman and farmer now (since his father's business allows him to live with us again), that I am not called upon, as formerly, to provide almost constant employment.

I give my experience to those who care for it. I do believe most heartily in the Kindergarten proper. I think every child would be profited by such a course of training, occupying three hours daily for three or four years. Of late I have sometimes feared that what I have said in its favor may lead some mothers to attempt too much, and thus to lose faith in the Kindergarten itself (the garden of children with a skilled child-gardener). Here, for instance, is one who says she "has tried the Kindergarten and does not think much of it"! I have no idea that she has tried the genuine thing with such result.

I want every earnest person to hear of the Kindergarten, and think about it, and help prepare the way for it, but we can not all reap the direct benefits. Mrs. W. writes, "I hope the day is coming when *every* mother may be able to make her child's care and culture her daily *business*"—quoting from a former article of mine. "O woman! great is thy faith!" But not too great. It is com-

ing. You and I would like to *see* it, and it costs a struggle to admit that *our* darlings must fall short of the culture we would gladly give them.

But there is a deal of comfort—to me, at least—in the belief that it will not always be so. We human beings are gradually learning—never so fast as in our day—that *it pays to help each other!*

Another time, I think, I will suggest some "helps" to mothers who have their "hands and hearts full." I have scarcely room for any at present.

Economies in Furniture—Oilcloth.

BY CARRIE CLOVERNOOK.

One of our neighbors sent a set of chair-frames to the cabinetmaker's to be re-seated. The foreman told her he could not promise to do them, as he had plenty of more profitable work, but he would sell the canes for a trifle and could show her in a few minutes how to put them in as well as it would be done in his shop. The chair-frames were sent home, the advice taken, and before night they were almost as good as new. The same lady has an old arm-chair, with a splint seat, or rather that had one when it was new, and she said if she could fix that, she would be quite happy. I suggested that a piece of strong canvas, firmly hemmed on all its edges, could be used. It should be large enough to wrap about the rounds that once held the splints, then should be sewed with twine, putting the needle through the edge—the hem will prevent pulling or tearing—and also through the canvas above the round, inclosing it tightly. This will make a firm seat, and a cushion can be added, if desired. It is a pity to have such chairs disabled, for all the family enjoy them, and if thrown aside, the old people miss them sadly. I have seen rocking chairs made prettier than when new, by fastening canvas with small tacks where the canes had been, taking care to have the wood-work hid as little as possible. If a few layers of old quilts sewed together, for stuffing, be added, and the whole covered with rep or Brussels carpeting, the cushion is finished.

An old lady dropped in just at night, with her knitting, and her bit of good news was, that she had a nice piece of oilcloth for her kitchen stove, and it had not cost her a cent. A couple of yards of coarse haggling, such as covers packages of bathing, had been given her at the store, and a few strokes of Sam's hammer fastened it securely to the side of the barn. It was first brushed over with thin rye-paste; when this was thoroughly dry, it was given a coat of dark-brown paint, and when this was well dried, another coat was added. When these had hardened, the edges were trimmed and bound with narrow strips of tin. It was pronounced a success. As the materials for painting were in the house, she enjoyed telling to her friends how comfortable an article she had made without expense. I have often seen in print directions for making oilcloth, but never have noticed any which advised a coating of paste first, but my friend said that she was taught by one who had followed oilcloth making, and that it was a great improvement.

MOVING MARBLES AND MIRRORS.—In packing mirrors or marble for removal, they should be placed by themselves in a box, and fixed in their places by side-pieces and wedges, driven closely, and nailed; laths should be placed across mirrors, and no elastic materials, as pillows or featherbeds, be used in packing them. Marble should be put in a box by itself, wetted sheets of clean paper laid between the pieces, and each piece held firmly in its place by side-pieces and wedges. It may then be carried over a rough road in a wagon, without injury. Glass and china ware should be packed upon the same principle—that is, they should be so firmly fixed that it will be impossible for them to move and jar against one another. The way the packing material is crowded in, to make the whole firm, is of much more consequence than its quality or quantity. Newspapers, soft straw, or hay may be used; but, whatever the material may be, have every crevice filled, and all well packed.

BOYS & GIRLS' COLUMNS.

**The Boys and Girls' Pictures—
More Prizes Offered.**

When one has made a mistake, he should acknowledge it. I admit that I made a blunder about the boys and girls' pictures. I said that the time during which the stories could be received would be up May 1st. As the paper for May goes to press about the fifteenth of April you will see that I can not announce the awards until next month. I am very sorry for it, but I really intended to put it so that they could appear in this number. Let us have patience. There is such a quantity of letters, and they keep coming every day, that it will be a fine task to read them all.

Now, while we are waiting, let us be doing something. We wish to have another competition in progress, and what shall it be? I have it. Girls first. I wish from the girls a list of the flowers they have seen during the month of May. From the girls in the country I shall expect lists of wild-flowers. Those who live in towns and villages may, if they prefer it, put down cultivated flowers, but wild and garden flowers must not go upon the same list. Choose whether you will hunt up the wild ones, or prefer to name those that grow in your own and other people's gardens. Use the common or botanical names, as you prefer. In making up the awards not only will numbers be considered, but accuracy in spelling. It is understood that the list is to contain only the flowers that the writer has seen. Mind, it must include only plants that are actually seen in flower.

Now for the boys. Boys do not generally care much for flowers, I am sorry to say, and I must set them at some livelier work. Young gentlemen, we will have from you a list of all the native wild animals you have seen during the month of May, exclusive of insects. Birds, quadrupeds, snakes, lizards, etc., may come in, but no "bugs." This gives the country boys a great advantage over town-dwellers, and we must allow those who live in cities and towns to take their choice, and if they can not go often into the country to see the wild birds and quadrupeds, they must make lists of domesticated ones. As these lists will be very much smaller than the others, if a boy chooses to put down the tame animals only, he must then tell what country they originally came from.

Now, boys and girls, the object of this is to induce you to use your eyes and your tongues. If you do not know the name of a plant, a bird, or other object you wish to include in your list, ask some one who does. Try and get the right name, and then to write it down correctly. Recollect that these observations are to be continued during the month of May, and the lists must reach me by the fifteenth of June. The prizes for these will be books—good, new, and useful ones. The publishers are very liberal in such matters, and I shall give at least six books among the boys, and as many among the girls, making due allowance for ages. Now look at the offer for the prizes in March. The same conditions about writing, giving name and age, etc., mentioned there, will be observed now. In the story prizes, those with the liveliest imaginations had the best chance, but now the matter-of-fact youngsters, who go about with their eyes open, have something suited to their tastes. So, girls, start after the flowers, and, boys, "stir up the animals," and when you have found out all that the month of May can tell you, do you tell it to THE DOCTOR.

Addresses Wanted.—Letters sent by "The Doctor" to Miss Mary Ross, Iowa, and Edmund D. Redd, Va., have been returned from the post-office. His letters were directed according to the addresses given by them. Some mistake, children.

A Boys and Girls' Bird-House.

We call it a boys and girls' bird-house, because any boy with ingenuity can make it for his sister, or the two can own it in common. The drawings were sent by J. L. Hyde, Pomfret Landing, Ct., and there was nothing to show whether Mr. J. L. H. is one of our boys, or one who was a boy once. At all events, we are much obliged for his bird-house, and will tell you how he makes it. The foundation of the house is any convenient-sized box, such as may be had at the stores. A piece is nailed to each end, cut to the slope it is desired to have the roof. As the roof is to be thatched, it had better be pretty steep, as it will not only shed the rain the more easily, but the house will look better. The upper end of the pole which is to support the house is made square; it passes through a hole in the bottom of the box, and extends far enough above the ridge of the roof, to form the chimney. A ridge-pole is then passed through the upright pole and the end-pieces, as shown in figure 1. Places for the windows are to be cut out, but the doorway may be only a dummy,

and painted black. Birds are not very particular how they enter the house, and will go through a window just as well as a door. As we wish the house to have a pleasing appearance, we must cover it so as to represent a log-cabin. For this purpose small branches of any straight, easy-splitting wood are to be cut of the proper lengths, and split lengthwise, as in figure 2. These, with the bark on, are then to be fastened by small nails all over the ex-

Fig. 1.—FRAMEWORK OF BIRD-HOUSE.

terior of the house, as shown in figure 3. The roof is then to be thatched, and though Mr. H. draws it as done, he does not tell how to do it. We should tie the straw into small bundles with twine (tarred would be best), making them long enough to reach from one side of the house to the other, and to project well over to form the eaves. Then we should nail the bundles, one by one, to the upper edges of the box, and bind them at the top to the ridge-pole, by means of twine. The bundles must be crowded up close to one another, to prevent leaking. If this way of putting on the straw does not work, you can no doubt hit upon some other that will. The house may be divided up to accommodate several families. The lower

Fig. 3.—BIRD-HOUSE COMPLETE.

story may be so partitioned as to form four rooms, with an entrance-window to each, and the garret can have a division across it, and make two rooms, which can be entered by windows in the gable ends. The appearance of the house will be much improved, and it will stand the weather better, if the wood has a coating of painter's oil. Birds will like a house of this kind better than they will the showy-painted things that are often provided for them. When the house is in place, you can put "To Let" on it, if you choose, but the birds will come just as soon without it, and it is very amusing to see the little things out house-hunting. The enjoyment of a bird-house may be much increased, if you put in some quiet place near by a plenty of such materials as the birds use in making their nests; cut hay, locks of wool, old curled hair, shreds and ravelings of cloth, feathers, and the like, will all be acceptable. We had nearly forgotten one thing. The whole affair may be made much more ornamental by setting some climbing plants at the bottom of the pole. A hop-vine will grow very quickly, and make a fine mass of green. If strong strings or wires are attached near the top of the post, and their other ends fastened to pegs driven into the ground, you can plant morning-glory

Fig. 2.—SPLIT STICK.

seeds, and soon have a fine pyramid of vines, which in the early morning will be covered with flowers.

Aunt Sue's Puzzle-Box.

CROSS-WORD ENIGMA.

- My first is in want but not in need.
- My next is in oats but not in feed.
- My third is in snow but not in rain.
- My fourth is in wheat but not in grain.
- My fifth is in pink but not in black.
- My sixth is in rail but not in tack.
- My seventh is in good but not in nice.
- My eighth is in rats but not in mice.
- My ninth is in corn but not in rice.
- My tenth is in once but not in twice.
- My whole is a man well known to fame,
- And a city, too; now tell the name.

ELLA E. FARGO.

DIAMOND CROSS-PUZZLE.

- 1. A vowel. 2. Time past. 3. Something lean and thin.
- 4. Not assisted. 5. Having power to reduce. 6. Delightful.

BIG BOYS AND GIRLS NEED NOT READ THIS.

WILLIE H. K. says, "I wish I knew how to make out those numerical enigmas." Why, bless your dear little heart! come and sit down by me, and I will tell you all about it. First I will make an easy one for you:

I am composed of 17 letters:

- My 11, 2, 13, is yourself.
- My 5, 3, 8, 4, is what you like to read.
- My 6, 16, 9, is what you hear with.

[COPYRIGHT SEQUEED.]

THE WHISTLE-MAKERS.—Drawn and Engraved for the American Agriculturist.

My 17, 12, 14, 10, is a long stick.

My 1, 15, 16, 7, grows on trees and plants.

My whole is a proverb.

There: get your slate and pencil, and write down 17 figures across, in a row. Now, "my 11, 2, 13, is yourself," that must be "you;" so put down y, under 11; o, under 2; and u, under 13. Now, what do you "like to read"? "Robinson Crusoe." Yes, but we only want four letters; I guess it is "book," so put those letters down under 5, 3, 8, and 4. You know "what you hear with." What "grows on trees and plants"? "Fruit?" Yes, but we only want four letters: try something else. Now I shall leave you to find out the rest, and you must write and tell me how you succeeded.

AUNT SUE'S NOTICES TO CORRESPONDENTS.

J. P. Let me first see how you will "square BABA-LOU" yourself.

W. J. D. Where do you find "AIDE"?

J. T. McA. You sent no answers with your puzzles.

ANNA BELLE C. Thanks for your nice little letter, especially for the lock of hair. What possible good could it do you to know what my "last name" is? Would you be any happier, if you knew "for certain" that it was Brown, or Jones, or Snooks? Yes, "any one may answer puzzles."

MAY A. W. Of course, you "may make up puzzles for the *Agriculturist*," and if they are good ones they shall be published.

GLEBERT A. S. I am sorry that you can not forget little unpleasantnesses. My Southern nieces and nephews are just as dear to me as the Northern ones, perhaps a little dearer, on the principle of the misguided lambskin

that strayed away from the ninety and nine. You may remember how glad the folks were to welcome it home again.

Glad to hear from A. M. Rice, Alice C. Taylor, Belle R., C. W. J., M. H. E., Jessie D., Anna H., Geo. V. R., Jere P., A. B. Leach, S. G. T., and C. W. W.

Thanks for puzzles, etc., to R. T. Isbester, J. E. M., A. S. H., W. H. K., E. S. C., O. A. Gage, and W. E. W.

The Whistle-Makers.

We are sorry for the man who can not look back upon a scene similar to the one represented in the engraving, and remember it as one of the happiest of his life. It may be that there are some of our readers who have always lived in cities, or who have only gone to the country when mid-summer made the town too hot for them, who never made whistles. How little do those who only visit the country in mid-summer, know of its beauties! Our country boys and girls—for girls like to have whistles—well know that there is no more delightful season than that in which they make whistles. Boys have ball-time, kite-time, and marble-time, and I do not know why they should not have a whistle-time. There is a whistle-time, but I never heard it called by that name. It is only when all vegetation is awakening, when spring proper, not the spring of the almanacs, has really come, that whistles can be made. Willow makes the best whistles, though poplar will do very well, and as willows generally grow by the side of streams, whistle-makers are likely to be led to pleasant spots. I can well recollect the day when Joe, who was always scolding about "them ar young 'uns," and who always did what the "young

'uns" wanted him to do, sharpened our knives, and how Aunt Mary put up our lunch, and we all went off together where, as the Atwell boys said, the willows "grew prime." In those days boys did not say "bully," but "prime" and "hunkum" were the biggest words we knew the use of. It is so long ago! and yet the rippling laugh of the boys and girls and the laughing ripple of the brook ring in my old ears with a freshness that almost startles me. We made our whistles, listened to the birds, looked for the early flowers, and had just such a Saturday as only comes once in a lifetime. What matter if Joe did make that knife so sharp that it cut my fingers, was not E. there to tie it up? and if in my eagerness to make a large whistle it made a sound more like a bull-frog than a bird, did we not all laugh? I could find the very spot now. The brook, the willows, the birds, and the flowers, would all be there—everything, but the young hearts that made the place ever memorable. Of all the half-dozen whose whistles and whose shouts made the time so merry, I can tell you of the whereabouts of but one, and he sits here, renewing the pleasures of his youth in thinking of the many happy whistle-making parties his boys and girls will have in these bright spring days.

Don't suppose I am going to tell you how to make a whistle. In my boy-days the worst thing that could be said of a stupid fellow was, "He don't know enough to make a poplar whistle." I really don't know how boys learn all about these things. The selection of the twig, the shaping of the mouth-piece, then the hammering of the bark, to make it slip off, and the final proper shaping of the wood—I can not recollect how I learned them any more than boys can now tell how they know when top-time comes.

EARTH-CLOSET COMPANY,
31 Cortlandt st., New York.

The uniform success of the Clipper Mowers in the field, the testimony of every farmer who has used them, that they are the *lightest in draft, the most durable, and the most economical* machine for the farmer to buy, fully substantiates what the proprietors have always claimed—that the Clipper is the **Best Mower in the World.**

To the No. 4 size is attached the Dropper (cutting 3/4 feet, with separate Finger-Bar for reaping), constructed with great improvements—in fact perfected; and in point of efficiency, strength, lightness of draft, and symmetry of proportions, it is, as a Reaper, also unequalled. Farmers! see it before you buy. Pass your own judgment upon it. Look at its many improvements possessed by no other machine. Remember, it is fully warranted. Send for Pamphlet.

THE CLIPPER MOWER & REAPER CO.,
P. O. Box 6, 173, 151 Chambers st., New York.

THE American Hay Tedder.

Enables the most important Agricultural product of America to be cut, cured, and stored in the barn in one day. Improves the quality and increases the value of the hay crop. Prevents all risk of damage from storms and sudden showers. Is simple, durable, and of light draft. Was awarded the New England Agricultural Society's only first prize, at the Great Field Trial, at Amherst, Mass., as being superior to all others, and the best and only perfect machine for tedding or turning hay.

Johnston's Self-Raking Reaper

is so well known among grain-growers generally, that it needs no extended heralding in print.

As manufactured by us, it is the only Reaper that will save the entire crop when badly lodged.

We warrant it to cut any grain that grows, and in any condition.

A pair of ordinary horses and a boy to drive it will cut from 10 to 20 acres a day in the most satisfactory manner.

Send for illustrated pamphlet.

ESSEX PIGS.

Last year, several readers of the *American Agriculturist* purchased Essex pigs from me.

So far as I have heard, they have given good satisfaction. I keep only pure Essex, and breed them with great care.

Last spring, I could not fill all my orders, and, much to my own regret and the loss of the intending purchaser, was obliged to return the money.

This spring I expect to be able to furnish very superior pigs, and shall be glad if those wishing to buy pure Essex from me will order early.

WITH BENCH,
IS THE
MOST PRACTICAL CLOTHES-WRINGER IN USE.

It is securely attached to a Bench, on which comes all the strain in wringing clothes. The tubs are unnumbered, and are free to be emptied or used for any other purpose. It has our Patent Flange Cog-Wheels on both ends of the Rolls, and a Tipping Water-Board for conducting the water on either side of the Wringer, as desired.

This Wringer is strong, durable, and will last a life-time.

EVERY HOUSEWIFE SHOULD HAVE ONE. It will save labor. It will save time. It will save its cost every year.

Sold Everywhere.
BAILEY WASHING & WRINGING MACHINE CO., 102 Chambers St., N. Y.

CHEAP CORN CULTURE.
THOMAS' SMOOTHING HARROW
81 SLANTING TEETH OF TEMPERED STEEL \$25

LATE SPRING! CROWDED WORK!
This year a large amount of work must be done in a very short time. With our wide HARROW more than twice as much ground can daily be prepared for seed as without it, and all crops HEAVILY CULTIVATED through the season in a SUPERIOR manner.
ALLEN HIGLEY Windsor, Ohio, says: "I saved half month's labor in two days, getting a much better crop without using a hoe."
ANDREW RAESSLER, Shelbyville, Ill., says: "I can harrow twice as much ground with it as with other harrows."
EDWIN THORNE, Millbrook, N. Y., says: "We can dispense with cultivating once each way, saving a vast amount of labor."
E. F. SMITH, Morning Sun, Iowa, says: "It was much easier on the team, though one third wider, doing more work."
L. R. AUSTIN, Coldwater, Mich., says: "I have a 40 and a 30-tooth square drag; but with your harrow can do twice the work in half the time."
IRA BEARD, Caloka, Mo.: "I think it equal to three common harrows."
F. PETIT, Salem, N. J.: "My brother says his does the work of three old harrows. Mine, I think, saved me \$5 in 1 1/2 hours' work."
BOYS BIDE AND DO ALL THE HARROWING.
24-page catalogue; eleven pages farmers' experience.

900,000 ACRES

OF
**EXCELLENT FARMING
AND SPLENDID**

Michigan Pine Lands

FOR SALE.

On which are **ONE THOUSAND MILLIONS OF PINE TIMBER**, and inexhaustible quantities of Maple, Beech, Elm, Ash, Hemlock, Oak, etc.

The grant of lands to the Grand Rapids and Indiana Railroad Company, to build their Road from Fort Wayne, Ind., to Traverse Bay and Mackinaw, Michigan, comprises in its farming lands every variety of soil, from the rich clay loam to the light sandy, and they are found in that section of Michigan, north of the city of Grand Rapids, and contiguous to the great fruit belt on the eastern shores of Lake Michigan, now being rapidly developed by railroad and other enterprises.

Farming Lands are sold to actual settlers, on credit, one quarter down, balance in yearly payments, interest 7 per cent. Persons desiring of locations for farms will, on application at the **Office in Grand Rapids**, be furnished with **Tickets over the Road**, in the event of purchasing any of the Company's farming land. For information about the lands, prices, location, etc., etc., address

Wm. A. HOWARD, Land Commissioner,
TITHE PERFECT. Grand Rapids, Michigan.

MARION

UNITED STATES WATCH CO'S WATCHES.

REPORT OF JUDGES

TO THE GENERAL COMMITTEE

CINCINNATI INDUSTRIAL EXPOSITION:

GENTLEMEN—The Judges appointed to examine into the merits of the articles contained in Class 10, beg leave to make the following report:

*No. 1650 United States Watch Company,
Marion, New Jersey. These watch movements,
the result of American capital, skill and
perseverance as specimens of this branch
of science and manufacture rival those
of European make. The watches exhibited by
this Company are of all grades, from that
of the most exact timekeeper, to the cheaper
kind for the millions. All are excellent of the
kind, and are too well known and appreciated
by the people to need further comment.
First Premium is awarded to the
United States Watch Company.*

*C. J. Payne
James Powell
William H. Davis* } Judges

Price Lists furnished the Trade on application, inclosing business card. For sale by the Trade generally.

Ask your Jeweler to see the MARION

WATCHES.

BEWARE of worthless imitations with which the country is flooded. To avoid imposition, see that the words MARION, N. J., are engraved on the plate over the Main-Spring Barrel. All others are spurious.

GILES, WALES & CO.

No. 13 Maiden Lane, New York.

E. BUTTERICK & CO.'S PATTERNS.

Why they are Superior to all Others.

FIRST.

They are reliable, each Pattern having been *practically tested* before being offered for sale.

SECOND.

They are in all sizes, so that any one can obtain a Pattern requiring little variation.

THIRD.

Each Pattern has a printed label, showing its size, the amount of Cloth, Trimming, etc., required, with necessary instructions for cutting and making, and a picture of the garment when finished.

FOURTH.

They are more perfectly cut than they can be by the ordinary method, *each part being perfect and fitted*. The difficult parts are notched so as to be easily put together.

NOTICE THIS.

 *Each of our Patterns has the name of the Proprietors printed on the label. Any others are spurious.*

The End of the World.

A LOVE STORY.*

BY EDWARD EGGLESTON.

CHAPTER I.

IN LOVE WITH A DUTCHMAN.

"I don't believe that you'd care a cent if she did marry a Dutchman! She might as well as to marry some white folks I know."

Samuel Anderson made no reply. It would be of no use to reply. Shrews are tamed only by silence. Anderson had long since learned that the little shred of influence which remained to him in his own house would disappear whenever his teeth were no longer able to shut his tongue securely in. So now, when his wife poured out this hot lava of *argumentum ad hominem*, he closed the teeth down in a deadlock way over the tongue, and compressed the lips tightly over the teeth, and shut his finger-nails into his work-hardened palms. And then, distrusting all these precautions, fearing lest he should be unable to hold on to his temper even with this grip, the little man strode out of the house with his wife's shrill voice in his ears.

Mrs. Anderson had good reason to fear that her daughter was in love with a "Dutchman," as she phrased it in her contempt. The few Germans who had penetrated to the West at that time were looked upon with hardly more favor than the Californians feel for the almond-eyed Chinaman. They were foreigners, who would talk gibberish instead of the plain English which everybody could understand, and they were not yet civilized enough to like the yellow saleratus-biscuit and the "salt-rising" bread of which their neighbors were so fond. Reason enough to hate them!

Only half an hour before this outburst of Mrs. Anderson's, she had set a trap for her daughter Julia, and had fairly caught her.

"Jule! Jule! O Jul-y-ee!" she had called. And Julia, who was down in the garden hoeing a bed in which she meant to plant some "Johnny-jump-ups," came quickly toward the house, though she knew it would be of no use to come quickly. Let her come quickly, or let her come slowly, the rebuke was sure to greet her all the same.

"Why don't you come, when you're called, I'd like to know! You're never in reach when you're wanted, and you're good-for-nothing when you are here!"

Julia Anderson's earliest lesson from her mother's lips had been that she was good for nothing. And every day and almost every hour since had brought her repeated assurances that she was good for nothing. If she had not been good for a great deal, she would long since have been good for nothing as the result of such teaching. But though this was not the first, nor the thousandth, nor the ten thousandth time that she had been told that she was good for nothing, the accustomed insult seemed to sting her now more than ever. Was it that, being almost

eighteen, she was beginning to feel the woman blossoming in her nature? Or, was it that the tender words of August Wehle had made her sure that she was good for something, that now her heart felt her mother's insult to be a stale, selfish, ill-natured lie?

"Take this cup of tea over to Mrs. Malcolm's, and tell her that it a'n't quite as good as what I horried of her last week. And tell her that they'll be a new-fangled preacher at the school-house a Sunday, a Millerite, or somethin', a preachin' about the end of the world."

Julia did not say "Yes, ma'am," in her usually meek style. She smarted a little yet from the harsh words, and so went away in silence.

Why did she walk fast? Had she noticed that August Wehle, who was "breaking up" her father's north field,

TAKING AN OBSERVATION.

was just plowing down the west side of his land? If she hastened, she might reach the cross-fence as he came round to it, and while he was yet hidden from the sight of the house by the turn of the hill. And would not a few words from August Wehle be pleasant to her ears after her mother's sharp depreciation? It is at least safe to conjecture that some such feeling made her hurry through the long, waving timothy of the meadow, and made her cross the log that spanned the brook without ever so much as stopping to look at the minnows glancing about in the

life she had never before crossed the meadow brook without stooping to look at the minnows.

All this haste Mrs. Anderson noticed. Having often scolded Julia for "talking to the fishes like a fool," she noticed the omission. And now she only waited until Julia was over the hill to take the path round the fence under shelter of the blackberry thicket, until she came to the clump of elders, from the midst of which she could plainly see if any conversation should take place between her Julia and the comely young Dutchman.

In fact, Julia need not have hurried so much. For August Wehle had kept one eye on his horses and the other on the house all that day. It was the quick look of intelligence between the two at dinner that had aroused the mother's suspicions. And Wehle had noticed the work on the garden bed, the call to the house, and the starting of Julia on the path toward Mrs. Malcolm's. His face had grown hot, and his hand had trembled. For once he had failed to see the stone in his way, until the plow was thrown clean from the furrow. And when he came to the shade of the butternut-tree by which she must pass, it had seemed to him imperative that the horses should rest. Besides, the harness-string wanted tightening on the bay, and old Dick's throat-latch must need a little fixing. He was not sure that the clevis-pin had not been loosened by the collision with the stone just now. And so, upon one pretext and another, he managed to delay starting his plow until Julia came by, and then, though his heart had counted all her steps from the door-stone to the tree, then he looked up surprised. Nothing could be so astonishing to him as to see her there! For love is needlessly crafty, it has always an instinct of concealment, of disguise, of indirection about it. The boy, and especially the girl, who will tell the truth in regard to a love affair is a miracle of veracity. But there are such, and they are to be revered—with the reverence paid to martyrs.

On her part, Julia Anderson had walked on as though she meant to pass the young plowman by, until he spoke, and then she started, and blushed, and stopped, and nervously broke off the top of a last year's iron-weed, and began to break it into bits while she talked, looking down most of the time, but lifting her eyes to his now and then. And to the sun-browned but delicate-faced young German it seemed a vision of Paradise—every glimpse of that fresh girl's face in the deep shade of the sun-bonnet. For girls' faces can never look so sweet in this generation as they did to the boys who caught sight of them, hidden away, precious things, in the obscurity of a tunnel of pasteboard and calico!

This was not their first love-talk. Were they engaged? Yes, and no. By all the speech their eyes were capable of in school, and of late by words, they were engaged in loving one another, and in telling one another of it. But they were young, and separated by circumstances, and they had hardly begun to think of marriage yet. It was enough for the present to love and be loved. It is the most delightful stage of a love-affair when the present is sufficient, and there is no past or future. And so August lung his elbow around the top of the bay horse's

hames, and talked to Julia. It is the highest praise of the German heart that it loves flowers and little children; and like a German and like a lover that he was, August began to speak of the anemones and the violets that were already blooming in the corners of the fence. Girls in love are not apt to say anything very fresh. And Julia only said she thought the flowers seemed happy in the sunlight. In answer to this speech, which seemed to the lover a bit of inspiration, he quoted from Schiller the lines:

"Yet weep, soft children of the spring;
The feelings Love alone can bring
Have been denied to you!"

With the quick and crafty modesty of her sex, Julia evaded this

very pleasant shaft by saying: "How much you know, August! How do you learn it?"

And August was pleased, partly because of the compliment, but chiefly because in saying it Julia had

A TALK WITH A PLOWMAN.

water flecked with the sunlight that struggled through the boughs of the water-willows. For, in her thorough loneliness, Julia Anderson had come to love the birds, the squirrels, and the fishes as companions, and in all her

* Entered, according to Act of Congress, in the year 1872, by ORANGE Judd & Co., in the Office of the Librarian of Congress, at Washington.

brought the sun-bonnet in such a range that he could see the bright eyes and blushing face at the bottom of this camera obscura. He did not hasten to reply. While the vision lasted he enjoyed the vision. Not until the sun-bonnet dropped did he take up the answer to her question.

"I don't know much, but what I do know I have learned out of your Uncle Andrew's books."

"Do you know my Uncle Andrew? What a strange man he is! He never comes here and we never go there and my mother never speaks to him, and my father doesn't often have anything to say to him. And so you have been at his house.

They say he has all up-stairs full of books, and ever so many cats and dogs and birds and squirrels about. But I thought he never let anybody go up-stairs."

"He lets me," said August, when she had ended her speech and dropped her sun-bonnet again out of the range of his eyes, which, in truth, were too steadfast in their gaze. "I spend many evenings up-stairs." August had just a trace of German in his idiom.

"What makes Uncle Andrew so curious, I wonder?"

"I don't exactly know. Some say he was treated not just right by a woman when he was a young man. I don't know. He seems happy. I don't wonder a man should be curious though when a woman that he loves treats him not just right. Any way, if he loves her with all his heart, as I love Julie Anderson!"

These last words came with an effort. And Julia just then remembered her errand, and said, "I must hurry," and, with a country girl's agility, she climbed over the fence before August could help her, and gave him another look through her bonnet-telescope from the other side, and then hastened on to return the tea, and to tell Mrs. Malcolm that there was to be a Millerite preacher at the school-house on Sunday night. And August found that his horse was quite cool, while he was quite hot. He cleaned his mold-board and swung his plow round, and then, with a "Whoa! haw!" and a pull upon the single line which Western plowmen use to guide their horses, he drew the team into their place, and set himself to watching the turning of the rich, fragrant black earth. And even as he set his plowshare, he set his purpose to overcome all obstacles, and to marry Julia Anderson. With the same steady, irresistible, onward course would he overcome all that lay between him and the soul that shone out of the face that dwelt in the bottom of the sun-bonnet.

From her covert in the elder-bushes Mrs. Anderson had seen the parley, and her cheeks had also grown hot, but from a very different emotion. She had not heard the words. She had seen the loitering girl and the loitering plowboy, and she went back to the house vowing that she'd "teach Julie Anderson how to spend her time talking to a Dutchman." And yet the more she thought of it, the more she was satisfied that it wasn't best to "make a fuss" just yet. She might hasten what she wanted to prevent. For though Julia was obedient and mild in word, she was none the less a little stubborn, and in a matter of this sort might take the bit in her teeth.

And so Mrs. Anderson had recourse, as usual, to her husband. She knew she could browbeat him. She demanded that August Wehle should be paid off and discharged. And when Anderson had hesitated, because he feared he could not get another so good a hand, and for other reasons, she burst out into the declaration:

"I don't believe that you'd care a cent if she did marry a Dutchman! She might as well as to marry some white folks I know."

CHAPTER II.

AN EXPLOSION.

It was settled that August was to be quietly discharged at the end of his month, which was Saturday night. Neither he nor Julia must suspect any opposi-

tion to their attachment, nor any discovery of it, indeed. This was settled by Mrs. Anderson. She usually settled things. First, she settled upon the course to be pursued. Then she settled her husband. He always made a show of resistance. His dignity required a show of resistance. But it was only a show. He always meant to surrender in the end. Whenever his wife ceased her fire of small-arms and herself hung out the flag of truce, he instantly capitulated. As in every other dispute, so in this one about the discharge of the "miserable, impudent Dutchman," Mrs. Anderson attacked her

in front of the house. Cynthia Ann was getting dinner in the kitchen at the other end of the hall, and Mrs. Anderson was busy in her usual battle with dirt. She kept the house clean, because it gratified her combativeness and her domineering disposition to have the house clean in spite of the ever-encroaching dirt. And so she scrubbed and scolded, and scolded and scrubbed, the scrubbing and scolding agreeing in time and rhythm. The scolding was the vocal music, the scrubbing an accompaniment. The concordant discord was perfect. Just at the moment I speak of there was a lull in her

scolding. The symphonious scrubbing went on as usual. Julia, wishing to divert the next thunder-storm from herself, erected what she imagined might prove a conversational lightning-rod, by asking a question on a topic foreign to the theme of the last march her mother had played and sung so sweetly with brush and voice.

"Mother, what makes Uncle Andrew so queer?"

"I don't know. He was always queer." This was spoken in a staccato, snapping-turtle way. But when one has lived all one's life with a snapping-turtle, one doesn't mind. Julia did not mind. She was curious to know what was the matter with her uncle, Andrew Anderson. So she said:

"I've heard that

some woman treated him cruelly; is that so?" Julia did not see how red her mother's face was, for she was not regarding her.

"Who told you that?" Julia was so used to hearing her mother speak in an excited way that she hardly noticed the strange tremor in this question.

"August."

The symphony ceased in a moment. The scrubbing-brush dropped in the pail of soapsuds. But the vocal storm burst forth with a violence that startled even Julia.

"August said that, did he? And you listened, did you? You listened to that? You listened to that? You listened to that? Hey? He slandered your mother. You listened to him slander your mother!" By this time Mrs. Anderson was at white heat. Julia was speechless. "I saw you yesterday flirting with that Dutchman, and listening to his abuse of your mother! And now you insult me! Well, to-morrow will be the

A LITTLE RUSTLE BROUGHT HER TO CONSCIOUSNESS.

husband at all his weak points, and she had learned by heart a catalogue of his weak points. Then, when he was sufficiently galled to be entirely miserable; when she had expressed her regret that she hadn't married somebody with some heart, and that she had ever left her father's house, for her father was always good to her; and when she had sufficiently reminded him of the lover she had given up for him, and of how much he had loved her, and how miserable she had made him by loving Samuel Anderson—when she had conducted the quarrel through all the preliminary stages, she always carried her point in the end by a *coup de partie* somewhat in this fashion:

"That's just the way! Always the way with you men! I suppose I must give up to you as usual. You've lorded it over me from the start. I can't even have the management of my own daughter. But I do think that after I've let you have your way in so many things, you might turn off that fellow. You might let me have my way in one little thing, and you would if you cared for me. You know how liable I am to die at any moment of heart-disease, and yet you will prolong this excitement in this way."

Now, there is nothing a weak man likes so much as to be considered strong, nothing a henpecked man likes so much as to be regarded a tyrant. If you ever hear a man boast of his determination to rule his own house you may feel sure that he is subdued. And a hen-pecked husband always makes a great show of opposing everything that looks toward the enlargement of the work or privileges of women. Such a man always insists on the shadow of authority because he can not have the substance. It is a great satisfaction to him that his wife can never be president, and that she can not make speeches in prayer-meeting. While he retains these badges of superiority, he is still in some sense head of the family.

So when Mrs. Anderson loyally reminded her husband that she had always let him have his own way, he believed her because he wanted to, though he could not just at the moment recall the particular instances. And knowing that he must yield, he rather liked to yield as an act of sovereign grace to the poor oppressed wife who begged it.

"Well, if you insist on it, of course, I will not refuse you," he said; "and perhaps you are right." He had yielded in this way almost every day of his married life, and in this way he yielded to the demand that August should be discharged. But he agreed with his wife that Julia should not know anything about it, and that there must be no leave-taking allowed.

The very next day Julia sat ewing on the long porch

GOTTLIEB.

last day that that Dutchman will hold a plow on this place. And you'd better look out for yourself, miss!

Here followed a volley of epithets which Julia received standing. But when her mother's voice grew to a scream, Julia took the word.

"Mother, hush!"

It was the first word of resistance she had ever uttered. The agony within must have been terrible to have wrung it from her. The mother was stunned with anger

and astonishment. She could not recover herself enough to speak until Jule had fled half-way up the stairs. Then her mother covered her defeat by screaming after her, "Go to your own room, you impudent hussy! You know I am liable to die of heart-disease any minute, and you want to kill me!"

CHAPTER III.

A FAREWELL.

Mrs. Anderson felt that she had made a mistake. She had not meant to tell Julia that August was to leave. But now that this stormy scene had taken place, she thought she could make a good use of it. She knew that her husband co-operated with her in her opposition to "the Dutchman," only because he was afraid of his wife. In his heart, Samuel Anderson could not refuse anything to his daughter. Denied any of the happiness which most men find in loving their wives, he found consolation in the love of his daughter. Secretly, as though his paternal affection were a crime, he caressed Julia, and his wife was not long in discovering that the father cared more for a loving daughter than for a shrewish wife. She watched him jealously, and had come to regard her daughter as one who had supplanted her in her husband's affections, and her husband as robbing her of the love of her daughter. In truth, Mrs. Samuel Anderson had come to stand so perpetually on guard against imaginary encroachments on her rights, that she saw enemies everywhere. She hated Wehle because he was a Dutchman; she would have hated him on a dozen other scores if he had been an American. It was offense enough that Julia loved him.

So now she resolved to gain her husband to her side by her version of the story, and before dinner she had told him how August had charged her with being false and cruel to Andrew many years ago, and how Jule had thrown it up to her, and how near she had come to dropping down with palpitation of the heart. And Samuel Anderson reddened, and declared that he would protect his wife from such insults. The notion that he protected his wife was a pleasant fiction of the little man's, which received a generous encouragement at the hands of his wife. It was a favorite trick of hers to throw herself, in a metaphorical way, at his feet, a helpless woman, and in her feebleness implore his protection. And Samuel felt all the courage of knighthood in defending his inoffensive wife. Under cover of this fiction so flattering to the vanity of an overawed husband, she had managed at one time or another to embroil him with almost all the neighbors, and his refusal to join fences had resulted in that crooked arrangement known as a "devil's lane" on three sides of his farm.

Julia dared not stay away from dinner, which was miserable enough. She did not venture so much as to look at August, who sat opposite her, and who was the most unhappy person at the table, because he did not know what all the unhappiness was about. Mr. Anderson's brow foreboded a storm. Mrs. Anderson's face was full of an earthquake, Cynthia Ann was sitting in shadow, and Julia's countenance perplexed him. Whether she was angry with him or not, he could not be sure. Of one thing he was certain: she was suffering a great deal, and that was enough to make him exceedingly unhappy.

Sitting through his hurried meal in this atmosphere surcharged with domestic electricity, he got the notion—he could hardly tell how—that all this lowering of the sky had something to do with him. What had he done? Nothing. His closest self-examination told him that he had done no wrong. But his spirits were depressed, and his sensitive conscience condemned him for some unknown crime that had brought about all this disturbance of the elements. The ham did not seem very good, the cabbage he could not eat, the corn-dodger choked him, he had no desire to wait for the pie. He abridged his meal, and went out to the barn to keep company with his horses and his misery until it should be time to return to his plow.

Julia sat and sewed in that tedious afternoon. She would have liked one more interview with August before he left. Looking through the open hall, she saw him leave the barn and go toward his plowing. Not that she looked up. Hawk never watched chicken more closely than Mrs. Anderson watched poor Jule. But out of the corners of her eyes Julia saw him drive his horses before him from the stable. As the field in which he worked was on the other side of the house from where she sat she could not so much as catch a glimpse of him as he held his plow on its steady course. She wished she might have helped Cynthia Ann in the kitchen, for then she could have seen him, but there was no chance for such a transfer.

Thus the tedious afternoon wore away, and just as the sun was settling down so that the shadow of the elm in the front-yard stretched across the road into the cow-pasture, the dead silence was broken. Julia had been wishing that somebody would speak. Her mother's

sulky speechlessness was worse than her scolding, and Julia had even wished her to resume her storming. But the silence was broken by Cynthia Ann, who came into the hall and called, "Jule, I wish you would go to the barn and gether the eggs; I want to make some cake."

Every evening of her life Julia gathered the eggs, and there was nothing uncommon in Cynthia Ann's making cake, so that nothing could be more innocent than this request. Julia sat opposite the front-door, her mother sat farther along. Julia could see the face of Cynthia Ann. Her mother could only hear the voice, which was dry and commonplace enough. Julia thought she detected something peculiar in Cynthia's manner. She would as soon have thought of the big oak gate-posts with their round ball-like heads telegraphing her in a sly way, as to have suspected any such craft on the part of Cynthia Ann, who was a good, pious, simple-hearted, Methodist old maid, strict with herself, and censorious toward others. But there stood Cynthia making some sort of gesture, which Julia took to mean that she was to go quick. She did not dare to show any eagerness. She laid down her work, and moved away listlessly. And evidently she had been too slow. For if August had been in sight when Cynthia Ann called her, he had now disappeared on the other side of the hill. She loitered along, hoping that he would come in sight, but he did not, and then she almost smiled to think how foolish she had been in imagining that Cynthia Ann had any interest in her love-affair. Doubtless Cynthia sided with her mother.

And so she climbed from mow to mow gathering the eggs. No place is sweeter than a mow, no occupation can be more delightful than gathering the fresh eggs—great glorious pearls, more beautiful than any that men dive for, despised only because they are so common and so useful! But Julia, gliding about noiselessly, did not think much of the eggs, did not give much attention to the hens scratching for wheat kernels amongst the straw, nor to the barn swallows chattering over the adobe dwellings which they were building among the rafters above her. She had often listened to the love-talk of these last, but now her heart was too heavy to hear. She slid down to the edge of one of the mows, and sat there a few feet above the threshing-floor with her bonnet in her hand, looking off sadly and vacantly. It was pleasant to sit here alone and think, without the feeling that her mother was penetrating her thoughts.

A little ruelle brought her to consciousness. Her face was fiery red in a minute. There, in one corner of the threshing-floor, stood August, gazing at her. He had come into the barn to find a single-tree in place of one which had broken. While he was looking for it, Julia had come, and he had stood and looked, unable to decide whether to speak or not, uncertain how deeply she might be offended, since she had never once let her eyes rest on him at dinner. And when she had come to the edge of the mow and stopped there in a reverie, August had been utterly spell-bound.

A minute she blushed. Then, perceiving her opportunity, she dropped herself to the floor and walked up to August.

"August, you are to be turned off to-morrow night."

"What have I done? Anything wrong?"

"No."

"Why do they send me away?"

"Because—because—" Julia stopped.

But silence is often better than speech. A sudden intelligence came into the blue eyes of August. "They turn me off because I love Jule Anderson."

Julia blushed just a little.

"I will love her all the same when I am gone. I will always love her."

Julia did not know what to say to this passionate speech, so she contented herself with looking a little grateful and very foolish.

"But I am only a poor boy, and a Dutchman at that"—he said this bitterly—"but if you will wait, Jule, I will show them I am of some account. Not good enough for you, but good enough for them. You will—"

"I will wait—forever—for you, Gus." Her head was down, and her voice could hardly be heard. "Good-by." She stretched out her hand, and he took it trembling.

"Wait a minute." He dropped the hand and taking a pencil wrote on a beam:

"March 18th, 1843."

"There, that's to remember the Dutchman by."

"Don't call yourself a Dutchman, August. One day in school, when I was sitting opposite to you, I learned this definition. 'August: grand, magnificent,' and I looked at you and said, Yes, that he is. August is grand and magnificent, and that's what you are. You're just grand!"

I do not think he was to blame. I am sure he was not responsible. It was done so quickly. He kissed her forehead and then her lips, and said good-by and was gone. And she, with her apron full of eggs and her cheeks very red—it makes one warm to climb—went back to the house, resolved in some way to thank

Cynthia Ann for sending her, but Cynthia Ann's face was so serious and austere in its look that Julia concluded she must have been mistaken, Cynthia Ann couldn't have known that August was in the barn. For all she said was:

"You got a right smart lot of eggs, didn't you? The hens is beginning to lay more peart since the warm spell set in."

CHAPTER IV.

A COUNTER-IRRITANT.

"Vot you kits doernt of vor? Hey?" Gottlieb Wehle always spoke English, or what he called English, when he was angry. "Vot for? Hey?"

All the way home from Anderson's on that Saturday night, August had been, in imagination, listening to the rough voice of his honest father asking this question, and he had been trying to find a satisfactory answer to it. He might say that Mr. Anderson did not want to keep a hand any longer. But that would not be true. And a young man with August's clear blue eyes was not likely to lie.

"Vot vor ton't you not speak? Can't you virshita blain English ven you hears it? Hey? You a'n't no teef vot shteele I shtooes, unt you ton't kit no troonks mit vishky? Vot you too tat you pe shamt of? Pin lazint' rount? Kon you nich English shtprechen? Oot mit id do vosat!"

"I did not do anything to be ashamed of," said August. And yet he looked ashamed.

"You tidn't pe no shami, hey? You tidn't! Vot vor you loogs so leig a teef in der bentenshry? Vot for you sprachen not mit me ven ich sprachs der blainest zort ov English mit you? You kooms sneaggin heim Zaturtag nocht leig a tog vots kot kigt, unt's got his dail dween his leks; and ven I aks you in blain English vot's der madder, you loogs zheepish leig, und says you a'n't tun nodin. I zay you tun sompin. If you a'n't tun nodin den, vy don't you dell me vot it is dat you has tan? Hey?"

All this time August found that it was getting harder and harder to tell his father the real state of the case. But the old man, seeing that he prevailed nothing, took a cajoling tone.

"Koom, August, mine knabe, ton't shtand dare leig a voel." Vot tit Anderson zay ven he shent you avay?"

"He said that I'd been seen a-talking to his daughter, Jule Anderson."

"Vell, you nebber said no hoorn doo Shule, tid you? If I dought you said vot you zhoondn't zay doo Shule, I voof ehst drash you on der shpot! Tid you gwarl mit Shule, already?"

[The above story, "The End of the World," will be continued from where it leaves off here, in *Hearth and Home* for April 27 (Vol. IV., No. 17), which can be obtained of any News-dealer; or of the Publishers (Orange Judd & Co., 245 Broadway, New York), who will send it post-paid for 10 cents. The succeeding chapters of this story will be found very interesting. See page 163.

Hearth and Home is one of the largest Illustrated Journals in our country. It gives in each volume \$25,000 to \$30,000 worth of large, splendid, interesting, and instructive Engravings. It contains a very great amount of useful, interesting, and trustworthy reading matter. Its Household Department is invaluable to every housekeeper. Its Children's and Youth's Department is unequaled—having a large amount of pictures, stories, and useful information that will delight, instruct, and improve every child in the land.

The News Sheet of *Hearth and Home* gives the *News of the World* for each week, brought up to the hour of mailing, in a clear, condensed form, and is of great value to every person who wishes to keep up with the times—to be intelligent—without having to wade through acres of loosely thrown-together printed matter.

Hearth and Home is supplied a whole year for \$3—the cheapest journal in the world! All New-mena will supply it. The Publishers will send it a year for \$3, and all subscribers now sent in, will receive all of Edward Eggleston's new story. \$11 (\$2.75 each) will pay for 4 copies for a year, or \$25 for 10 copies (\$2.50 each).

EXTRA.—\$3 will pay for both *Hearth and Home* and *American Agriculturist* from now to the end of 1872. \$1 will pay for *American Agriculturist*, and two dollars for *Hearth and Home* for the same time (over 8 months). Orange Judd & Co., Publishers, 245 roadway, New York.

SUPERIOR STANDARD WORKS.

For Sale by **ORANGE JUDD AND COMPANY.**

THE HORSE.

**FRANK FORESTER'S
HORSE & HORSEMANSHIP
OF AMERICA.**

**A Good Cheap
Sewing-Machine at Last.**

We have been offering as a Premium, for some weeks
past, the **Beck with new \$10 Sewing Ma-
chine**, which has been fully described in the *American
Agriculturist* for March and April. We have already given
and sold some hundreds of these machines, and testimo-
nials of satisfaction are coming from every quarter.

We have contracted with the Beck with Sewing Machine
Company for 1,000 of them to supply our own
friends, and as *Premiums*. Each machine is put
in a neat, compact box, with *hemmer and guide, oil-can,
bottle of oil, thread, different-sized needles, etc.*, with full
Printed Directions for using, and delivered to any express
office in this city, without extra charge above the \$10.
As we buy the machines at wholesale price, we have de-
cided to give our readers some advantage of this, and we
therefore propose to make a present for him-
self, or for any friend, of one copy of *Hearth and
Home* or two copies of the *AMERICAN AGRICULTURIST*
for the balance of this year (1872), to the first 800 per-
sons who send us \$10 for one of the new machines.
**The New Sewing Machine as a Premium
without Money.**

To enable those to get this machine who can not raise
even the \$10 to buy it, we make the following offer:

**We will send the Machine free to any
one who will collect and forward SIX sub-
scribers for HEARTH AND HOME one
year at \$3 each; or TWELVE subscri-
bers to AMERICAN AGRICULTURIST
for one year, at \$1.50 each.**

Almost any lady can readily secure this small
number of subscribers and **get a Machine free**; or
some friend can thus obtain it for her, as a present.

GOUX'S
Patent Absorbent Closet and Urinal.**

CONTAINER FOR FARM
USE.

MAY BE FITTED TO ANY
SEAT.

The Goux system possesses all the advantages of the dry-
earth system, without its disadvantages; it is economical,
deodorizing, and self-acting. The whole refuse of every
house—as excreta, liquid or solid, ashes, and sweepings—are
disposed of and turned to account, and it is applicable in
individual cases, dwellings, and in large communities.—*Sci-
entific American*, Jan. 1, 1872.

"Is, in an eminent degree, worthy of public attention,
and must, when its simplicity and practical utility come to
be fully understood, attain a wide popularity."—*Cultivator
and Country Gentleman*, March 23, 1872.

"The Goux system of closets is so simple and effective in
its operation, so scientifically correct, and of such practical
utility, it only needs to be understood to be appreciated."—
Moore's Rural New Yorker, March 16, 1872.

"The absolute necessity for disposing of our waste matter
in a manner which is not prejudicial to health, makes it im-
perative to use a dry-earth closet in some shape, and this
one has many advantages to recommend it."—*American
Agriculturist*, April, 1872.

[COPYRIGHT SECURED.]

A SEA-SIDE FARM.—DRAWN BY G. PERKINS.—Engraved for the American Agriculturist.

Our many inland readers, when they read the title to the engraving, will look around for the farm and the farmer. They are both in plain view, and as unlike the farm and farmer of any other part of the country as the sea-shore is unlike prairie or mountain-side. From their close proximity to the sea, most of these along-shore farms are, if not sterile, at least not over-fertile, and the sweeping storms and the salt atmosphere restrict the cultivator to a few crops, though it often happens that he can grow these few in great perfection. The farmer himself is something of an amphibian, and is quite

as handy at managing a boat as a mowing machine. Nets are quite as important to him as hay-rakes, and the oyster-dredge is as much a part of his outfit as the dairy utensils. We can recall pleasant visits to more than one of these shore-farms, where, if there was not much systematic agriculture, there was a great deal of comfort. The sea which carries away so much of value from the land returns much to those who live by its side. Fish, oysters, clams, lobsters, and other articles of food are abundant and easily obtained, and the sea which furnishes the provisions also sends drift-wood to cook

them with. Fertilizers for the fields are drawn from the ever-full storehouse of the sea. Fish, sea-weed, and marsh mud all go to the compost heap, and bring abundant returns from the meadow lands and fields. It often happens that the shore-farmer carries on a mechanical trade with his agriculture, and this is either boat-building or net-making. Perhaps this kind of life does not tend to make the best sort of "scientific" farmers, but it does tend to make, what is quite important, a useful and self-reliant people, among whom we have found more culture than their rough exterior would lead one to expect.

Contents for June, 1872.

Table listing various agricultural topics such as American Cuckoos, Apple-Worm Traps, California Churn, and Market Reports, with corresponding page numbers.

Calendar for June.

Calendar for June showing sunrise and sunset times for Boston, N.Y. City, Philadelphia, and Washington, along with moon phases.

labor as effective as possible. We do not advise farmers to employ less labor. This will be the effect of high wages and low prices of farm produce.

Hints about Work.

Planting Corn.—We have had a late and hurried spring, and much land intended for corn is not yet planted. An early variety of corn will sometimes ripen planted as late as the first or even the second week in June.

Beans.—We have had a good crop of beans planted the last week of June, but as a rule it is better to plant as soon after you are through planting corn as possible.

Potatoes.—It will save much labor in hoeing, just as the potatoes are breaking the crust to harrow the ground. We have repeatedly done this with a common harrow, with marked advantage.

AMERICAN AGRICULTURIST.

NEW YORK, JUNE, 1872.

Some of the readers of the American Agriculturist were vexed with us for saying that wages would not be lower. We fully realized that wages were far higher than farm produce; but we could not shut our eyes to the fact that, while so many new railroads were being constructed—while contractors were clamorous for men, and bidding against each other—farmers, though employing more labor than any other class, could not control prices.

weeds from starting. When the stems begin to run, set the cultivator narrower, and put on wings, to throw a little soil towards the plants. Repeat this two or three times, at intervals of a few days, and thus make a broad hill. If the land is tolerably clean, and the harrow was used freely, the cultivator will kill and keep down the weeds with a little aid from the hoe. Any weeds that escape, should be pulled out of the hills by hand. A weedy potato-field is a disgrace. The weeds retard the growth of the plants, and greatly increase the cost of digging. As a rule, farmers make a mistake in not planting their potatoes earlier. But a fair crop of some early variety may be obtained when planted the first week in June.

Cultivating Corn.—This is the most important work of the month. Great improvements are yet to be made in our methods of cultivating. But whatever method is adopted, the great point is to mellow the soil and kill every weed. It is no exaggeration to say that, taking the country through, the weeds rob us of half the profits of our corn crops. Study to kill the weeds in the most expeditious and least costly manner—but kill them. Do not wait for them to grow above the ground. The best time to kill weeds is as soon as the seeds begin to germinate. Use harrow, cultivator, or any other implement you prefer—only use it early and frequently. Our hot sun will kill the young plants by the million in a few hours. Weeds are like fire, easily controlled if taken in time, but if they get the start of us it is difficult to subdue them.

Mangel-Wurzel.—These may still be sown. Drill in rows, $2\frac{1}{2}$ to 3 feet apart. Four pounds of seed is required per acre. If the land is rich and the plants come up early, single out the plants in the rows, 15 inches apart. Later crops should be left thicker, say 12, 8, or 6 inches apart, according to the time the plants have to grow.

Turnip-Beetles.—Make the ground very mellow for this crop. Drill in rows $2\frac{1}{2}$ feet apart, 2 to 3 pounds of seed per acre. When in the rough leaf, thin out with a hoe, leaving single plants 12 to 15 inches apart. Sow as early this month as the land can be got in good condition. It is very important to sow the seed immediately after the land is plowed for the last time. The best, if not the only remedy for the turnip-beetle or "fly" is to have the land rich and mellow, and to deposit the seed in fresh, moist, warm earth, not over half an inch deep. The main point is to get a quick growth until the plants are in the rough leaf, when there is little danger from the fly. Dusting the plants while wet with rain or dew, with slaked lime, helps to check the ravages of this great pest of the turnip-grower.

Summer-Fallows for Wheat.—Tenacious clay loams are the soils most benefited by summer fallowing. To make thorough work such soils should be plowed three times. Either early in the spring (or, better still, the fall previous), and again the middle or end of June, and again just before sowing. The cultivator, roller, and harrows should be used freely, to kill weeds and mellow the soil. On light land, once plowing in June, and merely keeping the land clean with a cultivator and harrow, makes a good seed-bed. Whatever plan is adopted, it should be understood that no vegetation of any kind, in our dry climate, should be suffered to grow, as the plants pump up large quantities of water from the soil, and the land will be nearly as dry as if a spring crop was grown. See article "On Fallowing" in this number of the *Agriculturist*.

White Mustard.—The land for this crop must be made as fine and mellow as possible. If intended to plow under or feed off, and to sow winter wheat, it should be sown the early part of this month. But it will mature if sown as late as the middle of July. Sow from four to six quarts per acre, broadcast, and cover with a light harrow or roller.

Winter Rape or Cole-Seed requires the same treatment as mustard. It is a crop intended to be eaten off on the land by sheep. It is not injured by frost. For winter feed, sow from the middle of June until the middle of July. From 3 lbs. to 5 lbs. per acre is sufficient seed. It is better to drill it in and cultivate, but a fair crop can be obtained by sowing

broadcast. It is worthy of more extended cultivation, especially by breeders of mutton sheep.

Horses.—Give the horses some green clover, at noon, and cut it with a mowing machine, and rake it up with a horse-rake. It is little trouble, and as hay is scarce and high, it will pay. It is a great mistake to suppose that horses will not eat hay if they are allowed any green food. We have an object in advising you to cut it with the machine. You will then have your machine in readiness for haying.

Cows.—If the pastures are scant, or the grass too succulent, it is a good plan to allow the cows all the hay they will eat at night. And if cut, moistened, and a little bran or corn-meal mixed with it, so much the better.

Sheep.—It is a good time to weed out old and poor-bred sheep from the flock. If in fair condition, they can be sold to the butcher at good prices.

Pigs.—If possible, let all the pigs, old and young, have the run of a clover or grass pasture. Breeding sows of a good breed will keep plenty fat enough on clover alone; but young, growing stock should have some corn, every day, in addition to the clover. See that they have an abundant supply of fresh water, and let them have access to a mixture of salt, ashes, charcoal, and sulphur. Get a good, thorough-bred boar now for next winter's use. Many farmers who intend to do so, put it off until it is too late. Order at once. The best thorough-breds can now be had for \$20 or \$25 each, and they will pay for their cost ten times over.

Rainy Days.—Get ready for harvest. See that the machines, rakes, scythes, etc., are in perfect order. Get a barrel of crude petroleum, and wash or paint all the wagons, plows, harrows, and everything that is exposed to the air. They will last as long again. Do not mix anything with the oil.

Work in the Horticultural Departments.

The warm weather of June brings an abundance of flowers and fruits. Care and labor are necessary to keep the ground in proper order, so that the growth of the plants is not checked. Constant cultivation and stirring of the soil is necessary for all crops, whether of the farm or garden, but this labor is abundantly repaid by the large crops of fruits and vegetables, which reward the careful gardener. The crop of strawberries will be ready this month, and then will follow in rapid succession the other small fruits, so that there is a constant series of agreeable surprises in the ripening of some choice fruit or the flowering of a rare plant.

Orchard and Nursery.

The principal work this month in the established orchards is to thin the fruit and keep the trees free from insects. An orchard should be carefully plowed several times each season, and if any crop is raised between the rows of trees, an extra quantity of manure should be applied, so that the growth of the trees will not be interfered with.

Thinning, though not generally practiced among fruit-growers, ought to be more regarded, as the fruit from a tree thus thinned is much finer, and will easily bring a higher price than if the tree is allowed to ripen all that sets. After the fruit is fairly set, one third to one half should be thinned out, and the sooner the better.

Insects.—Do not allow any caterpillars to remain upon the trees long enough to destroy the foliage. Nests of the Tent-caterpillars can be removed either early in the morning or at night, by the bare or gloved hand, and nests that are on the extremities of the branches can be reached by means of a long-handled brush, dipped in petroleum.

Slugs which attack the leaves of pear and cherry trees may be destroyed by dusting lime upon them.

Grafts.—Look to the growth of grafts set this spring, and if there is room for only one, remove the second one entirely, and pinch back the growth of the remaining one, if very vigorous.

Pruning.—June is thought by many to be the best month for pruning, as the wounds heal very readily.

Others think that the removal of so much foliage checks the growth of the tree. If one can spare the time now to prune his orchards, it may be done at the present as well as at any other time.

Young Trees, if carefully watched and kept in proper shape by pinching, will seldom need pruning, or at least more than can be done with a knife.

Seedlings will need to be kept clear of weeds, so that they may make a healthy growth. Young seedlings of evergreens and deciduous forest trees will require shading for the first season.

Fruit Garden.

Strawberries.—If the strawberries were not mulched last spring, place cut hay or straw around each hill, to keep the fruit from touching the ground, else the rains will wash the dirt upon the berries, and render them gritty and unfit for use.

Gooseberries.—The ordinary way for marketing is to pick them when green, as the ripe fruit seldom amounts to much in this country. The fruit may be freed from sticks and leaves by allowing them to roll down a trough, slightly inclined.

Currants.—Place a mulch of hay around the roots; it will save much time in destroying the weeds, and also give a much finer quality of fruit. Cuttings planted out last month will need to be hoed, and kept free of weeds.

Grape-Vines planted this spring should be allowed to produce only one cane, and this must be tied to a simple stake, taking care not to injure the buds. Bearing vines require to be pinched during the growing season, and the fruit thinned, to prevent the vine from exhausting itself. Apply sulphur with a bellows, on the first appearance of mildew.

Raspberries and Blackberries.—Tie the canes to stakes, or, what is better with raspberries, stretch a wire along the row, and secure it firmly by means of a strong post at each end; the canes can then be secured to the wire, and so spread out as to allow the sun and air to reach all parts.

Dwarf and Cordon Fruit Trees.—Keep these carefully pinched and tied to their supports, and if they are old enough to fruit, thin out when fairly set.

Kitchen Garden.

June is a month for weeds, and only by constant cultivation can we keep the crops free from them. Where the cultivation can be performed by horse-power, much trouble is done away with. During a dry season, if the soil is frequently stirred, much good is done to the crops.

Asparagus.—Do not allow the bed to become filled with weeds, as much of the good effect of manuring is lost. It requires but little time to hoe up the weeds when small. The weeder described in the December number of last year is an excellent tool in a soil tolerably free from stones, as more work can be done with it in the same time than with any other implement we have ever used.

Beans.—Bush and pole varieties may still be planted early this month. Hoe those already up.

Beets.—Weed and thin; the young plants pulled out will make good greens, if cooked as spinach.

Cabbages.—The early sorts will now be ready for the table or market, and the later kinds will be ready to transplant. Sow seed for late sorts, and as soon as large enough, transplant to ground from which early peas and potatoes have been taken.

Carrots.—Keep the ground well cultivated between the early sorts, and sow seeds for general crop.

Celery.—The plants in the seed-bed must not be allowed to get weedy.

Corn.—Sow once in two weeks for a succession; the late sorts are more prolific than the early kinds. Keep free from weeds, and break away suckers.

Cucumbers.—Plant in hills, 6 or 8 feet apart each way, and use plenty of seed, to allow for the bugs.

Egg-Plants require plenty of heat, frequent hoeing, and occasionally a watering of liquid manure.

Lettuce does not usually do very well when sown so late, unless it can be in a partially shaded place.

Melons of all kinds require the same treatment as cucumbers.

Onions must be thoroughly weeded, and the soil stirred often, to secure a profitable crop.

Parsnips.—Keep the soil loose and free from weeds until the leaves cover the ground and prevent working.

Peas are not usually very successful when sown late, on account of the mildew. If planted at all, cover with 5 or 6 inches of earth, to prevent drying up.

Rhubarb.—Cut off the flower-stalks, as they needlessly exhaust the plants.

Ruta-Bagas may be sown the latter part of the month, and if there is any trouble from insects, dust with ashes, slaked lime, or plaster.

Spinach.—The New Zealand is the best for summer use, and should be planted in hills 6 feet apart, with three or four plants to the hill. Ordinary spinach runs to seed soon during the summer.

Salsify needs the same cultivation as recommended for parsnips.

Sweet Potatoes do well in most of the Northern States. The first week in June is early enough to plant. A well-manured ridge, about one foot high, should be prepared and the sets planted one foot apart. We have found the Southern Queen to be the best sort, but the Nansmond is also good.

Tomatoes must have their excessive growth kept in check by pinching, in order to get a good crop of fruit. Some sort of a trellis should be provided for training the plants upon.

Flower-Garden and Lawn.

Lawns will require to be cut every week or ten days, and the grass should be left to serve as a mulch and manure. Remove all weeds as soon as they show themselves. See article on page 222.

Bedding Plants ought to be all out now, and the weeds kept down until the plants cover the beds.

Tuberosees, started in pots, may be turned out now in a warm, rich spot, and as soon as the flower-stalks appear, tie them to small stakes, to prevent the wind from breaking them.

Bulbs.—After the leaves of the spring-flowering ones have died, take up the bulbs, and store in some dry place, and keep away from rats and mice.

Roses and Climbers.—Keep all climbing roses, etc., tied to the walls or trellises, and do not allow them to straggle about.

Greenhouse and Window Plants.

Most of the greenhouse plants will be turned out, or at least such as will flourish out of doors. The plants remaining in the greenhouse ought not to be neglected, but should be carefully watered and shaded from the sun. Plants that do not succeed if planted in the open ground, may often be plunged, pot and all, and when ready to remove them to the greenhouse in the fall, they can be easily raised and re-potted. This is a proper season to look after the next year's supply of manure and soil for potting purposes; sods, piled up and turned several times during the summer, make the best potting soil.

Commercial Matters—Market Prices.

Gold has advanced to 114 1/2, closing May 13th at 113 1/2. There has been an unusually active demand reported for Breadstuffs since our last, for home use, shipment, and, to a considerable extent, on speculative account, at a sharp and quite general rise in prices, particularly for Flour, Wheat, Rye, and Corn, which have been in most urgent request. Southern millers have been very free purchasers of wheat. Corn has been sold very liberally for forward as well as prompt delivery. The backwardness of canal navigation and the diminishing supplies of flour and grain at the sea-board have tended to strengthen values. The dealings in Rye have been mainly speculative. The general market closed strong and buoyant, influenced, in part, by the firmness in Gold, and the favorable foreign advices. Provisions have been more sought after and quoted rather dearer in many instances. New Butter and Cheese have been arriving more freely, and meeting with a readier sale. Eggs have declined materially, under

large receipts. Wool has been less active and quoted easier in price, but closes more steadily. Tobacco has been in more demand, and firmer. Hay has been unusually scarce, and in quite urgent request at much stronger prices. Hops, dull. Grass Seeds, quiet.

Northern Pacific Bonds.—Messrs. Jay Cooke & Co. report the sales of Northern Pacific Gold Bonds in the United States during March and April at \$1,891,900.

The following condensed, comprehensive tables, carefully prepared specially for the American Agriculturist, show at a glance the transactions for the month ending May 14, 1872, and for the corresponding month last year.

TRANSACTIONS AT THE NEW YORK MARKETS. RECEIPTS. Flour, Wheat, Corn, Rye, Barley, Oats. SALES. Flour, Wheat, Corn, Rye, Barley, Oats. Comparison with same period at this time last year. RECEIPTS. Flour, Wheat, Corn, Rye, Barley, Oats. SALES. Flour, Wheat, Corn, Rye, Barley, Oats. Exports from New York, Jan. 1 to May 10. Stock of grain in store at New York.

CURRENT WHOLESALE PRICES.

Table with columns for April 15 and May 14 prices. Items include Flour, Wheat, Corn, Rye, Barley, Oats, Hops, and various oils and seeds.

New York Live-Stock Markets.

Table showing weekly receipts and prices for Beef, Cows, Calves, Sheep, and Swine. Includes columns for week ending, receipts, and average prices.

Beef Cattle.—Grass cattle have been coming forward very freely of late, making the supply unusually large, especially for so early in the season. The quality is very fair. Many distillery-fed cattle have recently been sent

in, and there are more to come. The impression is general that we are using up stock which ordinarily comes to market later in the season, and that we may expect a lighter run in midsummer. The market has been somewhat variable, first declining, and then advancing, followed by a temporary decline, and now the rates are in favor of the seller again. There is a large out-of-town demand for beef. Some of the latest arrivals of Texas cattle, fed two years in Missouri, show very fair quality. They sell at 11c. @ 11 1/2c.

Below we give the range of prices, average prices and figures at which large lots were sold:

Table showing price ranges for large sales of cattle, including April 15, April 22d, April 28th, May 6th, and May 13th.

Milk Cows.—The supply of cows is rather light, but quite sufficient for the demand. The generally cool weather lessened the demand for milk, while fine grass caused a full yield, and milkmen had little occasion to add to their stock. Trade was very dull until within the last week. Now there is a little briskness again. Common cows sell at \$30 @ \$45, fair at \$55 @ \$65, and good to prime at \$70 @ \$80. Calves.—The greatest glut is just over, and calves begin to improve after very hard markets. The supply steadily increased up to last week, and many live calves were sold at 5c. @ 5 1/2c. 3 lb., live weight, with prime at 7c. @ 7 1/2c. Those low rates begat a heavy demand, and, as the arrivals are now lighter, they sell off readily. Quotations of dressed are dropped, the weather being too warm to send them from the country. Some of the latest receipts were seized as unfit to eat. Good to prime milk-fed live calves are worth 7 1/2c. @ 8 1/2c. 3 lb.; common to fair cull at 5 1/2c. @ 7c. Sheep and Lambs.—There has been a great falling off in receipts of sheep, the season of lambs preventing sending the ewes forward, while farmers preferred keeping most of their flocks until after the shearing season. The bulk of the sheep now coming forward are shorn, and quotations are for each. Wool lots are worth 7 1/2c. @ 10c., a few choice reaching 10 1/2c. Lambs are scarce and in demand at \$6 @ \$8.50 per head. Poor to medium sheep are quoted at 6 1/2c. @ 7 1/2c. 3 lb.; fair to good at 7 1/2c. @ 7 3/4c.; and lambs at 13c. @ 18c. 3 lb., live weight. Swine.—The weather, or something else, in sending hogs forward too fast for use, saved at very low rates. The market steadily declined until last Saturday, when 5 1/2c. was about the average price for slaughtered. Just now there is a little firmness, but the rates are still low. Live are worth 4 1/2c. @ 4 3/4c.; city-dressed Western, 5 1/2c. @ 5 3/4c.

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Remitting Money: — Checks on New York City Banks or Bankers are best for large sums; make payable to the order of Orange Judd & Co. Post-Office Money Orders, for \$50 or less, are cheap and safe also. When these are not obtainable, register letters, affixing stamps for postage and registry; put in the money and seal the letter in the presence of the postmaster, and take his receipt for it. Money sent in the above three methods is safe against loss.

Postage: On American Agriculturist, 3 cents a quarter, in advance; on Hearth and Home, 5 cents per quarter. Double rates if not paid in advance at the office where the papers are received. For subscribers in British America, the postage must be sent to this office for prepayment here.

Bound Copies of Volume Thirty are now ready. Price, \$2, at our office; or \$2.50 each, if sent by mail. Any of the last fifteen volumes (16 to 30) will also be forwarded at same price. Sets of numbers sent to our office will be neatly bound in our regular style, at 75 cents per vol. (50 cents extra, if returned by mail.) Missing numbers supplied at 12 cents each.

Clubs can at any time be increased by remitting for each addition the price paid by the original members; or a small club may be increased to a larger one; thus a person having sent 10 subscribers and \$12, may afterward send 10 more subscribers with only \$8; making a club of 20 at \$1 each; and so of the other club rates.

Thorough-bred Hogs.—A "Farmer," Northampton Co., Pa., asks what is the reason thorough-bred hogs don't look any better than common stock in a year or two; they run down if not taken extra care of, as

bad as any common sort.—Just so; why not? There is nothing in any improved stock to make them free from the consequences of neglect or starvation. If a farmer would succeed with thorough-bred stock, or any other, he must give them the best feed and care; it is this only that pays in this branch of farming, and the same is true of all other branches.

The Best Mower.—"H. W.," Alleghany Co., Pa., asks which is the best mower.—Our preference is the Buckeye, but there are several others so nearly equal to it, that facility in procuring them would with us have great weight in purchasing. There is very little difference, if any, in the prices of the leading machines. In selecting a machine to offer as a premium, we after carefully considering the matter, fixed upon the Buckeye, and after several years' experience have seen no reason to regret our choice.

Mixed Paints, ready for use, are offered by various manufacturers under different trade names. We learn that the painters attempt to throw discredit on these. There is no reason why paints put up in this way should not be as good as any others. We have tried some of them to our entire satisfaction. There may be poor paints of this kind in the market, as there are adulterated paints of the common sort, but those prepared by reputable manufacturers are a great convenience to people in general, whatever the painters may think about them.

American Jersey Cattle Club.—The fourth annual meeting of this association was held in Baltimore, April 17th. S. J. Sharpless, of Philadelphia, was elected President; G. E. Waring, Jr., of Newport, R. I., Secretary and Treasurer; and J. Howard McHenry, of Pikeville, Md., Andrew Robeson, of Boston, and T. J. Hand, of Sing Sing, N. Y., Executive Committee. The 2d volume of the Herd Register will be issued this summer, and entries for it should be sent at an early day to the Secretary, who will furnish blanks and instructions on application. The essay on Jersey Cattle, which was prepared by the Secretary for the first volume, will soon be published in a pamphlet form by Orange Judd & Co.

What the Physicians say—A Letter that tells its own Story.—"New York, 249 West 42d Street, April 22d, 1872.—Messrs. ORANGE Judd & Co.: Gentlemen: At a meeting of the 'NEW YORK MEDICAL UNION,' held on the 20th instant, it was resolved and adopted: 'That as an expression of personal and professional respect for a publisher who will battle against fraud and crime, under the guise of medical advertisements, as Orange Judd & Co. have done, in the case of Byrn against Judd & Co., we subscribe *en masse* to the *Hearth and Home*.' The Medical Union having authorized me to attend to the execution of the above resolution, I do myself the pleasure to inclose check for the amount of the year's subscription, together with a list of the names and addresses of the members, and beg you will order the paper sent to those addresses, commencing with the fourth volume. With very great respect, I remain yours, STEPHEN ROGERS, M.D."

Holding up Milk.—L. Pierce says he has found his cows will always let down their milk when inclined to hold it up if he gives them some salt to lick.

First Mortgage Railroad Bonds on any line of railroad having a present or prospective fair business are always considered good investments, and usually rise above par as soon as a road is completed. Good bonds are offered in our advertising columns by Messrs. Leonard, Sheldon & Foster. The Canada Southern Railroad is not only to be a trunk line, but it also passes through the finest agricultural region of Canada. The Cayuga Lake Railroad will have a very large coal business, while it traverses the splendid farming country along the margin of Cayuga Lake. At present, these bonds are offered at 90 and accrued interest.

Combined Reaper and Mower.—"W. J. L.," Wadesboro, N. C., asks if we would advise him to get a combined reaper and mower, or if separate machines would be on the whole the cheapest.—We have found the combined machine inconvenient, and would use separate machines whenever possible to procure them.

Natural History Journals.—"W. D. W.," Westmoreland Co., Pa. We have not, since the suspension of the American Entomologist, any journal devoted to Entomology. The Canadian Entomologist, monthly, is published at \$1.25 a year (U. S. currency), by Rev. C. J. S. Bethune, Port Hope, Ontario, Canada. The American Naturalist, published at Salem, Mass., monthly, at \$4 a year, treats on all branches of Natural History, including Entomology, and is a valuable work.

For other **Basket Items** see page 233.

Large Pay for Little Work,

and that, too, for rainy days, evenings, odd spells, or for a constant occupation—for MEN, WOMEN, and CHILDREN—anywhere, and everywhere.... Over 14,000 Persons have found it so; and here is how it is: The Publishers offer 108 Premiums, every one of them a first-rate article—just as good as so much money—for use or for sale. (See list on page 206, and send for a free, full description, if not having one.) Now, to get one of these articles without money, it is only necessary to solicit and forward a few subscribers for the *American Agriculturist* or *HEARTH AND HOME*, or for both of them. The number required is given against each premium. It is easily done. Show a copy of the papers, explain their value and cheapness—the cost being only a few cents a week. Few Post-Offices have around them less than twenty-five families, and many have hundreds, that would be profited in *mind* and *pocket* by reading one or both of these journals. They only need to have this shown to them. Any enterprising person, old or young, can do this just as easily as it has been done by the 14,000 who have already secured the premiums. Human nature and human wants are similar everywhere. Read page 208. These premium offers will remain open one month yet (to June 30), and June is a good month for getting them. Partly filled premium lists can be completed, and new ones be begun and completed. A subscriber a day will get a large premium. Many can get several each day or week. Begin to-day. Any one taking hold with a will, determined to succeed, will succeed. The Premiums are open to all.

Washing Wool.—"Maryland" wants the best method of washing wool, so that it will rate as "tub-washed," and if a Doty Washer would do the work.—"Tub-washed" wool is washed in soap and warm water until the dirt and grease is removed. As there is no rubbing, but merely continued squeezing for a short time, a washing machine is hardly needed. By placing the wool in water to soak for half a day previously the work is made easier. It is a good plan to run the wool through a "wringer" after washing.

Three Horses on a Mower or Reaper.—There is no way of attaching three horses abreast on a mower, except by placing the three-horse evener a foot or fifteen inches on the left-hand side of the pole. Any contrivance that will do this, will answer the purpose. Sometimes a piece of wood a foot or so thick, is firmly bolted on to the pole, and the evener is attached to this. We have never known grass so heavy that a pair of good horses will not cut it easily with a Woods or Buckeye machine. On a reaper we have sometimes found it well to put on four horses, attaching the first pair to the ead of the pole. If steady horses, one man can drive four as easily as three. If we had a mower that cut a swath wide enough to require three horses, we would put on four, and then go ahead at a good steady pace.

New Hampshire Board of Agriculture.—This Board was organized in 1870. It has held thirty meetings, and consumed forty days and evenings in discussion of questions of interest to farmers. Exchanges of reports and proceedings of kindred associations will be gladly made. Chairman, Moses Humphrey, Concord; Secretary, James O. Adams, Manchester.

Weight of Cotswold Sheep.—"C. A. L.," of Vermont, asks, "What is the largest Cotswold sheep you remember to have known?" This is a point on which we have never felt the slightest interest. Big oxen, big sheep, and big hogs have never had any attraction for us. A Cotswold sheep that will weigh 200 pounds at 14 months old is a far better test of a breeder's skill than one that will weigh 400 pounds at three years old. It is rare for a well-bred Cotswold to weigh over 350 lbs.

Clover Seed.—On rich limestone land, clover seed often proves one of the most profitable crops, in proportion to the labor, that can be raised on the farm.

Some good farmers think it impoverishes the soil, and this may be to a certain extent true, but if the money obtained for the seed is expended in purchasing bran, cotton-seed cake, or other food to feed out to animals next winter, the extra quantity of the manure so obtained will do far more towards enriching the farm than the growth of the clover seed will exhaust it. If you do not need the field for pasture, therefore, we would certainly recommend you to let it produce seed. Mow the first crop early and evenly. This is all that need be done until the seed is matured. If the clover was plastered in the spring, it is not well to sow any more on the crop left for seed. It sometimes produces such a luxuriant growth that the seed will not ripen. Even in this case, however, the crop can be mown for hay.

Ashes from Bark.—"J. R. M.," Flint Hill, Va., asks the value of the ashes from tanners' waste as compared with the value of those from wood.—The difference consists mainly in the lesser amount of potash in the ashes of bark, but as they contain some potash, also soda, phosphoric acid, and a large quantity of lime, they have a sufficient value to make them a cheap manure at eight cents per bushel.

Long-wooled Sheep in Large Flocks.—Some of our agricultural writers are still insisting that "one hundred" long-wooled sheep can not be profitably kept on one farm. They say a flock of forty or fifty may be so managed as to keep healthy. Arguments are wasted on such men. They have yet to learn the difference between cause and effect.

Buckwheat on Summer-Fallows.—On sandy soil that is being summer-fallowed for wheat, it is perhaps advantageous to sow buckwheat, and turn it under for manure; and on very heavy clay soil the same practice is sometimes resorted to for the purpose of making the soil more porous. But on ordinary loamy land we think the buckwheat would do more harm than good, as its growth robs the soil of moisture, and if we have dry weather in the fall, the wheat would probably not start as well as it would on a good bare fallow.

Large Grade or Small Thoroughbred Males.—"Would you carry your preference for thorough-bred males so far as to prefer a small pure-bred Shorthorn bull to a large, handsome, well-formed grade Shorthorn bull?"—Certainly, we would. The late Sir Charles Knightly once said: "No bull, if good enough, is ever too small." You may get good calves from the grade bull, but the tendency is towards deterioration. If you would improve your stock, you must resort to pure-bred males, and get the best you can afford.

How to Remove Foul Air from a Well.—Never go into a well without first lowering a candle into it. If it goes out, you may know that there is carbonic acid in the well. This gas is heavier than the air. The way to get it out is, to warm it in some way until it is light enough to ascend. This may be done by lowering down a tin pail of boiling-hot water with a rope, and moving it up and down in the dead air, or below the point where the candle goes out.

SUNDRY HUMBBUGS.—Several physicians write desiring us to print in pamphlet or book form a full report of Byrn's Libel Suit against us, for the particular use of the medical and legal professions, as much of the testimony is not fit for a general publication. It would doubtless be a valuable document, but without a large demand in advance we are hardly warranted in incurring this further heavy expense. The testimony of the witnesses, on the final trial, alone covered nearly 300 pages of large legal-cap paper. The whole proceedings, preliminary, interlocutory, various rulings, etc., all forming a part of the case, and necessary to a full report of it, would require a large volume. The condensed report given in a 16-column supplement to *Hearth and Home* for April 20th (No. 16), presents the important features and results, and a copy of that paper (which can be procured post-paid for 10 cents) should be in the hands of every physician at least, and would be very useful to every other person.... If the good people of Hinsdale, N. H., do not take hold and clear out from their midst the vendors (or one vendor under various names) of vile publications and sundry clap-traps, their fair town will have a taroished reputation throughout the country, and the one general watchword of the press will be: "Beware of any and every circular, document, or advertisement from Hinsdale, N. H.!" The so-called "New England Book Co.," is a libel on the name—with its advertisements of amorous books, pictures, medicines, etc. Parents write us that these circulars, setting forth vilely attractive books and pictures, are mailed directly to their sons

scarcely a dozen years old. . . . A swindler, calling himself Thomas D. Thorp, 737 Broadway, New York, is sending pretended notes for \$965 each to multitudes of parties at the South and West, with neatly lithographed letters, stating that he has failed, and wishes to sell these notes out of the State before he is examined by his creditors. He offers a large discount, and only wants the money when the notes are paid at the Park Bank, New Orleans, except \$5 down, to make the sale good. This \$5 is of course all he expects to get. It would seem that anybody having "gumption" enough to accumulate \$5, and to know what a note is, ought to be wise enough to escape this swindle. Yet we suppose there are people unsophisticated enough to bite the bait, or the enterprise would not be carried on. The small print, on what appears to be an Internal Revenue Stamp on the note, shows that it is not such a stamp at all. . . . Itinerant doctors circulate in many sections of the country, stop here a few days and there a few days, put out flaming circulars and advertisements, heralding their wonderful pedigree, antecedents, and superhuman skill; they eclipse all slow-going regular physicians, draw around them ignorant, trusting people with imaginary diseases which are cured by faith and gummion, and then they disappear for a season, to reappear in the same rôle again, if they have not killed too many people in a previous round. Every such itinerant "doctor" is a quack of the first water. . . . Those who have read our previous cautions, will not lose their money by sending \$5 to "T. Williams, M.D.," 5 Clinton place, New York, for his recipe for "nervous debility" and —, etc. There is no chartered Medical and Surgical "Institute" having any such agent as T. Williams, or any other. . . . J. H. Reeves, of 78 Nassau street, is too well known to our old readers to need any further showing up, under whatever guise he operates with this name. At one time he offers love powders (cantharides) to awaken illicit desires, and follows with offers of remedies for the effects of excesses—a bane and antidote. . . . J. T. Norris, whose name appears on a large catalogue as "proprietor" of the "Mohawk Small Fruit Farm," Springfield, Ohio, is so much in favor of one "womac's rights," that he vests his property in his wife, and after himself ordering goods and chattels of various kinds from various places, fails to pay for them, and has no property of his own. Nurserymen and other dealers who may receive his orders will do well to make a note of this. If the statements furnished to us be facts, the laws of Ohio ought to be full enough and stringent enough to incarcerate him as a swindler. . . . The "National Benefit, in Aid of Needy Families of Soldiers and Sailors," etc., at 267 Broadway, is another of the plausible lotteries that all good people should shun, no matter how many U. S. Senators may be represented as indorsers of the scheme. This appears to be an individual affair, ostensibly gotten up in aid of another *bona fide* movement for a like object, and the indorsements for that appropriated for this one. . . . Pity it is that there should be people ignorant enough to read and believe Mrs. Ver Plank's story about "Vinegar of Iridin," so ingeniously illustrated and set forth by A. J. White, of 319 Pearl st., New York, who tries to dodge Judge Brady's decision by saying he does not sell this stuff as a specific, though his medical sheet asserts it to be almost a specific for sundry diseases. . . . The Queer, or Sawdust, or pretended counterfeit money dealers still operate, the largest nest being at 16 S. nth Fifth avenue, ostensibly under such names as M. W. Anstie, alias W. E. Raymond, alias Geo. Danvers, alias Evan Green, alias James Price, alias Earnest Hines; C. A. Williams, corner Broadway and Fulton street; B. B. Wells, 23 Bowers, who implores you to come on and count out the money yourself, and will pay half your expenses. These fellows like to get a greenhorn into their dens, where they can, by aid of bogus policemen, strip him of his last dollar. James Price, 28 West 4th st., advertises (and several otherwise respectable newspapers admit him) "\$1,000 a Week, and an Immense Fortune," etc., all of which is to get names of parties to be swindled by pretending to send them good counterfeit money which is never sent. Turner & Wells mail letters in New York to be answered at 220 Chestnut st., Philadelphia, offering \$5,000 in perfect counterfeit for \$35. Of course, like all others of this class, they pocket the \$35, and send nothing, unless it be a box of sawdust or old paper, with a C. O. D. bill for more money, and a letter in advance describing the fine money in the box, so as to allure the victim to take it out of the Express office and pay the bill. Among the names of these operators we have Geo. Harrington, Monument square, Baltimore, Md., alias Sidney Messenger, corner John st. and Broadway, New York. . . . If any of our readers risk their time and money (a little money is always required *in advance*) in the great offers for employment, agencies, etc., emanating from three or four towns and cities in Maine, they will have to "learn wisdom by experience." The Young Men's Christian Associations of that State are doing something at investigating these concerns. We hope they will hurry up and expose the whole tribe, as they have done with some of them.

Knitting Machine.—R. Sproul, Texas, wants to know which is the best knitting machine for ordinary use.—We prefer the "Bickford" machine.

Fodder Crop.—"N." is going to be short of hay. What is the best crop he can sow for fodder, and how should it be sown?—Corn will give the greatest yield of any known fodder crop. Sow at once in drills three feet apart, grains about an inch apart in the drill, on rich ground, and cultivate until it completely shades the ground. Four tons of dry fodder, at the least, may be expected per acre.

Spinning Wool.—"S.," Velasco Co., Texas, asks for the most useful home machine for spinning wool, and the cost.—The simplest, and probably the best, is the common spinning-wheel; it costs from \$5 to \$10.

Living Fence-Posts.—"C. E. K.," Olmstead Co., Minn., having found that fence-posts rot at the longest in ten years, asks if it would injure trees to have wires fastened to them or go through a hole in the center, and thus have living fence posts. If trees were planted in rows at proper distances, the fence wires might be fastened to them with staples without any injury. A hole bored through the tree would in a short time close on the wire, and hold it fast if it did not injure the tree.

Gutter in Cow-Sheds.—"G. C. B.," North Platte, Mo., asks what should be the width and depth of a gutter behind the cows in a stable.—It may be eighteen inches wide and six inches deep. This will be deep enough to prevent the cows from standing in it. Square words and answers to puzzles should be sent direct to Aunt Sue, P. O. Box 111, Brooklyn, N. Y.

Mammoth Chester Co. Corn.—Thos. Wood, Doe Run, Pa., says the Mammoth Chester Co. Corn is nothing but the common corn of that locality. It is no new variety, but corn has been a little better fertilized and grown in that county than elsewhere, and consequently has improved. There is no advantage gained by purchasing it for seed over any other corn, which might be equally good if as well cultivated.

Ragweed.—"Wm. McM.," Venango Co., Pa., asks how to destroy Ragweed.—Ragweed is one of the easiest weeds to destroy. It is an annual, and if prevented from seeding can be overcome. If the soil is very foul, it would be well to summer-fallow it.

Subsoiling.—C. W. Houck, Ralls Co., Mo., writes that he has tried running a subsoil plow in the rows where corn or potatoes were to be planted, and gained an astonishing increase in the crop. This is the general testimony in regard to subsoiling. No soil can be injured by the deepest subsoiling, which merely loosens the deeper soil without burying the surface soil.

White-Mustard Seed.—"Walks and Talks" wishes to say to the scores of correspondents who have written to him in regard to white-mustard that he has no seed to sell. It can be obtained from any of the seed stores. They must excuse him for not replying to their letters privately. He thinks he has told all he knows about Mustard in the *Agriculturist*.

A Good Chester White Pig.—"W. P. T.," of Pennsylvania, sends us the weight and measurement of his Chester White boar, one year old. From snout to root of tail, 5 ft. 3½ in. (He does not give the length of the snout.) Girth, behind fore-shoulders, 4 ft. 6½ in. Height from floor to middle of back, 2 ft. 7½ in. Weight, 401½ lbs.

Manure for Potatoes in California.—Mr. A. T. Smith, of Sierra Co., Cal., writes: "I am an old subscriber to the *Agriculturist*, and the information derived from it has been hundreds of dollars in my pocket, and as I know of no one else capable of giving me the information, I take the liberty of asking you the following questions: I have a small ranch up here in the mountains, raise principally potatoes, and the land is getting pretty well run down by frequent cropping, and as manure is not to be had at any price, I have been corresponding with parties in San Francisco about getting guano. I can get Pacific Island guano containing 65 per cent of phosphate of lime, but Peruvian guano is not to be had. Will it pay to use the former on potatoes? I plant Early Rose and Peerless. Price in fall five cents per pound; in spring, seven cents."—As a rule, phosphatic manures have little direct effect on potatoes. You need ammonia as well. They are excellent for clover or mustard, and when these crops are grown and turned under, or eaten by stock and the manure applied, you get the ammonia and every other element of plant-food that

the potatoes require. Can not you keep pigs with advantage, and thus make manure? California needs some of the improved breeds, like the Essex or Berkshire. There is no reason why California should have to send to Chicago for good hams and pork. If you act on this suggestion, we think the *Agriculturist* will put several more "hundreds of dollars in your pocket"—which is precisely what we like to do for all our subscribers. Do not think you are taking a "liberty" in asking for information. It is always a pleasure to hear from our readers.

Lice on Cattle.—"C. D. W.," Coos, N. H., has his cattle troubled with lice, which carbolic soap does not seem to destroy. Has tried tobacco-water, which killed the lice on a calf, but also killed the calf. Tobacco-water should be used very cautiously on young animals, better not at all. Carbolic soap should be effective, but probably has not been used with sufficient perseverance. It must be remembered that the "nits" are very tenacious of life, and the young growing crop has to be cared for. It is best to persevere with the soap; also feed sulphur, a teaspoonful daily, until the cattle smell of it, when the lice will leave; at least, such has been our experience.

Mustard after Early Potatoes.—"Subscriber," Cook Co., Ill., asks if Mustard would be a good crop to sow on light, sandy land, in good condition, after taking off a crop of early potatoes, for the purpose of plowing it in for manure.—Yes. Sow as soon as the potatoes are dug on the fresh earth. Plow under when in blossom, or before. Do not let any seed form, or the Mustard plants will prove troublesome as a weed.

What Ails the Pig?—"T. G.," Kittrells, N. C., has a young Chester boar which eats well, but can not retain its food on its stomach. If he will give a handful or two of charcoal or of chalk, it will probably remedy this complaint. Pigs need something of this kind; in fact, a variety of such matter as charcoal, salt, ashes, ground bone, chalk, or earth, when they are closely penned up, is absolutely necessary to their health.

To Polish a Floor.—"E. L.," Williams-town, Mass., asks how to dress a floor of black walnut or yellow pine. A floor of any kind of wood may be polished by first smoothing with sand-paper, then rubbing with pumice-stone and water, until a good surface is made, then polished with boiled oil and tripoli, made into a paste. Take a piece of old felt hat, dip it into boiled linseed-oil, and rub the floor with it, then with another piece, dipped into the paste, rub until polished. If a very fine polish is desired, a paste of beeswax and spirits of turpentine may be used to finish. Some *elbow-grease* is needed. If a floor is intended to be polished, it should be laid in narrow strips, very accurately jointed, and of well-seasoned lumber.

Thick or Thin Sowing of Oats.—A correspondent at Alton, Maine, writes: "In the April number of the *Agriculturist*, in 'Hints about Work,' you say in regard to sowing oats, 'the richer the soil the less seed required.' My experience has been, the richer the soil the more seed it would bear."—Both these statements are correct. It depends on what is meant by rich or poor land. If land is so poor that it has not available plant-food sufficient to produce more than 20 bushels of oats per acre, it would be foolish to sow thick. Two bushels of seed per acre would probably produce as good a crop as if six bushels were sown. If rich enough to produce 50 bushels, three bushels of seed would be better than two bushels. If rich enough to produce 75 bushels, it might be well to sow four bushels of seed; but if rich enough to produce 85 bushels, we would not sow more than 3½ bushels; and if rich enough to produce 100 bushels, three bushels would probably be thick enough. On rich land, sown early, the plants *stool* more, and consequently less seed is required. As a rule, we seldom sow oats thick enough on good land. It should be observed, however, that the season has much to do with the question. Other things being equal, an excessively thick seeded crop is more apt to suffer from drouth than one sown thinner.

Ringed Hogs.—"J. B.," Winona, Minn., asks which is the best method of preventing hogs from rooting. A ring in the nose is the best method. All cutting of the cartilage of the snout is useless, as the wound heals very soon and the method is only temporary.

Steaming Feed.—"A Farmer" writes us that he has steamed feed for his stock for three years with very good effects, and could tell us a good deal about the business, but he is not a good hand at writing, though he understands farming well. He asks what we do with such letters. Such letters from farmers who know what they are writing about, are gladly received and well appreciated. A farmer who knows his business can very often give valuable hints to his brother-farmers, although his

sentences may not be exactly correct in their spelling or grammar. But this does not affect their real value. Let a "Farmer" write what he knows about steaming food if he has learned anything new.

Piling Manure.—"S." Nelson, O., wants advice about his manure pile. He uses 200 bushels of sawdust per week for bedding for four horses and sixteen cows, and has the manure piled in his yard, where it gets what rain falls on it, and no other water. He spreads half a bushel of plaster on it when he perceives a smell from it. Is he doing right?—Yes. We would, however, scatter the plaster in the stables. It is not probable that a manure pile of this character would ferment injuriously, except in dry hot weather.

Concrete Buildings.—W. Albert Lea, Minn., wants to know the *modus operandi* of making cement for building, and the cost. In the *American Agriculturist* for March, 1872, page 96, will be found an article on this subject, giving directions. The cost depends on so many contingencies that no accurate estimate can be given, useful for all localities. Hydraulic cement is worth about \$1.75 to \$2.25 per barrel in St. Louis, Louisville, and Chicago, and at this price for cement, if everything, including labor, is to be purchased, the cost will be from 10 to 15 cents per cubic foot.

Corn in Drills.—"W. A. L." Elliotta, asks if there is any gain in sowing corn for fodder in drills rather than in hills or broadcast. Generally the yield of corn in drills, when well cultivated, is fifteen to twenty-five per cent over the yield of hills and double of that sown broadcast. See last month's and this month's papers.

Stretches in Sheep.—"D. M." Union Grove, Wis., has lost several sheep by "stretches;" he wants a remedy. The cause of this disease (which is so called from the sheep stretching itself out) is costiveness. Anything that will prevent or cure this will be a remedy against stretches. Roots are especially useful as winter feed, and we have heard sulphur named as useful. We always give sulphur to our sheep, and feed roots, and never have trouble with stretches.

Chip-Manure.—"F." asks if chip-manure is good to mulch fruit trees with. Yes, better, if it is mixed with some lime, which will help it to rot.

Kidney-Worms in Hogs.—E. W. Tidd, Independence, Iowa, writes that his hogs are very weak in the back, and have lost the use of their hind-legs, which they drag after them when they move. What ails them?—These symptoms are attributed to worms in the kidneys, and turpentine rubbed on the back, or ashes given in the feed, is recommended as a cure. Half to a whole teaspoonful of copperas, according to the size of the hog, given daily in the feed, is another useful remedy.

Value of Feed.—"W. McF." St. Peters, Minn., asks which of the following articles furnishes the cheapest feed for cows, viz.: brewer's grains at 8 cents, oats 20 cents, corn 40 cents per bushel; hay, \$7 per ton; bran, \$15 per ton—milk being worth 20 cents per gallon and butter 25 cents per pound. Certainly, the most money can be made under these circumstances by producing milk for sale, and then hay, bran, and grains would be cheapest; if for butter, we would use bran and corn-meal.

Blindness in Horses.—"X. Y. Z." Iowa City, asks if, when a horse's eye is constantly watering, it is a sign that he is going blind, and whether the other eye will suffer by sympathy. This is a sign that something is wrong, which, if allowed to proceed, will probably end in blindness. It may be ophthalmia, or inflammation of the eye, causing an excessive flow of fluid, or it may be the result of a stricture of the nasal duct which prevents its escape. The first may possibly be remedied by giving a pound of glauber salts, and putting the animal on soft, cooling feed, as bran mash, and bathing the eye with cold water as often as convenient, and covering it with a rag kept wetted with a weak lotion of sulphate of zinc and water. The eye should be preserved from any strong light. If the latter, which can only be ascertained by a capable veterinary surgeon, a simple operation, such as forcing a passage with a syringe and water, may restore the duct, and give early relief. It is almost certain that sympathetic action will involve the other eye in time, if no early remedy is procured.

Grubs in the Back of Cattle.—"A. B. F." Sturbridge, asks us to ventilate the subject of "grubs." Does A. B. F. read the *American Agriculturist*? If so, he will find "grubs" or "warbles" have been written about very often. So lately as the March number, page 85, they were "ventilated." There is no prevention except in keeping the cattle in stables during the summer.

LAST MONTH OF THE Valuable Premiums.

Any person, anywhere, can obtain one or more of the valuable premium articles in this table, without money, by simply gathering a few names for one or both of the papers.

As a constant Business Employment, some persons canvass all the time, receive the premium articles, and sell them for cash, and thus secure large salaries. One lady has averaged over \$3,000 a year for years past, and others are getting large pay for their time, often \$5 to \$20 a day. Some who did poorly at first have, by perseverance, acquired the art of canvassing, and become very successful. The work is honorable. The Journals are useful in every family—in City, Village, and Country.

The *American Agriculturist* is everywhere known and approved. HEARTH AND HOME is now without a superior in the world as a splendidly illustrated Weekly Newspaper, for real value, cheapness, and adaptability to every home in America. The papers are entirely different. Taken together, they supply over \$35,000 worth of fine engravings, and more good reading than can be found in 100 books costing one Dollar each.

Premium Clubs can be made up of subscribers to either paper, or partly of both, as noted over the Table. We call especial attention to the last column of figures, showing the small number of names required where both papers are taken, at the reduced price of \$4 a year.

You, Reader, can get a Premium. TRY IT.

Explanatory Notes.

Read and carefully Note the following Items:

- (a) All subscribers sent by one person count, though from one or a dozen different Post-offices. But... (b) Tell us with each name or list of names sent, that it is for a premium....
- (c) Send the names as fast as obtained, that the subscribers may begin to receive the paper at once. You can have all of this month (June) to fill up your list.... (d) Send the exact money with each list of names, so that there may be no confusion of money accounts.... (e) Old and new subscribers all count in premium clubs....
- (f) Specimen Numbers, Cards, and Show-bills will be supplied free as needed by canvassers, but they should be used carefully and economically, as they are very costly.... (g) Remit money in Checks on New York Banks or Bankers, payable to order of Orange Judd & Co., or send Post-office Money Orders. If neither of these is obtainable, Register Money Letters, affixing stamps both for the postage and registry; put in the money and seal the letter in the presence of the Post-master, and take his receipt for it. Money sent in any of the above ways is at our risk; otherwise it is not.

[In the following table is given the price of each article, and the number of subscribers required to get it free, at the regular rates, \$1.50 and \$3.00 a year, for the two papers; also at the club rates of \$1 and \$1.50; also at the rates of \$4 a year for both papers together.]

N. B.—In all Premium Clubs for either paper, TWO copies of *American Agriculturist* at \$1.50 each, and ONE copy of *Hearth and Home* at \$3.00, will count exactly the same. So also two copies of *American Agriculturist* at \$1 each, and one copy of *Hearth and Home* at \$2.50, will count exactly the same. In this way Premium Clubs can be made up from the 2nd and 4th columns, or from the 3d and 5th, or wholly from the 6th column.

Table of Premiums and Terms, for American Agriculturist, and for Hearth and Home, for the Year 1872.

Open to all—No Competition.

No.	Names of Premium Articles.	Price of Article at \$1.50	at \$3.00	at \$4.00	(1) (2) (3) American Agriculturist.	(4) (5) Hearth and Home.	(6) Both Papers together.
1	Knives and Forks (Patterson Bros.)	\$14.00	21	70	11	35	13
2	Knives and Forks (do. do.)	\$15.50	27	90	14	45	16

Every Premium article is new and of the very best manufacture. No charge is made for packing or boxing any article in our Premium List. The Premiums, Nos. 8 to 12, 23 to 28, 34, 35, 36, 68 to 91, and 94 to 106 inclusive, will each be delivered FREE of all charges, by mail or express (at the Post-office or express office nearest recipient), to any place in the United States or Territories.—(No. 33 mailed for 30 cents extra.) The other articles cost the recipient only the freight after leaving the manufactory of each, by any conveyance desired. Full Description of each Premium sent free.

Fine Lettuce.—Mr. Albert Berdan, gardener at West Hackensack, sent us on May 8th specimens of finely-grown and well-headed lettuce of the Tennis-Ball or some related variety.

Potato-Bug.—L. Oswald, Cape Girardeau, Mo. If the bugs are too numerous for hand-picking, use Paris green, mixed with twelve to twenty parts of flour. Dust it upon the vines while the dew is on. Paris green can be had at the drug and paint stores. Recollect that it consists largely of arsenic, and is a most dangerous poison. Keep it entirely under your own control, and in dusting the vines be careful not to inhale the powder.

Artificial Incubation.—"G. W. C.," St. Genevieve, Mo. All the hatching machines we have seen involve the same general principles, and fail in nearly the same points. Very great nicety is required in apparatus, in order that the degree of heat shall be correct and uniform. Animal heat is regulated with a precision unrivaled by the most cunning appliances. The cost of artificial incubators is considerable, as is also fuel for the lamp, when one is used. The hot-water apparatus involves in its management time and care. Artificial incubation, if free from objections, would be much to be desired, because there would be no necessity of waiting for the spell to come upon the hen, and great convenience in putting the hatching nest wherever desired.

Keeping Hens apart for Breeding.—The following is like many other queries we often receive: "I have a trio of pure Brahmas that have been running with other fowls. How long must I keep them separate to keep the eggs pure?"—Ten days is a safe rule. Most breeders believe, however, that previous impregnations affect slightly eggs impregnated by other cocks for months afterwards. The evidence has not been collected, however, to set this last matter entirely at rest. It is not supposed that the egg germs are directly affected, but indirectly through the organization of the mother. Poultry keepers of a scientific turn will do well to institute a series of experiments to decide this question.

Tea-Plants.—"S.," Zanesville, O., can produce tea plants of our friend P. J. Berckmans, Augusta, Ga.

Purifying the Fowl-House.—"M. C.," Charleston, S. C. After killing your diseased fowls, make the premises ready for the new-comers as follows: Whitewash thoroughly, covering every spot, and filling up every crevice all over the building. Cover the floor by pouring down the last of your whitewash and spreading it in every corner with an old broom. Go over all the perches, and the nests and movable coops and fixtures. Keep everything clean with whitewash.

To Preserve Eggs.—George T. Fisk, Staffordville, Ct. There are numerous ways of preparing eggs to keep them a long time, but all present some difficulty which is hard to surmount. Some oil every egg all over, and they keep as long as the oil remains sweet. They can be varnished or coated with any substance which will exclude air from them, but the slightest imperfection in the coating produces a failure in keeping. We have known eggs kept from the summer, when they could be bought cheap, until midwinter, by packing in salt. Cover the bottom of your vessel with salt, stand your eggs in this, small ends down, then cover with salt, and imbed another layer, until fall, covering the top layer an inch deep with the salt.

Borers.—"J. M. F.," Kirksville, Mo. If the borers are already in your apple-trees, we can advise no external application. They must be killed in their retreats. A wire or sliver of whalebone, a sharp knife, and a gonge and mallet will be required. Sawdust or sunken places in the bark will show you where to work. Open a passage to the channel of the borer, and probe it out. The article upon the use of carbolic soap for the prevention of peach-borers was not from our own experience, but that of Mr. Bateman, and we have entire confidence in any statement that he may make.

Odd Eggs.—Hens seem to be freaky this year. Among the odd specimens of eggs sent us is one from B. L. Hubert, which is as large as one's little finger, several inches long, and looks like a great "wormum."

Scales upon Fowls' Feet.—Several letters are on file, asking us to tell the cause and cure of this trouble. We do not think it is owing to uncleanness of roost and yards, as has been often suggested, but is probably one of the various ways in which a bad state of the general system is manifested. A mixture of equal parts of spirits of turpentine and olive (sweet) oil, put on with a feather, every day, will generally effect a cure.

AMERICAN AGRICULTURIST.

ORANGE JUDD & Co., Publishers, 245 Broadway, N. Y. City.

ANNUAL SUBSCRIPTION TERMS (always in advance): \$1.50 each for less than four copies; Four to nine copies, \$1.25 each; Ten to nineteen copies, \$1.00 each; Twenty copies and upward, \$1 each. Papers are addressed to each name.  Either English or German Edition, at these prices.

HEARTH AND HOME: \$3 a year for less than four. Four to nine copies, \$2.75 each; 10 or more copies, \$2.50 each.

 **Hearth and Home** (weekly) with **American Agriculturist** sent to one address for \$4 a year.

& First-rate Things of many kinds?

(See List on page 207.)

You can have One or More of
the Above

THIS MONTH,

By simply soliciting a few of your friends and neighbors to take *American Agriculturist* or *Hearth and Home*, or both of them. The table on page 207 shows how few names are required to get any premium **free** of charge. For years past many persons have started up premium clubs during JUNE and quickly filled them. Last year a lady made up a full list and obtained a Steinway Piano, that saved her **\$625** cash, as she needed one as a music-teacher.

 Read over the list of excellent Premium articles on page 207. Select one or more and you can soon get names enough to secure it free. Over **14,000** others have done so with pleasure and profit.

The Premiums will be withdrawn after June 30th, except where persons are too distant to get this paper by June 1st. At such points enough extra time will be allowed to give them a month for work. Two half-year subscriptions count as one whole year in Premium Clubs sent this month.

 **Many partially made-up premium clubs should be filled this month.**

Applying Hen-Manure.—A correspondent asks, "After hen-manure is prepared for the garden according to your directions in the March number, can I use it freely, allowing it to come in contact with the seeds?"—As a general rule do not allow seeds to come in contact with strong manure of any kind. It is safer to separate the two with a little fine, mellow earth. Some sorts of seeds will bear direct contact with manure, and others will not. Hen-manure, even when composted with peat or earth, is strong stuff.

Setting out New Raspberry Beds.

—During wet weather, this month, raspberry suckers may be taken up and transplanted. We make the rows 5 feet apart, and set out four or five young suckers in each hill, making the hills 3 feet apart in the rows. Press the earth firmly round the plants, and if the work is done in moist weather and as much earth as possible is left round the roots, or, in other words, if the suckers are taken up, as gardeners say, "with a ball," they can be transplanted as easily as cabbage. You save a year's time by this plan. If the ground is rich and you mulch the young plants, they will bear a small crop the next season.

Sheep in England.—The advance in the price of sheep in England has been even greater than in this country. We hear of a Norfolk farmer who bought lambs last fall to eat off his turnips at 30 shillings each (say \$7.50), and sold them this spring to the butcher for 90 to 100 shillings each (say \$22.50 to \$25 each, in gold). We believe he fed about 400 of them, and the profits must be a very pleasant addition to his bank account.

Maggots on Sheep.—In warm, moist weather, maggots are sometimes quite troublesome. By shearing off the wool and washing with sweet whey, they may be destroyed. But a solution of carbolic acid, say one teaspoonful, in a pint of water, or a strong solution of carbolic soap, will kill them without shearing.

Every Physician, Druggist, Lawyer, Medicine-Vender, and Medicine-Buyer should without fail read the report of the "Libel Suit," occupying a 16-column supplement of *Hearth and Home* for April 20th (No. 16). The testimony, the important rulings of Judge Brady in regard to medicines, the exposure of medical quackery, etc., brought out on the trial, are of very great importance to the country, and to every individual. The paper is electrotyped, and can be reprinted. Post-paid copies are supplied at 10 cents each.

Elementary Drawing Book, by John G. Chapman. A. S. Barnes & Co., New York. The works of Mr. Chapman enjoy a well-earned reputation. The examples are numerous and excellent, and the instruction is conveyed in a manner easily to be understood. This book, which costs only \$1.50, would be a capital present for a child that shows a talent for drawing.

Sowing Wheat in the Corn.—"J. G. E.," Camden, N. J., wishes to sow down a piece of land now in corn, to grass, and proposes to sow with wheat and timothy before the corn is removed; he asks how this plan would answer. Not very well. It would be better to cut the corn first, and shock it in rows as far apart as possible, and then plow and sow the wheat and grass seed. Better still would be to sow down with oats in the spring, using only two bushels of seed per acre. We never found oats so thick as to injure grass or clover sown with them.

How to Make Cheese.—"H. M. T.," wants a recipe for making cheese. No directions which would be of use practically could be given in less space than a column of the *American Agriculturist*, for which at present we have no space. Flint's Milk Cows and Dairy Farming, \$2.50, treat of this subject at length.

Mules Wanted.—"C. M. de R.," Portsmouth, N. H., wants one or two pair of mules, and can not find them in New England. He asks if it would pay to go to Pennsylvania after them. He would find but few mules in Pennsylvania, as they are not bred there to any extent. Kentucky and Southern Ohio would be better places. They may be procured in New York City.

To Clean a Cesspool.—"S. J. B.," Ohio, wishes to clean out a vault which has been used for 30 years. We would provide a quantity of dry earth, which we would throw into the vault, and mix with the material to be removed, using diluted sulphuric acid (oil of vitriol) as a deodorizer. The material should be placed on a bed of dry earth as it is scooped out, and more earth mixed with it, until it is reduced to an inoffensive compost. If kept in a dry place, it will be ready to use in a few days.

For other **Basket Items** see page 233.

Guanos.—M. Eckendorff, Erie, Pa., asks several questions about guano, to which we reply: That guano of the best quality is worth \$90 per ton; 150 to 300 pounds may be used per acre on any crop with advantage, but especially on grass, wheat, corn, potatoes, etc.; with stable manure at two dollars per ton, we would rather buy guano at first, and make brown manure afterwards.

Marsh Hay.—"F. F. V.," Louisville, Wis., asks if it would injure the growth of wild marsh-grass to cut it for hay early every year. It will not injure the grass, and it will improve the hay.

Weeds in Iowa.—"J. M. P.," Fremont Co., Iowa, writes that it is difficult to raise timothy and clover, as the weeds choke the young crop before it gets a start. This will be found a difficulty for many years on rich prairies which have been seeded with a variety of the worst weeds a farmer can have to contend with—viz., those which spread from the root. But they will have to be fought down and choked out. We would suggest mowing the weeds often, and keeping them down as much as possible until the grass and clover get a start. Perhaps some of our readers have had experience which might help our correspondent.

Crude Petroleum.—"E. J.," Spring Valley, N. Y., asks where crude petroleum can be procured. It is generally kept at all country drug-stores, or wherever lubricating oils are sold. Its wholesale price in New York is about \$4 per barrel.

Cashmere Goats.—"A. F. L.," Lebanon, Mo., sends us a sample of Cashmere goat's hair, with a request to learn its value. We find there is no market in New York for this wool; the skins, with the fleece on, are bought in a small way, and used for trimming ladies' dresses. It is not likely with the present inconsiderable production that any regular market will be established for the wool, and we would not advise any investing in these animals. Our correspondent thinks his goats a nuisance; some others probably agree with him in this.

A Windmill Wanted.—"J. B. R.," Thomson, Ga., sends us the following brief and pithy letter—viz.: "What do you ask for a windmill?"—Windmills cost all the way from \$100 to \$1,000, or more. A simple mill (see page 177, last month) may be built for much less, possibly \$40 or \$50, that will do light work, as churning, pumping, etc. We do not make or sell them.

Cheap Stamp-Puller.—"A Subscriber" has a field which he desires to free from stumps, and asks if there is not an easier way than to dig or grub them out. Small stumps may be pulled out with a block and tackle and a pair of horses or oxen, and quite large ones if they are partly rotted. For larger stumps, a machine figured in *American Agriculturist* for September, 1871, page 333, will be found useful. It will cost from \$15 to \$30 to make it, including chains.

Why don't the Butter Come?—C. Wade, Fairview, Ky., asks what is the reason that sometimes butter can not be obtained in churns. This is one of those things it is difficult to understand. Our experience has been that it occurs only when cows have been long in milk, and never when they are fresh, and therefore may be due to a change in the quality of the milk; but it only occasionally happens even then. Who can explain it, and say how it may be obviated?

Cabbage Lice.—"M. A. H.," Pische, Nev. Soap-suds, tobacco water, and vigilance are the remedies. Taken at their first appearance, it is but little trouble to exterminate them, but they spread with great rapidity. Break off the lower leaves that are badly infested, and use either of the above liquids on the remainder. Salt is said to be efficacious, but we have not tried it.

Pruning.—"A. B. W.," Mich. Pruning may be done at any time with proper care. See article in March. The most unfavorable season is when the trees are making their spring growth.

Prices of Butter.—"P. W.," of Putnam, Ohio, complains that we "tantalyze Western farmers by such fabulous prices for butter," as Mr. Sargent's \$1.15 per pound. The fact, nevertheless, remains, that the butter in question was (and is) sold for this price. We did not say that others could get the same price. We stated a simple fact of agricultural interest. Would it tantalyze our correspondent if we were to tell him that we know a man who does not do a tenth part of the work that he does, yet whose salary is over \$70 a day? P. W. thinks he can buy as good butter in Putnam, Ohio, for 23c. per pound. We have no doubt it is even better butter, measured by our correspondent's standard. By the standard

of Mr. Sargent's customers it would be considered very poor trash. They pay the price, and they have the right to decide.

To Dye Green.—E. R. Shields, Wasioja, Minn., asks how to dye cotton a permanent green. A really permanent green can not be got with ordinary domestic appliances. It is a nice operation for a professional dyer. A fair green may be got by dyeing blue with sulphate of indigo first, and then immersing the goods in a bath of quercitron bark. Put the bark, tied up in a cloth, into cold water, along with the blue goods; gradually bring the bath to a boil—an hour should be occupied in this process; when boiling, permit the cloth to remain in only a few minutes, or the green will be dark and dingy.

Back Volumes.—M. A. Hull, Nevada. Bound volumes of the *Agriculturist* are \$2.00 at our office, \$2.50 by mail. Volumes unbound \$1.50, or \$2.00 by mail.

A Good Common Cow.—J. Coonradt sends us the following account of what his cow Katy did. She is nine years old, of the native breed, fed on grass in summer, and some ground feed in winter, with corn, straw, and stalks, and in nine months yielded 336 pounds of butter, easily churned, and good. Her largest mess of milk was 14 quarts. Katy did well, and a heifer calf from Katy by a good Jersey bull would be worth having.

Soiling Crop.—T. S. Sturge, Monroe Co., N. Y., asks which is the earliest spring-sown crop he can raise for the purpose of soiling cows. Oats and peas will come in first, then corn. Oats and peas should be sown in succession, at intervals of two weeks.

Hydraulic Cement.—"W. E. P.," Brunswick, Ga., asks what is the cost of hydraulic cement in New York, how many feet of twelve-inch wall one barrel will build, and if stones can be dispensed with and sand substituted?—The price of cement is \$1.75 per barrel. The proportion of sand to cement is three to one for the best work, and as it loses one third of its bulk when mixed, the calculation of wall built is easily made. If no stone is used, give a longer time for the cement to set, and the sand must be sharp, clean, and coarse.

The Moon.—C. W. Cumber, Jr. In years past we have discussed this Moon question, and prefer to use our space for matters relating to the planet Earth. The instances you cite are as old as ignorance itself. When these lunatics have any new points, we shall be glad to hear of them, but this pork and potato business belongs to the past generation.

Stain for a Brick Building.—L. B. Harrington, Bryan, Ohio, wants the best stain for a brick building, and the proportions of the ingredients. We suppose he means paint, as there is no method of staining brick, which would not be washed off by rain, unless it be oil-painting. Venetian red, mixed with raw linseed oil, is used for painting brick-work. Brick-work is often cleaned and the color brightened by rubbing with a soft red brick and water. If any other color than red is wished, the mineral or iron paints and the various ochres might be used in place of Venetian red.

Chicken Cholera.—"T. H. R.," Tenn., writes, Is there any certain cure for chicken cholera?—We know of no certain cure, but consider proper attention to feed, water, dry quarters, and perfect cleanliness as sure preventives. When it comes to the cure for this complaint, great difficulties and uncertainties arise.

To Pack Butter.—"R. H. Thorn, Juno, W. Tenn., wants to know how to pack "May" butter so that it will keep sweet until May following. It is not alone the packing which makes butter keep, although good butter may be spoiled by bad packing; but the best packing will not make poor butter good or keep sweet. Therefore first make good butter. Full directions are given in the *American Agriculturist* of May, 1872, in the "Ogden Farm Papers," for making the best butter. When that is made, it may be packed, using a double allowance of salt for packed butter, in new oaken tubs, which are first scalded, then soaked in brine, and the butter closely pressed in until quite full and level with the edge; then sprinkle a handful of salt on top, and cover with a piece of muslin, dipped into brine; nail down the cover and put away in a cool, sweet cellar or spring-house. It should then keep perfectly for a year or more.

Mineral Phosphates.—"H. C. A.," Brownsville, Tenn., asks what is meant by the statement in the "Agricultural Report" for 1859 to the effect that mineral phosphates may be treated with acids similarly to bones with equal efficacy, excepting that they may contain salts, which are absent in the bones. This is

said in reference to the "Apatites" or phosphatic rocks of New Jersey and New York, which contain fluorine acid, which would of course remain as an ingredient in the resulting superphosphate. The Charleston phosphates have been largely worked since that period, and have furnished superphosphate equal to that from bones. Directions for dissolving bones are given in *American Agriculturist* for April and May.

Phoenix Island Guano.—"J. W. C.," Newtonville, Mass., asks how he should use Phoenix Island guano. As this guano contains less soluble matter than Peruvian, it may be used in rather greater quantities, say 200 to 300 pounds per acre, on corn, potatoes, and tobacco, harrowed in just before planting or spread broadcast on grass.

How to Feed Corn-Stalks.—"E. M. A.," Forsyth Co., N. C., wants to know how to feed corn-stalks. The best way is to cut them up into pieces an inch long, wet them, and sprinkle a little salt and a quart of meal to a bushel of them, and give a bushel twice a day to a cow, with some hay or straw at noon.

Western Farming.—"Western Wilde" writes that he does not agree with the Western farmer who thinks we should not mention peat, bone-dust, etc., but is satisfied that farmers in the West need to give more attention to these and other fertilizers. He says farms in the West are running down fast, and need something to bring them up again.

Pickles.—"M. F. M.," Sioux City, Iowa. We have frequently stated that attractive appearance of the pickles found in stores is due to the use of colorless vinegar. It is called white wine-vinegar, but it is made from whisky.

What is a Maximum Crop of Beans?—Forty bushels per acre have been grown. A farmer in Western New York raised over 1,500 bushels from 60 acres, or over 30 bushels per acre.

Soda for Decomposing Bones.—"A. J. B." asks what kind of soda was referred to in the December number of *American Agriculturist* as used in decomposing pounded bones. It is common sal-soda, and is known in stores as washing-soda.

Iron Flower-Vases.—"Mrs. M. C.," Johnson Co., Mo., has some tops of parlor stoves which she wants to use for flower-vases, and wants to know how they may be painted to look like stone. First beat them to get rid of any grease, then, while hot, paint them with a coat of linseed oil, which when dry cover with a coat of drab or brown lead paint, and before the paint dries sift on them powdered sandstone.

What is Muck?—"A." asks: Is mud or dirt from the bottom of a branch or small run, muck?—No. Muck consists of vegetable matter which has accumulated in a swamp or boggy place by the fall and decay of grass, leaves, or plants which have grown there during a long series of years. Wash often collects in ponds or creeks, and consists generally of sand or earth, with some vegetable matter; but it is not muck. Muck consolidated becomes peat. This is the sense in which the word is used in America.

Hint for Mechanics.—Ed. Skinner, Middletown, N. Y., says by rubbing a piece of chalk on a square the lines and figures are filled up, and can be much more plainly read. This is especially useful for near-sighted persons.

For other **Basket Items** see page 233.

The Department of Agriculture.—The *Maryland Farmer*. It is pleasant to be criticised when it is done in the gentlemanly manner of a correspondent of the *Maryland Farmer*. It is a luxury to which we are not often treated—this having our views controverted in a fair and above-board style. The writer alluded to, reviews our notice of the Report of the Department of Agriculture for 1871, given in our February number. He does the best possible for the Commissioner, but we are not able to see that he invalidates any of our statements. Some portions of the report were so ridiculous, that a mere statement of them was all we needed to make. These awkward matters our reviewer gets over by assuming that they were the work of subordinates, and probably the Commissioner never saw them until they appeared in print. As our critic assumes a Latin name, "Viudex," we will ask him if he is not familiar with the Latin adage, *Qui facit per alium facit per se* ("Who does a thing by another, does it himself")? Would he accept it as an excuse if

we were to say that the article which displeases him was not written by the responsible editor, but by one of the young men in the office? Here is just what is the matter. Mr. Watts is too old to attend to the duties of his office, and his chief clerk is the head and front, the top and bottom of the affair. In the words of the hymn, "he can create and he destroy." Personally we have no objections to Mr. Watts, and never saw him, and never heard of him before he took the office, save in the mismanagement of the Pennsylvania Agricultural College. We have only judged him, as we did his predecessors, by his official acts and publications.

Our position in regard to the Department is this. It has thus far been a disappointment—not to say a nuisance. Let it be either abolished altogether or be put upon a respectable footing. It is yet a problem whether we really need a Department of Agriculture, and that will never be decided until the experiment is made on a respectable scale. No man who can be had for three thousand dollars a year, and is obliged to put his sons and daughters upon the pay-roll in order to get enough to live upon, is fit to occupy the position of Commissioner. We advocate ample appropriations, securing the best men the country affords, and a fair trial of say five years. Then if no good results are perceptible, abolish the Department, and let agriculture look out for itself, just as any other interest does.

Bees Notes for June. — By M. Quinby.

Be sure and put guide comb in every box. The whiter and cleaner, the better. Cut white comb in pieces, an inch square. Dip each piece in melted glue or bees-wax, and stick before it cools. It is very seldom that boxes are filled and finished ready to remove in this month, as far north as this—Montgomery Co., N. Y. When it does happen, be sure to know it, and remove them, putting on empty ones in their places. After they are finished, every day they are left on, renders the combs darker. The best way to get rid of the bees when these boxes are taken off, is to drum them out. It takes time, but it is safe. First lay down some bits of scantling or strips of wood. Lay a board on these, put on the boxes, with a passage at the side or top, so that the bees can pass out directly from the finished box into an empty one, without flying. With a hammer or stick strike the board steadily a few minutes, and all will run out. The boxes containing the bees should be put on the hive in the place of those removed. A number on the hive and box to correspond will prevent putting the bees on the wrong hive when the box is returned. As soon as the bees are out, set away the empty boxes until October in a dry, cool place, if possible. Examine all weak stocks, of which there will be many this season, and supply all with a laying queen at the earliest moment. If you give a weak colony, or any other, brood to raise a queen, it will take six or eight weeks before the bees raised from her will be of any use—in which time the worms might destroy the hive.

Leave no old pieces of comb lying around to breed worms. If no better use is found, either burn or make wax. It takes a larger force to get away from the main body of the hive to work in boxes than to simply store honey in comb furnished ready-made. When honey is extracted, from three to six pounds can be obtained where one of box-honey is to be had.

The first principle of extracting honey from comb is centrifugal force. It can be illustrated by different methods. A pail, or box with a flat bottom, large enough to allow a comb, with cells open, to lie on the bottom, or rather on wire cloth, a little above the bottom, may roughly represent it. If such a machine should be whirled, as a boy whirls a sling, the honey on the lower side of the comb would be forced out, especially in warm weather.

Now, instead of a pail take a barrel. If you make a frame of wire-cloth—tinned or galvanized wire is preferable—as large as the comb, set it vertically in the barrel, close to one side, securing it there—it is plain that whirling the barrel will throw out the honey on the same principle. But the finished machine is a vast improvement on this. A regular machine will empty four combs at one time. As there is no patent legally covering any of them, they can be made by any one having sufficient skill.

They are usually made by constructing a box, large enough to hold four combs, perhaps fifteen inches square by twenty deep. This will fit any sized frame. The box is made of wire-cloth, and outside of this a tin can, large enough for the box to be turned in, and to catch the honey as it is thrown out. The best machines are geared, giving the frames three or four revolutions while the hand makes but one. As most people will prefer getting a good extractor ready made, I will not describe it further.

A knife to cut the sealing from the cell, will be needed. One a little crooked at the end will work much better than a straight one. When ready to operate, choose a day when the bees are busy, doing nothing to them before

ten o'clock, at which time, if there is room for stores, most of the old bees will be out foraging. A bee that comes in laden is not disposed to sting until its load is discharged. Open the hive without jarring it, lift out a comb, and shake off the bees. The few that stick fast can be brushed off with a quill. There is an art in brushing bees. If you make a short, quick motion with the quill, you can throw them off from the comb, not simply roll them over. The latter may make them cross.

Take out four combs at a time. If any is sealed, cut off the sealing with the knife. Set the side from which you would take the honey, next the wire-cloth, and give the machine a few turns. You can see when the honey is discharging, and when it is out—that is, if you have a machine in which the outside is stationary. If that revolves with the rest, as in some extractors, you can not tell much about it. When one side is emptied, turn the other. The brood will not be disturbed, unless turned unreasonably fast. The combs may be returned to the hive. When all are emptied and returned, close up the hive. The process may be repeated in from three to seven days, according to the season. Most bee-keepers can save combs this season to work with.

This extracted honey is the purest that can be obtained, but of this another time.

The Boys and Girls' Pictures.

Award of Prizes.

To the Boys and Girls: Never did a poor Doctor have a more bewildering task before him. Those doctors who practice medicine and have to prescribe for people who have nothing the matter with them except the "whimsies" have a difficult job; but what is that to reading nearly seven hundred stories by boys and girls from five to sixteen? Well, I have done it as faithfully as I could, and with as much care as if hundreds of dollars depended upon the decision. In the first going-over about fifty of each boys' and girls' stories were selected; then these were looked over again, and about twelve of each of the four classes were selected, and at last—there was the rub—the three in each class chosen. The object in offering the prizes was to induce you to exercise your ingenuity in story-telling, so the inventive talent displayed was the first consideration. The next point taken into account after the story itself, was the style, or, as you will understand it better, the way of telling it. The spelling and handwriting, though these were generally creditable, were not much regarded. There are some curious things that I may tell you about if I have time; such as the number of writers who hit upon nearly the same stories, and the number of similar names chosen for the characters. Quite a number who did not receive prizes sent stories so creditable that they deserve honorable mention, which I will try to give next month. The little boy and little girl, too young to write but who dictated their stories to their parents, will hear from me. But now I have only space to add the list of

AWARDS.

Boys between 12 and 16.

- 1st. Cyrus D. Chapman, age 15, Irvington, N. J. Knife.
- 2d. Arthur S. Shumway, age 12, Madison, O. Book.
- 3d. James H. Brewster, age 15, Mt. Carmel, Ct. Book.

Boys under 12. Prize for each, a book.

- 1st. Herbert Alexander, age 10, North-East, Md.
- 2d. Elmer Frail, age 9, Franklin, N. Y.
- 3d. Harry C. Ladd, age 11, Beverly, Mo.

Girls between 12 and 16.

- 1st. Nellie G. Brown, age 13, New Canaan, Ct. Gold Pen.
- 2d. Sarah C. Lyman, age 15, East Hampton, Mass. Book.
- 3d. Julia B. Mansfield, age 15, Twyman's Store (Spottsylvania Co.), Va. Book.

Girls under 12. Prize for each, a book.

- 1st. Carrie M. Wheeler, age 10, Eyota, Minn.
- 2d. Nettie Van Ness, age 11, Boone Co., Ky.
- 3d. Lila A. Ripley, age 8, Hendersonville, N. C.

Of course, as I read story after story I could give each one a prize; but each one has tried, and that has done him or her much good. More than half of the children stated that it was their first attempt at composition. I think it has done some good to induce some four hundred children to write for the first time, and I hope their parents think so too. Now, as to the books to be sent. I would like to suit all, and if the boys and girls to whom books are awarded will send me the name of any work that retails for \$2.00 or less, I will send it. If they fail to do this before June 10th, I will exercise my discretion in the matter, and send such as I hope will please them; but I had rather they should indicate at least the kind of book they prefer. THE DOCTOR.

Roofing Materials.

Many inquiries have been made by our correspondents about roofing materials, and with regard especially to their cost, durability, and ease of application, to which we reply. The roof is the most important part of a building, and should be water-tight and fire-proof, or the whole building is comparatively useless, and in danger in case of a fire occurring near by. The materials for roofing are shingles, slates, tin, and the various fabrics of paper, felt, or other similar materials used in connection with some preparation of coal-tar. Shingles are by far the most commonly used; and when made of pine, split and well shaved, are light, durable, and able to resist rain. But they are becoming scarce and costly, and their cost will undoubtedly increase until it becomes necessary to use some other material in place of them. Sawn shingles make a very handsome roof, but lying very closely, and having a rough surface, they hold the water, and become moldy and decayed very soon unless some preventive measures, too troublesome for general use, are taken. Slates are exceedingly heavy, and are not well adapted for frame buildings unless they are very stoutly built; besides, the cost of freight on them restricts their use to the neighborhood of the quarries or to contiguous lines of railroads. Tin roofs are especially valuable in cities and towns where flat roofs are desirable, and where mechanics can be obtained who can lay them properly. They are probably more costly than any other roof. The most useful roofs for farmers or dwellers in the country, as we believe, are those which can be easily applied without the aid of skilled labor. Some of these forms of roofing are peculiarly valuable for their fire-proof qualities, as well as for their durability, lightness, cheapness, and the ease with which they are laid. Most prominent amongst all these is Johns' Asbestos Roofing, which is light, strong, and practically fire-proof, and being manufactured in rolls of sufficient length to reach quite across the roof, very few joints are made in laying it, and it is not likely to leak. Two men quite unskilled, or only sufficiently skilled to be able to lay one strip on another with a lap of one inch, can cover a large roof in one day. The roofs covered with it do not need much pitch; in fact, they are better to have only so much inclination as to cause the rain to flow off and no more. This saves expense of timber in the roof. The roof once laid is kept in order at a very trifling expense, and will last many years.

A Visit to Mr. Mackie's Jerseys.

BY GEORGE E. WARING, JR., CODDEN FARM.

Having to deliver the address at the Annual Fair of the Housatonic Agricultural Society last fall, I took occasion to visit the beautiful farm of Mr. J. Milton Mackie near by. By correspondence, I have kept myself informed of the condition of the establishment since that time, and the herd of Jerseys which forms its principal feature seems worthy of notice.

There are about thirty, all thorough-breds, several of them imported from the Island of Jersey. They are of various colors, from dark mulberry to creamy fawn. The lightest ones are quite as hardy as the dark, and both are as hardy and healthy, under the same treatment, as the native cattle—bearing the rigor of Berkshire winters with only ordinary care. Mr. Mackie has noticed the same tendency to the

production of cream rather than fat that is characteristic of the race in warmer climates.

Great importance is attached to the "escutcheon" or milk-mirror, and he has one family of ten or twelve females in which every heifer born has a perfect escutcheon. I state this fact without pretending to decide whether it has any certain influence on the product or not. It is my belief that it has a great deal to do with it. Whatever may be the incidental causes of Mr. Mackie's success, it is unquestionably such as he would find it impossible to secure with any other than Jersey or Guernsey cows.

During the past twelve months he has milked an average of eleven cows and heifers of all ages—these and no more. He made in that time 2,547 lbs. of first-quality butter—an average for each animal of 231½ lbs.—and this from cows of which four can be kept on the food needed for three of the larger native cows. Mr. Mackie sells his butter in Boston for 75c. per lb., but of course only a few farmers could get such a price. They could, however, get an advance on regular market rates, and the increased amount of the product would of itself be a great item. So much for the result. Concerning the methods of treatment, we quote the following from a recent letter from Mr. Mackie:

"I can not lay claim to any superior method of feeding. During the winter, good, moderately early cut hay is fed, morning and evening, after having been cut, moistened with cold water, and sprinkled over with equal parts of Indian meal and wheat bran, at the rate of one quart of the mixed grain for each cow. After the cut-feed in the morning, each one has about a peck of sugar-beets, also a little salt. A feeding of long hay is given in the middle of the day. The cows are let out into the yard for water after their morning and mid-day meals. They are carded and brushed every morning. In the stable they stand in stanchions and on a platform. They have the liberty of a warm, sunny yard for several hours every day when the weather permits. On this regimen—they are pastured and fed with sowed corn, pumpkins, or sugar-beets in summer and autumn—the cows are kept in good store or breeding condition.

"The calves are taught to drink milk when they are two or three days old. When about a month old, they are put on skimmed milk, with a trifle of wheaten shorts. The skimmed milk is sometimes continued for a year. The calves do remarkably well on it, being neither over nor undergrown, and well shaped. Almost without exception, I have found the heifers an improvement on the dams. I do not feed my cows with the aim of making the greatest possible amount of milk or butter, but mainly with reference to maintaining a good state of health, in order to raise healthy and improved calves."

HAYING TOOLS.—Thousands of farmers under whose eyes this item will fall will find it peculiarly addressed to themselves. Its object is to induce them to make use of the first stormy day to overhaul their mowing machines, tedders, horse-rakes, and forks; see that every worn part is renewed and every weak part made strong, and that everything connected with them is in first-rate running order, duplicates being provided of such pieces as are liable to break in the field. A dollar spent now may save many dollars in lost time and damaged hay. There is no more unpromising sight than that of a farmer driving five miles to town in the height of the haying season to repair last summer's damages to his hay-rake.

Ogden Farm Papers.—No. 29.

I think I have nothing more useful to say this month than to give an account of my experience with the use of wind-power. Four years ago, after a careful survey of the whole field, it seemed evident that the best way to get water for the stock was to force it up from a never-failing spring well, 800 ft. distant, and 35 ft. lower than the foundation of the barn. The well was the best in the neighborhood, and the only one on the place which could be depended upon in very dry seasons; its depth 17 ft., overflowing, except in very dry weather, when the water recedes to the depth of about 5 ft., and there stands. I went over the whole question of motive power as carefully as I could. A steam-engine at that distance from the buildings was out of the question, and there was never flow enough for any sort of water-power. A caloric engine was advised, but the interest on cost, and the expense for fuel and attendance, made it desirable to avoid it if possible, though its use was not impracticable. I had always had a fancy for self-regulating windmills, and knew enough of the various kinds previously in use to doubt their stability. Just then the Empire Windmill was brought to my notice, and it seemed to obviate one very serious difficulty by the fact that it exposes to the wind in no one piece more than about half a square foot, thus dividing the strain, and by its frequent spaces allowing free passage for the wind. Still, I had never seen one at work, had never heard of its success except from its interested friends, and had generally the consciousness that if I adopted it I should be trying an experiment for the success of which I should get few thanks, while its failure would bring down upon me yet one more "I told you so," and "I told you so" is a form of vituperation of which I had heard enough to have grown slightly weary. However, to water a big barnful of stock in the ordinary way looked so formidable, that I concluded to try the windmill and take the risk.

Its original cost, delivered at Newport, was \$200. The building on which to place it cost \$50 more. With the help of a common mechanic and of the printed directions that accompanied it I put it up myself. The rest of the arrangement—pipe, tank, watering-troughs, etc.—are the same that would have been used with any other power. It is only necessary to say of them that they enable us to water all the stock in the barn almost entirely without labor. The regulating machinery of this mill was rather crudely arranged, and weakened my faith in its durability; at the same time it did its work remarkably well. Neighbors and friends foretold its downfall with every storm, and I have never yet quite outgrown the habit of looking doubtfully as I go over the hill toward the farm to see whether it is still standing, although the great gale of September, 1869, which uprooted large trees, unroofed houses, and did more damage than any storm for fifty years, left the apparatus entirely uninjured, and satisfied all who saw it of its substantial utility.

Through carelessness in attending to such little details as screwing up loose nuts, tightening brace-rods, etc., the mill began, after three years of use, to grow shakily and to rock on its turn-table, so that finally a gale did it serious damage, which it cost over \$50 to repair. Then it ran a year longer without material injury, but the seeds of disease had become deeply seated with it. Loose bolts rattled and loose gudgeons ground away in spite of oil, until finally, after

four years of utility, my Empire Windmill went by the board, nearly a total wreck. Our confidence in its merits had become so great, and such radical improvements in its construction had been made, that we did not hesitate to order a complete new mill to take its place. This has now been in operation for some weeks, and there is every indication that it is safe against all injury except that of the ordinary wear and tear to which all mechanism is subject. The practical question now is, whether Ogden Farm has received a full return for the \$300 its windmill has cost?

To begin with, we have learned how to take care of such machinery, and even the old mill, if we had it new again, would surely last us twice as long as it did. In addition to this, the actual work done has been prodigious. There has been on the place during the whole time an average of seventy head of stock in winter and thirty-five in summer, or an average for the whole time of over fifty head. How much it would cost to pump by hand the water that this number of animals would require in four years my readers can judge as well as I. How much is lost all winter long by turning milking or fattening animals out into a cold barn-yard to shiver over a tub of ice-water few of us rightly understand. In addition to what the stock has required, we have had an ample supply for a large steam-boiler, and for moistening all the cut fodder that has been steamed for the stock. For a year past there has been an almost constant flow of water, fresh from the underground spring, to keep the deep milk-cans warm in winter and cool in summer. Before this, we had all summer a fresh and cooling flow over the concrete floor of the milk-house. This is the water that we have used; besides this, a large amount has run to waste, and the mill has not been working more than two thirds of the time when there was wind enough for it. It is not easy to compute the value of all this in dollars and cents; but when we consider the convenience of watering a whole line of cattle, standing in their stalls, by simply turning a faucet, the economy of not turning them out to water in severe weather, and the advantage of having water always before them at the temperature of the stable; and when, in addition to this, we fairly estimate the benefit of the deep-can system in making better butter, and in making it more easily in winter and in summer, we shall see that a yearly tax of \$1.50 on each animal kept is really of small moment.

At the same time, I believe that this is much more than will hereafter be necessary, for the construction of the new mill is so much more simple—avoiding so many of the objectionable features of the old one—that the chance is very much better that the present machine will last eight years than was the chance of the old mill's lasting four years.

Occasionally, when our water-works have been out of order, making it necessary to haul our water from an adjacent pond or from the house-well, we have been made to realize the importance of the saving they constantly effect.

I have made no other application of wind-power, and am not prepared from my own experience and observation to say anything very definitely in its favor, but I am not at all sure that the economy of a large windmill, consuming nothing but a little oil, would not be sufficient to justify one in substituting it for a steam-engine, costing more at the outset, consuming more oil and lots of fuel besides, and adding somewhat to the rate of insurance. If food is to be steamed, the extra cost of fire to

run an engine is not very great, but for any work such as cutting hay, grinding grain, sawing wood, etc., which may without disadvantage be postponed until a fair wind is blowing, the windmill has advantages that entitle it to careful consideration. This is only a suggestion, however. My positive advice must be confined to the very important question of water supply. But for this it is positive, and I should not hesitate to recommend it in any case where a permanent water-power can not be had.

A correspondent from York, Pa., asks "whether the slatted floor in our pig-pen has been a success or a failure; whether unpleasant draughts from below have been prevented, and whether dry earth can be used to prevent foul smells, at a cost that will certainly pay?" The slatted floor certainly has been of great advantage, especially in a country like this, where straw is too dear to be freely used for bedding. It is the driest floor that I have ever seen, all moisture running directly away. We have not, however, found that the use of dry earth in the pig-pen was a success. It does absorb and destroy foul odors without doubt, but it also absorbs urine, and becomes very wet and very troublesome earth, soiling the swine, clogging up the openings between the slats, and making itself generally nasty. If straw can not be used in abundance I prefer the dry boards. As to draughts from below, we are not troubled by them in the least, for the reason that the cellar is tight all around, and there is no chance for draughts from that source. We have not been especially annoyed by odor from the manure in the cellar. The house is by no means sweet-smelling (as what pig-pen is?), but it is no more offensive than those made on any other plan, and the health of the pigs sufficiently attests the wholesomeness of their quarters.

While advocating the use of slatted floors for swine, I do not especially recommend them for cattle stables with manure cellars underneath. They are advantageous in all of the points previously claimed for them, but they have one serious disadvantage that we did not previously foresee. With a tight floor, manure might be hauled out at pleasure at any time during the

Fig. 1.—CHEAP FARM-LABORERS' HOUSE.

winter, without reference to wind or to temperature. With a slatted floor, on the contrary, a cold cellar means a cold stable, and we are sometimes unable to open the cellar door for months together. Of course the manure is keeping well all this time, but it is accumulating work for the busy spring-time of the year which

it would be a great advantage to be able to avoid. If I were going to rebuild the barn I should adopt a short stall floor with a drop behind it as the best arrangement I know of.

Spring is upon us, butt-end foremost, and winter has hardly left. Everything is fully a month behind, and there is no reason to suppose that we shall be favored with a lengthening of the season at the other end. With us, corn-planting and oat-sowing will come about together. At this time, April 27th, not an acre of land on the farm has been plowed, nor has any considerable amount of out-of-door work been possible. Add to the lateness of the season and the length and severity of the winter the fact that we seem to be entering upon another season of severe drouth, and it will be seen that the prospect of profitable farming is not so flattering as we could wish. However, I won't grumble—that is a common failing of our craft which it may be as well to avoid. It is always too hot or too cold, too wet or too dry, too early or too late, or too something else to suit our ungrateful souls; and we ought, all of us, to be ashamed of ourselves for being so blind to our advantages. With high wages, expensive living, hard work, unfavorable seasons, and no end of

Fig. 2.—PLAN OF LOWER FLOOR.

annoyance to pull us down, we have high prices, good implements, easy transportation, and ready markets to cheer us up, and surely no agricultural population in the civilized world (laborers included) is so well housed, so well fed, and so well dressed, nor held in so good consideration in the community as the millions of dissatisfied, grumbling farmers of America. How it may be in what we are disposed to regard as the uncivilized world we have no means of knowing, but I suspect that the frugal industry and close economy of the cultivators of China and Japan produce as a result quite as much comfort and satisfaction as we get from our spendthrift ways.

Houses for Farm Help.

Doubtless many farmers' wives will gladly welcome this article with the illustrations belonging to it. No harder nor more wearisome work falls to the lot of a farmer's wife than the care of the "help," and the extra cooking involved. It is generally the case, too, that farm laborers are not just exactly the sort of men that we would desire our boys and girls to associate with, and the privacy of the family is interfered with when they are boarded in the house. Every inconvenience is at once avoided by erecting a tenant-house for occupation by the laborers. This also enables the farmer to get the most desirable and steadiest sort of help possible—that of a married man. With such help, all other hands, whether regular or occasional, may be provided for and entertained. The cost of such a house is comparatively trifling when the conveniences are considered.

Figure 1 represents a two-story frame cottage 16x24 feet. Figures 2 and 3 show the arrangement of the lower and upper floors. It will be seen that there are one large room for cooking and eating and two sleeping-rooms on the lower floor, and three sleeping-rooms on the upper

Fig. 3.—PLAN OF UPPER FLOOR.

floor; the large upper room may be used for a sitting-room for boarders. Twelve people may very well find room with provision for perfect privacy and other requisites in such a house. The cost of materials when built of boards, battened, with matched floors, plastered all through, and a shingle or felt roof, will be under \$200. Much of the labor may be done by the farmer himself, as digging the cellar, laying up the stone foundation, and hauling materials. With labor and materials all included, \$250 will be about the total cost. A large interest on the cost will be gained by the relief afforded to the owner's own family, and as much more by the steadier and more regular kind of labor to be secured. If money is to be spared for a more sightly building, that shown at fig. 4 might be adopted. The inside arrangements are the same, but the outside is made more ornamental, and is very much improved by the garden planted around it. It is worthy of consideration here whether it would not be of great benefit to those farmers who regularly keep hired men, to make it an object for them to retain their places permanently, and make them comfortable by providing them facilities for having gardens, a stable, and a cow and a pig of their own, as is done almost always on English farms. In that country, while farmers hold their farms mostly as ten-

Fig. 4.—LABORERS' HOUSE ORNAMENTED.

ants, and would seem therefore very liable to occasional or frequent removals, yet on the contrary the same family very often remain for generations on the same farm, and have grandfathers, fathers, and children working for them at one and the same time. Under such circumstances it is an object for them to surround themselves with those little comforts and conveniences which on the whole make up much of the pleasure of living.

Longhorned and Polled Cattle.

A hundred and fifty years ago, in the western part of Yorkshire and the eastern part of Lancashire—two adjoining northern counties in England—there existed a breed of very large-bodied, coarse-boned cattle with a very striking peculiarity in their horns, but which, having some favorable points, were about that time taken hold of by breeders and subjected to a course of improvement. Specimens of the breed were removed to the county of Leicestershire, and in a short time the well-known breeder, the first Bakewell, whose skillful efforts resulted so favorably for English stock, took hold of them, and in a few years succeeded in producing a great change for the better. The large, bony frame was covered with

flesh, and the form became more rotund and shapely. The natural aptitude of these cattle for feeding assisted largely in making the efforts of the breeders successful, and very soon they became favorably known, and much prized for feeding, as the improved Leicesters. At this period they were characterized by their fine head, thin neck, deep chest, low brisket, loin narrow at the chine but wide at the hips, fleshy thighs, and in general a round carcass, with ribs well covered, and a thick mellow hide. The horns, however, were still their most striking peculiarity, being about two feet long on the bulls, and often three and a half on the oxen and cows, fine and tapering, and hanging downwards by the sides of the cheeks. They became a favorite stock amongst the graziers, and at public sales so long ago as 1790 brought prices which would be thought large even at this time—viz., \$400 on an average of fifty head. When it is considered that this stock possessed, along with their other good qualities, that of early maturity, it is strange that they should so soon have disappeared from view behind the then rising Shorthorn. But the Durhams or Shorthorns coming then into fashion soon displaced the more ungainly Longhorns, and for some

years past the native county of the improved Leicesters has not contained a single herd of this breed. In their ancestral home, too, in Lancashire and Yorkshire, they have also given way to the more fashionable breed, but whether anything has really been gained in the change is doubtful, when it is remembered that this old

of America. As a curiosity, and as one of the ancient races which has done good service in its time, it is worthy of note. And yet it would not be at all surprising to see this stock come again into prominence, if in no other way than as a means of procuring a cross on the Shorthorn, hints being occasionally given by

breeders that such a cross might be desirable. In striking contrast to the Longhorns stand the no-horns or polled cattle, both in the matter of horns and general figure. We lately described the Scotch or Galloway polled cattle, and now present an illustration of the English or Norfolk and Suffolk breed of polled cattle. This race of cattle owes its origin to the introduction of the polled Galloways into the counties of Suffolk and Norfolk, where they have been for long periods, and are now, brought in

LONGHORNED CATTLE.

large droves for the purposes of feeding for the market. Having excellent qualities as beef cattle, the bulls were crossed upon the native stock of those counties, which although excellent milkers, were deficient in form, having, according to the eminent breeder Bakewell, "a back like a roof of a house, with a belly of an exactly opposite character," giving them just the points which would be undesirable in a beef stock but desirable as milkers. The cross resulted in improving their form without injuring

their milking qualities, and building up a race of brownish red and brindled cattle which have gained a reputation in England as producing the best butter which goes into the London market—and this in spite of the imperfect modes of dairying prevalent amongst the Suffolk farmers—and also of being fair beef stock. Still, dairying being the main object for which this stock is bred, and the absence of horns being equally desirable to the Suffolk dairymen, care has been taken for many years to

NORFOLK AND SUFFOLK RED POLLED CATTLE.

being owned by the Duke of Buckingham. It is not probable, however, that in the race for superiority, at least so far as fashion is concerned, the Longhorns will ever supersede the more favored Shorthorns, which seem to have taken a firm hold on breeders, especially those

breed their stock so as to perpetuate these desirable qualities. This care has led to success, and the race has long enjoyed the reputation of producing the best milking cows in England. Not infrequently cows of this breed give in their prime eight gallons of milk daily, and six gal-

lons daily is a common product. This large production is also sustained during a lengthened season. As this stock is now being introduced into this country, it would be well to note that amongst Norfolk and Suffolk farmers the greatest attention is paid to the health and condition of their cows, and to the production of proper feed for producing milk. Cabbages and turnips are raised largely for fodder, and it is not uncommon to see the cows tethered in the fields and feeding on these crops. With equal care in their management, and with our improved dairy system, we should expect this stock in the hands of American dairymen to produce butter of a quality equal to that of the Jerseys.

Walks and Talks on the Farm.—No. 102.

“Your Walks and Talks,” writes John Johnston, “are capital; but how you are going to get eight tons of barley straw from five acres I can not understand. I suspect it must be a mistake in the printer.” Is not that a pleasant way of putting it? Criticism tempered with compliment! But there is no mistake about the matter. I have raised over 500 bushels of barley on ten acres, and expect to do still better, and I have no doubt there was 16 tons of straw. True, I did not weigh the straw. But did I not weigh with my own hands both grain and straw and chaff of Mr. Lawes’s first experimental crop of barley in “Agdell-field”? and have I not a right to trust my judgment? Mr. Judd, who has since visited it, will recollect the field—and the facts, are they not recorded in the Journal of the Royal Agricultural Society, Vol. XVIII, Part II?

The barley was not manured. The field was in turnips the previous year. On Plot 1 the turnips were grown without manure; on Plot 2 they were manured with superphosphate alone; on Plot 3 they were manured with superphosphate, potash, soda, ammonia-salts, and rape-cake. After the turnips were grown, the plots were each divided into two parts. On one part the turnips were carted off, and on the other part they were eaten on the land by sheep. The following was the result:

	Plot 1. No manure.		Plot 2. Superphosphate for turnips.		Plot 3. Mixture of artificial ma- nures and rape-cake.	
	After turnips carted off.	After turnips fed on the land.	After turnips carted off.	After turnips fed on the land.	After turnips carted off.	After turnips fed on the land.
Grain per acre, lbs.	2,681	2,734	1,676	2,526	1,943	2,569
Straw per acre, lbs.	2,992	3,182	1,989	3,264	2,463	3,674
Grain in bushels of 48 lbs., bus.	55½	57	35	52½	40½	53½

I do not propose to discuss these results. I only give them to show that I was not so wild as Mr. J. supposed when I estimated that five acres of barley at 50 bushels per acre would give eight tons of straw. Or, in other words, that the crop would consist of six tons of grain and eight tons of straw and chaff. I am well aware that it requires very rich land and the best of tillage to produce such a crop.

The largest yield of grain in Mr. Lawes’s barley experiments was 3,696 lbs. per acre, or exactly 77 bushels of 48 lbs. per bushel. This was the sixth crop of barley in succession, every year on the same land! The plot was manured every year with salts of ammonia and superphosphate. The yield of straw on this plot

was 3,687 lbs. per acre. Two years before, however, one plot, dressed with salts of ammonia, superphosphate and sulphate of potash, soda, and magnesia, yielded 5,487 lbs. of straw per acre and 3,539 lbs. of grain, or a little over 4½ tons of total produce per acre. I only mention these facts to show what can be done. But I am well aware that not one farmer in a hundred believes them. When I told the Deacon that the barley on “Agdell-field” at Rothamstead weighed 57½ lbs per bushel—that I weighed it myself, that the bushel was not moved or shaken while being filled, and was struck off level—I could see that he did not believe it. And when my first crop of barley on this farm was 12 bushels per acre, weighing less than 40 lbs. per bushel, I can imagine that the good Deacon after church the next Sunday, when talking to his brother farmers under the shade of the maple-trees, might in reply to an observation remark: “An excellent sermon.—Yes, he thrashed last week. Wheat, 15 bushels per acre. But he did not sow that. Oats rusted—only 8 bushels per acre. Not worth thrashing. Barley, 12 bushels. Took it to the city. Couldn’t sell it. Had it ground for the hogs.” After a pause: “Well, they want it.—Yes; an excellent sermon.”

After Ezra Cornell visited Mr. Lawes’s experimental farm, in company with Mr. Judd and others, he wrote an elaborate paper showing that the crops, though large, would not pay. He went to a chemist and druggist, and ascertained what the ingredients which Mr. Lawes used would cost. He doubtless thought the argument a good one. He overlooked the fact that if Mr. Lawes wanted to ascertain the effect of potash it was necessary to separate the potash from other ingredients, and that this is a costly operation. But if Mr. Lawes proved that potash was good, Mr. Cornell, as a practical farmer, need not buy pure potash. He could use ashes, kainit, or any other article that would furnish potash in the cheapest form. Mr. Lawes used ammonia on one plot, potash on another plot, and soluble phosphates on another, and on other plots he used all three mixed together in different proportions. To do this, it was necessary to use these articles in an expensive form. But having ascertained that ammonia, phosphoric acid, and potash are the most valuable constituents of all manures, then it is no longer necessary to go to a “chemist and druggist” and pay high prices for them. We, as practical farmers, have only to study out for ourselves the cheapest form in which we can get these substances. It may be by following the land, or growing clover, or buying bran or cotton-seed cake and feeding it to animals; or by buying ashes, bone-dust, superphosphate, guano, dried blood, fish, or fish guano, castor-pomace, hair, horn shavings, hide or leather scraps, salts of ammonia, or nitrate of soda, according to circumstances. He is the wise farmer who accepts the teachings of true science, and uses them to his own advantage. Lawes’s experiments have been worth millions of dollars to the farmers of the world. They did not pay directly. He never expected they would. I can recollect his buying a quantity of rice (in order to ascertain the effect of carbonaceous matter), and grinding it into a fine flour, and then sowing it on the land. How the farmers laughed! But it was not many years before they presented him with a testimonial in the form of a new laboratory.

I asked our path-master the other day if I might work a day or two on the road at this

season (April), and have it deducted from my tax. I wanted to let off the water. I am assessed more days’ work than any other four men in the district, and am very anxious to have a good road, and have offered to double my tax if the others will, and make the bed of the road dry and firm by letting off all the water. But no. We must “work out” our tax in the old way. I am assessed eighteen days’ work. Some time in June I am notified that to-morrow they are going to “work on the road.” A man and team and scraper, or plow or wagon, count three. I send three teams and three men for two days, and the tax is paid. They do not half work. The path-master has had no experience in managing men. He does not know how to plan the work. To get rid of them, he sends a couple of teams to draw gravel, and they do not get back until half-past ten, and they think there is not time to draw another load before noon. Another team is started to plow along the side of the road, and the team with the scraper lies idle waiting until this is accomplished. There are stones to be picked up before the ground can be plowed. When this is done the plow is finally started. The ground is dry and hard. One man drives, another holds, and one or two more ride on the beam. The horses are overtaxed, and have to rest every few yards. The men rest too. All this time the scraper is waiting. By and by it starts, with one man to drive and another to hold the scraper. The plow is still going back and forward, and every bout it has to wait for the men with the scraper to get out of the way, and when the scraper comes back for another load it has to wait for the plow. And so the work goes on. Our path-master is an intelligent, industrious, and successful farmer. He is not to blame. It is the fault of the system. Fifty men, even if the work is well planned and properly executed, can not make as good a road in one day as one man can in fifty days.

Mr. Root has written an article for the Rural Home advocating the non-drainage of swamps in Western New York. He thinks it will not pay to drain them. “There are occasional exceptions,” he says, “when such lands are in the vicinity of cities, and can be made very valuable for garden uses, and thereby beautify the face of the country when it is desirable to bring them under improvement, but for the ordinary purposes of farm cultivation it is quite different. Nothing short of a thorough system of under-draining will fit these lands for profitable cultivation. . . . That large tracts of waste lands have been profitably reclaimed in the vicinity of large Eastern cities is no argument that the same course should be profitable here. The Hackensack salt meadows, near Newark, N. J., reclaimed at a cost of about \$185 per acre, are now valued at \$1,000 per acre; and yet if those lands were lying in this vicinity, and were wanted for only ordinary farming purposes, their value would be hardly equal to the cost of reclamation.” That is to say, they would “hardly” be worth \$185 per acre. Coming from such a man as Mr. Root, and published in one of our most respectable agricultural journals, such sentiments are calculated to retard the operation of our new drainage law. Those of us who are endeavoring to drain our swamps meet with sufficient opposition already, and have a right to expect moral support and sympathy from all intelligent friends of agricultural improvement. Mr. Root seems to forget that these swamps render the whole vicinity for miles around unhealthy. I could wish the malaria

arising from one of them might get hold of him and shake him three times a week, with an extra squeeze on Sunday, until he changes his sentiments. For a farmer to write such an article, at a time when few days pass that we are not called to mourn the loss of some friend or neighbor from spotted fever, is monstrous. The physicians in the city are fearing a great increase of disease. But, if possible, the country is more filthy and more unhealthy than the cities. And it will continue to be so until we drain our land.

It is ridiculous to talk of \$185 per acre as the cost of draining our swamps. After a good outlet is secured, most of the swamps that I am acquainted with could be drained for \$10 per acre. The land is quite porous, and a drain, if deep enough, is effective to a far greater distance on each side of it than in our firm, upland soils. Mr. Robert J. Swan, of Geneva, N. Y., who has laid *sixty-one miles* of underdrains on his farm of 344 acres, found that he required double the number of drains on the upland that he did on the lowland. Had he drained the upland first, the probabilities are that the low land would have needed little more than a few main drains. As it was, the draining of the whole farm cost less than \$20 per acre—and it is probably one of the best drained farms in the State.

The great error in draining low land is in not making the open ditches or outlets deep enough. I have heard farmers say that they did not want a ditch so deep that they could not drive across it! They must either give up this notion or be content with wet land. Hitherto, a farmer who wanted to drain was almost certain to find that he could not get sufficient fall on the low land without doing more or less ditching on the adjoining farms. And he would be pretty sure to meet with opposition. But the new drainage law in this State puts a new aspect on the matter. The friends of improved farming have so far triumphed. It is now too late for any man to oppose the draining of swamps.

Of course, it is far better and cheaper to do the work by mutual consent, and share the expense according to the benefit. And one of the best effects of the law is that it favors this result. When some stupid, stand-still neighbor finds that you can not only compel him to let you drain through his land, but that he can be made to pay a portion of the expense in proportion to the benefit the ditch will do him, and that if he compels you to ask for the appointment of commissioners, the legal expenses will probably be more than the actual cost of the work to be performed, he will be very likely to withdraw his opposition. He knows that if he does not you can proceed according to the law and beat him. The law is just in principle, and in the end public opinion will sustain it. If the proposed ditch injures your neighbor you must pay him for the damage; if it benefits him as much as it does you, he must pay half the cost.

Last year I raised three acres of Yellow Globe mangel-wurzel. The crop was a capital one, averaging at least a thousand bushels per acre. Part of the piece was on land that when I took the farm was so swampy that the cows mired in it nearly the whole summer. I have been only able to drain it partially, owing to the water setting back from the creek. I could do nothing more than cut an open ditch through it eighteen or twenty inches deep. I have one shallow underdrain in it laid on boards through a quicksand, but, with this exception, all the drainage it has is from the main ditch and a few

furrows made with the plow and hoe. On this swampy land thus partially, I might say miserably, drained, the mangels were the best in the field. You need not tell me that our swamps are poor, and will not pay for draining. They have been receiving the wash from the uplands for centuries, and are the richest parts of the farm. In fact, it is from these rich, alluvial soils that I look for the means of making manure for the upland portions of the farm. Innumerable instances might be mentioned where farms have been brought to a high state of fertility principally from the judicious management of the low land. But it is not necessary to cite them. The men who prefer to shake with the ague rather than to drain their swamps are beyond the reach of argument.

"Can footrot in sheep be cured?" asks a correspondent. "I am told that it can not, and my experience seems to confirm the opinion." It is certain that not one farmer in ten ever does cure an affected flock. And the reason is that they do not dress the whole flock, and stick to it until every particle of the virus is killed. The farmer who thinks he can not kill Quack grass would be very apt to think he could not cure footrot—and we might quote any number of cases to sustain his opinion. This kind of negative evidence proves nothing. If you try to get rid of Quack, you must kill every root of it, or it will grow and spread, and in a few years the land will be as foul as ever. And so will footrot. You may *nearly* cure it, but if the virus is not completely destroyed the disease will break out again. It is so with scab in sheep. The only way to cure it is to dress *every sheep*. After shearing, it is an easy matter to cure the scab, as the sheep can be dipped every week or ten days until the cure is certainly effected. Nothing is better for this purpose than a strong solution of carbolic soap. It would be well if we all dipped our entire flock of sheep and lambs every spring and fall. We should then seldom hear anything of the scab, and ticks would be abolished. I bought a barrel of crude carbolic acid for \$15, and use it very freely as a disinfectant. A quart of carbolic acid and a gallon of petroleum is a capital thing to use as a paint or wash on all the wood-work about pig-pens, hen-house, etc. It is death to every species of vermin except rats and mice, and I imagine they do not love it. I do not myself object to the smell, but I suppose others do, as I have heard my men call it "diabolic" acid—perhaps, however, this was only a mistake in chemical nomenclature.

This spring I washed the trunks and large branches of all my apple, pear, and cherry trees with a mixture of soap, carbolic acid, and lye from wood ashes. It killed every bit of moss, and has greatly improved the appearance of the trees. I smear the roosts in the hen-house with this and am not troubled with lice. It is a capital thing to wash pigs with. And for a dip for sheep nothing is equal to it. It kills every tick, and if used strong enough and often enough it is said to be a certain cure for the scab—and I think there can be no sort of doubt about it. It is the most penetrating substance I know anything about. I have used the crude acid alone mixed with water—say a quart of acid to six gallons of water—for dipping sheep, but prefer the soap.

For footrot, this crude carbolic acid is the cheapest and most effective remedy. But I prize it not so much as a cure as a preventive. I have no footrot among my sheep, and no symptoms of it, but I wash the feet of every sheep and

lamb two or three times a year with this acid simply as a preventive. Sheep are frequently driven along our roads that have footrot, and the most careful farmer may get the disease into his flock. Where sheep are sent to a common resort for washing, I would wash their feet with carbolic acid before they were sent, and again at shearing time. With a small brush the acid is quickly applied.

I have just finished harrowing my wheat with Thomas's harrow (April 19th). I harrowed it first the way of the drills, then crosswise, and then after sowing the clover seed we went over it again lengthwise. The field is as smooth as a barn-floor—and almost as bare. It seems pretty hard treatment, but on examination I could not find that it pulls up any of the plants. On the lighter, sandy portions of the field the plants look as though they were smothered. But we shall see. The Deacon's wheat is on an adjoining field of the same character of land, with only a fence between. Both fields are in full view from the public road, and if he beats me I shall be able to throw the blame on friend Thomas and try again. At present the Deacon's looks full as well as mine. But my land is pretty well drained, while some portions of the Deacon's is not—and if we should have a wet May and June I may come out ahead. So far, it has been one of the best seasons for wheat on wet land I ever knew. They say, "Poor farmers do well once in seven years," and this may be the one. The ground is dry, and very few of the underdrains are running. Generally at this season they are taxed to their full capacity.

Hay-Making.

The importance of the hay crop can not be overestimated. Not only are grass and clover at the basis of our method of agriculture, but the hay as an article of fodder is our great dependence during the feeding season. It is therefore important that it should be gathered in such a condition that its nutritious properties should be retained in the highest degree. Generally our hay crop is gathered so late that it has lost much of its value. This was clearly shown in a late instance, when some American hay was sent to the English market, and on being sold at Liverpool brought ten dollars per ton less than was then current for English-grown hay, the loss of value being solely due to its over-ripeness. We could not have a fairer test, for there are no better judges of the value of fodder than English feeders, who have learned by many years of experience. We may take it for granted that hay not in the barn by the end of June has lost one fourth of its money value. This is the true light in which to view it. Clover, then, should be cut before a head has turned brown, and timothy, orchard grass, or red-top before fairly in blossom. When cut in its best condition, still much of its value depends on its curing. Its greatest value is preserved when dried in the shade. It should therefore be cured in the cock, and not allowed to be exposed to the hot sun for a longer time than to completely wilt it. If dried more than this, the leaves of clover will become crisp and break up readily, and a mass of dry, hard stalks only be left. Our practice has been to cut up to ten o'clock in the forenoon, leave until four in the afternoon, then gather into cocks before the dew falls, and by six have all raked up and cocked, and if there is probability of rain to cover with caps. As soon as ten o'clock the

next day has arrived, open those cocks which were made on the previous day—or two days may elapse without any injury—and as soon as they are all opened, by merely throwing over

Fig. 1.—HAY-COCK AND CAP.

and loosening a little, commence to load and draw in until four o'clock. The exposure during loading and unloading removes all superabundant moisture, and it goes into the barn or stack without losing a leaf, and with many of the blossoms still opening. By providing ventilators, as in figure 3, the moisture remaining and the heat of the fermentation pass off without any injury or doing any more than thoroughly curing the hay. With such hay, we have made butter of a high golden color in January and February in no wise inferior to that made in June. The cocks should be made high and narrow. The moist hay soon commences to ferment, and if put up at four o'clock will be found quite warm at ten o'clock at night; but the heat easily passes off at the sides, and carries the vapor from the hay with it. Fig. 1 shows the form in which we have built

Fig. 2. PEGS.

Fig. 3.—FOUNDATION FOR A STACK.

the cocks, and the mode in which we have been used to cover them. They may be made large enough to contain 200 pounds of hay, or eight to a load. The cap is merely a square piece of sheeting, which may be procured of any width from a yard up to two yards, but a cap a yard square may be made to do good service, and will cost about twelve cents. The ends are hemmed, and at each corner an eyelet hole is worked, in which a loop of small cord is fixed. Pegs are to be made, either of a piece of shingle or of a twig, cut as figure 2. Hay thus protected may stay in the field for a week without injury, and in windy weather the tops of the cocks will not be blown off.

Stacking hay requires more care than is generally given to it. If stacks can be made rain-proof the expense of buildings is saved. They may be built in this way and so finished off that

there will be no waste in using the hay. A stack-yard to which cattle or hogs can not gain access, and near the barn or stables, is the best.

Fig. 4.—PROPER FORM OF STACK.

Here foundations (fig. 3) should be provided to raise the hay from the ground, on spots somewhat elevated so that water will not collect beneath them. The pole in the center should be set in the ground firmly; it will be a guide in building the stack, and will keep it from settling sideways and toppling over. The form shown in fig. 4 will be found perfectly rain-proof if the hay is well raked off from the sides as it is narrowed in, and the cap at the top neatly put on and kept tied closely to the post as the hay settles down. By making the stack quite steep the rain gets no chance to enter, and runs off freely at the eaves. In building, it is best to keep the hay well trodden down, and time is saved by having an extra hand on the stack for this express purpose. A ladder will be needed for the finishing off. A large sheet is very useful to have in readiness to cover the stack until it can be properly finished off. A straw rope should be passed across the top in two directions, to prevent the wind blowing the top loose, which would allow rain to enter, and should be tightly pegged down at the eaves. A straw rope may be twisted with a crank hooked at one end, as in fig. 5. This simple machine may be fastened to a fence-post or the post of a shed or barn. Any kind of straw or coarse hay may be used, but it should be well wetted previously to using it. One man feeds the straw, walking backwards, and a boy or girl

Fig. 5.—TWISTING STRAW-ROPE.

may turn the crank. Other contrivances for twisting a rope will readily suggest themselves.

Large Cows vs. Small Ones.

It is a very important and by no means a settled question, whether (other things being equal) large or small cows are the most profitable. It is not a question between different breeds, but between large and small animals of the same breed.

The following experiment, made in Germany, has a direct bearing on the question, so far as the production of milk is concerned. It does not necessarily apply with reference to the production of butter. Four Dutch cows were selected, two heavy (weighing together 2,112 lbs.) and two light (weighing together 1,537). The two pairs were kept separately, but they were fed exactly alike, each receiving as much green lucern as they would eat. The actual consumption of food, by weight, was recorded every day. At the end of sixteen days the following results appeared:

1. The weight of the animals was unchanged.
2. The heavy pair had consumed 4,921 lbs. of lucern, being 14⁹/₁₀ lbs. per day for each 100 lbs. of their live weight; while the light pair consumed 3,859 lbs., or 16 lbs. per day for each 100 lbs. of their live weight.
3. The heavy pair produced 272 quarts of milk, or 8¹/₂ quarts per day for each cow, while the light pair produced only 192 quarts, or 6 quarts per day for each.
4. The heavy pair produced 6 quarts of milk for each 100 lbs. of lucern consumed, and the light pair only 5 quarts.

It is to be remarked that these animals seem to have been enormous feeders and very poor milkers. We would like to see a report of a similar experiment with Ayrshires in the same condition, as to pregnancy, etc.

A Subsoil Plow.

The benefits to be derived from subsoiling are so great and varied, that no farmer should hesi-

A CHEAP SUBSOILER.

tate to provide himself with a subsoil plow, and use it on every possible occasion. We give a cut of a very simple and cheap plow which can be made by any blacksmith for a few dollars. It is made of 1/2 x 2 1/2-inch bar iron, with a simple shovel-scare, six inches broad. The handles are fastened with screw-bolts to the beam, and braced. The uses for such an implement are many. One horse can draw it when a depth of five or six inches only is taken, which is sufficient for a commencement. A field may be subsoiled wholly by taking furrows one foot apart, and two acres a day may be gone over. If run in the rows in which corn, potatoes, turnips, or beans are to be planted, and across in the check rows, great benefit will be derived. Used constantly in these ways, the farm will soon be completely gone over, and the soil loosened to a depth of twelve or fifteen inches. In a few years this loosened subsoil will become mellowed, and may gradually be brought to the top and mixed with the surface soil, and all the

advantages of deep plowing be gained without any of the evil effects which are so often experienced when the raw subsoil is suddenly brought up. A correspondent from Quincy, Ill., sends us the sketch from which the engraving has been made, and in sending it asks if it

A CALIFORNIAN CHURN.

pays to subsoil, and when it should be done—questions which are sufficiently answered above.

A Californian Churn.

A "Subscriber" from Yuba City, California, sends us a sketch of a churn which, he says, is in common use in his locality, and which he recommends to "J. P. C.," Dayton, Ohio, who lately inquired for a good one. It is a square box, hung on a frame by two corners, diagonally opposite to each other, and is turned by a crank, as shown in the illustration. A hole from which the buttermilk is drawn is made at one corner, and is closed by a peg. An opening for putting in the cream and removing the butter is made on one face of the box, and is closed by a bar, sliding across it. When the butter is made, the buttermilk is drawn out by removing the peg. Cold water is turned in, and the butter sufficiently washed and gathered by slowly turning the churn. In using a churn with so many corners, much care should be taken to keep it perfectly clean and thoroughly sweet.

A Cultivator with an Adjustable Wing.

John L. McColley, of Wood Co., Ohio, sends us a model of a movable wing cultivator which he made three years ago on a hint from the *American Agriculturist* that such a machine

ADJUSTABLE-WING CULTIVATOR.

was practicable and would be useful. With it he cultivates corn in rows that are of irregular

width, as almost all corn-rows are necessarily, more or less. He has used it for three years, and finds it a very useful implement, and desires to give it to the public through our columns. It is four feet long from point to heel, the handles three feet nine inches. The wings are hinged to the central piece by means of common wrought-iron butts. The central piece carries a wheel at its hinder end, and is pivoted so that the wheel can be depressed and the depth of working be thereby regulated. The spread of the wings is lessened or increased at will by pushing or drawing in of the handles, and they are kept stationary when desired by the adjustable bar, which passes through a slot or opening in the right-hand wing. This bar is flat, and is punched with several holes, into which a pin is pressed by the movement of the small handle hinged to the handle of the right wing. This small handle is kept elevated by a spring, and thus the pin is retained in its place and the wings prevented from spreading. By pressing down on the handle, the pin is raised and the wings can be spread or drawn in. The teeth are seven in number, three on each wing and one on the center. They are made in any desired shape, fixed to half-inch round iron stocks which pass through the wings, and are fastened with a nut so as to be removed when necessary. The different parts are all clearly shown in the engraving, where they are drawn to scale, which is three quarters of an inch to a foot.

To Fasten a Horse.

Where there is no hitching-post handy, a

MANNER OF HITCHING A HORSE.

horse may be safely tied in the following manner—viz.; Take the reins and pass them round underneath the hub outside of the wheel, and give them a hitch on to one of the spokes, as shown in the above cut. If the horse starts, the reins are drawn up, instantly checking him, and as soon as he commences to back they are instantly loosened. It is quite impossible with this method that a horse can go when he is not wanted to. The plan here presented is not a new one at all, and we believe a fixture to attach to the hub to hold the reins has been patented, but it in no wise interferes with the method itself, which, though very simple, is very effectual.

Loading Hay.

The more skillful a farmer or a farm laborer is in handling his tools the more valuable is his work. Time is saved, and the "useful effect," as mechanics would say, of his work is in-

Fig. 1.—HAY-BOLSTER.
