creased. Now, there is nothing more valuable in a farmer's work than rapidity and effectiveness at any time, but more especially at harvest time, when so much depends on the sudden changes of the weather. Thus, in loading hay or grain upon the wagon, it is important that it be done quickly, and in such a manner as to economize space, for it is scarcely possible to get more hay or straw at a load than a team will draw, and very often not half a load is made by reason of faulty loading. A farmer needs good hay-racks in the first place. Another needed thing is a bolster of a good shape on which to place the rack. We figure a bolster especially adapted for a hay-rack. It is made of a stout piece for the bottom of sufficient length to fit the wagon, and 4 x 4 inches thick. Standards of 3 x 3 are mortised in an outwardly sloping position near the ends of the bottom piece, fitting closely and pinned tightly. Short braces are then mortised in at *a, a*, fig. 1, fitting loosely, so that they may be easily removed and held in their places by pins, also easily movable. A hole is bored in the bolster for the king-bolt which retains it in its place. To place the rack, which is made of two ordinary hay-ladders, remove the braces (*a, a*), put the ladder in position as shown in the engraving, replace the braces, and put in the pins to retain them.

The ladders may be made of spruce poles, which are light and strong, peeled, and bored at distances of two feet apart, with three-quarter-inch holes. In these holes are placed the rungs of hickory or white-oak, which should be tough

Fig. 2.—HAY-LADDER.

and strong because they are needed to be light. The upper part of the rungs project six or eight inches through the upper pole, and wrought nails are driven into each pole and through the rungs to keep them in their places. The ladders may be made fourteen or sixteen feet long, and are kept spread by means of a stout board at each end, in which are bored holes to receive the ends of the rungs over which they are placed. A long, narrow slot is made in this board, through which is passed another narrower piece of board which stands up in front of the load, and is used to carry the lines on, so that they will not annoy the leader nor trail on

the ground. Holes are bored in the upper end to receive the lines, where they can always be reached in a moment when wanted. Another rack for hay, which permits the wagon to be turned round in a very small space, is shown at fig. 2. This rack is made of four bars, instead of two, and with fewer rungs; and when put together a piece of the lowest bar is cut out so as to admit the wheel when turning. This improved rack is sent us by a correspondent, "W. A. F.," of Cleveland, Minn., and is well

Fig. 3.—HAY BADLY LOADED.

worth using by those who need to turn sharp corners or in a small space. But the rack is nothing unless one can put the hay in properly. Few men load hay correctly. Most often the load is unevenly balanced, or not sufficiently spread out, and it either tips over, or only half a load is made. Fig. 3 shows this very common mode of loading. The hay within the ladders should be well tramped down, and kept hollow in the center until filled to the top. Then the corners should be built first, and a good forkful placed so as to bind them. Then the sides built in regular order from front to back, each forkful lapping the previous one, like a scale on a fish or shingles on a roof. This will enable the hay to be easily unloaded. The load should be gradually widened and lengthened with each layer of hay or grain, and the center kept hollow, and the load bound by a

Fig. 4.—HAY PROPERLY LOADED.

row of forkfuls along the middle. Thus the size of load is restricted only by the quantity the horses can draw or the rack bear. If well built and balanced, it may be carried out eight feet wide and more than twice as long, and sixteen to twenty hundred of hay easily taken at a load. The shape of the load will be similar to figure 4, which is one that can not upset, nor can any part of the load fall off. The forks should be stuck in the hay with the handles sloping backwards, as in fig. 4, and never forwards, as in fig. 3, which is a highly dangerous position when driving into a barn, as they might catch against the beams of an overway and cause serious mischief to the driver.

Cultivation of Fodder-Corn.

Notwithstanding the lateness of the season, the main crop of fodder-corn will generally have been planted before this number reaches its readers. It is, however, not yet too late to

plant and secure a full crop to be cut up in September. As the corn will stand in the drills too thick for much good to be done by hand-hoeing, the cultivator should be made to do double duty. If the land is of such a character that Thomas's Smoothing Harrow can with safety be run over the ground the moment the corn first begins to break through the surface, it will materially lessen the work of cultivation, and will considerably increase the crop, giving the corn a good start in advance of the weeds. If the corn has been planted two inches deep, there will be little danger of disturbing it by a harrowing that will completely eradicate all surface weeds.

Generally, owing to the press of other work, the corn crop is apt to be put off with less cultivation than it really needs. It ought to be thoroughly cultivated at least four times (going twice through each row every time). This work should be commenced as soon as the rows can be distinctly seen, and the last cultivation should be given after the crop has grown to such a size as to leave barely room for a short whiffle-tree to pass between the rows. Indeed, it is impossible to produce a first-rate crop, unless, by frequent stirring, the soil is kept loose and open. If the foregoing directions are followed, the corn will soon completely shade the ground, so that late-germinating weeds will make but little growth.

Immediately after the last cultivation it will be well to sow broadcast three quarters of a pound to the acre, of Purple-top, Strap-leaved turnip. These will make a fair growth between the time of cutting up the corn and the setting in of winter. If the corn is to be used for soiling, it may be profitably cut when from three to four feet high, and much of this will produce a second growth of considerable value. This, and so much of the first growth as has not been cut, should be allowed to stand until the latter part of September, or until after it has fully tasseled. It should then be cut up and bound in small stooks to cure. After so standing for ten days or two weeks, four stooks should be bound into one, the bases being broad, and the tops closely tied with two bands, so that they will not be disturbed by violent winds. According to the experience of many farmers, fodder so prepared may be safely stored in the barn, or in stacks, in the latter part of November. It is our own custom to leave it standing in the field until needed for use, hauling in only one load at a time. Our last crop kept perfectly in this condition until the middle of January, and its value for feeding was fully equal to hay, ton for ton.

How to Ring a Bull.

The only safe way to handle a bull that is at all inclined to be unruly—and most good bulls are so inclined—is by a ring in the nose. Clamp rings, having a couple of knobs which press into the nostrils, are by no means to be recommended, except for occasional use. It is best, always, before the animal is a year old, to put a good stout copper ring through the cartilage of the nose. This will last him his lifetime, and if he is fastened in his stall with a good, sound chain snapping into it, we may be sure of his making no serious attempt to break loose. When taken out for service he can be safely handled at pleasure. The old-fashioned plan of burning

a hole in the nose with a hot iron is cruel and difficult. We long ago adopted for this work the use of the trocar, a surgical instrument similar to that used for "tapping" in dropsy and for "hoove" in cows. It is a sharp-pointed, round dagger (the point three-sided), carrying a silver-plated shield reaching

Fig. 1.—BULL-RING, OPEN.

from the upper part of the point to the handle; the two parts are shown separately in figure 2.

The sheath being on the dagger, the whole is easily pushed through the nose, its sharp point piercing it with so little pain, that one man can easily hold the head still. The dagger is then withdrawn, leaving the sheath in the hole. The ring (shown open in fig. 1), is then inserted into the end of the sheath, which is slowly with-

Fig. 2.—TROCAR AND CANNULA.

drawn, leaving the ring in place. This is then closed and fastened with its screw. These rings are so well made, that both the hinge and the screw are perfectly smooth and almost imperceptible—turning freely through the hole, which, having been made with a three-cornered cut, will be more sensitive against a pull than the smooth burned hole. Indeed, it is sometimes necessary, with the latter, to take the ring out after a time and repeat the burning, to make the cartilage sufficiently sensitive for the ring to be effective in managing the animal. The engraving on page 220 shows the manner of inserting the ring.

What We Know about Beans.

We have had some experience in raising beans, and much observation. We are planting nearly twenty acres the present season. For some years past, taking one year with another, they have been one of the most profitable crops raised on the farm. They occupy the land only eight or ten weeks, and are harvested in time to sow winter wheat. No special skill or peculiar treatment is necessary in raising them, but some care and experience are required to harvest them. The real point is to have the land clean, mellow, and in good heart. The old saying, "too poor to raise beans," has led many astray. They have planted beans only on such land as was not considered rich enough or clean enough or dry enough to raise corn or small grain crops. And the result in nine cases out of ten is just what any one might expect—abundance of weeds, a light yield, and an inferior or mildewed sample of beans, fit only to feed to sheep. In fact, we have seen beans so mildewed that any sensible farmer would be afraid to feed them out to his animals without steaming them.

A crop of beans of thirty bushels per acre that has to grow and mature in so short a time, must have a liberal supply of available food, and the soil must be in the best possible mechanical condition. We are aware that a fair crop of beans is sometimes raised on soil so hard, that it would seem that the roots could not penetrate it. But a maximum yield can not be expected unless all the conditions of growth are favorable. The most common mistake is in trying to raise beans and weeds on the same land at the same time. We have seen part of a field of beans cultivated and hoed, and another part, equally

highly profitable crop. On land so thoroughly prepared, the Marrow will probably prove the more profitable variety, as it commands an extra price, and produces a large quantity of haulm of great value as fodder for sheep or cows.

A Home-made Roller.

A "Farmer" wants a description of a simple roller. We illustrate one which is made of a log, cut into sections, two feet long, that it may be more readily turned round. The log should be at least two feet in diameter, of heavy wood, such as oak or hard maple, and the sections should be sawed very true, so that the ends will work freely and not bind against each other. The sections are bored through the center with an auger an inch and three quarters in diameter, and the holes should be bored from each end to the middle, where they should meet; they can be made more true in this way than by boring through from one end. The axle is an iron rod of one and a half inch diameter. Washers, half an inch thick, should be placed between the sections. The frame should be made of heavy stuff, at least four inches square, so as to gain weight, and a driver's seat may be put on. When built, the sections should be raised from the ground, and planed smooth and true.

ROLLER MADE FROM LOGS.

good land, left uncultivated, and the latter produced less than one third of the former. The extra cost of pulling the beans out of the weeds was more than it would have cost to cultivate and hoe them. The beans on the weedy land did not mature properly, and could not be sold at any price. The most profitable crop of beans we ever raised was on a two-year-old clover sod, plowed in June, turning under clover equal perhaps to more than half a ton of hay per acre. The beans were drilled in immediately after the land was plowed and harrowed. We had a rain shortly afterwards, and the beans came up and grew rapidly. They were cultivated four or five times, but needed scarcely any hoeing. The yield was over twenty bushels per acre, and the beans brought \$3.25 per bushel. The land, after the beans were off, was plowed and sown to winter wheat, and produced a good crop. This was merely a lucky hit.

The largest yield we have ever had, was on land plowed twice in the fall and again twice in the spring, with the free use of the cultivator and harrow for the purpose of killing Quack. This year we are preparing our land for beans somewhat in the same way—a two-year-old clover sod, mown the first year for hay and afterwards for seed, the next year pastured with sheep. In the fall it was plowed and left rough for the winter. This spring it was harrowed as soon as the surface was dry enough, and before all the frost was out underneath. It was then, a few days later, cultivated and harrowed, first with a forty-tooth harrow, and afterwards with a Thomas harrow. This made the surface as fine as a garden. The field will be plowed again, harrowed, cultivated, rolled if necessary, and worked until it is as clean and mellow as we can make it. The seed will be drilled in rows two feet six inches apart, and from three to five beans in a hill, 15 inches apart.

It may be said that the crop will not pay for such an amount of work. We think it will. If it does not, we will report. It must be recollected that the soil is exposed to the ameliorating influences of the atmosphere for nearly eight months before the crop is planted. And after it is planted the land is constantly stirred with a cultivator. By this mode of culture beans become a "fallow crop." The land is just as clean as if it had been summer-fallowed, and if the land is rich enough or can be manured, an excellent crop of wheat may be expected. In this way beans can be made a very useful and

should be bored from each end to the middle, where they should meet; they can be made more true in this way than by boring through from one end. The axle is an iron rod of one and a half inch diameter. Washers, half an inch thick, should be placed between the sections. The frame should be made of heavy stuff, at least four inches square, so as to gain weight, and a driver's seat may be put on. When built, the sections should be raised from the ground, and planed smooth and true.

What is a Fallow?

There is considerable discussion among farmers as to whether it is better to summer-fallow for wheat, or to sow a spring crop, such as oats, barley, peas, or beans, to be followed by wheat. Figures are given and arguments used *pro* and *con*. But so far as we have observed, all the writers on this subject fail to tell us what a fallow is. One farmer in Western New York, who has written considerably on the subject, advocates breaking up a clover sod, in June, with a three-horse plow, ten inches deep; then harrow, roll, and cultivate, to keep down the weeds and mellow the surface. This is all that he does. The land is only plowed once. We have no doubt that good crops of wheat are frequently raised in this way. We say nothing against the practice. But we insist that there is no propriety in calling it a "summer-fallow."

The essential agricultural and chemical point in fallowing is, to plow the land for a crop, and then not sow it until the season following. This is the real significance of a fallow. It involves the idea of "rest," and at the same time cleans the land. There are various modifications in the manner of working the land, but there can be no true fallow where the land is not kept bare and without a crop for a whole year.

We are not arguing against the plan we have alluded to of preparing land for wheat. All we ask is that things should be called by their proper names. In England the most common method of raising wheat is to plow up a clover sod, and immediately drill in the wheat. This Western New York plan differs from it merely in this: the land is plowed six weeks or two months before sowing instead of six days or two weeks as in England. Let those adopt the plan who like, but do not call it a "summer-fallow."

A summer-fallow, or in other words, a true

fallow, aims to expose the soil as much and for as long a time as possible to the decomposing or "weathering" influence of the air, the sun, the heat, and the frost. No crop is grown to abstract plant-food, but on the other hand means are used to develop plant-food from the latent resources in the soil. At the same time we aim to mellow and clean the land. We do not aim to check the weeds. We endeavor to make them grow, in order that we may kill them. This the summer-fallow gives us an unimpeded opportunity of doing. By plowing the land early in the fall we cause many weeds to germinate that usually infest our wheat fields. The spring plowing not only destroys these, but starts thousands of weeds that usually infest our spring crops. These are destroyed by the cultivator, and others spring up to be killed at the next plowing. We thus get rid of millions of weeds. It may be that the first crop will not pay the cost of such a summer-fallow, with two years' interest on the value of the land, but on any good, strong, loamy soil, no cleaner than our farms usually are, it will prove highly profitable in the end. A tenant farmer, or a farmer who intends to sell at the first opportunity, or one whose necessities are such that he can not afford to wait, may well be excused from resorting to some method of culture that will hold back the growth of weeds for a single crop, but this should not prevent him from understanding that there is a better way, whenever his circumstances enable him to adopt it. We would most earnestly recommend the young, intelligent readers of the *American Agriculturist* to study out this matter for themselves and endeavor to master all the principles involved in summer-fallowing. They will find it better to thoroughly work and clean their land than to adopt any temporary makeshifts for checking weeds.

A GOOD LITTLE FIG.—A friend of the writer had a litter of pigs farrowed August 20th, 1871. The sow was a young common white one, and of small size. The boar was a young thoroughbred Essex. One of these pigs was killed April 2d, 1872, when he was 226 days old, and he weighed (dressed) 187 pounds. His form and condition were simply perfect. This is evidence (so far as any single instance can be) of the advantage of the Essex cross.

Our American Cuckoos.

BY ERNEST INGERSOLL.

The Cuckoo (*Coccyzus Americanus*) is one of the most beautiful of our birds. His form is slender, and elegantly proportioned. His whole upper plumage is a rich, glossy drab-brown, with greenish reflections, and is peculiarly fine and compact in its texture; beneath he is pure white, with long, silky thigh-feathers. His tail seems disproportionately long, yet it adds wonderfully to his graceful carriage.

His brother, the *C. erythrophthalmus*, is slightly smaller, and where the bill of the other is yellow his is black; his distinguishing feature, however, is a bare, wrinkled skin around the eye, deep red, whence his Greek specific name, which means "red-eyed."

One walking in May in retired woods, or where, along the border of a quiet stream, the drooping willows brush the alders' tops, and both together lean far over the shaded water, will hear as from a disembodied spirit, *ko-ee, ko-ee, ko, ko, ko, ko-k-k-k-k-k*, beginning slow and distinct, then rising louder, and gradually growing more rapid, until it runs all to-

gether, and seems to cease from mere lack of breath. It is the Yellow-bill, but you can neither see him nor fairly locate the sound. It is full, clear, and reverberating, yet has a weird, wandering character, which eludes your grasp, but irresistibly allures you to search it out. His song continues through the whole summer, though perhaps not so frequently rendered as during the mating season. You may hear it in warm, still nights for hours together; especially clamorous before a storm, Virginia farmers think.

Besides his loud rattle, he will sit on a low branch, and with a peculiar swaying motion of his body plaintively repeat the syllables *ko-koo, ko-koo, ko-koo*, which seem to be a love-song, addressed to his mate not so often as to himself. The Yellow-billed Cuckoo comes to us, along Lake Erie, the last week in April, and the Black-billed soon follows. Wintering in Mexico and the West Indies—where the Black-billed is known as the St. Domingo Bird—they spread over all the Eastern United States, as far north as Boston, where, it is said, the first-named is becoming rare. The males arrive some ten days before the females, and spend the time very amicably and busily, seeking the retired portions of the woods and the thickety banks of small streams. There one bird will take possession of a tree, and never leave it until every branch has been thoroughly explored; and lively must be the insect which escapes his sharp eyes and still sharper beak. Their taste is varied and their appetite always good. The abundance of different insects which make the trees their home, and deposit their eggs which hatch out larvæ under the bark or upon the leaves, particularly the canker-worms which infest the apple-trees, furnish their chief subsistence. Occasionally they treat themselves to berries; and luckless snails and small frogs find themselves in rather than on their bill of fare. If their epicurean habits stopped here, well and good; but they are accused, and justly too, I fear, of sucking their neighbors' nest-eggs. It is not infrequent to find shells indented by a bird's beak and emptied of their contents; sometimes left in the nest with others uninjured, but oftener lying on the ground under it. The many broken eggs which we find strewn about in the woods must, partially at least, be ascribed to the Cuckoo's depredations, though the Blue-jay is not less guilty.

A week or so after the first appearance of the males the females arrive. The busy food-hunting of the males ceases immediately, and they

devote themselves with all ardor to the females, courting them with the greatest assiduity, and wooing them by all the means in their power.

eggs in the nests of other birds; more generally (it is my opinion) in each other's nests. But they do not seem to intend to abandon them to the charge of a foster-parent, but rather to usurp the nest for their own use, being a little lazy perhaps. The eggs of the Cuckoo vary greatly in size—even those of the same "lay"—so that it is puzzling sometimes to determine whether they really are genuine; and it is said that you may often find one egg fresh, while the rest are more or less added, or even hatched.

One of the worst reputations in the animal kingdom is borne by the European Cuckoo, for its nefarious habit of leaving its eggs to the care of other birds, and building no nest of its own. Our Cow-bunting is equally wicked, and rumor says our Cuckoos do the same, but we have seen that this is not so, for both species build a nest and attend closely to home duties. Notwithstanding his piratical course of life, the American Cuckoo is an arrant coward, and small birds, when defending their homes, will whip him beautifully. Dr. Samuels tells us that he saw a Blue-bird drive a Yellow-bill into a barn, and keep him there, standing guard outside; and so badly scared was the Cuckoo, that he allowed the Doctor to catch him, preferring to fall into the hand of the enemy within rather than face the danger without.

Despite their bad habits and cowardly dispositions, I love the Cuckoos. They come early and stay late. They are lively and industrious, and their call is to me one of the most pleasing of sylvan notes. Then, too, they have a sort of well-bred air about them, and there is a charm in their carriage and flight, which, together with their rich dress and elegant form, makes them two of the most attractive of wood-birds, among which choice is so difficult.

THE BLACK-BILLED CUCKOO.—(*Coccyzus erythrophthalmus*.)

At this time the most obstinate battles take place between the jealous males for the possession of some coveted lady bird; but before long they all pair and commence building. This

USING THE TROCAR IN RINGING A BULL.—(See page 218.)

happens about the 15th of May in ordinary seasons. The nest is sometimes fixed on the horizontal branch of an apple-tree; usually in a solitary crab, thorn, or cedar, in sequestered woods. It is merely an almost level platform of twigs, intermixed with soft weeds and maple blossoms. That of the Yellow-bills can be seen through, it is so scant; but the Black-bill's is more compact, and contains more flowers. On this almost flat bed the two to four eggs are laid. These are uniform greenish blue, darker in the case of the Black-billed than of the Yellow-billed species, and of a size proportionate to that of the bird. There are some curious facts in connection with their nidification.

As if unable to break away altogether from the inscrutable nature of their foreign congeners, both Cuckoos sometimes lay one or two

Spatium (*Levisia rediviva*).

One of our friends holds a very comfortable doctrine. He says if one really wishes a thing, he will get it; if what he wishes does not come to pass, it only shows that he does not wish with sufficient earnestness. Our experience with the Spatium is a partial confirmation of our friend's peculiar belief. Having long known the plant by description and from dried specimens, we had a strong desire to see it in the living state, and had written to friends in the far West, in the hope of obtaining it. Just as we had ascertained the address of one who knew the plant and could send it, and were about

writing for it, a messenger came from one of our considerate seedsmen, bearing the very plant. The *Lewisia* was discovered on Lewis & Clark's expedition, and was named by Pursh in honor of its discoverer. The specific name *rediviva* (that lives again) was given on account

SPATLUM.—*Lewisia rediviva*.

of its remarkable vitality. The herbarium specimens brought home by Lewis were planted in a garden in Philadelphia, where they grew for a year, and some specimens collected by Douglas were planted in London, and grew, but for a short time only. The engraving shows the plant of about the natural size, though the root grows much larger than we have represented it. The narrow, succulent leaves grow in clusters, from the center of which the flower-stalks arise; these each bear a single rose-colored flower, which, like the Portulacas, to which it is closely related, remains open only during sunshine. The leaves die away soon after the flowers open, and the above-ground career of the plant occupies but a few weeks. The root, which is large for the size of the plant, is interesting as affording an important article of food to the Oregon Indians, who call it "Spatlum," or "Spæt'lum." It is also known to the French Canadians as *Racine amere*, or Bitter-root. The root is covered with a dark-colored bark, but the interior is white and consists largely of starch. The roots are boiled and used by the Indians as food, and though bitter, are very nutritious. It is said that three ounces of the dried roots will be sufficient provision for a man undergoing great fatigue. We do not know the exact range of the plant. Our specimen came from Montana. It has been found in Colorado, and is abundant in Oregon.

The Holly-leaved Cherry.

While botanizing some years ago upon the Pacific coast, we saw what at a little distance appeared to be a fine clump of Holly. A closer inspection showed that it was a cherry, with

leaves so exactly like those of the Holly that the name given it by Nuttall, *Cerasus* (now *Prunus*) *ilicifolia*, the Holly-leaved Cherry, is properly bestowed. The plants we met with were directly upon the shore of San Diego Bay, and were not more than six feet high. Farther inland, upon the hill-sides, within the mountain range, it becomes a small tree of twelve or twenty feet in height. The bark is gray and roughish, and the wood close-grained, tough, and somewhat reddish in color. The engraving shows a twig with the leaves and flowers of the natural size. The leaves are thick, smooth, and ever-green, like those of the holly, and armed with very sharp teeth. The flowers, like those of our common Wild-cherry, are in racemes, and are succeeded by a small fruit, which is said to be bitter and astringent. We have another Ever-green Cherry in the Southern States, *Prunus Caroliniana*, which is absurdly enough called "Wild-Orange," and both belong to the same section of the genus as the Cherry Laurel of Europe. The Holly-leaved Cherry seems to be confined to the southern portion of California, but would probably grow in most portions of that State, and would doubtless serve for ornamental hedges and all other uses to which Holly is put. We know of no attempts at cultivating it at the East, and we think its success here is doubtful. Still, we should like to make the experiment, and will do so if some of our

friends about San Diego or Santa Barbara will mail us a few seeds as soon as they are ripe.

What Varieties Come True from Seed?

BY PETER HENDERSON.

An intelligent correspondent from Burlington, Vt., asks the question given above. He queries still farther, and says: "An apple-seed produces an apple-tree, but a Baldwin apple-seed will not produce a Baldwin apple-tree. Wheat of any variety produces the same; seed of a scarlet variety of Verbena will not always produce its like. Why this anomaly?" The "why" of the matter can not be told, but a few general rules may be useful. Seeds of plants found in the wild state, in their native habitats, almost invariably produce a progeny identical with the parent, and many species, even after they have been subjected to long years of cultivation, never appear to change seemingly in the slightest degree. Other species under cultivation quickly develop varieties entirely different from the original, and become what is technically termed "broken." Thus the original species of our well-known Verbena is indigenous to South America, having a comparatively small scarlet flower. From this, and probably some other species hybridized with it, we have the gorgeous

and varied coloring of the variety of to-day. But it took many years to produce these, for we can well remember in our early gardening days there was no white, and the furor that took place in the floricultural world when *Verbena leucoides*, the first white, appeared.

THE HOLLY-LEAVED CHERRY.

It was far from being an attractive plant, but the color was novel, and single plants were sold by the florists of that time at a price that would now buy a hundred. The Verbena, then, is one genus whose species have given us innumerable varieties. The Chrysanthemum, Dahlia, Fuchsia, Geranium, Pansy, Petunia, the Rose, and many others, are also familiar examples where the original species has "broken" from what may be termed its primary condition into ever-changing variety. Thus changed, it is probable that their seeds will never produce two individual plants exactly alike any more than two identical human faces or forms are produced. It is probable that all species of animals and vegetables, under long years of domestication and cultivation, would ultimately "break" from the original type, though we know that in some species this tendency sooner develops than in others. It is not to be wondered at that amateur horticulturists, like my Vermont friend, are puzzled at what looks like inconsistency in nature—why she refuses to produce always again his Baldwin apple or his Rareripe peach, his Striped Petunia or his Double Carnation, yet gives him back seemingly identical with the parent his corn or his wheat, his tomato or his cabbage, or in flowers his Mignonette or Alys-sum. I say seemingly, for it may be doubted if they are identical, only that the variation is so

slightly marked that it escapes notice. Many whose experience in such matters should have taught them better are always confounding plants raised from cuttings or slips with those raised from seeds, and can not see why the plant raised from the slip or root of a White Dahlia, or the tree raised from the graft of a Baldwin apple, should be always identical with the plant or tree from which they are taken, while the seeds taken from either would not produce the same. Any cutting from a root or a branch, whether rooted itself or engrafted on another stock (except in rare cases of sports), will be identical with that of the original form from which it was taken; in fact, it is only a *separated part of the same plant*, while the plant raised from seed is a distinct individual.

The Evergreens.

From the number of inquiries we have had, the effects of the cold of March upon evergreens were truly disastrous. Even in close city yards, where the exposure is greatly less than in country places, the trees have not escaped. We have noticed Red-Cedars in the spot where they had grown from the seed, for twenty years or more, apparently quite killed, and a hemlock in its native locality badly injured. It often happens that a severe winter will brown evergreens, and they will after a while more or less completely recover, but the foliage in most species is at present of a very disheartening white color. We have been many times asked if the injured trees will recover. An examination of our own specimens gives but little hope. The spring has been an unusually dry one, and it is likely that this has put beyond recovery plants that might otherwise have recuperated.

Lawns and Lawn-Mowers.

With lawns sown this spring an encouraging green surface will be presented. Upon a close examination, it will be found that all that is green is no more grass than that that glitters is gold. Especially upon old ground will it be found that weeds are the rule and grass the exception. Shepherd's-purse, Carpet-weed, Land-wort, Mouse-ear, and a host of other humble weeds will go to make up what at a little distance appears like a good beginning for a lawn. If examination shows here and there a spear of grass, there is no need of being discouraged. Mow away at it; the weeds will soon get tired of it, while the grass if it is fairly started will do all the better for it. A few mowings will perceptibly diminish the weeds, and though the surface may not be so well covered as it first appeared to be, the grass will soon take possession. In July comes the worst enemy of all, the Purslane or "Pusley." A lawn made upon ground formerly in cultivation can hardly escape this pest. Here, too, the remedy is to mow, and often. If the Purslane is allowed to get too large, mowing will be found tedious work. The succulent Purslane will stick to and clog the machine; it will collect upon and cover the roller with a pasty mass that will fall off in flakes, which must be removed or they will kill the grass beneath them. During midsummer we would mow only so often as is necessary to keep the better of the Purslane. When the cool nights of autumn come, then the grass will make rapid progress, and with a little reseeded of the thin spots a good turf will be established before winter. The first season will be a constant struggle with weeds, and unless the fight is well

kept up success can not be hoped for. Perennial weeds will appear in the following years, but these give but little trouble if the grass is mowed sufficiently often. Should any of these weeds get large enough, they may be removed by means of a spud (an implement like a chisel) or a long knife. Docks must be pulled when the ground is moist, as cutting is of no use.

The introduction of lawn-mowers has rendered the establishment and keeping of lawns a comparatively easy matter. There is now a variety of these implements in the market, varying in price from \$12 to \$30 for the hand-mowers. Of several that we have tried, we give decided preference to the Excelsior. It is simple in its mechanism, requires but little power to propel it, and does its work well. There are some popular patterns that we have not tried, but it is not easy to see how the Excelsior can be excelled.

Hydrangeas—The Otaksa.

The old *Hydrangea Hortensia* is well known for its large snowball-like clusters of flowers, which are rose-colored or blue, according to the soil in which it is grown. At New York and southward it is measurably hardy, but in colder localities it is grown as a house plant, being planted out during summer and taken indoors for the winter. A more beautiful plant is the Japanese *Hydrangea Otaksa*, an old species, but only recently introduced into our cultivation. The general appearance is like that of the old *Hortensia*, but the flower-clusters are even larger, and slightly suffused with pink when indoors or with insufficient light, or with blue when fully exposed. Each flower has a small lavender-colored center, and the effect is very bright and pleasing. The flowers remain for a long time before decaying. The plant blooms when very small, and a specimen only a few inches high, with a flower-cluster nearly a foot across, presents a singular appearance. Our specimen, received from Olm Brothers, flowered most profusely. It will probably prove as hardy as the older species. But having but one plant, we did not care to test this point. It will prove a very popular plant, whether for house culture or for garden decoration.

The Grape-Vine in Summer.

Perhaps the most serious difficulty the vine-grower—whether he has a single vine or a thousand—has to contend with, is mildew. The trouble with this is that its approach is so insidious that the mischief is done before the inexperienced cultivator has detected the presence of the enemy. A discolored spot upon the upper part of the leaves is seen, in a few days this becomes brown, and the leaf, if severely attacked, curls up and dies. Mildew not only attacks the leaves but the fruit-clusters and the young wood. It may be arrested if attacked in time. The vines should be frequently watched, and if grayish patches appear upon the under side of the leaves, upon the stems of the bunches, indeed if they are found anywhere, apply sulphur immediately. Do not wait until the next day, nor even the next hour, but apply at once. So certain a remedy is sulphur, and so very apt are vines to be attacked by mildew, that many grape-growers find it to their advantage to pursue a systematic sulphurizing, whether indications of mildew are visible or not. The vines are dusted as soon as the leaves expand, when they are in flower, when the ber-

ries are of the size of peas, and when the fruit begins to color. This is done regularly, and if any signs of mildew are seen in the intervals, sulphurizing is immediately resorted to.

Flowers of sulphur is the form in which it is used, and it is best applied by a bellows. There are blowers and other implements in use, but a properly-constructed bellows, such as may be had at the implement and seed stores, is the most convenient for applying it. The bellows having a curved nozzle allows the under-sides of the leaves to be dusted, which is very important. The application should be made on a dry day, and if the rain should wash away the sulphur soon after it is applied, the dusting should be renewed. One, with a little practice, can so manage the bellows as to throw the sulphur in a fine cloud of dust, which will settle upon and cover all parts of the vine with an evenly distributed but almost imperceptible coating. Next in destructiveness to the mildew come the hordes of insects. The most effectual remedy for the majority of these is hand-picking. Old vines especially are disposed to push out adventitious buds and form branches where they are not needed. These should be rubbed off.

How to Get Good Raspberries.

Comparatively few people ever eat a really good raspberry. To have this delicious fruit in perfection you must raise it in your own garden and take a little pains with it. We do not now propose to go into the general subject of planting, pruning, and managing raspberries, but simply to throw out a few hints that may be of practical value at the present time.

Raspberries require very rich land, and it is not too late to fork in some well-rotted manure between the rows. If this can not be obtained, sow about three pounds of some good artificial manure to the square rod, and work it into the soil with a pronged hoe. A spade should never be used among raspberries. Keep the ground as clean and mellow as possible. Weeds pump up large quantities of water out of the soil. Suffer none to grow. And recollect that a raspberry sucker that is not needed is simply a weed, and should be treated accordingly. You want four strong suckers to each plant to form canes for next year. All the rest, unless needed to form new beds, should be killed as soon as they show themselves. This is a very important point in raising large, delicious raspberries. As dry weather approaches, the land having been repeatedly stirred to kill weeds, mulch the ground thickly with the clippings of the lawn or other material, to prevent the evaporation of moisture.

Thorns for Hedges—Thorn Seeds.

Every spring we have numerous inquiries concerning raising thorns from the seed and the forming of hedges from them. These questions are put mainly by persons from the old country, and we can well understand that they should desire to have their beautiful and familiar Hawthorn hedges in their new home. We have answered these questions very often in the "Basket," where perhaps they may have been overlooked, and we now reply to the many letters received this spring in a more conspicuous place, in the hope that one answer will serve for several. In the first place, the seeds of the European thorns, as well as those of our native species, are very slow of germination, and they

never, or rarely, come up the first year after planting. The seeds, after being separated from the fruit or "haws"—which is done by bruising and washing—are "stratified," *i. e.*, mixed with an abundance of earth and placed in a heap, covered with several inches of earth. In this situation the seeds are exposed to the action of frost during the winter, and are kept moist all summer, and if sown on the second spring will germinate freely.

The objections to Hawthorn as a hedge-plant are that it has a slow growth, it comes in leaf too late, and drops its foliage too early. In our hot summers it soon assumes a dull, half-dead, and unsightly appearance; and, more serious than all, it is liable to the attacks of a great number of insects. These objections apply in a greater or less degree to our native thorns, though some of these do much better than the Hawthorn. The best of our Northern species is the Cockspur Thorn, *Cytisus Crus-galli*; the Pyracanth Thorn is a fine evergreen hedge-plant in the warmer States, and its white-fruited variety has been considered perfectly hardy at the North before the past winter. We do not know how it has fared elsewhere, but our specimens have all the leaves destroyed, and the plant, the first week in May, shows no signs of life. We can not recommend our readers to use any of the thorns for hedges except by way of experiment. Our two reliable hedge-plants as yet are the Osage Orange, and, where that is not hardy, the Honey Locust.

Apple-Worm Traps.

"Old Apple-Jack" is disposed to ridicule Mr. Wier for patenting so simple a thing as his apple-worm trap. It puzzles us to see how a pomologist and nurseryman, whose whole business depends upon unpatented processes which have been freely contributed to the general stock of knowledge by generations of disinterested workers, could patent such a thing. But people look at things from different points of view; and though no one doubts Mr. Wier's right to patent this contrivance, all the money he will receive from it will not be an offset to the credit that would have been accorded him had he offered it as his contribution to the cause of pomology. Our correspondent, "O. A. J.," thinks he has a contrivance which in his opinion is much superior to that proposed by Mr. Wier, and he thinks he would like to see anybody patent it. He uses strips of sailcloth, a foot in width, and long enough to encircle the tree; to these he fastens two buckles at one end and two straps at the other. Two or three of these are made for each tree. One is buckled tightly around the tree; over this number two is put, with five or six small twigs between it and number one; then number three is put on with some more small sticks and buckled tightly over number two. It will be seen that this leaves all around the tree a number of enticing crevices or recesses into which the worm can crawl to make its chrysalis. The bands are readily taken off and the captives destroyed.

Transplanting Beets and Turnips.

BY GEORGE E. WARING, JR., OGDEN FARM.

The lateness of this season will have crowded together all manner of farm work, and will in many cases have induced the planting of smaller fields of mangold-wurzel than would have been planted under more favorable circumstances.

It may not yet be too late to remedy the defect in many cases. Where the seed has been sown in the usual way, there will be at least five times as many plants as can be allowed to grow. Every one of the extra plants may be made useful by being transplanted into well-prepared rich land, and a good crop may be obtained if the transplanting is postponed even until after an early hay harvest, though, as all transplanting is the most successful when done in damp or wet weather, odd half-days may be devoted to the work in the intervals of haying. The land in which the plants are to be set should be thoroughly fine, thoroughly clean, and thoroughly manured. When the plants are from $\frac{3}{4}$ of an inch to one inch in diameter they may be drawn from the seed-bed, trimmed of their upper leaves and tap-roots, and set out at intervals of $2\frac{1}{2}$ ft. by $1\frac{1}{2}$ ft. Their subsequent cultivation is the same as though they had grown from the seed where they stand. Full directions for transplanting were given in the Ogdon Farm Papers last year, and last month on page 184. This will not be quite so satisfactory as though the plants had been raised expressly for the purpose of transplanting, and the preparation of the land systematically commenced earlier in the season, but it opens the way for many an over-driven farmer to increase a crop which he has been prevented from planting as largely as usual.

It is still early enough to start a seed-bed of ruta-baga turnips to be transplanted about the middle of July, and after ample experience and observation in the matter, we do not hesitate to recommend such a course to all who desire to raise this crop, assuring them that they will find the result better and the labor of cultivation very much less than in the ordinary plan of planting the seed on the ground where the crop is to stand.

Chrysanthemums.

Chrysanthemums are generally allowed to have their own way, and are treated like other herbaceous perennials. Most of them are hardy, and when the clumps get too large, they are divided with a spade. All the care they get in most gardens is a stake, to prevent them from being blown about by the autumn winds. This rude treatment answers very well where the effect of color is all that is desired, and no regard is had to the shape of the plants or the perfection of the individual flowers. Towards autumn some of the smaller roots are taken up, and potted for blooming in the house. They bloom, it is true, but the plants are sorry-looking objects—a cluster of long, leafless stems, with a few bright-colored but half-developed flowers at the top. The only way to have a satisfactory show of chrysanthemums in the house—and nothing can be more cheery—is to begin now with young plants. Those grown from cuttings this spring, and consisting of a single stem, are the most suitable. These can be kept in pots from the beginning, but it is less trouble to grow them in the border until the buds are set, and then pot them. Having a plant with a single stem, its growth can be readily controlled by pinching. When the top or growing point is stopped by pinching, branches are developed in the axils of the leaves below, and these branches themselves can be induced to branch by pinching their extremities. With a little care a handsome bushy form can be produced, which, when covered with flowers, presents a striking contrast to the ragged things we usually see. The first point is, to get a good, strong, healthy plant to

operate upon, keep its foliage free from plant-lice and caterpillars, and when it has reached the desired height, the stopping may be commenced. The Pomponé or small-flowered sorts are very satisfactory when grown in this manner. We hope to return to the subject again.

Prospects of Cranberry Culture.

Shall we, who have suitable lands, continue to plant cranberry vines? This question is often asked by intelligent men who have good cranberry lands, and know that large sums have been invested in plantations the last five years. Some tell us that the season of high prices has gone by, and the business is over-done. In the Philadelphia market reports in February, 1868, they were quoted at \$24 per barrel, and in 1869 at \$32. In New York some were sold at \$35. It is probably true that this fruit may not reach these extreme figures again, but we see no reason to doubt that the raising of cranberries will continue to be always a paying business. The same fears were felt in regard to planting apple orchards, many years ago. Yet the average price of good winter apples is not diminished but rather increased. The demand outstrips the supply, and the orchard in all those districts where the apple flourishes, is one of the most lucrative branches of farming. The culture of cranberries is yet in its infancy. In 1869 the production for the whole country was estimated at 75,000 bbls., of which two thirds were produced in New Jersey. These, at ten dollars a barrel, would only be worth three quarters of a million of dollars, and if distributed among the people would give less than a quart to each family. This certainly can not be regarded as an adequate supply of the fruit. It might be increased thirty-fold, and still not give a bushel to each family of our own people. But the market is by no means confined to this country. The fruit keeps much better than apples, and can be shipped on sea voyages round the world. Europe has nothing to compare with our fruit in quality, and large quantities are marketed there. The consumption of this fruit in our own country is rapidly increasing and is likely to increase. In many families it has ceased to be a luxury. It is as much a part of the winter supplies as apples or potatoes. No roast is complete without cranberry sauce. It is one of the most palatable and wholesome of our native fruits, and is likely to maintain its place in any thrifty family where it has once been introduced. In looking at this question, we are to consider that there is but a very small portion of the land that is adapted to its cultivation. It demands as the conditions of uniform success peat, sand or gravel, and water for flowage, in juxtaposition, and these are rarely met with. There is peat enough, but it is not near the sand; or, if the sand or gravel is convenient, it is not where it can be flowed on short notice. Then climate has a good deal to do with success. The fruit is exceedingly sensitive to frosts, and grows best in lands liable to early frosts. The best region for the cranberry is a narrow belt along the sea-shore from Cape Cod to the mouth of the Delaware. Here the sea breeze keeps off the frosts, and the crops mature with great uniformity upon tracts that can not be flowed, except in winter. It is this exemption from frosts mainly that makes the plantations on Cape Cod and in South Jersey so profitable. More than three fourths of all the cultivated cranberries in this country are grown on this very narrow belt, and there is no doubt they can be grown cheaper here

than in any other part of the country. But in this favored belt only a very small fraction of the land is suitable for cranberries. The wild vines are found in all the Northern States, in swamps and peat bogs, and mature some fruit, but good crops are exceptions to the general rule. This uncertainty, we think, must always discourage planting in these regions. This, of course, must operate as a heavy premium upon the cultivation of the fruit in the narrow limits, where good crops are the rule and failures the rare exception. But even here there is much careless investment of capital. Plantations are made upon bogs that can not be graveled or sanded, and in places where they can not be flowed. Of course, crops will not be satisfactory in these plantations, and they will run out for want of care. This should encourage the opening of new plantations where all the conditions of success are present. We know of very shrewd business men, who have studied this subject thoroughly, that are still making investments in good cranberry land and in plantations. There is one very remarkable quality about this fruit, which encourages the planter. It requires no manure, and where the work is thoroughly done there is very little expense in keeping a yard in good order. The annual flowing supplies all the wants of the plant, and old vines bear as abundantly as those recently planted. There are natural bogs on Cape Cod that have been in good bearing condition for over sixty years. Those farmers who live in the favored belt and have good cranberry land are perfectly safe in developing it. The crop can hardly fail to become a paying specialty in all this region.

Cold-Frame Cabbage Plants.

This article contains information that it will

Fig. 1.—CABBAGE PLANT NOT TRANSPLANTED.

pay our horticultural readers to lay to heart against the "pricking out" days of next No-

vember. The winter, as we all know, has been exceedingly severe, and it commenced in full force as early as November 28th—fully three weeks ahead of time. Our cabbage seed had

A NEW PRIMROSE.—(*Primula cortusoides amena.*)

been mainly sown September 20th, in some unoccupied frames (for want of space elsewhere), and the weather had been so unfavorable that they had made but little growth. Because of their small size the pricking out had been deferred, and the frost caught us with only a part of the crop replanted. There was nothing for it but to put on the sashes and save the bulk of the plants as they stood in the seed-bed. At this writing (April 15th) they are all alive, and they look pretty well—until they are pulled and examined, when it turns out that *not one* of them is safe to plant. They are all split in the stem, as in figure 1, and plants thus affected will make loose heads. Of those which were pricked out, as in figure 2, not one is so affected. They had not quite such a firm foothold, and so their leaves are a little more scarred with the effects of the hard frosts, but their stems are short and firm and their hearts are sound. There are about 20,000 of the injured plants, and we have had to decline orders for over \$250, which they would have just about filled. What is nearly as bad, we shall have to buy several thousands to make out the quantity needed for our own fields. The moral of this unfortunate tale is as follows: Sow your cabbage seed from the 1st to the 5th of September, instead of from the 15th to the 20th; if they are inclined to grow too large because of a late autumn, pull them up and lay them in by the heels to check their growth; be sure to have them all pricked out in the frames by November 20th.

A New Primrose.

When we say "a new Primrose," we mean that it is new to our cultivation. The old Primrose of poetry, which includes the Cowslip and Polyanthus, seems to be passing out of cultivation; it is difficult to find more pleasing early flowers. Perhaps the introduction of a more showy kind will revive the taste for the old sorts. The plant we have figured comes to us from Japan as *Primula cortusoides amena*, and under this name it has just appeared in our catalogues. Our engraving is from one of the original stock sent from Japan by Mr. Thomas Hogg several years ago. Whether it is a native of that country is not quite certain. *Primula cortusoides*—the Primrose resembling Cortusa, a related plant—has been in cultivation for a great many years, but it is only recently that its varieties have been taken up by florists. The engraving shows the leaves and flower-clusters of the new variety reduced about one third in size. A strong plant makes a large tuft of leaves and throws up several vigorous flower-stalks, which bear from five to twelve flowers. The lobes of the corolla are beautifully "crimped" and delicately veined. The colors vary from pure white to rosy purple—the specimen from which our drawing was taken, was of a charming lavender color. The plant has proved quite hardy near New York, and we hope to be able to class it among our hardy herbaceous plants. It is said to seed very freely in Europe; if it does so with us, it will soon be sold at prices which will make it popular. There is another new hardy Primrose, *Primula Japonica*, which we hope to flower and figure. The seeds of these Primroses often lie dormant for a long time before they germinate. We have seen some accounts of their not coming up

Fig. 2.—CABBAGE PLANT TRANSPLANTED.

until the second year. The seeds of these Primroses should be sown as soon as they ripen.

THE HOUSEHOLD.

(For other Household Items, see "Basket" pages.)

The Warren Cooking Pot.

In the Household Department for January of last year we gave a description and engraving of the Warren Cooker or Warrener. Our knowledge of it was obtained from having partaken of a dinner at the house of a friend, where an imported utensil of this kind was used. The article gave rise to so many inquiries as to lead to the manufacture of an improved form of the Cooker in this country. The parties making it, no doubt find it to their interest to advertise it, and we think it is generally kept in household-furnishing stores. Cooking in this apparatus is entirely different from steaming. The

SECTION OF THE WARREN COOKING POT.

meat is placed in a closed vessel, which is surrounded, top, bottom, and sides, by steam, but no steam comes in contact with the meat. The cooking goes on at a temperature slightly below that of boiling water, and no amount of stupidity or carelessness can dry up the meat. There is neither steam nor water to extract the juices, and the vessel being tightly closed, the flavor can not be dissipated. Gravy is formed, and it is just what gravy should be, the juice of the meat. We have used this Cooker continuously for several months, and would on no account go back to the old method of baking in an oven. We have only used it for plain joints and roasts. These are cooked until within a short time before serving, when they are placed in a hot oven for a few minutes, for the surface to brown, except where boiled mutton is required, when it is served just as it comes from the Cooker. The meat is always thoroughly done, never dry, but always juicy and flavorful. Since its use was instituted, there have been no complaints of the butcher, and we who live in the country often have abundant cause of complaint. A small roasting piece of beef can be had rare-done and juicy, which is next to impossible with a stove oven. Veal is a meat that requires long cooking to make it digestible, and when done sufficiently in the ordinary way it becomes dried and stringy. By the use of the Cooker the slow cooking can be prolonged until the veal is thoroughly done, and the subsequent browning in the oven can be given without perceptibly drying it. We only give such points as are within our experience; the circulars accompanying the Cooker give directions for several compound dishes which we have not yet tried. The Cooker is provided with a chamber for steaming puddings and vegetables, with no extra heat. The illustration here given shows the American form of the Cooker, in section. First there is an outer vessel, containing water in its lower part. Next is an inner vessel which holds the meat; between this and the outer one is a space filled with steam. A pipe, shown at the right hand, conveys the steam from this space to the steaming chamber above, but no steam goes into the place

which contains the meat. A double or hollow cover, its cavity filled with steam, incloses the whole. When the steamer is not used, the cover fits directly over the meat compartment, and an opening in it fits upon the steam-tube before mentioned. After the meat is put in, all that is required is to keep the water in the outer vessel boiling. The meat does not shrink, and it is claimed that there is a saving on this account of two ounces in the pound. The larger Cooker is of sufficient capacity for a good-sized roast, and a second size is made to suit small families. We regard the Warren Cooker as one of the greatest household improvements yet introduced, and worthy of general adoption by those who desire well-cooked meats.

Home Topics.

BY FAITH ROCHESTER.

My dear good girl, my domestic, my servant, had been gone a month, and my hands were more than full of work.

I have not written anything on the servant-girl question, I believe, but this subject interests me very much. My sympathies are quite as much with the servant-girls as with the mistresses. We do well to remember that the papers, in which all these questions are discussed, if at all, are conducted by the representatives of education and capital, and ignorance and shiftlessness have not much chance for a hearing. We are all of the time blaming trees for inclining hopelessly in just the direction the little twigs were bent in childhood. We might better be engaged in looking after the little twigs of humanity around us now, doing our best to prevent their getting some wretched twist that will make good their chances for lives of poverty, incapacity, and crime.

But my "girl," of whom I began to speak, was a real treasure in the house, an element of peace in the family, a "helper" indeed. Her only trouble seemed to be the separation from her own particular friends. Reading and writing were unknown arts to them all, and as Greta left a lover behind in coming beyond visiting distance, to live with me, it is not strange that she suffered some from homesickness. If mistresses would remember that their hired girls have ties of family and friendship, that they love to make friends and to be approved, they might find some of their difficulties removed.

But my good girl was gone, and ere this she is probably married. I was kneading bread, with a child at work at the table, on each side of my bread-board. Some housekeepers could never stand that. But a bit of dough is such a fascinating plaything for a child that I can never refuse it—unless I am decidedly "cross"—in which case repentance is sure to follow. Each child has its own round stick for a rolling-pin, and its own bits of earthen and tin for baking dishes.

Bother? Yes, of course. But it is worse bother to have children unhappy. Once make up your mind that everything *can not* go on like clock-work where there are children in the family, and that the children's happiness is a matter of considerable importance, while *their real, lasting welfare and usefulness* is, or should be, the chief end for which the farm and shop and household are kept running, and then this subject of "bother" will be properly considered.

Well, we three were making bread. The baby had waked and called for mamma, and papa, coming in just then, had taken her up and brought her along to oversee the baking operations.

"I don't see how in the world I can write for the *Agriculturist* this month," I said. "It would be for the June number. What topics would be especially suitable for June? Please suggest."

And he very kindly did so. I asked him to write them down, and he did, saying that I could make them over as I pleased. But I am fain to copy them down just as he left them, though he has omitted from the notes some excellent things he said about the connection between a farmer's (or any other person's) health and ability to work, and the quality and cooking of his food.

Not wishing to draw needlessly upon the sympathies of any one, I may say that since that con-

Fig. 1.—STRAW BED.

versation, two weeks ago, the family force has been augmented by the helpful hands and clear head and kind heart of a relative—for in this region kind household helpers are very difficult to get. [We may say here, as it will answer several questions, that Mrs. Rochester lives in Minnesota.—Ed.]

Here are the notes:

RELATION OF THE HOUSE TO THE FARM.—June is a busy month for the farmer and for the farmer's wife. The growing crops are to be looked after, corn to be cultivated, new ground to be made ready for late potatoes and ruta-bagas, and in the latter part of the month hay harvest begins. The success of these various field operations depends in no small degree upon the administration of the commissary department. The effort of the farmer is to get in a fall day of well-planned labor, and to this end he must have breakfast over and his workmen and teams started in the early morning, and must have a good nourishing dinner promptly at noon.

Fig. 2.—TABLE BIB.

But in order to secure this, some matters require his attention in the house. It is his place to see—

- 1st. That there is an abundant store of provisions, suitable for the food of the working force of the farm.
- 2d. Plenty of help in the kitchen. If he fails to secure the necessary help in the house, he should reduce his farming operations accordingly.
- 3d. Ample supply of water, and well-seasoned, properly-prepared wood just at hand.
- 4th. It depends upon the master of the house (using this term as we do "mistress of the house") to start the day. His getting up early makes it easier for every other member of the family to rise.

MR. ROCHESTER.

"Very good!" said I, "I am rather pleased that your first help in these 'Topics' should come in the shape of hints as to men's duties in the household department. If there are men who need such suggestions, they may be able to receive them with better grace from a man than from a woman. There are men who 'never allow a woman to dictate' to them, you know."

Fig. 3.—BIB.

STRAW BEDS.—Most people who use feather beds in winter, put them away in the summer and sleep on straw beds. These should be very full, and they will not be found hard or uncomfortable by any except the sick or aged, and usually not even by them. Our grandmothers, who wove their own linen-ticking, used to call nine yards of three-fourths-yard-wide linen a bed tick pattern, but the modern bed requires cloth a little wider. Good striped ticking is best. The best form is box-shape (fig. 1), with four small holes near the corners, in the upper side, and one longer one in the middle. This admits of adjusting the straw all over the bed more easily than in case of a single slit. Each one

may be fastened by a single strap under one side and a button, or by narrow tapes. Oat straw is the best. It is more soft than wheat or rye straw. To make it lie evenly, do not be contented to pull the straw up light, simply, but pull it from the higher parts into the lower ones, until the bed is of even thickness in different parts. It is aggravating to find the same hollows in the same spots night after night. Never fill them up by stuffing pillows or other articles under the mattress or under the lower spots in the bed, as I have seen bed-makers do. There is no trouble in making an even bed, if care is taken in stirring it. A mattress, or a comforter, or at least a bed-quilt, should lie between the straw bed and the sheet. Husks are preferred to straw by many; they are cleaner and more durable, but nervous people are sometimes much annoyed by the rustling of the husks.

CHILDREN'S BIBS.—Common napkins do not serve the needs of children under six or eight years, at table, so well as bibs that may be tied or buttoned around the neck. They should be long enough to tuck under the table, or to cover the child's lap. A small gore in front, with a band of right length, secures a good fit around the neck. I give a pattern (fig. 2), for those who need it.

Bibs much like this are used for teething children. They are usually made of marseilles, or diaper-linen, and are lined. They may be scalloped and embroidered, or simply bound with braid. Some babies have them pinned down in front and behind with pretty little gold or fancy bib-pins. Here also is a pattern (fig. 3), for the baby's bib, but it admits of variation. The table bib may be kept with the table napkins. A child should be encouraged to keep its bib clean and neat.

FLOATING ISLAND.—Having just learned a new wrinkle in making this ornamental and delicious form of custard, I am led to give the full recipe here, as I do not see it in any late numbers of the *Agriculturist*, and am not sure as it has appeared there.

One quart of good milk. Heat this, add sugar "to the taste," and when nearly boiling, pour in the yolks of six eggs, thoroughly beaten, stirring briskly until the custard is cooked. Flavor as you like. Turn this into a suitable deep dish, and set it in a cool place. Beat the whites to a very stiff froth, turn them into a colander (here you have the "wrinkle" which was new to me, but is old to some), and pour boiling water through the foam, shake it together, and turn it carefully upon the custard. You may scatter bits of jelly over this, or not, as you please. All custards should be cold when eaten.

To separate the whites from the yolks is a tedious process, unless you know how. Then it is simple enough. Break the egg through the middle with a quick rap against the edge of the dish. Holding it over the dish, put your thumbs into the crevice, and pull the egg open into two cups. The yolk settles itself into one, a part of the albumen or white spills into the dish, and you can easily pour the rest off, turning the yolk from one shell-cup to the other, being careful not to break it, until it is free from the white. Then turn it into the dish in which you will beat the yolks. Many persons have no idea what a "stiff froth" is, and stop beating the whites when they have just begun to foam.

ABOUT USING THE MOP.—Mrs. L. H. O., Wayne Co., N. Y., writes: Where one has a hard-wood oak or maple floor, strong hot soapsuds may be freely used. If, on the contrary, the floor is pine and nicely painted, it will need painting two or three times a year, if hot or even cold strong soapsuds is used. Hired girls and washerwomen often make sad havoc with the paint, soaping and even scouring with hot ashes. With a clean mop and clean soft warm or hot water, first run the mop all along the mop-boards, in the corners, on the thresholds, over the oilcloths and zines, in the pantry, and all the particular places. Change the water before it assumes a muddy appearance. Draw out the table a little, and run a clean mop behind that. There is no need of breaking one's back, stooping down, if both mop and water are quite clean. It is the sign of an untidy woman to see

grimy, dirty thresholds, mop-boards, and corners. It was the custom of the Dutch women living in those counties in the eastern parts of New York, and bordering on the Mohawk, to wash the floor on their hands and knees, with a linen bag. This laborious manipulation was called "filing." Whole houses of uncarpeted floors were thus made to shine and glisten by these industrious women.

Another Flour-Box.

In March last we gave a plan for constructing a flour-box. One suggestion of this kind is quite sure to bring out others, and we have received from "L. B. H.," Bryan, O., an account of the manner in which he fitted up two flour-boxes in a house that he recently furnished. He sends us sketches and the following description:

I first formed a base, 5 inches high and 17½ inches wide. I placed one standard between the

Fig. 1.—DIAGRAM OF FLOUR-BOX.

boxes and one outside of the two boxes; they were 17 inches wide, 36 inches high, upon which I placed a shelf, 18 inches wide, which formed the base of a cupboard. I cut the end pieces (fig. 2) of the boxes 26½ inches long and 16 inches wide. I made a line, ½ inch above the bottom end, and on that line, 5½ inches from the front edge of the board, made a point and struck an inch circle, to form a foot (a) to hold the box in place. I measured up the front edge from the line mentioned 3½ inches, and made a point (b). I drew a line from that point to the center of the inch-circle; I sawed it to the circle, and sawed also from the back edge on the line first mentioned to the circle, leaving a foot 1 inch wide by ¾ long. I cut a furrow across from the two lower corners on the inside of the end-pieces, to receive the bottom. From the top on the back edge of the end-piece I measured down 1½ inches, and rounded the end to that point. I used ¾ lumber for front and back, rabbeting it to ½ inch. I measured from the front of the dividing stands in 6 inches, and with an inch-gauge I cut a socket or place for the foot to rest in the base-shelf, being particular about bringing the face of the box and the dividing stand even when the box was shut. Cast handles were put on with screws, the feet were placed in the sockets, and the boxes were completed. The boxes will stay open or shut, as desired.

Fig. 2.—END-PIECE.

COCOANUT PUDDING.—By Lizzie H.—Grate one cocoonut, and mix with five rolled crackers; pour over this mixture a pint and a half of scalded milk, add one pint of cream, six eggs—whites and yolks

beaten separately—and sugar to taste. Eat cold, with cream and sugar. Nice for Sunday's dinner.

How to Use Strawberries.

The strawberry is a fruit of such delicate flavor that it is best enjoyed fresh from the vines, either with sugar alone, or in the favorite form of strawberries and cream. All forms of preserved and canned strawberries are in point of flavor so much inferior to the fresh fruit, that they are among the most unsatisfactory of preserved or canned fruits. For the full enjoyment of strawberries, they should be allowed to remain upon the vines until thoroughly ripe; hence those purchased in market are seldom in their best condition. To allow them to bear transportation they must be picked as soon as they are colored, and before the slight softening that indicates full ripeness takes place. It is only those who grow their own fruit that can have them in this condition. After picking, the berries should be placed in a refrigerator to become somewhat cool, though not too cold. The fruit for the table should never be washed. Straw should have been placed around the vines in sufficient quantity to keep the fruit perfectly clean. Strawberries that have to be washed are only fit for preserves.

Canned or rather bottled strawberries, while never good representatives of the fresh fruit, can be made much superior to those generally met with by a little care in the selection of the varieties. The Wilson, on account of its acidity and firmness, is better than any of the soft varieties, and its deficiency in flavor may be in part overcome by using the juice of Russell's Prolific, Brooklyn Scarlet, or other high-flavored variety for the syrup.

STRAWBERRY ICE-CREAM is liked by many, and it allows the fruit to be used in a form which presents a pleasing variety. A quart of berries is sprinkled over with half a pound of fine white sugar. After standing for three hours, the berries are mashed and the juice strained. Add another half-pound of sugar to the juice, and a quart of fresh cream stirred in gradually. Freeze in the usual manner. This may be varied by adding to the cream when it is partly frozen a pint of unsugared berries, and when this is done it is necessary to add an extra cupful of sugar to the juice that is pressed from the first berries, and mixed with the cream.

STRAWBERRY SHORTCAKE is generally popular, and we have heretofore given recipes for it. We now give one from Marion Harland's "Common-Sense." We have not yet tried it, but we have generally found her approved recipes excellent. She takes 1 quart flour, 3 table-spoonfuls butter, 1 large cup sour cream or very rich lopped milk, 1 egg, 1 table-spoonful white sugar, 1 teaspoonful soda dissolved in warm water, 1 salt-spoon of salt. Chop up the shortening in the salted flour as for pastry. Add the eggs and soda to the milk; put all together, handling as little as may be. Roll lightly and quickly into two sheets, the one intended for the upper crust fully half an inch thick, the lower less than this. Lay one crust upon the other, and bake. While warm—not hot—separate them. Lay upon the lower a thick coating, several deep, of strawberries; sprinkle powdered sugar over them; cover with the upper crust.

KEEPING HAMS.—"E. R. A. S.," Hardinsburgh, Ind., sends the following: After your meat is well smoked, procure some clean, dry ashes, and have some water handy; take down the hams, moisten them a little so that the ashes will stick, put the ashes on them, and give them a good rubbing, and hang them up again. Any person trying this will find that the meat will keep sweet and nice, and will not be troubled with any insects on the hams. I have put mine up in this way for three seasons, and find it does well.

ORANGE PIE.—By Lizzie H.—Take the pulp and juice of two oranges, with a little of the grated peel, three eggs, one cup of milk, and one of sugar. Stir the sugar with the yolks, and add to the orange juice; next add the milk, and then whites of eggs.

BOYS & GIRLS' COLUMNS.

The Picture Prizes.

Well, children, the first of May was the day named, on which all the prize stories must be in. So on that day we took an account of stock, and how many do you suppose there were? Seven hundred—lacking ten! Yes, just six hundred and ninety letters to be opened and assorted, and afterwards read. These are divided up as follows: Boys twelve and over, 244; boys under twelve, 81; girls twelve and over, 240; girls under twelve, 103. Besides these there were 22 letters, which were either without addresses, or of which the writers failed to state their ages, which of course don't count. As it is quite impossible to read through all these letters in time to announce the successful ones on this page, you will have to turn to the "Basket" columns for the information, as that part of the paper goes to press a week later than this.

As there are but twelve prizes, of course there will be 678 of my youngsters who will not succeed this time, but we shall by and by have some other offers, at which they can try again. I have only read a portion of the letters, and am glad to see so many say that they write for the sake of the exercise. I was quite amused in looking over the letters that came with the maps, some time ago, to see that some insisted that Aunt Sue and myself must be the same person. This being denied, now several wish to know if I am not Uncle Tim, who writes in *Hearth and Home*. To this I must answer, no. Uncle Tim attends to his boys and girls in *Hearth and Home*, and I to mine in the *Agriculturist*, and neither of us ever "change works," or write in the department of the other. It is very odd to be obliged to insist that I am not some one else, and I hope that the youngsters will be satisfied with the declaration that I am "The Doctor," and do not appear under any other name.

Six hundred and ninety letters of all sizes of paper and envelopes, and written in every variety of hand, from the printing hand of the little one first using the pen, to the handsome script of the young master or miss, who evidently uses the pen with ease and grace. What an exhibition these letters would make! It would quite heat the patching and darning exhibition, in interest to young people at least. Then, if we could have all the six hundred and ninety boys and girls together, to see it, what a gathering it would be! The National Conventions would be as nothing to it. I can not hope to see such a meeting of my youngsters, but must content myself with going to them separately through the medium of the *Agriculturist*.

THE DOCTOR.

Insect Friends and Enemies.

If people know more about the ways of insects, they would not work so blindly when they try to get rid of them. Every one knows that insects do much damage to plants, but every one does not know that all insects are not injurious. There are many insects that do not feed upon plants at all, but eat other insects. This being so, the farmer or gardener who kills all the insects he sees, really does himself a wrong. Children should watch insects and learn to know one from another. You can learn much about the habits of insects without books, and when you become interested in the subject you will wish to become better acquainted with them, and perhaps will like to take up Entomology, as the study of insects is called. The artist who drew the picture which we have called "The Defender of the Herd" has taken some well-known facts of insect life as the foundation of his picture, and then used a little imagination to make it more striking. You have doubtless all of you seen plant-lice, or *aphides*, as they are sometimes called. You will not have to go far to find them; probably the first rose-bush will have altogether too many upon it. They are not confined to rose-bushes, but are found now and then upon almost every common plant, and the young shoots of fruit-trees are often completely covered with them. They are usually green, but are sometimes dark-brown or blackish. These little fellows are shown in the picture very much enlarged. They lead a very curious life; each one has a long, sharp bill or proboscis, which it thrusts into the tender leaf or stem, and sucks away at its juices. Once anchored in this way it seldom moves, and as they are frequently as thick as they can stand, you may be sure that the plant suffers. Each one of these plant-lice has two tubes at its rear end, from which it gives off a sweet juice, which often drops upon the leaves of the plant and upon the ground, and is called *honey-dew*. The ants are very fond of honey-dew, and not only eat that which the plant-lice let fall, but they go among them and secure the drop before it leaves the insect. It is said that the ants will even tickle the plant-lice with their feelers, to make them "give down" the desired drop. We never saw the ants do this, but we have seen them very busy among the *Aphides*, and if you watch them carefully, you

may be able to find out whether those who have made this statement are correct. At any rate, the *Aphides* have been called the "Aots' Cows," and the ants are considered their friends. But the *Aphides* have their enemies, which cause much havoc among them. The larva or grub of the well-known Lady-bird or Lady-bug is one of these, and the larva of several other insects feed upon the plant-lice. Of course, you know the different forms which most insects go through. When hatched from the egg we have the *larva*, commonly known as caterpillar or grub. After this has reached the proper age, it rolls itself up, often spinning a web or cocoon, but frequently taking on only a hard skin, and remains in this *chrysalis* or *pupa* state, some insects for months and others for days only, and finally comes out as butterfly, moth, beetle, etc. Well, one of the enemies of the plant-lice is the larva state of the pretty red and black Lady-bugs. It is a very lively, lead-colored grub, with red and yellow spots, and is very fond of making a breakfast off of the ants' cows. The artist has shown the *Aphides* and a destructive grub making an attack, and has represented the ant in the act of defending his flock. You probably will not succeed in seeing ants doing just this, but if they are intelligent enough to milk their cows, we should not be surprised to learn that they defend them from enemies in their own way, which may not be the way the artist has imagined, but probably one that will answer as well.

Aunt Sue's Puzzle-Box.

Now, children, old and young, get your dictionaries, and square some word of six letters, without any foreign word or proper noun. H. H. Clarke has sent a six-word square: who else will do so?

RIDDLE.

Half of me is senseless sound,
Yet therein my whole is found.
Rising from off the ocean deep,
I rouse the sailor from his sleep,
But soothe the landsman's list'ning ear,
And mourners' saddened thoughts oft cheer.
Now let me rise from o'er the land,
The sternest tyrant stays his hand,
Aye, princes, potentates, and powers
With trembling watch the laggard hours:
Reverse my half, (when cut asunder)
To rostrum and pulpit I furnish thunder;
A very fruitful source of ill—
Riot and noise, though sprung from "still."

BESSIE.

ANAGRAMS.

- 1. Burn near swan least.
- 2. O not fired cane.
- 3. Real men count.
- 4. Send, in belief.
- 5. Citron instead.
- 6. Send Roc.
- 7. Fine fable.
- 8. Eat trifles.
- 9. I hate a tab.
- 10. I can't hoc.

ARITHMOREMS.

MINNIE.

DIAMOND CROSS-PUZZLE.

The center letters, horizontal and perpendicular, are the same.

- 1. A vowel.
 - 2. A foreign word for love.
 - 3. Inactive.
 - 4. A continent.
 - 5. A printer's implement.
 - 6. A luxury.
 - 7. An article.
- R. T. ISHESTER.

EQUIFOCAL WORDS.

Find one word which will express the various significations given. Thus: "A corner—to fish with a bait." Ans.—Angle.

- 1. Deportment — dexterity — direction of a letter — a speech — to accost.
 - 2. Vile in man — what he must stand upon — indispensable to his house — a game.
 - 3. What many do in cities — a thin plank — a sailor's duty in close combat.
 - 4. Part of a stage-coach — profit — advantage — the point of discussion in a "swap" — an article of dress.
 - 5. A lever — a thicket — a plant — a tool.
- JOHNNIE.

NUMERICAL ENIGMA.
(A very easy one.)

I am composed of 10 letters.
My 8, 9, 10, is a weight.
My 7, 5, 6, is a spirit of grain.
My 1, 2, 3, 4, is to cleanse,
My 3, 2, 1, is a carpenter's tool.
My 1, 5, 10, 7, is what birds fly with.
My whole is a city.

- 3. Granite.
- 4. Dietator.
- 5. Alexis.

REBUSES.—424. Depend not upon fortune, but upon good conduct.

- 425. Vice is infamous though in a prince, and virtue honorable though in a peasant.
- 426. Cape Henlopen.

A PROBLEM.

J. TEACKLE sends us an old puzzle which may be new to some of you, and will give amusement to those who are fond of working out problems. I dare say W. P. SMITH will have it all figured out mathematically in no time.

This is the story. Twenty men (ten black and ten white) were out at sea when a storm arose, rendering it impossible to carry more than ten men aboard with safety. A council of war was held, and it was determined to throw over every fifth man. The white sailors arranged them in such order that "every fifth man" should be a black man. How did they manage it?

Thus they stood:

—and surely nothing could look less methodical, but by that arrangement you will see that every black man is doomed. Now I will give you the *formula* by which they were arranged, but you must find out the "why?" for yourselves. "A gray owl did eat a snake." The vowels (including y) are black men, the consonants white men.

AUNT SUE'S NOTICES TO CORRESPONDENTS.

JA-CE-PE-ES.—"Twelve brothers and sisters"! Do you have to chalk yourselves, to know which is which? The same "AUNT SUE," and glad to be "Dear" to "thousands."

ARAX.—I do not remember the location of all my correspondents, so can not inform you; don't remember any just now.

GUSTAVUS M.—So your "father will take the *Agriculturist*."

[COPYRIGHT SECURED.]

OUT FOR A BATH.—FROM A PAINTING BY F. S. CHURCH.—Drawn and Engraved for the American Agriculturist.

tourist and *Hearth and Home* as long as he lives." Long life to him!

EDWIN C. P.—Use only fair English words in "squaring."

MERRY THOUGHT has squared the word "care" 123 times, changing one word every time; it took 1,968 letters to write the squares with, and is certainly the most carefully written document I ever received.

H. H. M.—You can always tell if your answers are "right," by comparing them with the list of answers when they are published.

J. M. S.—Sorry not to oblige you, but it is contrary to our rules to advertise for correspondents.

PLowBOY.—Thanks for your rebus, so beautifully drawn; I am only sorry you did not select some other subject.

MINNIE T. E.—I do enjoy "a hearty laugh," but it is generally *with* folks, not *at* them.

GLAD to hear from Richie B. A., M. L. L., Anstin W. S., Claude, C. H. J., A. M. R., Johnnie, Ben S. S., Robt. W. M., and Nellie Bache.

Thanks for puzzles, etc. (though some may be looking for thanks in *Hearth and Home*) to J. S. Van O., Jacques, Claude, Annie, Alice H. P., Fred. A. S., Minnie, Hattie K., E. M. Brown, Orren P. A., Jacob N. R., and Mary Jacobs.

Out for a Bath.

When we saw Mr. Church's painting called "Out for a Bath," it seemed so funny, that we wished all the boys and girls could have a laugh at it, so we had an engraving of it made, and here it is. Some pictures that we give you

are intended to be instructive, and others are put in merely as pictures, to interest and amuse. The artist has represented three young snipe making their first acquaintance with water. Young birds are not, as a general thing, very handsome, but young snipe in their unfledged state, with their ridiculously long legs, are comical enough. Many artists can paint birds and give a correct representation of their forms and colors, but few succeed in giving them much expression. In this group we have a great amount of expression. A bath is evidently quite a new thing to these snipelets, and they hesitate before venturing in. The one on the left, more courageous than the others, is testing the water with the tips of his toes, while the rest await the verdict with most comical interest. See, too, how finely the sedges and other plants are represented. We think this a very clever and amusing picture, and hope that all our young readers do too.

The Smith AMERICAN ORGAN CO.

Respectfully announce to their musical friends that they have now ready a few

NEW INSTRUMENTS,
Beautiful in Appearance and Delightful in Tone.

They will be glad to send engravings and detailed descriptions to dealers and others who are interested. One of these new styles, containing **THREE SETS OF REEDS**, is believed to be the

FINEST PARLOR ORGAN

yet made in this country. It has a COMPLETE NEW REGISTER of a lovely and sympathetic quality, and is capable of producing very delicate effects.

Correspondence solicited.

CATALOGUES FREE on application. Address

THE SMITH AMERICAN ORGAN CO.,
TREMONT ST., BOSTON, opposite Waltham st.

What the N. Y. Weekly Tribune says, May 8th, 1872:

"We know whereof we speak when we pronounce the **Universal Clothes-Wringer** one of the best labor-saving inventions of the age. It not only economizes time and strength, but is a great saver of clothes by preventing the twist and strain of hand-wringing, and, when it is screwed on a **Doty Washer**, Monday loses all its terrors."

It will pay you to send to Porter Blanchard's Sons, Concord, N. H., or to any dealer in first-class dairy machinery, for the circulars of their excellent churn.

Every one who intends to buy a Watch this year should write for our Price-list of Waltham Watches. We send them everywhere at the lowest New York prices. Send for the Price-list now, and read it at your leisure. When you write, mention the *American Agriculturist*.

HOWARD & CO., No. 865 Broadway, New York.

TIN-LINED LEAD PIPE

is a **Block-Tin Pipe** heavily coated with solid lead. It is the best and cheapest Water Pipe when strength and durability are considered. By its use iron-rust, lead and zinc poison are all avoided, and general health promoted. Price, 15 cents a pound for all sizes. Circulars and sample of pipe sent by mail, free. Address the **CORWELLS, SHAW & WILLIAMS Mfg Co.**, No. 213 Center Street, New York. Also manufacturers of Block-Tin Pipe, Sheet Lead, Lead Pipe, Solder, etc. Orders filled at sight.

SAFE AND DESIRABLE MUNICIPAL BONDS

OF KANSAS, MISSOURI, COLORADO, and WISCONSIN, having from 5 to 20 years to run. Principal and interest payable in New York City. For sale at prices that will pay over 12 per Cent on the investment. First-class Investment Securities always on hand. Call or send for descriptive circular.

MOWER & SELF-RAKING REAPER
 165 OFFICE GREENWICH ST. N.Y.
 POKEEPSIE FACTORY N.Y.

MANUFACTURED BY ADRIANCE, PLATT & CO
 STYLES, SIZES & PRICES TO SUIT ALL FARMERS
 Descriptive Circulars Forwarded by Mail.

Johnston's Self-Raking Reaper

is so well known among grain-growers generally, that it needs no extended heralding in print. As manufactured by us, it is the only Reaper that will save the entire crop when badly lodged.

We warrant it to cut any grain that grows, and in any condition.

A pair of ordinary horses and a boy to drive it will cut from 10 to 20 acres a day in the most satisfactory manner. Send for illustrated pamphlet.

C. C. BRADLEY & SON, Syracuse, N. Y.

TWO GOLD MEDALS

AWARDED THIS MACHINE.

THE BEST IN AMERICA.
 Gardner's premium Railway Horse Power and Thresher and Cleaner, received, THE FIRST PRIZE at Great National Trial, at Auburn, N. Y.

For "Slow and easy movement of horses, 15 rods less than 1/4 miles per hour, Mechanical Construction of the very best kind, thorough and conscientious workmanship and material in every place, nothing slighted, excellent work, &c.," as shown by official Report of Judges. Treshers, Separators, Planing Mills, Wood saws, Seed Sowers and Planters, all of the best in market. Catalogue with price, full information, and Judges Report of Auburn Trial sent free. Address: MINARD HARDEK, Cobleskill, Schoharie Co., N. Y.

The uniform success of the Clipper Mowers in the field, the testimony of every farmer who has used them, that they are the lightest in draft, the most durable, and the most economical machine for the farmer to buy, fully substantiates what the proprietors have always claimed—that the Clipper is the Best Mower in the World.

To the No. 4 size is attached the Dropper (cutting 5/8 feet, with separate Finger-Bar for reaping), constructed with great improvements—in fact, perfected; and in point of efficiency, strength, lightness of draft, and symmetry of proportions, it is, as a Reaper, also unequalled. Farmers! see it before you buy. Pass your own judgment upon it. Look at its many improvements possessed by no other machine. Remember, it is fully warranted. Send for Pamphlet. THE CLIPPER MOWER & REAPER CO., P. O. Box 6, 175, 154 Chambers st., New York.

THE SUPERIOR HAY SPREADER.

Farmers, be sure and examine the only perfect Spreader ever put into the field. The SUPERIOR is acknowledged by all to be the only Machine that will spread, disentangle, and turn over all grass passed over. It is the neatest, best built, and only true working tedder. Send for Descriptive Circular, and read the numerous testimonials received.

JOHN L. KIPP,
 163 Eldridge street, New York.

BULLARD'S HAY-TEDDER.

Spreads from behind the wheels, and does not run over the grass after it is spread, as ALL others do. The only Tedder that will take up the grass from the bottom. Is light draft, never "winds" or clogs. With this machine, hay can be cured and put in the mow the day it is cut.

The "AMERICAN AGRICULTURIST" says: "Bullard's Tedder surpasses those previously introduced in strength, handiness, and ease of draft."

Union Mowing Machine.

EARTH-CLOSET COMPANY.

MOULE'S PATENT.

The simplest and cheapest effective Earth-Closet yet made. Call or send for Circular.

EARTH-CLOSET COMPANY,
31 Cortlandt st., New York.

The Lancet can be sharpened like an ordinary knife. Samples mailed post-paid on receipt of 50 cents.
DOOLITTLE MANUFACTURING CO., 599 Broadway, New York.

The manufacturers claim that the Sherman Wringer is superior to all others for the following reasons:

1st. It has all the capacity of any Clothes-Wringer, and is more Compact, Simple, and Durable than any other Wringer.

2d. The Frame is of nicely Galvanized Iron, and can not rust, rot, swell, or shrink.

3d. The Rolls are of Solid White Rubber, and are made under Moulton's Patent, wired on to the shaft, which makes them very durable.

4th. The Springs are made of Car-Spring Rubber, and possess much more elasticity and durability than the Wood or Iron Springs commonly used. And these springs are so arranged, that it is almost impossible, in any ordinary use, to throw the Cog-wheels out of gear.

5th. It may be applied to any Tub, Washing-Machine, or Barrel more readily than any other Wringer.

6th. It is warranted, in every particular, TO BE THE BEST CLOTHES-WRINGER MADE.

HALEY, MORSE & CO.,

31 Cortlandt st., New York.

THE PROTEAN LANCETTE.

Experience teaches that to secure for an article the favor and patronage of the LADIES, it must combine beauty and elegance of design, with practical utility. The favor with which our modification of the **BUTTON-HOLE CUT-TER** has been received, predicts that no Lady's Work-Basket will be regarded as complete without it. It is also an admirable Envelope, Leaf, and Paper Knife.

DIRECTIONS.

To extend the Lancet, hold the instrument as illustrated by the engraving; then, holding it as you would a pen, with the cutting edge from you, insert the point (where you wish to commence the button-hole) until you are stopped by the gauge. Be careful not to extend the point too far at first, but cut and try until the hole is a sufficient size to allow the button to pass through; then observe at what point the slide is on the scale, that you may be able to retain the size.

The **PRESERVING POWDER** is warranted as healthful as **Common Table-Salt.**

If the **Farmers and Fruit-Growers of the United States** will take hold of this method—either separately or by clubbing together—and put up their fruit for the market in kegs and barrels, it will find a **Ready Market and Sale** at good prices, and make **Millions of Dollars** annually to farmers of the United States that is now entirely lost. The fruits thus prepared will become a staple in the markets, as **Butter** now is in **Kegs and Firkins**. All the **Produce Commission Merchants** of all the large **Cities** will be glad to aid you in the sale of the **Fruit** thus prepared.

Every family putting up fruits, etc., for home use should try the **PRESERVING POWDER**. It will preserve any and all kinds of fruit, etc., at about one half the cost in time, trouble, and expense of the air-tightening method, and give the additional advantage of using the fruit as wanted from time to time from large jars or vessels.

Get it from your Grocer. If they have not got it they will get it for you. Price **One Dollar per Package.**

For the proof, or further particulars, try the Powder, or address

L. P. WORRALL, Proprietor, No. 153 Chambers Street, New York.

GUARD AGAINST THE COMING FAMINE!

FARMERS, be sure and preserve all your surplus fruit crop **this year**. It will be wanted in all the towns and cities of our country **next winter**, and will bring you a good price. And why so? Because the general fruit crop itself will be **short this season**, and the price of fresh fruit for canning will necessarily be high, and because tin cans for canning fruits have advanced about fifty per cent in price this spring, which must necessarily cause a large advance and high price for canned and preserved fruits next winter, and almost as surely cause a **very short supply**. Farmers of the interior (having little or no market for their fresh fruit) are urged to make up the full supply—which they can **cheaply, reliably, and profitably** do by using the

American Fruit-Preserving Powder,

and thereby keep the fruit in large **Earthenware or Stoneware Jars and Wooden Kegs and Barrels**, by simply corking or bunging them tight enough for shipment, and they will reliably keep during the year round, or longer, or for shipment to any part of our country, or, no doubt, to any part of the world. We have kept fruits by this method in store during **Four Years** without the least fermentation.

Only two to four or five ounces of sugar required to each pound of fruit, to suit the taste, or the fruit will keep just as reliably with less sugar, or without any sugar. However, it is always better to add a little sugar at time of preserving.

The **PRESERVING POWDER** will cost but a trifle for each quart of preserved fruit.

The directions given for using the **POWDER** are thorough and simple—none can possibly mistake them; and the cost and labor of preserving fruits in **Kegs and Barrels** by this method is less than one half that of the canning or air-tightening method; and the fruit when preserved will surely compare favorably with the best canned or preserved fruits, whilst many have pronounced them better.

**THE EXCELSIOR LAWN MOWER
FOR HAND OR HORSE POWER.**

Manufactured by **Chadborn & Coldwell M'g Co.,**
(Send for Circular.)
FOR SALE BY

RICHARDSON & COULD, Seedsmen, Am. Agriculturist B'ld'g, 245 Broadway, N.Y.
B. K. BLISS & SONS, 23 Park Place and 20 Murray Street, New York.

**HILL'S
"Archimedeian" Lawn Mower.**

In placing this LAWN MOWER before the Public for the season of 1871, it needs no recommendation, as it has a world-wide celebrity. With the improvements recently added to this favorite Mower, we are fully warranted in saying it has no equal in the WORLD. And its immense sale for the last 30 days throughout the United States is sufficient proof of the above assertion and of its great superiority. This Lawn Mower is constructed upon truly scientific principles, and it is the only PERFECTLY BALANCED Lawn Mower ever made, operated by a ball and adjustable handle, points that are indispensable, securing ease of operating, and a perfect, beautiful, and level cut.

The Hill's "Archimedeian"

was the FIRST (and original) BALANCED LAWN MOWER invented in this country or any other, was patented in the United States and Great Britain, and its invention brought into general use a machine that is now a necessity, and almost an indispensable article. All others now made are copies of this machine, and the public are cautioned against them.

For sale by all the leading Seedsmen and Agricultural Implement Dealers throughout the United States and Canada.

Illustrated Catalogues and Testimonials, post-free, upon application to us or any of our Agents.

Manufactured by
**The Hill's "Archimedeian" Lawn Mower Co.,
Hartford, Ct.**

(Works at Colt's Armory.)

ESSEX PIGS.

I keep no other breed of pigs except the Essex.

Taking everything into consideration, I regard them as the best, purest, most refined, quietest, and most thoroughly established breed of pigs now extant.

I do not know that they have a single fault.

I have never heard any one who examined them carefully object to them except on the ground of color.

They are a black breed.

I have heard many farmers say: "If they were only white, they would be perfect." This, of course, is mere prejudice.

When dressed, they are as white as the whitest, and the lard is firmer and whiter than that of any white hog; I have ever seen.

"But are they not too small?" They are classed with the small breeds, but they will dress over 400 lbs. They are quite large enough. They are the largest of the small breeds—larger than the small Berkshires, and much larger than the Prince Albert Suffolks, small Yorkshires, or Neapolitans.

So far as I know, I have the largest stock of pure-bred Essex in the United States, and I think my pigs are at least as good as any pure-bred Essex to be found in England.

My prices are reasonable, and I feel certain that I can give good satisfaction to all who favor me with their orders.

My spring pigs are the best I have ever raised, and I am selling sow pigs at reduced rates.

Please mention where you saw this advertisement.

The Poultry Bulletin.—Our contemporary and neighbor began its third year in April by appearing in an entire new dress, now as an octavo magazine, with cover, and embellished with many excellent engravings. We value the Bulletin highly as an exchange, and commend it to our readers.

Uneven Pulling of Teams.—We have received several letters on this subject, to which we reply generally, that it does not follow, because the double-tree is not even, that one horse is pulling more than another; neither does it follow that both horses are pulling exactly alike. The question was originally made, whether one horse must necessarily be drawing more than an equal part of the load, and we replied, no, and still hold to that opinion, as a general principle. There are many contingencies, which might occur, in which the draft would become unequal, but they don't affect the question on principle.

Hens - Houses.—“Subscriber,” Alleghany City, Pa. In a series of articles entitled “The Egg-Farm,” the whole subject of raising poultry for profit has been thoroughly discussed. The series began in May, 1871, and extend through twelve numbers. The questions you ask are fully answered there. We could not reply to your inquiries without writing a long article.

To Dissolve Bones.—“A Reader,” Stamford, Ct., asks us how to dissolve bones. A Boston paper (of which the editor is a chemist and therefore ought to know) says, “Bones may be dissolved in the following manner: take one barrel of finely-ground bone, mix it with a barrel of good wood-ashes in a heap on the barn-floor, during the mixing add gradually three pails of water. It must not be made too moist, and will be ready for use in a week. It needs to be used in small quantities, as the superphosphates.” “Bones may also be dissolved by using 50 pounds of sulphuric acid, mixed with 3½ gallons of water to 150 pounds of ground bones, in a similar manner to the above.” This is in the proportion of 33 pounds of acid to 100 pounds of bone. If the ground bones are quite fresh, 22 to 25 pounds of acid have with us been found sufficient.

Arkansas Moving.—A farmers' club has been organized at Little Rock, of which H. Brady is Secretary. He writes us that the club would be glad to open correspondence with other clubs, and also to receive from dealers in implements, stock-raisers, etc., their catalogues and circulars for the use of the club.

Unfermented Grape-Juice.—“D. L.,” Portsmouth, O. We know of no work upon this subject. We suppose grape-juice may be bottled, like other fruit juices, upon the same principle that fruits are canned and bottled.

Iodine Ointment.—“M. Van D.,” Martindale, N. Y., asks how the iodine ointment mentioned in *January Agriculturist*, page 6, is made. Twenty grains of iodine, four grains of iodide of potassium, water six drops, lard one ounce troy. Rub the iodine and iodide of potassium together with the water and then with the lard until well mixed, and preserve closely from the air. It should be used soon after mixing.

All about Colorado.—“Q.,” desires to inform “G. E. S.,” that the colonies of Greeley, Longmont, and at Evans are, in their own estimation, “cities” of no small importance; that “he can earn his bread with the sweat of his brow in Colorado with the greatest satisfaction;” that the “average of crops gained there is double that of Pennsylvania or New York, except oats;” that the climate is fine, and that it must be a good farm in either of those States which will compete with them.” But “all their crops must be irrigated.” We have not space for the whole letter.

Potato-Starch.—“D. M. H.,” wishes us to give him the process of making potato-starch and the amount of product of a bushel of potatoes. The process consists in rasping the potatoes to a fine pulp, and washing it on a strainer with cold water, which is permitted to pass through and carry the starch with it into shallow vats where it is deposited; after which, the water is drawn off and the starch dried. One hundred pounds of potatoes will produce about seventeen pounds of starch, or more or less, according to the variety.

Vegetable Gardening in June.—This most unusually backward season has upset the calculations of most persons who have their garden “made” and out of the way before June. Do not be discouraged. It usually happens that what is lost at one end of a season is made up at the other, and it rarely fails that the average comes right. Many things usually sown earlier can yet be put in with a fair prospect of a

good crop. We enumerate some things as a reminder. Beans of all kinds. Beets, both early and late sorts. Cabbage, Cauliflower, and all of that tribe. Carrots, in garden or in field. Sweet Corn. Cucumbers, Melons, and Squashes. Early Peas may be put in for a late crop, planting them deep, so that they may resist drouth. New Zealand Spinach, Okra, Herbs of all kinds, and even potatoes, if they have not already been planted. At this late season weeds will be abundant, and the young plants require extra care to keep them clean. We have often found it the case that things sown the first of June did as well as those sown earlier, which had to contend with long cold storms in May.

How to get a Farm for Nothing.—A young man, who is now teaching school, would like to have a farm, worth \$5,000, and writes to ask where he can borrow the money to buy it with. Now, a school teacher ought to have a better idea of things than to dream of the possibility of doing such a thing as he desires, and lest there may be others who might have an equally foolish idea in their scanty brains, we just say to such young men, Go West, go anywhere where a dollar can be earned, and spend only half of it, and lay by the rest until something has been saved. If \$100 only has been thus saved, it will go far to show that that man will be able to pay a debt he may contract, and he may risk doing it; if he can not thus save \$100, how can he ever hope to pay \$5,000 out of his own hard labor alone.

Kidney-Worms in Hogs.—“W. H. B.,” Turpentine rubbed on the back or wood-ashes given in the feed is often used with good effect for this complaint.

How to use Swamp-Muck.—“J. W. S.,” had better use muck in his stables, or compost it with stable manure, than to spread it raw upon his field.

How to Feed Grain to Oxen.—T. Bell, Osage Co., Kansas, asks how he shall feed corn to his oxen otherwise than in the ear; when fed in the ear they won't eat hay. Probably the best way would be to get the corn ground and chop the hay with an ax into short lengths (if there is no hay-cutter), and wet it and sprinkle the meal on it. If this can not be done, feed hay first and give the corn afterwards, and sprinkle salt water on the hay as an inducement.

Early Lambs.—Edwin Black, of New Jersey, writes; “I raise early lambs for the New York market, and want to get them to weigh 50 pounds as soon as possible. Will the lambs from a Cotswold ram and a Merino ewe fatten as soon as from a South-Down ram?” Perhaps the quality of the meat from the South-Down may be better, but the lambs from the Cotswold will weigh the most at a given age. The great point is to get a pure-bred ram, and one that has a tendency to mature early rather than to attain a great size. Feed the ewes liberally, and let the lambs have a plentiful supply of meal and sliced mangels in a trough, separate from the ewes.

Compost-Heaps.—A Maryland farmer asks how to build a compost-heap. Pile all the materials, stable manure, sod, sea-weed, straw, stalks, etc., in layers, but do not put ashes or lime in at all; when they have heated, commence at one end and turn all over, and mix, and let it heat again. It will soon rot under this treatment. Spread ashes and lime by themselves directly on the field.

Burning Stumps.—T. Greenwood, Miss., says it is a bad practice to burn stumps without wholly destroying them, as when charred they are preserved from rotting.

Garget.—A “Subscriber” asks for a cure for garget or caked bag. The udder should be fomented with warm water, and rubbed with ammonia water (or common hartshorn) and sweet oil several times a day; the rubbing is probably of more effect than the liniment. A quart of sliced poke-root fed with some potatoes has effected a cure. But it is generally the case that care previous to calving will prevent this troublesome complaint. Let cows coming in be watched, and if the bag becomes too full it should be relieved by drawing off the milk at once.

How Many Eggs in a Year?—“D. B. S.,” Brooklyn, N. Y. Eight or nine dozen is a very good average yield, indeed, for hens, taking good, bad, and indifferent together. It is all very well to talk about 150 to 200 eggs per head per annum, and about 25 to 30 quarts of milk per day from a cow, but it is extremely foolish to expect such things to happen generally. There is a wonderful difference in the laying capacities of different breeds, and feeding and management affect prolificness, so that no estimate can be made that will not fall very wide of the mark in many cases. It takes about 36 quarts of corn to feed a fowl of average size and appetite,

a year, with a considerable amount of other things, which it must either forage for, or be furnished with, if shut up. It is a marvel that so many as 100 eggs can be manufactured from the rations of one fowl, and the ordinary waste of the system be repaired at the same time. Individual birds that produce 150 eggs, or upwards, in a year, have the power of digesting and assimilating more than an ordinary quantity of food, without which such feats of laying could not be performed. In many cases when ten or twelve dozens of eggs are laid in a year, a part of the food and vital force of the last part of the year preceding is employed, it having been stored up in the system, and also profuse laying sometimes reduces flesh and strength so that the fowl is obliged to feed heartily, without laying, for some months after, in order to recuperate.

Steaming Feed.—“J. W. R.,” Hardock, Pa., asks if a wrought-iron cylinder boiler, eight feet long and eighteen inches in diameter, will steam feed for fifty cows and thirty hogs. Such a boiler will be amply sufficient, with a chest made steam-tight to contain the feed.

Navicular Disease.—“L.,” writes, he has treated his horses according to Prof. Coleman's method, and made them worse, as follows: pared the heels, leaving the frog and toe, expecting that the frog would sustain the pressure, and kept the foot moist. Also, according to another authority, with benefit, as follows: pared the toe as low as possible, trimmed the frog, cleaned out the inside of the hoof, and left the heels high, thus throwing the pressure on the rim of the hoof, and using liniment on the sole and around the coronet or upper edge of the hoof.

Strawberries on Bushes.—H. Sanford. We have already given our opinion of that article which makes strawberries grow upon bushes, three and four feet high. Don't believe it.

Test for Bone-Flour.—Jacob Duntun, Philadelphia, asks for an approximate test for the purity of bone-flour. Bones contain about 45 per cent of organic or combustible matter. If bone-flour is rendered dry, it should contain then about 55 per cent of incombustible matter, or ash. But this varies somewhat, according to the different kinds of bone; nevertheless it will be sufficiently accurate for an approximate test to calcine the sample, and note the amount of matter left after burning; if much greater than 55 per cent, mineral matter has probably been added; if much less, flesh or other animal matter.

Carbolic Acid.—“Yours Respectfully.” This is generally kept by druggists. We can not answer about the other.

Double-Furrow Plows.—H. Symonds, St. Louis de Gonzague, uses a double-furrow plow on light soils, which is drawn by one pair of horses, doing the work of four horses with the ordinary plow. In the Western country these plows will doubtless come into extensive use, but on rough or stony lands they are of too heavy draft for a common team.

How to Treat Manure.—“E. B.,” Carlton, Wis., has more straw than he can use. How can he work it up into manure? His cows eat all the horse manure. By bedding his stock up to the knees, and removing the litter every two weeks, and sprinkling plaster on the stables when any smell is perceived, the straw will become saturated, and should then be piled in a square heap, and allowed to heat and ferment, and occasionally turned over. Thus much straw may be used up. The horse manure is much more valuable in this way than as food for cows. If salt is given the cows in the yard, they probably will not eat the manure.

Feeding Bearded Straw.—“F. S. F.,” asks if feeding the straw of bearded wheat is injurious to cattle or horses. He has lately lost a horse, which his neighbors think died in consequence of feeding on it. We have heard of sheep and horses suffering from this cause, and can easily believe that irritation in the coats of the stomach may arise from feeding bearded straw. However, we have known horses fed on cut rye straw or fodder, and have permitted our cattle and sheep access to bearded straw, without noticing any ill effects. Had the stomach been opened, the doubt would have been solved.

Cutting Clover.—George Burr, Ohio, asks if he can cut two crops of clover hay and get a crop of seed in the same season, on good, rich land, well manured. We never knew this to be done and doubt its possibility. A rich soil will give heavier crops, but can not hasten maturity so much as to ripen the seed after two cuttings. But three cuttings for hay may be made.

SUPERIOR STANDARD WORKS.

Gardening for Profit

In the Market and Family Garden.

By Peter Henderson.

ILLUSTRATED.

NOTICES BY THE PRESS.

All the vegetables that thrive in the open air in our
latitude are described, together with the best methods
for growing them. The author also imparts practical
instructions on the subjects of drainage, and the forma-
tion and management of hot-beds. Numerous well-ex-
ecuted wood-cuts tend to make clearer the instructions of
the author.—*Philadelphia Inquirer*.

The author of this treatise is one of the best known
and most successful of those gardeners who supply New
York with green vegetables; and as he writes from long
and dear-bought experience, the positive, dogmatic tone
he often assumes is by no means becoming. The book
itself is intended to be a guide for beginners embarking
in the author's business, and gives full and explicit direc-
tions about all the operations connected with market-
gardening, lists of varieties of the most profitable vege-
tables, and much sound advice on kindred topics. Though
designed for a special class, it can not fail to be valuable
to the amateur and private gardener, and unlucky experi-
ence has taught us that the information contained in a
single chapter would have been worth to us the price of
the book.—*Daily Mercury* (New Bedford).

It is unquestionably the most thorough and the best
work of its kind we have yet had from the pen of an
American author. It is written in a clear, concise style,
and thus made more comprehensive than works which
smack more of the office than the farm or garden.
[*Daily Evening Times* (Bangor, Me.).

Mr. Henderson writes from knowledge, and is not one
of those amateur cultivators whose potatoes cost them
ten dollars a bushel, and whose eggs ought to be as
valuable as those of that other member of their family—
the goose of golden-egg-laying memory—for they are all
but priceless. No; he is a practical man, and he has the
art of imparting the knowledge he possesses in a very
agreeable manner; and he has brought together an ex-
traordinary amount of useful matter in a small volume,
which those who would "garden for profit" ought to
study carefully.—*Evening Traveller* (Boston).

There are marvels of transformation and rapid repro-
duction recorded therein, which might well shame the
dull fancy of the author of Aladdin or Kaloolah.
There is no theory about it; a man who has made him-
self rich by market-gardening plainly tells our young
men how they can get rich as easily as he did, and with-
out wandering to California or Montana for it either.
[HORACE GREELEY in the *N. Y. Tribune*.

We have devoted more space to this little work than
we usually do to tomes much more pretentious. We have
done so because of the rare merits of the book in its
fund of information, useful to the farmer and market-
gardener, and because of the dearth of that kind of
knowledge. We earnestly advise that fraternity, for
whom this work was written, to buy it and study it. If
any among them have never yet read a book, let this be
their primer, and we will vouch for the excellence and
endurance of the priming. The work is profusely illus-
trated with wood-cuts.—*Louisville Daily Journal*.

Price, post-paid, \$1.50.

ORANGE JUDD & COMPANY,
245 BROADWAY, NEW YORK.

**THE PRACTICAL
POULTRY KEEPER.**

**A COMPLETE AND STANDARD GUIDE TO THE
MANAGEMENT OF POULTRY,
FOR DOMESTIC USE, THE MARKETS, OR
EXHIBITION.**

Beautifully Illustrated.
By L. WRIGHT.

NOTICES BY THE PRESS.

This book is a valuable manual for everybody who feeds chickens or sells eggs. It suits at once the plain poulterer who must make the business pay, and the chicken fancier whose taste is for gay plumage, and strange, bright birds. The most valuable portion is the first section, extending through fifty-five pages. These were written with the intention of producing a manual so plain, minute, and practical, that any one could, by using it as a guide, with no previous experience with poultry, become at once successful in producing eggs, young chickens, and fat fowls for market. The author has not missed his aim. The middle parts of Mr. Wright's Manual are taken up with minute directions for making show fowls for fairs, a nice discussion of the good and bad points of the different breeds, and a brief sketch of such fancy stock as peafowl, pheasants, and water-fowl. Then follows a section on artificial hatching, and another, worth special attention, on large poultry yards. A study of Mr. Wright's book will convince any farmer's wife that all she needs is to give a half hour each day, of intelligent and sagacious attention to her poultry, in order to obtain from them, not tape, and knitting needles, and buttons, and nutmegs merely, but the family supplies of sugar, shoes, and cloth. *New York Tribune.*

It is the most complete and valuable work on the matters of which it treats yet published. It will be found a plain and sufficient guide to any one in any circumstances likely to occur, and is illustrated with elegant engravings of many breeds of fowls. *Farmers' Cabinet.*

This is a reprint, with numerous wood engravings, of an English book, the object of which is to convey in plain language a great deal of practical information about the breeding and management of poultry, whether for domestic use, the markets, or exhibition. The book is eminently practical, and we recommend it to farmers and others interested in breeding and selling poultry. *Philadelphia Press.*

It is a handsome volume, brought out in the best style, and enriched with nearly fifty illustrations. It is evidently the fruit of a thorough, practical experience and knowledge of fowls, and will be found a plain and sufficient guide in all the practical details of poultry management as a profitable business. *United Presbyterian.*

The subject is treated fully and ably by an experienced hand, and the volume will doubtless find a large sale among the growing class of poultry fanciers. It is embellished with numerous illustrative engravings. *New York Observer.*

The author has called to his aid all who were experienced in the subject whereof he writes, and the consequence is a volume of more than ordinary thoroughness and exhaustiveness. *Rochester Democrat.*

The book is a complete and standard guide to the management of poultry for domestic use, the market, and for exhibition. *Watchman and Reflector.*

PRICE, POST-PAID, \$2.00.

**ORANGE JUDD & CO.,

Corner Canal, Vestry, and Varick streets, New York.**

Parties seeking a safe and money-making business would do well to address us.

HOW CROPS GROW.

A Treatise on the Chemical Composition, structure, and Life of the Plant. With numerous illustrations and tables of analyses. By **Prof. Samuel W. Johnson**, of Yale College. Price \$2.00.

This book is a guide to the knowledge of agricultural plants, their composition, their structure, and modes of development and growth; of the complex organization of plants, and the uses of the parts; the germination of seeds, and the food of plants obtained both from the air and the soil. Very full and accurate tables of analyses are given, and tables of the proportions existing between different principles, oily, starchy, or nitrogenous, in the same and different plants. The book is an invaluable one to all real students of agriculture.

HOW CROPS FEED.

A Treatise on the Atmosphere, and the Soil as related to the Nutrition of Agricultural Plants. Illustrated. By **Prof. Samuel W. Johnson**, of Yale College. Price, \$2.00.

The work entitled "How Crops Grow" has been received with very great favor, not only in America, but in Europe. It has been republished in England under the joint editorship of Professors Church and Dyer, of the Royal Agricultural College, at Cirencester, and a translation into German is soon to appear, at the instigation of Professor von Liebig. The author, therefore, puts forth this volume—the companion and complement to the former—with the hope that it also will be welcomed by those who appreciate the scientific aspects of Agriculture, and are persuaded that a true Theory is the surest guide to a successful Practice.

PARSONS ON THE ROSE.

A Treatise on the Propagation, Culture, and History of the Rose. Revised and newly electrotyped. Illustrated. By **Samuel B. Parsons**. Price \$1.50.

The Rose is the only flower that can be said to have a history. It is popular now and was so centuries ago. In his work upon the Rose, Mr. Parsons has gathered up the curious legends concerning the flower, and gives us an idea of the esteem in which it was held in former times. A simple garden classification has been adopted, and the leading varieties under each class enumerated and briefly described. The chapters on multiplication, cultivation, and training, are very full, and the work is altogether the most complete of any before the public.

HARRIS ON THE PIG.

Breeding, Rearing, Management, and Improvement. With numerous illustrations. By **Joseph Harris**. Price, \$1.50.

This is the only American treatise upon the breeding, rearing, and management of swine, and is by one thoroughly familiar with the whole subject. The points of the various English and American breeds are thoroughly discussed, and the great advantage of using thorough-bred males clearly shown. The work is equally valuable to the farmer who keeps but few pigs, and to the breeder on an extensive scale.

AGRICULTURAL CHEMICAL ANALYSIS.

After E. Wolff, Fresenius, Krocker, and others. Edited by **Prof. G. C. Caldwell**, of Cornell University. Price \$2.00.

In this work Professor Caldwell has brought together the processes of analysis which apply especially to soils, fertilizers, animals and plants, and their products. He has tested the methods of the best foreign authorities, and presented them in a compact hand-book. Such a work has long been needed by all who teach agricultural chemistry, and by analytical chemists generally. Professor Caldwell modestly calls himself the editor, but his book shows that he has not contented himself with editing the works of others, but has given much of his own experience.

Either of the above books sent post-paid on receipt of price.

**ORANGE JUDD AND COMPANY,

AMERICAN CATTLE:

THEIR
HISTORY, BREEDING,
AND
MANAGEMENT.

By LEWIS F. ALLEN,

Late President New York State Agricultural Society, editor
"American Shorthorn Herd Book," author "Rural
Architecture," etc., etc.

NOTICES BY THE PRESS.

We consider this the most valuable work that has recently been issued from the American press. It embraces all branches of the important subject, and fills a vacancy in our agricultural literature for which work the author by his many years' experience and observation was eminently fitted. . . . It ought to be in the hands of every owner of cattle; and the country, as well as individuals, would soon be much richer for its teachings.

Journal of Agriculture (St. Louis).

The large experience of the author in improving the character of American herds adds to the weight of his observations, and has enabled him to produce a work which will at once make good its claims, as a standard authority on the subject. An excellent feature of this volume is its orderly, methodical arrangement; condensing a great variety of information into a comparatively small compass, and enabling the reader to find the point on which he is seeking light, without wasting his time in turning over the leaves.

N. Y. Tribune.

This will rank among the standard works of the country, and will be considered indispensable by every breeder of live-stock.

Practical Farmer (Phila.).

We think it is the most complete work upon neat-stock that we have seen; embodying as it does a vast amount of research and careful study and observation.

Wisconsin Farmer.

His history of cattle in general and of the individual breeds in particular, which occupies the first 180 pages of the volume, is written with much of the grace and charm of an Allison or a Macanlay. His description of the leading breeds is illustrated by cuts of a bull, a cow, and a fat ox, of each race. The next one hundred pages are devoted to the subject of breeding. This is followed by chapters on Beef Cattle, Working Oxen, Milch Cows, Cattle Food, Diseases, etc. The arrangement, illustrations, analytical index, etc., of the work are in the best style of modern book-making.

New England Farmer.

The work is one that has long been needed, as it takes the place of the foreign books of like nature to which our farmers have been obliged to refer, and furnishes in a compact and well-arranged volume all they desire upon this important subject.

Maine Farmer.

Whatever works the stock farmer may already have, he can not afford to do without this.

Ohio Farmer.

It is one of the best treatises within our knowledge, and contains information sound and sensible, on every page.

The People (Concord, N. H.).

The object of the work, as stated by the author in his preface, "is not only to give a historical account of the Bovine race, to suggest to our farmers and cattle breeders the best methods of their production and management, but to exalt and ennoble its pursuit to the dignity to which it is entitled, in the various departments of American agriculture." From the little examination we have been able to give it, we can not recommend it too highly.

Canada Farmer.

Considering that there are some ten millions milch cows in the United States, and nearly a thousand millions of dollars invested in cattle, the magnitude of this interest demands that the best skilled talent be devoted to the improvement of the various breeds, and the investigation of the best method of so caring for the animals, as to gain the greatest profit from them. This volume will give the farmer just the instruction which he wants.

N. Y. Independent.

Price, post-paid, \$2.50.

ORANGE JUDD AND COMPANY,
245 BROADWAY, NEW YORK.

NEW

American Farm Book.

ORIGINALLY BY

R. L. ALLEN,

Author of "Diseases of Domestic Animals," and formerly editor of the "American Agriculturist."

REVISED AND ENLARGED BY

LEWIS F. ALLEN,

Author of "American Cattle," editor of the "American Shorthorn Herd Book," etc.

NOTICES BY THE PRESS.

Everything connected with the business of farming finds a place in it; soils, manures of every kind, irrigation and draining, grasses, grain and root crops, fruits, cotton, hemp, fences, farm buildings, domestic cattle, sheep, poultry, and the like. The work has been written with great care by men qualified to discuss the subject, and it is really valuable. The chapter on soils should be read carefully by every farmer who desires to make the most of the land he cultivates. The chapter on fruits constitutes an important feature of the work; and there is nothing in it which is not well considered and useful.

Worcester Daily Spy.

Comprehensive and careful, telling, and telling specifically, just what the tillers of the soil need to know; it will prove of great advantage to all who faithfully follow its counsels in the spirit in they are given.

Congregationalist & Recorder.

It intelligently and quite fully discusses the various operations of farm life, and is invaluable to all engaged in agriculture.

Farmer's Cabinet.

For the young man of rural tastes, but without a training at the plow-handles, who asks for a general guide and instructor that shall be to agriculture what the map of the world is to geography, it is the best manual in print. For the working farmer, who, in summer noonings and by the winter fireside, would refresh his convictions and reassure his knowledge by old definitions and well-considered summaries, it is the most convenient hand-book. From its double authorship one might expect some show of patch-work, the original statement of the author of 1846, annotated and qualified by the writer of this year. But this has been wisely avoided. The book is a unit, and shows no disparity of style nor contradiction in statement. Practically it is altogether a recent and timely volume. Only so much of the original Book of the Farm, by R. F. Allen, as time could not change, has been adopted by the reviser.

New York Tribune.

It is a volume of over five hundred pages, and in its present shape comprises all that can well be condensed into an available volume of its kind.

Hartford Daily Times.

It is almost as comprehensive as a cyclopaedia. We can safely recommend it as a valuable and standard work.

Salem Gazette.

It has a very wide range of subjects, taking up nearly all matters that are most important to farmers. Comprising the combined wisdom and experience of two eminent agriculturists, it must prove of great value to the class for whom it is prepared.

New York Observer.

It is crammed full of just the information that is wanted, which it is a pleasure to recommend. We know of no better encyclopaedia of farming.

New York Independent.

In its present revised and enlarged form, it is a work that every practical farmer may consult with advantage, and none can well afford to do without.

Christian Intelligencer.

It is something in favor of this work, that it has been before the public for many years. The original work was prepared with extraordinary care, and contained a vast amount of general truth that is as applicable now as it was then; it has therefore been made the basis of the present work, which, to all intents and purposes, is new, since it is adapted to the present improved state of agricultural knowledge. Every department is prepared with conscientious care, and with a view of making the work a reliable source of agricultural information.

Chicago Republican.

PEAR CULTURE FOR PROFIT.

By P. T. QUINN,
PRACTICAL HORTICULTURIST.

ILLUSTRATED.

If one wishes to raise pears intelligently, and with the best results, he must know first the character of his soil, the best mode of preparing it, the best varieties to select under existing conditions, the best mode of planting, pruning, fertilizing, grafting, and utilizing the ground before the trees come into bearing, and finally, of gathering and packing for market.

The hope of furnishing practical information on all these points has induced the author to endeavor to draw for others the same lessons which years of practical experience have afforded him.

Contents:

Chap. I. Varieties.	Chap. IX. Varieties to Plant.
" II. Aspect.	" X. Pruning.
" III. Preparation of the Soil.	" XI. Manuring and Mulching.
" IV. Distance Apart in Planting.	" XII. Gathering Fruit.
" V. Dwarfs and Standards.	" XIII. Marketing Pears.
" VI. Planting-Time.	" XIV. Profits.
" VII. Planting.	" XV. Propagation, etc.
" VIII. Nursery Trees.	" XVI. Practical Suggestions.
	" XVII. Orchard Record.

PRICE, POST-PAID.....\$1.00

MONEY IN THE GARDEN.

A VEGETABLE MANUAL,

PREPARED WITH A VIEW TO

ECONOMY AND PROFIT,

By P. T. QUINN.

PRACTICAL HORTICULTURIST.

In this work the author aims to give, in a plain, practical style, instructions on three distinct although closely connected branches of gardening—the Kitchen-garden, market-garden, and field culture; the only and sufficient credentials for the fitness of his undertaking being a successful practical experience for a term of years.

CONTENTS.

Chapter I. Money in the Garden.	Chapter VIII. Melons.
" II. Hot-beds.	" IX. Onions.
" III. Artichoke.	" X. Parsley.
" IV. Beans.	" XI. Radishes.
" V. Cabbages.	" XII. Salsify.

Window Gardening.

By HENRY T. WILLIAMS,

EDITOR OF THE HORTICULTURIST, AND HORTICULTURAL EDITOR OF THE NEW YORK INDEPENDENT.

FINELY ILLUSTRATED.

There can be no more attractive ornaments about the house than beautiful flowers, and Mr. Williams's book tells exactly how they may be arranged, and what flowers to plant. It is seldom that a book is published on such subjects containing so much practical information.

—The World (New York).

CONTENTS:

Chap. 1.—Window Gardening—Its Pleasures—Increase in Popular Taste—Refining Influences.	Chap. 12.—Climbing Vines, Balcony Gardening.
Chap. 2.—Location and Designs for Window Gardens.	Chap. 13.—Bulbs.
Chap. 3.—General Management of Window Gardens.	Chap. 14.—Ferneries, Wardian Cases, Fern Decorations.
Chap. 4.—Special Care of Window Gardens.	Chap. 15.—The Camellia.
Chap. 5.—Insects, and how to Kill them.	Chap. 16.—The Rose.
Chap. 6.—Propagation from Seeds, Cuttings, etc.	Chap. 17.—The Fuchsia, Myrtle.
Chap. 7.—Propagating Boxes, Heating Cases, etc.	Chap. 18.—The Heliotrope.
Chap. 8.—Window Pots, Boxes, Plant Stands.	Chap. 19.—The Geranium.
Chap. 9.—Conservatories and Greenhouses.	Chap. 20.—The Oleander, Bouvardia.
Chap. 10.—Hanging Baskets.	Chap. 21.—Verbenas, Petunias, etc.
Chap. 11.—The Ivy for Decorative Purposes.	Chap. 22.—The Mignonette, Cinerarias.
	Chap. 23.—Carnations.
	Chap. 24.—Alpine Plants.
	Chap. 25.—Miscellaneous Plants.
	Chap. 26.—Parlor Decorations.

Practical Floriculture;

A GUIDE TO THE
Successful Propagation and Cultivation
OF
FLORISTS' PLANTS.

BY
PETER HENDERSON,
AUTHOR OF "GARDENING FOR PROFIT."

BERGEN CITY, N. J.

Mr. Henderson is known as the largest Commercial Florist in the country. In the present work he gives a full account of his modes of propagation and cultivation. It is adapted to the wants of the amateur, as well as the professional grower.

NOTICES BY FLORISTS AND OTHERS.

Certainly the most practical and desirable work that has ever been published on this subject. We are selling them rapidly. Some no doubt will say that it exposes the "secrets" of the Trade too freely, and that it will make Gardeners and Propagators so plenty that our occupation, like Othello's, will be gone. H. A. DREER, Seedsman and Florist, Philadelphia, Pa.

Truly "practical," and ought to be in the hands of every one engaged in the culture of Flowers.

T. C. MAXWELL & BROS., Geneva, N. Y.

It might be entitled "Floriculture Made Easy." I do not see why any one with ordinary common sense should not succeed, with this book in his hands.

L. C. LISURY, Florist, Nashville, Tenn.

No work ever before published in this country was practically valuable to those in want of direct information (upon this subject). WM. SAUNDERS, Sup't Dept of Agriculture, Washington, D. C.

Just the work for the young Florist or Amateur, as it tells him clearly there is no such thing as failure, if its simple teachings are followed.

GALVIN & GERAGHTY, Florists, Newport, R. I.

What is wonderful, the most of our Professional Florists here frankly admit their indebtedness to the work for information and suggestions. I am only an amateur in flowers, but feel gratefully indebted to its author for the pleasure its perusal has given.

GEORGE W. SANDERS, Baltimore, Md.

Without exception the most practical work on Floriculture in the English language. All the prosy fossils of ——— &c., I consign to the lumber room. I shall order a dozen from the publishers to give to my friends.

JAMES FLEMING, Nurseryman and Florist, Toronto, Canada.

Complete in all its departments, a thoroughly common-sense book, valuable to all interested in Plants and Flowers. GEO. W. CAMPBELL, Nurseryman, Delaware, O.

We have been asked hundreds of times by our customers for a work on flowers; now we get something creditable to recommend. ELLIOTT BROS. & BUNESS, Florists, Pittsburgh, Pa.

Apart from its great working value, the book is delightful reading.

MISS ANNA WARNER,

"The Island," West Point, N. Y.

Thoroughly practical, yet readable as a novel.

NEW YORK SUN.

A worthy contribution to every votary of Flora; style comprehensive, sharp and decisive, just what was to be expected from its well-known author.

F. K. PHENIX, Bloomington, Ill.

Full to overflowing with valuable information.

FRANCIS RICHARDSON, Toronto, Canada.

ILLUSTRATED.

SENT POST-PAID, PRICE, \$1.50.

ORANGE JUDD & CO.,

FARM IMPLEMENTS

AND

FARM MACHINERY,

AND THE

Principles of their Construction and Use:

WITH

SIMPLE AND PRACTICAL EXPLANATIONS

OF THE

LAWS OF MOTION AND FORCE

AS APPLIED

ON THE FARM.

With 287 Illustrations.

BY

JOHN J. THOMAS.

The basis of this admirable work was an essay published in 1850, in the Transactions of the N. Y. State Agricultural Society, which was enlarged, and in 1854 published by the Harpers. It has been, and remains, the only work in which the principles of Natural Philosophy, namely, the mechanical powers, and the powers of water, wind, and heat, are systematically discussed as applied to the operations of the farm.

The work has now been most carefully revised by the author. It is much enlarged, and a great part has been re-written, while the illustrations, before abundant, now number two hundred and eighty-seven. A large number of new implements are described, with the heavier farm machinery; and the use of steam, both in cooking and as power on the farm, is clearly discussed.

NOTICES BY THE PRESS.

The great value of this work is the application of natural philosophy to farm labor, in the use of power, and it will supply one of the best text-books in our agricultural schools. Every farmer's son should carefully study this book, and he will be saved much hard labor, accomplish more work, and have less wear and breakage in the implements he uses. The chapter on plowing is of great value to all plowmen, whether old or young, and is worth more than the cost of the book. *Chicago Tribune.*

We welcome this new and re-written edition of an old and very valuable work. The six pages on road-making are worth more than the price of the book to every highway surveyor in Vermont. Farmers need to study the mechanics of Agriculture. . . . This volume is admirably calculated to aid the farmer in determining what he needs and how to supply that want. *Burlington Free Press.*

The volume is one of great value, and should be in every Farmer's Library, for it is full of practical suggestions and useful information. *Salem Observer.*

Mr. Thomas' illustrations are largely drawn from objects with which the farmer is familiar, and any one of ordinary intelligence can readily grasp the whole, following the author step by step, from the inertia of the loaded wagon which snaps the harness traces on a sudden start, to the laws which govern the shape of the working parts of the plow, and the construction of the steam engine, or the radiation of heat causing the phenomena of dew and frost. *Cultivator and Country Gentleman.*

Those who are acquainted with Mr. Thomas' previous works need not be told that it is written in a clear, concise, practical style, and though eminently scientific, the language is so free from all unnecessary technicalities, and so pleasingly familiar, and at the same time so well illustrated and enlivened by appropriate incident, anecdotes, experiments, etc., as to excite and repay the continued attention of the reader. *Galesburg Free Press.*

The whole work is of a thoroughly practical character, and the application of the principles taught to the farmer's daily work makes its instructions of very great value. There is not an agricultural writer that could be named more respected than Mr. Thomas, or one whose judgment and freedom from personal bias in discussing new implements could be more implicitly relied upon. *Hartford Daily Times.*

No More Tough Meat.

Warren's Patent Cooker,

Represented in the following cut, is the most economical, the most useful, and the most satisfactory kitchen utensil ever invented.

It Saves Two Ounces in the Pound
over ordinary methods of baking and boiling, and so saves its cost in a few weeks.

A child can manage it, and a French cook can not surpass it.

It is within the reach of all—costing from \$5 to \$15.
Circulars on application. Address

NEWPORT LEAD WORKS,
Newport, R. I.

GEO. E. WABING, JR., of Orden Farm, says of it:

"I have used the Warren Cooker almost daily for the past two years, and would no more think of returning to the old system of boiling and roasting in the oven than I would of going back to hand mowing in the hay harvest. It is the rarest exception to have a joint of meat, any sort of poultry, or a ham, served in any but the most perfectly cooked condition. The amount of fuel and attention required are very much less than under the old system.

"We have never had a cook who did not like it from the first, and recommend it to her friends. It is as great a favorite in the farm-house kitchen as in our own."

The Evening Post says:

"We are, therefore, doing a real service to our readers in bringing Captain Warren's system to their notice. The principle on which he works is to bake his joints at a low temperature in a tightly-closed vessel, from which the escape of the volatile flavoring ingredients of the meat is impossible; where the heat will never be sufficient (as the heat of boiling water is) to harden the tissue of the meat, making it tough to chew and difficult to digest; and where the juices, that are dried away and destroyed or lost in an ordinary oven, are retained to keep the meat palatable, nutritious, and easily digestible."

The following is from the Atlantic Monthly for May, 1872:

"WARREN'S COOKER is an invention which has approved itself to all who have used it, and is, beyond doubt, the best thing of its kind. Experience enables us to give it the highest praise as an apparatus of such virtue, that it is no longer a question of cooks, but simply of time, about a dinner fit for the most exacting taste. The cook, in fact, is superseded, and the Cooker reigns. You have your meats and vegetables put into it, and you have them taken out—there human interference ceases; and the magical little agent has produced you a dinner of most perfect *doneness*, of most delicate and separate flavors, of most tempting appearance—a flattery to the eye, a joy to the palate. We can not all have a French chef, but most of us can afford Warren's Cooker, which has all the inspiration of such an artist, without his tempers and extravagance. It is convenient, economical, and most efficient."

Cayuga Lake R.R.,

STATE OF NEW YORK,
**7 Per Cent
FIRST MORTGAGE
GOLD BONDS,**

Thirty Years to Run, and Issued for
\$20,000 Per Mile,

At 90 and Accrued Interest in Currency.

This road forms the shortest and most direct route from the great anthracite and semi-bituminous coal fields of Pennsylvania into the central part of this State, and will run in connection with the New York Central Road, which it crosses at Cayuga Bridge. Traversing, as it does, the finest and most populous agricultural district, generally known as the "GARDEN OF THE STATE," its local traffic will be large, but its greatest source of revenue will be from its coal business. The road is being rapidly built. Iron is now being laid on a section covering more than one quarter of the distance, and work on the whole line being pushed with great vigor, so that it is expected to have coal trains running by the 1st of November next. From our knowledge of this enterprise, and after the most thorough investigation, we most confidently recommend the Bonds as a safe investment. We offer, for the present, the Bonds at 90 and accrued interest in currency.

FIRST MORTGAGE SINKING FUND
THIRTY YEARS

7 PER CENT GOLD BONDS

AT

90 and ACCRUED INTEREST.

The Road runs from Buffalo to the Detroit River, and is the Eastern link in the new AIR LINE FROM BUFFALO TO CHICAGO, and has been under construction for about two years past by railroad men who have seen the necessity for a STEEL-RAIL, LOW-GRADE SHORT ROUTE between the great railroad systems which diverge from Chicago, Toledo, and Buffalo.

Among the builders of the Road, by whose cash subscriptions 220 miles (out of 290) have already been graded, bridged, and made ready for the superstructure, a large part of the steel rails bought, all of the materials for the stations, and a part of the equipment purchased, are:

MILTON COURTRIGHT, JOHN F. TRACY, DAVID DOWS, WM. L. SCOTT, HENRY FARNHAM, R. A. FORSYTH, HENRY H. PORTER, JOHN M. BURKE, M. L. SYKES, JR., B. F. ALLEN, all directors, either in the Chicago and North-west, or the Chicago, Rock Island, and Pacific; GEORGE OPDYKE, of the Midland Road; JOHN B. ALLEN, SIDNEY DILLON, DANIEL DREW, J. S. CASEMENT, J. & J. STEWART, and F. H. WINSTON.

THE ROAD will be
33 MILES SHORTER
THAN ANY OTHER ROAD,
either BUILT or in contemplation between Buffalo and Chicago, and will also shorten the distance between Toledo and Buffalo 23 miles.

THE MAXIMUM GRADE on the entire line does not exceed FIFTEEN FEET to the mile, and Ninety-six per cent of the Road IS STRAIGHT.

THE ROAD WILL BE COMPLETED and in running order on or before December 31st, of this year.

The principal and interest of the Bonds are payable either in New York, London, or Frankfurt.

We confidently recommend the Bonds to all classes of investors.

CRANBERRY CULTURE.

Illustrated. By Joseph J. White. Price, \$1.25.

The author of this work has aimed to embody, in a plain and concise manner, all the useful and practical facts which study and experience have yielded to the inquiring cranberry grower of the present time. The business has increased enormously within the last ten years, and knowledge and experience have kept pace with that increase.

The endeavor has been to make this work as comprehensive as possible; and it is believed that it will prove an efficient guide to all who may have cause to consult its pages.

AMERICAN AGRICULTURIST.

NEW YORK, JULY, 1872.

We hope all the readers of the American Agriculturist are striving after improvement—aiming to be better this year than they were last, and to have their farms, their gardens, their houses, bars, fences, machines, implements, tools, and everything about them in better order and improved condition. We hope they are earnest men, active, industrious, energetic; men who control circumstances and do not let circumstances control them. To such men the present season, though one of the most discouraging in some respects we have had for many years, will teach and enforce an important lesson, and one which we shall all do well to heed. Slipshod, slovenly farming sometimes produces a paying crop, and the fact is eagerly seized by those who are opposed to an improved system of farming, and used as an argument against those of us who advocate more thorough cultivation, draining, and manuring. But this year poor farming certainly will not pay. Wages are high, and the crops on thousands of carelessly-worked farms will not more than pay the expense of harvesting and thrashing. On many good farms the profits will be small, but at any rate those of us who are aiming to make our land clean and rich, and do not over-crop, have no reason to feel discouraged when we compare our crops with those of our neighbors who adopt a makeshift system of farming. The season is a bad one, and the crops light, but poor as our prospects may be, they are far better than they would have been had we made no effort to improve our farms. The difference between good and poor farming the present year is most striking. You see a piece of wheat that will yield 30 bushels per acre, and on the other side of the fence a field that will not pay for harvesting. On the neglected farm we have stunted meadows, poor clover, yellow oats, and sickly-looking wheat, and we say it is "the drouth." Nothing flourishes but weeds. These pump up and evaporate nearly or quite as much water per acre as would make the difference between a wet season and a dry one. No wonder the crops suffer for want of rain. There is seldom a year, we repeat, when there is such a marked difference between a weedy, neglected, run-down

farm, and a clean, well-cultivated one. Let the good farmers take courage. Their labor is not in vain.

Hints about Work.

The great aim of the farmer must be to make the labor he employs, as well as his own and that of his teams, more effective. To do this requires much study. A man may work hard and accomplish little. He does not plan well, or he lacks system and order. Another lays good plans, but lacks energy sufficient to carry them out in all their details. It is a great thing to know when to work and when to let others work. In haying and harvesting, a farmer who employs a good many men should rarely undertake any steady work. He can accomplish far more by attending to the little details than by using up all his strength in pitching or binding. He should always be present, ready at any moment to lend a hand where his work can be most effective. He should be able to see at a glance that every important bolt in a machine is tight. He should know the weak spots in all his operations, and be prepared for all emergencies. He should realize that the weakest link determines the strength of the whole chain. In the innumerable details of farm work this weak link is sometimes in one thing and sometimes in another, but it is always somewhere. In one field it may be in the reaper and in another the binders; sometimes it is the pitcher, sometimes the unloader, or on the stack or mow. It is always somewhere, and the farmer should look out for it, and be prepared to strengthen that point.

Bigger Crops per Acre.—But it is not merely in the details of farming operations that we should aim to render our labor more effective—we must more than ever strive to get larger crops per acre. High wages will compel us to raise larger crops or not to raise any. It costs no more to plow and plant and cultivate an acre of potatoes that will yield 300 bushels than one that yields less than one hundred, and where there are many weeds little if any more to dig them. It may cost twelve cents a bushel to dig potatoes in the one case, and only four cents in the other. A field of wheat yielding less than ten bushels per acre, and so full of thistles that it is almost impossible to bind it, will cost more to harvest it than a clean crop yielding thirty-five bushels per acre. And the same principle holds good with all our crops.

Weeds.—We have one of the best climates in the world for killing weeds. Our hot summers and dry winds will take the sap out of even a thistle or quack-root, or a plant of purslane, if we only use the means necessary to discover its connection with the soil. The English farmer is obliged to spend in ordinary seasons far more labor to kill quack than is required here. We ought to have the cleanest farms in the world. And yet it is not too much to say that on thousands of farms in the United States the weeds run away with half the profits. We again and again urge the readers of the American Agriculturist to make an earnest effort to kill the weeds, and to make thorough work of it.

Summer-Fallows on strong, clayey land are often the best and cheapest means of killing weeds and enriching the soil at the same time. A true summer-fallow is preparing land for a crop, and then not sowing it until the next season. It cleans the land and concentrates the plant-food, which is rendered available in two years into manure for one crop. Instead of raising two wheat crops of fifteen bushels each, it enables us to raise one crop of thirty bushels, and cleans the land at the same time.

Fallows for Wheat.—A true summer-fallow is seldom seen. Our so-called summer-fallows for wheat are a modern invention, and often a very useful one. They are of two kinds. One is plowing under a clover sod in June or July, and then keeping the surface clean by the free use of the cultivator and harrow, and sowing the wheat without again plowing. The other is to plow in June, and cross-plow as soon as the sod is partially rotted. Then harrow thoroughly, and cultivate until the sods are pulled to pieces and the weeds all killed. Then plow

again and sow. In our climate, such a fallow frequently makes the land in splendid condition for wheat. Our chief objection to it is that the land is not exposed for a sufficient length of time to the ameliorating influences of the atmosphere. Whatever system is adopted, let the work be thoroughly done. Not a weed should be suffered to get a breathing spell. We should aim to induce every weed seed to germinate, and then kill the young plants. Roots of thistles, quack, etc., should be killed by exposing them to the sun. If the plants commence to grow, not a leaf should be allowed to get to the surface.

Fallows for Grass.—It is sometimes a great convenience to break up a meadow or pasture in July and re-seed it about the first of September. A still better plan is to break it up the fall previous or early in the spring, and thoroughly subdue the grass and weeds, and make the land as mellow as a garden; but we have found much benefit by breaking up in July and making the surface mellow by repeated harrowing and cultivating. Sow a peck of timothy seed per acre the last of August or first of September, and such other grasses as may be desired. Roll after seeding.

Cultivating Corn.—To hill or not to hill is still an open question, but no one doubts the advantage of thoroughly and repeatedly cultivating the corn crop. In the pressure of other work, however, many neglect to use the cultivator as freely as would be for their interest. Let the cultivators always be in readiness, so that when there is an hour to spare during haying, it may be profitably spent in the cornfield. It never pays to use a poor cultivator or to set a careless man to cultivate, as the hard spots that need it most, will be apt to be left unstirred. Our own plan is to throw dirt enough to the plants to smother small weeds in the hill.

Hay will be late this year, and the crop light. Make the best of it. See article on another page.

Harvesting Wheat.—Cut as soon as the kernels cease to have any milk in them, but not earlier. Bind carefully, and set the sheaves up firmly, so that they will not blow down. Much wheat is lost from careless shocking. If the weather is threatening, it is a good plan to cap the shocks with a couple of sheaves. If the wheat is to be thrashed as it is drawn in, it should be allowed to stand in the shock until the kernels are quite hard and dry, otherwise the wheat will be sure to heat in the granary, and in any case it will be necessary to turn it over occasionally. Wheat that is put in a stack or barn, may be drawn earlier. Thrust the hand into the middle of the sheaf under the band, and if there is no feeling of dampness, draw in at once, provided there is no dew or rain on the sheaves and the butts on the ground are dry. If the butts are damp, push over the shocks and expose the butts to the sun or wind for an hour or so ahead of the pitcher. If you are short of barn room, put two good men on the bay, and let every sheaf be properly laid in courses and pressed firmly together. A man who understands his business, can get one third more wheat into the barn than if the work is done carelessly. When wheat is once safely in the barn, it is a great mistake to thrash too early. The straw and wheat will both be better if allowed to remain for a month or two, or at any rate until the wheat is through sweating. The most economical way to draw in wheat is with three wagons, one man to pitch, one man to each wagon, to load, drive, and unload, and two on the bay. The "weak spot" is in not having the horses start promptly the moment the last sheaf in the shock is on its way to the load. It not unfrequently happens that more time is occupied in getting the wagon from one shock to another than in pitching the shock. A good pitcher, if the loaders understand their work, will send home a load every fifteen or twenty minutes, or $1\frac{1}{2}$ to 2 acres an hour of a fair crop of wheat of say 28 to 30 bushels per acre.

Barley.—A good crop of barley that ripens evenly, is not difficult to manage, but a poor, weedy crop, part green and part so ripe that it "crinkles" down, will tax a man's ingenuity and patience to get it into the barn without loss and in proper condition.

Our own plan is to cut with a self-raking reaper. Sometimes, when the straw is heavy, we bind it into sheaves. This is decidedly the better way. As a rule, however, we cure it loose, merely turning the gavels once in the forenoon and once in the afternoon, and putting into cock before night all that was cut in the forenoon. We think it is well to let that cut in the afternoon lie undisturbed as left by the machine until the next morning, when it should be turned once or twice, and drawn in, if ready, in the afternoon. It is very important to cure it thoroughly, and not to draw in while any dew is on it.

Peas.—We have tried many ways of harvesting peas. They can be pulled with a revolving wooden rake, but it is slovenly work. They can be "rolled" with a scythe into small heaps. With a short scythe they can be mown into swathes. Last year we cut a very heavy crop of peas and oats that was badly lodged, with a Johnston Reaper. It did the work to perfection. Pea straw, when well cured and not over-ripe, makes excellent fodder. Turn in an hour after cutting, and keep turning, so as to cure rapidly and avoid unnecessary risk of rain.

Animals.—In the busy, driving season of haying and harvesting the live-stock on the farm is very apt to be neglected. Be on your guard against this. Make it your personal business to see that the horses, cows, sheep, and pigs are attended to. Especially see that no animal suffers for want of water.

Sheep, especially the English breeds, do much better for a frequent change of pasture. After weaning turn the ewes into a rather poor pasture, and examine them every two or three days, to see that their bags are not caked. Draw out the milk from those that are much distended. Let the lambs be put in the best pasture you have, and also give them half a pound of oats or bran each per day for a week or so—the longer the better. If any scour, give them half a pint of milk-porridge, made with wheat flour, or in severe cases five to ten drops of landanum. Change the pasture as often as possible. If not already done, dip the lambs in a solution of carbolic soap, to kill ticks, etc. If there is the slightest symptom of footrot, dress the feet of every sheep in the flock with crude carbolic acid. Smear the noses of the sheep with tar to keep off flies.

Cows should have good pasture, plenty of water, and access to shade and shelter. If they have a little grain or bran, it will be a great help to them.

Cows, unless the pasture is unusually good, should have a feed of corn-fodder twice a day. If very succulent, let it wilt a little before feeding. A quart or two of corn-meal per day, fed in connection with the corn-fodder, will make the latter as nutritious as the best grass.

Take Care of your own Health, and of that of your family. See that the cellar is scrupulously clean. Whitewash frequently. Use chloride of lime freely about the sinks, sewers, etc. Recollect that dry earth is a capital disinfectant, and is cheap in the country. We have an idea that there are out-houses that would not be quite so offensive if half a load of earth was shoveled into them every few weeks.

Work in the Horticultural Departments.

The showers of June have started a fresh growth of weeds, and it is only by constant cultivation that they can be subdued. During a dry season, much good can be done to plants of all kinds by keeping the soil well stirred. Never allow the work of weed-killing to get behind, for when weeds are once established it is very difficult to kill them, except by extra expense in time and money.

Orchard and Nursery.

The fruit crop promises to be very large, and ample preparations must be made for harvesting and preserving it as fast as it ripens. Provide plenty of baskets, barrels, crates, etc., for transporting the fruit to market.

Thinning.—If growers would only take the time to thin out their fruit, the remainder would bring a much higher price, more than enough to pay for

the time and trouble expended, and they would besides be more certain of a crop every year. Where a tree is allowed to perfect all the fruit it sets, it becomes exhausted, and requires one or more years to regain its vigor.

Peaches.—Those ripening prematurely should be marketed, as they usually bring a good price.

Grafts.—Pinch back the most vigorous shoots, to prevent their breaking off in high winds.

Budding usually commences this month, or at least as soon as there are well-formed buds to be had, and when the bark of the stock will lift easily.

Insects.—Watch the trees for late broods of caterpillars, and if the trees are infested with borers dig them out as soon as discovered.

Black-Knot.—Cut out and burn on the first appearance, for if not destroyed it soon spreads over the entire tree, and finally throughout the orchard.

Slugs must be dusted with powdered lime.

Seeds.—Gather cherry-stones and mix with sand, to prevent drying. Many seeds of ornamental trees require to be sown as soon as ripe. Keep the rows of young seedlings clear of weeds.

Suckers should be rubbed off as soon as they make their appearance, as they injure the looks of the tree, as well as interfere with its growth.

Fruit Garden.

Grape-Vines.—Keep the new canes well tied up, to prevent them from being broken by high winds. Rub off all superfluous shoots as soon as they start. If mildew makes its appearance, use sulphur freely, applying it with a bellows made especially for the purpose. Do not allow young vines just coming into bearing to bear more than a bunch to the cane at their first fruiting.

Currants and Gooseberries.—These require but little attention, except to look out for insects, if they were properly pruned, so that plenty of light and air can reach the fruit to prevent mildew.

Strawberries.—New plants are best propagated by striking runners in small pots plunged in the soil. As soon as the plants are well rooted, they may be set out in permanent beds, and next season will produce a good crop. The old beds should be kept clear of weeds. If they were properly mulched last spring they will require but little attention.

Raspberries.—Old canes which have got through bearing must be cut out, and the new growth tied up to stakes or to a horizontal wire stretched along the row. Three or four new canes are enough to leave for fruiting next season.

Blackberries.—The new growth for bearing fruit next season must be kept in proper shape by pinching the shoots, none of which should be over five feet high, and the laterals cut back to 18 inches.

Dwarf Trees of whatever shape must be kept pinched back, and will need a good deal of attention during the growing season. Thinning is especially necessary in dwarf trees, as the best fruit is grown by allowing only a portion to perfect itself.

Preserving Fruit.—When one has an abundance of fruit, it is desirable to dry and can as much as possible, as it will keep for many years if put up in cans and jars perfectly air-tight.

Kitchen Garden.

Keep the soil constantly occupied with some crop, and give the land plenty of manure, to prevent exhaustion. The land cleared of spinach, early peas, or potatoes, may be used for growing turnips or late cabbages. Weeds should be kept under, taking care not to allow any to run to seed, and in a few years the ground may be cleared of most weeds.

Beans.—As soon as the vines have reached the top of the poles, they should be pinched, to induce their early bearing. Bush sorts may be planted in any cleared spot in the garden.

Beets may still be planted for late crops.

Cabbages and Cauliflowers.—Transplant the late sorts from the seed-bed, using only the most vigorous plants. They ought to be set out in well-man-

ured ground, and hoed often. Sprinkle the plants with air-slaked lime when the dew is on; it will tend to prevent injury by the cabbage-worm.

Carrots.—Thin out as soon as they are well up, and keep down all weeds until the tops are so large as to prevent working between the rows.

Corn.—Sow early sorts this month, as they will usually give one picking at least before the frost.

Cucumbers.—Sow the Long Green variety for pickles, using plenty of manure.

Egg-Plants need warm weather as well as plenty of manure, and an occasional watering of liquid manure, to enable them to bear profitably. Place hay or straw under the fruit, to keep it from touching the ground.

Endive may be sown for late salad, if it is used.

Herbs are best when grown as a second crop. They should be sown in beds or boxes, and afterwards transplanted; they do best when set out late.

Leeks, where the plants are too thick to remain, may be transplanted into a rich soil. Six inches is near enough to have them grow well.

Melons.—Keep the soil stirred until the vines cover the ground, and pinch back where they grow too vigorously.

Onions.—Keep the ground between the rows stirred often, and a dressing of salt and ashes will be of benefit; if too thick, thin out.

Potatoes.—The ground occupied by early potatoes may be planted with late cabbages or turnips. The green tops should be turned under with the plow, when they will decay rapidly.

Rhubarb.—As soon as fruit becomes plenty, allow the rhubarb to rest, cutting off the flower-stalks as fast as they appear, as they exhaust the plants.

Sweet-Potatoes, whether in hills or in ridges, must be hoed often, and the vines not allowed to root.

Squashes.—Hoe often until the vines cover the ground, and after this pull out the weeds which appear above the vines.

Tomatoes do best if trained upon trellises, as in this way they ripen more evenly. If trellises can not be made, brush, or some hay laid around each plant, will keep the fruit from contact with the ground. Pick off the green caterpillar, which destroys the foliage and young fruit.

Weeds.—The constant use of the hoe and rake is necessary to keep the weeds under, and if they are not allowed to grow higher than an inch, weeds can easily be destroyed with a sharp rake.

Flower-Garden and Lawn.

Lawns will need to be mowed once a week, in order to keep them in good condition. A large lawn may be cut quite easily with a lawn-mower; small hand-mowers are now very common and quite cheap. Any perennial weeds that make their appearance should be pulled out; the annual ones are easily destroyed by constant mowing.

Edgings around paths or flower-beds must be cut with the edging-knife, and the weeds and grass pulled out of the paths.

Stakes.—Many plants require support in the shape of stakes and trellises; these should be inconspicuous in color, and concealed as much as possible.

Climbers.—The new growth of Wistarias and other climbing plants ought to be trained, so that it may not be broken by high winds.

Dahlia.—Tie up to stakes as soon as the plants are tall enough to require it. Water if needed.

Roses.—A very neat and pretty way of training roses is to peg them upon the ground, so that the branches cover the entire surface. Pegs 6 or 8 inches long, with a hook at the end, are easily made, or willow-twigs, bent double, may be used in fastening down the shoots.

Bulbs.—As fast as the tops dry up and turn yellow, dig them up and place in a dry place to ripen off, and when thoroughly dry, store in a cool place, where rats and mice will not injure them.

Seeds.—Gather as fast as they ripen, and after the seed-pods are dry, clean the seed, and place them

in papers labeled with the name and date. Seeds of perennials should be sown as soon as ripe.

Greenhouse and Window Plants.

Shading and watering are the principal things to attend to in the greenhouse. Shade must be supplied to camellias by means of cloth screens, or whitewashing the glass. Give plenty of water to hanging baskets. Look after insects, and see that none are allowed to get a foothold in the houses. To destroy red spider, keep the air constantly moist. Make cuttings of all plants needed for winter blooming, in order that they may become well established before winter. This is a good time to look after a supply of potting earth, and for turning over the pile already prepared.

Commercial Matters—Market Prices.

Gold advanced to 114 1/2, closing June 13th at 113 1/2. Movements in Breadstuffs have been on a more extensive scale, particularly in Corn and Oats. The receipts of Corn have been very heavy, and receivers have been free sellers, reducing prices materially, and leading to a brisk business, in the main for export, though in part for home-trade purposes, and on speculative account. The arrivals of Corn on Wednesday, June 12th, were extraordinarily large, having exceeded 617,000 bushels, much of the amount "out of condition," rendering contract deliveries difficult and unusually unsatisfactory to operators. The dealings in Wheat have been comparatively moderate, shippers having given most of their attention to Corn, though prices were quoted lower. Rye and Barley have been in request, but much easier in price. Oats have been in fair demand, but quoted cheaper. Provisions have been less active; hog products have held their own well as to value. Beef nominally unchanged. Butter and Cheese closed dull and heavy, with buyers reluctant to operate freely at even the reduced figures, particularly for shipment. Eggs closed about steady, but very quiet. Hops, lower and less urgently sought after. Hops held firmly, but inactive. Few desirable lots were available at the close. Wool ruled quite dull, in the main, but toward the close attracted more attention, chiefly to meet the more urgent requirements of manufacturers, on the basis of previous quotations. Domestic has been in very light supply, and holders have been firm in their views. New clip arrives slowly from all sections. The offerings of foreign, particularly of other than prime to choice grades, have been comparatively liberal at the ruling figures, holders meeting the demand with promptness, the principal dealings having been in Cape. The final adjustment of the tariff has tended to stimulate purchases. Tobacco has been in good demand, largely for export, at steadier prices. Seeds have been dull and irregular in value. A Butter and Cheese Exchange is in contemplation, in the interest of receivers and dealers. The following condensed, comprehensive tables, carefully prepared specially for the American Agriculturist, show at a glance the transactions for the month ending June 14, 1872, and for the corresponding month last year.

Table with 5 main sections: 1. Transactions at the New York Markets (Receipts and Sales for Flour, Wheat, Corn, Rye, Barley, Oats); 2. Comparison with same period at this time last year; 3. Exports from New York, Jan. 1 to June 12, 1872; 4. Stock of grain in store at New York; 5. Receipts at head of tide-water at Albany each season to June 5th.

CURRENT WHOLESALE PRICES.

Table of current wholesale prices for various commodities including Gold, Flour, Wheat, Corn, Rye, Barley, Hops, and various oils and fats, with prices listed for May 14 and June 14.

New York Live-Stock Markets.

Table showing New York Live-Stock Markets data, including weekly ending prices for Beef Cows, Calves, Sheep, and Swine, with totals for the month and previous weeks.

Beef Cattle.—Cattle have been coming forward unusually free this spring, good markets encouraging shipments. Texas is giving us many cattle, no less than 3,160 arriving from that State during the past month, some of them made fat by feeding in Missouri. The demand has been very good, and prices gradually worked up until last Monday, when 5,310 were on sale and a dull trade was the result, some stock holding over. Hot weather was unfavorable. The railroads have been taxed to their full capacity, to bring stock forward, and there is talk of advancing the freights. Late rains make tall grass, and there is quite a demand for stock cattle, largely selected from the wholesale markets at Buffalo and Albany. Just at the close the feeling is heavy, but probably this dullness will be of short duration. Prices are not very much lower, but sales are slow.

Below we give the range of prices, average price, and figures at which large lots were sold:

Table showing price ranges and average prices for Beef Cattle, Milk Cows, and Calves, including details on fatness and market conditions.

ing season was over. Prices have gradually settled, and the market closes decidedly dull. Of course the prices of sheep are all given for shorn lots. Lambs have a wide range, some poor lots of 37 lbs. selling at 8½¢, common to fair Ohio, Virginia, and Kentucky at 10¢. @ 11¢; fair to prime Jerseys and State at 11¢. @ 11½¢, a few extras of 60 lbs. reaching 30¢. Poor to medium sheep are quoted at 5½¢. @ 6¢. ♂ D.; fair to good at 6½¢. @ 7¢., and choice 7½¢. **Swine.**—Hogs still come forward too fast for any improvement in prices. They have continued quite uniform during the entire month. The Western country is said to be full of hogs, made by a bountiful crop of corn last season. Live are worth 4¼¢. @ 4½¢; city-dressed Western, 5½¢. @ 5¢.

SPECIAL PREMIUMS STILL OFFERED.

MULTUM IN PARVO KNIFE, OPEN.—WEIGHT 2 OZ.

The General Premium List closed July 1st. The following Special Premiums are continued until further notice:

The Multum in Parvo Knife for 8 subscribers to *American Agriculturist* at \$1.50 a year; or 4 subscribers to *Hearth and Home* at \$3.00 a year; or 5 subscribers for one year to both the above papers at \$4.00 a year. (Knife sent post-paid.)

The Beckwith \$10 Sewing Machine for 12 subscribers to *American Agriculturist* at \$1.50 a year; or 6 subscribers to *Hearth and Home* at \$3.00 a year; or for 10 subscribers to both papers at \$4.00 a year.

N. B.—Two half-year subscribers in all the above cases may count for one full year in a Premium Club List.

MULTUM IN PARVO KNIFE, CLOSED.—3 inches long.

Pump for a Deep Well.—“A. S.,” Mercer Co., Pa., has a well 40 feet deep, and wishes to know the best pump for it. The American Submerged Pump is calculated for wells of this depth; the price is \$15, without the pipe. The Bridgeport Manufacturing Co., 55 Chambers st., New York, are the manufacturers.

containing a great variety of Items, including many good Hints and Suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Remitting Money:—Checks on New York City Banks or Bankers are best for large sums; make payable to the order of **Orange Judd & Co.**.... **Post-Office Money Orders**, for \$50 or less, are cheap and safe also. When these are not obtainable, register letters, affixing stamps for postage and registry; put in the money and seal the letter in the presence of the postmaster, and take his receipt for it. Money sent in the above three methods is safe against loss.

Postage: On *American Agriculturist*, 3 cents a quarter, in advance; on *Hearth and Home*, 5 cents per quarter. Double rates if not paid in advance at the office where the papers are received. For subscribers in British America, the postage must be sent to this office for prepayment here.

Bound Copies of Volume Thirty are now ready. Price, \$2, at our office; or \$2.50 each, if sent by mail. Any of the last fifteen volumes (16 to 30) will also be forwarded at same price. Sets of numbers sent to our office will be neatly bound in our regular style, at 75 cents per vol. (50 cents extra, if returned by mail.) Missing numbers supplied at 12 cents each.

Clubs can at any time be increased by remitting for each addition the price paid by the original members; or a small club may be increased to a larger one; thus: a person having sent 10 subscribers and \$12, may afterward send 10 more subscribers with only \$8; making a club of 20 at \$1 each; and so of the other club rates.

Potato Queries.—When a branch of a rose-bush that has usually borne white roses bears red ones, we call that a sport. When a shrub that usually bears green leaves pushes out a twig upon which the leaves are all veined with yellow, we call that a sport. When a potato that usually bears long and white tubers produces a short and red one, or one that differs in any marked manner from the ordinary character of the variety, we call that a sport of the potato. There is no proof that the impregnation of the blossoms of a potato plant with the pollen of another variety will effect any change in the tubers of that plant.

Northern Pacific R.R.—A Good Record.—“Investigating committees” have been the order of the day during a year past, and in most cases their necessity has been proved. A notable exception has occurred in the case of the Congressional Committee directed to examine thoroughly the affairs of the Northern Pacific Railroad Company. The report completely vindicates the officers and agents of the Company, and is in every sense very satisfactory. The work is thoroughly done, in the best manner, and no one is found dipping his own hand into the treasury, directly or indirectly, by means of contracts or supplies furnished.

Veterinary Education.—“Orphan Boy,” Waverley Heights, Pa.—Write to New York College of Veterinary Surgeons, Lexington ave., near 33d st., New York, for circular.

Lane's Beet.—“Subscriber,” Chattanooga, Tenn.—This will grow where other root crops will succeed. There is no more seed to be had, and you can not try it this year.

Asparagus Bed.—“A. A. B.,” Ontario.—Spring is the most convenient season for making an Asparagus bed. You will find directions at the proper season in our hints under Kitchen Garden. When well set, the bed will, if properly cared for, last many years.

Large Immigration.—Ten thousand immigrants landed in New York on Monday, May 20th. This is the largest number that has ever arrived in any one day.

Ginseng.—“A. E. T.,” Havre de Grace, Md.—Ginseng is the root of *Aralia quinquefolia* (*Panax quinquefolium* of the older botanists), a plant which grows in rich, moist woods, especially in mountainous districts. It is comparatively rare in the Eastern States, but is still abundant in some parts of the South and West. The root is from three to nine inches long, and as big round as one's finger. It has a peculiar aromatic and a some-

what sweetish and mucilaginous taste. Medicinally, it is of no value save as a mild aromatic. The Chinese Ginseng is the root of *Panax Schinseng*, and is highly valued by the Chinese, it being sometimes sold for its weight in gold. The word ginseng in Chinese signifies the “Wonder of the World,” and we do not wonder at it, as it has power, according to the Chinese physicians, “to make old people young,” and to “render a man immortal, if anything on earth can do so.” As our Ginseng is not essentially different from the Chinese, and probably quite as efficacious, it is exported in considerable quantities to immortalize the Celestials. We have not known of any attempts to cultivate it for commercial purposes.

Fairs in August.—Our regular list of fairs is published in September, as the majority occur in that month and later. We have received notice of two which take place in August, which are: Boone Co., Mo., at Columbia, Aug. 27-31, and Mahaska Co., Iowa, at Oakaloosa, Aug. 27-30.

Double-furrow Plow.—The double-furrow plow is no new invention, as is often supposed. It was in use in England 200 years ago, seventy years ago the first patent was taken out for improvements on the old form, sixty years ago several patterns were made by different makers, and now they are said to be used by ten thousand farmers in Great Britain.

We Give it up.—We have again and again requested that persons making inquiries to be answered by mail, should inclose only the return postage. Heretofore we have, when 25c., 50c., \$1, etc., have been sent “for information,” returned the amount minus the three cents for postage. We find that this costs altogether too much time and trouble. If people will disregard our repeated request, we give notice that while we have no information to sell at any price, we can not bother with making return change. If they put in more than a three-cent stamp, it is so much money thrown away. We wish it to be very distinctly understood that we do not accept the excess over the amount required for return postage as a compensation, and that we incur no obligation whatever in retaining what we have frequently requested should not be sent.

SUNDRY HUMBUGS.—An unusually light job we have this month, for though we have the basket full of letters and circulars, those referring to swindles not previously exposed in these columns belong largely to one class—the “Queer” operators.... At Bridgeport, Ct., in the “Land of Steady Habits,” they have a Mammoth Lottery, got up with no little ingenuity in the use of printer's ink, and pretty well calculated to draw in the dollars from the Micawber class, which is large everywhere. It is claimed that every payer gets his money's worth, to start with, and, in addition, a chance in a Grand Distribution of more than half a million dollars' worth of all sorts of things, such as houses, lots, engravings, carriages, pianos, shawls (\$850 to \$1,000 each), oil paintings (\$500 each), point-lace collars (\$40 each), a \$125 saddle, \$20 family Bibles, etc., etc., etc., etc.—a grand *melange* of gifts surely—when all the tickets are sold, amounting to “several hundred thousands!”—we don't know how many hundreds of thousands! Lots of indorsements of the manager are printed from Mayors, Congressmen, etc., down (or up) to “respectable citizens.” Probably “several hundred thousand” people will rush in with their \$1, \$2, and \$3 each. Sensible people will buy what they want at regular prices. If we granted all that the manager claims for this scheme, we should still advise all people to let it alone severely. Lotteries, and all schemes and games of chance, are bad in their influence. They cultivate a proclivity to look for chance fortune, rather than to honest effort and industry. Every person who invests a dollar in any chance scheme—be it lottery, gift enterprise, or otherwise—is positively and permanently injured thereby.... Thomas D. Thorp, the note swindler described last month, offers at 737 Broadway cigar Revenue Stamps at one fifth their value, on the pretense that his cousin is in the Government printing-office at Washington, and supplies him with extra sheets surreptitiously printed. He, of course, pockets all the receipts, and is not come-at-able when sought for. We have received a lot more of his swindling \$965 “notes” scattered over the country, as described last month.... A chap at Charlotte, Mich., calling himself F. A. Ellis & Co., successor to J. V. Johnson, is, or recently was, offering disgusting books, pictures, implements, etc. The good people of Charlotte, if there are any there, should clear out this disgraceful nuisance; parents should guard their sons from getting his numerous circulars, and only those who believe there is “honor among thieves” will forward money for his “goods,” if they are themselves depraved enough to want them for use or sale.... A Missouri subscriber writes that he sent 25c. for some fine watermelon seeds advertised in

New York City, and instead of the seeds received some tickets and circulars of L. T. Pardee & Co., the watch and jewelry operator of Binghamton, N. Y., who pretends to give you \$25 watches, etc., for \$2.24, which he don't. . . . We would gladly believe that every postmaster in all the country was too much of a man (or woman, as the case may be) to give any response to the solicitations of the Pittsburg man who offers such glowing financial returns to each one who will aid him in "gosing" the people with a new medicine. Every person who in any way, directly or indirectly, aids in the distribution of any patent, or specific, or secret remedies, is an enemy to his race. . . . All "Surgical and Medical Institutes" at New York, Chicago, Milwaukee, Philadelphia, and elsewhere, which advertise medicines, books, prescriptions, recipes, marriage guides, cures for private diseases, etc., are humbugs, and should be let alone. . . . PUT NO CONFIDENCE in any one of the hundreds of thousands of certificates of cures effected by this, that, or the other medicine. A large part of them are manufactured; another part come from persons who imagined themselves sick, and having recovered while taking some medicine, and in spite of it, are ready to praise it as their preserver or curer; and perhaps in one case in a hundred thousand some simple remedy happened to meet an individual want. But, even were all genuine and true, it would be no guarantee at all that the same medicine would not be even harmful to you. . . . The million people, more or less, who are looking for fortune from some deceased relative in England, and spending their money in advertisements and agencies, would be far more likely of success in life if they eschewed these hopes, and followed their honest callings. We have heard a great deal about expected fortunes from wealthy deceased relatives abroad, but can not recall a single instance where anything substantial was ever received. . . . The "Spanish Policy" at 22 West 4th st., alias 16 South 5th ave., New York, conducted by a chap under the name of A. B. Norton, alias Isaac Winchell, alias N. A. Persouin, alias James Allen, is a pure, numitigated swindle. . . . The "Queer," or pretended sellers of counterfeit money, still work vigorously. The safety of this swindle, because those who hold correspondence with operators can not appear against them without self-ermination, makes it more attractive than any other. The operators pocket all the money sent them, and have no expenses except for circulars. When they can get a line from any person, even of inquiry, they pursue a system of terrorism and threats of exposure, often getting hush-money in this way. We have before us an amusing assortment of such letters from one of these swindlers, who calls himself E. C. Haines, 688 Broadway, to a subscriber at Whitehall, Mich., and others. Of course, no one needs to heed the raving, scolding, or coaxing of such villains. As the N. Y. P. O. delivers no letters to swindlers, and is pretty sharp in discovering them, one operator (Elias) sends out slips under many names, such as John H. Kinkhead, David Curran, Henry Oatman, Lennel Haines, Joseph Hoffman, E. W. Tarrant, Herman Andrews, James Moore, Ezra Whitcomb, Martin Bowker, Rollin Burdick, Darius Driscoll, etc., all at No. 22 West 4th st., New York; alias M. Keating, No. 10 South 5th ave., alias James Moore, 305 W. 20th st. All the above fifteen different names are appended to the same circular offering counterfeit money, and each claiming that he had sole charge of engraving the plates on which the Government greenbacks were printed!

Lock for Bob-Sleds.—"A Subscriber" wants a description of the best lock for bob-sleds.—This will be timely a month or two hence, and possibly before then some of our readers will give us sketches or drawings of some new kinds which we can publish. There is a great variety of them in use.

To Keep Cistern-Water Pure.—"A Reader" asks how to keep cistern water from becoming stagnant (or impure) during the dry summer weather. We never found any difficulty in keeping water sweet during the summer months in a cistern to which a filter was attached similar to that described in March, page 96. If there is no filter, put into the cistern a bushel of fresh pounded charcoal, inclosed in a clean bag.

Farms of a Thousand Acres in New York.—"G. E. M." wishes to know if there are twenty-five farms in the State of New York, each possessing a thousand acres of tillable land. According to the census of 1870 (advanced sheets of which have been published) there are 36 farms of 1,000 acres and over in that State. If this does not fully answer the question, it is all the information we have on the subject.

Haw or Hooks.—"W. L. H.," Elizabethtown, Ky., has some valuable cows troubled with haw or hooks, which is an inflammation of the membrane which sweeps and clears the eyeball. Some of his valuable

cows have died.—It is doubtful whether this is the sole cause of the trouble; very probably there is general disturbance of the health, and the help of a good veterinary surgeon should be sought. Generally bathing with cold water, in which a dram of sulphate of zinc to a pint is dissolved, with a dose of cooling medicine, as a pound of Glanber's-salt, is sufficient to reduce the inflammation. The membrane, though much swollen, should not be cut off, as is sometimes done.

Poke-Root.—"C. L. Hill, Glasgow, Fla. (?), asks if garget or pokeweed, mentioned in the *Agriculturist* of July, 1871, is what is generally called poke-root.—Yes. It has a long, thick, fleshy root, and is a tall, branching plant, bearing clusters of dark purple berries.

Castings.—"X. Y. Z.," Elizabethtown, Ky., wants to know where he can get some small castings made.—At Louisville, Ky., which is in his neighborhood.

How to Warm Cream for Churning.—"Reader," Theresa, N. Y., wants to know how to warm his cream for churning, and what temperature is best for it, and what temperature is best for setting milk for cream to rise?—As good a way as any, where there are no other conveniences, is to have a shelf near the stove, and a few hours before churning set the cream-jar on it, and stir repeatedly until it is of the same temperature as the room, or about 62 degrees. Milk should be kept at about 55 degrees when set for cream, and the temperature should be uniform.

Petrified Squash.—"J. T. Ewbank sends us from Salado, Texas, a fossil known in that country as a "petrified squash." It, however, belongs to the animal kingdom, and is a very beautiful fossil Echinus, living forms of which are found upon our coasts, and are known as Sea-urchins and Sea-hedgehogs.

Walnuts.—"E. N. N.," Mount Joy, Pa.—Plant the walnuts in the fall where they are to grow, or keep the nuts in sand until spring.

Changing the Color of Hair.—"I. C.," Aiken, S. C., wants a method of changing the color of white spots of hair which grow over healed sores on his horse. We know of none, although we have heard of several, one of which is to rub hot, melted lard on the spots, but we have no confidence in it. If there are any effectual methods, we should be glad to hear of them.

Why Butter won't Come.—"J. M. B.," Quasqueton, Iowa, says his experience is, that if cows go too long without salt, the churning takes more than twice as long, and when this happens with him, the boys are scolded and sent for the salt-box, and next time the butter comes in reasonable time.

Clark's Compost.—"F. Hunt, Manchester, N. H., writes about a notice of Clark's Compost in the *Agriculturist* for May, and states that he believes Mr. Clark to be an honest man. We readily believe in the honesty of this opinion, as a man may sell a poor compost at a high price and yet honestly believe he is doing no wrong. But having paid Mr. Clark his price for the secret, and also having strictly kept the engagement made in purchasing it, we do not see there is anything to prevent us from considering it not worth the money asked for it, or from advising others to lay out five dollars in a more profitable manner.

Hay Conveyer.—"A Subscriber," Seneca Co., Ohio, asks if there is any better hay-conveyer for unloading in the barn than that figured in the *Agriculturist* of 1865, page 212. This was the Halstead hay-fork attachment. Since then the Human Conveyer has been introduced, which seems to us to be an improvement in some respects.

Sandford Corn.—"Northern New York" asks if we would recommend the Sandford Corn for that locality. Generally there is no good done by going from home for seed corn. It is the easiest crop to improve by selecting seed and good cultivation. We don't like the Sandford corn much.

American Fruit-Preserving Powder.—In answer to inquiries regarding this article advertised in *American Agriculturist*, we will say that we have advertised it each year for the past four years; and, before inserting the first advertisement, we investigated the matter, and satisfied ourselves that it was harmless and efficient. Since that time, and during the past three years, some of our associates have used the Preserving Powder, with satisfactory results, and esteem it a very valuable and praiseworthy article. As to keeping fruit in wooden kegs and barrels, that is a new feature, and

claimed for the first time in our last issue. We have not so tested it ourselves, but have every assurance of its truthfulness. As to the healthfulness of the powder—it is as healthful as common table-salt.

Refuse Hops.—"H. W.," Lafayette, Ind. These are considered by our market-gardeners as equal in value, load for load, to the best stable manure for all gardening purposes. We do not know that they have been used for potatoes.

Peas and Oats.—"F. S.," Akron, Pa., asks some questions about peas and oats as a mixed crop, to which we reply that they may be sown as late as June or even July, and make a good crop of fodder which may be cut and cured like hay. Two and a half bushels of oats and one and a half of peas of the earliest kinds, if sown late, are sufficient seed for an acre. If ripened, the grain may be threshed together and either chopped for feed, for which it is excellent, or separated, if desired, in the fanning mill. This mixed crop is nothing new, having been grown in Canada and in Scotland for years.

Personal.—People do make some odd queries; the following will serve as a specimen: "Will you please inform your readers what sound Col. Waring gives the *a* in his name, whether that of a *in war*, or a *in ware*; also, whence the title 'Colonel'?"—Just for the fun of the thing we will answer that the Colonel's name is pronounced as if it were spelled Waring, and the "whence" of the title Colonel is four years' hard service in the army. He is married and has been vaccinated.

American Horticulturists for Europe.—Our contributor, Peter Henderson, Esq., sailed for Europe on the 22d ult. He proposes to pass a few months in Great Britain and on the Continent, where he hopes to obtain a respite from business and the correspondence with which he is overwhelmed. On the same date there sailed by another steamship line, B. K. Bliss, P. T. Quinn, and Josiah Hoopes, all well known in the horticultural world. These gentlemen go upon a tour of observation and pleasure, and will no doubt bring back some interesting experiences.

Cabbage-Flies.—A correspondent in Brampton, Ontario, writes: "I saw to-day a (to me) novel method of getting ahead of, or rather getting over, the Cabbage-fly. The seed-bed was made on a scaffold raised on posts about five feet from the ground. The plants were about one and a half or two inches high (this is not New York latitude), and were absolutely untouched by the fly, while others, sown at the same time on the ground, within a short distance, and otherwise treated exactly the same, were nearly destroyed. I do not know how to account for it, unless the jumps of the insect are limited to a certain height, and these plants were beyond its reach."—This is not a new device, and our correspondent has suggested the cause of its success.

Camellias.—"E. C. B.," Beaufort, S. C.—Camellias can be grown from seed. There is no probability that the produce will be like the varieties from which the seed was taken, any more than with roses or other plants far removed from their natural state.

The Drive-Well.—"Farmer," Lexington, Tenn., asks if this is a humbug. He wants a well, but is afraid to try one of these until he knows something about it. It is no humbug, but a very useful thing under some circumstances. Where the water is within twenty feet of the surface, it is a cheap and convenient well. We have used one and know. It is patented.

Insects.—"E. P. S.," Clinton, N. Y. To answer your queries in full would require a treatise. Briefly, then. Air-slaked lime is the best thing we have tried for the green cabbage-worm. . . . The insect which bores into the stem of the cucumber is not the one that feeds on the leaves. It is the grub of a moth. We know of no remedy after the grub is in the vine. The parent insect may probably be kept away by sawdust, wet in carbolic soap-suds, but we have not had occasion to try it. . . . Frequent washing, particularly of the under-side of the leaves, will drive off red spiders. . . . We never tried introducing a remedy into the body of a tree. Have no belief in its utility. Borers in apple-trees can be probed out. Open a hole by means of a knife or gouge, and run in a wire probe.

Machine for making Nets.—John Gordon, Oregon, wants a machine for making "seines" and other nets.—There are machines of this kind, but we do not know who makes them. Makers should advertise, as doubtless there would be a demand for them.

Other Basket Items on page 273.

Celery.—"A. G. J.," West Cleveland, O. We know of no special manure for this crop. The market gardeners near New York grow celery as a second crop. The ground is heavily manured for early cabbages, and when they are off, the celery goes in without additional manure. Sometimes ashes, floor of bone, or other stimulating manure is strewed along the rows, in order to give the plants a good start. A dressing of salt may be useful in keeping the ground moist.

Red Spiders.—"Subscriber" has a bed of stocks which are badly injured by the red spider. He says "dampness has no effect upon them, as it has rained nearly every day since the plants were placed there."—The spiders naturally work upon the under side of the leaves, where they are sheltered from the rain. Use a syringe, by means of which the under surface of the leaves can be wetted with a solution of whale-oil soap or common soft-soap.

Seeds of Forest Trees.—T. F. Healy. With the exception of White and Red Maple and Elm, which should be sown in June, seeds should be planted in the fall, or properly kept in sand during the winter, and then planted in early spring. We can not tell you the best varieties unless we know whether you wish the trees for shelter, fire-wood, lumber, or ornament.

A Cook-Book.—"A Subscriber" writes: "Will you recommend through the columns of your paper a good, sensible, reliable cook-book?" The "easiest" cook-book we know of is "Common-Sense in the Household," by Marion Harland. It can be sent from this office for the price, \$1.75.

Those Patent Gates.—H. C. Blake, Louisa Co., Iowa, writes on behalf of several of his neighbors, stating that two men are going about claiming five dollars from each farmer who has a gate similar to the one figured in the *Agriculturist* as early as Nov., 1834, for the right to use this gate, which they say is patented. It may be patented; we have met men in the country selling rights, but the patent is invalid, and the claim should be resisted, for the gate has been public property for fifteen years at least. It is worth while for the farmers to consider whether some restriction should not be put on the issue of patents for inventions, so called, which are utterly devoid of novelty, and make a move in the matter for their own protection.

Bees, their Management and Culture.—We have received the advance sheets of a little work, by Mrs. Tupper and Savery, of Des Moines, Iowa, entitled, "Bees, their Management and Culture." It is devoted mainly to the ways of Italian bees, and to explaining the more difficult methods—to ordinary bee-keepers, at least—of managing artificial swarming, and increasing the production of honey. Mrs. Tupper is a bee-keeper, and what she knows of them has been learned by handling and observing them.

The Mahaleb Cherry.—J. Beachy, Preston Co., West Va.—The Mahaleb Cherry is a native of the mountain regions of Southern Europe. It differs from any of those cultivated for their fruit in having the flowers in racemes or strigs, after the manner of our common Wild Cherry. When young, the tree grows freely. You can ascertain whether the stocks you have purchased are the Mahaleb or Mazzard by the odor of the bark, which in the Mahaleb is very strong and peculiar.

Rape or Coleseed.—"S. T. H.," Leroy, N. Y.—Rape will flourish on a great variety of soils, provided they are clean, rich, and mellow. It is useless to sow it on cloddy, poorly-prepared land. Thorough cultivation previous to sowing the seed is absolutely essential to a good crop. Sow from three to five pounds of seed per acre, broadcast, and harrow in with a light harrow. Two bushels of plaster per acre will be beneficial. We presume the seed can be obtained at the Rochester or Buffalo seed-stores. We got our seed last year from R. H. Allen & Co., New York.

Thomas's Smoothing Harrow.—"H. V.," Mendocino Co., Cal., asks if Thomas's Smoothing Harrow is useful to harrow in grain. Yes, excellent.

Grapes in Indiana.—"W. A.," Logansport.—What you describe is apparently the grape-rot. We do not know of any cure for it. The best course is to get such varieties as do not rot in your soil and locality. You do not say what your varieties are.

Chester White Pigs.—"A Subscriber," Watertown, Ct., asks who is the most enterprising and active breeder of Chester White pigs. If he wants the

most trustworthy one amongst these breeders, possibly he may not be the most enterprising and active. Sometimes most enterprising and active men come to grief and bring their customers there too. The names of breeders who we have reason to believe are honest and trustworthy, will be found in the advertising columns. No other names are admitted.

Treating Hen-Manure with Sulphuric Acid.—"A Subscriber" asks whether hen-manure is benefited by treating with sulphuric acid. Not at all. It is as soluble as guano, and may be used in exactly the same manner.

Pondrette or Superphosphate.—"T. J. S.," Watertown, Ct., asks which is most valuable to apply with the seed, double-refined pondrette, or superphosphate. We believe from our experience that 100 pounds of superphosphate is equal to 1,000 pounds of pondrette as sold in the market, but we would rather use Peruvian guano at \$30 a ton, in preference to any other fertilizer, to be drilled with the seed.

Tanning Buckskins.—Seth Fuller, Bond Co., Ill., sends a method of tanning buckskins, viz.: take a skin, either green or well soaked, and flesh it with a dull knife; spread the skin on a smooth log and grain it by scraping with a sharp instrument; rub nearly dry over the oval end of a board held upright. Take the brains of the deer or a calf, dry by the fire gently, put them into a cloth and boil until soft, cool off the liquid until blood-warm, with water sufficient to soak the skin in, and soak until it is quite soft and pliable, and then wring out as dry as possible; wash in strong soap-suds and rub dry, and smoke well with wood smoke. Instead of brains, oil or lard may be used, and the skin soaked therein six hours. This is called "Indian tau."

Growing Grass.—"A Would-be Scientific Farmer" wants a few facts relative to the growing of heavy crops of grass. He thinks it equally possible to make six to eight tons of hay from one acre here as in England or Scotland. If he thinks so, why does he not try to do it? We have seen some good hay crops made in Great Britain, but certainly none so heavy as six tons per acre, and we have not so favorable a climate for grass as they have in that country. Still we are very certain that our average hay crops might very well be doubled in yield by attention to preparing, seeding, and manuring the soil in the best possible manner, and by making use of irrigation wherever practicable.

How to use Tallow Scraps.—A farmer has a quantity of tallow scraps which he is trying to decompose for manure, but they are insufferably offensive and he proposes to mix lime with them; how will that answer?—Very badly for the manure, and his sense of smell too. The only proper method is to mix earth in sufficient quantities—say five or six loads to one of scrap—to absorb all the odors, which it will do most completely if enough is used. They might also be spread on the field and at once plowed under, and the ground again plowed for a fall crop early in September.

Ayrshire Cows.—An Ayrshire cow (Lizzie, 562, A. H. B.), wined in Pennsylvania, is said, by her owner, to have given in seven consecutive days in March 27½ pounds of milk, from which was made 11 pounds 14 ounces of butter; the feed was hay and two quarts of oats and corn-meal per day. On grass she now gives 23 quarts of milk per day. The secret of the large milking of Ayrshire cows is that for scores of years they have been raised specially for this purpose by selecting for breeding stock only the produce, both male and female, of the most productive cows.

An Acre.—Our acre is the same as the "statute acre" of Great Britain, equal to 4,840 square yards. But it is a difficult matter in Great Britain to know what an acre is, for there are there in common use the Irish and Lancashire acre of 7,340 square yards, the Scotch of 6,104, the Cunningham of 6,253, the Cheshire of 10,240, the Derby of 9,000, the North Wales of 3,210, the Welsh (the "erw," however that may be pronounced) of 4,330, the Leicester of 2,308½, the Westmoreland of 6,750 yards, and others in still further variety; the same peculiarity exists with regard to miles. And yet we can not abide the little indefiniteness of our shillings.

Spavin.—"P. C.," Blairstown, Iowa, has a colt with an enlargement on the "hough" joint, which he lately blistered according to the advice of a horse-doctor, who called it "oscular joint." The swelling now grows harder. It would probably be best to use iodine ointment rubbed twice daily on the swelling, which is doubtless an approaching spavin. This may effect a cure. If this has no good effect, and the colt is

not lame, we would let it alone unless some really good surgeon can be procured to attend to it.

Quince and Pear Trees.—"O. Y. Z.," Mowqua, Ill. Quince as well as other fruit trees require such a soil as will produce a good crop of corn or potatoes. Stable manure, well decomposed, is useful. We should not use hen-manure on fruit-trees, but reserve it for corn and other quick-growing crops. Ashes never come amiss for pear or other fruit trees. Salt has been found useful as a special manure for quince. Mulching is beneficial to all newly-planted trees. Some growers prefer to have their quince-trees in a bush form, with several stems from the base. We prefer a single trunk. In either case it is necessary to look out for borers, and if they get into the trees, dig them out.

The Doctor's Talk about the Prizes.

You see, youngsters, that we for reasons stated could not get this prize matter into the regular Boys and Girls' pages, so we have to come over here among the old folks. I will get the printer to put a good big dash at the top of this to separate it from the talk about mowing machines, sick cows, and the like—matters important enough for grown people, but perhaps not quite so interesting to most of you young ones.

Well, the old Doctor has been happy. He did not think that so many of his boys and girls would use their eyes and put down what they saw. How the letters did come in! Twenty, forty, and sixty a day, and how many times did I sit up late looking them over, and in imagination taking walks with you! I have been in the grand old forests of Oregon, I have looked at the early spring flowers of Maine, I have seen the lizards and the Yellow Jessamine in Georgia, and I have watched for gophers in Kansas. I can tell you that I enjoyed it all, and those of you who do not get prizes will know that your letters were read and your lists looked over, no matter how small they were. So many pleasant letters there were, and such a kindly feeling—it almost makes an old fellow feel glad that he has no children of his own, and can take into his affections so many boys and girls whom he has never seen and never may see. So many touching letters, too! One poor little thing was taken down with measles, and had to leave her list incomplete. One boy, who sent a very good list, had to work all the time, and could only put down such animals as he saw while engaged in his farm labors. Some dear little chicks, too young to write, printed their lists. Such a good spirit, too, in most of the letters, ever so many saying that if they did not get a prize they were abundantly repaid for their trouble in the pleasure they had in making up their lists. You have all had a good time, and the only one who feels badly over it is the Doctor. I am so sorry that I can not give a prize or a personal acknowledgment to every blessed one of you. As in former cases, some who do not receive prizes will hear from me, and those who have sent plants to be named will be duly answered.

You will recollect that this time the prizes are all books. So I wish the prize-winners to tell me what book they would like that retails for \$3 or less, or at least say what subject they would like the book to treat of. I was glad to find that those who asked for book prizes for the stories selected works on botany and similar subjects.

There were in all a few over 570 letters.

Now for the prizes, which have only been determined on after long examination, comparison, counting, and much deliberation. If the prizes were twenty for each class, it would not be difficult, but where there are only three, you can imagine how hard the task must be.

Girls between 12 and 16.

- 1st. Lonie L. Batcham, Painesville, O.
- 2d. Josie Bell Stewart, Lowell, Mass.
- 3d. Mary J. Sinclair, New York City.

Girls under 12.

- 1st. Marian Hayward, Ayer, Mass.
- 2d. Alice L. Keith, Bridgewater, Mass.
- 3d. Alice Campbell Hotchkiss, New Hamburg, N. Y.

Boys between 12 and 16.

- 1st. Abraham Resh, Enterprise, Pa.
- 2d. Emis Dubois, Waverley, N. Y.
- 3d. G. E. Shiras, Newcastle, Pa.

Boys under 12.

- 1st. Willie B. Marlatt, Manhattan, Kas.
- 2d. Oscar M. Messenger, Baraboo, Wis.
- 3d. Wellington Woolfolk, Woolfolk's P. O., Va.

There are a number in each class to which I wish to give honorable mention, but as I write at the last minute, I have not time to do it here.

Now let us all enjoy ourselves quietly during the hot months, and be ready for more fun when the cooler days and longer evenings come.

THE DOCTOR.

Good Reasons.

The large class of Advertisements and of paid Business and Editorial "Notices" constantly rejected from the *American Agriculturist* and from *Hearth and Home*, if admitted, would alone supply tens of thousands of dollars to each journal every year. This lack of an income which is received by most other journals, is a good reason why such journals should have a large paying circulation, and would even justify comparatively higher subscription rates.

The readers themselves could, and in most cases would, pay more to find the desired information and reading matter in journals free from advertisements of patent medicines, humbugs, unreliable persons and things. They have less fear of being cheated themselves, or of having their children corrupted or led astray.

As the subscription rates of *American Agriculturist* and *Hearth and Home* are not higher, but on the contrary are lower, than those of most other journals prepared at similar expense, will not the readers take pleasure in doing something towards increasing the circulation? Can not each of our present readers influence the subscription of one other person, to begin with July 1st, in accordance with notices elsewhere? The publishers will appreciate the favor,

Honey-Dew.—"J. M. S.," Strawberry Plains, Tenn.—The article referred to should have stated that there are two kinds of Honey-dew—one exuded by plant-lice, as there described, and the other an exudation of a sugary liquid from the leaves themselves. The article told the truth, but was at fault in not telling the "whole truth."

Department of Agriculture.—"G. W. F.," Nashua, N. H.—The Report from which we quoted was that of the Commissioner, which is published in the form of a small pamphlet. The large volume, containing the reports of the subordinates and miscellaneous matter, will come later.

Chufas.—D. C. Webb, Macon Co., Ill.—The Chufa, or Ground Almond, is a nut-like tuber of a sedge, the *Cyperus esculentus*. It will grow in your climate, and may be sown in spring in drills like beans. Their chief use is for feeding swine, which will root them up. They have not met with much favor. The tubers are usually kept at the large seed-stores.

Canada Thistles.—"R. E. G."—It would be much easier for you to send a specimen of your thistle than for us to describe it that you would know it from all others. As to extermination—we know of nothing better than frequent cutting off the tops. If this be thoroughly and earnestly attended to it will destroy the thistles. Half-done, it will not.

Cotswold vs. South-Down Sheep.—"Why do you recommend Cotswold sheep instead of South-Downs?" asks a New England farmer. "Is not South-Down mutton better than Cotswold?"—"We think it is better. But we can not sell it at any higher price. At the "West End" of London there is a class of epicures that will have no mutton but South-Down, and they will pay two cents a pound more for it than for Cotswold or Leicester mutton. But here, as yet, there is no difference made in the price. Mr. Law's experiments proved that English farmers could afford to sell Cotswold mutton for two cents per pound less than South-Down—and this before the recent great advance in long wool. We recommend Cotswolds, therefore, because their wool is in great demand at high prices, and because a pound of mutton can be produced from a Cotswold at less cost than from any of the South-Down breeds.

Pigs on Clover.—"M. B. R.," Windsor, Mo., asks the following questions: First. Will hogs injure the clover or the trees if permitted to pasture in an orchard? Second. Will kitchen-slop fed to fattening swine make the pork soft, and should they be finished off on corn in the ear and cold water? Third. How can we prevent a young heifer from kicking?—Hogs do sometimes goaw the bark from young trees in orchards, and if the clover is eaten close they will often kill it by biting out the crowns of the plant. Kitchen-slop is not fit food for fattening swine, excepting given as a drink only; they may be finished off on corn-meal made into mush and fed cold, and yield the firmest of pork. A young heifer may be cured of kicking by gentle treatment and avoiding anything that will frighten or irritate her.

A Dyspeptic Horse.—We are asked what it is best to do with a horse that "does not seem to be well, while not actually sick. He looks forlorn, eats but little, and seems to have no life or spirit in him either for work or play."—"The very best thing to do with such a horse is to take his shoes off, and let him have two or three months' absolute rest at pasture. If he can not be spared, work him moderately, and be particular in regard to feeding, watering, and grooming. Let him have one full day's rest at least once a week. If you must work him on Sundays, let him rest Saturdays. Give him bran-mashes enough to keep his bowels moderately loose. If in spite of this he is costive, give a pint of linseed oil at night, and let him rest the next day. Let him have hay-tea to drink. Humor his appetite. Find out what he likes best, and let him have as much as he will eat up clean, and then remove all food from the rack and manger. See if he will eat boiled barley. If so, nothing can be better for him. Groom thoroughly, and make him as comfortable as possible. Let him have a lump of rock-salt to lick. Give green food if possible, as it is more easily digested than hay; but if this can not be had, eat his hay into chaff, and soak it in as much water as it will absorb for twelve hours. Then mix a little bran or oat-meal with it, and let him have as much as he will eat up clean, and no more. Never work him hard immediately after eating.

No Doubt about it.—An old farmer in the West writes us that his neighbors do not believe in "book-farming," but that the reading of agricultural papers is having a good effect on the rising generation. "I see it sticking out in my own boys," he says; and it will stick out more and more. It is one of the hopeful signs of the times.

How to Boil Barley.—Soak it for twelve hours in about twice its own bulk of water. Then boil, in the same water, until the kernels burst open. We know of nothing that will fatten a horse that is only moderately worked sooner than boiled barley. Add a little salt to the barley, and mix it while hot with an equal quantity of cut hay. It should be cooked fresh every day in warm weather, and fed before it gets sour.

Hay-Tea.—Steep some cut-hay in boiling water for two or three hours; pour off the water, and give it to the animal to drink, either warm or cold, as thought best. It is a capital thing for horse, cow, calf, sheep, or pig. Clover hay is best.

Measuring Corn.—E. B. Hill, Jasper Co., Ill., gives another rule for measuring corn in the crib—which is to take 4,032 cubic inches of ears for a bushel of shelled corn, equal to three half-bushels of 2,688 cubic inches to a bushel. If any one likes that bushel, the rule will do for large Western ears.

Judson Branching and Egyptian Corn.—The proprietors of both these swindles have come to grief. Judson has been compelled to pay \$750 and costs of suit in an Illinois court, as damages to a dealer whom he had victimized, and the Egyptian-corn man who swindled so many farmers a few years ago, has now got his deserts, although indirectly, by having been sent to the penitentiary for several years for robbing the mails while postmaster in Virginia.

Market Value of Hen-Manure.—"Geo. E. H.," Lowell, Mass., has a quantity of hen-manure, mixed with loam, which has been sprinkled in the house to keep it clean, and has no use for it; at what price could he afford to sell it?—If there is no more than half of it loam, it ought to be worth about one cent per pound, but the value will depend altogether upon the proportions.

Green Manuring Crop.—Geo. K. Morris, Macon Co., N. C., asks if lupines make a better crop to plow under than clover. We do not know of any advantage to be gained in sowing lupines over the crops ordinarily in use for this purpose. Better use peas than lupines, and clover in preference to any other crop.

White Specks in Butter.—"A Reader" asks why white specks come in the butter. There are several causes. One is too quick churning, which leaves many butter globules unbroken, the skins of which consist of caseine, or cheesy matter, and are left in the butter, but these are very minute, and are scarcely seen, though they are soon smelt. Another is, the cream is allowed to stand too long, and the milk becomes curdled and partly separated from the whey; the particles of curd remain in the butter, and being insoluble, can not be all washed out. These specks are large, and spoil the look as well as taste of the butter.

Please tell your Neighbors

All for \$2.

READ THIS.

Subscribers can have the *American Agriculturist* and *Hearth and Home* from July 1st to the end of the year for \$2.

OR

They can have the weekly *Hearth and Home*, which is now a superb, Illustrated Journal of the highest and best order, for \$1.50 from July 1st to the end of the year.

It will pay.

N.B.—Special.—New subscribers for *Hearth and Home* coming in now, if they specially desire it, will be supplied with the chapters issued prior to July 1st, of Edward Eggleston's most popular new American story, "The End of the World," capably illustrating Western life. This will, with the remaining numbers, give them the whole of the story complete. This, with the great number of splendid illustrations and great amount of excellent reading matter, will be found the best and cheapest family journal in the country.

Will not every present reader take pleasure in mentioning the above to their friends and neighbors, and each aid us in securing one new reader to begin July 1st?

. The previous chapters of the Story will only be sent when specially asked for.

Hide-bound.—"A Farmer" wants a remedy for hide-bound in a colt. The immediate cause should first be ascertained, as there are several. Generally impaired digestion, costiveness, cold, overfeeding, starvation, or anything which will affect the health unfavorably, shows its first effects in hide-bound. Remove the cause, and the trouble will cease. Bran-mashes with a little sulphur, given daily, and scalded oats or soft cut feed will work a cure, unless something serious in the matter, when proper advice should be taken.

Ringed Hogs.—"M. B. R.," Windsor, Mo., wants the best method of preventing hogs from rooting.—A ring in the snout is the best preventive. A horseshoe nail put through the snout, and the point twisted around the head (of the nail), makes a good ring.

A Mistake.—"S. P.," Iosco Co., Mich., writes that he has followed engineering all his life, and now has settled down on a farm in a new and poor location, on sandy soil, overgrown with scrub-pine and whortleberries six inches high, and he asks what artificial manures he shall use to grow crops of flax, or mustard, as clover does not take well.—This poor engineer is off the track worse than he ever could be on a railroad, and if he escapes a smash-up, will be fortunate. A man who can not choose a farm with judgment, can not succeed as a farmer, and is far better off as a passably good engineer than as a certain failure on a farm, if one can call such a piece of land as he describes, a farm at all. Our advice is, to give the land to some one, if he can, or to keep it for a huckleberry patch and go to engineering again, or, if he wants a farm, to buy good land.

Hybrid Corn.—"Experimenter" asks if corn can be improved by mixing distant varieties, and procuring hybrids. We think it can. We once planted some rows of Pennsylvania gourd-seed corn amongst rows of early Canada, and had a mixed corn which had larger ears than the early Canada, and ripened earlier than the Pennsylvania corn, which we thought an improvement.

Other Basket Items on page 273.

Steamed and Boiled Bones.—Wm. Ashberry, London, Canada, asks if it is true, as stated in "Morton's Farmers' Almanac" (English), that "fat as an element in bones has no fertilizing qualities whatever."—This is correctly stated. But steamed and boiled bones lose by the process, not only fat, but some gelatine, which is a positive loss of nitrogenous matter, and as fat is in no way injurious it is better to have raw bones as a basis for fertilizers.

Clover as a Fertilizer.—"Interrogator," Hempstead Co., Ark., asks if when clover is used as a fertilizer it should be used exclusively for that purpose, or should meadow and pasture come in rotation.—Where the soil is poor, and clover has been sown with a special view to a green manuring, we would plow in the whole bulk; but when the system has become established the clover is mown and lightly pastured and assisted with gypsum and lime, and becomes only an aid to the general course of manuring.

Mixed Grasses in Arkansas.—"O. J." wants our opinion as to whether clover, bluegrass, timothy, red-top, and orchard grass would succeed in Arkansas.—We do not doubt of their success if sown on suitable soils. Red-top needs a moist soil, and all the rest need soil of fair quality at least.

Measuring Corn in the Crib.—S. Fuller, Greenville, Ill., gives a rule for measuring corn in the crib as follows: Multiply length, height, and breadth of the crib in feet together, then by $4\frac{1}{2}$, and divide by ten; the result is bushels of shelled corn. This may do for some localities, but as ears and shelled corn bear as many relations to each other in quantity as there are localities and sorts, the safest way is to reduce the contents of the crib to cubic inches, and take 2,750 of them for a bushel of ears.

Kansas Agricultural College.—This College has, thanks to the efforts of its friends, been put on a thoroughly satisfactory footing as an agricultural institution, and promises to be of the greatest value to the farmers of that State. Amongst other important improvements, a veterinary hospital has been established, where diseased animals will be treated by a veterinary surgeon at only nominal charges. Prof. Detmers is in charge.

A Drain Wanted.—A "Subscriber" wants a method of diverting a flow of water from a cut in a hill-side where a road passes through it. The water constantly oozes from the bank. There is no help but digging a drain along the upper side of the road until the springs are cut and the water carried off in a covered drain where it will not overflow the road in winter. In similar places, drains have had to be cut seven feet deep to intersect the flow of water, which is necessary to make a perfect job.

Fencing Pastures.—"Inquirer" wants to know if we think it economical to fence a farm into fields in order to pasture cattle therein on clover or peas.—We do not. If special crops are grown for fodder, it is far more economical to cut and carry these crops to the yard or pen where the cattle may be fed, and thus save manure and the expense of fencing, and prevent the waste of feed by trampling underfoot.

What shall we do with our Bones?—"A Subscriber" living on the prairies of Nebraska, sees quantities of bones bleaching on those vast fields, where they have been left by luckless buffaloes and horses, and knows there are no bone-mills around, and no money to start them.—If we were in his case we would gather those bones and burn them, and crush them into powder, and spread them on the fields. They have but little animal matter left to be lost by burning, and they may be crushed very easily when burnt thoroughly. Thus they may be very profitably used.

Mustard in the Southern States.—"D. E. S.," of N. C. We do not think Mustard will make good fodder. It is very succulent, and would be difficult to cure without losing the leaves. But we have had no experience on this point. The white Mustard is not so "hot" or pungent as the black, and grows larger.

Pennsylvania State Fair.—The Pennsylvania State Agricultural Fair is to be held this year at Erie, beginning September 19th, and lasting three days.

Steam Plowing.—The Adams Co. (Ill.) Agricultural Society having offered a large premium for the best steam-plow and road steamer, it is expected

that the question of the practicability of steam-plowing on the prairies will receive a somewhat satisfactory test. Two steam-plows are already entered to contest for the premium, which will come off on the 2d September, and more are expected.

"Venus's Flower-Basket."—In February last we published a description and engraving of the singular sponge-structure known as Venus's Flower-Basket. Since then we have received from Messrs. Greenleaf & Anthony, No. 104 Court street, Boston, a much finer specimen than the one from which our illustration is taken. We learn from a friend that Messrs. G. & A. import largely of foreign curiosities, and that during the summer they open a branch establishment at the now much-frequented Martha's Vineyard.

Another of the Family.—A farmer in New Hampshire may thank the author of "What I Know about Farming" for a valuable discovery. He was "plowing deep" most likely "while sluggards sleep," and plowed up a petrified Indian, seven feet seven inches long. It belongs to the family of the Cardiff giant.

Land for Sale.—The impression is rife that land is rarely for sale in England; on the contrary, the chief advertising mediums of England are plentifully furnished with announcements of sales of estates, farms, and lots of all sizes, from single roods and acres up to immense estates, so that it would seem the possession of land is only circumscribed by the ability to purchase it, there as elsewhere.

Steam Cultivation.—An extensive English farmer, who has long practiced steam cultivation, thus testifies to its advantages: On two fields he has grown fifteen crops of grain, wheat, and beans in succession, without a fallow, and last year's crop of wheat was forty bushels per acre; on two other fields he has grown fifteen successive crops of wheat, the last crop quite equaling forty bushels per acre. Under horse cultivation the average crop of these fields was twenty bushels. The total cost of preparing the land for the seed is only \$1.00 per acre. Much similar testimony is now coming in.

English Agriculture.—An idea of the position of agricultural labor in England may be gathered from the fact that lately some laborers "struck," and refused to use double-furrow plows on a farm, for the reason that they tended to reduce the need for men. When brought up in court on complaint of their employer for not obeying orders (thus punishable in Great Britain) they were fined ten dollars, and costs two dollars, each. The judge said, this thing must be put down, or farming must come to a dead stop, which shows that across the Atlantic "their ways are not our ways."

American Pork.—Fifty thousand tons of American bacon and pork were imported into England in 1871, and seventeen thousand tons in the first three months of 1872, and the last hog has not been killed yet.

Fine Grinding.—We are asked whether our correspondent's miller is correct when he advises him to have his corn ground very coarse, because "if he grinds it fine, it kills the strength of the meal."—He is entirely wrong—except for his own interest. He can grind four times as much coarse meal in a day, as he can of fine, and so can make more money. The finer the grinding, the more digestible the meal—the more of its nutriment will the animal appropriate. The "strength" of the meal lies, not in its granular texture, but in its chemical composition, and this is not affected by grinding. Very fine meal is more apt to heat than that which is coarser, but this only implies more care in keeping.

Beet-Root Sugar in New Jersey.—The Legislature of New Jersey has passed a law to encourage the manufacture of beet-root sugar in that State, by exempting from taxation for ten years any factory with the necessary machinery, which may be put into operation after April, 1872.

Exportation of Shorthorn Cattle.—The importation of thorough-bred stock has been so very common for many years past, that it seems as though we had turned a very sharp and sudden corner when we come to write of the exportation of them. But it is a fact that at last American breeders have arrived at that point when English breeders send commissions here to purchase our choice stock at hitherto unheard-of prices. Mr. Richard Gibson sailed on Saturday, May 25th, on board the steamer Oceanic, of the White Star line, with a pair of Princess cows, purchased from Mr. Alexander, of Ky., for an English gentleman, at a price, as we understand, of \$18,000 for the pair. Besides these Mr. Gibson takes

out some other choice stock on his own account. It is a matter encouraging to all engaged in breeding stock, that the character of American cattle has become so well established; for although there are but few breeders who can hope to realize such handsome prices, yet the fact that some do receive them, makes it much easier for all others who raise good stock to realize fair and remunerative prices also, and thus all our stock takes a lift together.

Plants Named.—"Susie M.," Hickory Creek, Mo.—The flower sent is *Erythronium albidum*, or White Dog's-tooth Violet, a very pretty plant for garden cultivation. Wish you would send us a few bulbs by mail. . . . J. A. Hubbard, jr., Champion, N. Y.—The weed that is so troublesome to you is the Plantain-leaved Everlasting; its botanical name is *Antennaria plantaginifolia*. As it is a perennial, the best remedy is plowing up the grass lands where it is abundant, and planting some crop which requires hoeing.

Liquid-Manure Cart.—Mrs. S. J. S., Mendota, Ill., writes to ask if there is a cheap way of saving and spreading liquid manure. In the *Agriculturist* for May, 1872, directions were given for making a cistern for saving and tank for spreading it.

Chicken Cholera.—John J. Keating, Washington, Iowa, has lost a great many fowls by cholera, both this year and last summer, and wants a remedy. This probably arises at first from too much green food, in which case it may be remedied in the start by giving chalk or magnesia in the food; alum-water is also useful, or a small quantity of sulphate of iron, given in the drinking water. When very bad, ground rice, boiled in milk, fed slightly warm, has been found beneficial.

Lime-Kilns.—"T. S. G.," Brevards, N. C., wants a good plan for building lime-kilns. A long article, with illustrations, was published in *Agriculturist* for September, 1871, on this subject.

At what Age should Young Mules Work?—"A. S.," Mercer Co., Pa., asks at what age may young mules do light farm work.—At three years old they may do such light work as cultivating corn, or harrowing, or drawing light loads, but the work should really be light until they are a year older. At two years they might be taught to work by drawing an empty wagon.

Flax Fiber.—"W. W.," asks where he can dispose of a quantity of flax fiber or tow. Doubtless in New York or Philadelphia. Write to any of the produce commission agents advertised in *American Agriculturist*.

Bee Notes for July.—By M. Quinby.

So few bees are left in the country this season, that every one having them should manage to secure every pound of honey possible. Be sure and know the first day a box is finished, and take it off at once. It is unnecessary to wait until every cell is finished, because the bees will continue to find room for just a cell more around the outside, and keep adding. Economy, as well as the beauty of the honey, would dictate taking it off as soon as it can be called full.

This is the month to examine for foul brood, or three weeks from swarming. The matter has been fully described heretofore in the *Agriculturist*. So much has been done towards getting rid of it, that we hope yet to completely eradicate it. Those troubled with it, or those in sections where it is, should be energetic, and neglect no case at the right time. Catch the moth, as before recommended, in dishes of sweetened water set among the hives at night.

Queens are raised easier this month than earlier. In rearing them artificially, we wish to get as nearly as possible what we would have when reared in the natural course of swarming, or what we would ordinarily get when a colony loses the mother queen. The eggs in the abdomen of a healthy queen are probably all alike, yet the eggs deposited in worker cells make workers, in drone cells make drones. Sex is probably decided in the act of laying. The eggs that are laid in worker cells may produce queens; those laid in drone cells never do. When the egg has hatched, and the larva has been fed beyond a certain time as a worker, it can not be changed to a queen. Bees, when deprived of their queen, seem to think that the first thing necessary towards replacing her is the queen-cell, and they commence several. When they have grubs of the proper age, the queen-cells will be commenced over those first, or over those just a little too far advanced to be changed perfectly, if they happen to be suitably located in the hive. If these are not to be had, they commence over drone-cells, or cells of bread, or even empty cells. If a full colony is left destitute, several queens will be started at the right age—per-

haps a few may be too far advanced, others may be started several days later.

The Alderney Breed of Cattle

BY AN AMATEUR BREEDER.

The Channel Island breed of cattle, popularly known in this country as "Alderneys," consists of two classes of the same breed. The Guernsey is the larger of the two, usually of a light fawn color, patched with white. The Jersey class is smaller; and the color to which more attention has been paid is a dark, or, as the Scottish say, "dun" deer, and is popular in England, no doubt in consequence of its more aristocratic appearance. The Alderney is essentially a cream-and-butter-producing breed, giving more milk, and of richer quality in proportion to its size, than any other cow; the best have been known to give from 10 lbs. to 14 lbs. per week. This merit gives them their place in live-stock, either for dairies near fashionable towns like Brighton, or as cows for the park and the villa paddock, combining in the highest degree utility and ornament. The dairies of great cities are chiefly supplied by cows of the Dutch or the Shorthorn cross, which give large quantities of comparatively poor milk, and when dry fatten easily for the butcher. This is not the place of the Alderney, which, in England at any rate, is essentially the gentleman's cow.

Writers on the subject, copying one another, assume that, because the Channel Islands were once a dependency of Normandy, the Alderneys are an offshoot of the Normandy breed; but few breeds could have less resemblance. It has also been suggested that they are an offshoot of another good dairy tribe, the Ayrshires; but Ayrshires are much more like a small Shorthorn cultivated for milking purposes. At the great International Exhibition of live-stock in Paris in 1855, where nearly all the ox tribe of Europe were represented, the late Fisher Hobbs, of Boxted Lodge, Essex, a very good judge, came to the conclusion that the true ancestors of the Ayrshires were Danish, and that the Alderneys were more probably descended from some Swiss mountain breeds, of which many specimens were there exhibited—dark and light fawn in color, and fine in head and horns.

At the present time there is no doubt that in England, where the principles of selection have so long been successfully applied to horned stock and sheep, finer specimens of the Alderney have been produced than in their native islands.

For many years the farmers of the Channel Islands, while sternly prohibiting any importation of bulls, have made the rearing of heifers for the English market a profitable part of their business; but it is only within a comparatively recent period that they have learned from English breeders the advantages to be derived from a careful selection in obtaining symmetry as well as milk.

Amongst English breeders who have shown what could be done towards obtaining the best points of a milking cow by applying Bakewellian principles of selection, Mr. Philip Dauncey, of Horwood, near Winslow, Bucks, occupies, or rather occupied, the most distinguished position. For nearly half a century he devoted his attention to obtaining great milking qualities, symmetry, constitution, and a uniform fawn color without white. His success placed him at least half a century in advance of the Channel Islanders. When in 1867 Mr. Dauncey retired from stock-farming, in consequence of his advanced age, his sixty-nine cows and heifers produced £3,285. Mr. Marjoribanks gave over one hundred pounds for his cow "Landscape," and Mr. Walter Gibbey just under that sum for the heifer "Ban."

Mr. Dauncey produced a breed much more hardy than the original Channel Islanders; his stock lying out on the pastures throughout the year. The imported Alderneys are delicate, and on first introduction require slight shelter in the cold weather, but they soon afterwards become acclimatized.

A decided improvement has taken place in Alderneys since 1833. The Jersey Agricultural Society was founded in that year, under the presidency of General Thornton, the Lieutenant-Governor. The council of the Society drew up a scale of points from the examination of the best specimens of the animals then in the island, thirty of which were assumed to constitute perfection. Some years later, this table was revised and settled as follows:

SCALE OF POINTS FOR BULLS.

Article	Points.
1. Head, fine and tapering.....	1
2. Forehead, broad.....	1
3. Cheek, small.....	1
4. Throat, clean.....	1
5. Muzzle, fine, and encircled by a light color.....	1
6. Nostrils, high and open.....	1
7. Horns, smooth, crumpled, not too thick at the base, and tapering, tipped with black.....	1

8. Ears, small and thin.....	1
9. Ears, of a deep orange color within.....	1
10. Eyes, full and lively.....	1
11. Neck, arched, powerful, but not too coarse and heavy.....	1
12. Chest, broad and deep.....	1
13. Barrel, hooped, broad, and deep.....	1
14. Well-ribbed home, having but little space between the last rib and the hip.....	1
15. Back, straight from the withers to the top of the hip.....	1
16. Back, straight from the top of the hip to the setting on of the tail, and the tail at right angles with the back.....	1
17. Tail, fine.....	1
18. Tail, hanging down to the hocks.....	1
19. Hide, mellow and movable, but not too loose.....	1
20. Hide, covered with fine soft hair.....	1
21. Hide, of good color.....	1
22. Fore-legs, short and straight.....	1
23. Fore-arm, large and powerful, swelling, and full above the knee, and fine below it.....	1
24. Hind-quarters, from the hock to the point of the rump, long and well filled up.....	1
25. Hind-legs, short and straight (below the hocks), and bones rather fine.....	1
26. Hind-legs, squarely placed, and not too near together when viewed from behind.....	1
27. Hind-legs, not to cross in walking.....	1
28. Hoofs, small.....	1
29. Growth.....	1
30. General appearance.....	1
31. Condition.....	1

Perfection..... 31

No prize shall be awarded to bulls having less than 25 points.

Bulls having obtained 23 points shall be allowed to be branded, but can not take a prize.

SCALE OF POINTS FOR COWS AND HEIFERS.

Article	Points.
1. Head, small, fine, and tapering.....	1
2. Cheek, small.....	1
3. Throat, clean.....	1
4. Muzzle, fine, and encircled by a light color.....	1
5. Nostrils, high and open.....	1
6. Horns, smooth, crumpled, not too thick at the base, and tapering.....	1
7. Ears, small and thin.....	1
8. Ears, of a deep orange color within.....	1
9. Eye, full and placid.....	1
10. Neck, straight, fine, and placed lightly on the shoulders.....	1
11. Chest, broad and deep.....	1
12. Barrel, hooped, broad, and deep.....	1
13. Well-ribbed home, having but little space between the last rib and the hip.....	1
14. Back, straight from the withers to the top of the hip.....	1
15. Back, straight from the top of the hip to the setting on of the tail, and the tail at right angles with the back.....	1
16. Tail, fine.....	1
17. Tail, hanging down to the hocks.....	1
18. Hide, thin and movable, but not too loose.....	1
19. Hide, covered with fine soft hair.....	1
20. Hide, of good color.....	1
21. Fore-legs, short, straight, and fine.....	1
22. Fore-arm, swelling, and full above the knee.....	1
23. Hind-quarters, from the hock to the point of the rump, long, and well filled up.....	1
24. Hind-legs, short and straight (below the hocks), and bones rather fine.....	1
25. Hind-legs, squarely placed, not too close together when viewed from behind.....	1
26. Hind-legs, not to cross in walking.....	1
27. Hoofs, small.....	1
28. Udder, full in form—i. e., well in line with the belly.....	1
29. Udder, well up behind.....	1
30. Teats, large and squarely placed, behind wide apart.....	1
31. Milk-veins, very prominent.....	1
32. Growth.....	1
33. General appearance.....	1
34. Condition.....	1

Perfection..... 34

No prize shall be awarded to cows having less than 29 points.

No prize shall be awarded to heifers having less than 26 points.

Cows having obtained 27 points, and heifers 24 points, shall be allowed to be branded, but can not take a prize.

Three points—viz., Nos. 28, 29, and 31—shall be deducted from the number required for perfection in heifers, as their udder and milk-veins can not be fully developed; a heifer will therefore be considered perfect at 30 points.

In 1866 the Jersey Herd-Book was started, and in 1868 the Committee of the Royal Agricultural Society of Jersey called attention in a report to the advantageous results of

careful breeding as practiced by Mr. Dauncey and others in this country. In a subsequent report in December, 1871, the committee acknowledged a yearly grant from the State of Jersey of £50, to be applied solely in premiums for bulls, to check the exportation of good animals from the island.

In England, whole-colored Alderneys, whether dark or light fawn, are decidedly the most esteemed. We believe justly so, and in corroboration of this view we quote from an article by Gisborne in the Quarterly Review of 1849 and 1850:

With few exceptions, quadrupeds in a state of nature are self-colored; and we are not aware of any wild animal whose colors are patchy or glaring. The British wild cattle are of a dingy white, with tawny ears. The cattle of mountainous countries, which have been very inaccessible to agriculture, are always of self-colors, black, red, or dun. The queer little cow, which within the memory of man had a pure existence in Normandy and the Channel Islands, and which, being celebrated for the richness of its milk, came to our markets under the name of an Alderney, was fawn-color with tawny ears.

Amongst the herds maintained purely for profit, Mr. Dumbrill's, of Ditchling, near Brighton, is one of the most remarkable. Mr. Dumbrill, who has always adhered to the Jersey breed, keeps one hundred cows, divided into herds of twenty-five each, for the purpose of supplying his wealthy neighbors with butter and cream. In the Brighton market, during the two seasons, there is a demand for the very best of everything in the way of eating without regard to price. In April, 1862, Mr. Dumbrill read before the Farmers' London Club a paper on "Dairy Management," containing practical information of great value to the owners of either trade or fancy dairies.

Another breeder of Alderneys, who bears a name almost classical in the history of agriculture, is Mr. C. H. Bakewell, of Quorndon, near Derby, who has a small but select herd, and which is managed in a profitable manner. His average annual return has been from 220 lbs. to 240 lbs. of butter per cow.

This country is well off for breeds of meat-producing beasts, as clearly shown by your articles on Shorthorns, Herefords, Devons, Longhorns, and others. To breed Alderneys with success, in my opinion, no attempt should be made to combine meat-producing with milk-producing qualities. The Alderney breeder, therefore, must be satisfied with an animal almost equal in elegance to a deer, rich in cream, and bountiful in butter of the finest quality. All, however, do not think alike, and an attempt is now being made in a fine herd near London to attain this object. No doubt one great drawback to the Alderney as a gentleman's cow is that, when barren, it is often impossible to fatten her, causing thereby considerable loss. But from this herd last year a cow which had been milked for two years, was, after three months' feeding, sold in Watford Market by auction for £26 10s. to the butcher; and it remains to be proved whether or not this is an exceptional case.

Heifers kept until three years old before breeding will be larger in frame, but the gain in size is obtained at a sacrifice of dairy qualities, and with increased difficulty in getting them to breed. Alderney heifers should be so managed as to calve at not later than two years and a half old.

Most of the agricultural societies are now offering prizes for Channel Island cattle. The Royal Agricultural Society has recently made classes for both the Jersey and the Guernsey, on the principle that Judges who prefer the one, may not do justice to the other. This arrangement will, it is to be feared, make the entries in each class very small, particularly so in the Guernsey class, as in this country Guernseys are not numerous. The Bath and West of England Society has of late years secured very good entries for its Alderney classes; and amongst local shows, Essex has been successful in cultivating this truly elegant breed, stimulated perhaps by one or two local breeders, of whom the most successful exhibitor for the past few years, and particularly last year, was Mr. Walter Gibbey, whose bull "Banboy" took first honors at the Royal Agricultural Show, Bath and West of England Show, and the Essex Show at Romford, where also his cows "Duchess" and "Milkmaid" were equally successful.—*London Field.*

The Meadow-Lark or Meadow-Starling.

Upon the first page will be found an engraving from an excellent study by Mr. Herriek, showing Meadow-Larks of both sexes in various positions. This is one of the best known of all birds, as it is found from one end of the country to the other. While it is generally known in the Northern States as the Meadow-Lark, it is farther South called the Old-field Lark. It was

until recently supposed that this species extended wholly across the continent, but naturalists make the bird that extends from the great central plains to the Pacific, and from Texas to Washington Territory, a different species—the Western Lark. Our Eastern bird is *Sturnella magna*, while the Western one is called *Sturnella neglecta*, but when ornithologists come to describe the characters which distinguish the two, they are forced to admit that the differences are very slight. Prof. Baird, our highest authority, says: "To sum up the preceding remarks, it may be stated that the real difference between the species lies in the greater tendency to narrow transverse bands upon the upper surfaces, especially of the middle tail-feathers." He adds that all observers have attested to a remarkable difference between the notes of the bird found in the West and that of the East.

The Meadow-Lark is a very familiar bird, and does not seem to mind the "inroads of civilization;" indeed, it is not rare to meet with them within the limits of New York City. Notwithstanding the numbers of young vagrants that go about the vacant lots shooting everything that has life, the note of the Meadow-Lark is occasionally to be heard. What a sweet note it is, and what a pity that its song is so soon—almost abruptly, ended! It is hardly necessary to describe so familiar a bird; its yellow breast, marked by a broad black crescent, is familiar to all who roam the fields. When startled, it flutters like a young bird, and seems a long while in making up its mind whether to flee or not. The bird builds its nest in a cavity scooped out at the base of a tuft of grass, and lays four or five eggs at a time; these are white, blotched and dotted with reddish brown. The opening to the nest is only large enough to admit one bird at a time. The male and female both take their turn at sitting.

The birds gather in flocks in fall for their migration southward, and return singly or in small flocks in the spring.

The flesh of the young bird when fat is highly esteemed, but the old birds are said to be tough and of a disagreeable flavor. In the fall they are generally to be found in the city markets.

Ogden Farm Papers.—No. 30.

"It droppeth like the gentle rain from heaven upon the place beneath." How gentle it was! How softly it dropped, and how all nature thanked heaven for its merciful quality! How the place beneath drew the soothing balm into its thirsty pores! Shakespeare must have gone through a long, unseasonable drouth like ours, to have learned that simile for the unstrained "quality of mercy," and every farmer in our wind-burned districts must have felt its fitness, as the long-delayed and thrice-welcome rains of May came at last, to make him forget how dry and sad the world had been. It is no small part of the compensations of a farmer's life, to be able to enjoy to the full the blessed, fructifying showers of spring, with which nature heals the winter's scars and clothes field and forest with the promising green of early growth, and humbly to pay the tribute of his warmest gratitude for the "early rain" which melts our mother earth into life, and gives its value to all our work, its fulfillment to all our hope.

After four years of contention with the curse with which the earth-skinning of my predecessors had blighted every inch of our little farm—robbing it of its plant-food, puddling its clay to a water-holding firmness, and leaving its surface

to weeds and moss—I had at last, by dint of draining, and manuring, and plowing, and cultivation, got one of its nine-and-a-half-acre sections well laid down to grass. I had done my part, and nature must do the rest. There is a point where the most assiduous farmer must patiently sit down and wait for the hidden hands of warmth and air and moisture, to take up his work and carry it on to completion. I had reached that point, and could only wait and hope. Through long weeks I waited for the hand that never came, and hoped for the completion that seemed, every day, farther and farther away. March was colder and more savage than winter itself, and the late dry warmth and high winds of April seemed to sap the very fountains of growth. The first half of May had only rain enough to feed the drying winds, and even the grass of old meadows shivered and thirsted and stood still. But at last it came, the gentle rain from heaven, and hope grew high and completion marched on apace, until now the early days of June see my new meadow glorying in the fulfillment of the promise that never fails. The old curse is removed, and we rejoice in a fertility that I trust bad farming shall never again destroy.

Those who think we have a rosy time with the so-called high prices we receive for thorough-bred stock, do not, perhaps, understand that the picture has another side. High prices come after an effort which it costs some risk to make. A neighbor who saw me shipping a young Essex sow, bearing her first litter, rolled up his eyes when I told him she was sold for \$75, blandly remarking that he would sell me a bigger sow than that, and a first-rate one, too, for \$15. He was still more astonished a few weeks later, when I showed him a boar that I had just bought at auction for \$140, and on which expenses and commissions amounted to about \$20 more. "Well!" said he, "that beats me, and I don't see how you are going to get out of it." "Why," said he, "that hog is worth just about \$30." In one sense that was his value, but in another it would be difficult to fix his real worth. He is a very good pig, indeed, good enough to satisfy any breeder. Of this I felt confident before I bought him, but the reason why I bought him—and I gave my agent an order to buy at a much higher price, if necessary—was because he had the reputation of being the best Essex boar in the country. I might perhaps have got as good an animal for much less money, but I could not afford to let Lord Lyons II, *with his reputation*, go to another breeder. If there were not this necessity for keeping up the good name and fame of a herd, the breeding of thorough-bred stock would indeed be an enviable business; but no matter how much bad luck we have in the way of death, abortion, unsatisfactory progeny, and all the other ills a breeder knows, which affect the income most seriously, the *outgo* is sure and unfailling.

I am often asked by enterprising farmers whether I would advise them to pay a very high price for some thorough-bred animal. Advice in such cases must depend on the circumstances of the inquirer. If he can afford the investment, and if his object is to establish the foundation of a fine herd, I do not hesitate to advise him to pay whatever he must for the best animals (and those in the best repute) that he can find. The foundation may be very costly, when viewed by itself, but measured by the scale of its results, the case is bravely altered. One hundred dollars is a deal of money for a small farmer to pay for a Jersey bull-calf, but that calf will prob-

ably become the progenitor of twenty or more good dairy cows, and there can be no question that they will be worth, on the average, a good deal more than \$5 a head more than they would if sired by a scrub or grade bull. Two yearling heifers (not akin) of really first-class Jersey stock, both with calf to different bulls, may cost, if very choice, \$500. Supposing them each to have a bull-calf, or that their heifer-calves be exchanged for bulls (not akin) we have the foundation for a herd that may within a few years number fifty animals, all thorough-bred, and of distinct strains of blood. These animals will be worth, on an average, nearer \$50 than \$10 each, more than the same number of common stock.

A retired merchant, who pays \$500 for a cow for his lawn, and for the sake of Jersey cream for his coffee, commits a great extravagance, but a farmer buying the same animal to improve his stock for practical dairy purposes, makes a wise and prudent investment.

My own experience tends to show that the great sale of thorough-breds and high prices is to practical farmers, and not to "wealthy" men. The latter class are fast learning that good grades or thorough-breds without pedigrees are as good for their purposes, and the farmers are learning equally fast, that while they can not disregard quality in making their purchases, pedigree is the *sine qua non* of successful breeding.

Occasional letters received, asking for information about Jerusalem artichoke, remind me that I owe some amends to readers of the *Agriculturist* who have taken my advice to adopt this as a root crop. It is all very well so long as you want artichokes; they grow easily and anywhere, and produce enormously of nutritious roots, but if left in the same ground, they finally crowd it so closely as to make very small tubers, and then it becomes desirable to rotate them out of office. In this part of the programme I have signally failed, and any one who will show me how it is to be done, shall have my hearty thanks. I believe that they might be in time fed out by hogs, but as my patch is in the center of a farm without interior fences, this is impracticable, and I have tried plowing, mowing, freezing, pulling, digging, and hand-picking to no purpose. I have now over about a quarter-acre not less than ten robust plants to the square foot—the very worst weed I ever had to contend with. All that I have heretofore said in favor of this plant is strictly true. I did not know until now how true is the other side of the story, and I would advise no one to try it, except in a patch where hogs can be confined if necessary.

It is not pleasant to enter the lists of so free a fight as that now raging between the deep-plowers and the shallow plowers. Indeed, I think that each is right according to his success or failure under certain circumstances. But it is undoubtedly safest to advise all enterprising young farmers to leave well-enough alone, until they have found, by actual experience on their own land, that deeper plowing will not be injurious. One plowing, ten inches deep, has cost me already four years' use of eight acres of land, which, had I left its vegetable soil at the top and its "pizen" clay at the bottom, would have given me a fair return for the seed and manure and labor I have thus far squandered upon it. Four summers' heats and four winters' frosts, with manure enough to have made the adjoining land highly fertile, have hardly had an appreciable effect in overcoming the detestable impoverishment of the very unfertile sub-

soil we brought to the surface. I am now struggling to get it down to grass and clover, with some prospect of a fair catch. If we could once get it in good clover, the battle would be won, but how or when that can be done yet remains to be seen. As the case now stands, I might better have given \$100 per acre, and kept the plowing within six inches of the surface.

This means, understand me, that deep plowing on *that soil* is a failure. It does not mean that on your soil and your neighbor's it would not be a most brilliant success. Horace Greeley and Paschall Morris believe in it thoroughly, and they are right. The farmers in Salem Co., N. J., disbelieve in it most thoroughly, and they are right too. Circumstances alter cases, and we have here only a striking illustration of the fact that in farming, more than in almost everything else, there are few rules of universal application. It is this fact that has brought so much popular discredit on what is known as book-farming, and it shows that the discredit has not been altogether unmerited; but the trouble is, not that the art of agriculture may not be reduced to writing, but that the efforts thus far made in that direction have been incomplete. Soil, climate, seasons, and all their endless changes, have so much to do with success and failure in every case, that he is a bold man who, knowing the extent of their influence, would attempt to lay down rules for anything like general application. Yet, with all the discredit that has come upon it, merited or not, nothing has gained so sure a foothold, has wrought within a short time such marked results, and promises for the near future to meet with such general acceptance, as book-farming. Little by little we are learning vital truths, and we are learning to apply them in practice. Whenever we strike the right track there are thousands to follow us who will never turn back. If we hit upon a wrong road, there are thousands to hoot at us and to warn us away. The hooting is not amiable, nor pleasant to hear. It is neither kindly meant nor judiciously administered. It comes from the meanest and most churlish of our guild, but in spite of that it does good, and we end, unless we are foolish enough to be discouraged, by establishing some new truth or demonstrating some old one, or setting some good example that shall win to its way all those better men of our profession whom the worse ones inevitably follow.

A Farm Gate.

"F. R. S." sends a drawing of a farm gate, which he says can not sag. It is suitable for a field or barn-yard gate. As will be seen by the

A NON-SAGGING FARM GATE.

engraving, the back of the foot of the gate-post is braced by means of a block of wood wedged up tightly against the earth, and a sill being placed just beneath the level of the ground between the posts, and also wedged tightly, there can be no sagging. This, though by no means new, is a very simple and cheap gate.

A Cistern for Liquid Manure.

The preservation of the liquid refuse of stables and cow-sheds is of more importance than is generally supposed. In the vast majority of

CISTERN FOR LIQUID MANURE.

cases this is allowed to run to waste, when, if means of saving it were applied, a large amount of very valuable fertilizing matter, in a convenient shape, could be procured at a trifling expense. This material, when fermented, contains a large proportion of ammonia, so much so, that it is necessary to largely dilute it with water, or to mix dilute sulphuric acid with it to prevent its evaporation. A simple system of drains, with a receiving tank, is all that is necessary to preserve it, and if the drains are extended to the neighborhood of the kitchen, the liquid refuse of the house might profitably be saved as well. The construction of the tank, or cistern, is the principal item of expense and consideration. In reply to a subscriber, who requested a plan of such a cistern, we give the one here represented, as being cheap, substantial, and of a permanent character. It is built of brick (the wall is half a brick thick), laid in cement, with the bottom cemented. A cistern 12 feet deep and 10 feet in diameter, holding 6,500 gallons, may be built at an expense of \$50.

Will Draining injure Lowland Timber and Grass?

A singular lawsuit is now pending in Northern New York. By authority of an Act of Legislature, a commission has removed an obstruction in a river for the purpose of preventing the overflow of a large tract of swamp lands, and facilitating their drainage. The law provides that the cost of the work shall be assessed on the lands in proportion to the benefit received. Singularly (or naturally, according as the owners of these lands are honest or dishonest) those whose swamps are reclaimed, set up the plea that the drainage is a positive injury to the wood and grass grown on them. In the trial of the case the evidence has very clearly shown that, as was to be inferred, the benefit of such withdrawal of surplus moisture is marked and decided. Swamp-maple, Black-ash, Elm, Tamarack, etc., are all demonstrated to have been materially improved by drainage. There

was produced in court a cross-section of a Black-ash tree, having 42 yearly rings. The first 14 of these—produced before the drainage of the ground on which it grew—measured only an inch and a half in diameter, while the remaining 28 rings—produced since the drainage—added nine inches to the diameter of the tree. The change from the stunted to the vigorous growth was immediate, the very first ring after the improvement measuring *threetimes* as much as the last of those before it; and this proportion was maintained during the whole 28 years.

The evidence was equally conclusive in the case of all the trees under consideration; they were all immensely improved by being allowed to grow under the more favorable conditions consequent on draining. The fact is that these trees do not grow on wet lands because they prefer excessive moisture, only because, having more power to withstand it, they are not crowded out by other varieties as they are in dry land.

Another point set up was that over-wet lands produce better grass than drained lands. This is too absurd to merit discussion, and we can not doubt that the decision of the court will be such as to indicate the usefulness of what the best farmers regard as the most important improvement in farming—that is, draining.

A Rake-Cultivator.

"L. McC." writes us about corn cultivation. He has had a long experience as a farmer, which has shown him that corn needs only shallow cultivation. The destruction of weeds and the mellowing of the soil are all that is needed; any deeper stirring interferes with and injures the roots. He has abandoned the double shovel-plow or cultivator, and has changed it into the implement here figured, which he calls a rake-cultivator. After removing the shovels, he fixes in their place two blades of saw-plate fourteen inches long. These are attached to heavy tire-iron shanks, which are bolted to the standards. The rake-heads are made of 2 x 4 in. oak, with teeth of one-inch iron, sharpened at the point, and are hinged to the standards by bolts passing through and fastened with a nut. Cords are fastened to the rakes, by which they may be raised from the ground if any obstacle is in their way. The implement cuts off all grass or other weeds at two inches below the surface, and the rakes pulverize the soil and render it fine and mellow. When corn is planted in check-rows, and such an implement as this is used to cultivate it, weeds have no chance,

A RAKE-CULTIVATOR.

and the knives may be made by going twice in a row to cut them out close to the corn, and render hand-hoeing unnecessary. For root crops it would be found equally serviceable.

Glamorgan Cattle.

The once prominent and favorite Glamorgan race of cattle is fast disappearing; in fact, it may be considered as already extinct, for it is said that to procure a pure-bred bull would now be an impossibility. Its day drew to a close as that of the Shorthorn dawned. Its character and history, however, are both interesting. The well-known dairy trademark "Welsh tubs" had its origin in connection with these cattle, and was brought hither by the Welsh farmers who were driven from their occupations in their native country by the advance of iron and coal mining and smelting of iron and copper ores, at and around the well-known towns of Swansea and Merthyr-Tydvil, and who consequently emigrated to the United States. The

Glamorgan cattle were noted for the excellence and quantity of the cream they furnished, and "Welsh tubs" were highly thought of in the English markets. These cattle were one of the very ancient races whose origin was matter of tradition only; and were, when in their prime, jealously guarded by the Welshmen from admixture with other breeds. In size, they were classed amongst the large breeds. Their color was a rich brownish red, with a peculiar white stripe along the back and on the belly. Amongst the bulls, black very often replaced the brown color. The skin was a rich orange-yellow, the horns small, fine, a little curved towards the points, heads fine, neck tapering, and the carcass fattened on grass yielded from 800 to 1,200 pounds of choice beef. Probably this race reached its prime sixty years ago, and necessarily receded as agriculture began to advance from that period, and stall and grain feeding took the place of grazing. It was found then more profitable to feed Shorthorn steers, which would on the same food produce one half more beef. The finishing stroke

came when the previously flourishing meadows were torn up by mines and roads and covered with great heaps of refuse from furnaces, and the few remaining dairies became completely broken up. As a race which has passed its point of usefulness it has almost disappeared, and will soon be forgotten, and exist only in the records

of the past. However, it is quite probable that to the influence of this race the present excellence of the cheese dairies of Gloucester, an adjoining county in England, is due, for the Gloucester cows show a striking relationship to the ancient Glamorgans, but they too are also passing away, but one herd of pure stock now being in existence. Thus, in agriculture as in other

GLAMORGAN CATTLE.

matters, improvement makes short work with anything that stands in the way, and when once it has reached that point that it no longer "pays," place must be given to something new.

The engraving is redrawn from one of a series of admirable cattle portraits by Mr. Harrison Wier recently published by the "London Field."

The Neapolitan Pig of Sorrento.

BY A. B. ALLEN.

The Peninsula of Sorrento, forming the southern boundary of the Bay of Naples, in

NEAPOLITAN BOAR AND SOW.

Italy, is one of the loveliest and most favored spots on earth. It abounds with delicious tropical fruits, and grain and vegetables of a superior kind. But among its rare and varied products, perhaps nothing excels in its way their justly celebrated breed of pigs. These animals pass under the general name of Nea-

politan throughout Italy, and are said to have been perfected in the same way as the equally celebrated Berkshires were in England—that is, by a cross of the black or rather dark-colored Siamese or Tongway boar on the large, coarse females of the country. But the Berkshires, varying from the former in possessing a much greater proportion of lean meat to fat, give in their

produce the finely marbled, lean, tender, juicy hams and bacon so much sought after; while the Neapolitan pig abounds in pork of the delicacy and flavor of a well-fed six-months-old chicken.

The Neapolitan pig attains about the same weight full-grown as the Berkshire; but is generally longer in the barrel, thinner in the hams, shoulders, and face, with a more peaked nose, and ears turning forward rather than pricked up—thus giving him a more rangy style than any

other of the improved breeds. His bones and limbs are very fine, and smoothly rounded off with an uncommon fullness and delicacy of flesh. His color is a pure dark slate, and he is almost entirely destitute of hair. These are the general characteristics of the present fashionable style of breeding. Some of the pigs, however, differ a little from this description, in having a shorter nose and fuller face, and they are occasionally seen with pricked-up ears, like their male ancestor the Siamese.

Traveling north of Naples, the pigs become coarser, and show more hair. Some are of a nearly black color instead of slate; others have

large dark-colored spots on them, alternated with a dirty white or light ash color; others, again, have the front of the body of the latter color, and the hind part dark, or *vice versa*; or the whole may be slate, with the exception of a white sheet or belt round the body. Such pigs are also found on the Swiss Alps and other parts of Europe, but they do not rank as the pure improved Neapolitan of the Sorrento type. The Neapolitan pig is very docile, easily kept, fattens at any

age, and matures early. Being almost entirely destitute of hair, they suit a warm climate better than a cold one; still, when tolerably sheltered, they winter as well in our latitude as any other of the improved breeds. They make an excellent cross on common swine, especially if these are somewhat coarse and slow to mature.

These pigs are very docile, and much petted by the Italian peasantry. They even train them occasionally to guard and drive their sheep, and in this way they supply the place of shepherd-dogs. The people think so much of them as to have conferred upon them the title of *Cittadini di Sorrenti*—that is, citizens of Sorrento! Whether with this title they also add the privilege of the ballot, and admit them as representatives in their municipal councils, we are not informed; but this much we might infer, judging from their sleek, round forms and polished limbs, that they at least enjoy a due "share of the spoils" of this highly favored and fertile region. Perhaps if introduced among us, and made citizens of New York, they might prove as creditable to it as some others who of late years have favored us with their ballots and counsels. We think at least that they would keep us clear of the garbage which is now allowed to fester in our streets, polluting the atmosphere, and threatening us with the cholera, typhoid fever, and other deadly plagues.

[The engraving is from life of a pair of Neapolitans imported by Mr. Allen.—Ed.]

Walks and Talks on the Farm.—No. 103.

"It seems impossible. It is so contrary to nature."

So said a friend when I told him that a ewe would sometimes kill a new-born lamb by pawing it in order to make it get up.

It is hard to tell, I replied, what is and what is not contrary to nature. Did you ever think if anything could tax infinite power and wisdom what it would most likely be? It seems to me that it would not be creating the world, but rather in providing occupation for its millions of inhabitants, generation after generation. Men are always trying to get along with as little labor as possible. They have sought out many inventions. And yet the more discoveries they make, the more "labor-saving" implements are employed, the more work there is to do. This is the grand central law of the world, as pervading and fundamental as that of gravitation. The world was made for man, and what we call the laws of nature all tend to give him employment. It is most wonderful how, in the minutest things, these laws are contrived to encourage and stimulate us to work and study, or to punish us if we are indolent and stupid. Weeds are a curse, but when an energetic farmer goes intelligently and perseveringly to work to clean his land by repeated plowings, harrowings, and the free use of the cultivator and hoe, the weeds are not only destroyed, but the soil is enriched at the same time. The curse is converted into a blessing. Burying decaying animal and vegetable substances in the soil prevents them from polluting the atmosphere with offensive and deleterious gases. But this is not all. We get rid of a nuisance and enrich the land at the same time. Yonder swamp is now undermining our health with its malarious exhalations. The doctors tell us we can not be healthy until we get rid of the water, and draining will not only remove the malaria, but give us in addition many acres of the richest land in town.

It is certainly a "law of nature" that if we want any good thing we must work for it. You think no one doubts this simple truth; but in point of fact there are thousands of people, and I am sorry to say not a few farmers, who act as though they did not believe it. They are constantly trying to raise good crops without

using the means. "Why don't you sow that field to wheat?" asked the Deacon. "It is no use sowing wheat on it until it is drained, and I can not drain it until I get an outlet through your farm." The reply was a characteristic one: "I have known it to produce a good crop of wheat."

And so, because once or twice during the last forty years some good wheat had been raised in spots on that field, there was no necessity for draining it! Not a word was said about the numerous failures. The prizes are remembered, the blanks forgotten, and the good Deacon would have me keep on buying tickets in this agricultural lottery, while ten dollars per acre of honest industry expended in draining would double the value of the land.

If we could get at the real truth, I am inclined to believe that the main reason why the Deacon and others object to underdraining is a sort of indistinct feeling that it is "contrary to nature." If he would look at it in the right light he would find that plowing is at least equally so.

The canker-worm is making frightful havoc in many apple orchards. It was thought by some that the intense cold of the past winter while the ground was free from snow, would kill the chrysalids; but such was not the case, or at any rate there was plenty of them left, and I am glad to say that the farmers in this neighborhood are fully aroused to the importance of taking means to check the spread of this terribly destructive insect. The plan which seems to be simplest is to scrape all the rough bark from the trunk of the tree, and then take strips of paper about six inches wide and paste them round the trunk about three feet from the ground, and then put tar (*not* gas-tar) on the paper. The females have no wings, or none that I can see, and as they crawl up the trunk in the evening after a warm day in winter or spring are caught by the belt of tar and die. I have seen hundreds caught in this way on one tree. This is the only time to fight them successfully, unless it is after they have attained their caterpillar growth and descend to the ground. Some of the caterpillars come down the trunk, and might be caught with tar or killed with carbolic soap; others let themselves down with a silken thread to the ground. Now, can not some plan be contrived for killing these caterpillars before they burrow into the soil? If my orchard was affected, I believe I should spread from one to two bushels of slaked lime on the ground under every tree, just before the caterpillars began to descend, which in this section is in July. If this did not kill them, it would at any rate be valuable as a manure. As I understand the matter, they all leave the trees pretty much at the same time, and it would be worth while to keep a roller with Thomas's harrow attached behind going up and down the orchard for a few days.

The drouth is getting to be quite alarming. The winter wheat does not look as promising now (May 15th) as it did a month ago. I have not seen a good whole field of wheat this spring. There are many fields that will not give back the seed. The immediate prospects of farmers at this moment are anything but bright, though I still think that we are pretty sure of good prices in the near future, and those farmers who have their land in good condition will get pay for their pluck. It has required more than ordinary faith in good farming to sustain any one in doing much in the way of

improvement for the past two or three years. I am inclined to think there never was a time when farmers were employing so little labor on their farms. In this section, men never were so scarce nor wages so high. I do not recommend any one to spend money in building or similar improvements, but I feel sure that those farmers who make special efforts to clean and enrich their land will get their reward.

In 1868 one of my neighbors had a heavy field of clover. He commenced plowing it under for wheat in June, but the ground was hard and the crop so large that he abandoned the job. The clover dried up on the land, and formed a kind of mulch that kept the ground moist, and the clover commenced to grow through it. Sometime in July the whole was turned under, and the field afterwards sown to wheat. It was a noble crop. After the wheat, the field was planted with corn, and it was the best piece of corn I saw that year. The next spring it was sown to barley, which was also heavy, and then, last fall, the field was again sown with wheat, and I have not seen a more promising crop this season.

We have just weighed (May 15th) a couple of our grade Cotswold-Merino lambs. One, born March 2d, weighed 51½ lbs., and the other, born March 4th, weighed 54 lbs. At the same time we weighed some of the thorough-bred Cotswold lambs. They were all born within a few days of the grades, say from the 1st to the 8th of March. The weights were respectively, 48½ lbs., 50 lbs., 48½ lbs., 47½ lbs., 46½ lbs., and 48½ lbs. each. These thorough-breds are the perfection of the article. I do not believe there are any purer or better bred Cotswolds. They are all from the Mapleshade flock, imported by Mr. Wing, and, as I understand the matter, they were selected from the best flocks in England, without regard to cost. I never saw handsomer lambs than those whose weights are given above. And yet the grades, tested by the scales, beat them as early lambs for the butcher. The advocates of cross-bred animals are welcome to these facts, though I fear they will make a bad use of them. What they really prove, and all they prove, is the great benefit to be obtained from using thorough-bred rams on cross-bred or common ewes. What many say is: "Cross-bred sheep are the best; I want none of your fancy thorough-breds." It is lucky that mules will not breed, or Spanish Jacks would be kept only by the few who know something of the principles of breeding.

One of my neighbors has just driven past with a load of wheat. He has a strong wagon with four-inch tires, and rigged for three horses abreast. I stopped him to pay my respects and thank him for a good example. I have for years advocated the use of three-horse teams for *all* agricultural operations—plowing, harrowing, cultivating, rolling, drawing in hay, and for marketing the crops. We must study to economize labor. This man had on 108 bushels of wheat, and he thought it would "overrun" enough to weigh 110 bushels. The road was good, and the horses certainly showed no fatigue. In fact, when he left me, they trotted along gayly, and the man looked quite jolly mounted up on this high load of wheat. He got \$2.30 per bushel for it, or say \$253 for the load.

I have contended ever since last harvest, in the columns of the *Agriculturist*, that wheat would bring a high price this summer. I based

my opinion principally on the fact that Mr. Lawes's experimental field showed that the wheat crop of England was decidedly below the average, and that consequently there would be an active demand for export. I know too, or think I know, that our surplus is rarely as large as is estimated. Our population is rapidly increasing. Taken as a whole, we are the most active and industrious people in the world. Just now, especially, there is a great demand for labor. We work hard, get high wages, and require and will have abundance of good food. A man earning his \$1.75 to \$2.00 a day on a railroad can afford to eat bread from the best white-wheat flour. Few of us realize how much wheat forty millions of people will eat in 365 days. Just after harvest every year, the millers, speculators, railroad bulls, and newspaper correspondents all unite to exaggerate the yield of the wheat crop. Wheat may not bring a price equal to the actual cost of production; but no matter, farmers are urged to sell—and *when wheat is low* we are all more inclined to sell than when it is bringing a high price. Last fall we sold freely, and large quantities were shipped abroad, and as soon as the surplus was got rid of, and the remaining wheat was in the hands of those able to hold up go prices to a point far higher than the price abroad would warrant. We sell our wheat to the English at less than the cost of production, and make our own consumers in the end pay the loss!

I am not prepared to suggest a remedy. I leave that to abler men. But one thing I feel certain of, farmers need not abandon their business on account of temporary low prices. There is a chance for us yet. Let us study to raise good crops, improve our stock, keep up the fertility of our farms, vote for honest men, and we need have no fear that the country is going to the dogs, or that agricultural products on the whole will not sell for what they are worth.

We want to raise *better* wheat, better beef, better pork, better mutton, better cheese, and better butter. The best is the cheapest, and I think consumers are beginning to find it out. I am told that the demand for the choicest white-wheat flour is by no means confined to the wealthy. One of our large Rochester nurserymen tells me that his men, almost without exception, prefer to buy the best flour they can get, even at the almost extravagant price asked for it. They find it "goes farther," and is really cheaper than common brands of flour that can be bought for two or three dollars a barrel less money. The millers tell me, further, that it is exceedingly difficult at all times to find really choice, pure white wheat.

I am well aware that it is a very discouraging thing to take pains to raise a good article, and then have to sell it at the ordinary price. This is the fate of all who are ahead of the times. I do not believe I could get a cent a pound more for choice Essex pork from a Rochester butcher than for common pork. It is not yet sufficiently known to bring what it is intrinsically worth. But we must bide our time. I sold half a dozen well-fatted grade Essex pigs to a Rochester butcher, who packed them down. A farmer up the valley bought 50 lbs. of the pork, and in a few weeks he came again and said he "wanted some more of that pork, as it was the firmest, sweetest, and best he ever ate." "And," said the butcher, as he told me the story, "when you have any more pigs to sell I would like to buy them."

We must continue to raise a good article, and

as soon as the consumers get acquainted with it the butchers will pay something near what it is worth. I notice that the last Irish Farmers' Gazette quotes "Limerick middles 66s. to 68s. per cwt., American middles 36s. to 40s. per cwt." In other words, Limerick bacon brings 14½ cents per pound, and American 8½ cents. In a previous number, among the "Imports into Dublin during the week," I find the following item: "2,970 tons Indian-corn." I suppose that corn is used, at any rate to a considerable extent, to feed Irish pigs. And so the reason why our pork is not as good as the Irish is not owing to the food. Confessedly, there is nothing better than Indian-corn for making choice pork. Why, then, should our pork sell for 8½ cents and the Irish for 14½ cents per pound? It seems to me that this question is of vital importance to Western farmers and pork-packers.

The London Mark Lane Express says that a Norfolk farmer "sold off his farm, this spring 1,497 half-bred hoggets for £5,700," say \$31,190.40, or \$20.83 per head. For so large a flock this is a very high average.

The English papers have a great deal to say just now about the "meat supply." They seem to be seriously alarmed, and are discussing plans for getting preserved beef from South America and mutton from Australia, just as some of our Eastern papers tried to frighten us farmers with statements in regard to how cheap beef could be brought from Texas. For my part, I never was a bit frightened about it. I would like to see every one provided with cheap meat. The interests of the country demand it; but I am sure that the only cheap meat to be had is *good meat*. This apparently cheap meat is the dearest meat in the market. If the English could get this cheap mutton from Australia they would not eat it. Within a year or two past, with good, choice beef in New York, Boston, Philadelphia, and other large cities higher in the retail markets than in London, thousands of sheep were slaughtered and boiled down for the hogs and for tallow. I wish this matter was understood. Many of our farmers are deterred from paying more attention to the improvement of their stock from an idea that we shall be flooded with cheap meat from the new States and Territories. Depend upon it, nothing of the kind will ever permanently occur. You can not get good beef, mutton, and pork *anywhere* without paying some attention to the introduction of improved breeds and giving them constant care. The only way to get cheap meat is to breed animals that mature early, and feed liberally and regularly.

When I say cheap meat, I do not mean meat that sells for less than we are now paying. I do not think good meat will ever sell for less money per pound than now. What I mean is, that we should aim to produce meat so intrinsically good, that even if it sell for more money per pound it will be far cheaper than the low-priced meats are now. I am sure that this can be done. I have paid considerable attention to this matter for some years, and had I time could give facts to sustain this assertion. Taking into consideration the large percentage of water, bone, tallow, skin, gristle, and other uneatable or indigestible parts of our average meat, it is not too much to say that it is not half as nutritious as a skillful breeder and feeder can make it. Those who wish for cheap meat should look for it in this direction, and not from the half-wild animals of South America or Texas. Leaving out inside fat, there is more digestible nutriment in a well-bred, well-fed nine-months-old Essex or Berk-

shire pig than in the biggest wild hog that ever was killed—or in half a dozen three-year-old landpikes sometimes seen in the Southern States, and not entirely extinct at the North and West.

"But why did the ewe kill her lamb?" Perhaps because it was weak, and she was a believer in Darwin's doctrine of the "survival of the fittest." Perhaps because it was high-bred and of great value, and "nature" wished us to know that if we want good things we must look after them. If a good long-wooled or South-Down sheep gets on to her back, she will, if undisturbed, lie there until she dies. I do not know that this is any less mysterious or unnatural than it is for her to accidentally paw her lamb to death. If we have good stock, we must give it daily, almost hourly, attention.

Why High-priced Eggs do not Hatch.

High-priced eggs do not always hatch, for we have tried them and know. We set two dozen under orthodox hens of amiable disposition, that knew how to stick to the nest, and did it for twenty-three consecutive days. It wa'n't the fault of the expressman, for they did not come by express. They were not old. We *knew* the yard where they were laid, and they were fresh eggs. There was a twelve-pound rooster with the hens that laid them. And the result of the hatching was one thorough-bred Buff Cochin chick. Now, there are twenty reasons why they did not hatch—beginning with this, that the hens were kept confined in too small yards. We do not know what physiological laws are violated that hens kept in close confinement do not breed well. Perhaps it is because they are fowls of the air, and need a good deal of that article and plenty of mother earth to make them thrifty. The fact is pretty well established in the experience of poultrymen. There is no trouble of this kind with hens running at large. They steal their nests in hay-mows, under the barn, under the shed, in the woods, in out-of-the-way places with no protection at all, and nearly every egg hatches until frost comes. But with the fancy breeds, as they are called, come small yards, that several varieties may be kept upon the same place, and here trouble begins. All sorts of causes are alleged for the failure of the eggs to hatch. The expressman is roundly abused. The breeder is dishonest. He may be only ignorant, and over-anxious to sell eggs at six dollars a dozen. If small yards are not a good reason for infertile eggs, we will bring forward the other nineteen. The moral is: It is safer to buy high-priced eggs after seeing the fowls. CONNECTICUT.

How to Raise Roots.

To raise roots the soil must be well prepared. By whatever means it may be done, it should be brought into a rich and mellow condition to a considerable depth. A rich mellow surface is not alone sufficient for beets or mangels or other long-rooted varieties; they need to find not only sustenance, but an easy entrance into the soil for their penetrating roots; and for our climate probably beets and mangels are the best adapted and most easily cultivated. The chief requirement of a root crop being clean, mellow soil, a preparation during the previous summer and autumn is best. A stubble plowed early and well harrowed will soon show a large crop of weeds, which when all have started to grow

should be deeply turned down, the surface finely harrowed, and left to produce another crop, which the frost will destroy in its infancy. The

Fig. 1.—LAND IN RIDGES.

land should be ridged before the winter sets in, and left in this state until spring. Fig. 1 shows the shape in which these ridges may be made. There is a large surface of soil brought under the mellowing influence of the weather, and this is precisely what this crop needs. In the

Fig. 2.—RIDGES MANURED AND SOWN.

spring these may be leveled with a heavy harrow, and again opened in their proper places at distances of twenty-eight to thirty inches apart. If there has not been sufficient manure to spread twenty loads per acre broadcast in the fall to be plowed under, eight loads at least of well-rotted manure should be spread in the drills in spring. Fresh manure is not suited to roots, as it causes an unshapely and imperfect growth. With a light plow the drills may be then closed and the manure covered. The soil is then to be harrowed, and rolled if possible with a grooved roller, to suit the shape of the flat ridges, which when completed ready for sowing should be shaped like fig. 2. Before the last harrowing a dressing of fine bone-dust, of two hundred pounds up to a thousand pounds per acre, should be given, the quantity depend-

Fig. 3.—RIDGES AFTER FIRST PLOWING.

Fig. 4.—AFTER HAND-HOEING AND SINGLING.

ing on the amount and quality of the barn-yard manure or other considerations.

The seeding should not be delayed many days after the ground is fully prepared, and should not be later than early in May for mangels, and late in June for ruta-bagas. A hand-drill is a very convenient machine for sowing the seed, and, costing but little, will be found worth the expense in the saving of time and seed. Two pounds of ruta-bagas and five of mangels, of which the Yellow Globe is probably the best, is sufficient for an acre. As soon as the seed has started and the rows can be seen, a

light furrow with a one-horse plow should be thrown from the plants on each side, bringing the ridges into the shape shown in fig. 3. This destroys all the weeds excepting just in the row, which will be cut out in the first hand-hoeing. This process is performed by striking out with the hoe all the plants excepting two or three in spaces a foot or eighteen inches apart. The shorter distance will tend to give more and smaller roots, scarcely lessening the crop in weight, but increasing it in value, a well-grown, moderate-sized root being better feed than a coarse overgrown one.

After the hoeing the plants are singled, leaving but one at a place. During all these processes most of the accidents which affect the crop have been safely passed over, and there is little danger in leaving a single plant to grow. If needed, some of those removed may be replanted in vacant spaces by cutting back the root and top slightly when transplanting. When these processes are completed the ridges have the appearance shown in fig. 4, and the crop thereafter needs nothing but proper cultivation. But this is absolutely needed; neglect is fatal. Better cultivate one acre well than ten badly. One acre of mangels has yielded over two thousand bushels, but ten acres

Fig. 7.—HORSE-HOE FOR ROOTS.

neglected would not do as well as that. Therefore the hoe must be kept going. Any efficient horse-hoe which will scrape the surface, and can be brought close to the row, will answer. One of the best we have used is Shares' horse-hoe, fig. 6, with which the weeds may be cut out within an inch of the crop. Another very useful and easily made implement is shown at fig. 7. The blades are simply narrow plates of steel bent to a right angle, which cut an inch or so beneath the surface, and will work very close. The share at front stirs up the surface in the center of the drill, and helps to guide the machine. Both of these implements may be spread or contracted as the covering of the ground by the crop makes it necessary. But whatever tools are used, the utmost thoroughness must be adhered to until the ground is shaded. When mature, the crop is prepared for gathering by removing the tops with a sharp hoe, as shown in fig. 5. At a single blow, struck where the line is drawn in the figure, the top is severed, and the leaves if gathered furnish a large amount

Fig. 5.—PLOWING OUT THE ROOTS.

of useful fodder. After this has been done, a plow is run along one side of each row, and a furrow thrown away from the roots, leaving

them as in fig. 5. A harrow run across the rows in the right direction easily draws them from the soil and leaves them on the surface,

Fig. 6.—SHARES' HORSE-HOE.

where with the root-scoop (fig. 8) they may be rapidly gathered into carts or wagons. Sugar-beets, being very tender and easily damaged, should not be harrowed like mangels, but be carefully gathered by hand or with the scoop.

CURING CLOVER.—A New England correspondent writes: Now that the manure made from a ton of clover hay is proved to be worth about seventeen dollars, we ought to give clover a larger breadth upon the farm, and use the best methods of curing. Cut in the blossom, as it should be, it is full of juice, and requires several days' sun to make good hay of it, and much of its value as fodder is lost by breaking off the leaves. It saves much labor, and makes a better fodder, to put the clover into cocks after two or three hours' of exposure to the sun. Turn the cocks bottom side up the following day. The third day it may be stored in the barn, in alternate layers, with old hay, or straw, or salt hay. There should be at least as much as one fourth of the bulk of the old material. This will absorb all the moisture of the clover, and preserve it in the best condition in the mow. Cattle will eat clover-hay cured in this manner in preference to all other. Of all methods I have tried, this gives the best satisfaction.

Fig. 8.—ROOT-FORK.

The Turnip-Fly.

The small flea-beetle known as the Turnip-fly or Cabbage-fly is exceedingly destructive to all kinds of turnips when the plant is in its earliest and tenderest state. Very often the crop is totally destroyed, and resowing is made necessary when the proper means of destroying the beetles are neglected. As they are really troublesome only during a short period, and until the plants have put forth the rough leaves, one of the best preventives consists in having the soil rich and

Fig. 1.—LINE-DUSTER.

well prepared, that the crop may push forward rapidly. A method of destroying them is by passing along the rows a bag of fine light cambric or paper-muslin, made as in figure 2, and fastened on to a forked frame. The beetles

Fig. 2.—BAGGING THE TURNIP-FLY.

when disturbed jump into the bag, and a shake given to it occasionally gathers them to the bottom, where they may be destroyed. A dressing of lime in fine dry powder is effectual in preventing their ravages. The lime should be slaked dry, and if slaked with water in which carbolic acid has been dissolved is still more effectual. The lime-duster (fig. 1) is made

Fig. 1.—TOOLS FOR REPAIRING HARNESS.

of tin, with holes punched in the end, and a wooden handle fitted into the neck, by which it may be carried along the rows and the plants dusted. This should be done while they are wet with dew. By these means, with sow-

Fig. 2.—BENCH AND CLAMP FOR HARNESS.

ing an extra quantity of seed, the crop may be carried safely beyond the period of danger, after which the little pests give no trouble.

Repairing Harness.

Harness is a costly necessity, and as a matter of economy should be kept in good order, carefully repaired as soon as the least damage or wear is noticed, and be thus very easily made to last double the time it would if neglected. The materials for repairing should be always on hand, and be kept in a tool-box specially appropriated to them. This box is best connected with a work-bench as a drawer placed beneath it, where it may be readily reached by the operator. Figure 2 shows a harness work-bench, which is provided with a clamp for holding the work and a drawer for tools and materials. These consist of a ball of hemp, a piece of shoemakers' wax, a few bristles for making waxed-ends, a punch (A, in fig. 1) for making rivet-holes, some rivets and burrs (B) for splicing straps (as shown at C), sewing awls of two kinds (D, D), one with an eye to carry a thread in a similar manner to a needle, and having a strong curve, the other less curved and eyeless, a few very stout needles with large eyes, a pair of pincers with sharp jaws to cut off the ends of rivets (as shown at F), a light hammer to clinch the rivets, and a small block of iron, weighing a pound or two, to use when clinching rivets, unless a flat-iron, which will answer admirably, can be borrowed on such occasions. Furnished with all these appliances, there is no reason why a harness should go unrepaired over one night, and as "a stitch in time saves nine," it will be found very profitable to be ready to put in that stitch just when and where it is wanted. Figure 3 shows a method of sewing a loop for a tug or strap, which is sometimes found a difficult job. It was sent by a correspondent who forgot to attach his name, so that we do not know to whom we are obliged for it. He says it has been found of great use to him. He first places the awl as at a, fig. 3, passing through both strap and loop, and then (as at b) passes the awl in a contrary direction, so that both holes unite in one at the top. This enables the thread to be sunk below the surface of the loop, saving it from wear. The complete stitch is shown at c. Another method which we have used is shown at d. The needle-awl is passed through the strap, and comes out at the side of the loop, the thread is put through the eye, and the awl is brought back and the stitch drawn tight. With the common awl and two waxed-ends with bristles, a double stitch may be made which is very strong.

Grow Turnips.

Roots are always valuable as an adjunct to the winter supply of hay. This all farmers will confess. The extent to which they may be made useful as a substitute for hay few American farmers notice. Those who have already started a good breadth of beets and of ruta-baga turnips are fortunate. Those who have not done so should at once set about increasing their supply. It will do to plant ruta-bagas until

July 10th—the earlier the better of course—and by doing so we may insure a good crop that it will be very convenient to have for use late in the winter. Remember, that for this crop no other manure is more valuable than bone-dust—say 100 lbs. per acre in the drill at the time of planting, and the same amount or more broadcast after the crop has been thinned out, to be immediately covered with the hoe or cultivator.

From July 25th to August 10th (better at the earlier date) is the time to put in "round tur-

Fig. 3.—METHODS OF MAKING STITCHES.

nips," the best variety being the Strap-leaved red-top. These are not of much value after the first of January, but before that time they are excellent food for all neat stock and for sheep and swine. For milch-cows they must be fed sparingly, and only immediately after milking, else they will affect the taste of the milk and butter. However they may be used, they will help out the scanty winter's supply of hay in a most satisfactory manner.

A Simple Hay-Press.

We have received many inquiries about the hay-presses referred to in an article in the American Agriculturist of April, 1872. We now give a drawing of the one more particu-

Fig. 1.—HAY-PRESS—SIDE VIEW.

larly referred to as being of very moderate cost, and able to bale four tons of hay in a day with the labor of two men. It consists of a frame of oak or other hard wood, four feet wide (inside of the posts) on the side (shown in fig. 1) and three feet on the end (fig. 2). The height is eight

feet. The frame consists of four corner posts, a sill, a cap-piece, and two girts on each side and end. The lower girts are placed a foot from the sill, and on them rests the movable bottom (fig. 3), on the middle cross-bar of which is fixed two hooks, seen at *a, a*, fig. 1. At *b, b*, fig. 1, is shown a roller which works in boxes bolted to the posts on one side. This roller is furnished with guides (*c, c*), which confine the rope as it is wound up, and a ratchet and catch to keep it in position when turned by the lever shown in fig. 2. This lever fits in slots in the wheels (*d, d*), which are preferably of cast-iron, and as it is pressed down turns the roller and winds up the rope, which passes through a pulley-block at the top of the frame and raises the movable bottom. At the top of the frame are shown the ends of some loose bars (two or three are sufficient), *e, e, e*. These are slipped in over some loose boards placed on the hay when the press is filled, and confine them to their place when the press is worked. To work the press, it should be brought near the mow or

by its elasticity. A bale of hay made in this manner needs no slats or sticks of wood at the corners, and will weigh about 180 pounds. A

Fig. 4.—HAY-BALE WITHOUT LATHS.

common wooden screw, similar to those of the old-fashioned cider-presses, may also be fitted into the frame to work the press, but it is more cumbersome in working, and occupies more room than the roller.

Besides this sort of press, there are several more powerful, which may be worked by a two-horse power, and will bale ten tons per day. Their cost is \$100 and upwards. As by the process of baling, hay can be transported by rail at reasonable freights, when unbaled hay can not be moved unless by wagon, it is seen how easily a much increased value is given to this important product; this as well as straw, which is subject to the same conditions, always bears a high price in large towns and cities, while a hundred miles distant it may be comparatively valueless to turn into money.

What Lands will it Pay to Drain?

Our readers do not need to be told that we are firm advocates of underdraining. We believe that judiciously done it is the most profitable improvement that we can make. At the same time, we have narrowed down our ideas of what is judicious in draining, until we have reached the following conclusion:

It is not judicious to spend money in draining land that needs draining, so long as we can use the money to good advantage in the better cultivation of other good land that does not need draining.

In other words, we believe that the true maxim for the improving farmer is: "Be thorough as you go." Don't improve the whole farm at the same time—gradually getting the worst lands into condition to pay half their expenses—but (unless the working capital is a large one) confine yourself to land that will pay full expenses—and a profit. If a field that is otherwise the best of the farm fails to do as well as it ought because it needs draining, then drain it by all means, and when it is dry manure it and cultivate it thoroughly, and continue to devote to it all the manure and care for which it will pay a good profit. When it is in such good condition that more money can not profitably be spent on it, then take up the next best field and improve that. If it needs draining, then drain it; but if not, then, instead of draining some other field, let the draining wait, and use the money to make this land as good as, under the circumstances, it will pay us to make it. And so go on—being thorough as you go—devoting the first investment to the best land, and the next to the next best, and letting the character of the land determine whether the in-

vestment shall be in drains, in manure, or in labor, or in all three of these.

It may pay very well to underdrain land at a cost of \$70 per acre, when the effect will be to increase the hay crop from 1 1/4 ton to 2 tons. The 3/4 ton is an addition to a crop that we must go to the expense of making, and if hay is worth \$20 per ton it will pay a profit equal to about twenty per cent of the cost of the draining. But it will not pay to spend this amount to underdrain waste land for the sake of raising its produce from nothing to one ton per acre—for such a crop would pay no profit.

The old saw is right in saying that he is a benefactor of the human race, not who makes a blade of grass grow where none grew before, but who makes two blades grow where one grew before. If the old saw-master had been a high-farmer, he would have given even greater praise to him who made three blades grow where two grew before; for the reason that in this case the extra yield would have been produced at less cost of labor, leaving more labor for other productive work.

When this principle shall have been adopted, then we shall see underdraining much more largely resorted to. But farmers soon sicken of draining swamps to let them lie waste, because it won't pay to manure and work them at the expense of the better parts of the farm.

The Southern Park-Gate.

Dr. Gilbert, of Memphis, sends us a drawing of a park or plantation gate, which he says is "the only perfect gate, and the most economical one ever invented—plumb, immovable, and unchangeable. It can not sag; admits wagons loaded with cotton or hay; keeps out thieves; and is very valuable for stock and stable-yards near cities." The size of the opening is 10 ft. by 14 ft. The posts should be of cedar or locust, the brace straps of oak, and the other parts of light stuff, well seasoned. This gate is prevented from sagging by means of the diagonal rod across the top, in the middle of which is a screw by which it may be drawn up

SOUTHERN PARK-GATE.

tightly when needed. The gate-post turns in a cup in the sill. A small quantity of blacklead and tallow in this cup will cause it to turn easily and without creaking. The hole in

Fig. 2.—HAY-PRESS—END VIEW.

stack, the cords, made of proper length to tie the bale, looped at the end, and placed in position, as seen at figure 1, the hay thrown in, and one man in the press should tread it down as it is forked to him. When the space is filled as closely as possible, the top boards and cross-bars (*e, e*) are put in place, and the bale pressed until it is brought to a thickness of 2 1/2 feet, when it is tied securely, and lowered and removed from the press through the lower half of

Fig. 3.—BOTTOM FOR PRESS.

the side which is made movable. This movable side is held in place by four bolts, which are easily withdrawn when necessary. To facilitate the removal of the bale it is well to make the frame of the press two inches smaller each way at the top than at the bottom, then, by releasing the catch of the ratchet-wheel, the bale will slide downwards by its own weight without binding

the cap in which the upper part of the heel-post turns should be thus lubricated.

Hints on Haying.

Making hay "on paper" and making it on the farm are two very different things. In this case, as in so many others in agriculture, "to know is not to be able." A man may have a very accurate knowledge of the principles and practice of hay-making, he may understand all the changes that should and should not take place, and yet make very inferior hay. There seems to be a kind of "knack" in making hay that is hard to acquire, and still harder to communicate. We can not know too much about the science of hay-making, but it is still more important to have energy enough to apply our knowledge. And it must be energy of the right kind. We all know men who seem to be remarkably active and industrious, and who yet never accomplish anything. Such men rarely make good hay. What is needed is a disciplined mind, that can lay plans wisely and take every detail into consideration. He must know that his mowing machine is in complete order, and that he has on hand duplicates of such parts as are most liable to break. He will not put off grinding the knives, tightening the bolts, and examining and cleaning the journals until the moment he wants to be in the field. He will not cut down the hay and then go for the tedder or rake and find a bolt out or a tooth broken. He will have everything ready in advance—mower, scythe, whetstone, tedder, rakes, forks, wagons, racks, unloading tackle—all will be ready, and just where he can lay his hands on them in a moment. He will not have to spend an hour or two cleaning out the barn or making a stack-bottom, some afternoon when the hay is overcured in the field and a threatening cloud in the western sky. The good hay-maker is a man who not only knows *how* hay should be cured, but he is possessed of the energy, forethought, and patience to prepare for and direct every detail of the operation.

And recollect that *patience* is the crowning virtue of the farmer's life—not the false patience which springs from indifference, indolence, and a sluggish mind, but that quality which produces a "masterly inactivity," that waits until the right moment, and then puts forth all the powers of mind and body to accomplish the purpose. Give such a farmer a good crop of grass and an ordinary season, and he will be sure to make it into good hay and get it safe into the barn.

We can not go into details. The main points to be observed in making timothy or meadow hay with little or no clover in it are:

1st. Cutting the grass when in flower and before any seeds are formed. If we cut too early we lose substance, if too late we lose quality. If the hay is for market or for horses we should let it stand longer than if it is to be fed out on the farm to milk-cows or sheep.

2d. Cut it so that if it is necessarily exposed to dew the dew shall fall on while the grass is green rather than after it is partially cured. This is one of the most important practical points in hay-making. Dew or rain will not hurt fresh, green grass, provided it is got rid of before the grass begins to wilt. In heavy grass, therefore, that can not be cured in one day, we should start the mower late in the afternoon, say four o'clock, and cut as long as we could see. Rain or dew will not hurt it any more than if it was standing uncut. The next morn-

ing, the moment the dew is off, or a little earlier, start the tedding machine, *lively*, and *keep it going*, changing horses if necessary. The more frequently the grass is stirred the more rapidly it will cure. If kept well stirred, the hay will be ready to draw in immediately after dinner.

3d. When grass is cut in the morning, if a light crop and somewhat overripe, it may not unfrequently be drawn into the barn the same day. But with heavy green grass this can rarely be done. Keep stirring the hay until about four o'clock in the afternoon. Then rake into windrows, and put it into cock for the night. If exposed to rain or dew while spread out on the land in this partially cured state, it will be very seriously damaged. The next morning turn over the cocks, or open them out if necessary, and draw in as soon as dry enough.

4th. When grass is cut, and rain sets in immediately, while the grass is spread out on the land as left by the machine, or in swaths, nothing can be done. It is better not to touch it until there is a prospect of getting it sufficiently dry to put in cock. As long as it is green it will not hurt.

5th. When partially-cured grass is wet with a sudden shower while spread out, it can not be turned or shaken out too quickly after the rain is over. Do not wait for the ground to dry. Better spread out lightly on the wet grass, so that the wind can get through it, than allow it to lie flat and sodden. It is necessary to be very careful to get such hay *perfectly dry* before drawing in. Spread two or three quarts of salt on each ton of this damaged hay when put in.

CLOVER HAY requires more time in curing than timothy and meadow hay. But the principles involved are essentially the same, except that after the clover is partially dry care must be taken not to shake off the leaves and blossoms. If cut early, the tedder may be used to great advantage. A good plan is to cut the clover late in the afternoon, and the next morning, as soon as the dew is off, shake it out with the tedder. Then, in an hour or two, rake it into small windrows five or six feet apart with a steel-toothed rake. Turn these windrows with a fork, say once before dinner, and then immediately after dinner. About three or four o'clock, rake into large windrows and cock up carefully for the night. If necessary, spread it out the next morning and turn it over in an hour or two. That which was opened first will probably be ready to draw in by half-past ten or eleven o'clock. There are many other methods, but, all things considered, we prefer the one we have briefly described. If we could be sure of the weather, we should cure the hay in the cock, and it is often convenient to adopt both plans.

Keeping Roads in Repair.

The best system of mending the highway is that which mends soonest. The old method of working the roads annually by the tax-payers in person has gone out of use in many places. The work was not well done, although the tax-payers had to use the roads they mended. The highways need constant supervision by one man in each town who understands the business, and who can remedy a defect as soon as it makes its appearance. A deep rut is made deeper by every loaded team that passes over the road, and where the system of annual repairs prevails the highways are almost impassable in the early spring. We want the same thorough system of supervision that prevails on

our railroads transferred to the highway. This has been adopted in some towns in Massachusetts, and is found to be much better economy, and to give them much better roads. A load of gravel in season applied to the ruts and gullies saves the necessity of two loads applied at the end of the year. Travel on a well-made road does far less injury than the rains and frosts. If the inequalities are immediately remedied, travel rather helps than hinders road-making. Every one prefers the well-beaten track to a new-made road. It is quite possible to distribute the repairs so evenly through the year that the road-bed may be always in good condition. The loss to the farming community from bad roads is enormous. It is one of the heaviest taxes we have to pay. It is laid on every article that goes from the farm to market, and in many cases the tax is so heavy that it swallows all the profits. Good roads lessen the cost of production; they would cheapen the grocer's bill, the miller's bill, and especially the cost of fertilizers, which are the secret of economical farming in the older States. Work the roads to-day, and save money.

SHALL WE GRIND GRAIN FOR COWS?—A correspondent says: "If a cow in chewing her cud throws up all she eats and chews it over again, I do not see where the advantage is in getting corn ground at all to feed ruminating animals." The proof of that hasty-pudding is in the eating of the corn by the cow. Feed her on whole corn, and you will find that, even in twice chewing, she does but indifferent work, and that much of the grain in her food is passed in whole kernels. Grind her corn for her, and a smaller quantity will nourish her as well. More hogs can be fattened after animals fed on whole corn than after the same number fed on meal. Lastly, try the comparative experiment (under exactly the same circumstances) and you will satisfy yourself.

Fiber from Cane.

Every man or boy who has used a fishing-pole is acquainted with the cane, cane-pole, or reed, as it is variously called. There are two species of cane, the Large Cane (*Arundinaria macrosperma*), and the Small Cane (*Arundinaria tecta*), the one growing from ten to twenty feet high, and the other seldom reaching above ten feet. Both species are found from Virginia southward, but the large species is best known, and it forms extensive tracts in waste and swampy ground known as "cane-brakes."

Until recently, the chief use of canes was for fishing-rods and for making cages and such uses. In the search for material, for paper-making, the cane was found to yield a serviceable fiber, and now there are several manufactories of it in Virginia and North Carolina.

This manufacture is an interesting instance of the conversion of what is otherwise almost a waste product into a valuable article of commerce. In California vast tracts are covered by the Tule, and in the Eastern States hundreds of acres are covered only by the Cat-tail, and though the attempts to utilize these have not been quite successful, the time can not be far distant when such a vast amount of vegetable fiber will be made to serve some useful purpose.

We give sketches of the processes of fiber-making from cane, drawn by Mr. J. D. Woodward, at the factory on the Cape Fear River,

N. C. The notes furnished by Mr. W. say: "The cane on the borders on the Cape Fear River and its tributaries is particularly abun-

leaves that valve, and the steam in the dome rushes out with such force that it carries the cane before it. On reaching the atmosphere,

steam-pump under four beating engines, similar to those used in the paper-mills, except that the fiber passes from one to the other instead of

Fig. 1.—THE BATTERY—LOADING THE CANE AND FIRING OFF THE FIBER.

dant, the average height to which it grows being twelve feet. Large gangs of negroes are sent up into the swamps to cut it, under the superintendence of a white overseer. It is then made up into bundles, for convenience of future handling, corded up, and the tops cut off, the cutter being paid by the cord. Other gangs 'tote' the cane from where it is cut, and load it in large flats capable of carrying 150 cords at a trip. When landed at the company's dock, the bundles are opened, cleaned of all refuse matter, trimmed up, and made into compact bundles, from seven to eleven feet in length and one foot in diameter. The bundles are then taken in hand-cars to the gun-room of the factory. In the gun-room is arranged a battery of five guns, 23 feet in length, each surmounted by a steam-dome having connection with high-pressure boilers. The guns being loaded, and the front and rear valves screwed tight, steam is turned on at a pressure of 180 lbs. to the inch.

the steam with which all the pores of the cane are filled violently expands, thoroughly disintegrating it, and the load strikes a target, at about

traveling round and round. It then passes on to an endless wire apron, and is carried through several sets of iron rollers, the last set being covered with india-rubber. The fiber is thus squeezed of all water that will run from it, and comes off in a thick, solid sheet. By this washing the bulk is reduced one third, being deprived of all the gum, dirt, etc. Next, the fiber has to be dried. It is slightly picked apart and thrown on to an apron, which leads it through feed-rolls to a picker, revolving at a high rate of speed, which thoroughly pulls it apart, and throws it on to the apron of the drying-house. This house is seventy feet long, and is heated by four steam-pipes running side by side. The endless apron travels slowly over these pipes—taking about twenty minutes to make the trip—

Fig. 2.—CLEANING AND BUNDLING CANE.

thirty feet from the guns, a mass of brown, sugary-smelling fiber. The report made by the expansion of the steam is equal to that of a large cannon. The fiber is next submitted to

and the fiber is taken off at the end perfectly dry. It is then baled by one of Dederick's hay-presses, and made into bales, averaging 500 lbs. in weight. The pulp made from this fiber

Fig. 3.—WASHING THE FIBER.

After being in this steam-bath for twenty minutes, a trigger, or rather a rod connected by cranks to the front valve, is pulled, which re-

turns the washing process. It is gathered up, thrown into large tubs, and passed by means of a continuous stream of spring water thrown by a

is soft, and admirably adapted for making paper, either alone, or mixed with the harsher paper-making substances, such as straw, etc."

Fig. 4.—ROLLING THE FIBER.

The Indian Turnip (*Arisema triphyllum*).

But few of our wild-flowers are so likely to attract attention as the Indian Turnip. It is so unlike others in its form, its coloring is so peculiar, and it has altogether such a strange, weird look, that those who care but little about plants in general will be quite sure to notice this. It

ones, or one or the other kind of flowers may be abortive, and thus the plant becomes, as it often does, *dioecious*. The spadix is prolonged above the flowers into a smooth club-shaped body, which sticks up in the center of the spathe and is seen under its incurved point. Some imaginative person has seen the resemblance between this arrangement and the old-fashioned

ing plant, and desirable in a collection of aquatics. Its leaves, usually floating, are of a singularly beautiful green. These arise from a deep root-stock, as do the flower-stalks. The Golden-club belongs to the same family (the Arums) as does the Indian Turnip described elsewhere, but while in the last-named the spathe is the conspicuous part, and quite conceals the

INDIAN TURNIP.—(*Arisema triphyllum*.)GOLDEN-CLUB.—(*Orontium aquaticum*.)

is found in rich woods and on the margins of swamps, flowering in May and often much later. The engraving gives a representation of the plant, which varies much in both size and coloring. Below the surface we find a solid bulb or corm, which is dark-colored without, white within, and so much shaped like a turnip as to have suggested the common name—Indian Turnip. From this corm arise one or two leaves, which are divided into three parts or leaflets, and a flower-bearing stem. The conspicuous hood-shaped body which popularly passes for the flower is only a leafy envelope that surrounds and protects the flowers. Botanically, it is called a *spathe*, and it is just such an organ as we find, though of a different shape, in the cultivated and nearly related Calla. The spathe in the Calla is pure white, and it has its point turned back from the center, while in our Indian Turnip it is variously colored, and its point is bent inward toward the center. Sometimes the spathe is green, with yellowish markings, and frequently it is dark purple with whitish or yellowish stripes and spots, and the leaf-stalks freely marked with purple. To find the flowers we must look inside the spathe, where we shall find them clustered at the base of a fleshy stem called a *spadix*. We may find pistillate flowers at the base and above these staminate

pulpit with sounding-board, and has given the plant the fanciful name of Jack-in-the-Pulpit, a name quite popular in some localities.

The fleshy corm, or root as it is popularly called, is when fresh extremely acrid. A small piece placed on the tongue produces the same sensation as scalding. Mischievous people sometimes play tricks with it, and its great acridity has led to its use in domestic medicine. The pungent principle is destroyed by heat and dissipated by drying. The corm contains a large amount of starch of very fine quality. The starch is separated by grating the tuber and washing, and is nearly equal in quality to arrow-root. Another species, called the Green Dragon (*Arisema Dracontium*), is less common. It has its leaves divided into seven to eleven parts, and the point of the spathe is erect. This is less common than the other.

The Golden-Club (*Orontium aquaticum*).

The Golden-club is very common in the Southern States, and is found here and there as far north as Massachusetts. Mr. Hallock, of the firm of C. L. Allen & Co., florists, Brooklyn, recently brought us a fine lot of specimens from near Flushing. It is a very handsome and interest-

ing spadix which bears the flowers, in the Golden-club the spathe is small and at the lower part of the stem, while the spadix is quite showy. In the reduced engraving we give the leaves and the spadices; the spathe, being small and submerged, is not shown. Here the flowers are all perfect, and so crowded all over the spadix that they appear like a solid mass. They are of the brightest golden-yellow color. The stem just below the flowers is pure white, and the contrast between the white and deep yellow makes the plant quite showy. The root-stalks are starchy, and are said to have formed when roasted a part of the food of the Southern Indians.

Insects in Relation to Horticulture.

That insects frequent flowers is a matter of common observation. Not only do bees of various kinds and the large moths go to the flowers to feed upon their sweet juices, but multitudes of small insects that escape ordinary notice are engaged in the same occupation. The horticulturist sees his plants bloom, and he expects them to bear fruit and seed, with but little thought that the success of his crops often depends upon insects. We have so much to say about the injury done by insects that it is

pleasant to be able to speak of them in other aspects. The relation of plants to insects is a subject just now engaging the attention of naturalists, and there is much about it to interest every one who grows plants of any kind.

Most flowers offer nectar and pleasant odor to attract insects, and we know that some, especially the bees, are very busy in availing themselves of the sweets thus set before them. Does the plant offer this treat of sweets to the insects out of pure benevolence, so to speak? Not at all. This feast of nectar is offered to the insects as a compensation, if they will in turn do something for the plant. What this something is, we can only briefly indicate, but we can state sufficient to show that the relations between plants and insects are more complicated and more important than is generally supposed. It is within the knowledge of every intelligent person that plants have stamens and pistils; that the stamens produce a fine powder—pollen—which fertilizes the pistil, and that this contact between the pollen and pistil must take place before the pistil will develop into a fruit or seed-pod. It is well known to orchardists that a violent and long-continued rain-storm at blossoming time will seriously injure the fruit crop, as the pollen is washed away by the rain, and is prevented from performing its proper office. In some cases, as in the willows, poplars, the hop, etc., flowers with stamens only and flowers with pistils only are borne upon separate plants. These plants may be fertilized by the wind, which carries the pollen from one tree to another, or by insects which convey the pollen adhering to their bodies from one plant to another. Other cases show stamens and pistils in separate flowers but on the same plant. The squash, melon, and all of that family are familiar illustrations of flowers of this kind. Every one who has worked in a garden knows the male (staminate) flowers and the female (pistillate) flowers of these plants, and have seen the insects, "as busy as a bee in a pumpkin-blow," going from one flower to another, getting as dusty as millers in the staminate blooms, and then going to the pistillate ones, where, in their greedy search for nectar, they are sure to rub some of the pollen upon the pistil.

In these cases we can understand the use that insects are to plants in the matter of fertilization. But the greater number of plants present us with stamens and pistils in the same flower. The pistil stands in the center, surrounded by a few or a countless number of stamens all ready to fertilize it—only they don't as a general thing do it. One would think that the flower was so thoroughly arranged for self-fertilization that insect aid would not be welcomed, much less needed. This most interesting subject was first prominently brought forward by the great naturalist, Darwin. In the *American Agriculturist* for 1866, Prof. Asa Gray gave an admirable series of articles, illustrating them by reference to American plants. We are glad to know that the matter has again been popularly presented by Prof. Gray in a charming little book called "How Plants Behave," which, though intended for young people, presents in an attractive style the results of the most careful observers, and can be commended to maturer minds as well. We have not space to explain the curious relations of insects to those plants which have perfect flowers—i. e., containing stamens and pistils in the same flower—but must refer the reader to the articles and the work just named. This very frequent provision that a pistil shall not be fertilized by the pollen of the same flower, but that the pollen of an-

other flower shall be brought to it by means of insects, has an object, and that object is one which every farmer will understand—to prevent close breeding. Were in-and-in breeding carried on continuously in plants the result would be the same as with animals—certain individual peculiarities would be perpetuated, and become fixed, to the detriment of the general welfare of the species as a whole. A curious instance of injury resulting to an insect while it is working for the good of a plant is given in another article entitled "What Ails the Bees' Legs?"

A Good Rotation for Farm-Gardening.

It is now becoming a very important part of the business of farming in the vicinity of large towns to raise vegetables for sale in their markets, and the system pursued by those who are exclusively market-gardeners near the great cities, where land is very costly, is not the best adapted for the different conditions of farm-gardening. In the country, rents are lower, and manure is either higher, or more difficult to get, or more needed for other uses.

This points to the use of clover as a fertilizer. Almost any garden crop grows best on a well-tilled clover lea, and cabbages are especially benefited by it, while they are also the sheet-anchor of the market-gardener. Late cabbages are rather uncertain, and must sometimes be used for fodder for want of a market (though even then they are a profitable crop), but early cabbages hardly ever come amiss. A manufacturing population may be depended on to use a dozen heads per week of Jersey Wakefields for each family of six or eight persons, and the market is rarely overstocked, inasmuch as this crop requires special treatment, that can not be given, by the acre together, by common farmers who raise late cabbages without difficulty. After some years' experimenting, we have settled on the following plan as best adapted to our circumstances:

Our field is divided into three equal parts, and is planted on a three-year course. The diagram is copied from the one actually in use as a memorandum.

First Section, First Year.	Second Section, First Year.	Third Section, First Year.
All in clover, sowed early on land plowed in the fall after celery is removed.	½ in early cabbage, followed by horseradish ½ in early cabbage, followed by fall spioach	¼ spring spinach, followed by late celery. ¼ winter spinach, followed by early celery.
First Section, Second Year.	Second Section, Second Year.	Third Section, Second Year.
Two halves in early cabbage, horseradish, and spinach.	Two halves in spinach and celery.	All in clover.
First Section, Third Year.	Second Section, Third Year.	Third Section, Third Year.
Two halves in spinach and celery.	All in clover.	Two halves in early cabbage, horseradish, and spinach.

The fourth year repeats the first year; the fifth year repeats the second year, etc.

On land in good garden condition the clover will need no other manure than a couple of bushels of plaster sown over the leaves of the young plants when wet with the dew. It will produce an abundant supply of green food for soiling or other use, amply repaying the cost of production and rent of land. In November it

should be covered with a heavy dressing of the best manure, and at the earliest possible moment in the spring it should be plowed and very thoroughly harrowed. The plowing should be shallow, and if the land is hard below, the subsoiler should be used. On such land, a good crop of early cabbage is a moral certainty, and with the subsequent horseradish crop on one half the field, the return should pay a handsome profit on the first and second years' use of the ground.

The subsequent crops may be varied according to the market. Spinach is almost always profitable. Whether celery is so or not will depend on one's facilities for selling it. It may be well to substitute early beets or parsnips for the early celery, and transplanted mangolds, or ruta-bagas, or Lane's sugar-beet for the late celery. Whatever change is made, the land should be cleared and plowed for clover in the fall, so that we may have the full season's growth of this to prepare the field for the *sine qua non* of successful gardening—a crop of early cabbage.

Of course, the land must be well manured the second year. Bonedust or "Phosphatic Blood Guano," at the rate of 500 lbs. to the acre, will always pay on the cabbage land, before the last harrowing, no matter how much other manure has been used. 1,000 lbs. or 1,500 lbs. to the acre might enable us to get along without other manure.

Cold-Frame Cabbage Plants.

BY PETER HENDERSON.

An article in the June number of the *Agriculturist*, by a writer who gives no name, and, worse than that, no location, was written evidently with the desire to do good, but the advice, if followed, will most certainly do a great deal of harm in the latitude of New York, or even further north. He complains that by sowing on the 20th of September last year, his cabbages were too small to "prick out," and that in consequence he lost all those that were not so treated; and now advises to sow from the first to the fifth of September. If any of the early cabbages were sown in accordance with his advice in this locality, in nine years out of ten, three fourths of them would run to seed. This was the very ground upon which the Philadelphia market-gardener who sued Mr. Dreer for damages in having sold him bad seed got defeated. It was proved that he had sowed his seed upon the 5th of September, instead of the 15th, and numbers of experienced gardeners testified in court that no other result than a failure could be expected; besides, it was further corroborated by dozens of others who had bought the same seed of Mr. Dreer, that their crops had not run to seed when sown at the proper time. It may seem to the uninitiated in such matters, that a few days earlier or later in sowing could not be of material importance; but all experienced market-gardeners know it to be a fact beyond question, so that here no one ever begins to sow his seed before the 10th, and the great majority uniformly sow on the 15th. My own plan is to sow twice, on the 12th and on the 16th of September, and I should far rather risk even the 25th than the 5th. Much depends on the condition of the ground. It ought to be mellowed and enriched to the highest possible point by plowing and harrowing, or digging and raking, and well mixed with a heavy dressing of thoroughly-rotted stable manure, in quantity when spread sufficient to cover

the surface at least three inches. In absence of stable manure, *pure* bone-dust or blood and bone-dust should be used, in the ratio of at least one ton to the acre, and of course thoroughly mixed in with soil designed for the sowing of the cabbage. Ground thus prepared, will in any season I have ever seen in this vicinity give excellent plants, fit to "prick out" four weeks after sowing; that is, if we sow on September 15th, we have plants of just the right size to "prick" into the frames by Oct. 15th.

The article makes an assertion with which I can not agree. It says that when the stem of a cabbage plant is split it makes a loose head. If it is split severely enough to be decayed, it will die long before it gets a chance to form a head; but if not, the split part will form a callus, just as the slip of any plant does before it roots, and when planted the roots will develop from there better than any other part of the stem. In the area of a mile from where I write there is probably a million cabbages planted, most of them just beginning to "head up," and I think it safe to say at least one half of them when planted were split in the stem, and, by the way the most of them look now, I should say few of them will form loose heads, but will be likely to give good solid results to the owners. This cold-frame cabbage business is now an important one, engaging the attention of hundreds of your readers in every section of the country, and if the article in the June *Agriculturist* had been accepted as applicable to all localities it might have lessened some poor fellow's profits next season.

[The article to which Mr. Henderson takes exceptions was by Col. Waring, of Newport, R. I., and we should have so stated when we published it. Col. W. gives his experience in the climate of Newport, and Mr. H. his in that of New York, and our gardening readers have now both sides of a subject.—ED.]

Notes from the Pines.

WE HAVE BURIED OUR DEAD—or, what is the same thing, carted them to the brush-heap. They were mainly evergreens, but some deciduous things went too. Evergreens of great rarity, that had been established just long enough to give promise of future beauty, went to the same heap with the more common but not less useful Hemlock, Norway Spruce, and Arbor-vite. Among the deciduous trees that suffered most on my grounds were European Chestnut, Scotch Laburnum, Catalpa Kämpferi, Mahaleb Cherry, and Deciduous Cypress. Almond-trees were badly injured, while the Peach, though most of the flower-buds were killed, was all right as to its leaf-buds.

THE CAUSES OF THE WINTER-KILLING that have been assigned are principally these: The unusual depth to which the soil was frozen; the unusual cold (zero or near it) in March, following a mild spell in February; the unusual dryness of the soil during the winter, and the prevalence of drying winds. I think that a combination of the last two causes produced the results. Some curious cases appear difficult to account for. With trees, apparently just alike, standing side by side, one was taken and the other left unharmed; also one half of a tree would be killed, and the other half untouched.

THE BLOOMING OF FRUIT TREES was in our neighborhood something wonderful. There are numerous old orchards, the trees in which are fit only for fire-wood, yet every worthless, half-

decayed old tree was completely sheeted with bloom. Nor were the valuable trees less full. My little *cordon* apple-trees were what the name implies, garlands; and my bush apple-trees were filled from the ground to the very top, forming the most beautiful monster bouquets it is possible to imagine.

THE RED MAPLES have shed their seed. I have four trees, and am thankful that only one, and this not the largest, is a bearing one, but this supplies seeds enough to make it a complete nuisance. The fall of the maple keys is worth watching. The heavy end, which contains the seed, is downwards, while the wing acts as a parachute, and this being one sided, the key as it falls takes a rapid spinning motion, which delays its descent, and allows the least breeze to waft it to a distance from the tree. In watching this beautiful contrivance for the dispersion of the seeds, one is inclined to forget the trouble that the young maples will give him as weeds, springing up in every corner. A skilled sower could not cover the ground more evenly with grain than it is now strewn with maple-seeds.

TREE-LABELS.—If anything illustrates the "depravity of inanimate things," it is a tree-label. If any one is careful to have the wire loose, I am, yet I go about and find here and there some branch has grown so out of all reason that the wire is already strangulating the bark. Let me advise those who have set trees this spring just as they came from the nursery, to go over them at once and look to the labels. The nurseryman, when he wires on his tag, puts it there that the tree may be identified by the purchaser, and he fastens it securely. The wire is twisted on tight, and if left thus, strangulation and injury will result. With cherries and peaches, I find it makes no difference how loose the wire is. If it hangs in a crotch, the wire will somehow get imbedded in the bark.

PLANT-LABELS—by this I mean those stuck in the ground, as distinguished from those tied to trees and shrubs—are also annoying. If small, they will get lost at the first hoeing, and if large they disfigure the beds. If there is a garden workman who appreciates the importance of a label I have yet to make his acquaintance. I have adopted a stake so large that it can not be hoed up without considerable trouble. In small gardens one can trust to memory, but where the plants are numbered by hundreds, and many things are new and on trial, a label becomes a necessity.

PACKING PLANTS.—What a difference there is between good and bad packing! Most florists and nurserymen put up plants admirably, but once in a while one makes bad work of it. The general fault is too little moss or other packing material; sometimes this is too wet, and the plants put in so loosely that they can move about. Last year I paid \$5 for some plants, and as much more for express charges, from a distant nurseryman. When the box was opened, the whole lot was not worth a dollar. The plants were put in dripping-wet moss, and not closely packed. In the long transit, plants and moss were shaken up into a mush.

COLUMBINES have bloomed splendidly this spring. Too much can not be said in praise of *Aquilegia cerulea*, from the Rocky Mountains. It is the most graceful and charming of all. Do you know what a beautiful thing our native Columbine (*Aquilegia Canadensis*) is in cultivation? Not only are the flowers more abundant and finer than we usually see it in the wild state, but the foliage is much handsomer. I

think it a much better plant than the related *A. Skinneri*. Last year I obtained from Zurich seeds of a new Columbine, said to be from the Rocky Mountains, called *Aquilegia aurea*. I only succeeded in raising a single plant. It is certainly a beauty, not only in color, but in the form of the flower, which is unlike that of any other species with which I am acquainted.

SHALL WE KILL THE TOADS?—My garden is full of toads, with a rather large poetic license. The more manure and the better the cultivation, the more the toads thrive. This is probably with a sharp eye to business, for insects thrive best in rich land. Bugs are scarce on a gravel bank. But where the ground has been trenched, and the manure worked in unsparingly, and vegetation is rank, there insect-life abounds. And the toad makes his domicile under the cabbage or the squash-vine, and watches patiently for snails, worms, bugs, and millers. That smooth tongue that he darts out with such rapidity looks innocent enough, but it sticks like pitch to every living thing. His power of digestion is excellent. Harris fed one hundred black larvæ, three quarters of an inch long, to a single toad without destroying his appetite. We can not afford to lose such an agency as this for the destruction of insects. He does for the ground what the birds do for the trees. Give the toads the freedom of the garden.—C.

The Apple Maggot-Fly.

(*Trypeta pomonella*, Walsh.)

BY C. V. RILEY, STATE ENTOMOLOGIST OF MISSOURI.

The following letter was received some time ago from J. H. Spatter, Esq., Keene, N. H.:

"GENTLEMEN: We are troubled here with a new pest, which I have seen described by no writer yet. It is a worm about half an inch long—about as large as a large pin. It eats through the apple (fruit) in all directions, coming only to the skin (not through it), completely honeycombing it, rendering the fruit entirely worthless. It prefers the early sweet apple, commencing its ravages about the time it begins to ripen. Also attacks the later sub-acid apple 'Seek-no-Further,' etc. It does not puncture the skin. If you can give us its history, *modus operandi*, and destruction in your *Agriculturist* you will confer a great favor on the sufferers."

The matter being referred to Mr. Riley, he sends the following:

The insect referred to by your correspondent is known as the Apple-maggot, in contradistinction to the notorious and more wide-spread Apple-worm or Codling-moth. This last occurs all over the land, and was originally imported, with apples, from Europe. The insect which Mr. Spatter refers to is, on the contrary, an indigenous species, and feeds naturally on our wild haws or thorn-apples, and, as I have proved, also on our crabs. It was first described by the late Benj. D. Walsh in the *American Journal of Horticulture* for December, 1867, and further treated of in his Report as Acting State Entomologist of Illinois. Prior to the year 1866 it was not known as an injurious insect, but since then it has done much damage to apples—and especially to tender-skinned varieties—in Massachusetts, Connecticut, New York, and Vermont, and now we may add New Hampshire to the list.

This insect differs notably from the Codling-moth in the following respects: The parent fly has two transparent wings clouded with marks as in the engraving (fig. 1), and it consequently

belongs to the Order of Two-winged Flies (*Diptera*). The Codling-moth, on the other hand, has four scaly wings (appearing powdery with the unaided eye), and belongs to the Order of Scaly-winged Flies (*Lepidoptera*). The former is single-brooded, while I have clearly established

Fig. 1.—APPLE MAGGOT-FLY.

the fact that the latter is double-brooded. The one under consideration burrows in all directions, and in varied numbers, in the flesh of the fruit, giving it a discolored, honeycombed, rotten, and filthy appearance, but seldom penetrating to the core; while the other works for the most part around the core, and does not, directly, do so much harm to the flesh. The maggot is white, footless, tapers anteriorly, with no distinctive head; it quits the apple and enters the ground, in which it merely contracts until its skin hardens to a smooth, shiny (coarctate) pupa, with no indications of the future state. The Apple-worm, on the contrary, inclines to pink in color, has sixteen legs, a distinct head, spins a silken cocoon above ground, and, casting off its skin, assumes the chrysalis state, in which the members of the future moth may easily be traced. The parent flies of the apple-maggot do not make their appearance until July, and the pupæ remain quiescent underground all through the winter and spring.

No remedies for this pest have ever been suggested, and as it does not affect our cultivated apples out West, I have had no opportunity of experimenting with it. The remedies which would suggest themselves, from the habits of the insect, are of too expensive a nature to ever be generally used. Thus, by entirely covering the ground with flagstones, bricks, or any other hard substance, the maggots would not only be effectually prevented from completing their transformations, but such as are already in the

Fig. 3.—MILK-WEED FLOWER.

ground could not emerge as flies. Covering the ground thickly with salt, ashes, lime, or other substances might have a similar effect, and should at least be tried, especially in isolated orchards. It is also very certain that destruction of the infested fruit, either by feeding into cider, and stirring and disturbance of the ground in spring, so that birds and other predacious animals may get at the pupæ, are preventive measures, and we have no doubt will be attended with good results.

Not the least interesting or important feature in this insect's history is the fact that it exists all over the country, West as well as East, feeding on our wild haws; while it is only in the Eastern States, already indicated, that it has taken to feeding on the cultivated fruit. It furnishes one of the most perfect illustrations of the manner in which a new habit may be formed, and there is far more danger that this

Eastern race, which is so appreciative of the more delicious cultivated fruits, may spread until it also becomes a nuisance in the West, than that our Western maggots, which are now content with the more insipid wild fruit, should likewise learn to attack the cultivated kinds. In the event of such spread of your Eastern Apple-maggot, we should have in the West two distinct branches of the same species, the one working on wild fruit, and never multiplying unduly on account of the scattered nature and greater scarcity of its food, the other working on cultivated fruit and—because of the abundance and concentration of such fruit in orchards—multiplying and rioting in it in the manner described by Mr. Spatter.

As the Eastern-bred specimens in the Walsh cabinet were destroyed in the great Chicago fire, I should be pleased to get some to place alongside of those in my cabinet which have been reared from wild-haws and crabs here. For this purpose I hope Mr. Spatter will send me some of the pupæ next fall, mixed with moist earth, and inclosed in a tight tin box.

In further illustration of the difference between the Apple-worm and Apple-maggot, I introduce an engraving (fig. 2) of the first-named also.

St. Louis, Mo., May, 1872.

“What Ails the Bees' Legs?”

Last year we received complaints, accompanied by specimens, of a curious trouble with the bees. As the matter came to our notice late in the season, we thought it better to defer an

Fig. 1.—BEE WITH LEGS CLOGGED—(MAGNIFIED).

explanation of the difficulty until the time at which it is likely to occur should come round again. In the cases referred to the bees had some extraneous matter attached to their legs which impeded their movements to such an extent that the insects were unable to climb up the comb, and perished in great numbers. A

Fig. 2.

very much magnified bee, with its legs thus clogged, is shown in figure 1. It will be seen that numerous pear-shaped masses are attached to the legs; a single one of these objects is shown in figure 2. These curious bodies are the pollen masses of the Milk-weed (*Asclepias*) or, as it is sometimes called, Silk-weed. There are several species of *Asclepias*, some of which are very common. Most of them have a copious milky juice, whence their most common name, Milk-weed, and the seeds of all each have a beautiful tuft of silky down, from which is derived the other name, Silk-weed. In an article, “The Relations of Insects to Horticulture,” we have briefly hinted at the reciprocal benefits flowers and insects yield to one another. Flow-

ers furnish in their nectar food to insects, while these are of great service to the plant in distributing the pollen. In most plants, the pollen is an exceedingly fine dust, but in the Milk-weeds and some other plants the pollen grains

Fig. 2.—APPLE-WORM MOTH.

adhere together in masses. In the Milk-weed they are so compact that it takes a strong microscope to show any grains at all, so closely are they pressed together in a pear-shaped waxy mass. Two of these masses are connected together, as shown in the engraving, and the point where the filaments or strings which connect them join is very sticky. We might dismiss the subject by saying that the bee in its visits to the flowers of the Milk-weed steps upon these sticky portions, which adhere to its feet and legs and thus produce the trouble alluded to. Some may wish to know more about the matter, and we give a drawing of a Milk-weed flower (fig. 3), premising that its structure is difficult to explain by drawings, but if one has the fresh flowers it is more readily understood. The flowers of the Milk-weed are produced in large umbels or clusters, and in the engraving we show only an individual flower. The structure of these flowers is such that the pollen can only come in contact with the pistil through the agency of insects, though, as in the case of the bees, the insects sometimes suffer for their benevolence. The anthers are placed in a column around the pistil, with their filaments united into a tube. The anthers have each at the top a curious appendage or hood, which contains a horn curving toward the center of the flower, as in figure 4. Each anther is two-celled, each cell containing a pollen mass, but, singularly enough, the pollen masses of adjacent anthers are united. In the pollen masses shown in figure 2, the right-hand one came from one anther, and the left-hand one from the next anther to that. Stranger still, the top of the pistil, the stigma, bears projections by which these pollen masses are suspended, the adhesive portion before alluded to being well exposed. This adhesive portion is usually dark-colored and readily visible, and one having a flower can by inserting a pin or needle just below it lift out the pollen masses. This removal of the pollen masses is just what is done by the bees, who, in their search for nectar, bring the pollen in contact with the pistil, a place it would never reach without their aid. We are well aware of the difficulty of describing this matter, and advise those who are curious enough to make such observations to study the structure of the living flower of the Milk-weed, when they will see the singular arrangement of pollen, and be able to understand what is the matter with the bees.

THE HOUSEHOLD.

(For other Household Items, see "Basket" pages.)

Neighborhood Picnics.

I am glad we are growing wise enough to see the folly of leaving all of blessed childhood behind us, in putting away childish things. We are learning that play is as necessary as work, even for grown-up persons, and that innocent gayety pays. Besides, I do believe that we big folks are getting to feel more like brothers and sisters in the same great family. So we, who got cheated out of most of the fun of holidays in our childhood by the serious-minded parents and teachers of a former generation, are getting our Christmas presents and our holiday picnics at last. Isn't it nice?

Good-by to the old-fashioned village celebrations, with their pompous orators, their tedious processions, their heavy dinners, and solemn cannonading! And welcome to the village and neighborhood picnics, with their friendly greetings, social visits, fun, frolic, basket-dinners, and a safe good time generally, for old and young together! That is the best of it, after all—old and young, rich and poor, learned and ignorant, happy together!

The genuine neighborhood Fourth-of-July picnic is Christmas over again so far as the *spirit* of Christmas goes. Everybody wants everybody else to go to the picnic and have a good time. The more the merrier. Calico and muslin dresses are in the best taste, and no one need stay away on account of dress. Cakes and tarts and jellies and ices are in order, and so are biseuits and doughnuts and Graham gems and plain bread and butter. Everybody can furnish something. If there are homeless ones who can not, we will take them into our party, and make them believe that nobody is obliged to carry provisions, unless it is convenient, and that those of us who make preparations for our own families, always make provision for two or three more, so that there will surely be enough and to spare. And let us be sure that such is actually the case. Let us have all the fruit possible, and free to all—great saucers of berries for children who have never had enough of any good thing to eat at home. Somebody will delight to furnish plenty of nice sugar. Let us have "lots" of lemonade, and why not cool milk also?

In many country places ice-cream is a great rarity, but it need not be too rare or too expensive for our rural picnic. I guess we can manage it. Two or three of us can club together, and furnish milk and cream and sugar. Excellent ice-cream can be made as cheaply as custard. We may be able to borrow a freezer if there is none in the neighborhood. But there should be one in every neighborhood, if it has to be a "company concern."

Let us have plenty of light, sweet, delicate cake, but let it be wholesome. The great bane of cake is in the shortening. If you carry greasy cake to the picnic, somebody's darling will cry on account of "a pain under her apron." Look out for your tart-crusts, too. And don't let the children take lemonade, or ice-cream, or ice-water, when excessively heated.

Of course, you can take the baby along, if it is old enough to enjoy company, but keep it as secluded as possible. "Outdoors" won't hurt it at all, but too much handling and baby talk from a variety of people may excite its nerves. If let alone, nature will divert it with the nearest pretty thing, and you will only do mischief by trying to call its attention to what you fancy might please it better. Give it very plain and simple fare, if you feed it—as much as possible like home-food. Go prepared for a shower, with umbrellas and extra shawls.

At a picnic of this sort, every one should be ready and willing to help make the day as comfortable and pleasant one for all the rest. If you do not set tables, but simply spread your table-cloths on the grass and pass things around, sitting in groups here and there, there will be little work to do. Whatever work is to be done, the young men and maidens should take upon themselves. It is just

the opportunity country boys and girls need, and they will get a first-rate time out of it.

It is a common mistake to stay too late. The children should get home safely before the earliest bed-time. It is an excellent plan to go in the forenoon, have a good dinner in the grove at noon, and take quiet suppers at home. Let us have music and games, and perhaps dancing and swinging and boat-riding. There is no harm in having a good speech, but that should not be the main thing at such a social picnic. We neighbors might a good deal better talk together about our common interests than be talked at by an outsider. It is our nation's birthday—Fourth of July is—and we are the people, you know, and we had better see what kind of people we are when we are together, and what we can do to make better governors of ourselves for the great nation that we are. R.

Trapping Rats and Mice.

Most people, but especially those who live in the country, are at one time or another annoyed by rats and mice. The destruction caused by these animals amounts annually to a large sum in the aggregate. The garret, the cellar, the store-room, and all sheds and out-buildings belonging to the house, are liable to be infested by them, as are barns, granaries, poultry-houses, and other of the farm buildings. Poisoning is often attended by such unpleasant results, that it is not to be commended, and trapping is the most satisfactory manner of extermination.

Fig. 1.—BARREL TRAP.

Much may be done in the way of keeping rats and mice out of an apartment or a building. If a cellar is well cemented, the only chance a rat has to enter is through an open door or window. All rat and mouse-holes in store-rooms should be closed. Strips of tin or zinc tacked over the holes will be of service. When the way of ingress and egress is stopped the animal must hide somewhere in the room. Hence, no unnecessary lumber or rubbish that will afford a harbor should be allowed to remain. If we did less to make our buildings attractive to rats we should have fewer of them. Traps of various kinds are sold at the stores, some of which answer a good purpose. Almost any kind of a trap will catch a mouse, and the foolish little fellows are not deterred by the fate of a comrade from seeking a similar one. With the rat it is quite different, and it takes considerable cunning and patience to circumvent an old rat that knows traps and avoids them. The best way to manage these old stagers is to patiently bait them at the traps, which should be so arranged as not to spring. When the rats have ceased to be suspicious of the trap, and will come to take their food there, then is the time to catch them unawares. If a steel trap or any of the ordinary wire traps are used, they should be thoroughly washed after a capture. A gentleman who is very expert at rat-catching informed us that

Fig. 2.—MOUSE-TRAP.

he considered this important, as a rat will very rarely go into a trap in which one has been caught unless it be well washed.

A farmer friend, who has given considerable attention to the vermin question, gives us the following: "Have traps everywhere. I give some illustrations of handy traps, which can be made in odd hours, and which might be placed where the vermin are expected. Variations of the same plan

of traps will suggest themselves. Triangular pieces of tin, fastened about three feet above the floor at the corners of sheds, stables, and barns, will prevent rats from climbing up, while they will not prevent them coming down. And lastly, let it be

Fig. 3.—TRAP AT WORK.

remembered that owls find their natural food in such vermin, and will do no harm in the hen-roosts if these are kept closed at night. Therefore, if an owl should be seen around the premises in the dusk of the evening, it is not wise to rush to arms at once to destroy him as an invader of the peace. To make the traps, take a barrel (fig. 1) and support the head on pivots; a weight is fixed to one pivot to keep the head in position; a few grains of corn are glued on to the head. When a rat or mouse steps on the head it turns and the animal drops into the barrel; the weight immediately brings the head into position again. The trap (fig. 2) is a smaller one, for mice, made of wood or tin, on the same principle. These traps should for a few days be set in the haunts of the vermin, fixed so as not to work, so that they will become accustomed to them. Then set for use. Fig. 3 shows the trap in operation.

Home Topics.

BY FAITH ROCHESTER.

HINTS TO VISITORS.—Do people who always keep help, and who entertain few guests, understand that the hospitality of other people is often a very serious matter which they can ill afford?

I have known city people to give up housekeeping and go to boarding, because they could not afford to entertain the company which they could not escape. Country cousins and old neighbors coming to the city on errands of business or pleasure, used their house as a sort of free hotel, taking their own welcome for granted, and giving as an equivalent for the trouble and expense caused only invitations for return visits, which they knew would never be made.

It is certainly very convenient to have friends in the city, who will be really glad to see us at any time, and who can cordially and unaffectedly urge us to stay long and come again. One who has such sincere friends, need not be ashamed to accept their invitations, though unable to make any return of hospitality. Mutual love is sufficient reason, and will make all straight.

I hope we all of us know the pleasure there is to be found in entertaining our friends, and in making visitors comfortable and happy in our homes. But when we already have more work than we can perform or greater expenses than we can easily meet, we can only wonder at the assurance with which people who care nothing about us, make themselves at home in our houses. I have heard my mother tell of the family that quartered themselves upon her one night, when her own family was young and numerous—a man and his wife with two or three children. The woman of the party gave mother a very cordial greeting, but mother was obliged to confess that she did not remember the lady. "Why, don't you remember," said she, "that our folks used to sit in the church-pew adjoining yours, when your father's folks lived in Massachusetts?" With great effort mother remembered or pretended that she did, and on that pretext the traveling family got a good lodging and two or three meals.

Country people suffer quite as much as city people from selfish visitors—perhaps more. A whole family of city relatives will sometimes swoop down upon some farm-house, expecting all sorts of attentions from people who can not wait upon them

without overtaxing themselves. Hard-working people feel the hardness of their lot more than ever when brought into contact with the elegant leisure paraded by their unthinking visitors. Women who live at the old homesteads of their husband's families, sometimes suffer a good deal from such visitations, though they may suffer cheerfully, because they love and enjoy their visitors so much. This mitigates the severity of the care and labor, it is true, but the care and labor are there all the same, and the housekeepers and mothers will be especially liable to suffer in consequence.

Sometimes visitors realize this, and make themselves useful in many ways, saving steps for the busier members, and warding off trouble by attention and patience. It is always help for the parents when visitors win the children's love and confidence and manage to keep them interested and happy with innocent pleasure.

There are mothers, to be sure, who would rather be set free to take care of their own children, if that were possible, but they may be thankful if there is any one to watch over the little ones wisely while they are unavoidably tied by household tasks.

Does that sound heartless? Yet on this subject of mothers' rights my heart is especially tender. Even more so, however, in regard to children's rights. But when I set out with this topic I was going to say to visitors in general what no hostess will ever be likely to say to any guest in particular.

If you really want to help the "lady who does her own work" while you make her a friendly visit of a few weeks, probably the best thing you can do is to wash the dishes regularly. If she has a little girl or boy to do this work for her, there are other regular unavoidable tasks, like sweeping, dusting, taking care of bedrooms, which you can do without asking questions. Whatever you do, try to take something off from her hands and mind, so that she may be relieved of all concern about it.

"Too many cooks spoil the broth," and for this reason the one who is accustomed to do the cooking, and who knows just what is in the house and where it is, may as well keep to that department generally. Dish-washing is as easy as any work, but it is something that *must* be done, and often it drags along most unpleasantly, when one has frequent interruptions from small children and from callers.

When you visit at a house where there is plenty of hired help, you should still be careful not to make unnecessary trouble and labor.

ANOTHER WORD TO MEN.—Mr. Rochester says I would do well to advise farmers to quit work early, wash up, and put on their clean linen coats before supper, and get time to read a little while on the porch or piazza, before dark.

I say, "The clean linen coat by all means, if they want the pleasure of taking baby in their arms."

He says, "It does a man a deal of good to feel dressed up and decent once a day, if only for half an hour. Every hired man ought to enjoy this relief. I notice that good hired men don't grumble so much about being set to work too early in the morning, as about being worked too long at night. They want a chance to lounge about and chat with other folks a little while before bed-time. In the hottest of haying weather it is better to work late, and take a good long rest in the middle of the day, of course. But I believe in early suppers and evening rest and recreation as a general rule."

"And in clean clothes, too," say I. And then, if we can all have a ride, or some entertaining family reading, or a social game of some kind, it will do much to save us from feeling like drudges and slaves, and will help us to be kindly affectioned one toward another.

DRYING CORN.—During those months when green corn is out of season, dried corn may be made into a very palatable dish. I was told last year that the easiest way to dry the sweet corn (and we never dry any other) was, to cut it from the cob, spread it in the sun, and dry it without any scalding. This was said to be just as well as to go to the trouble of scalding the corn, either in a kettle of water, before cutting, or in the oven afterwards. I could not quite believe it, and did not try it. I did not think the dried corn would be as sweet as when cured

more rapidly. When I had an opportunity to make a comparison, my previous opinion was confirmed. The corn, simply sun-dried, lacked much of the sweetness and delicacy of flavor that I had always found in dried sweet-corn. So this year I shall scald the corn on the cob, putting it into boiling water, and cooking it a few minutes, then cut the corn from the cob as closely as I can, without shaving off the cob, scrape off the sweet yellow bits gently with the cut corn, spread all upon plates, and set the plates into a warm oven. When the corn is dry enough, so that two plates may be emptied together without spreading the corn too thickly for even drying, I shall probably set the corn in the sunshine, on a shed or out of reach of chickens and kittens. To keep off flies and bees I will spread over it a piece of mosquito-netting. When well dried, I shall tie it up in a cloth-bag, and hang it in a dry store-room. Before winter I will examine the corn at the top, to see if insects have laid eggs in it, and if I see any sign of their eggs or larvæ, I must spread it on plates again for a quick scalding in the heat of the oven. But I have never had corn get wormy. Next winter we will have sweet-corn on the table as often as twice a week, regularly, "wind and weather permitting." It shall be washed in cold water, and the hulls that rise on top of the water shall be turned off. Then it shall be put in a stew-pan, with cold water enough to soak it and boil it tender. The stew-pan shall be set upon the back of the stove, allowing the corn to heat slowly as it soaks. Then half an hour's boiling will be sufficient. Sometimes it shall be seasoned with rich milk (cream, when cream is plenty, but milk is good enough) and a little salt. This may be poured over toast or over dry bread, previously soaked in hot milk. Sometimes we shall season it with butter, salt, and a little black pepper, and crumb crackers in, oyster fashion; and sometimes we shall put in neither bread nor crackers, but fresh white gems—as we sometimes do, pot-pie fashion. And the dried corn will be good and wholesome, almost any way you can fix it.

Some housekeepers boil the corn as though for the table, before cutting it from the cob, and then do little more than soak out the dried corn when the time comes for cooking it. It can not be as sweet, I think, for so much boiling. For when you boil sweet-corn, the water in which you cook it becomes quite sweet, so that you might boil down the water in which you had cooked two dozen ears of corn into a spoonful or more of sweet-corn molasses. The longer you boil your corn, the sweeter the water in which it was boiled becomes. This sweetness ought to go into the dried corn, and not be thrown away.

Perhaps some one thinks that is a good reason for not boiling the corn at all, and I should think so myself, only I do not like to waste the milk of the corn, as one must in cutting it from the cob without scalding it enough to harden the juice a little. That is my reason for the water scalding. Then I put it in the oven and dry it rapidly at first, because I have learned that the flavor is best preserved if the outside is dried so quickly that the inside has no time to change before it is shut in by the dry outside or crust. One must be careful not to scorch it.

DRYING BERRIES AND OTHER FRUIT.—The last rule mentioned holds good in reference to drying berries or any kind of fruit. If you spread the sweetest of blackberries out to dry gradually in the sunshine, you will lose a large proportion of their goodness. The seeds will be left to you, and the color and the sourness, and a part of the flavor, but you can not get the best of pies out of the seedy things. Sister L. wouldn't do that on any account. She takes them as soon as they are brought home and spreads them rather thickly on earthen platters or plates, and puts them into the warm but not too hot oven for a few hours, then under the stove, unless the sun shines hot. Canning is carried on extensively in the same family, but when pies are expected twice a day, without fail (how can a housekeeper stand that?), dried fruit is also in demand. She dries apples, pears, peaches, etc., in the same way, and I have seen none better than hers.

Young housekeepers know so little, sometimes (at least, I did once!), that it is safe to suggest that of course all dried fruit or vegetables should be soaked in cold or tepid water, or be put to cook in cold water, coming slowly to a boil. Dried apples are just as good, so far as I can see, to be washed and put upon the stove at once in cold water, without soaking, heating gradually and stewing gently until they are done, as when soaked over night.

Nothing acid should be cooked in an iron dish or in tin that has worn down to the iron. Porcelain kettles, earthen stew-pans, or tin dishes, unworn, should be used.

"THE DOCTOR'S PRIZES."—Uncle Tim, of *Hearth and Home*, and "The Doctor," of the *Agriculturist*, make me almost wish to be a child again, there must be such pleasure in working for their prizes. I would like to see some of the letters from children which those worthy gentlemen get, especially the lists of animals and flowers seen in May. That is the first prize-business that has come within the range of our eldest child's abilities, and now we hear about his "lists" every day, and see the little fellow working his jaws in his efforts to print the names of the flowers and animals he sees, just as we spell them for him. He persists in making out both lists, which is good sport for him and won't hurt any one. For he knows how to print, and spells by the sounds of letters, though he has never been taught to read. I hope the "Doctor" will offer more prizes for work that will help on the healthy development of our children's faculties. Not that I care particularly for the prizes, though I dare say they are worth getting, but work that exercises a child's faculties *happily* is always good in the way of education. The puzzles, rebuses, anagrams, etc., which many narrow-minded people despise, are excellent in this way.

NETTING IN THE WINDOWS.—One thing that made the sitting-room at the B.'s seem so cool and pleasant in the summer-time, was the netting in the windows, *in place of the glazed sashes*. They had blinds upon the outside, which they would close to shut out the storm or hot sunshine when they chose. One window opened upon a piazza. The other two looked out upon the fruit and vegetable garden. They had frames to fit the windows with thin, firm white netting, stretched and tacked upon them. These were easily put in and taken out of the windows. They gave the room a good supply of fresh air, and kept out the mosquitos, moths, flies, and other insects generally. When the weather was cool, the room was heated by a register. It is too bad to take down the stove in the sitting-room as soon as warm weather comes, there are so many cool nights and mornings, and rainy days, when rooms are uncomfortable without fires, and it seems as unpleasant to have to close the windows in order to keep warm. After we have grown accustomed to open windows, it is hard to breathe with the room all closed. How to get the most fresh air together with a comfortable degree of warmth, that is the problem. We must have fresh air, anyhow.

Any woman can tack a square yard of netting across the lower half of a window, upon the outside, if that is the only way she can get a chance to breathe pure air without letting in mosquitos.

Fritters in Haste.—Sometimes an emergency arises when an extra dish is required, and the eggs can not be found, or the hens are sitting, and no eggs are to be had. To one quart of flour add one measure of Horsford's Baking Powder or its equivalent in cream-tartar and soda. Cut in two spoonfuls sugar, soften a piece of butter the size of an egg, and salt as to judgment, then milk enough to make a thin batter. Bake quickly on a griddle. The sugar makes them brown as well as eggs. If one has buttermilk, Horsford's Preparation and the butter are not necessary.

Indian Cake.—Two cups flour, two cups Indian meal, one measure Horsford's baking powder, half a cup of white sugar, and four table-spoons of melted butter, salt, and milk to make a rather thin batter. Bake in a quick oven.

BOYS & GIRLS' COLUMNS.

About Our Prizes.

In the *Agriculturist* for May, I offered prizes for the best lists of plants in flower, made by the girls, and the best list of animals made by the boys. The lists were to reach me by the fifteenth of June. As this part of the paper goes to press on the fourth of June, I shall be obliged this time, as I have been before, to announce the awards in another part of the paper. As there are some ten days yet in which to receive the lists, I can not tell you how many there are, but for the past few days they have been coming in quite lively. I do not expect near as many lists as there were stories, as it requires a great deal more time and care to make out such a list than it does to write a story. Besides, with boys and girls who live in the country, it is a very busy time of year, as many of them have to help at the farm work and take care of their gardens. The parents of some of you have written to thank me for proposing something that will teach you to use your eyes and set down what you see. Now that so many of you have done it with the hope of getting a prize, I hope some of you will continue for your own improvement, and another spring make a record of the time of blooming of the principal trees and plants about you, and the first appearance of the familiar birds. Lists like these made each spring, will become an interesting record of the seasons. The hot weather is now upon us, and we do not any of us care to do much in-door work, at least I do not, and you may be sure it is no small task to read over the stories and lists, and decide upon prizes. So we will let the hot months go by without proposing any prizes. But you must be ready for some more when the dog-days are over and the cool nights come. THE DOCTOR.

Wonderment.

So long as that little duckling has been conscious of anything, its world has been the bounds of the shell which inclosed it. It could see the light shine through its walls when the mother was off of the nest, and probably wondered what was outside. Now that it has grown large enough and strong enough to break its shell, it looks out in perfect wonderment. We do not know that ducklings think, but if they do, we can imagine this little fellow as hesitating about leaving the cosy shell that he has known, for the unknown and untried world. But he has grown too large and must leave. The little chap has never seen water, and we are quite sure has never heard of it, yet when he goes out and sees a puddle or a pond, he will go for it at once, and swim off without the least teaching. Is it not strange that if we set three kinds of eggs, that are not very unlike except in size, a hen's, a turkey's, and a duck's, the young birds will at once behave so differently?

The chickens will scratch for food of their own accord, the young turkeys will run for their food and not scratch, while the ducklings will neither scratch nor run but waddle and swim. These birds are guided to do these things by what is called instinct.

Aunt Sue's Puzzle-Box.

I have received a great many lists of square words from "PLOW" and "CARE." Some I shall not notice, as proper nouns and obsolete words were used, contrary to orders. Many of my correspondents conscientiously refrained from using a word twice, which necessarily curtailed their lists.

I will credit the names as they stand, and another time we will start more fairly, with a better understanding.

From the word "CARE" B. F. Bidwell made 96 squares; Leander J., 45; M. O. N. Key, 23; H. H. Clarke, 23; O. A. Gage, 20; Ajax, 20; Bay State, 14; A. B. Leach, 13; Edward P. S., 13; Frank Winship, 12; W. E. H., 12;

Gustavus M., 11; Minnie T. B., 4; Annie M. R., 4; Willie G., 3.

From the word "PLOW" B. F. Bidwell made 74 (1) squares; A. B. Leach, 21; O. A. Gage, 19; Bay State, 18; R. W. Moore, 13; Frank W., 10; Edwin E. P., 7; Gustavus M., 8; Minnie T. B., 9.

Now, who will send me the greatest number of squares on the word "OVEN," using no proper nouns, no obsolete words, and using no word (except "oven") twice?

TO CORRESPONDENTS.

A. G. S.—The answer to that original charade (1) "My first stands for company, my second shuns, my third calls, and my whole entertains company," is "Conundrum," and may be found in some of the most ancient puzzle-books that were ever published.

Thanks for letters and puzzles to Laura V. Matthews, Alice N. P., O. A. Gage, Belle Sparr, W. E. H., B. F. Bidwell, and Minnie S. G.

Little Mischief and her Doll.

Ah, ha! Little Mischief, you are caught at it! Oh yes, because you are obliged to take a bath, you think it will be good for dolly, do you? It will be a nice doll that you will have after this scrape. Probably the paint will

wash off, the kid arms and legs will dry all out of shape, and the poor thing, instead of being the better for its bath, will look sorry enough to be sent to a dolls' hospital. The doll in the picture looks as if it knew that the bath was not good for its constitution, which is more than Little Mischief knows now—but she will learn.

[COPYRIGHT SECURED.]

THE LITTLE DRILL-MASTER.—Drawn by Wm. M. Cary, by permission of Goupil & Co., from a painting by G. Arnold.—Engraved for the Am. Agriculturist.

The Fourth of July.

Hurrah! you all say. So I say, "Hurrah for the Fourth of July!" What are we all going to do? For every American boy, born or adopted, must do something on the Fourth. What a saving of cents (I won't say pennies, for we have no such coin) there has been in view of a proper celebration, and many will think necessary to go to some unusual expense in honor of the day. Perhaps you youngsters will ask me what I am going to do. I can recollect when I was foolish enough to stay up all night so as to be ready to make a terrible noise at day-break, and then be sleepy all the next day—a course that I can not recommend to any of you. Well, in the first place, the flag must go up; then, if my nephews happen to be here, there will be noise enough without the necessity for my making any. Living in a lone house in the country, I have kept up my old traveling habit of keeping a revolver in some safe place, and on the fourth day of the seventh month it occurs to me that the piece needs cleaning, and as I can not clean it without firing off the charges, why, off they go. Then the rest of the day I shall be very quiet, perhaps go up into my woods which cover the side of a hill, from the top of which I can see a wide landscape, and try to be thankful that my lot is cast in such a pleasant place, where any man of ordinary industry can own a piece of God's beautiful earth, and there are no kings nor emperors to fear. But perhaps you will not be content with such a quiet Fourth, and must

burn powder. I don't exactly know why it is necessary to celebrate with noise, or why we should be so fond of firing the crackers the Chinese use in their idolatrous worship upon our national festival. The fearful burning of the city of Portland, a few years ago, which resulted from the use of fire-crackers, is enough to make one wish that these noisy explosives had never been invented. There is one safe rule for the Fourth of July (and for 364 other days) and that is, to do nothing of which your parents do not approve. If they sanction fireworks and gunpowder-burning, they will take care that no harm can come from them.

It is possible to have a very good time without gunpowder. Look at the little fellow in the picture. I don't know that it is the Fourth of July with him, but it might as well be, for he looks happy enough. He imagines that his army is passing in review, and is band and commanding officer all in one, while the standard-bearer is quite up to the importance of the occasion. The one spectator is so taken up with the review that she does not see the enemy in the rear.

Now, if you were to ask me what would be the best thing to do on the Fourth, I should first advise what not to do—do not undertake anything that will annoy any one else, and do not get so tired that on the morrow you will be glad that the holiday comes but once a year. What I would advise is, to get all the boys and girls together, and have a nice picnic. There are plenty of flowers, and there can be wreaths and garlands, which

are vastly better than powder and crackers, and then of course you will sing the "Star-spangled Banner," "My Country, 'tis of Thee," and such songs, and then some good reader can read the Declaration of Independence, and maybe some selections from patriotic writings can also be read, unless you can get up an original speech yourselves. Do not have too many of these exercises, but just enough to make the Fourth-of-July picnic seem different from every other. Now, do you, boys and girls, both know *why* we celebrate this particular day? It is because on this day our people declared themselves able to govern themselves without any help from a king and rulers away across the water. Our people are now so accustomed to self-government that we accept it as a matter of course. So when you raise your flag on this day, think how much it stands for—the right of people to govern themselves without asking kings and princes what they may do; the right of every one to worship God as seems best to him; the right of every man to his own self and the fruits of his own labor. So our Fourth of July is a day always to be remembered, and our flag is always an emblem to be respected, and even children can understand and be thankful for the blessings that make the day worthy and the flag honored.

So after this bit of seasonable talk, which to my surprise I find has almost come to be a Fourth-of-July oration, I say, don't get tired, don't burn your fingers, but have a jolly good time. This is the wish of

THE DOCTOR.

A Railroad Watch.

Travelers by Railroad frequently find their watches completely demoralized by the continuous jar of the train. To overcome this difficulty has long been a problem with watchmakers, and it is now successfully accomplished in the new grade made by the

American Watch Co. of Waltham.

This Watch is made in the most substantial manner, on the most approved principles, and combines all the recent improvements. It has a new micrometrical regulator, by which the slightest variation can be easily corrected. It is carefully adjusted, and may be entirely relied on to run accurately, wear well, and ENDURE THE HARDEST USAGE, without any derangement whatever. We confidently recommend this watch to the trade and the public as the BEST WATCH FOR THE PRICE IN THIS MARKET.

The full trade-mark engraved on the plate of each watch is "AMERICAN WATCH CO., CRESCENT ST., WALTHAM, MASS.,"

and it is distinctively known as the CRESCENT-ST. Watch. For sale by all leading Jewelers.

AND
MELODEONS.
The Oldest, Largest, and Most Perfect Manufactory in the United States.

50,000

Now in use. No other Musical Instrument ever obtained the same popularity.

Send for Price-Lists. Address BUFFALO, N. Y., Or CHICAGO, ILL.

Three weeks is the extent of wear for children's Shoes unless they have a Silver Tip on to protect the toe.

Time is Money.

This old-timed axiom is aptly illustrated in the use of DOOLEY'S YEAST POWDER. It is well known that the common process of raising dough is a slow one, and often attended with unfavorable results from the use of poor baker's yeast and improper heat. With DOOLEY'S YEAST POWDER, the best of rolls, biscuits, corn-cakes, etc., can be made in the short space of ten minutes, and uniform success will certainly attend its use. This is owing to its purity, strength, and the care with which it is manufactured. Dooley & Brother, 69 New street, New York, Proprietors. For sale by all Grocers.

Hear our Side and know why we sell on Trial the best Four-Ton Hay Scale, made at \$75. Free Price-list. THE JONES SCALE WORKS, Binghamton, N. Y.

MOWER AND REAPER, combined, Wood's, new, for sale. Address G. TIMPSON, Box 243, Williamsburgh, N. Y.

If You Write and Mail a Letter as Follows:

Messrs. Howard & Co.,
No. 865 Broadway, New York:
Please send me your Price-list of Waltham Watches for 1872, as per advertisement in the AMERICAN AGRICULTURIST.
(Sign Name and Address in full):

You will receive, post-paid, by return mail, a very interesting pamphlet, illustrated with fine engravings, describing the details of the Waltham Factory, and telling how the Watches are made. You will also receive our Price-list, which describes all the different grades of watches, gives weight and quality of the cases, with prices of each, and also explains our plan of sending Single Watches by Express to any part of the country, no matter how remote, with the privilege of examination before paying the bill. Two new Watches have been added to the list, the "Boy's Watch" and the "Railroad Time-keeper." Please keep in mind that we will REFUND the MONEY for any watch that is not satisfactory. Address HOWARD & CO., No. 865 Broadway, New York.

Residents of California, Oregon, and other distant places, will find a great advantage in dealing with us.

A splendid opportunity for every one to aid themselves, their loved ones, or some needy friend, as DANA BICKFORD, of 689 Broadway, New York, is willing to send, for \$25, one of his EXTRA FINE \$35 NICKEL-PLATED FAMILY KNITTING MACHINES. This wonderful Household Assistant is of more service than the sewing machine—as it will knit a pair of socks complete in 30 minutes, and every kind and style of plain or fancy work. It is an easy support to those that require it; to others, a never-ending source of amusement and solid enjoyment. His object in offering such inducements during the summer months is to have it better known before the fall trade opens. Send in your orders with the money at once, with address plain and distinct. Address as above.

AMERICAN SUBMERGED PUMP.

"The Best Pump in the World."

Our Agents report over \$300,000 worth of property saved from Fire this year by these pumps, being the most powerful force-pumps in the world, as well as Non-Freezing.

See October number, page 596, also the Premium-List, page 303, of the Am. Agriculturist. This paper never deceives the farmers. See notice in February number, page 45. Try one. If it don't do the work claimed, send it back and get your money, as we warrant our pumps to do all we claim for them on our circulars.

Send for circulars or orders to the Bridgeport M'f'g Co., No. 55 Chambers St., New York.

An order for nine No. 1 Pumps secures an exclusive town agency.

ESSEX PIGS.

I keep no other breed of pigs except the Essex. Taking everything into consideration, I regard them as the best, purest, most refined, quietest, and most thoroughly established breed of pigs now extant.

I do not know that they have a single fault, I have never heard any one who examined them carefully object to them except on the ground of color. They are a black breed.

I have heard many farmers say: "If they were only white, they would be perfect." This, of course, is mere prejudice.

When dressed, they are as white as the whitest, and the lard is firmer and whiter than that of any white hog I have ever seen.

"But are they not too small?" They are classed with the small breeds, but they will dress over 400 lbs. They are quite large enough. They are the largest of the small breeds—larger than the small Berkshires, and much larger than the Prince Albert Suffolks, small Yorkshires, or Neapolitans.

So far as I know, I have the largest stock of pure-bred Essex in the United States, and I think my pigs are at least as good as any pure-bred Essex to be found in England.

My prices are reasonable, and I feel certain that I can give good satisfaction to all who favor me with their orders.

My spring pigs are the best I have ever raised, and I am selling sow pigs at reduced rates.

Address **JOSEPH HARRIS,
Moreton Farm,
Rochester, N. Y.**

P. S.—I am also Sole Manufacturer of the Lightning and Turn-Table Apple-Parers.

**900,000 ACRES
OF
EXCELLENT FARMING
AND SPLENDID
Michigan Pine Lands
FOR SALE,**

On which are **ONE THOUSAND MILLIONS OF PINE TIMBER**, and inexhaustible quantities of Maple, Beech, Elm, Ash, Hemlock, Oak, etc. The grant of lands to the Grand Rapids and Indiana Railroad Company, to build their Road from Fort Wayne, Ind., to Traverse Bay and Mackinaw, Michigan, comprises in its farming lands every variety of soil, from the rich clay loam to the light sandy, and they are found in that section of Michigan, north of the city of Grand Rapids, and contiguous to the great fruit belt on the eastern shores of Lake Michigan, now being rapidly developed by railroad and other enterprises.

Farming Lands are sold to actual settlers, on credit, one quarter down, balance in yearly payments, interest 7 per cent. Persons desirous of locations for farms will, on application at the Office in Grand Rapids, be furnished with Tickets over the Road, entitling them to Return of Fares, in the event of purchasing any of the Company's farming land. For information about the lands, prices, location, etc., address

WM. A. HOWARD, Land Commissioner.
TITLE PERFECT. Grand Rapids, Michigan.

**1,500,000 ACRES
OF THE
RICHEST FARMING LANDS
IN THE WORLD,**

For Sale to Actual Settlers,
NEOSHO VALLEY, KANSAS.
Missouri, Kansas, & Texas Railway Co.
CARS NOW RUNNING 500 MILES.

The Lands now offered by this Company are mainly within 20 miles of each side of the road, extending 170 miles along the **NEOSHO VALLEY**, the richest, finest, and most inviting valley for settlement in the West.

PRICE OF LAND.—\$2 to \$8 per acre; credit of ten years' time. For further information, address **ISAAC T. GOODNOW,
Land Commissioner, Neosho Falls, Kansas.**

VALUABLE ESTATE FOR SALE near ANNAPOLIS, the CAPITAL OF MARYLAND.—The undersigned offers for sale his Farm, known as "Primrose," containing 435 1/2 acres; not over a half-mile by water, and a mile and a half by the county road from the City. All of the farm buildings, which are ample for all the wants of such property, are either new or in excellent repair, except the dwelling-house, which is a double, two-story, brick house and wing, and for a small sum can be made a first-class residence.

The location is healthful and beautiful, commanding an extensive view of the waters of the Bay, and the grounds are planted with shade-trees, shrubbery, and flowers. The cultivated land of about 300 acres has all been heavily limed, and is in the best state of cultivation, adapted to the growth of all the crops raised in this region, but especially adapted to the cultivation of melons, berries, vegetables, and all tree fruits, with which the estate is abundantly supplied, and for which its vicinity to Annapolis and access to Baltimore by rail, and daily and nightly by steamer, furnish ready sales. There are about 4,000 bearing peach-trees; 500 pears, dwarf and standard; and 500 apple-trees now bearing, or all rapidly becoming so, on this property. The location of the Naval Academy, and the cultivated society of the City, furnish superior attractions to those who desire recreation. St. John's College, and excellent Schools, furnish the best opportunity for educating children, whilst the growth of the City is rapidly enhancing the value of all property in the neighborhood.

As an investment for future advantages, or for profit from cultivation, few estates in the country present greater advantages than the purchase of the property now offered, or than the terms for which it can be purchased.

Price, \$25,000, of which \$10,000 to be paid in cash, residue on easy terms of credit.
**FRANK H. STOCKETT,
Annapolis, Md.**

FOREST TREES

FOR

Shelter, Ornament, and Profit.

BY **ARTHUR BRYANT, SEN.,**

President Illinois State Horticultural Society, 1871.

A new and valuable Book, specially written to meet the Forest Tree necessities of our Country. Gives tree planters every needed instruction what to plant for Screens, for Ornamental Purposes, and for Profitable Tree Plantations. Tells the Cultivator how to plant, when, and where; is written in a simple and practical manner, and suited to the taste and comprehension of every one. Every Farmer, Horticulturist, and Tree Planter will find it one of the most valuable volumes ever published, absolutely necessary for their own use, and indispensable for every rural library.

Contents:

- Chap. 1. Introduction.
- " 2. Evils attending the Destruction of the Forests.
- " 3. Favorable Influences of the Forest.
- " 4. Influence of Wood upon Moisture and Rain Fall.
- " 5. Change of Climate in the Prairie Region.
- " 6. Practicability of Raising Timber.
- " 7. Propagation and Planting of Forest Trees.
- " 8. Pruning and Thinning.
- " 9. Exclusion of Animals from Woodlands.
- " 10. Screens for Shelter.
- " 11. Profit of Timber Culture.
- " 12. Description of Individual Deciduous Trees.
- " 13. Coniferous Trees.
- " 14. Propagation of Conifers from Seed.
- " 15. Transplantation of Conifers.
- " 16. Description of Individual Coniferous Trees.
- " 17. Broad-leaved Evergreens not Coniferous.

The Descriptive List of Trees and Evergreens is believed to be the most full and accurate yet written for American use.

Finely Illustrated with 12 Full-Page Engravings.

PRICE, POST-PAID.....\$1.50.

Farmers & Fruit-Growers

You are informed that our method of preserving the various kinds of fruits, etc., beyond their natural season by means of chemical antiseptics—the American Preserving Powder—has established the fact that fruit, etc., can be reliably and most cheaply kept in large earthen and stoneware jars, and wooden kegs and barrels, by simply corking or bunging them tight enough for shipment, and that they will reliably keep during the year round or longer, or for shipment by land or water to any part of our country, and no doubt to any part of the world; and enabling grocers or vendors to deal them out of large vessels, as wanted from time to time, by the quart or gallon, without fermentation being occasioned by weeks or months of full exposure to the air.

As to the quality and flavor of the fruits thus preserved, I will boldly and defiantly claim that, with an equal quantity of sugar, they will be pronounced by three-fourths of the public as equal to canned fruits for the dessert and finer uses; and by the general public and pie-bakers as equally good for all cooking and baking purposes.

Again, the cheapness of this method will admit of using an extra quantity of sugar with the fruit, without increasing its cost above that of canned fruit, and thereby for the dessert and finer uses produce them superior to canned fruits.

Again, for keeping fruit for cooking and baking purposes, the cheapness and good quality of our fruits will argue for themselves, and defy competition. And, for this purpose, this method comes to the rescue and profit of the extensive fruit-growers, and to the pie-bakers of the cities and towns of the world; and I will herein dwell upon that most important feature only long enough and strong enough to assure the fruit-growers that there is an already established demand for this purpose equal to the full supply of fruit produced annually, only requiring the means of meeting out the supply to meet the demand during the year round, and reducing the price to such as the pie-bakers can profitably pay.

All of which it is within the province of this method to do, more effectually and profitably than by any other method, enabling the least fortunate fruit-grower to compete with the most fortunate fruit-grower in preparing the fruit for market, and when sold to pie-bakers at about one half the price now realized for canned fruits, the fruit-grower will realize at least one dollar (\$1) per bushel for his fruit, and the pie-bakers will multiply and increase the demand. Nor does it stop here, for the reason that fruits prepared and kept in the cheapest and most crude manner by this method, will for all cooking and baking purposes prove more acceptable to all classes of consumers than desiccated or dried fruits—being infinitely superior in flavor, and even cheaper, and more healthful even than fresh fruits themselves.

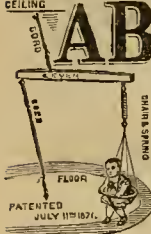

All of which I will exhibit, demonstrate, and establish to the satisfaction of interested parties who will favor me with a call at my office.

Farmers, take hold and preserve your fruit for the market. Families putting up fruit for home use, do not fail to try the American Preserving Powder. It will preserve all kinds of fruit more cheaply and with less trouble than any other method. Get it from your grocer; if he has not got it he will get it for you.

THE COUX Fertilizing and Sanitary Company

Beget to call the attention of Farmers, Market-Gardeners, and others to their natural manure. This manure, manufactured from the pure human excreta, collected on Coux's patent closet system, mixed with the best fertilizer ingredients, is suitable for every kind of crop and being remarkably rich in organic matter and humus, transmits its fertilizing properties to the plant in the most soluble and advantageous form possible.

For further information, apply at or address to the Company's office, corner of Varick, Vestry, and Canal streets, New York.

THE EXCELSIOR LAWN MOWER FOR HAND OR HORSE POWER.

Manufactured by **Chadborn & Coldwell M'f'g Co.,**
(Send for Circular.)
NEWBURCH, N. Y.

FOR SALE BY
RICHARDSON & GOULD, Seedsmen, Am. Agriculturist B'ld'g, 245 Broadway, N. Y.
B. K. BLISS & SONS, 23 Park Place and 20 Murray Street, New York.

VEGETABLE PLANTS, FOR Fall and Winter Crops, NOW READY.

- CABBAGE,** Drumhead, Flat Dutch.
 - " Savoy, and Red, for pickling.
 - CAULIFLOWER,** Erfurt and Paris.
 - CELERY,** New Dwarf White.
 - " Sandringham, Dwarf White and Red.
 - " Leviathan.
- Splendid plants of all the above will be mailed, post-paid, at the uniform rate of \$1 per 100. Circulars of prices for larger quantities sent on application.
- Full directions for cultivation of Celery sent with each package.

HILL'S "Archimedean" Lawn Mower.

In placing this LAWN MOWER before the Public for the season of 1874, it needs no recommendation, as it has a world-wide celebrity. With the improvements recently added to this favorite Mower, we are fully warranted in saying it has no equal in the WORLD. And its immense sale for the last 30 days throughout the United States is sufficient proof of the above assertion and of its great superiority. This Lawn Mower is constructed upon truly scientific principles, and it is the only PERFECTLY BALANCED Lawn Mower ever made, operated by a bail and adjustable handle, points that are indispensable, securing ease of operating, and a perfect, beautiful, and level cut.

The Hill's "Archimedean"

was the FIRST (and original) BALANCED LAWN MOWER invented in this country or any other, was patented in the United States and Great Britain, and its invention brought into general use a machine that is now a necessity, and almost an indispensable article. All others now made are copies of this machine, and the public are cautioned against them.

For sale by all the leading Seedsmen and Agricultural Implement Dealers throughout the United States and Canada.

Illustrated Catalogues and Testimonials, post-free, upon application to us or any of our Agents.

Manufactured by
The Hill's "Archimedean" Lawn Mower Co.,
Hartford, Ct.

(Works at Colt's Armory.)

AGENTS wanted to sell household articles needed by every one. Address **PLUMB & Co., Phila., Pa.**

ESSEX PIGS.

For crossing with common sows or with the large breeds, there is nothing superior to a highly refined thorough-bred Essex. Read the following:

HANNIBAL, Mo., December 22d, 1871.

The Essex pig I received from you has grown finely, and given perfect satisfaction. I have this fall slaughtered four grade Essex that averaged 301 lbs. each. One weighed 335 lbs. alive, and dressed 280 lbs., making 86.2-13 per cent of his live weight. They were eight months and eight days old the day they were slaughtered.

JAMES C. ASHMORE.

CLARKSVILLE, OHIO, Jan. 15th, 1872.

The Essex pig I got from you is growing finely, and I am well pleased with him.

W. CLIMEI.

MONMOUTH, ILL.

The Essex sow I got from you is doing splendidly. She is admired by all who see her. I think she is the handsomest pig I ever saw—and I have seen a great many.

IRVINE MCCARTNEY.

ARCADIA, N. Y., May 10th, 1872.

The Essex pig arrived safe and in good order, and I am well pleased with him. He is all that I anticipated.

L. J. BENTON.

AUSTIN, TEXAS, Feb. 6th, 1872.

The pigs arrived yesterday, and look remarkably well. To say that I am thoroughly pleased is scarce enough. I am more than pleased, and you have my thanks for giving me more than my money's worth. I have two Scotchmen in my employ who were in ecstasies over them (for Scotchmen). I would not take \$150 for the pair of pigs.

B. I. TOWNSEND.

I am breeding Essex pigs with great care, and selling them at reasonable rates. They give good satisfaction. Orders promptly attended to. Address

Please Observe.—It often causes much delay when matters that relate to business and those that belong to the editorial department are included in the same letter. All business letters should be directed: Orange Judd & Company. Letters relating to editorial matters only should be directed to the Editor of the *American Agriculturist*, 245 Broadway. When one wishes to write about business and editorial matters at the same time, he should write upon separate sheets, and direct to the publishers. Many answers to questions are delayed until too late for the answers to be of use because the questions are included in business letters.

How to Trap Moles.—V. D. Van Nest, Hightstown, N. J., writes: The trap a man or boy, time from 5 to 7 and 10 to 12 A. M. and 5 to 7 P. M. First plow the field, then harrow and roll; if the piece is so large that it can not be all rolled by 10 A. M., roll three or four times around it. Then at the hours before named let the person walk carefully around the field, and he will find the moles at work. Place the foot on the borrow, two or three feet behind the mole, and dig it out. The mole is very sensitive, and will turn back at a slight noise; so, to be successful, it requires care. As the mole lives along the fences and under stumps and trees, they should be looked after in the walks. A man can catch more moles in one day, working as here described, than can be caught in one month with a trap.

Protection to Orchards.—A large orchard near Girard, Pa., of several thousand trees, is protected on the north and west by a tract of woodland, and during fifteen years there has not been a failure in the crops on this orchard. This may be due to other causes, but it is very doubtful if anything other than the protection of the woodland should be credited with it.

Steam Plows and Tackle.—The new tariff bill, which goes into operation August 1st, permits the free importation of steam-plows and necessary engines and tackle for individual use on farms.

"Corner" in Grain-Bags.—The California harvest is progressing with rapidity; but the farmers are laboring under a difficulty arising from a scarcity of bags. Bags are the farmers' barn and granary in California, for the wheat is cut, thrashed, and bagged on the field. If, therefore, bags are wanting, harvesting is seriously interfered with. The Eastern markets are receiving large orders by telegraph, and by and by the "corner" will be turned.

The Wheat Market.—It is a singular fact that the condition of the weather in England just now is a sufficient cause for the rise or fall in value of wheat over the whole civilized world. A week's rain there lately caused an advance, and now a week's favorable weather checks the rise, and falling markets occur all over Europe and America.

Buying a Farm.—"M. W.," New Preston, Ct., asks if it would be advisable to run in debt for a farm, which would be sufficient to keep a horse, cow, and ten sheep, and leave five acres for market-gardening, and how much land would be required, and lastly, if it would be better to buy land with a house, or without and build one; he has \$500 to start with.—This depends altogether on the kind of man Mr. W. is. For some men it would be quite safe to go in debt for a farm, while for others it would not; of this he must be his own judge. Fifteen to twenty acres of fair land would be sufficient to keep the stock mentioned, and generally farms with buildings can be purchased relatively cheaper than without them.

Tree Planting.—The champion tree-planter of Nebraska, and doubtless of the world, is J. D. Smith, who lives near Lincoln in that State, who planted on "Arbor day" one tree per second for nearly ten hours. The result is a grove of 33,550 trees. Thus says the *Nebraska Herald*.

Value of Farms in England.—At a sale of estates in England lately farms were sold at \$230 per acre. These farms rented at \$5 per acre, or less than 2½ per cent on the value. Few good farms in New York or Pennsylvania could be purchased or rented for any less.

Fancy Stock Raising.—"J. G.," Idaville, Pennsylvania, puts the following question: he has 100 acres of land worth ten thousand dollars, not all paid for, but by raising grain clears only three hundred dollars per year; could he make more by selling his farm or by raising fancy thorough-bred stock?—It is very doubtful; after paying interest on part of the cost of the farm,

he has rent and all expenses paid and \$300 left and a safe business, and this is better than many other professions can secure. Raising fancy stock is a poor business, except to a few men, and to them it is profitable because they are few. J. G. is better off on his farm; if he will keep and sell more stock he can improve in this direction.

A Defense of the Gopher.—W. O. White, Kalamazoo Co., Mich., writes that he thinks that "the gopher" has been unjustly accused of being very destructive to vegetation. He examined the contents of the stomach of one, and found the remains of a large bug, eleven cut-worms, and two kernels of corn. He thinks that when the animal pulls up the corn, it is to get at the grub at the root. The true Gopher, or Pouched Gopher, about the destructiveness of which there can be no doubt, as it will kill a whole row of young trees, is not found in Michigan. The animal to which our correspondent refers is probably the Striped Gopher, or Leopard Spermophile, which is not accused of the serious mischief committed by the larger and more western Gopher. It is unfortunate that the name Gopher should be applied to three or four squirrel-like animals and to a tortoise, as it often leads to confusion.

Old Plaster.—"J. C. G." wants to know if old plaster is worth hauling two miles to put on his land, and if it will do to mix in mortar to plaster a log-cabin with.—Yes. If the old plaster is finely broken up and mixed with some fresh lime, it will make very good mortar for this work.

Lime, Salt, and Plaster.—"L. C.," Laurel, Md., asks if he is doing right to top-dress his corn and clover with lime, salt, and plaster.—Yes; but a crop of clover should be plowed in occasionally; this dressing will not do always alone; it is good as a help.

Propagating the Ivy.—Mrs. S. T. M., Garden City, Minn. Nothing is easier. Make cuttings six inches long and set them in a moist, shady place, or you can set out a plant and layer the branches, each of which will be a good plant by fall.

Sulphur in Fruit-Trees.—The gentleman in British Columbia who writes us an account of boring his fruit-trees, filling the holes with sulphur, and plugging them up, must excuse us from publishing his communication. This medicating trees by introducing foreign substances into their trunks, is one of the old fallacies that is every now and then revived. Sulphur is quite insoluble, and sand would have answered just as well. The sulphur being placed well into the center of the tree, is beyond the circulating sap, and if it were soluble, would not be taken up. Besides, it is an unnecessary mutilation of the trees. If, as our correspondent states, his trees regained their health, some cause must be looked for other than the sulphur.

Hedge for Texas.—"E. H. C.," Houston, writes that the China Tree, recommended by a correspondent in February, makes a good ornamental hedge, but will not turn cattle until it has grown very strong. He thinks that the best hedge-plant for Western Texas is the Pyracantha Thorn.

Mulching Grapes.—"S. M. F.," Hannibal, Mo. We do not think it advisable to use a mulch upon bearing vines. The soil needs all the sun's heat, in order to produce the best fruit. What say your Missouri grape-growers?

How to Kill Docks.—"T. S. S.," of Venango Co., Pa., writes us that, in his experience, the only certain method of destroying docks is to "dig them up, root and branch, and burn them." He thinks John Johnston's plan of mowing them early in clover while they are in blossom will not kill them. He says he had a patch near the barn covered with docks, and he has mown them at least half a dozen times every year, and has cut them up below the crown time and time again with a hoe, and all to no purpose. In his dooryard he has dug them up with a mattock, and then in some places put two feet of earth on top of them with a scraper, and after thus being dug up, the roots that remained in the ground grew as thrifty a crop as ever, and worse than before, for now they run down or up so much deeper!

We are well aware that where docks once get full possession of the soil they are a very troublesome weed to kill. But still, in ordinary farm practice, the plan recommended by Mr. Johnston is certainly a good one. It prevents the docks from going to seed, and if the method is persisted in, and the land is thoroughly cultivated when under the plow, and no docks are

suffered to go to seed, a few years of such treatment will unquestionably rid the farm of this troublesome pest. We do not think that mowing alone will kill them, but mowing in conjunction with thorough cultivation will in time do so.

Lime on Garden Land.—"G. R. V.," Williamsport, Va., has been advised to put a hundred bushels of lime per acre on his garden, which is rich with horse manure, but wants to hear from the *Agriculturist* before he acts. We would rather use fifty bushels now, and fifty bushels in three or four years, than a hundred all at once.

Rye-Grass.—"E. P.," Milltown, N. J., wishes to know all about rye-grass, and which kind is best. Italian rye-grass (*Lolium Italicum*) is the best of the rye-grasses. It needs a rich moist soil, is not suited to sandy thin soils, makes good hay, and requires two bushels of seed (18 lbs. per bushel) per acre. It is inferior to timothy or orchard grass in some respects.

Rape or Coleseed.—"A Subscriber" asks us to tell him something about that rape or coleseed mentioned in the March *Agriculturist*, and where the seed can be procured. Rape is a plant related to the turnip, but has not a root like that. It is grown wholly for the green fodder, or for the seed. It is, like the turnip, a biennial, and flowers in the second year. It thrives well on black peaty or mucky soils, and is useful for bringing such soils into condition for other crops. A rich sandy loam is also very suitable. When sown early in July, it will be ready for sheep to be turned on in October and November, and they will get it during winter from beneath the snow if it is not too deep; it may be fed again early in spring, and the refuse should be or may be plowed in when not completely fed off before it seeds, when a crop of wheat may follow with advantage. It is often grown for the seed, which produces rape-oil, and the cake left after the oil is expressed makes a rich feed for sheep or cattle. The haulm or stalks furnish very good dry feed. It would be a valuable winter fodder crop for sheep where the snow does not lie deeper than a few inches. A peck of seed per acre is needed when sown broadcast, three pounds when in drills. The seed can be purchased at most of the large seed-stores. The black seed fed to canary-birds is rape-seed.

Farming on the Eastern Shore, Md.

Thos. G. Reynolds, Talbot Co., Md., writes us a very interesting letter on his mode of cultivating the flat lands of the Eastern Shore. The soil is a rich, heavy loam, underlaid by a compact clay, which necessitates surface-draining. His rotation is the "three-field system"—corn, wheat, and pasture—chosen mainly to keep down the blue-grass or wire-grass. The corn is cut and carted off, and the wheat sown and covered with a three-furrowed plow, by which the land is thrown into four-foot ridges with water-furrows between them. The wheat is harvested with the reaping machine, one wheel running in the furrow, and a four-foot swath is cut. The next year the field is pastured, and then the ridges are reversed for corn, the land being heavily manured for this crop, and none given to the wheat. The corn is sown with the drill, and the furrows between the ridges being cleaned out, the planting is complete. On this system crops are made of 50 bushels of corn (sometimes 80 bushels), and 30 bushels (sometimes 50 bushels) of wheat per acre. Now, he asks what is our opinion of this mode of cultivation, and especially if we would recommend under-draining.—In reply, we have no fault to find with this system of cropping, believing that certain special rotations are well adapted to certain localities and circumstances. But, as regards the question of drainage, we should certainly in this case advise under-draining, not only to get rid of the water, but as a means of preventing the rampant growth of grass, which is the chief source of trouble. If ever there was a soil that needed under-draining this is one, and it is one also which freed from surface water would soon admit of deeper cultivation being gradually brought in. We have known of similar cases in which draining led to an effectual cleansing of the ground from grass, especially couch-grass, a nuisance equally troublesome as wire-grass. Having some personal acquaintance with the Eastern Shore, we have greater confidence in making this statement than if we wrote only on general principles, knowing that a want of drainage is the great trouble generally in this particular district. With a fine climate, a rich soil, and teeming wealth of luxuries in and on their numerous bays and creeks, and water communication to almost every considerable farm, the farmers of this district yet need one thing—which is drainage.

GARDENING FOR THE SOUTH;

OR, HOW TO GROW

VEGETABLES AND FRUITS.

BY THE LATE

WILLIAM N. WHITE,

OF ATHENS, GA.

WITH ADDITIONS BY MR. J. VAN BUREN AND
DR. JAS. CAMAK.

REVISED AND NEWLY STEREOTYPED.

ILLUSTRATED.

NOTICES BY THE PRESS

It supplies a place long vacant in Southern literature, and should be in the hands of every man or woman who cultivates a foot of ground. While it treats very freely of the vegetable garden, it devotes much space also to fruits, etc.—*Tribune* (Mobile, Ala.)

It is illustrated by a portrait of the author, and numerous engravings of subjects treated. It is a work of 450 pages, and is a complete manual of kitchen gardening and fruit culture.—*Telegraph* (Macon, Ga.)

Mr. White was prime authority in his specialty, and this volume is a complete manual for gardening for Southern latitudes. Besides the usual fruits and vegetables of Northern gardens, there are full instructions as to the culture of the almond, fig, orange, lemon, shaddock, olive, yam, ground-nut, Madeira nut, and pistachio. In view of the rising importance of "truck farming" in the South to supply Northern markets with early vegetables and fruit, this book is quite important to the gardeners of either section.—*Register* (Wheeling, W. Va.)

Coming from the pen of an experienced cultivator of Southern vegetables and fruits, the reader, whether of old or recent residence, is put in possession of facts relating to the soil, climate, and varieties of plants adapted to the South that would otherwise require much time and expense to acquire. The vineyard and orchard receive sufficient attention to furnish all the necessary information for the beginner. We regard the book as especially adapted for the private garden, and if a copy could be placed in the hands of every farmer, we might expect, on our visits to the country, to be regaled upon something else than "bacon and greens."—*Daily State Journal*.

The first edition of this work appeared in 1856, but the second, now just issued, is much enlarged, containing 441 pages. It embraces a much larger range of topics than the title indicates, and is one of the most valuable compilations of facts that we have anywhere seen in a single volume, relating to different kinds of soil, and their adaptation to different kinds of fruit and vegetables.—*Journal of Agriculture* (St. Louis, Mo.)

The book itself we can commend to our farmers and gardeners. Its author was formerly connected with the "Southern Agriculturist," a most excellent farmers' paper, and was thoroughly acquainted with the wants of the Southern people in respect to their farming and gardening operations.—*Gazette and Banner*.

A complete gardening book for the localities which it specifies. It is full and comprehensive, and written in a clear, perspicuous style. A volume of 441 pages, well printed and bound.—*Republican* (St. Louis, Mo.)

It is very comprehensive, embracing all the improved kinds of fruits and vegetables, and the modern modes and implements of tillage. Its arrangement is systematic, and entirely convenient for prompt reference. It is illustrated by a large number of drawings relating to garden and fruit cultivation, such as trailing, grafting, draining, transplanting, together with pictures of novel fruits and vegetables.—*Dispatch* (Richmond, Va.)

Price, post-paid, \$2.00.

ORANGE JUDD AND COMPANY,
245 BROADWAY, NEW YORK.

Gardening for Profit

In the Market and Family Garden.

By Peter Henderson.

ILLUSTRATED.

NOTICES BY THE PRESS.

All the vegetables that thrive in the open air in our latitude are described, together with the best methods for growing them. The author also imparts practical instructions on the subjects of drainage, and the formation and management of hot-beds. Numerous well-executed wood-cuts tend to make clearer the instructions of the author.—*Philadelphia Inquirer*.

The author of this treatise is one of the best known and most successful of those gardeners who supply New York with green vegetables; and as he writes from long and dear-bought experience, the positive, dogmatic tone he often assumes is by no means unbecoming. The book itself is intended to be a guide for beginners embarking in the author's business, and gives full and explicit directions about all the operations connected with market-gardening, lists of varieties of the most profitable vegetables, and much sound advice on kindred topics. Though designed for a special class, it can not fail to be valuable to the amateur and private gardener, and unluckily experience has taught us that the information contained in a single chapter would have been worth to us the price of the book.—*Daily Mercury* (New Bedford).

It is unquestionably the most thorough and the best work of its kind we have yet had from the pen of an American author. It is written in a clear, concise style, and thus made more comprehensive than works which smack more of the office than the farm or garden.—*Daily Evening Times* (Bangor, Me.)

Mr. Henderson writes from knowledge, and is not one of those amateur cultivators whose potatoes cost them ten dollars a bushel, and whose eggs ought to be as valuable as those of that other member of their family—the goose of golden-egg-laying memory—for they are all but priceless. No; he is a practical man, and he has the art of imparting the knowledge he possesses in a very agreeable manner; and he has brought together an extraordinary amount of useful matter in a small volume, which those who would "garden for profit" ought to study carefully.—*Evening Traveller* (Boston).

There are marvels of transformation and rapid reproduction recorded therein, which might well shame the dull fancy of the author of Aladdin or of Kaloolah. There is no theory about it; a man who has made himself rich by market-gardening plainly tells our young men how they can get rich as easily as he did, and without wandering to California or Montana for it either.—*Horace Greeley in the N. Y. Tribune*.

We have devoted more space to this little work than we usually do to tomes much more pretentious. We have done so because of the rare merits of the book in its fund of information, useful to the farmer and market-gardener, and because of the dearth of that kind of knowledge. We earnestly advise that fraternity, for whom this work was written, to buy it and study it. If any among them have never yet read a book, let this be their primer, and we will vouch for the excellence and endurance of the priming. The work is profusely illustrated with wood-cuts.—*Louisville Daily Journal*.

Price, post-paid, \$1.50.

ORANGE JUDD & COMPANY,

HARRIS ON THE PIG.

Breeding, Rearing, Management,

AND

Improvement.

With Numerous Illustrations.

By JOSEPH HARRIS,

OF MORETON FARM, ROCHESTER, N. Y.

NOTICES BY THE PRESS.

To say that this work on the pig is by Joseph Harris, that genial philosopher-farmer of Rochester, N. Y., who writes the "Walks and Talks upon the Farm" in the *Agriculturist*, is to insure for his book at once a large circle of delighted readers. He is just the man to lay down the gospel for the raising of pigs or any other domestic animal. If all breeders and farmers would follow Mr. Harris's directions, pork would be a very different article of food from what it is now, and could be eaten without any fears of the trichina.—*Springfield Republican*.

The author discusses the pig—for he takes exception to the word hog as applied to the domesticated animal—with a view of showing how the most pork and lard can be produced from the smallest amount of feed. He gives elaborate descriptions of the different breeds of swine, showing the peculiarities of each, and the relative advantages to the producer.—*Prairie Farmer* (Chicago).

The pig is doubtless one of the most valuable animals that a farmer can raise, and it is the laudable purpose of Mr. Harris to tell farmers how to treat their pigs so as to get the most profit from them, and what kind of pigs are best.—*Daily Evening Traveller* (Boston).

It treats of breeding, rearing, managing, and improving swine; and what Mr. Harris don't know on these topics, is hardly worth knowing at all. The book is fully illustrated, and is very valuable to all who are interested in this branch of stock-raising.—*Lowell* (Mass.) *Daily Courier*.

The author is a practical farmer, and has gathered the results of many experiments besides his own. The book is amply illustrated.—*Republican Statesman* (Concord, N. H.).

Almost everything a farmer wants to know about the breeding, keeping, and fattening of pigs, is here put down in plain, common sense, and is mainly the result of the writer's own management.—*Maine Farmer*.

This is an interesting, valuable, and a much-needed treatise on an important department of rural economy. It contains about 56 illustrations of pigs, piggeries, troughs, etc. We are heartily glad our old friend Harris was persuaded to prepare this useful Manual on the Pig—breeds, breeding, feeding, etc., comprising what farmers need know respecting this department of husbandry.—*Boston Cultivator*.

This little book is profusely illustrated, and contains information in abundance, which every farmer ought to possess.—*Weekly Mail* (St. Louis).

Here is a book written by a practical farmer, who has brought to the aid of his own large experience and observation the most extensive acquaintance with the science of breeding, and, as might reasonably be expected, we have from his pen the best book on the Pig ever written.—*Western Stock Journal*.

REPORT OF JUDGES

AT THE SECOND

INTERNATIONAL INDUSTRIAL EXPOSITION

OF THE

MECHANICS' INSTITUTE:

To THE EXHIBITION COMMITTEE:

Gentlemen: The undersigned, Judges in Department 1, Group 7, report that they have carefully and impartially examined, according to the "Instructions to Judges" transmitted to them, the several competing articles submitted for their judgment, and that the following are their conclusions:

No. 795. American Watches, Entered by

T. & E. DICKINSON,

Buffalo, N. Y.

"T. & E. Dickinson, exhibit American Watches, manufactured by the United States Watch Co., (Giles, Wales & Co.) Marion, N. J.

"These Watches are, without doubt, the best manufactured in this country."

ALLEN CHURCH,
GEO. I. BENTLEY, } Judges.
B. S. BENTLEY,

I hereby certify, that the above is a correct copy of the report of Judges on Entry No. 795, and that the same was awarded First Premium. (Large Medal.)

D. B. McNISH,

Buffalo, N. Y., Dec. 29th, 1871.

Secretary.

Price List furnished the Trade on application, inclosing business card. For sale by the Trade generally.

Ask your Jeweler to see the **MARION**

WATCHES

BEWARE of worthless imitations with which the country is flooded. To avoid imposition, see that the words **MARION, N. J.,** are engraved on the plate over the Main-Spring Barrel. All others are spurious.

ORANGE JUDD & CO., 245 Broadway, New York.

**WARING'S
BOOKS FOR FARMERS.**

**DRAINING FOR PROFIT
AND
DRAINING FOR HEALTH.**

By **GEO. E. WARING, Jr.,**
Engineer of the Drainage of Central Park, New York.

CONTENTS.

**LAND TO BE DRAINED; HOW DRAINS ACT; HOW TO
MAKE DRAINS; HOW TO TAKE CARE OF DRAINS;
WHAT DRAINING COSTS; WILL IT PAY? HOW TO MAKE
TILES; RECLAIMING SALT MARSHES; HOUSE AND TOWN
DRAINAGE.**

EXTRACTS FROM NOTICES BY THE PRESS.

He (the author) describes the action of draining upon
the soil, the construction of single drains and systems of
drains, the cost and the profit of thorough drainage, the
making of tiles, and the reclaiming of salt marshes,
treats sensibly of malarial diseases, and closes with a
chapter which should be widely read, on house drainage
and town sewerage in their relations to the public health.
[Portland (Me.) Press.

Nowhere does this book merit a wider circulation than
in the West. Every year adds to the thousands of dollars
lost to this State from want of proper surface drainage,
to say nothing of the added gain to result from a com-
plete system of under-drainage. This book will prove
an aid to any farmer who may consult it.

[Chicago (Ill.) Republican.

A Book that ought to be in the hands of every Farmer.
SENT POST-PAID, PRICE, \$1.50.

EARTH-CLOSETS

AND

EARTH-SEWAGE.

By **GEO. E. WARING, Jr.** (of Ogden Farm).

INCLUDING:

- THE EARTH SYSTEM (Details).
- THE MANURE QUESTION.
- SEWAGE AND CESS-POOL DISEASES.
- THE DRY-EARTH SYSTEM FOR CITIES AND TOWNS.
- THE DETAILS OF EARTH SEWAGE.
- THE PHILOSOPHY OF THE EARTH SYSTEM.

With Seventeen Illustrations.

Paper Covers, Price, Post-paid 50 cts.

ELEMENTS OF AGRICULTURE.

A BOOK FOR YOUNG FARMERS,

By **GEO. E. WARING, Jr.,**

Formerly Agricultural Engineer of the Central Park, in
New York.

CAREFULLY REVISED.

CONTENTS.

**THE PLANT; THE SOIL; MANURES; MECHANICAL CUL-
TIVATION; ANALYSIS.**

The foregoing subjects are all discussed in plain and
simple language, that any farmer's boy may understand.
The book is written by a successful *practical farmer*, and
is full of information, good advice, and sound doctrine.

HORACE GREELEY says of it: "Though dealing
with facts unfamiliar to many, there is no obscure sen-
tence, and scarcely a hard word in the book; its 254 fair,
open pages may be read in the course of two evenings
and thoroughly studied in the leisure hours of a week;
and we pity the man or boy, however old or young, who
can find it dull reading. Hardly any one is so wise that
he will not learn something of value from its perusal; no
one is so ignorant or undeveloped that he cannot generally
understand it; and no farmer or farmer's son can study it
thoughtfully without being a better and more successful
cultivator than before."

SENT POST-PAID, PRICE, \$1.00.

THE BECKWITH \$10 SEWING MACHINE.

DESCRIPTION.—*c*, clamp holding machine upon edge of table; *w*, shield over wheels, with an opening to show the wheels; *a*, the crank-bar or pinion-arm, by which *b*, the upper arm, is moved; *d*, the lower arm; *f*, cloth plate; *n*, needle; *t*, thumb-screw to hold the needle; *s*, spool; *r*, tension screw and disks; *s*, spool of thread; *m* moves the stitch-maker which can not be readily shown. It is very simple in form and sure.

A GREAT BOON. A Good Cheap Sewing-Machine at Last.

We have been offering as a Premium, for some weeks past, the Beckwith new \$10 Sewing Machine, which has been fully described in the *American Agriculturist* for March and April. We have already given and sold some hundreds of these machines, and testimonials of satisfaction are coming from every quarter.

Hundreds of letters have been received by us and by the Beckwith Sewing Machine Co., extracts from a few of which are given below.

VAN BUREN, ARK., May, 1872.

GENTLEMEN: We have just received from Orange Judd & Co. one of your machines. We are very much pleased with it, and write to know terms to agents.

Respectfully,
DECHERD BROS.

CONCORD, OHIO, April, 1872.

GENTLEMEN: I purchased one of your machines of Orange Judd & Co. My wife is learning to use it. We are much pleased with it thus far.

Yours truly,
R. BURR.

No. 3, A. & G. R.R., GEORGIA, April, 1872.

GENTLEMEN: Seeing your improved machine advertised in the *American Agriculturist*, and relying on Orange Judd & Co.'s statements, we sent to them and got one of your machines, with which we are much pleased. Have shown it to several friends, and I presume several orders will soon be sent to Orange Judd & Co. or to you.

Respectfully yours,
J. A. M. KING.

NEW YORK, May, 1872.

GENTLEMEN: It is due your laudable enterprise to state that, having had in my family one of the Beckwith Sewing Machines from its first appearance, its great merits are more apparent the longer we use it. My wife makes all her dresses on it with ease and perfect satisfaction, as well as everything else she desires to sew. She has recently made a heavy silk dress with it, and is now making a light summer dress. Having formerly been accustomed to the use

of first-class large machines, she greatly prefers the little Beckwith. Its ease of operation, its simplicity, and always being in perfect order, together with the great convenience of taking it with her wherever she goes, and of using it wherever she pleases, are considerations so greatly in its favor, that it must soon become the favorite of every household.

Yours respectfully,
LEANDER FOX, 26 Varlek St., N. Y.

WASHINGTON, D. C., March, 1872.

GENTLEMEN: Received the machine and letter sent by you on the 8th inst. After an examination and trial of the former, sewing with it nearly the whole of several garments, including one of cloth, I can say that it gives entire satisfaction.

Very respectfully yours, etc.,
H. L. CLARK.

CRESTNUT CREEK, ALA., April, 1872.

GENTLEMEN: On the 30th day of March last, my wife, Mrs. E. A. Floyd, inclosed \$10 to the Beckwith Sewing Machine Co., and waiting several weeks she became very impatient, as women usually do, but she has received the Beckwith Sewing Machine in good order and complete in every part, and says she would not take fifty dollars for it if she could not get another like it. It does all you claim for it. Several persons have seen this machine at work, and are well pleased with it. If you would receive the money through the Express Co. on delivery, I would like to have one dozen of them sent immediately to this office. I am satisfied that I can sell one dozen per week easily. I am County Surveyor for Baker County, and mixing with the people daily.

Respectfully yours, etc.,
GEO. W. FLOYD.

KENANSVILLE, DUPLIN Co., N. C., April, 1872.

GENTLEMEN: The machine has been received, and works like a charm. - Yours respectfully,
R. H. BROWN.

BUNSWICK, MAINE, March, 1872.

GENTLEMEN: Your machine was received in good order, and I think very highly of it, and they will find a ready sale. Should be very happy to take the agency or buy machines of you to sell again.

Yours truly,
B. L. DENNISON.

HAMILTON, LOUDOUN Co., Va.

GENTLEMEN: Please send me your terms to agents for the Beckwith Sewing Machine. We are much pleased with ours. I would like to have the agency of this county, if terms are satisfactory.

Very respectfully,
WM. H. BALL.

ANNA, UNION Co., ILL., March, 1872.

GENTLEMEN: Yours of late date to hand, and contents noted. Am glad to learn your demand is more than you can supply, and hope you every success possible. My machine came all right, and such a novelty you can imagine, and so surprising to do such work, is really astonishing! Have experimented considerably, and am well pleased, and think I will soon be an expert at the business.

Yours truly,
W. S. MORGAN.

SALISBURY, MD., March, 1872.

GENTLEMEN: The sewing machine, came safely to hand, and on trial I find it complete. The dearest little machine ever was made. I am quite in love with it. A gentleman told me last night that he believed I could sell a hundred here in town, and urged me to write and get the agency.

Yours respectfully,
Miss SALLIE BUSH.

FOND DU LAC, WIS., March, 1872.

GENTLEMEN: I have received from the office of the *American Agriculturist* one of your \$10 sewing machines, and am so much pleased with it that I would like to know on what terms you supply agents, and what is required of them. An early reply will oblige

Mrs. EDWARD COLMAN.

COLUMBUS, GA., April, 1872.

GENTLEMEN: I purchased a sample of the "Beckwith Sewing-Machine" while in Savannah, Ga., for a lady friend. She has received it, and is perfectly satisfied with it. I am confident, from the merits of the machine, that many of them can be sold in the Southern country, from the fact that thousands would buy machines if they could get a cheap meritorious one.

Yours truly,
L. C. DUER.

LOWER MACCAN, CUMBERLAND Co., N. S., April, 1872.

GENTLEMEN: I received the Beckwith Sewing-Machine a few days ago, and am perfectly satisfied with it. It exceeds my expectations, and those who have seen it pronounce it beautiful.

Very truly yours,
ISAAC HARRISON.

BEDFORD Co., VA., March, 1872.

GENTLEMEN: Some time since, I got for my wife one of your sewing-machines, and she and I are so well pleased with it, and think it comes up so nigh to what it promises, that I have determined to apply to you for an agency. I believe I can sell a good many of them, and can make a good thing of it both for yourselves and me. I do not know of there being another machine of the kind in the county. If you choose to entertain my proposition, I refer you (for my character) to our Circuit County Judge, or the Clerks of our County or Circuit Court, or any one you may happen to know in the County of Bedford, Va.

Yours very respectfully,
Dr. JNO. S. MITCHELL,
Liberty, Bedford Co., Va.

We have contracted with the Beckwith Sewing Machine Company for a large number of them to supply our own friends, and as *Premiums*. Each machine is put in a neat, compact box, with *hemmer and guide, oil-can, bottle of oil, thread, different-sized needles, etc.*, with full Printed Directions for using, and delivered to any express office in this city, without extra charge above the \$10. As we buy the machines at wholesale price, we have decided to give our readers some advantage of this, and we therefore propose to make a present for himself or herself, or for any friend, of one copy of *Heath and Home* or two copies of the *AMERICAN AGRICULTURIST* for the balance of this year (1872), to those persons who send us \$10 for one of the machines while this offer is continued.

The New Sewing Machine as a Premium without Money.

To enable those to get this machine who can not raise even the \$10 to buy it, we make the following offer:

We will send the Machine free to any one who will collect and forward SIX subscribers for HEARTH AND HOME one year at \$3 each; or TWELVE subscribers to AMERICAN AGRICULTURIST for one year, at \$1.50 each.

Almost any lady can readily secure this small number of subscribers and get a machine free; or some friend can thus obtain it for her, as a present.

Cayuga Lake R.R.,

STATE OF NEW YORK,
**7 Per Cent
FIRST MORTGAGE
GOLD BONDS,**

Thirty Years to Run, and Issued for
\$20,000 Per Mile,
At 90 and Accrued Interest in Currency.

This road forms the shortest and most direct route from
the great anthracite and semi-bituminous coal fields of
Pennsylvania into the central part of this State, and will
run in connection with the New York Central Road, and
which it crosses at Cayuga Bridge. Traversing, as it
does, the finest and most populous agricultural district,
generally known as the "GARDEN OF THE STATE," its
local traffic will be large, but its greatest source of revenue
will be from its coal business. The road is being
rapidly built. Iron is now being laid on a section cover-
ing more than one quarter of the distance, and work on
the whole line being pushed with great vigor, so that it
is expected to have coal trains running by the 1st of
November next. From our knowledge of this enterprise,
and after the most thorough investigation, we most con-
fidently recommend the Bonds as a safe investment.
We offer, for the present, the Bonds at 90 and accrued
interest in currency.

ORANGE JUDD & CO.,
245 BROADWAY, NEW YORK

Safe and Profitable.

THE
Canada Southern
FIRST MORTGAGE SINKING FUND
THIRTY YEARS
7 PER CENT GOLD BONDS
AT
90 and ACCRUED INTEREST.

The Road runs from Buffalo to the
Detroit River, and is the Eastern link
in the new AIR LINE FROM BUFFALO
TO CHICAGO, and has been under
construction for about two years past
by railroad men who have seen the
necessity for a STEEL-RAIL, LOW-
GRADE SHORT ROUTE between the
great railroad systems which diverge
from Chicago, Toledo, and Buffalo.

Among the builders of the Road, by whose cash sub-
scriptions 220 miles (out of 290) have already been graded,
bridged, and made ready for the superstructure, a large
part of the steel rails bought, all of the materials for the
stations, and a part of the equipment purchased, are:

MILTON COURTRIGHT, JOHN F. TRACY, DAVID
DOWS, WM. L. SCOTT, HENRY FARNHAM, R. A.
FORSYTH, HENRY H. PORTER, JOHN M. BURKE,
M. L. SYKES, JR., B. F. ALLEN, all directors, either
in the Chicago and North-west, or the Chicago, Rock
Island, and Pacific; GEORGE OPDYKE, of the Midland
Road; JOHN B. ALLEN, SIDNEY DILLON, DANIEL
DREW, J. S. CASEMENT, J. & J. STEWART, and
F. H. WINSTON.

THE ROAD will be
33 MILES SHORTER
THAN ANY OTHER ROAD,
either BUILT or in contemplation be-
tween Buffalo and Chicago, and will
also shorten the distance between
Toledo and Buffalo 23 miles.

THE MAXIMUM GRADE on the entire
line does not exceed FIFTEEN FEET
to the mile, and Ninety-six per cent
of the Road IS STRAIGHT.

THE ROAD WILL BE COMPLETED
and in running order on or before
December 31st, of this year.

The principal and interest of the Bonds are payable
either in New York, London, or Frankfurt.

We confidently recommend the Bonds to all classes of
Investors.

AGRICULTURAL CHEMICAL ANALYSIS.

After E. Wolf, Fresenius, Krockner, and others. Edited by
Prof. G. C. Caldwell, of Cornell University. Price \$2.00.

In this work Professor Caldwell has brought together the
processes of analysis which apply especially to soils, fertil-
izers, animals and plants, and their products. He has tested
the methods of the best foreign authorities, and presented
them in a compact hand-book. Such a work has long been
needed by all who teach agricultural chemistry, and by
analytical chemists generally. Professor Caldwell modestly
calls himself the editor, but his book shows that he has not
contented himself with editing the works of others, but has
given much of his own experience.

THOROUGH-BRED HORSE LONGFELLOW.—DRAWN FROM A PHOTOGRAPH.—Engraved for the American Agriculturist.

Whatever we may think of races and racing, every one likes a fine horse, and has a curiosity to see and know something about the animal whose exploits have been heralded from one end of the country to the other. *Longfellow*, now five years old, was bred and raised by John Harper, of Midway, Ky., and is by *Leamington*, dam *Nantiorah*. *Leamington* is a celebrated imported racer, whose portrait we gave in June, 1870, and has a world-wide reputation to which

his progeny are not likely to do discredit. As a three-year-old, *Longfellow* won several important races at the West. In his career as a four-year-old, last year, he won several races, but was beaten at Saratoga in August by *Helmbold*. His owner, determined that he should recover his lost prestige, entered him for the Monmouth Cup (Long Branch), which was run for on July 2d, against *Harry Bassett*. The race, 2½ miles, was easily won by *Longfellow* by a hundred yards,

in 4:34. *Longfellow* is 16½ hands high, of a full brown color, very strong quarters, and has, according to the opinion of his owner, the best set of legs ever put under a horse. He has a very neat and intelligent head, but his neck is defective on account of an accident which occurred to him when quite young. We understand that Mr. Harper has declined an offer of \$80,000 for *Longfellow*, but he does not care to part with his pet for a less sum than \$100,000.

AMERICAN AGRICULTURIST.

NEW YORK, AUGUST, 1872.

Many farmers have had much to try their temper and test their patience during the past month. Hoeing, haying, and harvest have been crowded together. Men have been scarce and have had things all their own way. And we know of nothing more disagreeable than to be obliged to submit to the dictation of a lot of ignorant, selfish, conceited men, who are blind to their own permanent interests, and utterly regardless of the interests of others. It is useless to reason with them. All that we can do is, the moment we are through the hurrying season, to discharge those who have behaved the worst. We do not complain so much of the high wages as of the short hours and of the general listlessness, indifference, unskillfulness, and indolence of a large class of farm men. We have all been complaining of this evil for some years. We have thought that it would cure itself. But instead of getting better, it is getting worse and worse. It is time that the subject was carefully considered and concerted action resorted to. We must be just and liberal with our men, but should insist on a faithful performance of contracts. No farmer should hire a man who has broken an engagement with a brother-farmer.

During the latter part of this month and the next there will be comparatively little to do on many farms, and day-men can be obtained at lower rates. If a man has been faithful, give him steady work and fair wages. But you owe it to yourself and to the good men, to dismiss every man who has not acted properly. This policy, generally carried out, would have a salutary effect.

Hints about Work.

Finish the Harvest.—The better plan is to finish each field as you go, but we can not always do just what we know to be best. In the hurry of harvest, and with fewer men than we need, it is sometimes necessary to "get the biggest of it," and trust to finding time to clear up afterwards. As soon as the main bulk of the crops is secured, a farmer is very apt to relax his exertions. This should be guarded against. There should be no let-up until everything is finished. Then take a rest and enjoy yourself.
Oats.—This is generally the last grain crop to

harvest. Where the straw is used for fodder, it is well to cut the crop before the oats get fully ripe. Or where oats and straw are to be all cut up together and fed to horses, the crop may be cut while there is considerable "milk" in the grain. In this case it is necessary to be very careful in curing. On the whole, we are inclined to think that the better plan is to let the oats stand until they are nearly or quite ripe. The grain will be heavier, and less time is required for curing. Much, however, depends on circumstances. If we are likely to have settled hot weather, we should cut early, but if the weather is unsettled, we should prefer to let the oats stand until quite ripe. Oats are not unfrequently damaged by being drawn in before they are sufficiently cured, especially after they have been exposed to rain. It is important that the oats are perfectly dry inside and outside the sheaves and at the butts.

Thrashing.—If the grain is safe in the barn, we should be in no hurry to thrash. It is not probable that wheat will rule permanently lower during the next twelve months than at the present time. We do not say that it will be higher. We are not urging farmers to hold on to their grain, but simply not to be in a hurry to thrash, unless there is some object to be gained. Wheat keeps far better in the straw than in the granary, and it is far better not to thrash until the straw or grain is needed. But where grain has to be stacked, and where thatching is not practiced, it is better to thrash as early as possible.

Thrashing by Steam.—Steam-engines for thrashing are being rapidly introduced. The old ten-horse-power machines have done good service, and deserve to be held in grateful remembrance. But we rejoice to believe that their days are numbered. If there is a steam thrasher in the neighborhood, patronize it. This is the only way to banish the old horse-machines.

Look to your Insurance.—This is always good advice; but it is particularly so at this season. Many farmers have a good deal of property, in the form of wool, hay, and grain, exposed to fire, that is not covered by insurance, because they expect to keep it only a short time. If they can afford to be their "own insurers," all very well. But if a fire would cripple them, it is the part of wisdom to be at least partially insured. We fear that many farmers have property that they think is insured which their policies do not cover. Your wool or grain may be insured in one barn but not in another, and you may have overlooked or forgotten the fact. If you are going to thrash with a steam-engine, see if it does not invalidate your policy. There is little or no risk from a properly-constructed engine, but it is a very unpleasant thing when you think you are insured to burn up and find that there is a clause in the policy that forfeits your claim.

Thrashing with a Sweep-Power.—The general practice in our neighborhood when thrashing with a hired ten-horse-power machine is to pay five cents per bushel for wheat, four cents for barley, and three cents for oats, the owner of the machine furnishing four men and four horses. One of the "thrashers" drives, and he is naturally inclined to spare his own teams at the expense of ours. This should be looked to. If possible, let the horses have a level track, for in going up-hill a good team is inclined to pull harder than on a level. Give the outside horse a longer half of the evener. With quiet, thoughtful, and experienced thrashers everything will go smooth, and the horses will not be injured, but new hands get excited, and drive too hard. What is wanted is steady work. See not only that the machine thrashes clean, but that none of the grain is carried over in the chaff.

Making the Straw-Stack.—It is rare to see a really good straw-stack. If the object is to rot down the straw for manure, the stacks as frequently made can not be improved. But where the object is to save the straw for fodder and for litter, much more pains than is generally the case should be taken in making the stack. We can not go into details, but the main points are to keep the middle full and well trodden down, so that the sides shall settle more than the center. Keep the chaff and short

straw well scattered about in the middle of the stack, and especially avoid letting it lie in a mass where deposited by the straw-carrier. Aim to have good straw to top off with. In a few days after the stack is completed, place a long ladder on the roof, and rake the straw down smooth so that the water will run off rapidly.

Thatching.—We do not advocate stacking hay; but we do most earnestly recommend any of our readers who have hay-stacks to thatch them as soon as they can get the straw. It is a mistake to suppose that it is necessary to have long, straight straw to thatch with. Short straw will answer the purpose. The first point is to *wet* it thoroughly and lay it out straight on the roof, commencing at the eaves, and lapping the courses as you would with shingles. Rake smooth, and fasten carefully with pegs and hay-rope or twine.

Grain, when thrashed early, is very liable to heat. Turn it frequently, or run it through a fanning-mill. If it is very damp, mix dry cut-straw or chaff with it, and turn it every two or three days.

Weeds.—The best thing to do with the weed-seeds cleaned out of the grain is to burn them. If the screenings contain weeds, as they almost always do, they should be thoroughly boiled before feeding. If possible, allow no weeds to go to seed in the growing crops or in the fence-corners and waste places. Mow the weeds in the pastures. If the wheat or barley stubbles are weedy, it is a capital plan to go over them with a mowing machine.

Beans.—Our own plan is to pull five rows at a time, and place the handfuls, with the roots up, on the middle row. If the weather is favorable, this is the easiest and quickest way of curing. They should be lifted or turned as often as necessary to prevent the leaves on the ground from molding. If the weather is unsettled, it is the safest plan to cure them in large heaps made so as to shed the rain. If carefully made, beans may stand in such heaps for weeks without injury.

Wheat on Stubble Land.—A large and increasing breadth of winter-wheat is now sown after barley, oats, peas, or beans. Whether it is best to plow such land once or twice depends on circumstances. As a rule, we think it best on rather heavy soil to plow twice—once immediately after the crop is gathered, and again just previous to sowing. On light sandy land we should harrow the stubble, or cultivate it to start the weeds and fillen grain, and plow as soon as they had germinated. Then harrow, and keep the surface clean and mellow by the use of the cultivator until it was time to sow.

Root Crops, such as mangel-wurzel, ruta-bagas, carrots, parsnips, etc., should be kept scrupulously clean. Use the hoe and cultivator freely. By using 200 lbs. of good superphosphate per acre, a fair crop of Strap leaf turnips may be grown on good clean land sown as late as the first or even the second week in August. Sow on fresh-plowed land.

Draining Swamps and Getting out Muck are always in order this month. Grind the spades as sharp as possible, and go to work with a will. It is nothing like as difficult a job as most people imagine. On flat, level land the true way to dig a ditch is to commence at the lowest point, and dig just deep enough to have the water follow you up into the higher land. You will then lose no fall. Such muck as you intend to use for manure or compost should be thrown on one side of the ditch only, and by taking a little pains it may be thrown in good-sized heaps with little extra labor.

Cows.—During the hot weather in August the flow of milk is apt to fall off considerably, and it is difficult afterwards to bring it up again. Bran and spout-feed are unusually cheap, and can be used to great advantage. Our own plan is to keep a large trough of water in the yard, and mix as much mill-feed with the water every day as the cows will drink. It pays in the manure, in the increase of milk, and in the improved condition of the cows. If you have any green corn, now is the time to feed it liberally. If very succulent, let it wilt a little, and if very large and coarse, and consequently rather deficient in nutriment, let the

cows have enough corn-meal to make the fodder as nutritious as the best pasture grass.

Sheep.—Lambs should now be weaned. Put the ewes in a poor pasture, and let the lambs have the run of some second growth clover or other rich grass. If the weather is wet and the grass succulent, give some dry food, such as clover hay, or, better still, bran. Remove the rams from the flock.

Swine.—Let the breeding sows and store pigs have the run of the stubbles. Pigs intended to be fatted this fall should now be fed liberally, but should be allowed to run in the pasture.

Water.—See that all animals have a plenty.

Work in the Horticultural Departments.

During August the gardener will have a little time for rest if he has succeeded in subduing the weeds, and has not allowed his work to get ahead of him. A day or two of fishing or picnicking will afford a pleasing variation from the regular routine of daily labor. There are many odd jobs that can be done before harvesting commences, which will save a great deal of time next season. Around most gardens, weeds are allowed to find a harbor along the fences and walls, and if permitted to go to seed it will be hard work to kill them next year. Preparations for draining may be made.

Orchard and Nursery.

The present month will be a trying one to the trees planted last spring unless a good mulch was applied after they were set out. It will not be too late to save many if a mulch is put around the trees now. If late web-worms infest the trees, the branches must be cut off and burned, or they will soon destroy the foliage of the whole tree.

Marketing.—Care should be taken in sending fruit to market to assort and pack it in such a way that the highest prices can be obtained. The fruit should be packed so firmly in the box or crate that there will be no danger of bruising in transit.

Insects.—There is often much fruit which falls prematurely, which on examination will be found to contain insects, and should be given to the pigs as fast as they fall, or, if preferred, the pigs may be allowed to run in the orchard.

Budding may be done whenever the bark is loose enough to lift readily, and well-ripened buds can be obtained. The maturity of buds may be hastened by pinching the end of the shoot on which they are borne. When sticks of buds are cut, remove the leaf, leaving the leaf-stalk attached to the twig. The twigs must be kept moist until used.

Weeds.—If the nursery rows have been allowed to become weedy, they should be thoroughly cultivated, and afterwards hand-weeded. A heavy mulch between the rows will save many seedlings which would otherwise die from the extreme dry weather which often occurs at this season.

Kitchen Garden.

Nothing can furnish more real enjoyment than a good garden well stocked with a variety of vegetables, and a family can obtain their principal supply of food from it.

Asparagus.—There is danger of neglecting this during the rush of work, and allowing it to become filled with weeds, to the injury of the next year's crop. It ought to be hoed frequently to keep the soil light, and manure applied at any time now, will be of great benefit to it.

Beans.—It is rather late to plant beans unless wanted for late snaps; a fair crop may be secured for salting or pickling.

Cabbages and Cauliflowers.—Hoe frequently, especially early in the morning when the dew is on. Liquid manure occasionally will be of benefit. Lime or salt may be used for destroying slugs.

Carrots.—Cultivate between the rows until the tops are so large as to cover the ground, and when very large weeds make their appearance pull them out by hand. Thin out the late sowings.

Celery.—Continue to earth up, and keep the ground well cultivated. Plants may still be put out, and will make a late crop.

Corn.—Reserve the earliest and best formed ears for seed. Cut off all smutty ears and burn them.

Cucumbers.—Pick every day for pickles; those not more than two or three inches in length make the best pickles. Those that ripen may be made into cucumber salad for winter use.

Egg-Plants.—The present warm weather will give these a start, and a little liquid manure will benefit them. Hay around the plants will keep the fruit from touching the ground and rotting.

Melons.—Cultivate until the vines cover the ground, and pinch back the ends of the vines where they are too long.

Onions.—As soon as the tops fall down they are ready for harvesting. Pull and allow them to dry thoroughly before storing; when stored, spread thinly so that they will not heat. Store onion sets in the same way.

Radishes.—Sow Chinese Rose-colored Winter.

Spinach.—Sow now for fall use; the winter crop is put in later.

Sweet-Totatoes should be making a rapid growth now, and the ridges must be kept clear of weeds. Move the vines often to prevent taking root.

Tomatoes.—Tie up to some sort of trellis, or place brush or hay around the plants to keep the fruit off from the ground. Destroy the green worm wherever found.

Turnips.—Ground from which early peas, potatoes, etc., have been taken, may be set with transplanted ruta-bagas or sown with turnips.

Fruit Garden.

The principal work in this department is the harvesting of the fruit, which promises to be very abundant. Surplus fruit should be preserved in cans or bottles, or dried.

Blackberries.—Three or four canes only should be allowed to grow, and these must be cut off when they reach a height of 4 or 5 feet, and the laterals pinched back when they are 18 inches long. Fruit for home use ought to be thoroughly ripe before picking, while that for market must be picked before it is fully ripe.

Dwarf Trees.—Pick off all deformed fruit, and do not allow the trees to overbear.

Grapes.—Use sulphur if mildew makes its appearance. Keep the vines tied to trellises or stakes.

Raspberries.—After the fruit has been harvested, cut away the old canes, and dig in a good dressing of manure between the rows.

Strawberries.—Now is a good time to plant new beds, and to renovate the old ones. Beds set out now, will produce a moderate crop next season. Plenty of stable manure is the basis of good crops.

Flower-Garden and Lawn.

The fine growing weather of July has pushed forward the growth of plants very rapidly, but the weeds have made correspondingly rapid march, and if the hoe and rake have not been in constant use, a great deal of weeding will be necessary to make the flower-garden look respectable.

Box.—This beautiful edging must be clipped, to keep it in proper shape, and the present month is the time to do it.

Climbers require to be kept neatly tied up to show off to the best advantage. A few small iron brackets screwed to the posts of the piazza or side of the house, and galvanized iron-wire stretched between the brackets, will make very serviceable supports, as they allow a free circulation of air between the house and vines.

Grass.—Edgings and borders need a good deal of attention in order to look well, and if cared for often, will require but little time. The lawn needs mowing over at least every week or ten days, in order to make it look well.

Dollias and Gladioluses need stakes, to keep them

from being blown down during high winds or rains. Most florists have for sale stakes of different sizes and lengths, which are very serviceable, and last well, if properly taken care of.

Hedges.—Give the summer clipping this month.

Potted Plants, which have been placed in different parts of the grounds for summer decoration, need to be watered often, as the soil dries very rapidly when exposed to the wind.

Perennials.—A suitable frame or bed must be prepared, where seeds of perennials and biennials can be sown as soon as they ripen. Keep the beds or boxes well watered and shaded during the dry, hot weather.

Chrysanthemums.—Bring them into good shape by pinching, and remove any imperfect flowers which show themselves.

Seeds.—Gather as soon as they commence to ripen, and after they are thoroughly dry, clean and put away in a dry place, secure from mice.

Greenhouse and Window Plants.

Hanging baskets and window-boxes must have plenty of water and be shaded during the middle of the day. The greenhouse will need a thorough renovation, to clear it of all insects, and to make it ready for the reception of the plants in autumn.

All glass should be set before cold weather sets in, and the heating apparatus put in good order. Put in a good stock of potting soil and sand for winter use, and provide plenty of pots and boxes for large plants.

Commercial Matters—Market Prices.

Gold receded to 113 @ 113 1/4, closing July 13th at 114 1/4, against 113 3/4 on the 13th of June. There has been a less satisfactory trade reported in Breadstuffs, with prices generally quoted much lower, in most instances, on increased offerings of stock. The home demand has been on a restricted scale, while the export inquiry has been mainly for Spring Wheat and mixed Western Corn. Toward the close, the market exhibited more steadiness, particularly for Flour, Wheat, Corn, and Oats, which were less abundant, under lighter arrivals, though the scarcity of ocean freight room and the sharp advance in rates were against free export purchases. Provisions have been in less confident demand. Hog products closed more firmly; while Butter and Cheese showed weakness as to values; and Beef products were depressed. Eggs have been less sought after, closing in favor of buyers. Hay has declined in price, and closed dull. Hops and Tobacco have attracted more attention, at steadier rates. Wool was dull and lower early in the month under review. Toward the close there was more inquiry noted for desirable lots, which, however, have been offered with reserve and at prices generally above the views of buyers, thus checking operations, particularly in Domestic Fleece and Pulled. Comparatively little of the New Clip is being forwarded to market, as farmers are not willing to sell at less than the extreme asking figures, and do not seem eager to realize on their holdings. Cotton has declined materially, closing tamely and heavily.

The following condensed, comprehensive tables, carefully prepared specially for the American Agriculturist, show at a glance the transactions for the month ending July 13, 1872, and for the corresponding month last year.

Table with 4 main sections: 1. TRANSACTIONS AT THE NEW YORK MARKETS. 2. Comparison with same period at this time last year. 3. Exports from New York, Jan. 1 to July 12. 4. Receipts at head of tide-water at Albany each season to July 7th.

Stock of grain in store at New York. Table with columns for Wheat, Corn, Rye, Barley, Oats, and Mill, with sub-columns for bush and bbl.

CURRENT WHOLESALE PRICES.

Table of current wholesale prices for various commodities including gold, flour, corn, wheat, rye, barley, oats, and various oils and fats.

New York Live-Stock Markets.

Table showing live-stock market data including week ending, beef cows, calves, sheep, swine, and total.

Beef Cattle.—Several causes combined to make a dull cattle market the past month. One was the generally poor quality of the stock after the corn-fed cattle had nearly run out, and before the grass steers had become fat. They are now improving in condition each week. Besides this we have had too many cattle for the extreme heat of the past few weeks. Much of the meat would spoil before it could be used, while those employed in getting out and distributing ice took advantage of the situation, and struck for higher wages. Then, again, so many men of the various trades were unemployed and out on strikes, that the laboring classes had not the money with which to buy beef. Just at the close there is a better tone to the market, the prospect being favorable for a lighter run of stock. Still the decline for the month has been more than 1/2 c. per lb.

Milk Cows.—With a larger average, the cow trade has been variable during the past month. The market has been largely overstocked with milk, so that farmers were more inclined to reduce than add to their stock of cows. Just now there is more inquiry, and all the good cows are selling. Prices are rather higher all around. Common cows sell at \$35 @ \$50, fair at \$60 @ \$65, and good to prime at \$70 @ \$80. Calves.—These decrease in numbers as summer wears away, but their use is also less.

The quality is poorer. Some of the best milk veals are as good as those sent in last month, but we now get a good many grass and buttermilk calves. Farmers were in market for such last year, but they do not come now. Such animals sell low. Quotations of grass calves are 3c. @ 5c. per lb., live weight; common to fair milk veals 7c. @ 8 1/2 c.; good to choice, 9c. @ 9 1/2 c. Sheep and Lambs.—As lambs are ready for sale, and some of the ewes can be turned off, we are getting quite an increase of stock. The demand has also improved during the hot weather, mutton being decidedly a favorite meat during the summer. Sheep declined at first, and have since improved, though they are scarcely as high as they were one month ago. Lambs have held their own, notwithstanding it is the season when they are expected to decline. Quotations: Ordinary sheep, 5c. @ 5 1/2 c. per lb., live weight; fair to good, 6c. @ 6 1/2 c.; prime to extra, 6 1/2 c. @ 6 3/4 c.; few very choice, 7c. Lambs, 8 1/2 c. @ 10c. for poor; 11c. @ 12 1/2 c. for medium to good, and 13c. for choice Jerseys. Swine.—With a falling off in arrivals there is little change in the market. Heavy dressed declined to 5 1/2 c. during a scarcity of ice, but are now improved. There is seldom a sale alive, nearly all the hogs being consigned to slaughterers. Live are worth 4 1/2 c. @ 4 3/4 c.; city-dressed Western, 5 1/2 c. @ 6c.

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Remitting Money: — Checks on New York City Banks or Bankers are best for large sums; make payable to the order of Orange Judd & Co., Post-Office Money Orders, for \$50 or less, are cheap and safe also. When these are not obtainable, register letters, affixing stamps for postage and registry; put in the money and seal the letter in the presence of the postmaster, and take his receipt for it. Money sent in the above three methods is safe against loss.

Postage: On American Agriculturist, 3 cents a quarter, in advance; on Hearth and Home, 5 cents per quarter. Double rates if not paid in advance at the office where the papers are received. For subscribers in British America, the postage must be sent to this office for prepayment here.

Bound Copies of Volume Thirty are now ready. Price, \$3, at our office; or \$2.50 each, if sent by mail. Any of the last fifteen volumes (16 to 30) will also be forwarded at same price. Sets of numbers sent to our office will be neatly bound in our regular style, at 75 cents per vol. (50 cents extra, if returned by mail.) Missing numbers supplied at 12 cents each.

Clubs can at any time be increased by remitting for each addition the price paid by the original members; or a small club may be increased to a larger one; thus: a person having sent 10 subscribers and \$12, may afterward send 10 more subscribers with only \$8; making a club of 20 at \$1 each; and so of the other club rates.

The Union Pacific Railroad Co.—The Land Department at Omaha, Neb., reports: "The sales of the Land Department of the Union Pacific Railroad Co., for the month of June, 1872, were 23,900 1/4 acres, amounting to \$103,610.63, at an average of \$4.30 per acre. The total sales from July 23rd, 1869, to the present date are 571,169 1/8 acres, amounting to \$2,399,410.55, at an average of \$4.20 per acre. Sales in April, 1872, were 12,466 3/4 acres, for \$51,000.05. Sales in May, 1872, were 16,935 1/4 acres, for \$76,746."

The Georgia State College solicits for its Industrial Museum models of machines of any character; models of bridges; plans and photographs of buildings, bridges, etc.; minerals, specimens of ores; specimens of woods; products of agriculture; products of manufactures, exhibiting as far as possible the various stages of preparation; and generally whatever may illustrate the industrial arts. Donations will be acknowledged by publication in the Catalogue. Direct all articles to President State College, Athens, Georgia, marked "For Industrial Museum."

The A. A. F. T. A. O. S., which of course everybody knows means the yearly "mud-fog," as an irreverent lady of our acquaintance calls the "American Association for the Advancement of Science," will hold its meeting at Dabnque, Iowa, on the 21st inst. The

meeting was appointed for San Francisco, but for some reason of which we have not been informed the executive officers have changed it as above. We may add that the meetings of this association with the abominable name are most charming re-unions, and we advise all lovers of science to attend the coming one.

Post-Hole Augers.—"J. M. J.," Halifax, N. S., asks if post-hole augers can be used on other than soft soils.—Yes; they can be used anywhere in the absence of large stones. Clay, gravel with stones no larger than hen's eggs, sand, and peat can be bored with them.

Grass-Rake.—"J. M. J.," Halifax, N. S., wants a machine for collecting grass and weeds after mowing, so as to burn them.—The common spring-tooth hay-rake does this work excellently. A very useful rake can be made with a piece of 4 × 4 oak scantling, ten feet long, armed with teeth of half-inch round iron a foot long, and slightly curved forwards, furnished with a tongue to draw by, and a pair of stilt by which it may be lifted to release the load when gathered.

Patent Rights.—"J. N. S.," Oconee Co., S. C., is about to organize a tile manufacturing company, and asks if he purchases a tile machine will he have to pay for a right to use it?—The purchase of a machine does not always include the right except for private use. If tiles are made for sale it is a matter for agreement if any royalty is to be paid on what are sold.

Syrup from Cane.—"N. S.," Bounty Land, S. C., writes us that a neighbor made very fine syrup from cane cut before it headed out. If he will send an account of the process, from and including the cutting of the cane to the clearing of the syrup, it may be of interest to many of our readers.

Rape-Seed in the South.—"E. B. S.," Virginia, asks if rape-seed will succeed in the South.—Yes; wherever the soil is in good heart, and if it be sown in the early part of the fall, so as to get well started before winter. Rape, turnips, and cabbages grow well with proper care as far south as Florida.

Sulphur for Lice.—"J. Ferry, Sonoma Co., Cal.," says if "C. D. W." would rub sulphur into the skin of his cattle it will clear them of lice. He has used it several years with complete success.

Beans with Sunflowers.—"G. W. W.," Greencastle, Ind., asks if it will do to plant beans with sunflowers. One of his neighbors is making the experiment.—With a good rich soil, beans are often planted with corn and potatoes, and make a very fair additional crop. There is no reason why they should not succeed as well with sunflowers. Let us know the result of the experiment when complete.

Subsoil Plow.—"J. M. J.," Nova Scotia, wants the best subsoil plow for breaking up light sandy ground filled with roots of trees and shrubs.—The plow figured in *American Agriculturist* of June, 1872 (page 216), made with a sharp edge on the front, which might be steeled if necessary, would be as effectual an implement as any we know or could devise.

The Best Force-Pump.—"J. M. J.,"—"The best force-pump to be used in a cemented cistern" that we know of is the American Submerged Pump, often of late referred to in the *Agriculturist*. It may be set either in or out of the water.

Moles and their "Dark Ways."—Valentine P. Hoffman, Egg Harbor, N. J., asks what he shall do with a species of mice which make underground ways like moles, and injure the roots of his trees and vegetables.—These are the American moles, which are much smaller than some of the European ones, and not mice, and the best way perhaps to get rid of them is to trap them in their holes, which is difficult, or to poison them with pieces of apple covered with arsenic dropped in their holes, which often is of no use. A great many folks would like to know just how to get rid of them. A new mole-trap is advertised in the *Agriculturist*, which he might try.

Rennet.—G. L. Porter, Cedar Mountain, N. C., asks if cheese can be made without rennet, and if rennet can be procured at the North.—Cheese can be and is made by using acetic acid to procure the curd; but it is hard, and has not a good flavor. Rennet can be bought at or procured by almost any of the Northern seed-stores; but it can very easily be made by taking the stomach of a sucking calf, and, without emptying the contents, filling it with salt, allowing it to remain for two days, and then stretching it on a hoop of stout twig and drying it.

Composting.—"H. R. McC.," Clarksburgh, W. Va., asks if it would be proper to compost hog-pen manure with stable manure.—This would not be composting at all, but mixing, and nothing would be gained by the labor (or lost, except the labor). A compost is a mixture of fermenting substances with earth or other inert matter, which serves to dilute the richer materials, and they in their turn by their chemical activity render the added matter more soluble or more immediately available as fertilizers.

Butter-Worker.—"Thos. C. S.," Mount Auburn, N. Y., wants a butter-worker to put up butter taken in at stores into "straight lots."—We know of nothing better than the Eureka butter-worker.

A Good Native Cow.—"J. W. Moore," Augusta, Ga., sends us the record of his native cow, which with her third calf, twenty-eight days old, gives five gallons of milk per day, besides feeding her calf. The cream of three days' milk yielded five and three quarter pounds of butter. The cow is fed on two quarts of cracked peas boiled with kitchen slops at a feed, and hay. His wife is not satisfied with her churn. She should get a "Blanchard."

China White Pigs.—"N.," New Albany, Ind., asks, "What kind of breed are the China White pigs?"—We would suggest that this conundrum be propounded to the Swine Breeders' Convention, which will probably meet in Indiana next fall, and at which a committee on "breeds" will be prepared to entertain it.

Circumventing the Cutworm.—"D. S. K.," Fort Plain, N. Y., has a plan to save his corn from the cutworm. He plants ten grains in a hill an inch apart, in a direct row, and not dropped promiscuously. Then, when the cutworm attacks the corn, it leaves sufficient untouched to make a crop where, if the plants were all in a bunch, they would be all destroyed. It is also easier to hoe a crop thus planted.

Fence Wire.—Chas. E. Whitcombe, Ancaster, Can., wants to know the best-sized wire for a fence to turn stock. We have used No. 9, one rod of which weighs one pound; we believe this size is in general use.

Grades and Crosses.—"A Farmer," Bloomington, Ill., asks what is the difference between grades and crosses.—A grade is the offspring of native or grade and thorough-bred parents; a cross is the offspring of two thorough-bred parents of different breeds.

A Series of Questions.—"T. W. S.," Ripley Co., Ind., asks a batch of questions as follows: "Which is the best book on raising Shorthorn bulls?" "Does the *American Agriculturist* publish 'pieces' sent by others than those employed to write for it?" "Does the *Agriculturist* insert pieces on all parts of agriculture?"—Replies: We know of no book specially devoted to Shorthorn bulls. If the "piece" is of sufficient interest to our readers and sufficiently condensed for our crowded columns, we are always happy to receive the ideas of those who are interested in agriculture, and publish them; a reference to the contents of the various numbers of the *Agriculturist* will answer this question fully.

Mange.—"J. A. O.," Elkhart Co., Ind., has a horse which is always rubbing his neck when in the stable, and seems to be very itchy beneath the mane; what is the cause and remedy?—It is probably mange, or an irritation of the skin which may develop into mange. Sulphur should be given to the horse in his feed—a teaspoonful in each feed would be a proper quantity during a week or ten days. The neck should be washed with carbolic soapsuds, and sulphur and lard rubbed into an ointment be applied to the parts affected.

Cashmere Goats' Wool.—"J. W. M.," Mount Vernon, Tenn., has a quantity of Cashmere goats' wool, and wants to know its value and where there is a market for it. There is no market for the wool in New York. We have seen it stated that there is a demand for it in Philadelphia. But with the present insignificant production of this material there can be no regular market for it. The unshorn pelts can be sold in New York, where they are made into rugs and trimmings for ladies' sacks. Write to some of the commission agents who advertise.

Soap-Scraps.—"Subscriber," East Providence, R. I., has a quantity of soap-scraps, and asks advice as to the best mode of using them and for what crops. One of the best ways of using them is to spread lightly on a clover sod and plow them in for corn. Another but more laborious method is to compost them with earth, lime, and ashes, until they are all reduced to a fine mass, and then spread at the rate of a two-horse load per acre

on a newly-mown meadow, or harrow the same quantity in with the seed of fall wheat, or put a small shovelful into the hill with corn or potatoes. It is not lasting, but quick in its effects and good for grass or corn or roots.

Kerosene and Lice.—"Wm. King, Green Bay, Wis.," "has tried kerosene oil as an application to kill lice on calves, but their backs became sore; was it the kerosene that caused it?"—We suppose he means the calves' backs became sore, and do not wonder, for kerosene oil will readily inflame the skin. Crude petroleum should have been used in small quantities, or the kerosene should have been mixed with lard.

Running at the Nose.—"O.," Elkhart, Ind., wants a remedy for a horse troubled with running at the nose.—It is quite impossible to answer such ill-defined questions. The complaint may be catarrh, the result of a cold merely, or it may have progressed into a confirmed nasal gleet or glanders, in which case the disease would be either too serious or dangerous to trifle with. Better take advice from a veterinary surgeon. A catarrh may generally be cured by giving warm bran-mashes with a teaspoonful of salt-pepper added, and a bag of scalded bran hung so that the nose can be steamed for a few minutes daily.

Clover-Seed.—"A Subscriber," Hopkinsville, Ky., asks which is the best method of saving clover-seed, the best machine for hulling the same, its cost, and where it is to be procured.—Clover-seed should be saved by cutting the second crop when the seed is ripe, generally about September. The crop should be stacked or put away until cold frosty weather, when it should be thrashed and hulled. Hulling machines may be bought at any large agricultural implement store; price about \$55.

Warbles.—"L. W. B.," says if "A. B. F.," "or any other man," will bring the backs of his cattle once every week during the summer months they will not be troubled with warbles or grubs.—We notice in a "journal" devoted to stock the ridiculous statement that these grubs are the larvæ of the sheep-fly (*Estro mus ovæ*); that they will kill small cattle, and squirrels and rabbits. This is quite wrong. The parent fly is one of the gad-flies, the *Estro mus bovis*, and no other animals but horned stock are troubled by them, and although there are few cattle altogether free from these grubs, we never heard or read of a case in which an animal was seriously injured or killed by them.

For other Items see page 313.

SUNDRY HUMBUGS.—*Lies Told.*—Several readers inform us that when we denounce medicines and other humbugs, and country agents write to the head-quarters of these operators, they are told that the reason for our denouncing them is, because they do not advertise with us, or because we have tried and failed to get the printing of their circulars, etc. This dodge was tried also before the jury in the Byrn libel suit. Two simple statements will squelch these dastardly falsehoods. *First:* We have no job printing-office; we do no printing for others, but even hire our own circulars and job-work done in other offices. *Second:* We never admit medical advertisements, nor any others, except from good, reliable parties, doing a fair square business in a fair way, though tens of thousands—yea, hundreds of thousands of dollars have been offered us to advertise these things. We could get rich in a year if we admitted the advertisements of these medicine-sellers and of others who give little or nothing, or worse than nothing, for the money they receive, and who can therefore pay largely for advertising. . . . The "Queer" operators are shown up in another article, giving an interesting account of their mode of reaching people. Brown & Billings, 293 Chestnut street, Philadelphia, Geo. Harrington, Monument square, Baltimore, Arthur Debenham, 190 Broadway, N. Y., and others, are in the same line, with the Masonic and I. O. O. F. dodge. They operate in Ontario as well as in the United States. . . . The "Queer" operators at 22 West 4th street, New York, have carried on the "Spanish Policy" dodge, with new features, under many names, such as Edward Barnes, Martin Ellenwood, etc., to confuse the Post-Office clerks. He sends out gilded certificates, pretended to be signed by N. A. Personia, Madrid, Spain, which state that the recipient has drawn a \$200 gold watch, or other valuable article, that will be forwarded to him on receipt of the usual five per cent (\$10)—and some ignorant people bite the bait and lose their money. . . . "Constant Readers" and others will be worse than foolish if they give the slightest credence to those advertising doctors with high-sounding names and positions. . . . A Connecticut reader gives us an account of a visit to an Ann-street swindling shop of the envelope order. We have often shown these up. The only safe rule is to avoid all those shops (and

their circulars) which pretend to give \$2 for \$1, whether by ticket, envelope, or otherwise. . . . If any reader is so simple as to believe the medical story of the so-called "old Marcus Pettigrew" and his daughter, they will have to suffer for their greenness. Any one who receives and distributes the circulars or medicines of this or any other advertised medicine is a nuisance to the community in which he or she lives. The plausible stories make well people sick. . . . Thos. D. Thorp, 737 Broadway, the note swindler, previously exposed, continues his offers of Internal Revenue Brewers' Stamps at eighty per cent discount, on the plea that his cousin prints them in the Government printing-office. Of course he never supplies any, claims that his offer is not criminal, and escapes by a legal quibble. Those who send money lose it, but will not appear as witnesses, as that would show them "*particeps criminis*"—in attempting to buy professedly stolen stamps—and so the villain stands unconvicted. . . . Those foolish enough to send fifty cents to H. T. Moore, Box 2,751, New York City, for a "sure way to succeed," and get \$2,000 a year, have not "gumption" enough to succeed in anything, or to keep money if they get it. . . . The "Silent Friend," proposing to teach everything, and some more, is another catch-penny humbug. . . . T. S. Pattison, Elmira, N. Y., is vigorously pushing his detestable lottery scheme,yclept a "Premium Land Sale," and we are sorry to see several otherwise respectable newspapers helping him by inserting his column advertisement. . . . Numerous letters give us details of how the writers have been swindled out of \$10 to \$500 each by those pretending to cure private diseases, early indiscretions, etc. Every one advertising such medicines is a quack. . . . If you want a "radical regenerator," go to a good well-known physician, but on no account touch any of the quack medicines, and don't read the circulars or symptoms, or you will surely be sick. . . . Dr. Fittler, of Philadelphia, claiming to be a Professor of Toxicology, etc. (where? and by what authority?), doesn't have as much confidence in others as he wants others to have in his medicines, for he requires pay of agents in advance, on his promise to buy the medicine back after six months if not sold. "It's a poor rule that don't work both ways." . . . Give a cold shoulder to all "Silent Friends," "Roads to Fortune," oroid watches, butter-powders, and those who offer them. . . . "Just the Thing for Boys" is a villainous advertisement of just the thing no boy should have. Beware of "Lock-Box 26, Lincoln, Ill." A mean villain offers vile things from that address. No wonder he is ashamed of using any name that the people there could find. How about the P. M.? He must know who gets letters there. . . . Our space is exhausted, with sundry other humbings on hand which must go over to next paper.

Hedges.—R. C. Hall, Montgomery Co., N. Y. Warder's is the best, and indeed the only work on hedges. As you say, it is only full on the Osage Orange. This is the only subject he intended to treat, and the other matter was, as we understand, only added at the earnest request of the publisher who originally brought out the work. In the matter of articles on hedges, we will endeavor to comply with your request at the proper season.

Ice on Weed.—Cyrus Nade, Christian Co., Ky. It is impossible to tell the name of your plant, which "in the fall has beautiful specimens of ice attached to its bark," from the bark only. If you can send us the flowers, we can tell you what it is.

Those Mules.—We have received about a dozen letters from parties who have mules for sale, and have forwarded the names of the writers to the party who made the inquiry for them. This occurrence seems to point out that there are many parties wanting what others have to dispose of, and it is obvious that the mutual interest of these parties would be best served by making their needs known to the public through the advertising columns of the *Agriculturist*.

A Specimen of Rock.—"F. N.," New Albany, Ind., sends a specimen of rock, and wants to know if it contains lime, or is of any agricultural value, and if it occurs under the "old red" or "new red" sandstone. This rock is a fragment of clay slate, contains no lime, and is of no agricultural value; it is not crystalline in texture, and does not occur beneath the old red sandstone. It is very similar to some of the clays of the coal measures, but may belong to a still later age than the new red sandstone; without seeing it "in place," it is impossible to give the exact geological position.

Wants to be a Farmer.—"C. I.," Paluted Post, N. Y., wants advice. He was raised on a farm, knows all about farm work, and wants to be a farmer, but fears that he will not be able to make it as profitable as his present occupation, which brings him a salary of \$1,200 a year, out of which he can save \$300 to

\$400. There is an old proverb applicable to C. I.'s case, which is, "Let well enough alone." He is better off as he is than thousands of farmers who work harder and make less than he does.

Cooking Feed.—J. N. Robertson, Cass Co., Ill., cooks corn in the ear or meal for his stock, and finds it conducive to their health, and economical in the use of feed. He uses a trough with sheet-iron bottom and pine-plank sides, and ends similar to a syrup evaporator, in which water may be made to boil in a few minutes.

Warts on Cows' Teats.—"Subscriber," Snowshoe, Pa., wants a remedy for warts on cows' teats. If the warts are quite small, cut them off with a sharp shears, and canterize the wound with nitrate of silver (or Iodo-castic). If they are large, wet the wart, and rub the caustic on it twice a day, after milking, until it disappears.

Beef and Butter.—"H. H.," Fern's Mills, Mich., asks what breed of cattle are, on the whole, best to raise for beef and butter. If the pasture is luxuriant and can be kept "knee-high" all the time, or plenty of feed can always be procured, grade Shorthorns of a good milking family will be the best; otherwise, Ayrshires.

Ashes and Hen-Manure.—H. Hutchins, Allegan Co., Mich., asks if ashes and hen-manure are good for corn and potatoes, and how they should be applied. They are excellent for both crops, and should be applied a handful in the hill, at planting time, well mixed with the soil.

The Largest Milking in Twenty-four Hours.—"S. S.," Alexandria, La., asks what is the largest milking of a cow, during twenty-four hours, on record. Allen, in his *American Cattle*, mentions a Dutch cow owned by W. Chenery, of Mass., which gave in one day 3½ quarts. We have a scrap cut from a French paper some years ago, which states that a cow in Holland gave in one day 3½ quarts. These are the largest recorded milkings we know of.

Farm Gate.—A correspondent who forgot to affix his name to his letter, sends a sketch of a gate, "not patented," but the principle on which it works is patented; it would therefore be an infringement.

Concrete Buildings.—"A Subscriber" wants the address of a man who erects concrete buildings. As this is a well-understood process, we should think any intelligent mason could put up such a building. We do not know any one who makes a business of it.

Poison Ivy.—Paulus Keck, Dorseyville, Pa., asks how to destroy poison ivy. We killed by keeping the fence rows mowed during one summer. If there is any easier way, we should be glad to learn it.

Sugar-Waste as Manure.—"A Constant Reader," Philadelphia, asks if the waste from a grocery-store, which consists of sugar and molasses mixed with sawdust, is worth hauling six miles in preference to paying 50 cents per month per horse for stable manure. The stable manure is better worth paying for than the sweet stuff, which is little else than carbon and of slight use. All cattle have a sweet tooth, and are very fond of sugar, occasionally. It will do them no harm if they lick such waste stuff.

Value of Sorghum Bagasse.—"J. W. G.," Ohio, wants to dispose of a quantity of bagasse of sugar cane. We would burn it and save the ashes, if we could not plow it under, and spread the ashes on wheat or grass.

To Bring New Land into Cultivation.—An "Admirer," Spring Lake, Mich., asks what he shall do with a piece of newly-cleared woodland, to get it into cultivation. The usual mode is, to plow it as far as possible and plant potatoes, cultivating with the hoe. Take up the crop in time to sow wheat, which is harrowed in the loose soil, without plowing. Sow with the wheat six quarts of timothy, and in the spring four quarts of clover. Leave it in grass until the stumps and roots are rotten.

Iron-Weed.—Geo. Hoke, Mount Pleasant, Frederick Co., Md., has been looking out for roots of "Iron-weed," and writes us for the address of the party who inquired how to destroy this weed, in October *Agriculturist*. As his letter was without State or county, and a town of the same name is in five different States, we were unable to comply with his request. [N. B.—All letters should have county and State invariably added to post-office; many inquiries come to us that depend on correct locality for a proper reply.]

Lard-Makers' Refuse.—"I. F.," Edwardsville, Ind., has a quantity of refuse from a lard-rendering factory, which consists of dry flesh, hair, and bones, easily pulverized; how can he best use it?—His method of composting this valuable material with fermenting stable manure and earth is excellent, and will make a very active and lasting fertilizer, of which ten to twenty loads per acre will be a fair dressing.

Cure for Stifle.—"B. J. C.," Wilton, Minn., asks if there is any cure for a colt that was "stified" a year ago. It is probably past cure now; taken at the earliest moment, it is often incurable, but when confirmed by long standing, the case is hopeless. Strong astringent lotions applied to the stifle-joint, chiefly on the inside of the thigh, good food, and absolute rest are the only remedies.

Clover in Virginia.—"F.," Concord Depot, Va., has lately removed from New York State to Virginia, and finds the country suitable for sheep and clover. He can show a nice stand of clover and a good flock of Merinos there.

To Destroy Milk-Weed.—"F. Van D.," Oneida Co., N. Y., asks how to destroy Milk-weed. We know of no plan but plowing the ground and harrowing up the roots and picking them off. No surface application will answer.

A Calcareous Soil.—"A Subscriber" asks, What is a calcareous soil?—It is one which naturally contains carbonate of lime. Lime exists in the soil generally in the state of carbonate, and sometimes as sulphate, in small quantities.

Hay-Press.—"G. L.," Blairsville, asks for a hay-press that will press 400 to 500 pounds of hay into a bale. We don't believe there is such a press in existence. The heaviest bales of hay we have seen averaged six to a ton, or 333 pounds each; the majority are lighter.

The Lime Interest.—H. Wildey, Carroll Co., Ill., asks if we know of any paper published in the lime interest. We do not know of any; if there is any such, we should like to know of it.

Hard-milking Cows.—E. Ryder, Brewsters, N. Y., writes that he improved a hard-milking cow by enlarging the orifice of the teat by inserting carefully the sharp blade of a fine penknife. The orifice should be enlarged sufficiently to allow for some contraction, which will occur during healing. If a small wooden plug is kept in the teat, during healing, no contraction will occur; the plug should be rubbed with sweet oil.

A Pig that has Fits.—"Wm. A. W.," Foster Center, R. I., has a Chester White pig that is troubled with fits. He feeds meal-pudding, warm. This may be the cause. Fits are caused sometimes by worms, and sometimes by indigestion; warm feed causes indigestion. Feed cold mash.

To Cut Corn-Fodder.—"W. S. H.," Niagara Co., N. Y. Corn, sown for green fodder, may be cut either with the mowing machine or with the common cradle. Our practice has been to cut with a one-horse mower sufficient for one day, and cart it to the barn in a one-horse wagon. The horse is moved from the wagon to the machine, and back again, when needed, and the work is very quickly performed; when the field is near to the barn, fifteen minutes' time is sufficient.

The Cost of Keeping Rats.—A stack of wheat was lately thrashed on an English farm, according to the *Farmers' Chronicle*, out of which 1,040 rats were taken; only three escaped out of the lot. The damage done is not stated, but can easily be estimated.

An Aged Parrot.—A parrot lately died in England, which belonged to an old lady, a Mrs. Turner, and which had belonged in turn to her mother and grandmother; it was said to be 113 years old at its death.

Strawberries set in July.—"W. M. B.," Weston, Ct., asks if strawberries set out in a peabed in July will bear next year, or if it will pay better to plant turnips.—If the strawberries can be taken up with a ball of earth—better if potted—and put out so that they will not be checked in their growth, they will give a good crop next year. The other question depends upon the relative price of strawberries and turnips in your market. Properly managed, there should be no difficulty in getting a good crop of strawberries.

For other items see page 313.

Read Tax in Ohio.—Referring to some remarks in "Walks and Talks" in the June number of the *American Agriculturist*, Jno. S. Bowles, of Ohio, writes: "Here in Ohio a man is taxed so many dollars road-tax according to property, but he has the privilege of working it out at \$1.50 per day, or \$3 per day for a man and team, and wagon, or scraper. No supervisor of roads ever objects to a man's working his road tax in the spring. On the contrary, he very often insists on it. It is the farmers who generally object to working out road tax until fall, when they have nothing else to do. Sometimes, however, they do the work in May. When we plow and scrape we only have as many teams as there are scrapers. When we draw gravel, in which most of our work consists, we have a number of teams and wagons at it, and enough extra shovellers to keep the teams on the road, and not at the gravel-pit, nearly all the time. Every man has a poll-tax of two days' work to perform yearly. The supervisor can either allow one day with a team, or call for two days at shovelling gravel. If he needs shovellers, he will do the latter. More work can be accomplished at the same expense by the teams being constantly on the road than if every man's team stood still until he filled his own wagon."—No doubt about that. We fear, however, that every district is not favored with such a sensible supervisor. Road-making or repairing requires some experience and much good judgment, and we can not but fear that a good deal of time is lost in doing work at the wrong season, and in not half-doing it. The commonest mistake is in not providing good drainage. Three inches of well-screened gravel laid on a thoroughly-drained and rounded road-bed will make a far better and more enduring road than a foot of unscreened gravel laid in the wet spots. There is dirt and sand enough on our roads without drawing them from a gravel-pit.

Night-Soil.—"C. C." asks how he shall use two loads of night-soil.—Mix it with a few loads of fine earth, and put a handful or two into each hill of corn.

The Wisconsin State Dairymen's Association has decided to establish the coming season semi-monthly market days at the city of Watertown, for the sale of dairy products.

What is the Matter with the Horse?—"A. L. B.," Trenton, Pa., has a horse which is stupid and dull, as though something were the matter with the head. Possibly there is: if there is redness of the eyes, it may be caused by inflammation of the brain, or it may be caused by overfeeding, or a too tightly fitting collar. Books in such a case are useless, and the trouble is so ill-defined that we can not offer any advice except to consult a veterinary surgeon about it.

A Patent Wanted.—"S. S.," Bedford, Pa., sends us a sketch of a farm-gate which he claims is a new thing, and wants our opinion about it. As the claimed improvement has not the least novelty, we give our opinion, and would not advise "S. S." to spend any money over it. We think that the gate business, being already hampered with over 100 patents, should now be left in peace, and inventors turn their attention to methods of doing without gates at all; and fences as well.

Buffalo Bulls.—If "P. B. B." will send his address (former one mislaid), we will give him the address of parties who can furnish him with a young buffalo bull, or he can apply to the party who advertised them for sale in the *July Agriculturist*. People often don't know that they want many such things until they discover that they can get them, and the "Basket" is not exactly the proper vehicle for carrying buffalo bulls and the like between seller and buyer.

Shall He Buy or Hire a Bull?—"P. M.," Pleasant Run, Kansas, asks if he shall buy a thorough-bred Shorthorn bull at \$200, on a year's credit, or take him on shares of half the value of his services. He has 20 good native cows. We would advise the latter course, lest when pay-day comes inconvenience should arise in meeting it. A farmer, as a rule, should never run in debt, except to drain or manure his farm, and then only in rare cases. When the funds are *in hand*, then buy a bull as soon as possible.

To Improve an old Meadow.—"J. E. R.," Norwalk, Ct., wants the best manner to start the grass on an old, run-out meadow, in the absence of stable manure. We would harrow the meadow with a sharp, heavy harrow, and spread 800 lbs. of fine bone-dust early in spring, with a little timothy seed where the ground is bare. Harrow again with a very light harrow or a bush. If swamp muck could be dug through the summer, a top-dressing in the fall would be useful.

Is it too Late to Sow Mangel-Wurzel?—It is too late to grow a large crop. But if the ground is rich, mellow, and clean, a fair crop may be grown, sown as late as the first week in July. Seed-growers who raise moderate-sized roots for the purpose of setting them out for seed next spring, often sow as late as the first or middle of July. They sow in rows, say 2½ feet apart, and leave the plants six inches in the rows. If the ground is moist and the seeds are sown by hand, a week or so may be gained and much weeding saved by soaking the seeds for 48 hours before sowing, taking care to change the water at least every 12 hours. If, after soaking for 48 hours, the ground is not ready, pour off the water and keep the seed moist until you are ready to plant. It can be kept two or three days, or even until it sprouts, without injury, provided the sprouts are not knocked off in planting.

"What is a Hogget?"—It is an English term applied to sheep, and, like many other similar terms, does not seem to have any very definite meaning. Webster, quoting from the *American agricultural writer Skinner*, says, "A hogget is a sheep two years old." As we understand the matter, however, the general meaning of the term as used by English farmers is a sheep, male or female, from the time it ceases to be a lamb until it is shorn for the first time. After it is shorn it is a "shearing" or "shearling;" when shorn the second time, it is a "two-shear" sheep, and when shorn the third time, a "three-shear" ram, ewe, or wether, as the case may be. A "hogget," then, is a lamb, without regard to sex, from five to fifteen months old, or until it is sheared. After that it ceases to be a hogget and becomes a shearing. For the sake of distinction it is, we believe, proper to say ewe hogget, wether hogget, etc.

Artificial Cider.—"D. P. B." We have no formula for artificial cider, and if we had, should not publish it; we do not believe in sophisticating.

Roaches—Insect-Powder.—L. G. Hedge. If you can get fresh Persian Insect-Powder, you can get rid of roaches or cockroaches. Here let us state that all the various "lightning," "electric," and other bug-powders are only this done up in small packages. The Persian Insect Powder is the ground flowers of several species of Pyrethrum, and is put up in chests in the Caucasus. Its value depends upon its aroma, and consequently upon the care with which it is kept. The importers, when they open a case, immediately put the powder into pound bottles, securely corked. We get ours of Lasell, Marsh & Gardener, No. 10 Gold st., New York, in pound bottles, at \$1.25 each. It is sure death to every cockroach it touches. We use a bellows and blow it into all the cracks. Get your druggist to order it for you.

Clover amongst Corn.—"A Young Farmer" in New Jersey is engaged in raising green corn for the city market and wishes to grow a crop of clover between the crops of corn. The corn is to be off by the first of August, and some of it by July 20th. He asks if clover will do well sown at this season of the year; if so, he can grow corn every alternate year.—Yes, it will do well, sown in July or August, provided the land is clean, moist, and in good condition. Sow seed enough, say 8 to 10 quarts per acre. If the crop can be removed and the land got in good condition by the middle of August, we should prefer to wait and plow, and thoroughly harrow the land before sowing the seed, and then roll. But otherwise it will be better to sow the seed among the corn after the last cultivating.

Buggy Peas.—"J. R.," Wayne Co., N. Y. We know of no remedy. All you can do is to feed out your peas to the pigs early in the fall, before the "bugs" grow large enough to eat their way out of the peas and escape. If fed out before the first of November, there will be little loss of nutriment, as the pigs will eat peas and bugs together and grow fat on them.

Pigs for Choice Family Pork.—A Jersey farmer writes: "I raise quite a number of pigs, and sell them to people who get the city slops, and who want them to fatten at from six to ten months old. Have got my name pretty well up for raising the right quality of pigs, so that orders come in from three months to one year ahead. This with a common stock of hogs, lightly crossed with Chester Whites, such pigs ranging from 275 to 300 lbs. at ten months old. Last fall I thought to still further improve part of my stock by using a Jefferson County boar, which has perfectly disgusted me with them. The pigs are now six weeks old, and I could put any of them in my overcoat-pocket, while my other pigs go from 25 to 35 lbs. at eight weeks old. Now, what I want to know is, whether you think a thorough-bred Essex boar put to Chester White or other large sows would give me pigs that would grow faster while young and mature earlier than others in which there is no Essex blood?"—The pigs

from such a cross may not weigh any more at two or three months old than the Chesters, but they will be finer boned, smaller eared, fatter, and more stylish-looking. At any rate, this is our experience and observation. A second cross, if you select the best and most vigorous sows, will improve them still more. And if well fed, the quality of the pork can not be excelled. But it should be understood that such pigs will not stand starvation and neglect. They are bred to grow rapidly and mature early, and must have something to grow with.

Chester Co. Mammoth Corn.—"D. H. B.," West Brandywine, Pa., disagrees with Thomas Wood, of Doe Run, Pa., when he states that the Chester Co. Mammoth corn is simply the result of good culture. He asks if heavy feeding would make native cattle equal in size to the Kentucky Shorthorns, and if not, could heavy manuring change an inferior grain into one of great excellence? The theory and practice of culture and breeding are against the views of "D. H. B.," and in favor of those of Thomas Wood, and they prove that "the careful cultivation of one distinct variety" does not deteriorate it, but within certain well-defined bounds improves it. The highly-bred Shorthorns are the result of the careful and long-continued culture of a race of native British cattle, and are totally different in character from the uncultivated progeny of the same race now existing. Besides it can be shown that corn cultivated without change of seed for sixty or eighty years, at least has not degenerated. Yet great improvement often results from the introduction of new or fresh varieties.

Value of Bone-Black.—"W. A. G.," Washington, asks what is the value of bone-black and Guanape guano as compared with raw bone and Peruvian guano. Bone-black having by burning lost its animal matter, contains little or no ammonia, and its value is therefore less than that of raw bone, probably one fourth or even more. Guanape guano is so variable in composition that its actual value can not be stated. Generally, Dr. Voelker states it to be less in the best samples than Peruvian guano. What the poorest samples are worth it is impossible to say.

How to Smoke Meat.—"T. M. D.," Baden, Mo., wants to know which is the best weather in which to smoke meat, wet or dry. It is quite immaterial as far as regards the dryness or juiciness of the meat. This is affected by the degree of heat in the smoke-house. If the house is kept cool the smoking will leave the meat juicy, but if the temperature becomes too high the meat is dried. Damp weather affects only the surface.

Stripping Cows.—W. H. Barns, Oakwood, Kansas, has heard of folks stripping their cows into a small pail, and putting it directly into the cream-jar, claiming it is nearly pure cream, and always thought it absurd. It is true, nevertheless, and we supposed everybody who had a cow knew that the last drawn milk is much richer in cream than the first.

About Borrowing.—A "Subscriber" asks if we would advise a farmer who has a good farm of one hundred acres to borrow \$2,000 to purchase stock for a butter-dairy farm. If the farmer knows enough to lay out the money judiciously, the stock ought to be always worth the cost, so that he really is not in debt; and we don't hesitate to advise any farmer to borrow money to improve the productive capacity of his farm.

The Sawdust, or "Queer," Humbug.

This has been shown up often in these columns. The most extensive operator in this line now sends out the following circular, under seal, with no name attached, but a name is written and inclosed in it on a separate slip. As all letters to swindlers are stopped at the New York Post-Office, this fellow sees a great variety of names, changing them faster than they can be followed up by the Post-Office clerks. Thus, in a lot of the same circulars before us, we find slips with the following names and many others, all giving the address of 22 West 4th street or 16 South Fifth ave., New York: Wm. Dalley, S. Yetter, Jonas Phillips, Wm. Coombs, Joel Jewells, John H. Klinkard, David Driscoll, David Curran, Rollin Burdick, Henry Outman, Martin Bowker, Lemuel Haines, Ezra Whitcomb, Joseph Hoffman, Jonas Moore, Herman Andrews, David Curran, etc., etc. As a curiosity, we give the circular entire. It will be understood that nothing is ever returned for the money sent, the sender not daring to expose himself as a would-be dealer in counterfeits. If one comes to the shop he is scared out of his money, or has it taken from him by a bogus policeman. If parcels are sent out by express, C. O. D., they are filled with "sawdust" or other trash, the character of which is not known until the recipient has paid a large bill and taken

his box to a private place. If he is suspicious, and don't take out the box, he gets a lot of letters threatening exposure, etc.—all of no account. Here is the circular, which is sent out by the hundred thousand, and enough dishonest greenhorns are caught to make it very profitable: "STRICTLY SUB-ROSA, AND THE SECRET NEVER TO BE IMPARTED TO A LIVING BEING.

"MY DEAR SIR: I take the liberty of sending you a Circular that is printed by myself in my own printing office, in order that its contents may be known only to the few that I conclude to take into my confidence.

"I hope that after I have placed confidence enough in you to send a circular of this kind, relating the nature of my business, that you would not be so treacherous as to even breathe the contents of this document to a living being; should you betray me, I will find means to be avenged in way perhaps you would not dream of. If you do not wish to enter into this confidential business with me, all I ask is, that you burn this circular and let the secret die with the flame. On the other hand, if you conclude to enter into this speculation, that will in a few weeks make you a wealthy man, I would advise you to burn the circular and preserve the secret, as when this circular is destroyed all evidence against you and me is obliterated.

"A person in a business of this character must be true to themselves, and as true as steel to the person they are doing business with. You should always abstain from the use of strong drink, there is great danger that a person knows not what he might say when drunk. You should also keep the secret of the business as still as the grave, not even hint at it to your nearest relation or breathe it to your second self. Now, with all the warnings I have given you that is most necessary to adhere to without a single exception, I will proceed to state facts in reference to the business, which, if managed with care and shrewdness, will lead you to fortune without any one dreaming from whence your wealth came.

"In the first place, I wish to state that I am an engraver, and said to be by those who are competent of judging, the most expert one in America. I have been employed by the U. S. Government for ten years. I superintended the engraving of all the plates for the United States money. When the Government ceased to issue Greenbacks my services were no longer required, and as soon as I found that my time was my own I conceived the idea of engraving a few plates for myself and for my benefit, as I am well aware that a man can never become wealthy working for a salary. I have only recently finished the work that I began almost two years since, that is, the engraving of six plates which are exact duplicates of the Governments. Mine are the Fifty Cents, the One, Two, Five, Ten, and Twenty Dollar plates. I have taken the greatest care in engraving these plates, and I defy the best experts to detect the counterfeits from the genuine. In a few days since a large amount of my money in six different banks in New York City they all accepted it without saying a word; my money being all new, I thought it would not be advisable to deposit any more, for fear they might think something wrong. When it is deposited in banks there should be other money that has been in use mixed with it, then there will be no suspicion, and I now need only to be careful not to be caught. If you do, then we will secure a fortune that will enable us to enjoy all the pleasures that money can procure on earth. My bills are printed on exactly the same paper as the United States money, so that there is not a possible chance to detect the difference only in one way, which is this: The Government bills are numbered from one up to one million. If you should come across two of the same number, one will certainly be counterfeit and the other genuine. If it is convenient for you to come to New York, I wish you would; then you could see the money, and I would give you a few dollars to pass, then you would see that everybody would take it exactly as if it was genuine money.

"The price of my money is ten cents on the dollar; one half cash, and the other half as soon as the money is passed. State in your letter, when you order, how many \$500s, \$1.00, \$2.00, \$5.00, \$10.00, and \$20.00 bills you wish, so that I will know exactly how many of each to send. You must be sure to seal your letter perfectly tight, and write my name very plainly. I will make the following discounts when large amounts are ordered. For a three hundred dollar order the price will be thirty dollars. You must inclose ten dollars with the order, and the other twenty dollars when the money is passed; and for larger orders at the following rates:

- \$400 order for \$40. Send \$12 cash, and \$28 when money is passed.
- \$500 order for \$50. Send \$15 cash, and \$35 when money is passed.
- \$1,000 order for \$100. Send \$25 cash, and \$75 when money is passed.
- \$5,000 order for \$500. Send \$100 cash, and \$400 when money is passed.
- \$10,000 order for \$1,000. Send \$200 cash, and \$800 when money is passed.

"When a large amount is sent, I pack it in a box and mark it in such a manner that no one would suspect it being money, and send it by Express. Always state when you order how you wish the money sent, and if by Express.

"I will send you a hundred dollars assorted, on receipt of five dollars, so you can see how it passes, then you can order a large lot.

"By all means come at once and see me; if possible, and bring all the money you can possibly raise with you, so you will be prepared to buy a large stock; for this may be the last chance you will ever have to make a fortune at a single stroke. After you arrive in the city you can take the Broadway stage and get out at Fourth street, walk down Fourth street, west side, until you come to No. 23; you will see the sign "Book Agency" over the door to the office. I occupy the ground floor, so you will have no trouble in finding me. But if you can not possibly come on here now, send me 10, 20, 50, or 100 dollars in a thick envelope, by mail, or by express. Do not send by registered letter under any circumstances. All registered letters are supposed to contain money, and Post Office Clerks are apt to open them, take the money out, and then seal them up as before, and send them through. You see if this were to happen it would expose the whole thing. I guarantee to send you back ten times the amount I receive, in the best counterfeit money ever issued, or if you prefer I will send my money you C. O. D. by express, and you can pay the money due me to the express agent when he hands you the package. I sew the money up in the lining of a coat, and pack it in many other ways before I ship it, so no one would dream of its being money. Now, my dear sir, I have disclosed this golden opportunity to you in faith and hope—faith in your ability and fidelity, and hoping that one year hence you may find us both wealthy and happy, and I here pledge you my word of honor that while you are faithful to me I will be true to you. My name and address is on the enclosed slip, which you will keep, but burn this circular.

"This is the compact which I sign, and to which you must agree: 1st—We mutually agree not to betray each other, and to disclose this matter to no living soul. 2d—I am to return to you, secure from observation, ten dollars of the best counterfeit money made for every dollar I receive from you. 3d—When you come here to see me, I am to count you out \$10.00 for every dollar you give me, and you need not pay me until you have my money in your hands. We must do business in a discreet and honest manner, and let him who first violates it suffer the consequences."

Arsenic for Pigs.—W. W. Chance, Naples, Ill., says he has cured his pigs of paralysis of the hind parts, or kidney complaint, by giving a quarter of a teaspoonful of arsenic in their feed once a day. Pigs had been thus cured which had been affected for two months. [There are several other less dangerous remedies than arsenic, which are therefore preferable in all such cases.—Ed.]

Canker of the Frog.—"X," Randolph Co., Ill., has a mare whose feet are out of order; the frog is swollen, soft, spongy, and tender. What must he do?—This is probably canker, or it may be a commencement of thrush, caused by standing in a wet, foul stable or yard, or roving in a wet, mucky field, or by an unhealthy condition of the blood. The soles should be washed with warm water and soap, then with a strong solution of blue vitriol (sulphate of copper); if there are any cracks in the sole, they should be filled with tow, soaked in the solution. If the general health is poor, that should be remedied at once by proper treatment.

Bones.—"N," New Albany, Ind., asks, if bones can be purchased at \$8 per ton, whether it would be cheaper to burn them to reduce them to powder than to buy bone-dust at \$35 per ton. If the bone-phosphate alone is wanted, it would be cheaper to burn and crush them. If the ammonia is wanted as well as the phosphate, bone-dust from unsteamed bones would be cheaper at the price, as the nitrogen from fresh raw bones is considered by Prof. Johnson to be worth \$24 per ton of bones.

Buffalo Crosses.—"Army," Fort Leavenworth, Kansas, advises "P. B. B." (see *Agriculturist*, May, 1872) not to use the buffalo bull for crossing purposes. He has lived during several years in the buffalo country, and they say there that a half-bred buffalo calf will have the hump common to the buffalo, which will be fatal to the cow in her efforts to produce the calf. Domestic bulls will not breed with buffalo cows. Near Chicago several valuable cows have been lost in the effort to give birth to half-bred buffalo calves. We give "Army's" letter, but he seems not aware of the fact that the buffalo bull has been crossed with success with the native cow, and the heifer calf from this union has bred with a buffalo bull.

Salt-Cake.—"L. S.," Saratoga Co., N. Y., asks, what is salt-cake, and what is it worth as a fertilizer? Salt-cake, the refuse of the salt manufactory, contains mainly sulphates of soda and magnesia or Epsom and Glauber salts and chloride of calcium, which are practically of no value in agriculture, or but very little; in fact, they often do more harm than good. Such matters should not be used without a well-understood purpose.

Artificial Manures.—"A Subscriber," Bousacks, Va., last year collected two tons of horse and cattle droppings, which he mixed with nine bushels of unslaked lime, same quantity of leached ashes, and four hundred pounds of guano. The mixture was pulverized and sowed with the drill at the rate of 100 pounds per acre on the wheat crop, with what advantage to the crop is not known. He thinks that if farmers knew what ingredients to add to their compost heaps much valuable and cheap manure might be made.—This experiment is not a satisfactory one, because there is no result, for the reason that the effects were not watched and noted. 100 pounds of such a compost is too small an application except for comparison. 500 pounds per acre would have been better, but the effects of it should be closely observed as a guide for the future. Besides, the mixing of fresh lime with ammoniacal manures is contrary to what is considered sound principle, unless plenty of absorbent matter, as leaf-mold, swamp-muck, or even earth, is added to retain the escaping ammonia.

Saltpeter.—"W. J.," Fitchburg, Mass., asks if saltpeter would be of any benefit as a dressing for grass land. Nitrate of potash, which is one form of saltpeter (nitrate of soda, called soda-saltpeter, being another), has been used as a dressing for grass with very good results in England, but in dry seasons it is apt to "burn" the crop. It should therefore be used with caution, and in quantities of not over 100 pounds per acre at a time. It encourages the growth of clover and the most valuable grasses, and tends to make the soil more absorbent and retentive of moisture. Nitrate of soda is not so highly thought of as nitrate of potash.

To Drain a Flat Beaver Meadow.—"Old Field" has a beaver meadow which he wants to drain, but there is not sufficient fall on his land. He suggests digging a fish-pond. This would not reduce the level of the water. If permission could be got, the creek might doubtless be lowered a foot or two in much less than a mile; if not, there is no resource but digging channels to collect the water, and sowing Red-top.

SPECIAL PREMIUMS STILL OFFERED.

MULTUM IN PARVO KNIFE, OPEN.—WEIGHT 2 OZ.

The General Premium List closed July 1st. The following Special Premiums are continued until further notice:

The Multum in Parvo Knife for 8 subscribers to *American Agriculturist* at \$1.50 a year; or 4 subscribers to *Hearth and Home* at \$3.00 a year; or 5 subscribers for one year to both the above papers at \$4.00 a year. (Knife sent post-paid.)

The Beckwith \$10 Sewing Machine for 12 subscribers to *American Agriculturist* at \$1.50 a year; or 6 subscribers to *Hearth and Home* at \$3.00 a year; or for 10 subscribers to both papers at \$4.00 a year.

N. B.—Two half-year subscribers in all the above cases may count for one full year in a Premium Club List.

MULTUM IN PARVO KNIFE, CLOSED.—3 inches long.

Raising Water.—"T. N." has his house 40 feet above a spring, and 150 feet distant from it. What would be the best and cheapest way to bring the water to the house?—If there is a fall of several feet within 30 or 40 feet of the spring a ram could be used, at a cost for pipe and ram altogether of about forty dollars. If there is no fall, a windmill might be used, at a cost of about \$150, or less if made at home. See *Agriculturist* for May, 1872.

What Manures?—"J. M. J." asks what manures, artificial or otherwise, would be best for soil composed of "siliceous silica," oxide of iron, alumina, and sulphates and carbonates of lime and magnesia. This description is very incomplete, and although it might form the basis of a theoretical chemical formula as to the necessary manures, we do not consider it of any value practically. We never knew a soil which could not be improved by barn-yard manure, with a dressing of lime every five years, and good plowing; and in the absence of a knowledge of the amount of silica or alumina contained in it, we would advise "J. M. J." to pin his faith on to barn-yard manure as his main reliance.

A Technological Dictionary.—The greatest trouble one experiences in studying a language other than his own, is with the purely technical words—words that occur in business or the arts. If we think of the varied meanings that the words "stick" and "bar" and such like have, we can appreciate the difficulties which beset one in learning English; and the same trouble attends us in learning French and German. Ordinary dictionaries fail to give us the technical uses of words, and we gladly welcome three small volumes from L. W. Schmidt, 24 Barclay st., entitled "A Technological Pocket Dictionary in the English, German, and French Languages." The title sufficiently explains the scope of the work. The real value of a dictionary can only be learned by use, and we can only say that this appears to be as valuable as its mechanical appearance is neat.

Carbolic Acid in Soap.—"F. N.," New Albany, Ind. The use of carbolic acid in soap is patented. We do not know the proportions, but in using it you would be infringing upon a patent right.

Barberry Hedge.—"F. N.," New Albany, Ind. Procure the seeds in fall, and sow them then, or keep them in sand over winter and sow in spring. Treat them for one year just like cabbages or other seedling plants, by keeping them clear of weeds and thinning where too thick.

Holly-leaved Cherry.—"P. W. M.," We trust we have no one in our office so stupid as not to know the difference between the Holly-leaved Cherry and the Holly-leaved Barberry, especially when the one has simple leaves and the other compound ones; besides, the structure of the flowers is entirely different in the two.

Sweet-Corn Suckering.—We have reports that one and another variety of sweet corn suckers badly in different parts of the country. As the same complaint has been made of different kinds of field corn, we are inclined to think that soil and climate affect the suckering. The only remedy we can suggest, is to grow those kinds in each particular locality that seem best adapted to it. Corn, whether sweet or field, is very readily modified by locality, and any one can by a little care in selection obtain what the gardeners call a "strain" suited to his wants.

Colorado Potato-Bug.—Many inquirers. We must repeat, that if the bugs are too abundant for hand-picking, the only resort is the deadly poison, Paris green. Mix this with from twelve to twenty parts of flour, and sift from a perforated tin box, or one with a gauze cover, over the vines, while the dew is on. Keep the stuff away from children, and do not inhale the dust in using. If you must use it, keep in mind its virulently poisonous character.

Yeast Powders.—The immense and growing consumption of the various substitutes for the old-fashioned saleratus we believe to be favorable to the health of the community. These mixtures are, in the main, carefully compounded, so that there shall be no preponderance of either acid or alkali, thus forming in the bread only a harmless, neutral salt. We have used, with much satisfaction, the preparation manufactured by Messrs. Dooley & Brother, and sold by them very largely throughout the country.

Grape Cuttings.—"J. B. S.," Madison, Neb. You can do nothing about grape cuttings until the leaves fall. Then when you trim your vines make cuttings of two buds or eyes each, tie them in convenient bundles, and bury them in sand in the cellar, or out of doors in a place where water does not settle. In spring set in rows, putting the cuttings six inches apart, and one bud at the surface, taking care to get them right side up; press the soil well to the bottom of the cuttings, and give the bed a mulch of leaves or litter. Most grapes will grow, treated in this way, but some varieties require a propagating-house. These you can raise from layers.

"The Garden."—Mr. Robinson's paper, the establishment of which we announced at the time, continues its career with every appearance of prosperity. It differs in many respects from other English horticultural journals, and would probably best suit those of our readers who wish to keep the run of British horticulture. We are glad to notice that the editor finds frequent occasion to quote from our columns, and to transfer our engravings. He always gives credit in the most courteous manner, and is most heartily welcome.

Mezquit or Muskeet Grass.—J. A. Reagan, M.D., Buncombe Co., N. C., asks about the value of "Muskeet Grass," its cultivation, and where seed can be procured—This is one of several queries of the same

purport. In a pretty extended tour in Texas, some years ago, we found that several grasses were called Mezquit, and we do not know of any particular one which can be designated as the *Mezquit*. It may be that some of our Texan readers can help our correspondent. We should be glad to get from our friends in different parts of Texas specimens (*in flower*) of the grass known in their localities as Mezquit. Even so intelligent an observer as the late Mr. Affleck sent us the Buffalo grass as what he considered the true Mezquit.

Fruit Trees.—A correspondent at Bealton, Va., writes: "Can you tell me how to make my fruit trees grow down, or heavier in the body of the tree? I have 400 apple-trees, and as a general thing they are too light in the body."—Unless the trees are crowded, we do not see why they should be "too light in the body." An apple-tree that has room to develop itself properly, will naturally keep a proper proportion between the trunk and head.

Night-Soil for Fruit Trees.—"Inquirer," Brunswick, Me., asks if night-soil is good dressing for apple-trees, young or old, and if so, best way of application.—We would use night-soil for corn and other quick-growing crops, and apply a compost of stable manure or of muck and lime to the trees.

The Plymouth Pulpit.—Messrs. J. B. Ford & Co., under the title above given, publish a sermon of Henry Ward Beecher each week. They now send us the fifth and sixth series, bound in two handsome volumes, and including the sermons of a part of 1870 and the whole of 1871. Mr. Beecher is a full-hearted, manly, hopeful man, and thoroughly impresses these characteristics upon his sermons. We can not conceive that one, whatever his "denomination," or even if of no particular faith, can read these sermons without feeling refreshed. There is something in them to meet every phase of life, and every mood and temperament. Though the writer is not of the Plymouth pastor's "denomination," he would no sooner be deprived of his Beecher than our regular readers would be of their *Agriculturist*.

Garden and Lawn Weed.—"F. S.," Rothsville, Pa. Your weed is the Low or Running Malloes, *Malva rotundifolia*. Children eat the slimy, unripe fruit-capsules, and call them "cheeses." There is no better mode of getting rid of it than the one you suggest—"pulling and digging it out by the roots." There are no specifics for destroying weeds and leaving useful plants unharmed.

The Babcock Fire-Extinguisher.—A bucket of water at the right moment is of more use in checking a conflagration than a whole fire department would be a few moments later. The Babcock Fire-Extinguisher claims to have at hand a liquid more efficacious in extinguishing fire than simple water, and with a self-generating force to throw the stream where it is needed. As we understand the apparatus, it is upon the principle of a soda-fountain. By the turn of a screw a quantity of acid is emptied into a solution of alkaline carbonate, thus generating a force sufficient to propel the liquid, and the solution, being highly charged with carbonic acid, is more effective than the same amount of water. The apparatus seems to be constructed upon correct principles, and there is abundant evidence as to its utility.

Chicken Cholera.—"J. H. D.," Perry Co., Ill., says that he never knew *assafoetida* to fail in curing chicken cholera. He uses a piece of the drug the size of a marble to two quarts of corn-meal mixed with water. We suppose that he first dissolves the *assafoetida* in water, though he does not say so. The drug is not really soluble, but if soaked in water can be rubbed up into a milky mixture.

Curious Corn.—"Bermudian Subscriber" will accept our thanks for specimens of abnormal corn. Such malformations are not very rare, had people eyes to notice them. One of yours is different from any we have seen, and with some others that we have on hand will serve to illustrate an article on the structure of corn that we hope to write when the weather is less tropical. We are always glad to hear from our Bermudian friends.

Akebia—Kalmias from Seed.—"Mrs. L. E. D.," Ohio.—We have no trouble with Akebia, treating it as we would any other hardy climber. In the last very severe winter some of the younger twigs were killed. The seeds of Kalmia are so small, and the young plants so delicate, that it requires an experienced cultivator to succeed with them. The trouble with the Abronia and other seeds named is probably due to the fact that they were not sown as soon as ripe. It is fat to many seeds to keep them over winter. We never succeeded with *Abronia fragrans*.

A Locust-stung Orchard.—"J. R. E.," California, Ky. The "stinging" is mainly due to the incisions made by the female for the purpose of depositing her eggs. The wounds, as well as the presence of a foreign body, the eggs, of course injure young trees. When the trouble "extends nearly to the ground," it will be cheaper to replace the trees with new ones. When the branches only are injured, we should cut off and burn the perforated portions. Probably before another visitation your trees will get as large as not to be seriously damaged. When the locusts once come there is no known help.

Bee Notes for August.—By M. Quinby.

Any diseased stocks that have been neglected should be driven now. What little they may do will come good another year. In sections where buckwheat is abundant, boxes should be put on with reference to it. Remove all boxes containing clover honey, to prevent their being discolored by that from buckwheat. As honey grows scarce, a weak stock will sometimes take every particle of honey from a box that they may have partly filled, while strong swarms may be gradually filling boxes. To secure honey from swarms disposed to remove it from the boxes, will require close watching. Honey in these boxes is nice for the table, and it might not be safe to put the boxes on another hive for filling, the supply of honey being limited. Any swarm coming out now, should be returned to the hive from which it issued, after taking away the queen; or the half, with the queen, might be given to some queenless stock, and the remainder returned to the old hive. Surplus honey that has been taken off, should be watched for worms. Should there be any indications of the presence of worms, the boxes should be put in a close box and smoked with brimstone, care being taken not to have the fumes so strong as to discolor the combs. Keep good watch of weak colonies. If such are in movable frames, they may be given a comb or two of sealed brood from stronger ones. Queenless colonies, if in box-hives, may be broken up, and contents secured, unless in sections where buckwheat is plenty, when it pays sometimes to give them a queen, thereby gaining a few combs for another year.

If it is desired to rear Italian queens late in the fall, when native drones are gone, measures to secure the Italian drones at that time should be attended to now. A strong Italian stock that is getting honey should be well provided with drone combs, that they may be filled with drone brood. Or, if they do not raise drones, for want of honey, it will be necessary to save what they have already. No drones are reared for the season, after this month. A queenless hive, or at least one without a laying queen, will preserve their drones best. Remove the queen until about October. She may be given for the time to some nucleus, or some other colony.

ANOTHER JERSEY COW.—Mr. Andrew Roberson, of Tiverton, R. I., has an imported Jersey cow which dropped her first calf April 1st, 1871 (when she was less than twenty-eight months old). From April 11th to January 6th, when she was dried for calving, she gave of milk 6,023 lbs. She dropped her second calf February 8th, 1872, and from February 12th to March 30th, both inclusive, she gave 1,339 lbs. Total for the year, 7,362 lbs. Of the 365 days she was dry 23 days, and her milk was not used for 14 days. During the 319 days when the milk was weighed she gave a daily average of 20 lbs. per day. We cite this case rather because it is a carefully recorded one than because of the amount of milk given, but, at the same time, the cow must be commended as a very good one indeed, and a good representative of her valuable race.

The Value of Night-Soil.

From a German work, on "The Employment of Human Excreta and Animal Remains in Agriculture," by Wilhelm Hahn, we extract the following statement of the value to the farmer of a manure that is now almost entirely wasted in every part of our country. According to these tables, the human excrement of our population of 40,000,000 is equal, in respect

to its nitrogen, to one hundred million tons of cattle dung. This is a statement that needs no comment. We commend it to the careful consideration of all who care for the problems of national prosperity.

Inquiry has shown that a grown person produces daily 2 lbs. of fæces, of which 1½ lb. is fluid, and ½ lb. solid.

In every 100 lbs. of urine there are 4½ lbs. nitrogenous matter, in the proportion of 100:46¾; so that in 100 lbs. of urine we have about 2¼ lbs. nitrogen.

In 100 lbs. of solid fæces we have 4¼ lbs. nitrogen, so that in the yearly product of a grown person (547 lbs. fluid and 183 lbs. solid fæces) we have:

In the fluid.....12½ lbs. nitrogen.
" solid..... 7½ lbs. "

Or.....19½ lbs. nitrogen per annum.

Or, in 100 lbs. of the mixed fæces we have 2¾ lbs. nitrogen.

So that, in respect to nitrogen, 100 lbs. mixed human fæces are equal to:

417¾ lbs. horse dung. 753½ lbs. cattle dung.
445½ lbs. pig dung. 298½ lbs. sheep dung.

As compared with the best guano, which contains 13 per cent of nitrogen, the yearly product of a grown person would equal 1½ cwt. of the latter, as regards nitrogen, or 100 lbs. of mixed fæces would equal 34½ lbs. of best guano.

In respect to alkalies, 100 lbs. human fæces equal

109 lbs. horse dung. 111 lbs. cow dung,
112 lbs. pig dung, 51 lbs. sheep dung.

In respect to phosphates, 100 lbs. human fæces equal

208 lbs. horse dung, 415 lbs. cow dung.
208 lbs. pig dung, 134 lbs. sheep dung.

In comparing human fæces with that of animals, it would be well to take into consideration the fact that quantities of straw, etc., are mixed therewith. A comparison of human fæces with stable manure will show that 100 lbs. of the former are equal in respect to nitrogen to

550 lbs. horse stable manure, 753 lbs. cow stable manure,
560 lbs. pig " " 400 lbs. sheep " " "

In respect to alkalies, to

135 lbs. horse stable manure, 140 lbs. cow stable manure
142 lbs. pig " " 75 lbs. sheep " " "

Or, in respect to phosphoric acid, to

320 lbs. horse stable manure, 500 lbs. cow stable manure.
330 lbs. pig " " 250 lbs. sheep " " "

As the best guano contains about 12 per cent alkali salts, and an equal quantity of phosphoric acid, 100 lbs. mixed fæces will equal 8 lbs. guano in respect to alkalies, and 5½ lbs. in respect to phosphoric acid.

Tim Bunker on Underselling the Butcher.

"Twenty-five cents a pound for fresh lamb in Hookertown!" said Seth Twiggs, knocking the ashes from his second pipe, and loading again. With his forefinger fumbling over the bowl and acting as rammer, he continued: "Who'd ever 'ave tho't when he was a boy, that he should live to see sich times! Why, I can remember when my father used to sell the hind quarters of sheep and calves for four cents a pound, and tho't they were pretty well sold at that."

"Mighty hard times to get a livin', now," exclaimed George Washington Tucker.

"It's allers ben hard times, sense I know'd any thing about 'em," chimed in Jake Frink. "What is the difference, whether lamb is five

cents a pound or twenty-five, so long as a feller haint got any to sell, and is too blamed poor to buy any! I take it he is outside of lamb, altogether, high or low."

"It is a long time since I have been outside of any," said Tucker slyly.

"You must eat veal," suggested uncle Jotham Sparrowgrass, who came limping up the walk, cane in hand. "Veal is only twenty cents a pound, and half of that for the soup pieces. Soup is wholesome."

"But what is folks gwine to do that haint got the dimes to buy soup pieces—which means bones, I take it?" inquired Benjamin Franklin Jones. "I'm put to 't every week to get enough to pay the butcher's bill, lettin' alone rent. And it'll git to be pretty soon jest as bad here as it is in the old country, where poor folks can't get meat more'n twice a week. It's jest orful now."

"The butchers make about all the money," said Deacon Smith. "I sell a calf for seven dollars, which dresses a hundred pounds. He dresses it in less than half an hour, puts it in his shop, and retails it at an average of fifteen cents a pound, and gets a dollar for the pelt. He gets nine dollars clear for his time in peddling my calf, and at the same time he is selling lamb, beef, chickens, goslings, and other things, and making them pay quite as well."

"That's so," exclaimed Uncle Jotham; "I don't know a butcher within twenty miles of Hookertown, that isn't a prosperous man. There is Brown, over in Shadtown, begun business there twenty-five years ago, so poor that he was hardly worth the clothes he stood in. He borrowed a little money, and begun to butcher and carry meat around on a wheelbarrow. He couldn't afford a horse and wagon. Next year he bought one. Then he bought a piece of land and put up a slaughter-house. Then he bought more land, to put his slaughter-house manure upon, and raised the biggest crops in town. And it has been more meat sold and more land bought every year since, until Brown is as well off as any man in Shadtown. There was Jim Johnson, from the Whiteoaks, so poor that he used to grease the wheels for Kier Frink's coal-cart at a cent a piece, and glad to get the job. He started business at the Ferry, just as the war broke out, buying lambs, calves, etc., of the farmers, and peddling them, until he opened a butcher's shop in the village. Now Johnson is worth twenty thousand dollars, and is doing a business worth three thousand dollars a year. Any man with a decent character makes money as a butcher in our villages."

"Wall, what ye gwine to do about it?" asked Jake Frink, philosophically. "It stands tu reason that they'll buy cheap jist as long as folks is fools enough to sell so, and they'll sell dear jist as long as folks will buy of 'em."

"Undersell 'em," I suggested.

"That wou'd du hardly," said Seth Twiggs, puffing away at his pipe; "ye see we've got two butchers in Hookertown, and I've noticed that meat is a plaguey sight dearer than when we only had one. Now ye see, if we bring in another butcher to undersell 'em, they'll jist buy up this third man, and fix prices to suit themselves. Another family has got to be supported in Hookertown by selling meat, and those who eat meat have got to foot the bills. You don't catch butchers doing business at their own expense." There was a puff of smoke at this last sentence by way of emphasis.

"Suppose farmers undersell the butchers," I suggested.

"That will do," said Deacon Smith. "As near as I can calculate, our butcher just about

doubles his money on every calf and lamb he buys. If he gives seven dollars for a calf, he gets, for his time in dressing and selling, seven more, and while he is doing this he is doing the same thing by the other meats in his stall. He might do this at much less profit and still do a thriving business. If his meat costs him ten, and he sells at twenty, I, who raise the meat, can sell at fifteen, and still do quite as good a business as I am doing on the farm. If I was a large farmer, raising calves and lambs by the hundred, instead of by the score, I might not be able to do this. It might be better for me to sell in the lump at a less price. But I only do a small business, like most Connecticut farmers, and I have time to speculate a little and attend to anything outside of my regular business that promises to pay well. It won't interfere with my day's work to dress a calf or lamb at evening, and send it round to my neighbors next morning. If I have two or more to dress, I have only to take them with me to Shadtown when I go to mill, and I dispose of them at the store without any loss of time. I have to go to mill every two or three weeks, and I almost always manage to take something to market at the same time—eggs, poultry, lamb, veal, or beef. At the end of the year I have sold fifty lambs or more, and a dozen calves, and all my poultry, and have had the advantage of retail prices, which is, at least, twenty-five per cent better than the butchers would have given me. People get their meats cheaper, and nobody has any cause to grumble. It makes about four hundred dollars difference in the yearly receipts of my farm, and that comes to a good deal in the run of a lifetime."

"Butcher Clark does grumble though," said Jake Frink, "and says if it wern't for Deacon Smith, Tim Bunker, and a few more old skin-flints, he could make some money."

You see the drift of things up here in Hookertown from this talk of my neighbors. The high price of meats is under discussion, and how to get them cheaper. Farmers sell cheap enough, and it does seem as if some way ought to be contrived to prevent the doubling of prices before the meat gets to the consumers. Some of us send dressed calves to New York and get returns at six and seven cents a pound, when such meats are quoted wholesale at eleven to twelve cents, and are sold to the consumer at an average of twenty. I guess Deacon Smith has got hold of the root of the matter, and farmers must kill their own animals and peddle more. It will cultivate the spirit of trade a good deal more, and that is what is needed to wake up the farming population. Full one half of the success of farming depends upon selling well. Farm products are not well sold when the farmer does not get three fourths of what they cost the consumer. I have noticed that these trading farmers always get ahead and increase their lands and flocks wonderfully. There was Giles Bailey, on Sweet Briar Hill, as rough a region as can be found in New England, who followed meat peddling until he was eighty years old. He appeared regularly in Hookertown on Tuesday morning, after a ride of a dozen miles, with his load of home-dressed lamb, veal, poultry, or whatever he had to sell, and was generally known as Tuesday Bailey. He always kept first-rate meats, dressed them neatly, and undersold the butchers, who never quite forgave him. He became one of the largest landholders and richest men in his town long before he died. Underselling the butchers did it.

Hookertown, Ct., } Yours to command,
June 16, 1872. } TIMOTHY BUNKER, Esq.

Digging and Storing Early Potatoes.

We know a large potato-grower in Western New York who dug ten or a dozen acres of Early Rose potatoes last year in August. He was offered forty cents a bushel for them at the time, but thinking they would be higher he pitted them in the field. He apprehended no danger, and it was only for some casual reason that he opened one of the heaps, when he was surprised to find it so hot that he could scarcely bear his hand in it. Had they been left a few days longer every potato would have been spoiled. As it was, he immediately drew them into his barns and basement cellar, and was glad to take the first offer he could get for them.

Early potatoes should be barreled and marketed as soon as they are dug, or else they should be placed in thin layers or small heaps in a barn or cellar, and turned over occasionally if there are any signs of heating. If this can not be done, it is better to leave them in the ground until cool weather sets in. In the case we have alluded to, the farmer dug them because he wanted to sow the land to winter-wheat. The expense of handling potatoes is so great, that, as a rule, those farmers make the most profit, especially in the case of early potatoes, who ship them directly from the field.

Shad-Planting in the Mississippi Valley.

EDITORIAL CORRESPONDENCE.

DENVER, COL., July 8th, 1872.

Connecticut River shad were planted in the South Platte yesterday, after a five-days passage from the hatching-boxes at Hadley Falls, Mass. This brief item of news will be read with more interest a few years hence when the shad has taken possession of the Platte and the streams below, and fishing stations are as numerous upon their banks as they now are upon the Hudson and the Connecticut. We all know that the shad could be eaten here in the fresh state, brought over the plains packed in ice, and served up at the tables of the rich as a rare and costly delicacy. But can the *Alosa prestabilis* of our Atlantic streams be transplanted to the valleys of the Ohio, the Missouri, and the Mississippi, and become as plenty and cheap as they are in their native streams? Can the sons of the East take along with them their fish as they do their cattle, and make them a source of pleasure and profit in their new homes? These questions, discussed by fish culturists for a few years back with great interest, got into Congress at the close of the session, and a small appropriation was made to test the practicability of planting shad west of the Alleghanies, and of transferring some of the varieties of the Salmon that swarm in the rivers of the Pacific to the streams of our Atlantic coast. The appropriation was put in the hands of Prof. Spencer F. Baird, United States Fish Commissioner, who acted with great promptness in the matter of shad-planting. We took interest enough in the *Agriculturist* families of the great West to take a share in the work of distribution. Seth Green was at the close of the shad-hatching season upon the Hudson, and started with 25,000 fry for the Mississippi, near St. Paul, Minn. We left Hadley Falls at six o'clock A.M., July 2d, with 2,000,000 shad fry, just taken from the hatching-boxes in the river. The season is several days later than last year, but the parent shad are more numerous, and Mr. Smith, who has charge of the hatching, in-

formed us that they were larger than he had seen in late years. Seven-pound fish were not uncommon in the hauls he made for spawners. We had nine eight-gallon tin cans for the fry, supplied with Connecticut River water, and an extra can of ice to keep the water of proper temperature. The shad has a much more delicate organization than the Salmonidæ, and the range of temperature within which the ova will hatch and the fry will live is much more limited. We have not determined these limits very accurately, but the few essays that have been made at transplanting shad show very clearly that the temperature must not be much above 80° nor under 60°. The weather was very much against us, a sultry July morning with the thermometer at 84°, and by noon reaching 96° in the cars. We got a change of water at Albany from a city hydrant, which proved to be good. Frequent partial changes were made at the railway stations during the day and night. We reached Salamanca, on the Erie road, on the morning of July 3d, and put 400,000 fry, in good condition, into the Alleghany, one of the large feeders of the Ohio. The stock was made very large here, as it must necessarily supply the whole river.

Another very-hot day, with about the same range of thermometer. With careful watching we got through with our charge safely, and put about 400,000 fry into the White River at Indianapolis on the morning of July 4th. We had now but one can of fish left, much reduced in numbers by the journey, but still lively and in good condition. We determined to make an experimental trip to this point to test the practicability of stocking rivers remotest from the sources of supply. If they could be transported a five-days journey, and the last half of the way over a region affording no suitable water for them, there would be no insurmountable difficulty in supplying every stream in the land. The weather favored us for the last three days, so that the consumption of ice was small, and the frequent change of water less necessary. We reached Denver about 10 A.M., July 7th, five days and five hours from Hadley Falls, and planted about 2,000 fry in Platte River. They seemed to be at home in the new waters, and at once headed up stream. We found no good water for the fry west of the Mississippi, except at Wilson's Station on the Kansas Pacific road.

Of course the planting of shad in these streams is an experiment. However men may differ about the probabilities of success, all will agree that success is exceedingly desirable. The principal objections urged against the stocking of the streams are the extreme length of the rivers and the large amount of sediment in the waters. But some of the shad streams are six or seven hundred miles long, and if the fish will go this distance to seek a spawning-bed, why would not the instinct of propagation carry it still farther, if it were necessary? Some twenty years ago Dr. Daniels, of Georgia, carried a few shad spawn from the head-waters of the Savannah to those of the Alabama. The shad are now abundant not only in the Alabama, but in the Black Warrior, a large stream which joins it before it reaches the Gulf. These rivers are quite as muddy as the Mississippi and its branches. The probabilities are, that if a stream has clear water of a suitable temperature for spawning, the shad will find it, and deposit their spawn, no matter how remote it may be from the sea. Three years must pass before the results of the present

planting can be known and all doubts be solved. W. C.

Why Do not the Eggs Hatch?

I would say in reply to CONNECTICUT (p. 255), that the keeping of fowls in small yards is not a sufficient reason why the eggs do not hatch, and that in this part of the country the same difficulty is complained of by all parties, whether the fowls be thorough-bred or dunghills, either yarded or running at large. I read a large number of the poultry journals, and find the same complaint everywhere. I have talked with many breeders and farmers, and all agree that the experience of this year is different from any previous one, and all complain alike of poor results. The trouble is not caused by small yards, and the fact that the same results are attained, at least in this region, from fowls which run at large, shows that it is not. Moreover, the eggs are not infertile, as he claims. My experience shows that in a large proportion of the eggs the chicks will be partly or fully formed, but for some unaccountable reason they fail to complete the process of incubation. I have in some cases found that fully formed chicks would have the head turned in such a way that they could not pip the shell, and so would fail to come out. One of my hens sat until the twenty-seventh day, and then came off with but one chick. A previous examination had shown but one had egg, which I removed, and I kept her at it. After she came off, I found the remaining eggs all contained chicks, those partly formed being alive. Other investigating men tell me that they also find few bad eggs, but many that contain unhatched chicks in various stages. We find then that small yards do not cause infertile eggs, and again, that the eggs are not infertile. But why do they not hatch? If "Connecticut" will bring forward his other nineteen reasons, it may be that we shall find the true solution among them; but please let the reasons be based on careful examination into cause and effect, and do not jump at conclusions. I have been giving the matter careful consideration, and am obliged to confess myself apparently no nearer a solution of the problem than two months since. OHIO.

Ogden Farm Papers.—No. 31.

A neighbor, who is a very good farmer, accosted me recently on the subject of transplanting beets, saying, "I agree with a good deal that you write, but not with all," etc. I told him that the last thing I expect from any man who has brains of his own is that he should agree with me in everything. "Opinions differ," and when I find a man who accepts all the opinions of another I set him down as of small account. It is much more satisfactory to have the partial assent of one who does his own thinking than the entire assent of one who lets me do his thinking for him. The most good that any agricultural writer can do, is to set his readers a-thinking. No matter that they agree or disagree with what is written, the one thing needed, or the most important thing, is that they be stimulated to harness their brains in with their farm teams, and do their work with a fuller consciousness of its real character. It is, of course, important and interesting to a farmer to be told how to do this or that sort of work, but it is far more important that he be made to realize that all his work is founded on a rational basis—on "science," if this much-hated word may be allowed—and everything connected with it will become daily more and more inter-

esting if he once finds that it is *intellectual* work. Consequently, even though we were to tell our readers seriously that the grass of their fields is made of the sunbeams which dance upon the meadow, we should do them some good. They would soon find out that we were wrong, of course, but in hunting for proof of our error they would bring into play a spirit of investigation that would lead them to inquire what it really is made of, and they would not stop thinking about it until they had learned some important facts which would make farming for evermore a very different sort of occupation for them from what it thus far had been. I hope we do some good to those who believe we are right, but I am sure we do more good to those who try in earnest to prove us wrong.

Speaking of the composition of grass, I am reminded that it is a very long time since I have seen in an agricultural paper any statement of the fundamental principles of the science of agriculture, which had such a fascination for me in the early days of my study, and that these papers may have some readers to whom they will even now be a revelation. To all, they have an importance that will justify their re-statement.

The object of farming is to convert air and water and earth into the materials on which the world depends for food and for the comforts and luxuries of life—to turn matter from a useless to a useful form. The agent through which we work is the laws of vegetable and animal life and growth. Nature furnishes the conditions for the constant operation of these laws; our office is so to influence their action as to cause them to produce the particular kind of growth that is best suited to our ends. The composition of all of the common plants is about the same: a little earth, more water, and a good deal of air. If we first dry and then burn a ton (2,000 lbs.) of meadow grass, cut when in bloom, we shall find that it contains about 1,400 lbs. of water and 46 lbs. of ash or earthy matter. The remaining 554 lbs. is combustible solid matter. It is the business of the farmer to cause these raw materials to come together in such a way as to produce the grass. The ash comes from the soil. It consists (approximately) of potash, 12 lbs.; soda, $3\frac{2}{10}$ lbs.; magnesia, $2\frac{2}{10}$ lbs.; lime, $5\frac{4}{10}$ lbs.; phosphoric acid, 3 lbs.; sulphuric acid, $2\frac{4}{10}$ lbs.; silica (or sand), $13\frac{9}{10}$ lbs.; chlorine, $3\frac{9}{10}$ lbs.; and sulphur $1\frac{1}{10}$ lbs. Just about this, and nothing more, the soil *must* contribute of its mineral matter toward the ton of grass. Some of the ingredients named may vary in quantity, and some may supplant each other, but for the illustration the list given will suffice. The quantities are small, but they are to the last degree important. Any soil that can not furnish the little that is needed must receive an artificial supply before it can produce its crop.

The 554 lbs. of combustible solid matter consist of carbon (charcoal), oxygen and hydrogen (the constituents of water), and *nitrogen*—of this latter about 10 lbs. The carbon is taken entirely from carbonic acid—a gas of which the atmosphere always contains an ample store—and the oxygen and hydrogen are abundantly supplied by the water of the sap; but the nitrogen can be furnished only by some product of organic decomposition, either already existing in the soil, or brought to it in the impurities of rain-water, or in manure. As in the case of the ash of the plant, it must be supplied by the soil. If it does not already exist there, it must be added before the soil can be fertile, and if the soil be-

comes exhausted of it, it must be added—naturally or artificially—before fertility can be restored. Man has to concern himself chiefly with about 10 lbs. of nitrogen, 3 lbs. of phosphoric acid, and 15 lbs. of potash and soda (the other elements of the ash are abundantly present in all tolerable soils). *Given these twenty-eight pounds of matter, nature—properly guided—produces two thousand pounds of grass.*

The *proper guidance* is the farmer's affair. So is the supply and guarding of the all-important twenty-eight pounds. Concerning all the rest—the 1,972 lbs.—he can only exercise a fostering care. The mass of material in the soil, the water that moistens its pores, and the winds that sweep its surface, supply it all. To prepare the land for the best action of the wonderful alchemy of growth; to sow the proper seed; to keep down the competition of other plants; to supply the needed nitrogen and alkalis and acids; and to stimulate in every way in his power the favorable action of natural influences—these are the duty of the farmer. It seems a short story, but it holds the kernel of practical farming, which is only a slight aiding and a very constant and careful guiding of the impulse that is born of sunshine, moisture, air, and a fertile soil. Whether we turn the elements into grass, or the grass into flesh, we are handling tools whose use should ennoble us, as what they perform enriches us.

Does all this sound a little bifalutin? Possibly it does; and where's the harm? There is enough in our lives that is humdrum, and stupid, and dull, to make a flight of the fancy, now and then, a relief and a delight. No man will be a worse farmer because he knows something of the principles on which his farming depends, and if he will look oftener to the inner side of the picture—to the silver lining of his cloud—he will see that his occupation comprises more than he now believes of that which he envies in others.

To return to my neighbor and his beets. We talked for some time and failed to convince each other. He claims that he can clean and thin an acre with three days' labor. (If he can, his land is cleaner than mine.) I claim that the land would be benefited by repeated harrowings during all of May and June, and that my man, with a boy to drop, can set out an acre in two days. (He says if he can he is a smarter man than he can hire.) And so we separated—he taking some of my plants to set out in his field, to see how the two will compare in their subsequent growth. His are long, red mangolds, and mine are Lane's sugar-beets, but I hope to make at least half a convert of him, nevertheless, for I think it helps the growth of a beet to nip off the end of its tap-root and make it throw out more fibers.

I wrote in my last of the field I had juggled with too deep plowing; this season has shown that it is not beyond the help of manure. Last year, Mr. Hand sent me a bag of "Phosphatic Blood Guano" for an experiment with cabbages. I planted four rows across the field in question, and had a passable result. It was a close race between good manure and poor land. I thought the land was a little ahead. This year that side of the field is in oats for soiling, but they hardly soil the ground. After two months' trial they have reached a brown eminence of perhaps four inches. Where the four rows of cabbages stood, there is a thick and luxuriant growth of

oats, now ready for the scythe. Another part of the field was last year very heavily manured for beets with stable-manure, and that, too, is covered with a very good growth of oats. I think I have found out what will at last cure the disease, or, rather, I think the disease has been so far cured by time, that I can now commence to build up the patient's constitution by the aid of stimulants; and now follow the interesting questions whether the turning under of the surface soil to so great a depth is going to make the land more permanently fertile, and whether the subsoil which has been brought to the top will finally—when it becomes well mellowed and well manured—have some of the productive power of a virgin soil. I think a favorable answer will eventually be given to both of these questions, but it has been a tedious and an expensive experiment, and however good the land may become, its improvement will have cost more than it is worth. One half the cost in fallows and top-dressings would have had a better effect.

The Dairy is thriving. We are now making about 150 pounds of butter per week—fully 600 pounds per month—from 27 animals, old and young, big and little, sick and well, good, bad, and indifferent. This is very well for a breeding herd, in which no pains are taken to have the cows come in with reference to the flush of feed. Our main object is to turn out thorough-bred Jersey calves for sale, and we keep the mill going as fast as the health of the cows will allow. The result is that calves are dropped at all seasons, and there is no "flush time" with us in June, as with most farmers. Neither are we in the flush of feed; that comes with us in September, when the fodder corn is in blossom. Just one quarter of the herd consists of two-year-old heifers with their first calves, and about another quarter of animals that are nearly dry, or that for one reason or another are giving but little milk—some nearly dry, and some very old. I don't brag about the quantity, but I am, on the whole, quite well satisfied with it. If I have a touch of vanity, it is stimulated by the *quality* and *uniformity* of the butter. It has never been more easily made, and never better; and the advantage of the deep-can system was never better demonstrated. I am sure that any dairyman who makes even 50 pounds of butter per week, would be more than satisfied with his investment if he would rearrange his milk-room so as to set his milk in deep cans, even if he had to use a windmill, as we do, to get a supply of fresh cool water to set them in.

There is one exception to the above statement about the time of having the cows come in. We try to have all our yearlings—say all heifers dropped before October—served by the bull in time to calve not earlier than April 15th, and not later than June 15th, of their second year, so that their first secretion of milk may be stimulated (and their milking habits formed) by the tender grass of May and June.

We find it advantageous—having a pasture farm for our young stock—to turn the cows out in the daytime during the month of June, so that as much as possible of the men's time may be given to the crowding work of that month, and so that we may save for hay as much as possible of the grass on which we would have to depend for soiling until the oats are ready. With this exception we stick to soiling, and like it.

Asiatic Fowls.

Were the "poultry fever" at the high it attained not long ago, Mr. Conklin, the obliging gentleman in charge of the animals at Central Park, would no doubt be besieged for eggs of the Asiatic fowls he has in his collection. Mr. Forbes, the artist, has taken the portraits of these fowls as they appear in the aviary at the Park, and it will be seen that they do not appear essentially different from some breeds of game fowls. Those who have most carefully investigated the origin of our breeds of domestic fowls all come to the conclusion that their parent is the Asiatic fowl, the *Gallus Bankiva*. It hardly seems possible that the minute and pompous Bantam should have the same origin with the portly and leisurely Brahma, but as different investigators have arrived at the same determination, we accept it as a fact in natural history, and until testimony

can be brought to show to the contrary we must admit that all, from the half-domesticated Leghorn to the dumpy Cochin, are from one original species. When we ask an old poultry-fancier, who has run through all the breeds, "What is the best fowl, all things considered?" he is quite sure to say the Game, as the best for the table, and the best in the long run for eggs. It is the close relationship to the wild fowl that has made the breed of Leghorns so popular.

Of course, it is not possible to trace the origin of our now popular breeds. Domestic fowls were kept before the commencement of the Christian era. The Romans at that historical epoch had six or seven named breeds, and paid as much attention to "toes" and "ears" as our breeders now do. It is a curious fact that in many savage countries, insular as well as continental, domestic fowls are kept, and even distinct breeds are known. While the fowls here figured are much like our Game birds, other specimens from Asia, also claiming to be native fowls, were very heavy, and more like the Cochins in their style and build. We have no doubt that a cross of either of these native birds

upon our refined breeds would be attended with good results, as it would introduce new and vigorous blood into our yards. Those who would like to know the evidence brought forward to support the statement that our domestic fowls are from one species, are referred to that remarkable work, "Darwin's Animals and Plants under Domestication." It is Mr. Darwin's belief that all our breeds "have diverged by independent and different roads from a single

origin of our domestic breeds of sheep is very obscure. While some claim that they originated from six or more wild species, others regard them as having all descended from one. Where animals, as is the case of the sheep, have been under domestication from the earliest times, to trace their origin becomes almost an impossibility. There is good reason to believe that sheep were kept as domestic animals even in prehistoric times, as the remains of a peculiar

breed have been found in the Swiss lake-dwellings. No domestic animal is more readily modified by local influences than the sheep. This is shown by the production of particular grades of wool in the different sheep-growing districts of England, but in a more marked manner by the changes wrought upon sheep that are taken to peculiar climates. Thus, in certain countries, the sheep take on a remarkable development of tail, in others the horns attain an enormous size, and

A PAIR OF ASIATIC FOWLS.

type," and he gives the characters and illustrations of several of the most distinct breeds.

African Sheep.

There are, or were a short time ago, in the collection at Central Park some "African sheep." Our artist has taken their portraits, and it will

in others again the wool ceases to be wool, but becomes a coarse hair like that of the goat. The fat-tailed sheep have been often described; in these the tail takes on such an unusual enlargement, and becomes so loaded with fat, that it is regarded as a great luxury, and a truck is provided for its support, which is dragged about by the animal. In other countries this deposit

of fat is not made in the tail, but it accumulates in two large masses upon the rump, while the tail itself remains in a rudimentary state. In an Angola variety of sheep there is a great accumulation of fat upon the back of the head and beneath the jaws. Besides these peculiarities of taking on fat upon different parts of the body, there is the greatest possible variety in the horns. One writer states that there is a constant relation between the wool and the horns of the various breeds of sheep; that long

AFRICAN SHEEP AT CENTRAL PARK, N. Y.

be seen that they are as unlike our ideas of a fine sheep as a Western "landpike" is unlike a thorough-bred Berkshire or Essex. Animals of this kind are always interesting and instructive. These specimens are undoubtedly sheep, but how different from the South-Downs that are grazing upon the broad lawns of the Park! The

and smooth wool is accompanied by long and smooth horns, and that breeds which bear close and curled wool have corrugated and twisted horns. To the breeder as well as to the naturalist every unusual form of domesticated animal is of interest, and these curious lank sheep will no doubt be more attractive to the wool-

grower who visits the Park than the well-fed and well-known South-Down.

Walks and Talks on the Farm.—No. 104.

At this date, June 18th, my wheat is better than the Deacon's. All admit that the harrowing did it good. It broke the crust, and freshened up the soil, and made a splendid seed-bed for the clover. The ground was very dry, but there was moisture enough in the freshly-stirred soil to start the clover-seed at once. I never saw a better catch. I do not say, neither do I believe, that the harrowing is the only or main reason why my wheat looks better than the Deacon's in the adjoining field. I have spent more labor on it, and gave it a slight dressing of dried blood. I think there is wheat in the field that will go over 40 bushels per acre, but there are other parts where the crop is light, and these will pull down the average. The wheat on the clay land, where I expected the heaviest growth, is the poorest in the field. And I imagine that this is generally the case the present year. I suppose it is owing to the severe spring drouth. We had a glorious rain the last week in May, but it was too late to save the wheat. In this section—and I presume the same is true of the Middle States generally—we shall not have more than two thirds of an average crop. There are thousands of acres which will barely pay the expense of harvesting. I have just been through one of the finest wheat-growing sections in Monroe County, and did not see one really good field of wheat. This is not the fault of our system of agriculture, for while it is emphatically true that the best farmers have decidedly the best crops, yet even those fields which have received good treatment have many spots where the crop has either failed entirely, or been so weakened by the cold and the drouth that they will yield little more than the seed.

The Deacon and I both sowed our wheat too late last fall. I have generally aimed to sow from the 10th to the 15th of September; and in ordinary years, on good land, this is the best time, but this season, as a rule, the early sown wheat is the best. And *drilled wheat is very decidedly better than that sown broadcast*. I have never been an enthusiastic advocate of drilling. I have seen wheat that was sown broadcast just as good as that sown with a drill. But few will claim that broadcast wheat is ever better than drilled. And so, if every few years we have a season in which drilled wheat is decidedly the best, and never one in which it is worse, it would seem to be the part of wisdom to always drill in the wheat.

John Johnston writes me from Seneca Co., which is one of the best wheat-growing counties in Western New York: "Wheat is bad around here, and I believe over all the winter-wheat-growing sections of the Eastern, Middle, and Western States, as well as in Canada. I have seen 51 crops grown here, but never saw such a failure except in 1836. I am really afraid of a wheat famine."

I do not feel at all alarmed. Wheat will doubtless command a high price before the harvest of 1873. But we need not starve. High prices always check consumption. If wheat is very high, we shall eat less wheat-bread, and more corn-bread, potatoes, and meat. Corn, pork, and potatoes are so abundant that they are now selling far below the cost of production. Cheese, butter, and beef are compara-

tively low, and fruit of all kinds bids fair to be exceedingly abundant. We shall not starve. But I have said for many months that all the signs pointed to a higher range of prices for our leading agricultural products. I believe such would have been the case even if we had had a favorable season for wheat. But the failure of the wheat crop will undoubtedly hasten the time, and serve to carry prices higher than I had anticipated.

Farmers have seen hard times for a few years past, and a higher range of prices will not hurt us. The lesson that we, as farmers, have to learn is not to be discouraged, but to keep on the even tenor of our ways, studying how to improve our farms, to cheapen the cost of production, to raise such crops and keep such stock as are adapted to our soils and situations, to sell when we can get reasonable prices, and be content with fair profits, and not rush into every new thing that for the time being is bringing an extravagant price.

There is seldom a year when a good, steady-going, enterprising, intelligent farmer who works his land thoroughly and improves his stock has not something to sell that affords a good profit. If pork is low, wool is high; if beef is cheap, wheat is dear. If corn can not be sold for what it costs to produce it, he knows that in a well-ventilated corn-crib it will keep for any length of time. Some years ago I was offered corn in the streets of Bloomington, Ill., for "nine cents, cash, per bushel, and ten cents in trade." In less than two years I was in Illinois again, and asked the price of corn in the same neighborhood, and was answered "one dollar and ten cents a bushel." Of course such fluctuations are demoralizing. But we must make the best of our situation.

"E. W. H.," of Grand Rapids, Mich., writes me that he has a field of eight acres of dark, gravelly soil that he broke up three years ago. Plowed once, cultivated twice; then plowed again, cultivated, and sowed to winter-wheat. Had an average crop, or about 20 bushels per acre. Next spring he covered the field with stable-manure, plowed, and planted with corn. Yield, 40 bushels per acre. The next spring (1871) plowed and sowed oats and seeded with timothy and clover. The season was dry, and the oats a light crop. This spring he top-dressed the field with manure. There was a good stand of timothy and clover, but now (June 2d) the clover and timothy are literally choked out with sorrel. He asks what he had better do.

If I had such a field on my farm I think I should plow it up early in August, cultivate and harrow as often as was necessary to kill weeds, and also with a view to cause as many weed-seeds to germinate as possible. Then in October I would plow it again. The next spring sow it to barley, peas, or oats. Then follow with winter-wheat, and seed with timothy in the fall, at the time the wheat was sown, and with clover in the spring, say twelve pounds red clover and two pounds white Dutch clover. If lime could be obtained at anything like a reasonable price, say from fifteen to twenty cents a bushel, I would put on from 50 to 100 bushels per acre before the wheat was sown, and cultivate and harrow it in. I should do this not because I believe in the old theory that sorrel indicates a sour soil, and that lime is needed to neutralize the acid, but simply because it is a matter of experience that liming land is one of the best means of bringing in good grasses and clover.

And if we can get a good crop of grass and clover, especially white clover, the sorrel will be crowded out and disappear.

I have great faith in lime as a manure, even on our limestone soils, and should use it freely if I could get it for twenty cents a bushel, but I can not buy it for less than thirty cents. We must try and get along without it until some one has sense enough to burn lime for agricultural purposes and sell it at a fair price. As long as I can get a good crop of clover I feel pretty sure of getting good grain crops. But when clover begins to fail we shall then have to resort to the use of ashes or kainit to furnish potash, or we shall use lime to render the latent potash and nitrogen in the soil available. On my land at present I have no doubt the latter would be the cheaper method, if I could get lime at twenty cents a bushel, as I need nitrogen rather than potash. But as long as good tillage, or an occasional summer-fallow, with the free use of gypsum, will give us good crops of clover, we can get along without lime.

John S. Bowles, of Hamilton Co., Ohio, thinks that I must live in a very benighted agricultural section, because we plow with double lines, and put the lines back of our shoulders. I dislike the practice as much as he does. But it is of no use to talk to us about single lines and left-hand plows. Neither men nor horses understand the system, and even if we acknowledge all the advantages claimed, which I am not prepared to do, it would take us some years to make the change. "In another number of your 'Walks and Talks,'" he says, "you speak of the Deacon hoeing his corn. If you will come here next fall, I will show you a clean corn-field that has never had a hoe in it the whole season." I have no doubt about it. Neither do I despair of doing the same thing, before many years, on my own farm. Mr. B. raises corn after corn for several years, and by the free use of the cultivator can hardly fail to make his land clean. Mr. B. says he believes "one man and horse with a good cultivator will accomplish as much as four men with hoes." There is no doubt about it. But it seems curious to us to hear so intelligent a man as my correspondent say: "I do not know whether it would be possible to cultivate corn properly without driving *with a single line*, but I doubt it." The truth is, you want a steady horse that will haw and gee promptly as you tell him, and that does not need any lines at all. In such a case two lines do no harm, and may occasionally be useful. I think this is all there is to the question. I once saw a boy take the first prize at a plowing match of the Royal Agricultural Society of England who had no lines on his horses. I do not think that if a pair of rope lines had been hanging by their sides they would have done any harm, and in case the horses had got frightened they might have proved useful. Still, I should be heartily glad to have my horses so well trained that no lines were needed.

Mr. Bowles says he has drained some of his swamp land with tiles, three feet deep, and the underdrains three rods apart, at a cost of \$31 per acre, reckoning labor at \$1.75 per day of ten hours. "But, in point of fact," he says, "it has not cost me nearly so much. I do it in this manner. I hire my men by the month for six months or a year at a time. I hire at least one more than I would want if I carried on no improvement. Whenever in the spring I have no work for my men to do I set them at under-

draining. When I have plenty of other necessary work I put all the men at it, but if I have a man to spare he goes to the drains. Thus my underdraining is often performed when the men would have nothing else to do. A man too many is very useful. If one gets sick or quits work, his team does not then lie idle. He is also very useful at harvest-time."

This is all very true, and it is the plan I have always advocated. Hiring extra men for a few days to do extra work that *must* be done, no matter what wages the men ask, is a bad practice. It has a demoralizing effect. The extra hands boast of how much they are getting, while they say nothing of how many days they lie idle. It is certain that as a rule the men who engage by the year save the most money. The days when a man is not earning money he is very apt to be spending it.

As a rule, however, ordinary farm hands make very poor ditchers. They do not like the work. I have had many ditches cut on the plan practiced by Mr. Bowles, but am satisfied that they have cost me a good deal more than those I had cut by the rod. I am inclined to think that we might adopt both plans. We might hire the men by the season at so much a day, and when there is much ditching to be done let out the work to them by the rod. If they were out and industrious they would earn more money, while we should get the work done cheaper. With married men who have boys to help them, there is a good deal of work on the farm that they could take with advantage to themselves and their employers, such as hoeing, pulling beans, digging potatoes, husking corn, etc. In fact, I do not see why the plan might not be extended to nearly all the operations on the farm.

"My swamp land," says Mr. B., "used to grow only smart-weed. The first year after it was underdrained it grew about 35 bushels (68 lbs. of ears) of corn per acre. The next year it grew 80 bushels of corn per acre. The next year (1871) 85 bushels per acre. It is now in corn again." Is not that better than letting it produce smart-weed and fever and ague?

I have harrowed my corn three times with Thomas's Smoothing Harrow. I went over it the first time a few days after the plants made their appearance, and then at intervals of four or five days. We are now (June 18th) cultivating it, and I propose to go over it again in a day or two with the harrow. There are a good many thistles in the field, and it will be necessary to hoe these out of the rows where the cultivator will not reach them. But for this, I would not put a hoe in the field, as there are few things that annoy me more than to see men during this hurrying season wasting their time dressing up a hill of corn with a hoe. I have never yet been able to convince a man that I want him to hoe the weeds. He says and thinks that he is engaged to "hoe the corn." And it is curious how tenaciously this idea clings to the mind of even intelligent farm men. The very boys seem to inherit the same tendency. If a hill of corn has missed, it requires a special training to induce the boys to cut out the weeds. If there is not a weed to be seen they will hoe all round the corn, but if there is no corn they will not hoe the land, no matter how many weeds there may be in the hill. Thomas's harrow has certainly killed thousands of weeds, and greatly lessened the necessity for hoeing. In fact, an active man, if he could get rid of the idea that he was hoeing corn, and would merely cut out

the weeds, could go over two, three, or four acres a day and do all that was necessary.

So far as my observation extends, there is no branch of farming in which such a marked improvement has taken place during the last twenty years as in the cultivation of corn. The old plan in this section was to run a cultivator through the rows each way, and then hoe. Then in two or three weeks run the cultivator through again both ways, and hill up the corn, and dress off the hills with a hoe. That was all the cultivation it received. Now, our cultivators are not only far more effective implements, but we use them more frequently. Farmers are fully convinced of the advantage of keeping the land constantly stirred and free from weeds. I know of no crop, unless it is cotton, that affords such a splendid opportunity of cleaning land as our magnificent cereal, Indian corn. And I have no little pleasure in witnessing the avidity with which all good farmers avail themselves of this chance to kill the weeds. I have always said that it will not be many years before the best farming in the world will be found on this continent, and the more thorough cultivation of the land while in corn will do much to hasten the time.

My English friend smiles at this remark. He thinks it will be a good many years before our farming will compare favorably with that in Norfolk and Lincolnshire or Scotland. I am well aware that much of our farming at the present time is about as bad as it will can be. I know farms where every well-established principle of agricultural science and practice is daily violated. But the American agricultural press, which is sending its sheets broadcast over the land by the million, has become a prodigious power for good, and is having a mighty influence on the minds of men. Farmers are constitutionally cautious and slow to change. But when they get hold of a good idea they digest it thoroughly and make it their own. By and by you see the effect. All improvements in agriculture are slow. It is often a life-work to bring up a farm to the highest state of cultivation and productiveness. Bearing these facts in mind, and admitting, as I must, that much of our farming is now wretched in the extreme, I can see beneath the surface most cheering indications of great and far-reaching improvement in our general agriculture. Recollect that *we own the land*. We are not tenants liable to be turned off our farms if we express political or religious views different from those of the landlord. If we plant a tree, dig a drain, or get out a stone, we can feel that it is our own land that we are improving. And this thought *does* have an influence. We must look out, however, and not let the great railroad corporations virtually become our landlords. For my part, I have no fear. They oppress us sorely at times, but, on the whole, it must be confessed that the condition and prospects of the American farmer will compare favorably with those of any industrial class in the world.

Let us take a cheerful view of things, and go ahead with our improvements. Farm products will always be in demand, and will, taking one year with another, always bring what they are worth. Our aim must be to produce them as cheaply as possible. And the first thing to be done is to stop growing weeds.

I have said that we are cultivating our corn better. Such is the case. Our cornfields are much cleaner than formerly. But our wheat and spring grain crops are too frequently full

of weeds. Such is the case on my own farm, though I am making encouraging headway against them. With rare exceptions, it is generally the case in this section. The Deacon's oats, sown after corn, are a mass of thistles. And the reason of this weedy condition of our spring grain and wheat crops is mainly due to the fact that the great aim of the Deacon and of the majority of farmers is to plant corn in such a way as to "save hoeing." They do not want the weeds to grow. They fail to take advantage of the splendid opportunity which a corn crop affords for killing weeds. The weeds and weed-seeds are lying dormant beneath a tough sod, where the cultivator does not reach them. Next spring the land is plowed, and all these weeds spring up in the oats, barley, or wheat, where we have no chance to kill them. It is a great error. We must either plant corn two years in succession, or we must break up our sod land early the fall previous, and plow it again in the spring before planting the corn. In other words, we must adopt some method of *making the weeds grow* in the corn, where we can get at them with the cultivator. I know I have said the same thing again and again. It is one of my pet ideas. And I am trying to carry it out in my own practice. I have planted my corn this year on land purposely treated in the best way I could think of to make the weeds grow. It looks like rough and slovenly work, but I think I shall have pretty good corn, and I know the land will be cleaner for years to come. I plowed a clover sod last fall with one of Holbrook's side-hill plows. I put on three horses, and turned a furrow twenty inches wide. The plow is designed to break the furrow as much as possible. The land was very dry and hard, and being a two-horse plow the three-horse evened made it run a little wider than it is calculated for. It made rough work, but that was precisely what I wanted. At any rate, I wanted to try the experiment. I plowed part of the field with an ordinary plow, turning over a neat, smooth furrow. This spring I harrowed the land and then cross-plowed it, and I think the rough-plowed land was in the best condition, though owing to the great drouth the sod had not rotted on any of it as much as I expected. If I was going to do it again I would plow earlier, say in August or September, and then cross-plow the last of November in such a way as to let the land lie up rough for the winter. A thorough harrowing in the spring, with the free use of a two-horse cultivator, and then plowing it up just before planting the corn, would give the weeds a good chance to start, and we could then kill them by the million with Thomas's harrow and cultivator. At any rate, until I get my land clean, or unless some one will tell me a better plan, I think I shall adopt this method of growing corn. As soon as my land is clean I shall then probably plant on a freshly-inverted clover sod.

But as long as our farms are as weedy as they are at present, I am satisfied that the plan of "fall-fallowing" which I have advocated is the true plan in this section. We only lose the use of the land for about two months in the fall, and at a season when grass is usually abundant, while the soil is exposed to the ameliorating influences of the atmosphere for a period of about nine months, or say from August to May. The work can be done at odd times when there is little else for the teams to do. You are not obliged to break up the whole field at once, as is the case when you intend to sow a crop. Part may be left in grass, and pastured until

you can find time to go on with the plowing. But the earlier it can be done in the fall the better will be the condition of the land. It is very desirable to cross-plow before winter.

Horse-Powers.

There has been much discussion as to the most economical horse-power. Without entering into the merits of the question in a mechanical sense, which involves many considerations, we would merely say that having tried and used both the lever and the railway power, we believe that for general use the railway power is the simplest and best, and that almost any well-built railway power now made and in use will be found a handy and economical thing to have around the barn. Some of its advantages are that the weather, whatever it may be, need not interfere with its use, that it is always ready, that for light work, as cutting feed or cleaning grain, one horse may be used, and that it is easily moved about. The chief objections to railway powers are, the seeming danger to the horses in case anything gives way, and also the seeming severe work on the team. But both these are more imaginary than real. With a pretty large acquaintance with them, we never had or heard of an accident in their use, and although we confess to feeling a dread of something happening, yet no accident has occurred, and with the precautions we have learned to take there does not seem to be any possibility of it. Perfect safety may be secured by the following methods: Let the horses have all the harness on when they are put in, fasten the breast-chains on to the rings of the harness, and let them pass through the rings on the breast-

HORSE-POWER WITH SAFETY-BRAKE AND PLATFORM.

ba. at a in the figure, and straps from the breeching may also pass through the rings on the seat. The horses then could not in any case lean out, nor can they back out even if so disposed, and should they under any circumstances whatever endeavor to back out, the platform should be at the rear of the machine will allow them to do so without injury. This platform should be made of two-inch plank, and should be attached to the machine by means of a bolt passing through the sills at the rear of the machine, as shown by dotted lines. It will be found very convenient for the passage of the horses in and out in a very short time they may be so trained to walk up and back out by word of command and without handling. The only real danger consists in the effects of a breakage of the belt, or the slipping off of the belt. The machinery, provided for effectually by an arrangement of an arm which carries a pulley is fixed to the arm of the brake-block. The pulley at b rests on the belt, and serves when run right as a tightener, and prevents the need

of keeping a dangerous strain on the belt to obviate slipping. Should the belt break or fly off, the pulley drops and brings the brake into immediate action, and the machine can not by any possibility run away. If these precautions are taken, there need be no fear of any accident occurring in the use of these horse-powers, and the chief objections to their use are removed. With reference to the excessive labor of the team, this is quite a gratuitous alarm. The horse walks up an elevation of a foot and a half in ten at the rate of two miles in an hour, or something over that, and thus, carrying no load but merely his own weight up that moderate elevation, if he weighs a thousand pounds, he performs the work of a standard horse-power, and this with greater ease than in any other method we know of.

To Bore Wooden Drains or Water-Logs.

"G. F." Rochester, Ind., asks how to bore drain-logs eight or ten feet in length. He has a quantity of spruce poles of which he wants to construct water-pipes. For this purpose a frame should be constructed as shown in the figure. It consists of a series of trestles firmly placed on the ground, or they may be connected together by a strip nailed along the ends of the trestles so that they are kept in position. Each trestle has a pair of stakes fixed on the top, between which the logs are placed and keyed fast with wedges. The boring tool is an auger of two or three (or more if necessary) inches in diameter, fixed on to a long iron rod—half-inch or three quarters thick would be sufficiently strong—and at the end of the rod a double-crank handle is welded. This tool rests on trestles furnished with guides to keep it exactly in position during the boring. When the trestles are placed in position and the log keyed fast, the boring tool is then carefully placed in line each way with the center of the log. A line, similar to a carpenter's chalk-line, should be used for this purpose, and it depends on the care with which this is done whether the bore-hole keeps the center of the log or not.

When all is accurately placed, the work is commenced and continued until the middle of the log is reached, when it is turned end for end and bored from the other extremity. This is always advisable, as it very much lessens the risk of the auger running out of line. When the logs are bored, they should be peeled and seasoned before using. An excellent method of doing this is to put them for a few days into a creek or pond, where they will become thoroughly saturated with water, and on drying afterwards for a few weeks they will season rapidly. To fit them together, one end should be brought to a taper, and the other end bored out with a tapering reamer to fit the end of the

log which connects with it. In laying the logs, the end of one should be driven into the enlarged bore of the other. A little tar may be used to get a close fit if the pipes are to be used for conveying water; if for drains, the ends may be left loosely connecting, and stones packed around the joint. A coating of hot tar given when the logs are thoroughly dry will make

BORING A WATER OR DRAIN LOG.

them more durable, and an iron ring driven over the end which receives the point of the connected log will prevent it splitting when it comes to swell in consequence of being saturated with water.

Farm-Mills.

We have had several inquiries about farm-mills for grinding coarse feed for stock. There are but two kinds of these mills—viz., those with steel plates to form the grinding surfaces, and those with burr-stones. The former kind does very fair work, but occasionally the plates need replacing, and as soon as they become worn the work is badly done. Such mills are largely advertised in the agricultural papers, and are relatively cheaper than the stones, but they are not so durable, and not easily kept in such good order as the stone mills. The cost for a horse-power steel mill is not far from \$50, and one of this price will grind from five to ten bushels per hour. The burr-stone mill will cost about double this amount with all the fittings complete, but one can be got up very much cheaper by purchasing a pair of what are called country stones—which are of native manufacture, and cost less than half the price

A FARM-MILL.

of French burr—and having them framed and mounted by a country millwright or miller. We give an illustration of such a mill, which we have used very satisfactorily, and which, run by two horses, has chopped fifty bushels of oats and corn in a day with great ease. The stones were country stones, and were hard enough to

grind a thousand bushels without dressing, and cost \$20. The frame is a very simple affair, made very stout; the lower stone is stationary, and is bedded on the frame; the upper stone is suspended on the spindle, and is turned by means of the pulley above. A screw on the upper part of the spindle raised and lowered the stone as became necessary. The hopper above fed the grain into the eye of the stone by a shoe and shaker, as in any ordinary mill. A hoop surrounds the upper stone, and the meal is discharged through a spout in front into a box or bag placed to receive it. The economy and convenience of such a mill are very great when one is located at a distance from a miller, and even when this is not the case it is a great convenience to be able to do all the work of the farm at home on days when the weather is not fit for out-door work. The saving made in feeding ground grain is such that where no more than ten head of stock are to be fed it would be profitable to incur the cost of a mill to do the grinding. These mills are very easily kept in order, and the method of dressing the stones is so simple that any one can learn to do it by trying a few times and following directions.

How to Ring a Pig.

There are circumstances in which pigs should not be allowed to root. In fact, when they are not constantly penned up, or where a lot can not be appropriated altogether to their use, it is absolutely necessary to prevent them from rooting. All methods of cutting the snout have with us been unavailing; the wound very rapidly heals, and nature seems to have provided so effectually for the perfection of the rooting implement, that nothing save a ring which acts mechanically prevents its use altogether. The best ring we have used is a horseshoe nail with the point beaten out into a slender wire, which may be passed through a hole made in the snout with a common awl, and twisted two or three

RINGING A PIG.

times around the head of the nail. This stays in place, and offers so much obstruction to the action of the edge of the snout, that the hog can not root while it remains there. It does not operate by any sharp points pressing on the snout painfully, and therefore may be used by the most humane and considerate man without any qualms of conscience.

The main difficulty in ringing a hog is to hold him during the operation. This is done very easily by coaxing him up to a trough, and taking him by one ear; he immediately squeals, and when the mouth is open a noose is slipped over the upper jaw back of the tusks and drawn tight. The end of the rope is passed round a fence-post or anything which may be handy,

and the pig will hold back, steadily hanging on the rope, without making any other movement. It is then the work of an instant, having everything all ready, to pierce the snout and insert and fasten the nail. The rope is loosened, and slips off the pig's jaw in an instant. Good-sized hogs may be thus ringed by one man without the need of any help besides the tools.

A "Buck-Board" Wagon.

All the costly appliances of modern carriage-building hardly accomplish a better result—so far as comfort goes—than is secured by the very simple "buck-board" of the backwoods, which is cheap, simple, and effective. The accompanying illustration shows a modification of the original device, which is in use in some parts of the country, and which deserves to be more generally adopted. The two axles are connected by a platform of oak or ash boards, which does duty at the same time as a reach, as a body, and as springs. On this platform, which is about three feet wide, there is built a common buggy-seat, with or without springs, for two persons, so placed as to bring the weight half-way between the axles.

This wagon, which may be built at any country shop, will be found as easy and comfortable as the best buggy. It is susceptible of a fine finish, and may be made an elegant vehicle.

Applying Manure to Wheat.

We know two quite distinguished farmers in Western New York whose land is thoroughly underdrained and in very high condition. Both grow a great deal of clover and feed a large number of sheep. All the clover and straw grown on the farm, as well as the corn and corn-stalks, are fed out, and a large amount of rich manure is made every winter. Both pile their manure in the spring, and keep it over until the fall. One applies it to his winter-wheat, and the other spreads it on his grass land that he intends to break up in the spring for corn. The farms adjoin. Both are noted for their great productiveness. It would be difficult to select two better managed farms in the State. But we noticed that the farm on which the manure is applied to the grass land is *far cleaner* than that on which the manure is applied to the wheat. We think that it will not be an easy matter to get rid of the weeds so long as the manure is applied to a crop, like wheat, that can not be cultivated or hoed.

We are well aware of the advantages resulting from applying manure to wheat. It is a crop which we sell, and which brings in a good round sum of money at once. We are all anxious to get a large yield, and it is certainly not

an easy matter when there is some good manure in the yard to refrain from drawing it on to the wheat fallows when we know that it is likely to add ten or fifteen bushels per acre to the crop.

When land is clean, and when the hay, straw, and grain crops are free from weeds, the practice of applying manure to wheat has many advantages. But on farms where even clover is not free from docks and red-root, and where the wheat, oat, and barley straw is mixed with injurious plants, the manure must contain large numbers of weed-seeds. Piling and fermenting the manure will not destroy the vitality of these

A BUCK-BOARD WAGON.

seeds. Many of them will be pretty sure to grow in the wheat, and will go to seed, and so land and manure will become more and more infested with these troublesome plants.

It would seem, therefore, that as long as our farms and crops are weedy we must adopt some other method of enriching our land for wheat. If the land is poor, we might apply the manure to a one or two-year-old grass or clover sward in the fall, say in August or September. Spread evenly and harrow thoroughly. The weed-seeds would germinate in the fall or spring. Then pasture the field next spring, and plow it up before the weeds go to seed, and fallow it for wheat. We should be pretty sure of getting a good crop, and the land would be clean, and the following crop of clover would be heavy and free from weeds, and we should have made a commencement towards that cleaner and better farming, which we must ultimately adopt.

Harvesting Buckwheat.

"A Young Farmer" wants information about harvesting buckwheat, which we give somewhat

A STOOK OF BUCKWHEAT.

in full, as it is of general interest, and the crop is sufficiently valuable to make the proper harvesting of it worthy of more care and attention than are generally given to it. No crop is more care-

lessly put in the ground or harvested than this, and the result is that a considerable loss both in yield and quality is sustained. It is thus that the crop has come to be called "the lazy man's crop." It is too late in the season now to say anything more as to the best methods of cultivating it than that the crop deserves and will pay well to be put in in the best manner and on good soil. In harvesting, too, it will pay for good care. No crop suffers more from wet, or shells out more easily. The slender attachment by which the grain hangs, is broken very readily when dry, and it is thus best to cut it when the dew is still on it and the grain is damp. It should be cut with the cradle, and allowed to lie until again damp with dew, when it may be raked up into bunches, and set up in small shocks, without being bound, as shown in the cut. The haulm or straw will always tangle sufficiently to make the shocks hang together, and binding would cause much unnecessary waste. It should stay in these shocks, which are very open and admit air and sunshine, until the grain is cured, when it should be thrashed immediately. It will not do to stack it or put it away in a mow, as it heats and spoils very readily, and after being heated its value for flour is very much diminished. It should be hauled on a bright, windy day, if possible, and thrashed as it is hauled, the grain cleaned up immediately, and either sold at once, or stored in an airy room or granary. The earliest buckwheat flour in the market brings the best price, and that ground on a clear, windy, dry day, both yields more and better flour than when ground in damp, close weather. Buckwheat chopped with oats or rye makes excellent feed for horses, hogs, or milch-cows, and the bran will increase the flow of milk in cows, but at the same time it makes poor white butter.

Building Concrete Houses.

Edwin D. Knapp, Tompkins Co., N. Y., sends us the following directions for putting up con-

Fig. 1.—SIDE OF BOX FOR CONCRETE WALL.

crete buildings. In his neighborhood there are eighteen buildings, including one fine residence, several smaller dwelling-houses, and barns. The principle is the same as that described in the *Agriculturist* for March, 1872, but the material used is common lime instead of cement,

Fig. 2.—BOX FOR BUILDING WALL.

and the construction of the boxes is somewhat different. He says after the foundations are ready the boxes are to be set up. They are made of strips of 2 x 4 inch stuff, ten or more

feet long, as may be desired to fit the length of wall to be built. On these strips are nailed boards twenty-one inches long, fitting close to-

Fig. 3.—MANNER OF MAKING ANGLES.

gether. A sufficient number of boxes is provided to go once around the building. Fig. 1 shows the side of the box put together. These sides are kept in place by 3/8-inch iron rods, two inches of which is bent into an angle at one end, and a screw and thumb-nut is made at the other

Fig. 4.—WINDOW-FRAME.

end. The length of these rods will depend on the thickness of the wall. Each box should have three rods, and holes are bored in the bottom of each side to receive them. The sides of the boxes are kept in place on the top by strips laid across with notches cut to receive the sides. These are shown, and also the rods, in fig. 2. Care is to be taken in setting the boxes to have the sides plumb, and always the same distance apart, or the wall will not go up evenly. These buildings should not have sharp corners, and in the arrangement made for the corners, as shown in fig. 3, a beveled piece is fastened (as shown at a) into the corner of the box to provide for this. When the boxes are placed properly they are filled with the concrete. This is made of common mortar of coarse, sharp sand and lime, in the ordinary proportions, and is put into the box, and the stone is compactly bedded into it. The stone may be common field stone, large and small together, but too many large stones are not advisable; it is best to break most of them if they run all large. It is very important that the stone should be perfectly imbedded and packed in the mortar. When the window and door frames are put in, they should be made with beveled sides, as in fig. 4, and the ends of the boxes should be tacked to them with a close fit. It is not necessary to make this attachment to the boxes at the ends, unless it happens to come so; the beveled sides of the frames may be tacked to any part of the boxes they may happen to come against. It is not necessary to have any skilled labor about these buildings; common smart laborers properly superintended will do the work very well. When the course is finished, the bolts are unscrewed and drawn out, the boxes come apart, and are set up again for another course as soon as the previous one

is sufficiently set. One to two days are required to make it solid. As the walls are carried up, the flues for the chimneys are made by inserting in the wall the block shown at fig. 5. This is made in three tapering pieces. The center one has a ring fixed in it by which it is drawn out, then the sides are taken out, and the blocks set higher up for the next round. These are made large enough to suit the size of flue required. A wall sixteen inches thick is sufficient for a large building, a foot is thick enough for a smaller one. If it is desired to finish off the wall smoothly, a floating is given with common mortar, and a wash to color it may be made by taking five parts of water to one part of molasses, and thickened with cement to a proper consistency for a wash, and mineral paints or ochers may be added to suit the taste as to the color.

Double-Trees and Uneven Pulling.

Some months ago the question was submitted, to us whether, when one horse of a team was pulling ahead of another, either horse was necessarily doing more work than his mate. This question was so simple that a plain answer was easily given, and we gave it, as we believe correctly, in replying no. This reply has given rise to a large number of communications, amongst which was one from the propounder of the original question, who we discovered had a dispute about the matter, and had agreed to refer to the *American Agriculturist* for a decision. Of course, it was unsatisfactory to the defeated party, who felt himself aggrieved, which seems not to be exactly the way of submitting to the decision of a referee. Had we known that we were to be placed in the position of umpire we should have declined it as a thankless and useless piece of business.

The question, as originally propounded, ad-

Fig. 1.—DOUBLE-TREE.

mitted of no contingency or limitation, and was therefore answered on its merits as a plain and simple one. But it is in practice subject to so many complications, that much confusion is likely to arise in the minds of those who can not easily view a question in several ways at once. Now, we propose to place the matter finally in such a way that the ques-

Fig. 2.—SINGLE-TREE.

tion will be readily understood, and may be practically useful. Freed from all those little niceties of mechanics, which practically are of no account, there are three ways in which uneven pulling operates, and these wholly depend on the position of the holes in the double-tree. If they are all in a straight line with each other, as in fig. 1, practically each horse will pull equally in whatever position the double-tree may be, so long as it is free from entanglement. If the middle hole is behind the line of the end holes, the horse in advance is doing more than his share of the work; and if the center hole is ahead of the line of the end holes the rear horse will do most work; and lastly, the further the center hole is out of line the greater difference in draft is occasioned by the unevenness of the draft.

While considering this question, it is worth while to notice the forms of double and single-trees, both as relating to the case in point and

Fig. 5. BLOCK FOR FLUE.

to their strength in use. While we need to have them light, they must be strong, and the form that will best include these two requisites is the best to use. In figs. 1 and 2 we give forms of double and single trees which have been used by us for many years in farm work and in heavy lumbering, and we consider them preferable to any other. The double-tree has the three holes in line, and is strengthened by light iron bands, so placed as to resist the tendency to rupture the wood. This enables them to be made much lighter than they otherwise could be to be equally strong. Fig. 2 shows a single-tree with the "belly" placed in the front. There it is of greatest use in resisting strain; when placed behind it is of the very least service. We have to acknowledge a communication from Prof. Miles, of the State Agricultural College of Michigan, on this subject, which we should gladly publish had we space, but as he entirely indorses our views as to the effects of uneven pulling in the several shapes it may be made to take, its purpose is accomplished in this earlier prepared article. We hope the matter is now finally set at rest.

A Case of Mixed Husbandry.

We have no doubt that in all the older States, near good markets, mixed husbandry is better both for the farmer and the farm. The grain farms of the West are deteriorating, and the plantations of the South are becoming barren by the persistent cultivation of cotton and tobacco, without fertilizers. Every crop impoverishes the land and takes something from the capital of the land-holder. With mixed husbandry it is quite possible to return to the soil more than is carried off every year. The annual sales may be steadily increased, and the soil be kept constantly increasing in fertility from the products of the farm. There is a great safeguard, too, in mixed husbandry against loss of crops from peculiarities of the season. The cultivator does not put all his eggs in one basket. He is certain to have something that will be specially adapted to the season. If great heat comes, and drouth, Indian corn will be successful. If he has a wet season, grass and roots will flourish, and the extra growth of potatoes, beets, and turnips will compensate for the deficiency in the corn-bin. In the variety of his crops he is certain to have something that will sell at paying prices.

As an example of mixed farming we present the sales of a New England farm for the past year, taken from the record:

FROM THE HERD.	
Heifers and beef cows.....	\$743 84
Veal calves.....	106 73
Butter.....	149 47
Total from herd.....	\$1,000 04
FROM THE FLOCK.	
Lambs, sheep, and wool.....	113 76
Pigs and Pork.....	256 33
Turkeys.....	389 23
Hens.....	46 33
Eggs—261 dozen.....	68 33
Geese.....	35 42
Ducks.....	24 64
Total animal products.....	\$1,933 93
Potatoes.....	108 12
Lima beans.....	25 50
Onions.....	26 77
Straw.....	68 95
Pasture.....	4 50
Vegetables.....	130 92
Pickles.....	22 50
Cranberries.....	8 00
Rye.....	6 85
Wood.....	372 74
Railroad ties.....	123 20
Total amount of sales.....	\$2,832 03

In looking at these figures it will be noticed that the sales of animal products are \$1,933.93,

while the vegetable products amount to only \$898.05, and of this nearly \$500 is for wood and timber. The hay, corn, oats, rye, and the large root crop, carrots, beets, mangels, and turnips, were nearly all consumed upon the farm. And in addition to these there were large purchases of corn and hay to winter thirty head of horses and cattle and thirty-two sheep. Large quantities of peat, loam, and leaves are used in the yards and stables in making manure, and in addition the wood sold is exchanged for fertilizers. These are used extensively in top-dressing the meadows as well as in raising hoed crops. The purchase of fertilizers is regarded as only a temporary necessity to bring up exhausted fields. The farm will soon be in a condition to keep fifty head of cattle, and to make manure enough to keep the fields constantly increasing in fertility.

Another item worthy of notice is that of poultry and its products, amounting to \$563.85. Nearly four hundred of this is from turkeys. They have a good range through pastures and woodland, and pick up their own living mainly from June to October. Poultry, especially the turkeys, is regarded as more profitable than any other stock kept on the farm. The best varieties are selected, and none but the largest and best are kept for breeders. Sheep stand next to poultry in the profit they yield. The sales for this year were from a flock of ten sheep only. They paid more than one hundred per cent above the cost of keeping. The least profitable stock kept is swine. They consume the buttermilk, and make a good deal of manure of excellent quality, and if there is any profit, it is found only in the item of manure. But it is doubted if swine can be raised profitably in New England, at the present prices of pork. Of course, those who know the great superiority of home-grown pork and hams, will continue to raise enough for home consumption at whatever cost. But to compete in the market with Western pork does not pay even at the extra price which the Eastern article commands. The grain would give much better results if fed to poultry, sheep, or cows. With this single exception the policy of raising animal products for market rather than vegetable is regarded as sound.

Of the common farm crops rye probably pays better than any other grain. There has been increasing demand for rye-straw in all Eastern markets for litter, until it is nearly as valuable as hay. As a rule, the straw sells for as much per acre as the grain, and if the grain can be kept at home, the farm can easily bear the loss of the straw. With a light dressing of manure it is easy to get 12 or 15 bushels of rye and a ton of straw to the acre. The labor is mainly that of getting in the seed, and it comes at a season when other work is not pressing. Corn pays only because there is so much excellent fodder in the stalks, when they are properly cured. Market-gardening will pay very well near cities and villages, where the business is not already overdone. But it is properly a business by itself, and requires more skill and capital than most farmers possess to make it pay. It wants glass, large stores of manure, which are likely to rob other parts of the farm, early hours, and close attention to marketing, which will absorb the attention of one man during the season. Root crops may be grown to almost any extent. If the market is dull, they may safely be fed out to stock, where they are certain to pay a handsome profit. With suitable soil and improved tools ruta-bagas and mangels can be raised at eight cents a bushel, and we know of nothing better to make up for a short hay

or grain crop. On any farm devoted to mixed husbandry roots should have a large place.

Top-dressing Grass Land.

It is a good thing at this season of the year, or before we thrash the new crops, to clean up the yards, sheds, and every part of the premises where any kind of fertilizing material can be found. The amount of manure that can be seraped together in this way will be far greater than most farmers imagine. If it is allowed to lie spread out in the yards the fall rains will wash out nearly all the valuable ingredients.

There seems to be a general idea that manure spread out on the land during the hot weather in August must lose much of its valuable ingredients by evaporation. With very rare exceptions, such is not the case. Many farmers would find it greatly to their advantage to draw out all the manure they can gather together and spread it out at this season on their grass land, either on meadows, permanent pastures, or on grass land that is to be plowed up next spring.

We would specially recommend the free use

Fig. 1.—FRAME AND SASH FOR DRYING FRUIT.

of the harrow after the manure is spread. Go over it several times, and respread any of the manure that the harrows may draw into heaps. It is a great mistake to suppose that cows and sheep do not like the grass after it has been top-dressed. If the manure is well harrowed and completely broken up, the first rain will wash much of the soluble matter into the soil, and the grass will spring up and be sweet and tender, and all animals will eat it with far greater avidity than grass not top-dressed.

About Drying Fruit.

That there are better ways of preserving fruit than drying, all who put up their cans of peaches, cherries, and other fruits will admit. There is really nothing equal to properly canned or bottled fruit. But there are thousands who live where fruit is plenty and bottles and cans are scarce. It requires no little skill and some

Fig. 2.—OVEN FOR DRYING FRUIT.

outlay to bottle fruit, and but few care to put up more than will be needed by their own families. The sun and the air are free to all, hence thousands dry fruit where one puts it up in the improved method. They may not be for

some purposes as good as that which is canned, but there is a flavor about dried apples and dried peaches peculiar to them, and while we have a plenty of canned peaches we like

fruit of some kind curing in the yard. Many of the dry-houses were of the rudest description—built of logs, with a flue running through the bottom. The sketch (fig. 4) is of one of the

best quality is very white, but not so fine in flavor, as the fruit to obtain this color must be pulled and dried when green. Old housewives prefer the mahogany-colored apple for cooking.”

Fig. 3.—DRYING FRUIT IN THE OPEN AIR AT HIGH POINT, N. C.

now and then a pie made of the dried fruit. Persons far away from all access to cans and jars, having an abundance of fruit, dry it and turn it into cash. Many a hard-working woman in the mountains of North Carolina or in the abundant orchards of Ohio and Illinois and other Western States dries fruit enough to supply her family with groceries for the year. There are various ways of drying fruit.

A few years ago we were much interested in seeing how a share of the abundant peach crop in Missouri was disposed of. A rude oven was made in the side of a bank, some broad stones formed the top, and underneath these a slow fire was made. Upon the stones were placed peaches, cut through to the center. A slow fire was kept up in the oven, and the fruit gradually dried. A rude shelter was made over this drying oven to protect the fruit from sudden showers. Peaches dried in this rude way are highly prized by the German population of the West, and have a local name which we have forgotten.

An enormous business in the aggregate is done in North Carolina in drying fruit. Mr. Woodward, our artist in the South, sent us an account of the drying of fruit at High Point, N. C. He says that dried fruit to the value of three to four hundred thousand dollars is annually sent from that point alone. He writes:

“As enormous as the business is in the aggregate, no one person carries it on to any great extent. Every family has its orchard and dry-house. In my travels through the surrounding country, I did not see a house that did not have

most improved kinds—a circular building, with a revolving post in the center, on which are racks to place the triangular-shaped trays. A person standing outside can in this way turn the rack and reach any tray without difficulty. The flue is at the base inside, extending around the

Drying fruit in the open air on trays or shelves is not altogether a satisfactory process. It is slow and uncleanly, is often interfered with by the weather, and the fruit is very often damaged by flies. A very simple and effectual method may be taken by using the sash and frame of a

hot-bed. As soon as the hot-bed has served its purpose in the spring, it should be cleared out and the boards washed off; shelves may be laid within it, which should be covered with clean white paper, to receive the fruit and to reflect the heat, and a strip of wire-gauze or mosquito-net fastened at the back to permit the escape of the damp heated air. The glazed sash may then be kept closed, and the entrance of flies prevented. The temperature within the sash will be sufficient to dry the fruit very rapidly, and rain does not interfere with the operation except to suspend it temporarily.

The arrangement is shown at figure 1. At figure 2 is shown a cheap and useful dry-house for the use of artificial heat. It is made of sheet-iron, with perforated sheet-iron shelves, the edges of which are turned up so as to form shallow pans, and a tube similar to a common stove-pipe passes through it, having an opening at the outside, as shown in the figure. A handful of live

Fig. 4.—A SOUTHERN DRYING-HOUSE.

whole house, thereby securing an even temperature. The house (built of brick) is very close, so that no heat escapes. It takes a day and night for peaches to dry thoroughly. Apples, as a general thing, are dried in the sun (as shown in fig. 3), taking about two days. The

sufficient to raise the requisite heat, and care only is needed to keep the heat low enough to dry and not to cook the fruit. Fruit dried in this manner is sweeter, and retains its natural flavor better, than that dried by the sun. The more rapidly the drying is performed, the better.

The Green Dragon.

In July we gave an engraving of a common but very interesting plant, the Indian Turnip, *Arisæma triphyllum*. We now present a draw-

Farther south it is replaced by a more hairy and simple-leaved species, *Lupinus villosus*.

But the Lupines of the Atlantic States sink into insignificance when compared with the fine species of the Pacific coast. In California and

seeds are generally kept by our best seedsmen, and we may remark that this, and all other perennial Lupines that we have cultivated, are very impatient of removal after they become large. We start the seed in boxes, and after

THE GREEN DRAGON.—(*Arisæma Dracontium*.)

THE MANY-LEAVED LUPINE.—(*Lupinus polyphyllus*.)

ing of another species, *Arisæma Dracontium*, the Green Dragon or Dragon Root. This is much less common than the other species, and though not quite so showy is nevertheless a plant that is likely to arrest attention. Its leaf—it usually has but one—is singularly divided into from seven to eleven and even as many as thirteen leaflets. The flower is greenish, and not showy. The spathe, or envelope that surrounds the flowers, instead of being broad and bent over at the top as in the other species, is rolled into a narrow tube and terminates in a short erect point, and the spadix upon which the small flowers are fixed extends considerably beyond the spathe. This has not the turnip-shaped root-stock of the Indian Turnip, but a cluster of small tubers. The plant is found on rich river banks in most parts of the Atlantic States. The drawing was made from a specimen from our garden, where we find it a curious if not very showy member of the collection.

The Many-leaved Lupine.

The genus Lupine (or *Lupinus*) is a very fine one. It includes annuals, biennials, and perennials. Some of these are in Europe important forage plants, and others are grown for ornament. The common Wild Lupine, *Lupinus perennis*, is well known, it being common in sandy soil in the Northern and Middle States.

Oregon there are forty or more species, some of them forming large branching plants, with showy racemes of flowers, which are white, yellow, and through all shades of blue to deep purple. Only a few of these far Western Lupines have been brought into cultivation, and the best known of these is the Many-leaved Lupine, *Lupinus polyphyllus*, which is now a not rare and very showy ornament in our gardens. We have grown it for several years, but have never succeeded in raising such fine plants as we saw growing wild in California. It was near a miserable little Indian village called San Felipe that we came across a large patch which seemed to us one of the finest floral displays we ever witnessed. The plants stood at least six feet high, and the flower-racemes were from one to two feet in length. These stood up above a wonderfully luxuriant mass of foliage, and the whole formed a flower-show that we shall never forget. As we grow it in the garden, the stems seldom reach higher than three feet; still, though it falls far short of the beauty it possesses in its native locality, the plant is a very desirable one for the garden, as it remains in bloom a long time, and has a stately aspect that is very pleasing. The specific name, *polyphyllus*, has reference to the many divisions of the leaf, which are sometimes as many as fifteen. The flowers are variously colored, being purple, blue, and even white in different seedings. The

the plants show a few leaves transplant them to the place where they are to bloom. Removing large plants is not likely to be successful.

The Cabbage-Worm (*Pieris rapæ*).

The "Cabbage-worm" is not a pleasant subject, but he is a very important one. Where he came from, and how he got here, are matters which have been sufficiently discussed. The cultivator's interest begins and ends with the more important facts that he is here, and that he must be got rid of, or cabbage-growers must find another occupation.

With the worm, as a worm, there is little use in contending. It is not a sensitive creature, and cares little for bad tastes and bad smells. Its mission is to eat cabbage, and it fulfills it in spite of all obstacles. The only way to attack it with any hope of success is to nip it in the bud, and its particular bud is the pretty white butterfly that lays the myriad eggs from which it is hatched. Fortunately, these butterflies are somewhat influenced by foul odors, and whale-oil soap, fish pomace, carbolic soap, flowers of sulphur, and such nastiness, will incline them to seek other foraging ground. This means will do much to abate the nuisance, but the further precaution should be taken to catch and kill as many of them as possible.

Farmers and gardeners should combine to

make up a purse from which to pay children for hunting them. It would be a very good investment to pay \$1 per 100 for all the white butterflies that are delivered, and an active boy with a light net (made of ordinary mosquito-cloth) can catch several hundred in a day. Every butterfly killed, especially if early in the season, means a good many heads of sound cabbage saved from the destroyer. It behooves cultivators to give their minds to this matter, for this insignificant-looking worm promises within a very short time to remove the cabbage from the bill of fare of that very large part of our population to whom "boiled dinner" is a semi-weekly necessity.

[While we agree with our associate, from whom the above is received, as to the importance of attacking the "worm" in the butterfly state, we can not subscribe to his statement that it can not be fought successfully while a worm. Our garden patch of early cabbages was badly infested by the worms early in the season. A few siftings of air-slaked lime completely routed them.—Ed.]

Eggs in Grape Canes and Apple Twigs.

BY C. V. RILEY.

[The following note, with specimens, from M. H. Garland, Amherst Co., Va., was forwarded to Mr. C. V. Riley, State Entomologist of Missouri, who returns the accompanying full reply, with illustrations.—Ed.]

"Inclosed you will find a cutting from a grapevine (*Eumelan*), which you will observe has been punctured by some insect. By splitting through the center you will find imbedded in the pith a small worm or grub, about 1/8 of an inch in length; yellowish white in color; but apparently in a dormant state. Is the vine injured by it? If so, what is the remedy? What is its name?"

The above letter with the accompanying twigs came to hand some time ago. From the frequency with which queries regarding these and similar punctures are made, it is evident that little is known about them, and that a few explanations will prove interesting to many of your readers.

Those sent by Mr. Garland are illustrated at Fig. 1. The punctures are in a straight row, about one third to one half-inch apart, and appear as though made by a rather large-sized pin (*b b*). Each puncture leads to from ten to twelve slender, elongate eggs (*c*), about a tenth of an inch long, and deposited on either side of the puncture, lengthwise, in the pith (*a*). About the first of May they hatch out into little dingy crickets, and though I have not yet kept them until the last molt, and no one has ever bred the perfect insect, I have little doubt but it will prove to be the Jumping Cricket (*Orocharis saltator*, Uhler), so named, I suppose, by my friend P. R. Uhler, of Baltimore, because it does not jump as much as some of its confreres. This insect (Fig. 2) is of a pale yellowish brown color, and the female (*a*) differs from the male (*b*) in possessing a long ovipositor, and in her wings being more rounded and less ribbed and veined, so that she can not chat and sing as does her lord.

These Jumping Crickets are at times quite injurious, for they have a vicious habit of sever-

ing green grapes from their stems, and uselessly scattering them upon the ground—always performing their nefarious work at night. The eggs should therefore be destroyed; and this is best done by cutting and burning in the winter-time.

Other eggs, which I receive quite often, are those illustrated at figure 3.

The twigs or canes of various cultivated plants, and notably those of the Grape-vine, Apple, Peach, Raspberry, Blackberry, White Willow, and Soft Maple, are often more or less split or disfigured by a series of closely set but irregular punctures, as illustrated at *a*. Upon cutting into such twigs we find that, unlike the eggs we have already mentioned, these all lie diagonally across the pith, close together, in a single, irregular,

Fig. 2.—JUMPING CRICKET, MALE AND FEMALE.

longitudinal row, as at *b*. More carefully examined with a lens, each egg appears pale yellowish, sub-elliptical, a little curved, more pointed at lower end (*c*), and capped at the head or more rounded end with regularly arranged white, opaque granulations, which, under a low-power microscope, appear as shown at *d*.

These are the eggs of the Snowy Tree-cricket (*Eoanthus niveus*, Harr.). The young also hatch about the first of May. After eating through its egg-cap, the new-born cricket is still enveloped in an exceedingly fine membrane, from which it soon extricates itself, and which it leaves at the orifice of the puncture. These young crickets are whitish and very active, and generally conceal themselves in the thick June foliage of our woods or our orchards. At this time of their life they subsist principally on plant-lice, eggs of insects, and other delicate animal food; and if they can get nothing better, will exhibit their cannibalistic propensities by devouring the weaker individuals of their own kind. Subsequently, as they grow larger, they are often content with a vegetable diet, and thus they perfectly combine in one species herbivorous and carnivorous habits. After the first molt they begin to vary a good deal in color, the females generally being quite dark. When mature, the female insect presents the appearance of figure 4, and the male that of figure 5.

I have at the present time an extensive young brood of these little crickets in one of my breed-

ing cages. They were hatched from a Soft-maple twig, which furnished material for our illustration, and it is astonishing how quickly they will clean off an aphid-crowded twig, of what-

Fig. 4.—SNOWY TREE-CRICKET—FEMALE.

soever kind. When in the course of a few weeks more they acquire their full growth, and with it their wings, it is likely that I shall consign them to chloroformed oblivion; for the male swells with such pride at the acquisition of wings, that he sets them a-going, fiddle-and-bow-fashion, until the shrilling and shrieking fairly distract. He becomes almost as much of a nuisance in-doors, as the young and ambitious musical boarder who grates eternally on his catgut. The only difference is that our little six-legged musician is denied (but not very justly, since he has an object discriminating reason, while the two-legged fiddler is supposed to have reason, which, however, does not always make him considerate of others' feelings!

5.—SNOWY TREE-CRICKET—MALE.

But—not to wander—this Snowy Cricket shares with his more robust Jumping companion in the nefarious midnight-work of gnawing, girdling, or severing different parts of the grape thyrses, causing the berries either to shrivel or fall, and producing what is often known as "shanking." The virtues of its youth do not

Fig. 6.—PUNCTURED TWIG.

atone for the bad habits of its after-life; and this *Eoanthus* must be classed with the bad bugs.

Still a third kind of punctured twig is illustrated at fig. 6. The punctures consist of a row—more or less straight—of little raised slits in the bark (*b*) in each of which upon careful examination may be found an oval, dark-colored egg (*a*). These slits have been mistaken by the uninitiated for the crescent cuts of the Plum Curculio, and thus the false story goes that Madam Turk sometimes oviposits in twigs. They are in reality those of the Buffalo Tree-hopper (*Ceresa bubalus*, Fabr.), a yellowish-green, hump-backed insect, with two little horns on the prothorax, which render its name not inappropriate. A side view, natural size, is shown at *a* and a back view at *b*, fig. 7. The young are at first brownish, with a formidable row of ten pairs of compound spines, and looking totally unlike the mature insect. After the first and second molts they are still furnished with these sprangling spines on the back, but are of a paler color, with some transverse lilac-colored lines. With the third and last molt they suddenly acquire the mature characteristics.

Fig. 7.—BUFFALO TREE-HOPPER.

This insect subsists during its whole life on the sap of apple, pear, and other trees, but never does serious injury.

These three are the more common kinds of twig-eggs that attract attention; and although there are many other kinds that are of interest to the fruit-grower as well as to the entomologist, this article is already too long to allow us to undertake a description of them at present.

Fig. 3.—PUNCTURED TWIGS.

COLD-FRAME CABBAGE PLANTS.—Col. Waring wrote an article on cold-frame cabbage plants, to some points in which Mr. Henderson took exceptions. We give Col. W.'s rejoinder, which closes the discussion: "I would not presume to dispute the statements of a wise old gardener like Peter Henderson, but you must not try to screen me behind 'climate.' Bless you, Newport is green and growing after Bergen Point is brown with the frost. I have not my previous article before me, but I think I said—I surely should have said—that when the plants are large enough to prick out, if it is too early, we pull them up and heel them in. If they recover from this check in time to threaten to run to seed, we pull them up again and give them a fresh start. This treatment will save them, if they are planted in August. If you doubt it, just try it. My experience of this year with some plants whose stems had been split by frost, show Mr. Henderson to be about right—these plants are heading about as well as the others, but this does not shake my belief in his statement, 'Gardening for Profit,' page 126: 'In planting, it is very important with cabbage or cauliflower that the plant is set down to the first leaf, so that the stem or stalk is all under ground, for we find that if exposed it will be split by the action of the frost, and will be injured in consequence.'"

The Baldwin Apple and its Origin.

BY MRS. ELIZABETH OAKES SMITH.

It is not improbable that of the many who are able to procure a taste of the delicious Baldwin Apple not more than one in ten knows from whence it originated, or knows anything of some interesting historic points associated therewith. I have so often heard my husband, Seba Smith, speak of this fruit, and of the Pearce family, with whom he was associated by the warmest ties of friendship for nearly sixty years, that I am induced to offer your readers a brief sketch of the same.

The Baldwin Apple came from a seedling planted by Josiah Pearce, Esq., of the town of Baldwin, Me. From this stock innumerable grafts have extended the fruit far and wide, but from a well-known law of extension, the Baldwin Apple is rarely found in perfection when far removed from the place where it originated. In Maine, the color, texture, aroma, and solidity of the apple leave nothing to desire, being in truth so delicious, that it might have been akin to the one said to have brought difficulty upon our mother Eve. In other localities, where the soil, climate, or culture may have proved unfriendly, what is called the Baldwin Apple may often be found a total failure, being puffy, insipid, and subject to early decay.

It is not generally known that "Squire Pearce," of Baldwin, Me., was half-brother to Benjamin Thompson, better known as Count Rumford. The mother of these two men was twice married, the first husband being Benjamin Thompson, the second Josiah Pearce, both men of culture and influence in their day. Mrs. Thompson, afterwards Mrs. Pearce, was a woman of strong sense, one of those self-poised, wise women so prominent in our Revolutionary annals. Count Rumford was born in the then town of Rumford, now Concord, N. H., being some twelve years older than his half-brother Pearce. He received a military commission under the Royal Governor of the Colony of Massachusetts. At the breaking out of hostility to the British Crown, young Thompson was supposed unfriendly to the popular move-

ment for freedom, and was most rudely driven from his home by his more zealous neighbors, and compelled to take refuge in Boston, where he became associated with Governor Gage. He was unquestionably what was then known as a "Tory," a circumstance which for many subsequent years was considered as a blot upon the family escutcheon by its patriotic members, although he never took up arms against his country. The subsequent career of Benjamin Thompson is well known. He seems to have cast lingering looks of fondness toward the place of his birth, though familiar with courts and loaded with honors by crowned heads, as is evident by his assuming the name of his native town when the honor of knighthood was conferred upon him by the King of Bavaria—hence his title of Count Rumford.

He was a brave soldier and accomplished military leader, but his character, essentially observant and philosophic, was more naturally employed in those scientific pursuits which for many years engaged his attention. He unquestionably anticipated many of our modern improvements, and was one of the first to turn public thought in the direction of economizing the fuel of the laboring classes. It was a jest in regard to him in Bavaria that he "would soon be able to cook his dinner from the smoke of his neighbor's chimney." He was philanthropic in the highest sense. He devised methods for improving the condition of the poor, by making their labor more productive, by founding better dwellings for them, by teaching them order, cleanliness, and economy, and thus doing away with beggary and disease. Few men of our country have enjoyed more general approbation abroad than Count Rumford, and our own people are beginning to learn that he was a great and estimable man.

In the mean while, the other brother, Josiah Pearce, had become the possessor of a large landed estate, and was living in Baldwin, Me., where he was plowing and planting, and helping on the interests of a scattered but thrifty population. Like his brother, Count Rumford, he was a generous, warm-hearted man, striving to make better what other men considered well enough, if not absolutely good. He experimented much in horticulture, endeavoring to ascertain what fruits could be cultivated to highest perfection in the inhospitable climate of Maine. He bestowed much attention upon the native grape, many varieties of which have large and well-flavored fruit. He planted the seeds of the potato, as did my grandfather David Prince, and thus produced new varieties, well-suited to the soil, and of superior quality. But it was in the cultivation of the Apple that he finally settled down upon as the fruit most genial to the soil, and best adapted to the climate of a State whose long winters are the fostering nurse of a social virtuous population, and whose brief summers vie in intensity with the heat of the tropics. The apple-blossom is the first harbinger of its springs, and the frosty airs of October are rendered more aromatic by the perfume of the apple-tree laden with its richly-colored fruitage. Thus an entire season is required to perfect this kingly fruit.

The old Pearce homestead at Baldwin still attests the skill and enterprise of its ancient owner by its extensive orchards, amongst which may be found the Baldwin, richly productive. The tree has been known to yield an almost fabulous quantity of fruit, and in the season for pruning its thrifty branches were carefully preserved, and liberally distributed to the neighboring farmers.

I have often heard my husband describe this intelligent and most hospitable family. Mr. Pearce was a sort of lord of the manor, to whom everybody came in time of trouble, and was sure of the best aid and advice. He was an eloquent converser, and recited admirably.

Some time in the early part of this century, the Countess of Rumford, daughter of Benjamin Thompson, visited her transatlantic cousins, and was for many months domesticated with the cheerful household. She was a plain, unmarried woman of great good sense, and somewhat learned.

It was the custom for New England teachers of public schools to "board round" with the families of the district until the amount each one was to pay the "master" was boarded out, and such experience was not always of the most agreeable kind. My husband kept the district school of Baldwin for several seasons, but was generally exempted from this contingency by being warmly welcomed at the Pearce homestead, whence he wrote comical rhyming letters to his friends describing the good cheer. One couplet I remember was thought very grotesque:

"We have apples, and doughnuts, and cider,
And curious things fried in a spider,"

the last-named being of course sausages, and the apples the favorite Baldwin.

Shortly before the demise of my husband he received a long letter from his unfailing friend Josiah Pearce, Jun., who had been a judge for many years, in which he thus refers to the family: "Baldwin has greatly changed since you were there. My sister Hannah, who is unmarried, lives at the homestead, and owns the house by division of the property, all the out-buildings, and one hundred acres of the farm. I oversee her business for her. All is still, where once had been so much harmless mirth and activity."

It may be remarked that George W. Pearce, brother to the judge, and son of the first-named Pearce, married a sister of the poet Longfellow. He gave very great promise of a brilliant career, having beauty, genius, and wealth, but died suddenly, while little more than twenty-five years of age. His widow has never since married.

PATCHOGUE, L. I., June 29th, 1872.

Vegetable Plants for the South.

BY PETER HENDERSON.

Every few days, during the summer months, I am written to by some of your readers in the Southern States, wanting to know how they can procure plants of celery, cabbage, cauliflower, etc., to plant so as to produce crops of these during the fall and winter months. Plants can easily be raised here at any season, from May to October, but the time that it is necessary to plant for the fall or winter crops in South Carolina or Louisiana (August and September), it is hardly practicable to ship with safety, particularly celery plants, for if packed more than three or four days (unless the weather is very favorable when set out), the chances are that many would die. To produce plants in these latitudes by seed sown in the ordinary methods, during the month of June, July, or August, rarely results in success, but an experiment in raising celery plants in which we have just been successful here this season, suggests that the same plan may be adopted in the Southern States. Our celery plants are always sown here from the

first week in April to the first week in May, but this season the weather was unusually hot and dry during May, so that our crop of celery plants sown April 15th was found, on examination the first week in June, to be a partial failure. I had never sown as late as this before, but plants must be had, and the experiment was worth trying. So we again sowed on well-prepared ground, rolled carefully, and covered the seed-bed an inch deep with salt-meadow hay. Of course, any similar covering will do, if salt-hay is not procurable. The seeds germinated in 6 or 8 days from time of sowing. As soon as this was apparent, the covering was partially removed, and in two or three days more further removed, except just enough to cover the soil, so that the bed got the full rays of the sun, yet modified by the sprinkling of hay over its surface. The advantage of the hay-covering is twofold; it prevents heavy rains from battering the soil, and it also prevents the escape of moisture. Our experiment has been a complete success, as we have more plants from one pound of seed sown in June than from four pounds sown in April, though under the ordinary conditions the opposite result might have been the case. Now, plants of celery, cabbage, or cauliflower can no doubt be successfully raised by this plan in the Southern States, when the ordinary method of sowing without covering with hay would be almost certain to fail. Where hay is not procurable for covering, an excellent substitute would be the pendulous moss (*Tillandsia*) which grows so abundantly in the woods of most of the Southern States. It is difficult to say at what time the sowing should be made, as much would depend on locality and the condition of the atmosphere

after sowing. So the safest way would be to sow at different times, say from June 15th to August 15th. The result, if successful, would well justify the trouble and expense, as all these vegetables, from the hitherto difficulty of getting plants to set out, have brought enormous prices, celery often selling in the markets of New Orleans and Charleston for 25 cents per head, while the average in New York is hardly 3 cents. There is no reason, either, why cauliflowers could not be grown finely in the mild, temperate atmosphere of November and December in Charleston or Savannah, and shipped to New York. The transportation at that cool season would be safe, and during the month of December it is safe to say that average heads of cauli-

flower would sell for \$30 or \$40 per 100 in the markets of New York. I saw some in the grounds of Mr. Van Sicklen, of Jamaica, L. I., in November of 1870 (which he had protected from the frost), for which he was receiving \$10 per dozen, or nearly \$1 each! There is a wide field in the South for enterprises of this kind, if energetically undertaken. All cultivation so

The Water-Violet or Featherfoil.

In illustrating as we frequently do our native plants, we sometimes select those subjects that it is desirable to introduce into cultivation, and at others plants that are interesting for their rarity or curious in their structure. The Water-Violet or Featherfoil, *Hottonia inflata*, is rather rare, and has a structure sufficiently peculiar to commend it to notice. The name Water-Violet is likely to mislead, as its relationship to the Violet is exceedingly remote, it really belonging to the Primrose Family. The plant, as will be seen by the engraving, is purely an aquatic, with its leaves all submerged, and very handsomely divided. It is no doubt rooted when young in the mud at the bottom of the pond or pool in which it grows, but at flowering time it appears to be floating. The flower-stalks form a symmetrical cluster; each is marked with joints, from which arise whorls of small white or slightly bluish flowers. The flower-stems are hollow and inflated, enabling the plant to float; they sometimes are as large as one's finger, and give the plant a striking appearance. It makes an interesting plant for a fresh-water aquarium. The genus *Hottonia* was named in honor of a Leyden botanist of the seventeenth century. The specific name of our species, *inflata*, has reference to the peculiar character of the flower-stems. In Europe another species, *H. palustris*, has much more showy flowers than ours, but is without the peculiar bladderly flower-stems. Our specimens came from a pool near Hackensack, N. J. Although the plant has been so long known to botanists, we believe that no engraving of it was ever published before the one which we give accompanying this article.

THE WATER-VIOLET.—(*Hottonia inflata*.)

far has been with a view to get vegetables early, but in my opinion they might be raised in many instances to better advantage, if grown to fill up the blank in vegetation that our frost-bound earth at the North makes during the winter months.

For example, spinach sold here the past March for a few weeks at \$20, horseradish at \$30, and lettuce at \$10 per barrel, simply for the reason that everything was frozen up solid. Now there is no reason why these—particularly spinach and lettuce—could not have been grown in as good condition in the neighborhood of Charleston or Savannah in March as they could be raised here in June, when we are abundantly glad to get from \$1 to \$2 per barrel for them.

ROSES ON APPLE-TREES.—"G. H. C.," Benson, Ky.—The case to which you refer is of frequent occurrence. Certain papers seem to have a set of items that they bring out every year. The old negro woman who was nurse to Washington, the toad found in the center of the oak-tree, and the wonderful apple-tree that bears double roses—all belong to the same set. It is not at all a rare thing for apple-trees, especially the Early Harvest, to bear a few late flowers which are more or less double. The apple belongs to the same family with the rose, and when its flower becomes double it very strongly resembles a small rose.

THE HOUSEHOLD.

(For other Household Items, see "Basket" pages.)

Barefoot Boys,

And girls, too! There is something to be said on both sides. Some people have an unreasonable prejudice against bare feet, except in poems, pictures, and statuary.

Is anything in nature much more beautiful than a baby's soft pinky foot? Of course not. And here is Miss Two-year-old sweetly pleading, "May I go bare-footed 'till 'hile?" when you give her a bath and clean clothes in the afternoon.

Say "yes" to the little darling. Her "while" will be little enough, for the soft feet are as tender as a maiden's cheek, and she will be glad enough of shoes and stockings very soon. How daintily she steps, and the working of her curly toes shows how they rejoice in their freedom! When she goes out of doors she chooses soft grass or soft mud to walk upon. The heroine of Jean Ingelow's story is none too extravagant in speaking of the delightful sensation little feet have when set free upon soft grass, but who shall describe the pleasure of paddling in the mud on a warm summer day?

The barefoot school-boy knows all about it. His is a tough foot. He probably makes some involuntary choice of stepping-places as he runs like a free wild animal over weedy roadsides, pavements, chip-yards, stubble-fields, but it is a wonder that he gets so few cuts and stone-bruises.

The country school-ma'am prefers to have her pupils come with bare feet—unless she has a good deal of conventional pride in their appearance. The restless lads and lassies make noise enough with their buzzing lips and their shuffling of books and slates, but on rainy days, when many of the children come in their heavy leather shoes and boots, the added noise of their scraping and stamping makes the day's work almost doubly wearisome.

I like to see the bare feet of young Americans, even when they are scratched and muddy. The outlines are as good in flesh as in marble. I believe in letting children go barefoot in the country during the warm weather. But this is often carried too far. I believe the vital power of children is often weakened by too much exposure of the feet to cold. The barefoot country children are likely to be healthy because they live out of doors almost constantly, except when confined in school-rooms, and in summer these school-rooms have every window opened for fresh breezes.

But if children have their own way they get off their shoes and stockings too early in the spring, and thus often change directly from thick shoes and woolen stockings to bare feet. In chilly mornings and evenings the little unclad feet go through the heavy dews, and then they have to be washed, often in cold well or spring water, before they are fit to rest between white sheets.

Cold foot-baths are good in their place, but some children get far too many. They wade in the streams and ponds too often and too long at a time. It undermines their constitutional vigor, and makes them an easy prey to disease. Upon the temperature of the feet the general health in very large measure depends. The blood in different parts of the body is affected by the condition of the feet. If they are not sufficiently protected from cold, it is unduly cooled in its passage through the capillaries of the feet. If they are overheated, the whole system will be refreshed by reducing the heat of the feet to a comfortable temperature.

Ask any wise physician of your acquaintance (if your own experience or observation has not taught you) whether bathing in lakes and rivers (or "going in swimming," as country boys say) and wading in shallow streams are not usually practiced too much by boys who like such things—whether it does not make them often grow thin and languid during the summer months.

Then let the children have the blessed freedom

and delight of bare feet on warm days, but guard them from injuries that may result from improper exposure of the feet.

Home Topics.

BY FAITH ROCHESTER.

AT SCHOOL TOO YOUNG.—I know a mother whose three youngest children are aged respectively four years, two years, and seven or eight months. The mother is loving and intelligent, and has health as good as that of the average American woman. No human being, not even a mother, is infinite in capacity to do and endure. The oldest child needs as constant looking after as either of the others, especially because he is so much tempted to tyrannize over the second child. And so

"To school the little exile goes,
Torn from his mother's arms."

I don't know as this mother can do any better—but isn't it a pity? She says she would much prefer a kindergarten, but there is none within reach, and so the ordinary district school is resorted to. Perhaps the school-ma'am will have mercy on the little fellow, and let him play out of doors most of the time during school hours. I used to do so with the babies sent to me when I was a district school-teacher, and I am glad I did.

I can understand that a relief to hard-working mothers it must be to get their mischievous, inquisitive children off to school for six hours every day, provided they can feel that such a course is best for the children. And it is sometimes the case that the country school-teacher has so few pupils that she can afford to act the part of nurse to four-year-old children. A school not far from here has only eight or ten pupils in the summer-time; and I remember that my first school would not have averaged a larger attendance, except for the little class of A-B-C scholars.

The danger is that the teacher will feel called upon to put the little ones ahead in reading as fast as possible. If she has read Miss Peabody's and Mrs. Mann's and Miss Youmans's essays and letters about primary education, and has duly considered that remark of a British Commoner, "It is better (or more important) that a child should like his lesson than that he should learn it," she may be able to do the fair thing by her infant pupils. Play is the proper business of a child. Its five senses should be awake and active, and its education should come through them chiefly until it is seven or eight years old.

I anticipate great pleasure in seeing my little son enjoy his reading when he gets to that, but his father and I congratulate ourselves very often on having delayed that event so long. So much better things are being done for him than would be likely to be done if he could immerse himself in a story at any leisure moment. There is time enough for the book study in the course of a lifetime, but the golden years when the observing faculties are developing and taking on habits can never come again after early childhood is once passed. This child learned all his letters long ago, from newspaper headings and advertisements chiefly, and we were tempted to lead him right along in a path that seemed so easy for him. I should think he might "read in readings," after a very little practice, any time when we set about it, for he knows the letters by their sounds, and spells any plain word you pronounce to him. He seems to have an idea that what papa and mamma can not tell him about the things which arouse his curiosity, books can; and he stands by while I consult a book to find an answer to his question with a feeling, apparently, that this universe is full of wonderful things, in which a great many folks besides himself and mamma are interested, and these folks—Gray, Youmans, Agassiz, and the rest of them—will help a little fellow if they can. It is a sight that I enjoy. He "likes his lesson," and his *liking* will lead him on farther and deeper in the pursuit of knowledge. Almost any child can be made to hate school and to loathe the study by tasks inappropriate to its stage of mental growth. This would be a great calamity.

It would also be a calamity if a child should love reading and spelling too well, too mechanically, enjoying the parrot-like exercises that constitute the routine of many schools, preferring to commit to memory some description of a bird or flower or mechanical operation, rather than to use its own observation and learn all the facts at first-hand. Let me quote a paragraph from that excellent essay on primary education in Miss Youmans's First Book of Botany:

"The glaring deficiency of our popular systems of instruction is, that words are not subordinated to their real purposes, but are permitted to usurp that supreme attention which should be given to the formation of ideas by the study of things. It is at this point that true mental growth is checked, and the minds of children are switched off from the main line of natural development into a course of artificial acquisition, in which the semblance of knowledge takes the place of the reality of knowledge. We have seen that the growth of mind results from the exercise of its powers upon the direct objects of experience, and consists in its recognition of distinctions among the properties and relations of things, and in the classing and organization of ideas thus acquired. These operations can be facilitated by the use of words and books, but only when the ideas themselves are first clearly conceived as the accurate representations of things. But, the ordinary word-studies of our schools, which are truly designed to assist these operations, are actually made to *exclude* them. The child glides into the habit of accepting words for ideas, and thus evades those mental actions which are only to be performed upon the ideas themselves."

A child is old enough to go into a kindergarten at three years of age, because the training it gets there (I mean the genuine Froebel kindergarten) is in the line of its natural development. It has play, society, and discipline all at the same time.

An acquaintance says he means to send his little son to Germany as soon as he is ten years old to some good kindergarten there. He thinks the child could not leave his parents earlier, but he must have the kindergarten training. But you see it can not be the real kindergarten training at that age. For Froebel's "plays" are adapted to the mental necessities of children several years younger. It is good training for a child of any age, but the mind of a child of ten may be already so demoralized by wrong education, that it can get but a small part of the good intended.

JAM AND JELLY.—The fruit that comes from the vines or canes latest in the season makes the poorest jelly. If currants hang long upon the bushes, they lose most of their jelly-making property. They need to be used as soon as possible after gathering. One who desires clear, fine-flavored jelly will not squeeze the jelly-bag if it be of loose material. Fine flannel is best for this purpose, and when this is used some pressure is allowable; but we wish to strain the juice not only free from stems, skins, and seeds, but free from all fine particles.

Sister M., who makes excellent raspberry-jam, and a good deal of it every year, gives me the following recipe as the one she prefers: "One pound of sugar to each pound of berries, and nearly a pint of currant juice. Put the sugar and berries together in a pan over the fire, and with potato-masher or wooden spoon keep mashing and stirring them constantly to prevent burning. When they are well mashed, add the currant-juice, and boil briskly still stirring it carefully. Just before it actually boils skim it well. Let it boil about three quarters of an hour to bring it to the right consistency. It is best to put it up in cups, bowls, or fruit-jars; it does not keep so well after being disturbed. Cover the cups with firm paper varnished with white of egg, and pressed closely around over the edges of the cups. Jam should be kept in cool dry place." Sister adds, in her letter to me: "This is splendid as dessert with Graham meal and sweet cream."

A TOUGH OLD TURKEY.—In the same letter from

which I extract the above recipe, I find something else which may furnish a hint to some one who has a tough fowl to cook:

"There were three turkeys on the place when we came here, also half a dozen hens and a rooster. The gobbler persisted in fighting the rooster, and one day C. thought to separate them by catching the gobbler. J. was using the ax near by, and after a brief consultation the old fighter's head separated from his body. All this was duly reported indoors. Mother and I took him in hand, and gained two nice wings, which are very handy in the kitchen. We soon stripped him of his feathers. He looked pretty tough. He was large, but not fatted to kill, and I thought we should all get tired of turkey before we should get him eaten, if ever he could be cooked tender. After breakfast next morning I put over the wash-boiler with a pail of water, and when it came to a boil laid in the turkey." [Better not tell this to our esteemed countryman "T. W. H.," for I see he does not know that a tin wash-boiler can be made clean enough even for fish-chowder.]

"Just then I weighed him. Sixteen pounds said the scales. For two hours he boiled and steamed. I made ready some bread-and-butter stuffing, moistening it with the water in which the turkey had been boiled, and then baked it two hours more. It made a fine appearance on the table, and six of us did our duty by him at dinner, the children being at school. For the next three days we had turkey once a day, and to-day we had a good 'chicken-pie' of the fragments, with enough left from it for washing-day dinner, for we are not tired of turkey yet."

BABIES TROUBLED WITH CONSTIPATION.—A mother writes to me about her baby, four months old, who has been troubled with constipation for a month past so that she has to give it daily injections. Change its diet. You need not wean it yet, but begin feeding it Graham gruel seasoned with milk. When it is time to nurse it, feed it as much of the gruel as it is inclined to take. It will not take much at first, but that little will very soon correct its bowels. I had the same experience with my youngest nestling. The water injections kept her in health, but I soon saw that her bowels were depending upon that assistance too much, and I tried the gruel with speedy success. I sifted out the coarsest part of the bran with a very coarse sieve, but now I usually take the whole meal, and do not find it too coarse for her. She is very jolly over her gruel. I thin it with considerable milk, but never add sugar, and seldom use salt in it.

Habitual constipation is a result and a cause of disease. The habit can never be overcome by physic. Careful habits in respect to exercise, rest, cleanliness, pure air, and especially wholesome diet, are the reasonable methods of cure. All these things should be carefully looked after in baby's case.

If unsifted Graham seems to irritate the child's bowels, sift the meal. It is still quite different from common fine flour.

[The types made me say in June: "In this region kind household helpers are very difficult to get." It should have been "hired household helpers." Kindness is no more scarce in Minnesota than elsewhere. It is almost impossible to hire a girl at all—one at least who would really be a helper.]

Another Way to Cook Egg-Plants.

BY MRS. G. A. W. M., TRENTON, N. J.

In your March number of the *Agriculturist* I noticed a short article headed "Cooking the Egg-Plant." Now, of the three ways there given, the first in my estimation is the best; but they need a slow fire and cooking thoroughly. Many persons do not like the taste of egg-plants, simply for the reason that they are not cooked enough or not prepared right. Our family prefer them to meat on a hot summer's day, provided mother cooks them in her old-fashioned way—the way I used to cook them when I was a little maiden at home with my

parents. Now I am at the head of my own little family, and I still think I must be at the head of egg-plants when they are being cooked. No one can get them "just as mother does;" either too much flour or not enough spoils them—they want to be "just so."

I take a large-sized egg-plant, leave the stem and skin on, and boil it in a porcelain kettle until very soft, just so you can get it out with the aid of a fork and spoon. Then take all the skin off, and mash it very fine in a bowl (not tin or earthen). Add a teaspoonful of salt, plenty of pepper, a large iron spoonful of flour (when it is cold), a half-teaspoonful of milk or cream, and three eggs. This forms a nice batter. Now have some butter and lard brown-hot, and drop the batter in with a spoon, as you would fritters, and brown them nicely each side.

My husband would not taste egg-plants before we were married; now he and the children can hardly get enough. Girls should learn the different modes of cooking while they are at their fathers' homes. Alas! too many in these days are brought up young ladies for the parlor, but let them get married, and go into the kitchen to give their orders to Biddy for dinner, and what do they know themselves? Do they know how to tell her to cook such and such dishes? No, no! Sorry I am for the poor husbands of such wives, but you see them every day. I shall instruct all my daughters well in housekeeping, and have the graceful accomplishments come afterwards.

Squash or mashed potatoes mixed the same as the egg-plants are nice fried for breakfast.

Best Way to Prepare Salt-Fish Dinners.

By Mrs. W.

Cut the fish in rather small pieces, wash it thoroughly in warm water, and leave it in cold water over night. Early in the morning remove the skin from the pieces, wash again, and put them in cold water over a fire, and let come very gradually to a boil. Then remove the vessel farther back on the stove, and let it remain at an almost boiling point. Actual boiling hardens the fish. Change the water once during the process, adding hot water; keep it at the same temperature, letting it boil only once for a few minutes when nearly done. While the fish is cooking, pare nicely as many potatoes as necessary, removing carefully every imperfection from the surface, and put them as fast as pared into cold water, with a little salt in it.

Boil in separate utensils small onions, beets, or parsnips if in season. Put the potatoes into boiling water half an hour before dinner-time, add a little salt to the water, and do not let them remain covered after they are fairly boiling. While the vegetables are cooking, remove the fish from the water, carefully take out every bone, and with a sharp chopping-knife mince the fish to an even fineness throughout, then put it into a deep dish, add to it half a cupful of hot water with a little butter melted in it, cover closely, and place in a hot oven until dinner is ready. Prepare drawn butter for sauce, being careful not to let the butter boil, as it will become oily. Boil eggs hard, if they are liked. Some persons prefer the eggs added to the melted butter, cut in circles; others add them to the fish as they prepare it on their plates. When the potatoes are just done (not too soft), pour off the water, take the kettle on an open door (where the wind is blowing) and mash with a wooden pestle.

Replace the kettle on the fire, and do not cover it. The potatoes will keep hot and nice for one or two hours, if necessary. When dinner is served, place the dish of fish and the hot potato on the table the last things. For dessert after a fish-dinner a deep apple-pie without an under-crust is most suitable, or ripe apples, if in season, are better still.

If those who dislike fish-dinners because they are troublesome in the preparation, and doubly so in the serving at table, especially where there are children to be served, will try this way, they will find there is no trouble or annoyance at table, as

all is hot and easily served, and it becomes a dinner desired by all members of the family.

Domestic Coloring.

A lady, whose address we have mislaid, sends the following: "Some one has asked about coloring. Here is a recipe to color orange: Take copperas a half-pound, and two large heaping spoonfuls of salsoda. Dissolve in two separate dishes of warm water. Wring the material out of the copperas solution, and then through the soda, and hang it out to air. Let it air a short time, then wring again as before, until the cloth has passed through the liquids three times. It will make cotton cloth very bright if done in a sunny day. This colors several pounds.

"The bark of the common yellow willow, set with copperas, and colored in an iron vessel, makes a permanent slate color on cotton. It is very useful for coloring linings, cotton stockings, etc."

Washing by Dog-Power.

BY MRS. E. J. JOHNS, DYBERRY, PA.

I have been reading in the February number of the *Agriculturist* about "How we Live at our House," and I thought I would write you how we wash at our house. You advertise Doty's Washing Machine, but you do not tell your readers that it can be made to run by dog-power. I have Doty's washer, and also a churning machine, and when I wash I attach the handle of the washer to the churning machine by a pitman. My husband says it works like a saw-mill, but suffice it to say the dog does the work. The difficulty with the washer is, it is hard work to operate it by hand, so hired help say. By using the dog this labor is done away with. I wash my clothes in boiling-hot suds, and they look white, even if they are washed by a black dog. I can do a washing for a family of seven in two hours or less. I write this in hopes it may reach some weakly woman who has a large family, and finds it difficult to get along with her work.

VASES OF FLOWERS.—What horrid things some of the florists do give us in the way of bouquets! They pack the dear little flowers so close together, such crowds of sweet faces massed, that you can not half-enjoy any of them. I should think that any one who really loves a flower would do it better justice. Each fine blossom or cluster of blossoms ought to have some quiet background, to set it forth. Green foliage, in delicate sprays or handsome leaves, is according to nature's general plan.

I remember the exquisite little floral ornaments in that pleasant sitting-room of the B.'s. Shells of various kinds were made to do duty as vases, here a few geranium-leaves, with rosebuds or pansies in a shell turned up, so as to hold water enough to preserve the flowers, and there a cluster of sweet-pea blossoms, with foliage of some light, graceful character.

One handsome lily, with leaves, is often quite enough for a flower-vase. I was not more than half a score of years old when I saw two vases of flowers on a mantel, which pleased me better than anything I had ever seen before, and their memory is still pleasing through all the years since that time. The vases were tall, old-fashioned wide-glasses, and the flowers were only nasturtiums, a spray in each, with their brilliant flowers, odd-looking leaves, and smooth, curling stems.

We want some large, wide-mouthed vases and some big bouquets when flowers are plenty. Some large vases we must have for the children to fill.

Some flowers have such short stems that they can not be managed in bouquets without they are furnished with artificial stems of wire or straw. Hollyhocks and Balsams are of this kind. The best way to arrange these is in a plate of clean wet sand. Use plenty of ferns or green leaves with the flowers.

R. L. F.

BOYS & GIRLS' COLUMNS.

The Doctor has a Word to Say.

My Dear Children: Since those last prizes were awarded, I have been too ill to attend to any business. Now I do not wish any of you to whom prizes were awarded to think that I have neglected you, and I hope that if any boy or girl has been overlooked, he or she will let me know at once. I always try to send such things very promptly, but what can one do flat on his back with fever? So be patient, my dear little ones. We will have more prizes when the weather gets cooler, and I will try that there shall hereafter be no delay on my part.

THE DOCTOR.

The Little Swiss.

ONE OF THE PICTURE STORIES.

[All the boys and girls saw the pictures in the March number, and the offer of prizes for the best stories suggested by them. The award of prizes was made in June. Several have written to ask me to publish some of the prize stories. I will comply so far as to publish what I, or rather we, thought the best of those written by the boys. I say "we," because there always is a family council over these prize matters. The council consists of Annt Sarah—to her face we call her by the more home-like name of Aunt Sally—the "young Doctor," and the old fellow himself. After reading and re-reading, we all three concluded that this story, by Cyrus D. Chapman, of Irvington, N. J., showed more originality than any other, and we gave him the first prize.—THE DOCTOR.]

Far away, many hundreds of miles from this country, among the grand and beautiful Alps of Switzerland, lives a little Swiss boy. His name we will call Guillimot. His mother lives in a little cot at the foot of the Alps. Little Guillimot's father is dead. His mother supports herself and little boy by selling milk in the Swiss village some two miles from their cottage. Their goats always furnish a good supply—enough for themselves and their customers in the village.

Guillimot was a very thoughtful boy, and one bright summer's day he put on his thinking-cap, that he might find something to do by which he could help his mother and lighten her labors, for his mother was very poor, and she got very tired carrying the milk so far. All at once a thought popped into his head. He had five pretty hens, which were given to him by his grandmother. They laid him three eggs every day, so he thought he would take his eggs (he had three dozen now) to the village. It was a pretty long walk, for he was only six years old, but he was healthy and strong. So he got his little basket, and putting his eggs into it, started off on his journey (for it was a journey to him), with his faithful little dog trotting along before him. By and by he came to a little mountain brook that ran merrily over the pebbles on its way to the lake of Geneva. Guillimot sat down on a stone to rest, for he was getting tired, and putting his feet into the water was soon refreshed, and resumed his journey, arriving safely at the village, where he had been once before with his mother. He found a ready sale for his eggs, and returned to the mountain cot feeling very proud and rich, with fifty cents held tightly in his hand, and sitting down on the door-steps, quite tired out, dropped asleep with his head pillowed against his faithful little dog, who sat very still, lest he should awaken his little master.

As Guillimot slept, he had this most wonderful dream: A beautiful little being, clothed in the finest dress, made from the wings of flies, appeared before him. Little Guillimot looked with surprise and wonder. He knew it must be a fairy, for his grandmother told him about the fairies that used to live in the valleys long ago, so he was not frightened very much.

The fairy said in a voice of music: "I am the queen of the fairies; now, because you have been a good boy, I will give you whatever you wish."

Little Guillimot thought one minute, and then he said: "O good fairy! make me a big strong man, that I may help my mother, so she need not work so hard."

Instantly his wish was gratified, and Guillimot found himself a great strong man, able to do almost anything.

Just as he was preparing to go to work, somebody touched him lightly on the cheek, when he awoke, and starting up he saw his mother, looking very tired. Then he said: "O mamma! I had such a pretty dream. I wished I was a big strong man, so you need not work so hard, and a good fairy gave me my wish. I was just going to work for you, and now I am only a little boy. But, mamma, here are fifty pennies; I sold my thirty-six eggs for you, and if I can not be my mother's big man, I can be your little man."

The mother clasped her child to her bosom, thankful to God for such a good little boy.

Do as I Do.

This game, if properly managed, must be a very amusing one. The following account of it comes from Miss Mary A. Hutchings. A company of children sit in line. One, the leader, sitting in front, begins the game by moving the right hand up and down, and saying, "Massa sent me to you, sir." The first in line answers, "What for to do, sir?" The leader replies, "Do as I do." Question and replies are repeated until all have their right hands in motion.

2. The leader, moving both hands, asks the same questions, getting the same replies, until all have both hands in motion.

3. The leader lifts the right foot up and down until all have their right feet moving, meanwhile asking question and getting the same replies.

4. Leader moves the head, then opens and shuts the eyes, and lastly the mouth. By this time the scene is so ludicrous that all are unable to keep from laughing any longer, and the game is suddenly brought to a close.

Aunt Sue's Puzzle-Box.

DIAMOND PUZZLE.

The center letters—perpendicular and horizontal—will give the name of a man distinguished for virtue.

1. A consonant.
2. An oily substance.
3. Part of a house.
4. Rumor.
5. An ambassador who repudiated the presents of Pyrrhus.
6. Not clear.
7. A glass vessel.
8. A bird.
9. A consonant.

1. O Pat! pies.
 2. Ida, let's put.
 3. I spite a sad son.
 4. Dnst up nose.
 5. I melt air, Sam.
 6. Silent sea.
 7. Set fiber.
 8. Set it duet.
 9. Lare dun, Dave.
 10. Ran in codes.

NUMERICAL ENIGMAS.

1. I am composed of 21 letters: My 15, 3, 12, 20, 14, 18, 3, is convenience of time. My 10, 11, 7, 13, 3, is a girl's name. My 21, 5, 2, 3, is a great destroyer. My 6, 9, 21, is an animal. My 13, 1, 19, 8, is a man mentioned in the Bible. (I never heard of a child being named after him.) My 17, 20, is a pronoun. My 16, 4, 19, 2, is to shave. My whole is much valued. SNICKER.
2. I am composed of 7 letters: My 1, 2, 4, is something that the young ladies wear, though they would not give it that name. My 6, 7, 5, is a number. My 3, 6, is a verb. My whole is a bird. BAYARD W. P.

COMPOUND ARITHMOREMS.

(Transpose the word in Italics, and add it to the Roman numeral to make the original word, e. g. "1000 and *tea*:—consumed every day."—Meal.)

1. 50 and *map*:—a household article.
2. 100 and *pea*:—geographical.
3. 50 and *beat*:—a piece of furniture.
4. 1000 and *teas*:—much used in factories.
5. 100 and *at*:—high.
6. 501 and *me*:—a coin. HARRY.

CROSS-WORD ENIGMA.

My first is in hatchet but not in ax.
My next is in hammer but not in tacks.
My third is in lie but not in untruth.
My fourth is in Clara but not in Rath.
My fifth is in wake but not in sleep.
My sixth is in hog but not in sheep.
My seventh is in boots but not in skates.
My whole is a city in the United States. W. E. W.

SQUARE WORDS.

1. Square the word "FATE." SCIENTIFIC.
2. Square the word "PLAN."

BLANKS.

(Fill the blanks with words pronounced alike but spelled differently.)

1. They do not _____ to accept him because he _____ tobaccn.
2. One of the soldiers belonging to the _____ threw the apple _____ away.
3. The lovely _____ was _____ by many.
4. The _____ was hung upon the _____ to dry.
5. In the _____ he intends to put all that he _____.

NUMERICAL ENIGMA.—Washington.

Pr.—Be slow to promise and quick to perform.

AUNT SUE'S NOTICES TO CORRESPONDENTS.

F. C. R.—I am curious to know what you mean by sending such a ridiculous "square word." Each word must be perfect in itself, and not such rubbish as "CREAYE," "LUSYRE," "ESYEEM."

MARY VAN EMAN.—Answers must always accompany the puzzles sent to me for publication. I am glad the explanation assisted you.

KATIE.—Let us suppose you want to make a cross-word on your own name. Get your slate and write down five figures perpendicularly; then the letters of your name, then find words to suit. For instance, your first letter is K; well, K is in *dark* but not in *bite*; that will give you a good start. Now I will show you how to write them down:

1. K—bark—bite.
2. A—dark—light.
3. T—cat—dog.
4. I—pig—hog.
5. E—sea—foam.

[COPYRIGHT SECURED.]

THE LITTLE FISHERMAN.—DRAWN BY CARY.—Engraved for the American Agriculturist.

It will be easy enough to fill in the other words:—

“My first is in bark but not in bite.

My next is in dark but not in light.”

Then you can finish with:—

“My fifth is in sea but not in foam;

And my whole is the name that they call me at home.”

Now do you know “how to work those cross-words”?

L. T.—I am afraid if I gave you their names and address you might write to them, and set them a bad example in spelling, grammar, and politeness. If I should publish your letter just as you wrote it, I think you would be rather “a shamed of it” yourself.

L. A. Des B.—I will publish your “enigma” in the *Agriculturist*; it is “against the rules” to allow the same puzzle to appear in this paper and in *Hearth and Home*. The rhus is too simple and palpable. But thanks for your trouble in sending them. The “conundrum” is very old but very good.

Thanks for puzzles, letters, etc., to Katie, M. Van E., Phiz, Laura V. M., James T. II., and Robt. W. M.

Going A-Fishing.

We suppose that it is as natural for boys to go a-fishing as it is for them to eat; and if there is anything that comes easier to boys than eating, we should like to know what it is. If a boy lives anywhere near a stream or pool of water, be it fresh or salt, and if there be any finny inhabitant of that water, be it minnow or pickerel, the boy will have a try at it. He will go a-fishing whether he catches anything or not. Our youngster in the picture

looks altogether too much dressed to make a successful fisherman. He is probably the son of some city parents who have gone to the country for the summer, and he is trying his luck in a half don't-care way, that makes us think that, whatever present success has attended his efforts, he will never make a fisherman. If one would catch fish he must give his mind to it, and exercise all his ingenuity. This is what makes us approve of allowing boys to go a-fishing; they learn that to accomplish a certain end—the catching of fish—they have got to think. They must, in the first place, know the habits of the fish they are after, whether they are to be caught at the bottom with dead bait, or near the surface with what appears to be a live bait. They must learn enough of the habits of the fish to know upon what they feed, and what part of the stream they frequent, the time of day they feed, and many other things that teach them a great deal of the history of fishes. Some fishes can only be caught in deep water, others hide in holes along the banks and at certain times come out to feed, and others can only be caught by presenting to them what appears to be a living insect. It is not rare to see two boys, or men, fishing together, and one will take a plenty of fish, while the other catches none at all. They will tell you that it is a difference in luck, but the real fact is, that the successful one knows or has accidentally hit upon the habits of the fish. A few inches more of line below the float, or a little different arrangement of the sucker, will make all the difference between “luck” and “no luck.” The successful fisherman or fisherboy must learn the ways of the fish. One outfit of the fisherboy is more important than silk lines, improved floats, gut snoods, or even “silver-spin-

ners.” Do you wish to know what it is? It is a very home-made article, but it is better than all the fancy artificial flies, better than lancewood rods and multiplying reels—it is the good old-fashioned virtue, *patience*. There is an old saying, “If you swear, you will catch no fish.” Now we don't believe that any of our youngsters would swear on any account, fish or no fish, but there is a kind of impatience which in persons who know no better finds vent in swearing, and in others in rude acts, which, if not so wicked, are almost as improper as swearing. *Patience* should be the ever-present motto of the fisherman, and it is really the great lesson taught by fishing. If you have no luck—patience. If your hook gets caught by a snaken tree—patience. Are you fishing with a friend and your lines get apparently hopelessly tangled, only that good old-fashioned patience will help you out of the scrape. So, then, we like to have our boys go a-fishing, if they will take to it the right way, and accept all the lessons that it will teach them. It will give them abundant opportunities to control themselves—the worst thing they will ever have to control—and to learn the value of patience. Some parents do not like to have their children catch fish, because it seems cruel. Naturalists tell us that the fish, when he comes from the water into the air, experiences the same sensations that a land animal does when put into the water. Those who have been restored after being apparently drowned, say that the sensation of drowning is a pleasant one, and we may infer that the fish, when taken from the water, experiences no pain. Fish were evidently made to be eaten, and if we exercise no unnecessary cruelty in capturing them, we need not fear that we are doing wrong.

CINCINNATI National Industrial Exposition.

THE BOARD OF COMMISSIONERS ANNOUNCE THAT THE

THIRD GRAND EXPOSITION

WILL BE OPEN FROM

Sept. 4th to Oct. 5th, 1872. Goods will be received from Aug. 14th to 31st.

The Sixteen Grand Departments have been greatly extended, and the Exposition will be the

LARGEST EVER HELD IN AMERICA.

The extensive transportation arrangements for visitors will largely increase the unprecedented attendance of last year.

Exhibitors should make immediate application for space. Rules and Premium List furnished on application.

IMPORTED COTSWOLD RAM, "DIAMOND FLEECE,"

Imported, owned, and used by M. H. COCHRANE, Esq., of Canada, for two seasons; now owned and used at the

"LINDEN GROVE STOCK FARM."

I am now prepared to book orders, and fill in rotation, Spring Buck and Ewe Lambs, also a few Yearling Bucks and Ewes, all sired by Imported "Diamond Fleece," out of Imported Ewes, amongst which is a pen of yearlings which received first prize at the Royal Agricultural Society, at Oxford, England, 1870. "D. F." clipped 18 lbs. of clean washed wool—twelve months' growth. Address

T. S. COOPER (Linden Grove Stock Farm),
Coopersburgh, Lehigh Co., Pa.

ESSEX PIGS.

For crossing with common sows or with the large breeds, there is nothing superior to a highly refined thorough-bred Essex. Read the following:

HANNIBAL, Mo., December 23d, 1871.

The Essex pig I received from you has grown finely, and given perfect satisfaction. I have this fall slaughtered four grade Essex that averaged 303 lbs. each. One weighed 325 lbs. alive, and dressed 280 lbs., making 56 2-13 per cent of his live weight. They were eight months and eight days old the day they were slaughtered.

JAMES C. ASHMORE.

CLARESVILLE, OHIO, Jan. 15th, 1872.

The Essex pig I got from you is growing finely, and I am well pleased with him.

W. CLIMER.

MONMOUTH, ILL.

The Essex sow I got from you is doing splendidly. She is admired by all who see her. I think she is the handsomest pig I ever saw—and I have seen a great many.

IRVINE MCCARTNEY.

ARCADIA, N. Y., May 10th, 1872.

The Essex pig arrived safe and in good order, and I am well pleased with him. He is all that I anticipated.

L. J. BENTON.

AUSTIN, TEXAS, Feb. 6th, 1872.

The pigs arrived yesterday, and look remarkably well. To say that I am thoroughly pleased is scarce enough. I am more than pleased, and you have my thanks for giving me more than my money's worth. I have two Scotchmen in my employ who were in ecstasies over them (for Scotchmen). I would not take \$150 for the pair of pigs.

R. R. TOWNSEND.

I am breeding Essex pigs with great care, and selling them at reasonable rates. They give good satisfaction. Orders promptly attended to. Address

JOSEPH HARRIS,
Moreton Farm,
Rochester, N. Y.

THOROUGH - BRED STOCK.

E. MOODY & SONS, Lockport, N. Y.

White Rye. SEND for Price-list of Seeds, Fowls, and choice Stock to **G. A. DEITZ,** Chambersburg, Pa.

Pure White Winter-Wheat.

All things considered, and on good, clean, rich, dry land, the DIEHL is the best variety of WHITE Wheat now grown. The straw is very stiff, the head very plump and full, and the yield on good land eminently satisfactory. The greatest difficulty we have experienced with it is to get pure seed. It is almost impossible to find it unmixt with Mediterranean and other red varieties. For some years past, many readers of the *American Agriculturist* have written to me for seed, but I have never been able to get any that I thought pure. I have now, however, the pleasure of stating that I raised this year ten acres of DIEHL WHEAT that is the PUREST I have ever seen, and I can send it out with confidence.

I will send *four pounds* by mail, prepaid, to any address, on receipt of ONE DOLLAR.

I will send by express or ns freight, at the following rates:

1/2 bushel.....	\$3 00
1 bushel.....	5 00
2 bushels.....	9 00
6 bushels.....	25 00
10 bushels.....	40 00

Larger quantities at the same rate, or \$1 per bushel. The Wheat will be put in strong, new bags, carefully directed, and delivered at express office or freight-house without any extra charge.

Orders will be filled immediately. Address

JOSEPH HARRIS,
Moreton Farm,
Rochester, N. Y.

Important to Farmers & Stock-Owners.

TAYLOR'S HORSE AND CATTLE FOOD is used with great success in fattening horses, cattle, and swine. It gives a good appetite, acts on the kidneys, destroys worms, and gives a glossy coat. Stage proprietors, dairymen, farmers, stock dealers, and other reliable gentlemen have given it a thorough trial, and say it is the best article they have ever used for putting and for keeping stock in a good, healthy condition.

It is manufactured exclusively by the **MANHATTAN FEED MILL CO.**
N. B. TAYLOR, President. 508 W. 26th st., New York.
Small packages, 50 cts.; large, \$1.00. Send for samples or circulars with testimonials. For sale at Feed-stores. Reliable agents wanted everywhere.

The Celebrated Bone Fertilizers,

GROUND BONE, BONE MEAL, BONE FLOUR.
Fresh Bone Superphosphate of Lime, or Dissolved Bone. Send for Circulars.
LISTER BROS., Newark, N. J.

900,000 ACRES

OF EXCELLENT FARMING

AND SLENDID

Michigan Pine Lands

FOR SALE,

On which are ONE THOUSAND MILLIONS OF PINE TIMBER, and inexhaustible quantities of Maple, Beech, Elm, Ash, Hemlock, Oak, etc.

The grant of lands to the Grand Rapids and Indiana Railroad Company, to build their Road from Fort Wayne, Ind. to Traverse Bay and Mackinaw, Michigan, comprises in its farming lands every variety of soil, from the rich clay loam to the light sandy, and they are found in that section of Michigan, north of the city of Grand Rapids, and contiguous to the great fruit belt on the eastern shores of Lake Michigan, now being rapidly developed by railroad and other enterprises.

Farming Lands are sold to actual settlers, on credit, one quarter down, balance in yearly payments, interest 7 per cent. Persons desirous of locations for farms will, on application at the Office in Grand Rapids, be furnished with Tickets over the Road, entitling them to Return of Fare, in the event of purchasing any of the Company's farming land. For information about the lands, prices, location, etc., etc., address

WM. A. HOWARD, Land Commissioner.
TITLE PERFECT. Grand Rapids, Michigan.

VALUABLE FARM FOR SALE

Albany, N. Y.

ESSEX PIGS.

I keep no other breed of pigs except the Essex.

Taking everything into consideration, I regard them as the best, purest, most refined, quietest, and most thoroughly established breed of pigs now extant.

I do not know that they have a single fault.

I have never heard any one who examined them carefully object to them except on the ground of color.

They are a black breed.

I have heard many farmers say: "If they were only white, they would be perfect." This, of course, is mere prejudice.

When dressed, they are as white as the whitest, and the lard is firmer and whiter than that of any white hog I have ever seen.

"But are they not too small?" They are classed with the small breeds, but they will dress over 400 lbs. They are quite large enough. They are the largest of the small breeds—larger than the small Berkshires, and much larger than the Prince Albert Suffolks, small Yorkshires, or Neapolitans.

So far as I know, I have the largest stock of pure-bred Essex in the United States, and I think my pigs are at least as good as any pure-bred Essex to be found in England.

My prices are reasonable, and I feel certain that I can give good satisfaction to all who favor me with their orders.

My spring pigs are the best I have ever raised, and I am selling sow pigs at reduced rates.

CLIMAX FIRE-KINDLING PELLETS.

Two years' experience in the manufacture of fire-kindlings has directed our attention to the utilizing in their manufacture a waste material found in every family, that, when prepared according to our invention, will supply them continually with the best kindling in the world for a mere trifling expense. How well our efforts have been crowned with success, we need only say that after a careful examination at the Patent Office of all the inventions in this line, this is pronounced to be the most practical, best, and most convenient of anything yet invented. They commend themselves to the favor of all, even where the kindling of fires is intrusted to servants and children. We have also invented a perforated metallic Mold Press for family use, for molding this material, with which a year's supply can be molded in a day. Having perfected our inventions, and taken measures to secure the same by letters patent, we desire that every family in the land may have the benefit of this great convenience. For this purpose, we will send by mail, postage paid, to any address, on receipt of one dollar and twenty-five cents, a mold, sample of kindling, instructions how to prepare the material, mold, and use, and grant a family right to make and use the same.

A RELIABLE AGENT WANTED in every city and town to sell Molds and Family Rights, or make and supply families with this kindling. Address Lock-Box 367, CLIMAX KINDLING CO., Springfield, O.

S. A. SMITH, Successor to **STEPHEN W. SMITH,** 90 William St., New York.

Condensed Agricultural Items.

There are sixty-one starch factories in the State of New Hampshire, and over three thousand tons of starch were made last season from potatoes alone. . . . Western farmers have quite an easy time on their prairie farms; just now they are fighting the potato-bug, the chinch-bug, cutworms, wire-worms, army-worms, gophers, ground-squirrels, meadow-moles, grasshoppers, locusts, and are looking out for fighting fire by and by. . . . J. C. Allison, of Missouri, sheared an average of nine pounds of wool per head of his flock of native sheep. W. L. Victor sheared 154 pounds from 15 Co. swolds, which sold for \$77. . . . Extensive cattle-yards are now building at Atchison for the Atchison, Topeka, and Santa Fe R.R. . . . E. L. Davidson, of Kentucky, has sold twenty-eight young Shorthorn bulls to Mr. Guthrie, of Montana. . . . Corn and cotton promise to yield very abundantly the present season. . . . At Col. King's sale of stock at Minneapolis, thorough-bred Ayrshire bulls sold for \$63 and cows at \$123. . . . Thomas Jackson, Chautauqua Co., N. Y., made \$73 pounds of butter from 35 cows in seven days. . . . Hiram Thayer's cow (of Carroll, N. Y.) lately produced three calves at a birth, and all are doing well. . . . The farmers of Hannibal, Mo., get their fun by means of ox-races held weekly through the season. . . . Prairie-schooners still navigate the plains of Nebraska. The present summer large numbers of these emigrant wagons have been seen, mostly accompanied by more or less stock. . . . In Iowa, the average wealth of the State is \$601 for each individual. . . . Plowing up fall wheat in the spring has not been profitable in Kansas this season. Those who permitted their wheat to grow have gathered a much better harvest than they expected. . . . In Cowley Co., Kansas, a premium of \$5 is offered at the Agricultural Fair for the best baby. . . . At Ottumwa, Iowa, an Artesian well seventy feet deep discharges at the surface a stream of pure water equal to one gallon per second. . . . The Illinois farmers near Freeport are growing sugar-beets for a new sugar-factory lately established there, and are to be paid \$1.50 per ton for them. . . . In Illinois, on farms worth \$60 per acre, wheat costs 91 cts., corn 21 cents, oats 26 cents per bushel, and hay \$4.75 per ton. . . . The Campaign Co. (Ill.) Farmers' Club offers \$100 for the best thirty acres of corn raised this season in that county. . . . The sheep in California have doubled in number since 1869. There are now in that State eleven millions of them. . . . A man in Illinois has counted up the Canada thistles in that State, and finds they cover exactly ten thousand acres. . . . A New Hampshire farmer who soils his cows believes millet to be the most profitable fodder crop he can raise. . . . Plant walnuts and chestnuts; they are by far the most profitable trees for all uses a farmer can raise. . . . Hops are looking well in this country, but are not very promising in Europe. . . . Wisconsin raises more hops than any other State. . . . Osier-raising and basket-making is now becoming a favorite specialty with some farmers. . . . A farmer who can not make a good living on his farm, should hire out with a good farmer and learn how he does it. . . . Early Rose potatoes appeared in the Kansas market on June 8th. . . . The "Heathen Chinese" want 50,000 tons of our cheese every year after this. . . . A great deal of poor American cheese is sold in England for hog feed; so says an English paper; if so, why do our dairymen make such cheese, and such a reputation along with it. . . . Cistern-water may be kept free from insects and leaves by having a strainer of wire-gauze on the inlet pipe. . . . Chain-pumps and water-drawers serve to aerate the water of cisterns and improve its flavor for drinking purposes. . . . Horace Greeley has a lot at Greeley, Colorado, which he has caused to be planted with walnuts, chestnuts, and hickories successfully. It is now more than probable that all these nuts can be grown in Colorado, but Mr. Greeley's perseverance should have due credit. . . . Montana claims to have produced the largest crops of wheat ever harvested in any country; oats, rye, and barley yield bountifully, and all varieties of grass flourish surprisingly, while the crops of roots of all kinds produce enormously. . . . There are eighteen millions of fertile acres waiting for occupiers in Montana. . . . Minnesota is fourteen years old, and has a population of half a million; there is room for more yet. . . . In California they claim that fifteen sheep can be fed on an acre of alfalfa; their name for lucern. . . . At Bakersfield, Cal., an irrigating ditch, eight miles long, twenty-four feet wide, and three feet deep, was dug by a co-operative colony of farmers in six weeks. It waters sixteen thousand acres of land, and runs a grist-mill. . . . It costs \$10 per acre in Tulare Co., Cal., to prepare the land for a vineyard and plant the cuttings; at seven years old, the grapes will produce 1,000 gallons of juice per acre, worth \$300. . . . In Tulare Lake, Cal., the hogs wade out half a mile in shallow waters, and dig clams and mussels. . . . In an English agricultural paper, it is stated that "the wretchedest being under the canopy of heaven is an English agricultural laborer," which is stating the thing strongly certainly. . . . The Mark Lane Express, an English paper, says when cows are fed high the milk product increases, but it soon begins to decrease, and no amount of feed avails to keep up the quantity. . . . The root crop of England is being largely increased by steam cultivation, with the curious effect of increasing the production of brandy, which is made from the surplus potato crop; sixteen million bushels being thus used. . . . Steam-plows are used now quite largely in Germany, and it is said that the average of the crops of barley is already considerably increased by their use. . . . The system of summer-fallowing is now going out of use in England. The farmers, to pay their high rents, are obliged to keep more stock to make more manure, and keep their land in continual cultivation.

At a farmers' meeting at Durham, N. H., Mr. Bedou, of Fremont, said one load of fine manure at the surface was worth three loads covered nine inches deep; he uses 800 pounds of ground bone per acre when seeding down. . . . In Boston ripe timothy hay from Illinois has sold for \$26, and urine, or that from which the heads will not strip, at \$32 per ton. . . . In Pennsylvania the deep milk-pans have long been in general use, and experiments with shallow pans have shown that deep setting is far more profitable; the pans or crocks used are of the common red earthenware. . . . A pound of peat freshly dug contains fourteen ounces of water. A cord

of peat therefore contains only one eighth of its weight, or five hundred pounds of dry matter. . . . Vermont produces more beans than any other State. . . . A Massachusetts farmer made a profit of \$42.25 from a dozen light Brahma fowls last year; they consumed in that time 31 bushels of grain and 60 pounds of scraps. . . . The farmers of Rutland, Vt., lately tarred and feathered a peddler who had come on a swindling tour in that neighborhood. . . . Horace Greeley will deliver the address at the next State fair in Vermont. . . . Mr. Whitman, of Fitchburg, Mass., has imported five valuable Shorthorn heifers from a noted English herd, for the purpose of improving his own stock. . . . A Pennsylvania farmer has found the capital invested in draining to be returned every five years in the increase of his crops. . . . Dr. Warder, of Ohio, lately stated that he had planted some land in locust-timber fifteen years ago, and had sold last year from one acre 4,000 fence posts at twenty-five cents each, clearing \$1,000 from that acre. . . . Col. Sweet, of Paris, N. H., seven years ago put 150 bushels of ashes on an acre and a half of grass land, and has mowed an average of a ton and a half per acre every year since. . . . A farmer of South Hadley, Ct., is the owner of a sow two years and a half old, which has produced and brought to maturity forty-one pigs, and now has a litter of twenty, all doing well. . . . A turkey killed by Dr. O. Fisk, of Shelburne, Mass., even more than old, weighed twenty-one pounds. . . . A sandy farm in sometimes a valuable one; such a one at Red Bank, N. J., was lately sold to the United States Government for \$25,000 on account of the immense quantity of sand it contained.

Henry Dow, of Pittston, Maine, has a pair of oxen which weigh, in working order, 4,600 pounds; they draw usually at a load two and a half cords of green wood on a pair of sleds, and often, when the roads are good, three cords. . . . A farmer in Litchfield, Maine, lately killed a sheep whose four quarters dressed 151 pounds, and the tallow weighed 80 pounds tried out. . . . Isaac Rowell, of the same State, has fed during the past winter 100 grade merinos on hay morning and night, with twelve quarts of corn at noon, salt and ashes always at hand, and running water in the yard constantly; they came out this spring in good condition. . . . E. S. Wood, of Pomfret, Vt., made from three grade Jersey cows in one year 900 pounds of butter. . . . A heifer owned by S. Hills, Windsor, Ct., now weighs 3,000 pounds, and is still growing. . . . H. S. Porter, of Connecticut, has used 2,300 pounds of guano on an acre of tobacco, the tobacco was bad quality; with 3,000 pounds of barley meal per acre the quality was superior. . . . G. F. Beebe, of New Hampshire, sows millet in July on a plowed sod, and cuts two tons of fodder per acre in September; he thinks it the cheapest feed he can raise. . . . Dr. Dana, of Lowell, Mass., thinks he has found by observation that a cow in consuming one ton of hay makes one cord or four and a half tons of solid manure. . . . A cow in the course of a year produces ten tons of solid and four tons of liquid manure. . . . In a sale of fourteen head Shorthorn stock in Massachusetts, the average price was \$320; in Illinois, the average of eleven head was \$520, and in another sale the average of twenty-one head was \$278. . . . Mr. Cheney, of Boston, Mass., has sold in all forty-two head of Holstein cattle at an average of \$730. . . . Joseph Harris, of Moreton Farm, Rochester, N. Y., has sold to parties in fourteen States 73 head of Essex pigs for \$2,605, or an average of over \$35 each. . . . Shephard & Alexander, of Charleston, Ill., report sales of 387 head of Poland-China hogs at an average of \$7.50. . . . Some years since a breeder of Berkshire swine defined pure-bred animals of that breed as those having three white feet and three white hairs in the tail.

The best crop of rye last season was grown in Massachusetts. It produced 54 bushels per acre. . . . The experience of many fancy farmers is summed up in that of one who said his cattle ate up his crops, and his hired men ate up his cattle. . . . Make a roller; all crops are improved by rolling at the proper season—winter grain and meadows in the spring, and sown crops immediately after sowing. . . . It is economy to feed Western corn on Eastern farms; it enriches the manure, and when, as now, it is equal in price to hay, in many places, money is made by buying corn and selling hay. . . . Six thousand acres of tobacco were grown in Rock Co., Wis., the past season. . . . A Western farmer has come to the conclusion that wheat when injured produces cheese and cheese produces timothy. The same man believes mules will breed together. A few more discoveries of this nature will make him famous. . . . The heaviest lot of hogs in the Chicago market at any time was marketed January last; they amounted to 100 head, averaged 523 pounds, and were fed by one feeder in Page Co., Iowa. . . . J. Whang, Maine, thinks 12 hens equally profitable as one cow. He cleared \$36 last year from a dozen fowls, and from three turkey-hens, in two years, cleared \$147. . . . A farmer at Fort Scott, Kansas, has a grove of soft maples on his farm, one year from seed, which are four feet high. . . . In New Hampshire, farms are being deserted very rapidly; a traveler, in passing twenty-six miles on a main road, saw twenty-six deserted farm-houses. . . . Miss Fanny Campbell, of Bozeman City, Montana, has settled 160 acres of land, fulfilled the conditions of settlement, got her deed, and is farming successfully. Mrs. Ray, of the same place, raised on her farm 60 acres of wheat last year. . . . The prospect of a large yield of wheat this season in California is excellent. Generally in all other localities reports of serious injury are current. . . . The wool crop of California last year amounted to over twenty-four million pounds. . . . A lecturer at Cornell University recommends a variety of grasses in seeding meadows. English farmers often sow as many as twenty-six varieties when laying down pastures. . . . A meadow irrigated by running water is said to be double the value of one irrigated by flooding, a flooded one double the value of a rich loam not irrigated. . . . A speaker at a farmers' club said if farmers determined to stick to their farms and fight it out on them, there would be fewer makeshifts to be seen, and more improved farms. . . . At a New York State agricultural meeting, T. S. Gold said: "For the production of milk from an equal amount of food, the Ayrshire cows stood first. Dutch cattle were enormous eaters, although good milkers." Mr. Goodale had an Ayrshire cow which gave forty-seven pounds of milk per day. Another speaker said the use of machines saved a great amount of time to a farmer, which he could use profitably in considering how he could improve the productive capacity of his

farm. . . . At the Orleans County (N. Y.) farmers' meeting, Mr. Smith said the laws of New York did not compel a farmer to fence his farm. He thought the appearance of the country would be improved if fences were abolished. Judge Sawyer said if this were done and grass grown to the edge of the road, and mown, the production of woods would be reduced very much, if not altogether prevented. Mr. Tripp thought in such cases the road-sides could be planted with fruit profitably, as cattle would not then destroy them. A. Onderdonk said it would pay a farmer better to pasture a cow for a poor villager free than have it on the road. . . . The calf of a cow that has been kept poor all winter will never make a good cow. . . . A Vermont farmer says sheep are the most profitable stock he can keep; hay fed to sheep has brought him \$18 a ton in wool and lambs, while that fed to cows yielded only \$11, and there is less labor in shepherding than in dairying. . . . W. M. Place fed eighteen hens with sour milk mixed with meal (in water scalded). They produced, in the year, a profit of \$50, besides eggs and chickens used in the family.

An excellent compost for grass-lands is soda, lime, and earth from fences and ditches, piled up for fourteen days, then well mixed and spread in spring. . . . In England, by the use of a steam-engine, one pound of coal will turn over nine tons of earth in the shape of furrows. On the Duke of Northumberland's property plowing is done by steam, at two dollars per acre; the land is then cultivated 30 inches deep, the first time for one dollar, and the second time for fifty cents per acre. It is then harrowed, with harrows with 12-inch teeth, for thirty cents per acre. This had been done for three years satisfactorily, on fields of twenty, thirty, and forty acres. . . . Hereford cattle are gaining in favor in England. During ten years the number exhibited at the principal agricultural fair had increased from 211 to 574 head. . . . Four hundred plows have been distributed amongst the farmers of Michigan rendered destitute by the great fires of last year. . . . The colony at Longmont, Colorado, has planted fifteen thousand larch-trees, which are succeeding very well. . . . Bone-dust is being adulterated with raspsina of vegetable-ivory and ground dried fish. These ingredients may be detected by calcining the bone, when a loss will occur in burning over and above the 45 per cent of organic matter naturally contained in the bones. . . . Forty barrels of pop-corn have been shipped from Illinois to England. The English people have found a novel amusement in popping it. . . . In Ohio farmers are averse to pasturing meadows at any time. . . . Charles B. Leonard, of Woodbury, N. J., has twelve cows which last year averaged 238 pounds of butter each. They were fed corn-meal and bran all the year round. . . . William Knight bought sixteen calves, which were fattened by six cows, and realized \$491.68 for the veal. He fed his cows one quart of corn-meal and two of bran, each, per day. The calves averaged 250 pounds each. . . . Cooper Clond made his cows bring him in \$55 each, by fattening purchased calves. . . . A New Jersey farmer sold milk at five cents a quart, and made \$125 per cow in the year. He found it a slavish business. . . . W. Tatum fed his steers twelve quarts of corn and cob-meal each day, and thought it better than pure corn-meal. . . . At the Cheango County (N. Y.) fair, H. Crain received a premium of \$25 for the greatest produce of butter in one week, from one cow. The cow was a grade Shorthorn, and 154 pounds of butter were churned in the week. The second premium of \$10 was taken by W. L. Moon, who made 14 pounds in the week from a pure Jersey cow. Both cows were on pasture only. . . . In Washington Territory there were raised last year, and exhibited in New York, a turnip weighing 34 pounds, which measured nearly four feet in circumference, a ruta-baga which weighed 30 pounds, and carrots 18 inches long. . . . The Sacramento Beet-Sugar Company last season raised 2,000 tons of beets, which they are now profitably working up, at the rate of 33 tons per day. Some of their beets are said to contain 18 per cent of sugar. . . . Draft-horses in France and Belgium are becoming scarce, and the probability is that few will be exported for some years. . . . The Ohio Dairymen's Association elected the following officers for the ensuing year, viz.: *President*, D. L. Pope, of Geauga County; *Vice-President*, Lucius Bartlett, of Geauga Co.; *Secretary and Treasurer*, Cal. S. D. Harris, of Cleveland; *Cor. Secretary*, Anson Bartlett, of Madison County. . . . The Ohio State fairs for 1872 and 1873 will be held at Mansfield, Richland Co. The next fair will commence Sept. 2d, and continue one week. . . . On the 18th June, the Ohio State Board of Agriculture held a trial of plows and earth-working instruments at Springfield. . . . California is becoming a wine-producing country of respectability; they now have vines sufficiently large to give balls in, and find room not only for the dancers, but the musicians, and seats for spectators in them. . . . The products of California now include large quantities of castor-oil and mustard; 700,000 pounds of castor-beans and 13,000 bushels of mustard-seed were produced last year, besides \$40,000 worth of wild-mustard seed was gathered in one county alone. . . . Tobacco is said to be injured in quality by strong animal manures. . . . In some parts of Germany and Eastern France, 2,500 pounds of guano per acre is used as a fertilizer for tobacco. . . . Another Chester Co., Pa., swindler has been detected in receiving money for stock, and keeping it without forwarding the stock; in all cases when parties are unknown, it is safest to inquire of the postmaster, or to deal only with known responsible parties, although their prices may be higher than those of swindlers. . . . Mr. R. R. Seymour, Bainbridge, Ohio, has purchased a half-interest in the young Shorthorn bull, 3d Duke of Oudia. This bull will divide his time between Ross and Licking Counties for the future, and will, without doubt, leave his mark. . . . An Ohio farmer keeps his hogs healthy by furnishing them, in a covered trough, with a continuous supply of soft stone coal, salt, and ashes; this assists their digestion. . . . A New York farmer saved a calf which was choking with a potato in its throat, by bending a fence wire, putting it down the calf's throat, and working it behind the potato, which he was thus enabled to draw out. . . . A farmer of Kane Co., Ill., lately sold 1,500 pounds of wool, which was the clip of five years past, at 65 cents a pound, amounting to \$970. He made money by holding on to his wool. He keeps 800 sheep. . . . A farmer of Linn Co., Mo., with the help of his two young sons, raised last season over 10,000 pounds of tobacco, which brought him over \$300 net profit.

Standard Books on Architecture.

PUBLISHED BY

ORANGE JUDD & COMPANY,

245 BROADWAY, NEW YORK.

Monckton's National Builder and Stair-Builder.—A new and original work, covering every practical branch of Constructive Carpentry, with 1,000 Working Scale Drawings, in two colors. Showing the simplest methods of finding all Joints and Forms; method of constructing all varieties of French Roof; all other methods of Roofing, all styles of Framing; Splayed Work, Ceilings, Domes, Niches, Raking and Level Moldings, etc., with a Treatise on Stair-Building and Hand-Railing, and Designs for Stair-Cases, Newels, Balusters, and Hand-Rails. One royal quarto volume, uniform with "Woodward's National Architect." (*Ready October 1, 1872.*) Post-paid, \$12.00.

Harney's Barns, Out-Buildings, and Fences.—Containing Designs and Plans of Stables, Farm Barns, Out-Buildings, Gates, Gateways, Fences, Stable Fittings and Furniture, with nearly 200 Illustrations. Royal quarto. Post-paid, \$10.00.

Rural Church Architecture.—Exemplified in Plans, Elevations, Sections, and Details. By Upjohn, Renwick, etc. Printed in colors, 45 Plates. Post-paid, \$12.00.

Woodward's National Architect.—1,000 Designs, Plans, and Details for Country, Suburban, and Village Houses; with Perspective Views, Front and Side Elevations, Sections, Full Detail Drawings, Specifications, and Estimates. Also, Detail Drawings to Working Scale, of Brackets, Cornices, French Roofs, Sectional and Framing Plans of French Roofs, Dormer-Windows for French Roofs, Bay-Windows, Verandas, Porches, Plaster Finish, Cornices, Ceilings, Hard-wood Mantels, and all that is required by a Builder to design, specify, erect, and finish in the most approved style. One superb quarto volume. Post-paid, \$12.00.

Jacques' Manual of the House.—How to Build Dwellings, Barns, Stables, and Out-Buildings of all kinds. 126 Designs and Plans. Post-paid, \$1.50.

Woodward's Cottages and Farm Houses.—188 Designs and Plans of low-priced Cottages, Farm Houses, and Out-Buildings. Post-paid, \$1.50.

Woodward's Suburban and Country Houses.—70 Designs and Plans, and numerous examples of the French Roof. Post-paid, \$1.50.

Woodward's Country Homes.—150 Designs and Plans, with Description of the Manner of Constructing Balloon Frames. Post-paid, \$1.50.

Woodward's Graperies and Horticultural Buildings.—Designs and Plans of Hot-Beds, Cold-Pits, Propagating Houses, Forcing Houses, Hot and Cold Graperies, Green Houses, Conservatories, Orchard Houses, etc., with the various modes of Ventilating and Heating. Post-paid, \$1.50.

Woodward's Suburban Homes for New Yorkers.—Post-paid, 10c.

Wheeler's Rural Homes.—Houses suited to Country Life. Post-paid, \$2.00.

Wheeler's Homes for the People.—100 Original Designs, with full Descriptions, and Constructive and Miscellaneous Details. Post-paid, \$3.00.

Eveleth's School-house Architecture.—A new and original work, containing Seventeen Designs for School-houses, Sixty-seven Plates with Perspectives, Elevations, Plans, Sections, Details, Specifications all drawn to working scale, with methods of Heating and Ventilation. Large quarto. Post-paid, \$10.00.

Copley's Plain and Ornamental Alphabets.—Giving examples in all styles, together with Maps, Titles, Borders, Meridians, Ciphers, Monograms, Flourishes, etc., adapted for the practical use of Surveyors, Civil Engineers, Draughtsmen, Architects, Sign Painters, Schools, etc. Post-paid, \$3.00.

Frank Forester's Complete Manual

For Young Sportsmen, of Fowling, Fishing, and Field
Sports. With directions for handling the Gun, the Rifle,
and the Rod. Art of Shooting on the Wing. The Break-
ing, Management, and Hunting of the Dog. The vari-
eties and habits of Game. River, Lake, and Sea Fishing.
Post octavo. Post-paid, \$3.00.

**Frank Forester's American Game in its
SEASONS, Fully Illustrated and Described.** New edi-
tion, post-paid, \$3.00.

The Dog.

By Dinks, Mayhew & Hutchinson. Compiled and edited
by Frank Forester. Containing full instructions in all
that relates to the Breeding, Rearing, Breaking, Kennel-
ing, and Conditioning of Dogs, with valuable recipes for
the treatment of all diseases. Illustrated. Post octavo.
Post-paid, \$3.00.

The Dead Shot:

Or, Sportsman's Complete Guide; a Treatise on the use
of the Gun, with Rudimentary and Finishing Lessons in
the Art of Shooting Game of all kinds. By Marksman.
Post-paid, \$1.75.

The Crack Shot:

Or, Young Rifleman's Complete Guide; being a Treatise
on the use of the Rifle, with Lessons, including a full de-
scription of the latest improved breech-loading weapons;
rules and regulations for Target Practice, and directions
for Hunting Game. By Edward C. Barber. Post-paid, \$1.75.

Gun, Rod, and Saddle.

Nearly fifty practical articles on subjects connected with
Fishing, Shooting, Racing, Trotting, etc. Post-paid, \$1.

**Frank Forester.—The Captains of the Old
WORLD,** as Compared with the Great Modern Strat-
egists; their Campaigns, Characters, and Conduct, from
the Persians to the Punic Wars. By **HENRY WILLIAM
HERBERT.** Post-paid, \$3.00.

**Frank Forester.—The Captains of the
GREAT ROMAN REPUBLIC,** as Compared with the
Great Modern Strategists; their Campaigns, Characters,
and Conduct, from the Punic Wars to the death of Cæsar.
By **HENRY WILLIAM HERBERT.** Post-paid, \$3.00.

AGRICULTURE.

**Woodward's Graperies and Horticultural
BUILDINGS.** Designs and Plans of Hot-beds, Cold Pits,
Propagating Houses, Forcing Houses, Hot and Cold
Graperies, Greenhouses, Conservatories, Orchard Houses,
etc., with the various modes of Ventilating and Heating.
Post-paid, \$1.50.

**Jacques' Manual of the Garden, Farm,
AND BARN-YARD.** Embracing the Cultivation of
Vegetables, Fruit, Flowers, all Field Crops, Details of
Farm Work and Rearing Domestic Animals. New and
Revised Edition. One volume. Post-paid, \$1.75.

Young Farmer's Manual.

Vol. I. The Farm and the Workshop, with Practical
Directions for Laying out a Farm, Erecting Buildings,
Fences, Farm Gates, Selecting good Farm and Shop
Tools, and performing Farm Operations. Fully illus-
trated. Post-paid, \$1.75.

Young Farmer's Manual.

Vol. II. How to Make Farming Pay, with full Details of
Farm Management, Character of Soils, Plowing, Manage-
ment of Grass Lands, Manures, Farm Implements, Stock,
Drairage, Planting, Harvesting, etc. Illustrated. Post-
paid, \$1.75.

Husmann's Grapes and Wine.

The Cultivation of the Native Grape and Manufacture
of American Wine. By Geo. Husmann, of Missouri.
Post-paid, 8c.

Elliott's Lawn and Shade Trees.

For Planting Parks, Gardens, Cemeteries, Private
Grounds, and Avenues. Fully illustrated and described.
Post-paid, \$1.50.

Fuller's Forest Tree Culturist.

The Cultivation of Forest Trees for Shade, for Shelter,
for Fuel, for Timber, and for Profit. Illustrated. Post-
paid, \$1.50.

ORANGE JUDD & CO., 245 Broadway, New York.

GARDENING FOR THE SOUTH;

OR, HOW TO GROW

VEGETABLES AND FRUITS.

BY THE LATE

WILLIAM N. WHITE,

OF ATHENS, GA.

WITH ADDITIONS BY MR. J. VAN BUREN AND
DR. JAS. CAMAK.

REVISED AND NEWLY STEREOTYPED.

ILLUSTRATED.

NOTICES BY THE PRESS.

It supplies a place long vacant in Southern literature, and
should be in the hands of every man or woman who culti-
vates a foot of ground. While it treats very freely of the
vegetable garden, it devotes much space also to fruits, etc.
—*Tribune* (Mobile, Ala.)

It is illustrated by a portrait of the author, and numerous
engravings of subjects treated. It is a work of 450 pages,
and is a complete manual of kitchen gardening and fruit
culture.—*Telegraph* (Macon, Ga.)

Mr. White was prime authority in his specialty, and this
volume is a complete manual for gardening for Southern
latitudes. Besides the usual fruits and vegetables of North-
ern gardens, there are full instructions as to the culture of
the almond, fig, orange, lemon, shaddock, olive, yam,
ground-nut, Madeira nut, and pistachio. In view of the ris-
ing importance of "truck farming" in the South to supply
Northern markets with early vegetables and fruit, this book
is quite important to the gardeners of either section.—
Register (Wheeling, W. Va.)

Coming from the pen of an experienced cultivator of
Southern vegetables and fruits, the reader, whether of old
or recent residence, is put in possession of facts relating to
the soil, climate, and varieties of plants adapted to the
South that would otherwise require much time and expense
to acquire. The vineyard and orchard receive sufficient
attention to furnish all the necessary information for the
beginner. We regard the book as especially adapted for the
private gardener, and if a copy could be placed in the hands
of every farmer, we might expect, on our visits to the coun-
try, to be regaled upon something else than "bacon and
greens."—*Daily State Journal.*

The first edition of this work appeared in 1856, but the
second, now just issued, is much enlarged, containing 444
pages. It embraces a much larger range of topics than the
title indicates, and is one of the most valuable compilations
of facts that we have anywhere seen in a single volume, re-
lating to different kinds of soil, and their adaptation to dif-
ferent kinds of fruit and vegetables.—*Journal of Agricul-
ture* (St. Louis, Mo.)

The book itself we can commend to our farmers and gar-
deners. Its author was formerly connected with the
"Southern Agriculturist," a most excellent farmers' paper,
and was thoroughly acquainted with the wants of the
Southern people in respect to their farming and gardening
operations.—*Cassette and Danner.*

A complete gardening book for the localities which it
specifies. It is full and comprehensive, and written in a
clear, perspicuous style. A volume of 444 pages, well
printed and bound.—*Republican* (St. Louis, Mo.)

It is very comprehensive, embracing all the improved
kinds of fruits and vegetables, and the modern modes and
implements of tillage. Its arrangement is systematic, and
entirely convenient for prompt reference. It is illustrated
by a large number of drawings relating to garden and fruit
cultivation, such as trellis, grafting, draining, transplant-
ing, together with pictures of novel fruits and vegetables.—
Dispatch (Richmond, Va.)

Price, post-paid, \$2.00.

ORANGE JUDD AND COMPANY,

245 BROADWAY, NEW YORK.

HINTS TO HORSE-KEEPERS, A COMPLETE MANUAL FOR HORSEMEN.

BY THE LATE HENRY WILLIAM HERBERT. (FRANK FORESTER.) Beautifully Illustrated.

HOW TO BREED A HORSE.—

CHOICE OF STALLION.—National Value of the Horse.—The best class of Horses the cheapest for all purposes.—What constitutes excellence.—Blood: What it gives, should be on the side of the Sire.—Breed up, not down.—Diseases and Defects Hereditary.—General Rules.

CHOICE OF THE MARE.—Size, Symmetry and Soundness more important than Blood.—Points of the Brood Mare.—Diseases Hereditary.—Condition of the Mare.—Should have moderate work when with Foal.—Food and care during gestation.—Health and temper.

MUTUAL ADAPTATION OF SIRE AND DAM.—First consideration in improvement of "cold" Blood.—Relative size of Sire and Dam.—Defects in either Parent.—How Remedied in Progeny.—Bloods which "hit."

CANADIAN BLOOD.—The Canadian originally the French Norman.—Characteristics.—Hardhood.—Speed.—Mode of Improvement.—Crossing with Thorough-breds.

NORMAN BLOOD.—Origin and History of the Percheron Norman.—A pure race.—Characteristics and Points.

MODERN ARAB BLOOD.—English and American Thorough-breds derived from Oriental Blood.—are now superior to the Modern Arabs.—NOLA ARAB.

PONIES — DIFFERENT BREEDS,

CHARACTERISTICS AND UTILITY.—Origin.—Different Breeds.—Shetlands and Scots.—Galloways and Narragansets.—Mustangs and Indians.—Profit of raising Ponies.

HOW TO BREED MULES.

Value of Mules.—Their History and Natural History.—The Mule and Muley.—Thorough-bred wasted in the Dam for Mules.—The Mule in the United States.—Large size not desirable.—Varieties of the Ass.—The kind of Mares to be selected.

HOW TO BUY A HORSE.

Of whom to Buy It.—Extraordinary Cheapness and Extraordinary Excellence not consistent with each other.—Points to be regarded.—How to Examine the Eye.—Broken Wind.—Roaring.—Whistling.—Broken Knees.—To examine the Legs.—Splents.—Damaged Back Sinews.—Spavins.—Ringbones.—Curls.—How to tell the Age of a Horse.

HOW TO FEED A HORSE.

Consequences of Improper Feeding.—Different Food for different conditions.—Food for the Brood Mare.—for the Foal.—For Working Horses.—Green Food.—Carrots.—Corn.—Feeding Horses in Training.—While Travelling.—Summering Horses.—The Best Method.—Management of Omnibus Horses in New York.

HOW TO STABLE AND GROOM A HORSE.

Requisites for a good Stable.—The economy of Proper Arrangements.—Ventilation.—Grooming; its necessity for all descriptions of Horses.—How Performed.—Clothing.—Treatment when brought in from Work.

HOW TO BREAK, AND USE A HORSE.

What is required in a well-broken Horse.—His education should commence when a Colt.—Bringing.—Putting in Harness.—How to Use a Horse.—Travelling.—Working.—Pleasure Horses.—Punishment.

HOW TO PHYSIC A HORSE —

SIMPLE REMEDIES FOR SIMPLE AILMENTS.—Causes of Ailments.—Medicines to be given only by the order of the Master.—Depletion and Purging.—Spasmodic Colic.—Inflammation of the Bowels.—Inflammation of the Lungs.—How to Bleed.—Balls and Purgatives.—Costiveness.—Cough.—Bronchitis.—Distemper.—Worms.—Diseases of the Feet.—Scratches.—Thrush.—Broken Knees.

FARRIERY, ETC.

Castration.—Docking and Nicking.—Blood-letting.—Treatment of Strains and Wounds.—A Colt.—Bringing.—Cracked Heels.—Clipping and Singeing.—Administering Medicines.—Diseases of the Feet.

HOW TO SHOE A HORSE.

Unskilful Shoers.—Anatomy of the Foot Illustrated.—The Foot of a Colt.—Preparation of the Foot.—Removing the Old Shoe.—Fitting the Foot.—Shoe.—Fitting the Shoe.—Nailing.—Number of Nails.—Diseases of the Foot.

BAUCHER'S METHOD OF TRAINING HORSES.

What Constitutes a Well-trained Horse.—To make him come at your call.—The Philosophy of Training.—Flexions of the Jaw.—Flexions of the Neck.—Flexions of the Croup.—Backing.—The Paces.—Leaping.

HOW TO RIDE A HORSE.

The Saddle.—The Girths.—The Stirrups.—Saddle-Cloths.—The Crupper.—The Martingale.—The Bridle.—Spurs.—Mounting and Dismounting.—The Seat.—The Hands.—The Legs.—The Paces.—Hints for Special Cases.—The Art of Falling.—Riding with Ladies.

LADIES' RIDING—WRITTEN BY A LADY.

Learning to Ride.—The Side-saddle.—The Girths.—The Stirrup.—The Bridle.—The Martingale.—The Bit.—The Dress.—Mounting and Dismounting.—The Position.—The Hands.—The Leg and Whip.—Accidents.

HOW TO DRIVE A HORSE.

The Art of Driving.—Pleasure Driving.—How to Hold the Reins.—Driving a Pair.—Four-in-hand Driving.—Driving Working Horses.—Plowing.—Three-a-breast.

RAREY'S SYSTEM OF HORSE-TAMING.

Rarey's System a New Discovery.—Previous System.—Principles of this System.—Instructions for practicing Rarey's Method.—To Stable the Horse.—To Approach the Horse.—Trying up the Leg.—Laying the Horse Down.—Finals.—Vices and Bad Habits.—Rearing.—Kicking.—Baulking.—Pulling on the Halter.—Shying.

VETERINARY HOMOEOPATHY.

Principles of the System.—Table of Remedies.—General Directions.—Treatment of a Sick Animal.—Diet.—Remedies for Specific Cases.—Glossary of Diseases.

12mo. 425 p.—Sent by mail post-paid. \$1.75.

ORANGE JUDD & CO., 245 Broadway, New York.

THE TRAPPER'S GUIDE;

A Manual of Instructions

For capturing all kinds of fur-bearing animals, and curing their skins; with observations on the fur trade, hints on life in the woods, and narratives of trapping and hunting excursions.

By S. NEWHOUSE,

And other Trappers and Sportsmen.

Edited by the Oneida Community.

216 Pages Octavo.

With 32 full page Illustrations, and numerous smaller Engravings.

CONTENTS.

INTRODUCTION.

Connection of Trapping with other Trades.—Observations on the Fur Trade.—Season for Trapping.—Statistics of the Fur Trade.

THE TRAPPER'S ART.

- I. PRELIMINARIES. II. CAPTURE OF ANIMALS. III. CURING SKINS. IV. LIFE IN THE WOODS.

THE TRAPPER'S FOOD.

The Deer.—The Buffalo.—The Rocky Mountain Sheep, or Bighorn.—The Argali.—The Prong-horn Antelope.—Squirrel Hunting.—The Ruffed Grouse.—Pinnated Grouse.—Sharp-tail Grouse.—Cock of the Plains.—Dusky Grouse.—Canada or Spruce Grouse.—White-tailed Ptarmigan.—Willow Ptarmigan.—European Grouse.—Water Fowl.

FISHING IN AUTUMN AND WINTER.

Spearing Fish.—Fishing through the Ice.—Net-fishing in Winter.

NOTES ON TRAPPING AND WOOD-CRAFT. PLAN OF A TRAPPING CAMPAIGN. BOAT BUILDING. SNOW-SHOES.

NARRATIVES.

An Evening with an old Trapper.—A Young Trapper's Experience.—The Deer Hunt.—Muskrat Hunting.—An Amateur in the North Woods.—Traveling in a Circle.—An Expedition to the Laurentian Hills.

APPENDIX.

History and description of the Newhouse Trap.—Conclusion.

SENT POST-PAID. PRICE \$1.50.

ORANGE JUDD & CO., 245 Broadway, New York.

WARING'S BOOKS FOR FARMERS.

DRAINING FOR PROFIT AND DRAINING FOR HEALTH.

By GEO. E. WARING, JR., Engineer of the Drainage of Central Park, New York.

CONTENTS.

LAND TO BE DRAINED; HOW DRAINS ACT; HOW TO MAKE DRAINS; HOW TO TAKE CARE OF DRAINS; WHAT DRAINING COSTS; WILL IT PAY? HOW TO MAKE TILES; RECLAIMING SALT MARSHES; HOUSE AND TOWN DRAINAGE.

EXTRACTS FROM NOTICES BY THE PRESS.

He (the author) describes the action of draining upon the soil, the construction of single drains and systems of drains, the cost and the profit of thorough drainage, the making of tiles, and the reclaiming of salt marshes, treats sensibly of malarial diseases, and closes with a chapter which should be widely read, on house drainage and town sewerage in their relations to the public health. [Portland (Me.) Press.

Nowhere does this book merit a wider circulation than in the West. Every year adds to the thousands of dollars lost to this State from want of proper surface drainage, to say nothing of the added gain to result from a complete system of under-drainage. This book will prove an aid to any farmer who may consult it. [Chicago (Ill.) Republican.

A Book that ought to be in the hands of every Farmer. SENT POST-PAID, PRICE, \$1.50.

EARTH-CLOSETS

AND

EARTH-SEWAGE.

By GEO. E. WARING, JR. (of Ogden Farm).

INCLUDING:

- THE EARTH SYSTEM (Details), THE MANURE QUESTION, SEWAGE AND CESS-POOL DISEASES, THE DRY-EARTH SYSTEM FOR CITIES AND TOWNS, THE DETAILS OF EARTH SEWAGE, THE PHILOSOPHY OF THE EARTH SYSTEM.

With Seventeen Illustrations.

Paper Covers, Price, Post-paid, 50 cts.

ELEMENTS OF AGRICULTURE.

A BOOK FOR YOUNG FARMERS,

By GEO. E. WARING, JR., Formerly Agricultural Engineer of the Central Park, in New York.

CAREFULLY REVISED.

CONTENTS.

THE PLANT; THE SOIL; MANURES; MECHANICAL CULTIVATION; ANALYSIS.

The foregoing subjects are all discussed in plain and simple language, that any farmer's boy may understand. The book is written by a successful practical farmer, and is full of information, good advice, and sound doctrine.

HORACE GREELEY says of it: "Though dealing with facts unfamiliar to many, there is no obscure sentence, and scarcely a hard word in the book; its 254 fair, open pages may be read in the course of two evenings and thoroughly studied in the leisure hours of a week; and we pity the man or boy, however old or young, who can find it dull reading. Hardly any one is so wise that he will not learn something of value from its perusal; no one is so ignorant or undeveloped that he cannot generally understand it; and no farmer or farmer's son can study it thoughtfully without being a better and more successful cultivator than before."

SENT POST-PAID, PRICE, \$1.00.

READ THE NEW BOOK
ON
Farm - Gardening
AND
SEED - GROWING.

BY FRANCIS BRILL.

NOTICES BY THE PRESS.

Orange Judd & Co. have added to their splendid catalogue of agricultural books "Farm-Gardening and Seed-Growing," by Francis Brill; it is practical, plain, complete, and satisfactory, so that for a small amount of money a great deal of desirable information can be obtained. If there is any firm anywhere which is to-day disseminating so much knowledge in regard to tilling of the soil as this same said firm of Orange Judd & Co., we will present a medal to our informer.—*Watchman and Reflector* (Boston).

The want occasionally expressed to us of a work on the cognate subjects above named (Farm-Gardening and Seed-Growing), is now met in a book under this title from the pen of Mr. Francis Brill, formerly a market-gardener and seed-grower at Newark, N. J., and at present engaged in raising seeds at Mattituck, L. I. Its directions are concise and practical, covering those points on which a beginner is most likely to require information.—*Country Gentleman*.

Mr. Brill has had large experience, and derived his knowledge wholly from the school of actual tests.—*Chicago Evening Journal*.

We have in this volume the results of a practical man's experience in raising root crops and other vegetables in the market-garden. Not only the professional seed-grower and trucker, but the amateur gardener who has a little patch in his suburban home, will find many a valuable hint and direction in this full and comprehensive manual.—*Sunday-School Times*.

It seems to be a very sensible, practical work by a practical man. Mr. Brill's father was a gardener, and he himself has had an extensive experience, and he talks about what he knows, which is more than can be said of many authors of industrial works.—*Moore's Rural New Yorker*.

There can be no question that this farm-gardening can be made in many districts of the Southern Atlantic States, especially near the coast, far more profitable than growing the ordinary staple crops. In connection with producing the vegetables, the growing and saving their seeds receive minute attention.—*American Farmer* (Baltimore).

A very useful hand-book, not merely for farmers and growers of seed on an extensive scale, but for all who, whether for recreation or for the purpose of supplying their own families with garden products, desire to know something about the adaptation of seed to soil and the mode of culture.—*Church Journal* (New York).

This industry is now occupying the attention of many persons who sell their products to the great seed-houses, and novices who have the facilities, and wish to enter upon the business, will find in this book just the hints needed.—*Springfield Republican*.

Mr. Brill has been a successful farm-gardener and seed-grower for a number of years, and gives in a clear and concise form the knowledge he has gained. . . . It gives the best method of manuring, planting, and cultivating every vegetable sold in markets—in short, everything required to be known, plainly and fully—and should be in the hands of every one who cultivates so much as a rod of land, for family use, pleasure, or profit.—*Suffolk* (L. I.) *Times*.

The seal of Orange Judd & Co. upon an agricultural publication is sufficient guarantee of its worth. Francis Brill's book, published by them, is a very complete work, giving plain, minute instructions as to raising, taking care of, and bringing to market those vegetables which are most in demand in the large cities, and those seeds which are being called for throughout the country.—*N. Y. Evening Mail*.

The work of showing how this can be accomplished has fallen in good hands, and it has been done well. The book will sell well perusal, and we hope soon to see its good effects in a more intelligent direction of farm industry, and accompanied by more satisfactory pecuniary results.—*The Signal* (L. I.)

To the market-gardener, or even the owner of a small piece of tillable land, this book will be of great value. Qualities of soil required for the growth of different vegetables, how to plant, how to cultivate, to harvest, and preserve during winter.—*N. Y. Citizen and Round Table*.

Price, Post-paid, \$1.00.

ORANGE JUDD AND COMPANY,
245 BROADWAY, NEW YORK.

Gardening for Profit

In the Market and Family Garden.

By Peter Henderson.

ILLUSTRATED.

NOTICES BY THE PRESS.

All the vegetables that thrive in the open air in our latitude are described, together with the best methods for growing them. The author also imparts practical instructions on the subjects of drainage, and the formation and management of hot-beds. Numerous well-executed wood-cuts tend to make clearer the instructions of the author.—*Philadelphia Inquirer*.

The author of this treatise is one of the best known and most successful of those gardeners who supply New York with green vegetables; and as he writes from long and dear-bought experience, the positive, dogmatic tone he often assumes is by no means unbecoming. The book itself is intended to be a guide for beginners embarking in the author's business, and gives full and explicit directions about all the operations connected with market-gardening, lists of varieties of the most profitable vegetables, and much sound advice on kindred topics. Though designed for a special class, it can not fail to be valuable to the amateur and private gardener, and unlucky experience has taught us that the information contained in a single chapter would have been worth to us the price of the book.—*Daily Mercury* (New Bedford).

It is unquestionably the most thorough and the best work of its kind we have yet had from the pen of an American author. It is written in a clear, concise style, and thus made more comprehensive than works which smack more of the office than the farm or garden.—*Daily Evening Times* (Bangor, Me.).

Mr. Henderson writes from knowledge, and is not one of those amateur cultivators whose potatoes cost them ten dollars a bushel, and whose eggs ought to be as valuable as those of that other member of their family—the goose of golden-egg-laying memory—for they are all but priceless. No; he is a practical man, and he has the art of imparting the knowledge he possesses in a very agreeable manner; and he has brought together an extraordinary amount of useful matter in a small volume, which those who would "garden for profit" ought to study carefully.—*Evening Traveller* (Boston).

There are marvels of transformation and rapid reproduction recorded therein, which might well shame the dull fancy of the author of Aladdin or of Kaloolah. There is no theory about it; a man who has made himself rich by market-gardening plainly tells our young men how they can get rich as easily as he did, and without wandering to California or Montana for it either.

[HORACE GREELEY in the *N. Y. Tribune*.

We have devoted more space to this little work than we usually do to tomes much more pretentious. We have done so because of the rare merits of the book in its fund of information, useful to the farmer and market-gardener, and because of the dearth of that kind of knowledge. We earnestly advise that fraternity, for whom this work was written, to buy it and study it. If any among them have never yet read a book, let this be their primer, and we will vouch for the excellence and endurance of the priming. The work is profusely illustrated with wood-cuts.—*Louisville Daily Journal*.

Price, post-paid, \$1.50.

ORANGE JUDD & COMPANY,
245 BROADWAY, NEW YORK.

HARRIS ON THE PIG.

Breeding, Rearing, Management,
AND
Improvement.

With Numerous Illustrations.

By JOSEPH HARRIS,

OF MORETON FARM, ROCHESTER, N. Y.

NOTICES BY THE PRESS.

To say that this work on the pig is by Joseph Harris, that genial philosopher-farmer of Rochester, N. Y., who writes the "Walks and Talks upon the Farm" in the *Agriculturist*, is to insure for his book at once a large circle of delighted readers. He is just the man to lay down the gospel for the raising of pigs or any other domestic animal. If all breeders and farmers would follow Mr. Harris's directions, pork would be a very different article of food from what it is now, and could be eaten without any fears of the trichina.

[*Springfield Republican*.

The author discusses the pig—for he takes exception to the word hog as applied to the domesticated animal—with a view of showing how the most pork and lard can be produced from the smallest amount of feed. He gives elaborate descriptions of the different breeds of swine, showing the peculiarities of each, and the relative advantages to the producer.—[*Prairie Farmer* (Chicago).

The pig is doubtless one of the most valuable animals that a farmer can raise, and it is the laudable purpose of Mr. Harris to tell farmers how to treat their pigs so as to get the most profit from them, and what kind of pigs are best.—[*Daily Evening Traveller* (Boston).

It treats of breeding, rearing, managing, and improving swine; and what Mr. Harris doesn't know on these topics, is hardly worth knowing at all. The book is fully illustrated, and is very valuable to all who are interested in this branch of stock-raising.

[*Lowell* (Mass.) *Daily Courier*.

The author is a practical farmer, and has gathered the results of many experiments besides his own. The book is amply illustrated.

[*Republican Statesman* (Concord, N. H.).

Almost everything a farmer wants to know about the breeding, keeping, and fattening of pigs, is here put down in plain, common sense, and is mainly the result of the writer's own management.—[*Maine Farmer*.

This is an interesting, valuable, and a much-needed treatise on an important department of rural economy. It contains about 50 illustrations of pigs, piggeries, troughs, etc. We are heartily glad our old friend Harris was persuaded to prepare this useful Manual on the Pig—breeds, breeding, feeding, etc., comprising what farmers need know respecting this department of husbandry.

[*Boston Cultivator*.

This little book is profusely illustrated, and contains information in abundance, which every farmer ought to possess.—[*Weekly Mail* (St. Louis).

Here is a book written by a practical farmer, who has brought to the aid of his own large experience and observation the most extensive acquaintance with the science of breeding, and, as might reasonably be expected, we have from his pen the best book on the Pig ever written.—[*Western Stock Journal*.

Price, Post-paid, \$1.50.

ORANGE JUDD AND COMPANY,
245 BROADWAY, NEW YORK.

READ SOME OF THE NOTICES BY THE PRESS
OF ONE OF THE MOST INTENSELY INTERESTING
AMERICAN STORIES
EVER WRITTEN.

The Hoosier School-Master.

By EDWARD EGGLESTON.

Finely Illustrated with Twelve Full-page Engravings on Tinted Paper, and Numerous other Cuts.

NOTICES BY THE PRESS.

It is in the fullest sense a powerful novel, and displays an originality as rare as it is fascinating.—*St. Louis Democrat*.

It is one of the best works of fiction we have read for many a day. We knew many of the characters in it, that is, we have seen men, women, and children like them. It will do.—*Central Christian Advocate*.

It is the best serial we ever remember to have read. Except in length and number of characters, it is not behind Dickens's masterpiece, "David Copperfield." It is true to nature; nothing is distorted, nothing overdrawn; it has not an impossible character in it.—*The Commonwealth, Salem, O.*

Though many will view the book from every other stand-point, we think its greatest charm is in the fact that it brings one nearer to Christ. Oh! with our hand in Shacky's, we assure all that are in any doubt that God hasn't forgot, and that He never will forget; and though sometimes He chooses to lead us through the night, the way is always heavenward.—*Wood's Household Magazine*.

The plot is very simple, and of easy prevision from the first, being the struggles of Ralph Hartsook with the young idea in the district school on Flat Creek, where the twig was early bent to thrash the school-master. . . . The story is very well told, in a plain fashion, without finely-studied points. . . . Mr. Eggleston is the first to touch in fiction the kind of life he has represented, and we imagine that future observers will hardly touch it in more points. Its traits seem to be all here, both the good and the bad; but that it is a past or passing state of things is sufficiently testified by the fact, to which Mr. Eggleston alludes in his preface, that the story, as it appeared serially, was nowhere more popular than in Southern Indiana. Flat Creek, Hoopole County, would not, we imagine, have been so well pleased thirty years ago with a portrait which, at any rate, is not flattered.—*Atlantic Monthly*.

Eggleston's "Hoosier School-Master" is full of rich and racy humor, and makes us regret that its author has turned his back to the pulpit, in which wit is needed quite as much as wisdom, and the ability to make men laugh is only less valuable than the power of making them weep. In fact, as a general thing, he who can not raise a smile on people's faces may pump in vain for tears.—*Golden Age, N. Y.*

Dr. Eggleston lived as a boy in this region (Southern Indiana), and this book is a faithful witness that the impression made upon his mind by its social peculiarities remains to this day perfectly distinct and legible. Indeed, we have rarely read any story whose truthfulness as a picture of life was more apparent. The characters are clearly drawn; the conversation is natural; the whole view of the backwoods society is consistent and lifelike.—*N. Y. Independent*.

It might be dramatized so as to make a most effective play. There is all the material in the book, and a good deal of the work already done to hand.—*Newburyport (Mass.) Herald*.

It is published in the neat and attractive form which makes all the publications of Orange Judd & Co. such a tasty and welcome addition to the library or library table. Of the story itself we have had occasion to speak before in terms of unqualified admiration.—*Kentucky Spirit, Lawrence, Kansas*.

Mr. Eggleston's powerful novel, "The Hoosier School-Master," increases in interest as it goes on, and contains some characters truly original.—*Springfield Republican*.

OLD MRS. MEANS.

"Git a plenty while you're a-gittin'."

"Ralph sat by the fire the next morning trying to read a few minutes before school-time, while the boys were doing the chores, and the bound girl was milking the cows, with no one in the room but the old woman. She was generally as silent as Bud, but now she seemed for some unaccountable reason disposed to talk. She had sat down on the broad hearth to have her usual morning smoke; the poplar table, adorned by no cloth, sat in the floor; the unwashed hinc tea-cups sat in the unwashed blue saucers; the unwashed blue plates kept company with the begrimed blue pitcher. The dirty skillets by the fire were kept in countenance by the dirtier pots, and the ashes were drifted and strewn over the hearth-stones in a most picturesque way.

"'You see,' said the old woman, knocking the residuum from her cob-pipe, and chafing some dry leaf between her withered hands preparatory to filling it again, 'you see, Mr. Hartsook, my ole man's purty well along in the world. He's got a right smart lot of this world's plunder, one way and another.' And while she studied the tobacco in her pipe Ralph wondered why she should mention it to him. 'You see we moved in here nigh upon twenty-five year ago. 'Twas when my Jack, him as died afore Dad was born, was a baby. Dad'll be twenty-one the fifth of next June.'

"Here Mrs. Means stopped to rake a live coal out of the fire with her skinny finger, and then to carry it in her skinny palm to the bowl—or to the hole—of her cob-pipe. When she got the smoke agog she proceeded:

"'You see this ere bottom land was all Congress land in them there days, and it sold for a dollar and a quarter, and I says to my ole man, 'Jack,' says I, 'Jack, do you git a plenty while you're a-gittin'. Git a plenty while you're a-gittin','' says I, 'fer 'twon't never be no cheaper'n 'tis now,' and it ha'n't been, I knowed 'twouldn't,' and Mrs. Means took the pipe from her mouth to indulge in a good chuckle at the thought of her financial shrewdness. "'Git a plenty while you're a gittin','' says I. I could see, you know, they was a powerful sight of money in Congress land. "'Git a plenty while you're a gittin','' And Jack, he's wuth lots and gobs of money, all made out of Congress land. Jack didn't git rich by hard work. Bless you, no! Not him. That a'n't his way. Hard work a'n't, you know. 'Twas that air six hundred dollars he got along of me, all salted down into Flat Crick bottoms at a dollar and a quarter a acre, and 'twas my sayin' 'Git a plenty while you're a gittin','' as doze it.' And here the old ogre laughed, or grinned horribly, at Ralph, showing her few straggling, discolored teeth."—*From "The Hoosier School-Master."*

NOTICES BY THE PRESS.

The development of the story is substantially a rude epic of truth, gentleness and true pluck. For the young master, younger than most of his pupils, far more cultivated in every direction than any of the population, and practically religious, instructs the community as well as the school; reclaims some of the worst, foils some, and has some detected and punished; encourage and loves, and is loved by a charming orphan, and graduates into a higher position with the highest honors. The moral is one of robust manhood confirmed in the worst conditions.—*American and Gazette (Philadelphia)*.

The talent of the author is by no means limited to external observation, but extends below the surface to shrewd recognition of the lights and shades of character. He makes free use of the comic element in his descriptions, but only when comic objects fall in his way; he is not always bound on a forlorn pursuit of fun, and does his readers the justice to remember that they are capable of amusement without being kept on a broad laugh by perpetual caricature. Although possessing a strong sense of the ludicrous, he is no cynic; he is not one who rejoices in making sport of the faults and foibles of his fellow-creatures; his power of satire furnishes him with a trenchant blade, but he has too much good-nature to use it for mischief. The kindly tone of his volume does not at all detract from its piquant effect, while it will recommend it to many readers who prefer humanity to ill-humor.—*New York Tribune*.

It is full of quaint humor, a tender pathos, and vivid descriptions.—*New York Standard*.

The "events" are stirring and dramatic, and the style is quiet, impersonal, and almost epigrammatic in its ability to lay bare an entire situation or character in a sentence or phrase.—*Brooklyn Daily Eagle*.

It is at once quaint and truthful, and illustrated as it is by masterly cuts, it should be one of the most popular books.—*Christian Standard (Cincinnati)*.

For realistic conception and life-like delineation of character, it is not excelled by any American story.—*Methodist*.

Some passages in it, for life-like delineation and the simple, artless beauty which constitute the highest perfection of story-writing, are equal to some of the very best passages in Dickens.—*Religious Telescope*.

Edward Eggleston's genius for story-telling is now flowering out in "The Hoosier School-Master," an illustrated story, which promises to be of rare interest.—*Sunday-school Times*.

Edward Eggleston's story, "The Hoosier School-Master," affords one of the most graphic and picturesque portraits of the early frontier life of the West which has ever been written. Some of his character sketches are inimitable, and all have an individuality and freshness which stamp him as a genuine artist.—*N. Y. Evening Mail*.

The *London Fun* says of this book, an edition of which has appeared in England:

"The *Hoosier School-Master*, both by its description as a book of American humor and by the cut on the wrapper, would lead one to suppose it was something in the 'Josh Billings' line. It is, however, a pleasant disappointment to find it a charming story in the vein of Wendell Holmes: humorous it is true, but full of a rough, natural pathos that will commend itself to all readers. We must keep an eye on Mr. Eggleston."

THE HUNTER AND TRAPPER.

By HALSEY THRASHER, AN EXPERIENCED HUNTER.

ILLUSTRATED.

This little book will be read with interest by all who would find instruction and entertainment in the narrative of an old hunter's experience.

CONTENTS.

- I. Deer Hunting.—
- II. How to Catch the Fox.—
- III. How to Hunt and Catch the Beaver.—
- IV. How to Catch the Otter.—
- V. How to Catch the Mink.—
- VI. How to Hunt and Catch the Muskrat.—
- VII. How to Catch the Marten.—
- VIII. How to Catch the Fisher.—
- IX. How to Catch the Raccoon.—
- X. How to Hunt and Trap the Bear.—
- XI. How to Hunt and Trap the Wolf.—
- XII. How to Trap the Pocket Gopher.—
- XIII. Fishing for Trout, Pickerel, and Bass.—
- XIV. How to Hunt the Honey Bee.—
- XV. Hints About Shot-Guns and Rifles.—
- XVI. Traps.—
- XVII. Dressing and Tanning Skins and Furs.

AMERICAN OTTER.

Notices by the Press.

Mr. Thrasher is an old hunter, and he gives the results of his experience in hunting and trapping in a plain, unpretending way. He not only gives many useful hints to the hunter, but intersperses his work with notes on the habits of our wild animals, and anecdotes of hunting. The book is illustrated, and will be found of interest to the naturalist, as well as the trapper. — [Boston Transcript.

It contains hints about trapping all sorts of game, from a honey-bee to a bear, with a chapter on fishing, and another on dressing and tanning skins and furs. The book is written by an experienced hunter, and is readable. — [Portland Advertiser.

PARSONS ON THE ROSE.

A Treatise on the Propagation, Culture, and History of
the Rose. Revised and newly electrotyped. Illustrated.
By **Samuel B. Parsons.** Price \$1.50.

The Rose is the only flower that can be said to have a his-
tory. It is popular now and was so centuries ago. In his
work upon the Rose, Mr. Parsons has gathered up the curi-
ous legends concerning the flower, and gives us an idea of
the esteem in which it was held in former times. A simple
garden classification has been adopted, and the leading vari-
eties under each class enumerated and briefly described.
The chapters on multiplication, cultivation, and training,
are very full, and the work is altogether the most complete
of any before the public.

AMERICAN CATTLE:

THEIR

HISTORY, BREEDING,

AND

MANAGEMENT.

By **LEWIS F. ALLEN,**

Late President New York State Agricultural Society, editor

"*American Shorthorn Herd Book*," author "*Rural
Architecture*," etc., etc.

NOTICES BY THE PRESS.

We consider this the most valuable work that has
recently been issued from the American press. It em-
braces all branches of the important subject, and fills a
vacancy in our agricultural literature for which work the
author by his many years' experience and observation was
eminently fitted. . . . It ought to be in the hands of every
owner of cattle; and the country, as well as individuals,
would soon be much richer for its teachings.

Journal of Agriculture (St. Louis).

The large experience of the author in improving the
character of American herds adds to the weight of his
observations, and has enabled him to produce a work
which will at once make good its claims, as a standard
authority on the subject. An excellent feature of this
volume is its orderly, methodical arrangement; condens-
ing a great variety of information into a comparatively
small compass, and enabling the reader to find the point
on which he is seeking light, without wasting his time
in turning over the leaves. *N. Y. Tribune.*

This will rank among the standard works of the coun-
try, and will be considered indispensable by every breed-
er of live-stock. *Practical Farmer (Phila.).*

We think it is the most complete work upon neat-
stock that we have seen; embodying as it does a vast
amount of research and careful study and observation.
Wisconsin Farmer.

His history of cattle in general and of the individual
breeds in particular, which occupies the first 180 pages
of the volume, is written with much of the grace and
charm of an Allison or a Macaulay. His description of
the leading breeds is illustrated by cuts of a bull, a cow,
and a fat ox, of each race. The next one hundred pages
are devoted to the subject of Breeding. This is followed
by chapters on Beef Cattle, Working Oxen, Milch Cows,
Cattle Food, Diseases, etc. The arrangement, illustra-
tions, analytical index, etc., of the work are in the best
style of modern book-making. *New England Farmer.*

The work is one that has long been needed, as it takes
the place of the foreign books of like nature to which
our farmers have been obliged to refer, and furnishes in
a compact and well-arranged volume all they desire upon
this important subject. *Maine Farmer.*

Whatever works the stock farmer may already have, he
can not afford to do without this. *Ohio Farmer.*

It is one of the best treatises within our knowledge,
and contains information sound and sensible, on every
page. *The People (Concord, N. H.)*

The object of the work, as stated by the author in his
preface, "is not only to give a historical account of the
Bovine race, to suggest to our farmers and cattle breeders
the best methods of their production and management,
but to exalt and ennoble its pursuit to the dignity to which
it is entitled, in the various departments of American
agriculture." From the little examination we have been
able to give it, we can not recommend it too highly.
Canada Farmer.

Considering that there are some ten millions milch cows
in the United States, and nearly a thousand millions of
dollars invested in cattle, the magnitude of this interest
demands that the best skilled talent be devoted to the
improvement of the various breeds, and the investigation
of the best method of so caring for the animals, as to gain
the greatest profit from them. This volume will give the
farmer just the instruction which he wants. *N. Y. Independent.*

Price, post-paid, \$2.50.

HOW CROPS GROW.

A Treatise on the Chemical Composition, structure, and
Life of the Plant. With numerous illustrations and tables
of analyses. By **Prof. Samuel W. Johnson,** of
Yale College. Price \$2.00.

This book is a guide to the knowledge of agricultural
plants, their composition, their structure, and modes of de-
velopment and growth; of the complex organization of
plants, and the uses of the parts; the germination of seeds,
and the food of plants obtained both from the air and the
soil. Very full and accurate tables of analyses are given,
and tables of the proportions existing between different
principles, oily, starchy, or nitrogenous, in the same and
different plants. The book is an invaluable one to all real
students of agriculture.

HOW CROPS FEED.

A Treatise on the Atmosphere, and the Soil as related to
the Nutrition of Agricultural Plants. Illustrated. By **Prof.
Samuel W. Johnson,** of Yale College. Price, \$2.00.

The work entitled "How Crops Grow" has been received
with very great favor, not only in America, but in Europe.
It has been republished in England under the joint Editor-
ship of Professors Church and Dyer, of the Royal Agricul-
tural College, at Cirencester, and a translation into German
has been published, at the instigation of Professor von Liebig.
The author, therefore, puts forth this volume—the com-
panion and complement to the former—with the hope that it
also will be welcomed by those who appreciate the scientific
aspects of Agriculture, and are persuaded that a true
Theory is the surest guide to a successful Practice.

AGRICULTURAL CHEMICAL ANALYSIS.

After E. Wolff, Fresenius, Krockner, and others. Edited by
Prof. G. C. Caldwell, of Cornell University. Price \$2.00.

In this work Professor Caldwell has brought together the
processes of analysis which apply especially to soils, fertil-
izers, animals and plants, and their products. He has tested
the methods of the best foreign authorities, and presented
them in a compact hand-book. Such a work has long been
needed by all who teach agricultural chemistry, and by
analytical chemists generally. Professor Caldwell modestly
calls himself the editor, but his book shows that he has not
contented himself with editing the works of others, but has
given much of his own experience.

Either of the above books sent post-paid on receipt of
price by

Calendar for September.

Table with columns for Day of Month, Day of Week, and Moon phases for Boston, N.Y., Wash'n, and Chicago. Includes sunrise, sunset, and moon rise/set times.

PHASES OF THE MOON.

Table showing moon phases (New Moon, 1st Quart., Full, 3d Quart.) and times for Boston, N.Y., Wash'n, and Chicago.

AMERICAN AGRICULTURIST.

NEW YORK, SEPTEMBER, 1872.

On many farms, September is a comparatively leisure month. It is a good time to build stone walls, to repair fences, to put up new gates, or rehang the old ones that sag.

We do not know how it is with other farmers, but in our own case we find it more difficult to get "odd jobs" properly and promptly done than the steady, more prolonged, and in some sense more important operations of the farm.

Hints about Work.

Sowing Winter-Wheat.—In the Middle and Northwestern States nearly all our winter-wheat is sown

the first, second, and third week in September. Occasionally, some farmers who like to be ahead of their neighbors sow in August, but four times out of five the later-sown wheat, on good land, proves best at harvest.

Pickling Wheat to Prevent Smut.—Moisten the wheat with fermented chamber-lye, and dry it with lime. Or, take three ounces of blue vitriol and dissolve in one quart of boiling water, for each bushel of wheat.

Drilling in Wheat.—This is by far the neatest way of putting in wheat, and when the land is dry it often makes all the difference between a good and poor crop.

Quantity of Seed per Acre.—Our own rule is two bushels per acre. Thick seeding favors early ripening. Many excellent farmers think 1 1/2 bushel per acre is a plenty of seed, and when the land is rich, clean, mellow, and moist, we have seen heavy crops obtained from a bushel to the acre.

Wheat likes a Firm Soil, but we prefer to have it mellow underneath and somewhat cloddy on top, rather than to have the surface very fine and the bottom hard and dry.

Harrowing Wheat in the Fall to Kill Small Weeds is very common in England, and is well worthy of a trial here. Any fine-tooth harrow will answer, but those of our readers who have Thomas's Harrow will, we think, find it just the thing for the purpose.

Sowing Grass Seeds with Wheat.—Where the wheat is to be harrowed, either in the fall or spring, we must give up sowing timothy with the wheat. We do not think this a serious objection, especially where clover is largely sown on the wheat in the spring.

Sowing Grass-Seed Alone.—This is a good practice, and one which we should like to see greatly extended. The ground should be very fine and mellow. The earlier the seed is sown in September the better.

Rye.—This crop may be sown any time this month, or as late as October. Where the straw is in demand, it is often a very profitable crop, and can be grown on soil too light and sandy for winter-wheat.

Fall Plowing.—Except on very light land, there can be no doubt of the advantages of fall plowing. The earlier the work is performed the better will the soil rot, and the more weeds will be killed.

Clover-Seed.—The most convenient way of cutting clover-seed is with a mowing-machine and a reaper platform which carries the clover into heaps or windrows. If the clover is heavy and green, the

crop may be cured partly for hay and partly for seed. That is to say, if properly cured, it may be worth thrashing for seed, and the clover-seed straw will be valuable for fodder. In this case, the better way is to make the crop into good-sized cocks, and let it cure with as little exposure to rain as possible. In other words, cure it as you would hay. But where the crop is grown simply for seed, the more it is exposed to rain the easier it will thrash and hull. Let it be thoroughly dry when drawn in, and if possible put it in the barn. It is one of the very worst of crops to put in a stack. Unless it is thatched, it is almost impossible to so make the stack that it will shed water.

Cutting up Corn.—We usually take five rows. Commence on the center row, and cut two hills, and stand it up against the third hill, which is left uncut to form a support for the stook. Twenty-five hills are placed in a stook. Make it as upright and compact as possible. Bind firmly with two bands. Where corn is to be husked with a machine, it is much the better plan to bind the corn into sheaves or bundles of a convenient size to pitch and haul. Corn may be cut as soon as it is glazed, or when there is no appearance of milk in the kernel. It is better to cut a little too early, than to run much risk of having the fodder injured by frost. We need hardly say that frost does not hurt the stalks after the corn is cut, but an early frost while the corn is standing and full of sap greatly lessens the value of the fodder.

Cultivating Corn-Stubble.—As soon as the corn is cut, it is an excellent plan to cultivate the land between the stooks with a good two-horse cultivator. We have practiced it with advantage.

Digging Potatoes.—We would dig potatoes as soon as they are ripe. October and November are busy months, and it is very desirable to do as much work as possible while the weather is favorable and the days long. Cart the potato-vines into the barn-yard. They make excellent manure.

Thrashing.—See Hints for last month.

Grain in the Granary should be watched, and if there is indication of its heating turn it at once.

Rats and Mice should be looked after. Keep two or three good cats about the barns.

Fattening Pigs.—Pork is low, but so also is corn. At this season, seven bushels of corn should produce 100 lbs. of pork, or if the pigs are running in a good clover pasture, three or four bushels of corn fed in addition to the clover should give a gain of 100 lbs. in live-weight. It is a great mistake not to give fattening pigs nearly or quite all the corn they will eat at this season while running in pasture.

Sheep.—Those intended to be fattened next winter should be separated from the rest of the flock, and be allowed a good pasture. It does not pay to try to fatten poor sheep in winter. Ewes intended to raise early lambs for the butcher should have extra feed for a few weeks before turning the ram into the flock. If you have neglected to mark your sheep, neglect it no longer. Wethers may be marked on the rump, and ewes on the sides, or in any other way most convenient for distinguishing them. And those you intend to sell should be marked in such a way that they can be easily separated when a purchaser wishes to examine them.

Horses.—If grass is abundant, let the horses run out, but if regularly worked they should be allowed grain and hay in addition. It costs so much to keep horses, that the rule should be to keep only such as are capable of doing a good day's work. Feed liberally, work steadily, and groom thoroughly.

Milk Cows.—Bran and corn-meal are comparatively cheap. A good cow should have all the food she can eat, digest, and turn into milk, and if she gains in flesh at this season it will not hurt her.

Young Stock should have the best of care and feed. Nothing is more unwise than to starve a young, growing animal.

Weeds.—The destruction of weeds is always in order. Let none go to seed in fence-corners, in pastures, or on the sides of the road, or around stone heaps or other waste places.

Pasturing Young Clover.—If the growth is very large, it will not hurt young clover to pasture it moderately. But if it can be spared, it is best not to turn anything into it.

Plaster.—If you have leisure, it is a good plan to sow plaster on the clover. It will do full as much good sown now as in the spring.

Buckwheat.—See article on harvesting this crop in the August number of the *Agriculturist*. Our own plan is to cut it with a reaper. Wood's Reaper, by taking off the reel, will do the work, but a Johnston Reaper will cut buckwheat better than it can be done with a cradle, and lay it off in bundles of any desired size. If ripe enough to shell, cut when the dew is on.

Work in the Horticultural Departments.

Now that the warm summer weather is over, the gardener may prosecute his planting and harvesting with renewed vigor. There are many varieties of vegetable and flower seeds which do best when planted in the fall. The annual fairs of the agricultural and horticultural societies are sources of great pleasure and profit to the gardener. The numerous books and papers relating to horticulture are now so cheap that any one of moderate means can supply himself with an ample stock of reading for the winter and during the long evenings of late fall and early spring. The evenings can be profitably employed also in writing out an account of the operations of the year. This no intelligent man will fail to do, however unnecessary it may seem at first. In the extended account of several years its advantage becomes apparent, and by means of it he will be able to profit by the various successes or failures which have attended him.

Orchard and Nursery.

Harvesting and marketing will be the principal work to attend to in this department. Care must be used in picking to keep the fruit free from bruises. Always pick the fruit carefully by hand, and never shake it off, as is too often done. The assorting is also a matter of a good deal of importance, as the money returns depend upon the quality of the fruit. Make at least two qualities, and on no account mix the good and bad. The increased price of the first quality will more than pay for the trouble of assorting.

Dried Apples.—Many windfalls, and fruit unfit to ship, and too good to put with the cider-apples, may be dried and put away for use during the spring, when there is little fruit to be had.

Budding.—Stocks which were budded last month will need to have the ties cut now. See article on budding on page 343.

Nursery Stock.—If any nursery stock is needed, order early, so that no delay will occur when the ground is ready for planting. Should the trees come before the ground is ready, heel them in to keep the roots from drying.

Seeds should be secured now. Peach and other stone fruits are to be mixed with earth and buried in the open ground; in the spring many will be found to have commenced growing.

Fruit Garden.

Where the winters are not very severe, fall planting is desirable, as it gives the plants ample time to become established, so that they can commence their growth early in the spring. In localities where the winter sets in early, planting had better be deferred until spring.

Blackberries.—As soon as the canes have done fruiting, cut them away, and dig up all suckers which appear between the rows. Tie up the new growth to stakes five feet high, and cut back the side shoots to eighteen inches. Three or four canes are enough to a stool.

Raspberries.—The old fruiting canes must be treated the same as recommended for blackberries.

Black-caps.—To propagate these, bend down the

tips of the canes, and throw a little earth over them to keep the wind from moving them. When treated thus they soon take root, and in spring may be severed from the old plants and set out in rows in rich soil. In tying up the new growth, a wire stretched tightly along the rows, and securely fastened at each end to posts three feet high, is much more durable than wooden stakes.

Strawberries.—Fill up the vacancies in the old beds from plants rooted in pots, or from well-rooted runners, and set out new beds where wanted. Before planting, dip the roots in thin mud.

Grapes.—The grape crop will be ready for harvesting this month, or at least a part of it, and care must be taken not to break or injure the bunches in any way. Use scissors in gathering, and do not handle the fruit much, as it injures the bloom. Grapes intended for home use are the best when allowed to remain on the vines until fully ripe.

Gooseberries and Currants.—Make cuttings as soon as the wood is thoroughly ripe, and either set them in nursery rows or tie them in small bunches, and bury them in earth in a cold-frame or in the cellar.

Kitchen Garden.

As fast as a crop matures it should be harvested, and the ground plowed and manured, and other quick-growing or winter crops planted.

Beans.—Gather string-beans from the later plantings, and salt them for winter use. Dry plenty of Limas and other pole sorts; they form a pleasing variety in the winter bill of fare.

Cabbages and Cauliflowers.—Sow seeds of these at the North about the middle of the month for the spring crops, in order to get good strong plants before the ground freezes. These plants are afterwards set out in cold-frames, and kept as nearly dormant as possible until it is time to set them out in the spring. The seed-beds should be well prepared before the seed is sown, and the plants afterwards thinned and weeded as in spring.

Corn.—Dry a supply for winter, using that which is just fit for the table. Boil it long enough to set the milk, and afterwards cut it from the cob.

Cucumbers for pickles ought to be gathered every other day, those of small size being preferable, at least so far as appearance goes. While gathering, take care not to injure the vines by trampling.

Celery grown in flat culture should be kept well cultivated.

Melons.—Pick off all fruit which will not ripen, and use for mangoes. A thin piece of board placed under the fruit will insure even ripening.

Martynias.—There are comparatively few persons who have eaten good pickles unless they have tasted of martynias. They should be pickled before the skin becomes hard, and placed in a brine the same as cucumbers; they are afterwards put into sugared vinegar, and flavored with cloves, allspice, etc., according to taste.

Onions.—When the tops have fallen, it is time to harvest them. Do not store in large heaps, but spread thinly in a dry, airy place.

Radishes.—Sow Chinese Rose-colored Winter Radish for winter use this month.

Shallots.—Plant in rows one foot apart; allow six inches between the bulbs. Keep clear of weeds as long as the ground can be worked. A slight covering of hay is beneficial.

Spinach may be sown for wintering over; sow in 15-inch drills, and if too thick the rows may be thinned and the thinnings used.

Sweet-Potato Vines must be lifted occasionally to prevent their rooting. Keep down all weeds between the rows.

Squashes.—The early summer sorts which have done bearing should be pulled up, and not be allowed to remain a breeding nest for insects. Allow the vines of the winter sorts to root freely at the joints, and do not disturb them after they cover the ground, as they are often injured if handled roughly.

Tomatoes.—If there is a surplus of ripe fruit, it

can be canned and preserved for winter use. Place either straw or brush around the plants to keep the fruit from touching the ground and decaying. Destroy all green "worms" found upon the vines.

Turnips.—Use the hoe between the rows of ruta-bagas. Sow flat sorts early this month.

Flower-Garden and Lawn.

A large number of annuals and bedding plants will make the garden attractive at this season if plenty of them were planted out in the spring. Pull out all weeds from the beds and borders.

Bulbs.—The hardy bulbs may be planted late this month or early next. Make the beds planted rich by the addition of well-rotted stable-manure.

Dallias and all plants requiring stakes must be attended to at once, before the high winds have broken or otherwise disfigured the plants.

Herbaceous Perennials do best when moved in the fall, as they then have time to recover and form new roots ready for an early start in the spring.

Pits and Cellars for preserving half-hardy plants should be put in order, so that they may be ready in case of an emergency.

Gladiolus should be tied up to stakes, as they are very easily broken by the wind.

Perennials and Biennials.—Sow seeds of these in pots or boxes of well-prepared earth; this is a much better way than sowing them in the open ground, unless one has a great many seeds. Keep the pots and boxes watered, and if the sun is too hot they may be sheltered by a lattice or wooden shutters.

Greenhouse and Window Plants.

All alterations and repairs ought to be finished by this time, so that in case of a sudden frost the tender plants can be carried into the greenhouse. Plenty of coal, soil, and everything necessary must be provided at the earliest opportunity.

Potting of plants that have been turned out into the border needs attention, and also the potting of plants which are to be used for propagating from.

Annuals.—Plant seeds of these for early winter flowering; Mignonette, Sweet Alyssum, Candy-tuft are the sorts usually planted.

Hanging-Baskets and Window-Boxes.—Refit these early, in order to get a good start before cold weather.

Cuttings of bedding plants may be put in if any young plants are wanted for house decoration.

Commercial Matters—Market Prices.

Gold advanced to 115 1/4 @ 115 3/4, closing August 13th at 115 1/4 against 114 1/4 on the 13th of July. Flour has been in better demand and has been much firmer in price, with lighter supplies available of desirable brands. The Wheat stock has been reduced to an unusually limited amount, and prices have advanced materially, checking business, though there has been a fair export and moderate home demand. Corn has been in brisk request and dearer. Rye and Oats have been more sought after at stronger rates. Provisions have been more freely dealt in and quoted firmer. At the close other than the finer makes of Butter were difficult to market; and most grades of Cheese were weak and drooping. Hay and Tobacco attracted more attention on the basis of our quotations. Hops and Seeds quiet. Domestic Fleece Wool has been moving slowly in most instances. Holders have been somewhat more confident in their views, and insisting on full asking rates on restricted offerings of stock, thus checking operations. Manufacturers have not been eager to make purchases beyond the limits of present requirements. The trade bids have been reserved, and generally under the views of sellers. Domestic Felled has been in light request within the previous nominal range. Texas Wool has met with a moderate call, particularly grades available at from 35c. @ 45c. Oregon Wool has been in some demand and about steady. California Wool has not been in much favor with buyers, especially spring clip, the chief inquiry having been for fall clip, at the ruling figures. Cotton has been depressed and lower, closing about steady. The following condensed, comprehensive tables, carefully prepared specially for the American Agriculturist,

show at a glance the transactions for the month ending August 13, 1872, and for the corresponding month last year.

TRANSACTIONS AT THE NEW YORK MARKETS.

Table with columns: RECEIPTS, FLOUR, WHEAT, CORN, RYE, BARLEY, OATS. Includes data for 26 days ending 1872 and 27 days last month.

Table with columns: SALES, FLOUR, WHEAT, CORN, RYE, BARLEY, OATS. Includes data for 26 days ending 1872 and 26 days last month.

Exports from New York, Jan. 1 to Aug. 13.

Table with columns: FLOUR, WHEAT, CORN, RYE, BARLEY, OATS. Shows monthly export data from 1872 to 1868.

Receipts at head of tide-water at Albany each season to July 25th.

Table with columns: FLOUR, WHEAT, CORN, RYE, BARLEY, OATS. Shows monthly receipt data from 1872 to 1870.

Stock of grain in store at New York.

Table with columns: WHEAT, CORN, RYE, BARLEY, OATS, MALT. Shows stock levels for 1872 and 1871.

CURRENT WHOLESALE PRICES.

Large table of current wholesale prices for various commodities like Gold, Flour, Wheat, Corn, etc., with columns for July 13 and Aug. 13.

New York Live-Stock Markets.

Table showing weekly ending prices for Beesves, Cows, Calves, Sheep, Swine, etc., from July 15th to August 12th.

Table showing average per week prices for Beesves, Cows, Calves, Sheep, Swine for the current week and previous weeks.

Beef Cattle.—Soon after the close, one week ago, the markets began to improve, and now we have a strong, active trade, with all that was lost during the first week or two fully restored. There are a great many Stock Markets

coming forward, some of them very green, and have to be sold low, but well-matured stock sells even better by contract. Fat Illinois, Ohio, and Kentucky grades readily command 13c., while the best selections sell at 13 1/2c. The bulk of Texas go at 8 1/2c. @ 9 1/2c. Sales were made below 8c. in one of the glutted markets. More than 300,000 Texas have already been driven into Kansas this season, and they are still coming, showing that this is an important branch of the trade.

The prices of the past 5 weeks were:

Table showing price ranges for Large Sales and Average prices for various dates from July 15 to Aug. 13.

Milk Cows.—Seldom have we had so bad a cow trade at any season of the year, much less in hot weather, when the demand for milk is usually such that all the producers are anxious to add to their stock of milkers. Milk has sold at \$1 @ \$1.25 per 40-quart can, much of the time during the past month, which leads those in the business to lessen rather than increase the number of cows. Common cows sell at \$25 @ \$40, fair at \$50 @ \$60, and good to prime at \$65 @ \$70. Calves.—There was a good demand for veals during the first half of the month, and prices improved. Fat milk calves sold at 10c. @ 10 1/2c. Just now there is a surplus, especially of grass calves. The latter sell very low, and ought not to be sent in, or, if they are, farmers should buy them for raising. Quotations of grass calves are 2 1/2c. @ 3 1/2c. per lb., live weight; common to fair milk veals, 7c. @ 8 1/2c.; good to choice, 9c. @ 9 1/2c. Sheep and Lambs.—We have had an increase in numbers and not much variation in the price of sheep, but lambs are very much lower, and glut the market. They are coming from the West, but largely from this State, from Canada, and from Kentucky. Fat sheep reached 7c., and even 7 1/2c., a fortnight ago, but it now takes good lots to sell above 6 1/2c. The majority of the lambs sell at 8c. @ 9c. Quotations: Ordinary sheep, 5c. @ 5 1/2c. per lb., live weight; fair to good, 6c. @ 6 1/2c.; prime to extra, 6 1/2c. @ 6 3/4c.; few very choice, 7c. Lambs, 7c. @ 7 1/2c. for poor; 8c. @ 8 1/2c. for medium to good, and 9c. @ 9 1/2c. for extras. Swine.—With lighter receipts hogs have improved in price. They are now being sold alive, and the close is strong, with rather an upward tendency. Live are worth 4 1/2c. @ 5c. city-dressed Western, 6 1/2c. @ 6 3/4c.

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Remitting Money:—Checks on New York City Banks or Bankers are best for large sums; make payable to the order of Orange Judd & Co. Post-Office Money Orders, for \$50 or less, are cheap and safe also. When these are not obtainable, register letters, affixing stamps for postage and registry; put in the money and seal the letter in the presence of the postmaster, and take his receipt for it. Money sent in the above three methods is safe against loss.

Postage: On American Agriculturist, 3 cents a quarter, in advance; on Hearth and Home, 5 cents per quarter. Double rates if not paid in advance at the office where the papers are received. For subscribers in British America, the postage must be sent to this office for prepayment here.

Bound Copies of Volume Thirty are now ready. Price, \$2, at our office; or \$2.50 each, if sent by mail. Any of the last fifteen volumes (16 to 30) will also be forwarded at same price. Sets of numbers sent to our office will be neatly bound in our regular style, at 75 cents per vol. (50 cents extra, if returned by mail.) Missing numbers supplied at 12 cents each.

Clubs can at any time be increased by remitting for each addition the price paid by the original members; or a small club may be increased to a larger one; thus a person having sent 10 subscribers and \$12, may afterward send 10 more subscribers with only \$3; making a club of 20 at \$1 each; and so of the other club rates.

State and County Fairs.—According to our usual custom we give, on pages 353 and 354, a list of the Fairs to be held during the present month and the two following ones. The preparation of a list of this kind demands a great deal of patient labor, and we have endeavored to make it as perfect as possible. If Secretaries would send us notice of their Fairs earlier than most of them do, our list would be very satisfactory.

Whiskey Pickles.—Several correspondents have asked how to make whiskey pickles. We have had no experience in making pickles in this manner. A correspondent of the Rural New Yorker gives the following: "Take one gallon of whiskey and three of water. Put into a tub or cask as you pick them, the cucumbers; put them in the pickle and cover with a cloth, which will have to be washed every few days, as often as the mold gathers on it. That is the way I did and had splendid pickles. You must use pure whiskey." In this process the vinegar is made in contact with the cucumbers. All vinegar comes from the decomposition of alcohol, whether made from cider, wine, molasses and water, or by whatever process. In the above a dilute alcohol—probably through the influence of the fermenting matter in the cucumber—becomes converted gradually into vinegar. The process does not seem to be an economical one.

Preserving Okra.—"J. T. S.," Sullivan Co., Mo. Okra is preserved by slicing the pods (tender and fit for the table) crosswise in sections about half an inch long, running them upon a string and drying them in the sun. When wanted for use they are soaked until soft. Besides its use in soups and stews, fresh okra is liked by many boiled and dressed with drawn butter in the manner of asparagus.

Lombardy Poplars.—"E. E. W.," of Nebraska, asks: "How far apart should Lombardy poplars be planted to appear best as a feature in the landscape on a rolling prairie. I wish to set out a single row for three quarters of a mile, in the shape of a carpenter's square."—We should say that fifty miles was near enough for Lombardy poplars in Nebraska or anywhere else. A more worthless tree can not be planted. It makes an insufficient wind-break, and is almost valueless as timber and fuel. Besides, it is excessively ugly, having no more beauty than a telegraph-pole. A plantation of the size proposed would be "a feature in the landscape" that would be horrible to contemplate. Plant Silver Maple, Black Walnut, White Willow, or even Cottonwood or Ailanthus, but don't disfigure your place with miserable Lombardy Poplars.

A Book on Gardening—How Not to Do.—We print the following as a specimen to show the queer things people will do, and how they seem to take pains to defeat their own objects: "May 23. Would you please tell me in your next issue of *American Agriculturist* where to get a good book, not too expensive, about gardening? If you have any in stock, please let me know the price. Yours respectfully, W. C."—Had the writer signed his name we could have sent him a marked catalogue, and he would not have been obliged to wait until September for an answer. Even now we do not know whether he wants a book on kitchen, fruit, flower, or vegetable gardening. Month after month we advertise the largest collection of works on gardening in the country, and yet our correspondent writes to know where to get one. We have hundreds of just such indefinite letters. If "W. C." will tell us what he wants, we shall be very glad to reply. "A. E. S.," who writes for Pastel Board, may consider the above. Had he sent his name we should have replied by letter. We do not answer purely personal matters through the paper.

Landscape Gardening.—The author of that valuable work, "Beautifying Country Homes," Mr. J. Weidenmann, having returned from a residence of some years abroad, is again practicing his profession in Hartford, Ct. Mr. W.'s work at Hartford and elsewhere attests his ability, and those who wish to consult a landscape architect can be sure of being well served if they apply to Mr. Weidenmann.

Castor Beans.—"D. W.," Polk Co., Texas. There are several kinds of beans cultivated for ornament, but, so far as we are aware, only one species is grown for commercial purposes. As this is a plant largely affected by climate, it would be advisable for you to procure seed that has been found profitable in your State. Probably your seedsmen could supply you. The pomace or cake, after the oil has been expressed, is of positive value as a fertilizer. It contains a large amount of nitrogen, and forms a highly stimulating compost.

Rock Oil for Caterpillars.—Jas. H. Robinson, Lawrence Co., Pa., writes that for the last eight or ten years he has used crude rock-oil with great success. He keeps a vessel of oil at hand, and when he discovers a caterpillar's nest, he applies the oil by means of a quill. He also uses it effectively for worms that molest his grape-vines. The oil he uses is the Mahoning crude oil, and no injury has resulted from its application. Whether this particular kind of petroleum is different from that from other localities, we are not informed. The

use of petroleum in general upon plants has been attended with variable results—sometimes injury has been done, while others, like Mr. R., use it with impunity. This induces us to think that there is a difference in petroleum as far as its influence upon vegetation goes.

Agricultural Colleges.—The "Kansas Farmer" is doing a good work in showing up the manner in which in several States the Agricultural College Fund has been misappropriated. It is through the efforts of this paper that the management of the Kansas College has been kept out of the hands of lawyers, doctors, and antiquated clergymen.

Crops in Southern Ohio.—Col. J. T. Worthington, of Chillicothe, writes: "The hay crop is short all over Southern Ohio, wheat very good in quality but not over two thirds of an average in quantity. Our main crop, corn, promises well, and will probably be over an average. We have a fine fruit year. Apples, peaches, pears, grapes, melons, and figs are doing or promising well."

Budding.—In the article upon "Propagation by Budding," pages 343 and 344, it should have been stated that figure 1 was from "Warder's American Pomology," figures 2, 8, and 9 are from Mr. Fulton's very thorough work upon "Peach Culture," and figures 3 to 7 from "Barry's Fruit-Garden," a work that should be in the hands of every one who wishes to propagate or grow fruit trees. There is no other work that contains so much of just the information that every grower of fruit, whether on the large or small scale, requires.

English Gardeners in America.—Our associate, Peter Henderson, now in Europe, has written an article to "The Garden" with the above title. Its object is to give advice to English gardeners who propose emigrating to this country. One point that he particularly insists upon is that they should not arrive here during the summer and fall months. In February and March labor is always in demand, and there is no difficulty in obtaining places, while at other seasons it is very rare that a competent man can find a situation. He also advises men with families not to come out unless they have first engaged a suitable place.

Wire for Pegs and Stitches.—The American Cable Screw Wire Co. manufacture boots and shoes in which a screw-twisted wire takes the place of pegs or stitches. A trial of these goods for several months past, and the testimony we have from dealers, proves this method of fastening soles to be a good improvement. There is no ripping; the wire holds until the sole of the shoe is fairly worn out.

Sowing Clover on Timothy.—"B. H. W.," Iowa City, Iowa, asks if he can get a catch of clover on a timothy meadow, by sowing the seed on the snow. It would be better to wait until the sod can be harrowed in the spring as early as possible, and sow six quarts of clover per acre, immediately afterward, and then run over the field with a brush harrow.

Injury to the Hoof.—"J. G.," Macon Co., Mo., has a horse which injured its hoof, and proud flesh has appeared in the wound. He wants to know what to do in this case. A solution of sixteen grains of chloride of zinc in a pint of water, applied as a wash to the wound, would probably remove the proud flesh and cause a healthy action.

Jersey Cattle.—Col. Waring, of Ogden Farm, Secretary of the American Jersey Cattle Club, has edited a very comprehensive essay on this breed, as a contribution to the first volume of the Club's Herd Register. This essay is now published in pamphlet form, together with the Constitution of the Club; a list of its members, with their addresses; and instructions for offering pedigrees for registry. The price is 50 cents, by mail, post-paid; for sale by Orange Judd & Co., 245 Broadway, New York.

Parsons & Co.—This well-known firm has dissolved, and formed two separate establishments. The extensive stock of evergreens, rhododendrons, camellias, and other specialties, has been divided between the two new firms, Samuel B. Parsons & Sons, and Robert B. Parsons & Co., both of which will carry on the business in Flushing.

Jersey Herd-Book.—R. Q. Teuney, Colorado. The cost of a record in the "Jersey Herd-Book" is two dollars.

Smith's Traveling-Chairs for Invalids.—It often happens that invalids who are unable

to walk, and persons who have received injuries, retain considerable strength in their hands. All such can enjoy the pleasures of locomotion in-doors and out, by using Smith's chairs. These are made of different sizes and patterns, but the principle is the same in all. There are large driving wheels which are easily moved by the hand, and the contrivance for changing direction is very simple and easily managed. Hundreds of invalids would derive great comfort from a chair of this kind.

SUNDRY HUMBUGS.—"Stealing the Livery of Heaven" to serve mammon, is variously practiced. We don't like to throw a straw in the way of securing wide contributions to assist feeble churches, and, whenever there is a spare dollar in the exchequer, we enjoy taking a hand in any effort to establish a beacon-light of the gospel in a dark corner. But those who send out circulars to the general public, asking for small sums in aid of churches, will need nowadays to furnish pretty strong evidence of the genuineness of such appeals, and that the money will be properly used, because sordid thieves, locating themselves in out-of-the-way places, make up very plausible appeals for such objects, which are well calculated to deceive unwary benevolent people. The money generously sent to aid such churches is pocketed by pseudo "treasurers," who usually assume a name of the feminine gender. We have exposed some such operators, and have before us circulars not yet investigated fully, that are suspicious, to say the least. In one case of this kind we wrote for information, and received an answer "All right," but, as it afterwards appeared, our letter was intercepted and answered by the operator himself. Every leading Christian denomination has a regular organization (called Church Extension Society, or similar name), which will receive and properly apply contributions of this kind. . . . Another Thief of Heaven's Livery is the following:

TO CONSUMPTIVES.—The advertiser, having been permanently cured of that dread disease, Consumption, by a simple remedy, is anxious to make known to his fellow-sufferers the means of cure. To all who desire it, he will send a copy of the prescription used (free of charge), with the directions for preparing and using the same, which they will find a **SURE CURE FOR CONSUMPTION, ASTHMA, BRONCHITIS, &c.** Parties wishing the prescription will please address: **REV. EDWARD A. WILSON, 194 Penn street, Williamsburgh, N. Y.**

This fellow has been operating for many years. We have often exposed him, but he still finds plenty of ignorant dupes, for we see the above advertisement in many papers, marked to be inserted for a whole year, and he has paid a great many thousands of dollars for advertising, all of which has of course come out of the pockets of poor, deluded sick people, or those who think they are sick. This so-called Rev. Wilson claimed to belong to the "Methodist New Haven Conference," until we published the fact that there was no such conference known to Methodists, since which time he has used other subterfuges. In his circulars he talks very sanctimoniously, and works upon the feelings of his patrons—says "he sends the prescription to consumptive sufferers, not from any mercenary or selfish motive, but from a sense of Christian duty," etc., etc.—a lot of bosh that ought to put any intelligent person on his guard. For the benefit of our newer readers, we republish his prescription as he now gives it to those who answer his advertisements:

Extract Blodgett's, 3 ounces; Hypophosphites of Lime and Soda, $\frac{1}{2}$ ounce; Alutln (pura), 1 drachm; Meconin (pura), $\frac{1}{2}$ scruple; Extract Cinchona, 2 drachms; Loaf Sugar, 1 lb.; Pure Port-wine, $\frac{1}{2}$ pint; Cold Water, 1 quart. Mix well, &c. Dose, one large table-spoonful before each meal, and a fourth one before going to bed. This for adults. For delicate females, and persons under 18, one third less for the first week.

There you have what the very Rev. fellow pays thousands of dollars in advertising, to inform you you can get free by sending to him. We make you no charge for giving it to everybody free. But we will just hint that you can not get any such dose put up by a druggist, even if it were worth buying. But here comes the benevolent, very Rev. Wilson (so called), and offers to supply it to you for \$4, you paying the express; or, he will send all *except* the wine, sugar, and water, by mail, post-paid, for \$3.50; and here is where the "prophet" comes in to this fellow, who claims to be a "poor man." He is an outrageous swindler, one of that mean kind who work upon the fears and hopes of poor sick people by his hypocritical, pious asseverations, and take from them money which they can ill spare, without returning an equivalent. We are sorry to see editors of respectable papers helping him, by inserting his advertisement—because he divides his profits with them in the form of pay for the use of their columns. . . . And here let us remind the reader that, as a rule, they can place no reliance on quotations from newspapers recommending various medicines, etc. It is a trick of operators to insert notices, letters, and other commendations of themselves, or their wares, in the advertising columns of newspapers, and then give quotations from these advertisements as if they were editorial endorsements. . . . "Married women," and all others, should promptly burn all the printed trash sent them by the fellow calling himself "Madams (Mmes.) Geary,

Stevens & Co.," who, to dodge the surveillance of the New York Post-Office and the new laws of N. Y. State, puts his P. O. address at Jersey City (N. J.) P. O. Their (his) medicines, instruments, etc., if ever sent at all, are villainous, and of no effect except to deceive people into vice and trouble, and put money into his pocket. He operates safely because no one of his patrons would dare to publicly appear as a witness. . . . Why will the press continue to advertise J. H. Reeves, 73 Nassau st., N. Y.? Has he not sent cantharides "love-powders" enough, and cheated enough "victims of early indiscretions," to be shut out of all decent journals? . . . Robt. E. Bell, 147 E. 15th st., N. Y., and what he calls "the Clinton Medical and Surgical Institute," are not found in the New York City Directory. . . . W. H. Chichester has appeared too often in these columns to need further attention from us at present. . . . Hugh Lassing, 170 Broadway, pretends to be Supt. of a Safe Deposit Company, and writes to parties to send him the storage dues on valuable parcels left for them—an out-and-out swindle. . . . Several parties advertise to secure loans, etc., on Southern real estate—always asking from \$5 to \$20 in advance. We have inquired after several of these, and in every case found them swindlers. We advise all who receive such circulars and blank forms of application to give them no heed whatever, and especially to send no money to them, unless through a trustworthy friend in the city, who will go in person and see the parties—if they can find them, which is seldom if ever the case. As a rule, they hither you for particulars, report against your application, and pocket the money you have sent, which is what, and all, they are after. . . . The "N. W. Fire Relief Concert," and "National Benefit for Needy Families of Soldiers and Sailors," 267 Broadway, is an exploded concern, if ever anything but a humbug. . . . An adventurer in Lincoln, Neb., is advertising a \$250,000 legal drawing, ostensibly for the benefit of a City Hospital there. Prudent people will avoid the loss of their money by keeping it out of this concern. If disposed to invest, first write to the Mayor of Lincoln, Neb., and see how much he indorses it. . . . Pardee & Co., Binghamton, N. Y., still operate upon greenhorns, selling them "tickets" at fifteen to twenty-five cents each, which tickets are so many falsehoods, as they promise, for example, that for \$2.24 sent to the said Pardee & Co. you will receive a \$20 watch. Will not the authorities of Binghamton conserve the credit of their beautiful city, and benefit the public by speedily quenching or jugging this swindling concern? We are tired of receiving from all over the State the circulars and tickets sent out by Pardee & Co., so called. . . . R. H. Foster, Fourth street, Williamsburgh, N. Y., is like Pardee, or worse if possible. We thought this swindle dead last year, but we have new circulars dated 1872. He orders money sent to "R. H. Foster, care of Westcott's Express, Brooklyn, N. Y." We hope no decent express company favors this swindle. . . . The "Spanish Policy" swindler, at 16 S. 5th ave., N. Y., works under such new names as C. W. Alter, D. B. White, C. M. Payne, etc. Would it not be well for the N. Y. P. O. to deliver no letters, except for well-known, responsible parties, at No. 16 S. 5th ave., or No. 22 W. 4th st., or No. 34 Amity st., or No. 89 Fourth ave., etc.? . . . Among the names assumed by the "Queen" operators we find for 22 W. 4th st., James Hippel, *alias* B. S. Carey, *alias* F. Benton; at 24 Amity st., Geo. W. Beach, *alias* D. M. Palmer, *alias* James P. Sargent; at 89 Fourth ave., J. E. Morrell; at 23 Wooster st., W. B. Messler; at 105 Bleeker st., Levi P. Rose, *alias* Warner Ely; at 292 Chestnut st., Philadelphia, Brown & Billings. . . . In reference to "Lock-box 26, Lincoln, Ill.," spoken of last month, the Postmaster, H. D. Cadwallader, Esq., writes us that one James P. Freeman edited a little sheet, there called the "Silver Leaf," and took the above box, and that letters were delivered to him on the supposition that they were upon business connected with the paper; but that they are now sent to the Dead-Letter office. All right; we are glad for the credit of both the people and the Postmaster that they are rid of that discreditable nuisance. Of the political operations of Freeman we have nothing to say in this journal, because we admit no political matters or allusions whatever. . . . John M. Tullman, 3 Dutch st., N. Y., is on a stealing raid. No one offering such vile hooks as are named in his circular would hesitate a moment to steal and appropriate every penny sent to him. Wesley Smith, of Palatine, Cooke Co., Ill., is no better. Let no one be deceived by his "Private Instructions." He will pocket your money, or at most send you a small, villainous sheet, unreliable, deceptive, and dangerous.

The Old Trouble.—"J. M.," Camp Hill, Pa., has the same trouble we all have—want of manure—and wants to know how he can get over it. His rotation is that usual in the East—corn, oats, wheat, grass, with manure on the oat-stubble; and he asks would 300 pounds of superphosphate, at three cents per pound, pay to use.—"J. M." should read the article in this present number of the *Agriculturist*, "Hints about Wheat," which will

convey the information wanted. It will be useful for him to consider whether it would not pay to put all his manure on half his land, and raise larger crops, and so gradually increase his supply of manure.

Hay-Press.—J. Newton, Alstead, N. H., writes us that there is a hay-press made in Albany, N. Y., which will pack 500 pounds in a bale. This is intended for the benefit of G. L.

Salt.—"A Young Farmer," Chester Co., Pa., asks what is the effect of salt on land.—Practically, salt is found to stiffen the straw of grain crops, and to increase the amount of the clover and grass crops. This is doubtless due to the fact that water in which salt is dissolved is able to dissolve more silica than pure water, and this helps to improve the straw, the ash of which consists almost wholly of silica; also, salt enables water to dissolve more gypsum, or other forms of lime which improve the crops of grass and clover. Thus far we can speak understandingly, but little further, as salt itself, or its component substances, chlorine and soda, are but very sparingly found in the substance of plants grown on farms.

Fair Lists.—For very full list of Fairs see pages 333 and 334.

About Beans.—A. Chavannes, Knoxville, Tenn., wants to know all about gathering beans and keeping them from the weevils. Beans should be gathered by pulling them up by the roots when they are ripe, leaving them on the ground until dry, or, if there is danger of rain, stacking them around a pole five feet long stuck in the ground, in tall narrow stacks, and capping them with straw, until they are ready to thrash. They should be well preserved from rain, as their color is much injured by damp or mildew. The weevil gets into the bean during its early growth, when the pod is soft, at which time the parent beetle deposits its egg in the pod, and the grub eats its way into the bean, where it remains until the next spring. Therefore no management after harvest can affect it.

Fish-Nets and Sheep-Nets.—The various inquiries about fish-nets and nets for folding sheep on pasture need illustrations for satisfactory replies; and these require time to prepare. We shall endeavor to have these in season.

Size of a Quart Measure.—"J. C. B.," Eau Claire, Wis., asks what is the size of the quart used by milk dealers.—The quart is the fourth part of a gallon. A gallon, by United States law, in force where no conflicting State law fixes any other standard, is 231 cubic inches, and contains 8.355 (eight and three hundred and fifty-five thousandths) pounds of distilled water at a temperature of 62°. This measure is, or ought to be, used by milk dealers and all sellers of liquids.

A Leaky Cistern.—R. Ripley, Brown Co., O., has a cistern, in the bottom of which a vein of water has forced its way through the cement, and now the soakage from the barn-yard finds its way into it; how shall he remedy it?—There is no remedy but to dig a new cistern. Where a stream of water is cut it is useless to try to keep it out; it will work through sooner or later, unless means are taken which will be more troublesome than making a new cistern.

Pumping by Clock-Work.—Geo. E. Johnstone, Louisville, asks if it would be practicable for a machine run by weights to pump water from a well, and to raise in twenty-four hours 100 gallons to a height of 35 feet.—This is perfectly practicable and easy, and a machine on the principle of that figured in the *Agriculturist* of March, 1872, page 97, to be wound up by a horse, might be constructed at a slight cost, that would run twenty-four hours, and do the work required.

Weather Indicator.—"A Reader" wants a cheap weather indicator that will foretell rain and storms. A barometer is the most reliable. The cheap weather indicators soon become useless, and are not to be depended on at the best.

Tanning.—"T. S. S." sends the following directions for preparing skins when, as it often happens, "brains" can not be procured for dressing them: If the skins are dry, soak them two or three days; then break them—that is, rub them on the flesh side with the back of a fleshing-knife until they are perfectly soft. Remove the hair by immersing them in lime-water. Then steep them a week or ten days in a fermenting mixture of bran, say two pounds of wheat-bran to every gallon of water. Then scrape and clean them, and put them into what is called the "white bath," composed, for one hundred deer or sheep skins, of a boiling solution of twelve

to eighteen pounds of alum in twelve gallons of water, to which add two and a half pounds salt. Pass the skins separately through the bath, and then immerse the whole together for ten minutes. A paste is then made, by gradually adding, during careful stirring, first fifteen pounds of wheat-flour to the above alum bath, gently heated, and subsequently the yolks of fifty eggs, and then incorporating the whole thoroughly. The skins, after being passed through this paste singly, are then transferred to it in bulk and left for twenty-four hours. They are then stretched on poles to dry, when they are worked on the "softening iron"—that is, rub them over a shovel or any kind of round iron to stretch them and develop whiteness. They will be white as snow and soft as velvet. Color can be imparted with dye stuffs.

To Remove a Cow's Horn.—"R. M. H." wants to cut off a cow's horn which grows too close to her face, and wants directions.—If the end of the horn only requires removal, merely sawing it off with a fine sharp saw will be sufficient. But the lower part of the horn is filled with a sensitive cellular substance, and if the horn needs cutting there the animal must be secured, and when the horn is removed by means of the saw the stump must be bound up with a cloth saturated with tar to exclude the air, when the wound will gradually heal over. The same treatment should be applied to a horn broken off at the lower part.

Ventriloquism.—"Sailor-boy." This is something so far out of our line, that we are unable to give you any advice about it.

Colorado Wheat.—Spring wheat raised by irrigation in Colorado the past season, stood five feet five inches in height.

New York State Poultry Society.—The Semi-Annual Meeting of the New York State Poultry Society was held at their rooms, No. 27 Chatham street, New York, on Tuesday, July 9th. After some preliminary business, it was "Resolved, That the business of the Poultry Bulletin having become a burden on the Executive Committee, and personally upon the Treasurer, if, in the judgment of said Committee, any arrangement can be made for the conducting of the Journal by another publisher, they are empowered to take any action they deem best in the premises, considering the interests of all concerned." The time and place for the next Exhibition were then considered, and it was finally "Resolved, That this Society do not now decide upon holding an Exhibition, but that the whole subject be referred to a special meeting of the Society, to be called by the President, and held at Elmira, N. Y., on Wednesday, October 2d, at 2 o'clock p.m., during the Annual Fair of the New York State Agricultural Society."

Pickles.—G. W. Drew, Menomonee Co., Mich., and several others. All that we know about the pickles "such as you see in the stores," is that they are put up in perfectly white vinegar made from whiskey. Pickle-making is a trade that has to be learned the same as the confectioner's, baker's, or similar trades. If you wish to go into the business, it would be best to employ a workman who understands it.

The Best Breed of Dogs.—"A Sailor-boy," of Canada, wants a dog of the best breed for a watch-dog, one that is faithful and kind.—Old Dog Tray would just suit him, "for he was faithful, he was kind," but we believe he is dead, unfortunately, and there is no help for the sailor-boy but to get a Newfoundland dog. Bot, like all other dogs, they like mutton "ow'er weel."

Plowing Under Weeds.—"H. H. H.," Fennville, Mich., sends us a plan of plowing under weeds and long grass, which we supposed everybody knew of, but as he thinks it new perhaps it may be worth repeating. It is to hang a chain from the plow-beam near the conter to the right-hand end of the evener, and allowing it to drag in a loop in the furrow, so as just to clear the falling earth and drag the weeds under it.

Level for Irrigation.—"R. Q. T.," Fort Collins, C. T., asks if there is any simple instrument that can be used for taking levels for irrigation, which would serve the purpose of the costly surveyor's level. A very good substitute for the surveyor's instrument may be made with a common mason's spirit-level, to the ends of which sights, with cross-hairs, may be attached. The level may be rested on a "Jacob-staff," or a tripod furnished with a small table at the top. Any carpenter or mechanic can get it up at the expense of two or three dollars in addition to the cost of the level.

Exhibitors at Fairs will find our list of coming Fairs on pages 333 and 334.

Bed-Bugs.—"J. W. W.," Windsor, N. S., has purchased a wooden house, which he finds tenanted with bed-bugs, and asks what to do. One of our associates was troubled in a similar manner, and completely conquered them by blowing the Persian insect-powder into every crack and cranny. This powder to be effective must be fresh, and have been well preserved. That put up in small tins, as "magnetic powder," and under various other names, is often worthless. Get your druggist to order from a New York importer a pound-bottle, and you will be likely to get the real thing.

Cold-Frame Cabbage Plants.—"R. H.," Chester Co., Pa. Your questions indicate that you should have Henderson's, Drill's, or some other practical work on market-gardening. We must assume that our readers are familiar with the first principles, and can not in every issue repeat the alphabet of gardening. In the case in point, cabbage seed is sown in the open ground about the middle of September. Before cold weather the plants are pricked (set out with a dibble) into cold-frames. Here they are kept in a dormant state as much as possible by the proper management of the glass. They are not to grow, nor are they to be subjected to sudden alternations of temperature. As soon as the ground can be worked in the spring, these plants are set out where they are to mature.

Grape-Vine Leaves.—"S. T. Gilbert, M. D., Memphis, Tenn. The leaves sent are covered with the excrescences of the Grape-leaf Gall-louse, *Phylloxera vitifolia*. It has heretofore been mainly confined to the Clinton, and the only remedy that has been suggested is to root up that variety. We have not before known it to attack the Delaware and Creveling. You will find a full account of this insect in the report of C. V. Riley, Entomologist of the State of Missouri, in the report of the Board of Agriculture of that State for 1871.

Strawberries.—"G. H. T.," St. Catharines, Ont. We had written a letter in reply to your inquiry, but upon looking at the bottom of your note we found that you had given only your initials. We have so often stated that we did not answer personal inquiries through the paper, that we supposed all our readers were aware of the fact. As you live over the border, we will so far depart from our rule as to say that we think you can get what you desire from Louis Ritz, Plainville, Ohio. People in writing to business men usually give their names. If they write to editors, they must give names or expect no reply.

The Radish-Bug—A New Insect.—Mr. W. R. Howard, Entomological Editor of the *Southern Farmer*, sends us an account of a new bug which has not been before described. It is called *Nysius Raphanus*, as it was first noticed upon the radish. It seems to be a universal feeder, attacking radishes, cabbages, grapevines, and potatoes, to which it is particularly destructive. It is related to the Chinch-bug. The description sent is so thoroughly technical that it would be of no use, except to entomologists, were we to publish it. We regret that Mr. Howard did not give a popular description by which any one could recognize the insect.

Failure of Spring.—"J. S. Frederick, Dubuque, Iowa, has a spring which for the past five years has been gradually failing, and would like to know if he may expect to lose it altogether, or if there is any way to restore it.—The probability is that the underground stream has opened a new channel or found a new outlet, which sometimes happens, and whether or not this can be remedied is doubtful. On some occasions flowing wells which have fallen off have been restored by pneumatic exhaustion, but we know of no way of applying this to a surface spring.

Imperfection in a Bull.—"O. C. G.," Lynd, Minn., has purchased a full-blood Devon bull, but finds that it has but one testicle, and he asks will that destroy his usefulness.—Probably the other is not far off, though not in sight; and were it altogether wanting, would not necessarily render him useless.

Lawn on Sandy Soil.—"J. H. K.," Dunn Co., Wis. You do not say what kind of grass you have on your lawn. At all events, we should sow some Red-top, and give a dressing of ashes and ground bone. Manure will bring in weeds, of which you have enough already; frequent mowing will eradicate the sorrel.

Land for Stock-raising in the West.—John A. Oakes, Elkhart, Ind., asks where in the West can land be procured for stock-raising purposes, and at what prices.—In the northern parts of Kansas there are railroad lands to be purchased for five dollars and upwards per acre, suitable for stock-raising,

and in other parts of that State government lands may be pre-empted or "homesteaded." Particulars may be learned by writing to the United States Land Office, Topeka, Kansas. Nebraska and Minnesota also offer favorable locations for stock-raising.

Clover Seeding in Fall.—E. Weimann, Mecosta Co., Mich., has had trouble in getting his clover to catch in the spring by reason of the drouth; he would like to sow it with rye this fall if it would be advisable.—It would not be advisable. The frosts of early winter would destroy the young plants. It would be better to try again in the spring, and harrow the rye with a Thomas harrow just after the clover is sown, when it would not be so likely to fail.

Molting Hens.—G. E. Harris, Lowell, Mass., asks what is the best treatment for hens during the molting season. Keep them dry and their houses clean, give them fresh dry ashes or road dust to wallow in, feed the best of food and give them some ground pepper or other warm stimulant with it, and fresh water with a very small quantity of sulphate of iron (or common copperas) dissolved in it. As soon as they recover they should be fed wheat until they commence to lay again.

Mange.—"Monarch," Perry Co., Mo., wants to know what ails his mare, which is constantly rubbing her mane and tail, and making sore spots on her neck by so doing, and what shall he do for her.—The mare has the mange, which is a skin disease similar to the itch. Give a table-spoonful of sulphur in her feed once a day for a week, and wash the tail and neck with soap and water, and then rub lard and sulphur ground up together, on the spots or the itchy parts.

Peas.—A farmer wants to know how he can grow peas free from "bugs." The only way is to sow them after the weevil has disappeared, which is generally about the 10th of June; at least peas sown after that time are seldom affected, when early peas are much injured. The best pea to sow with oats for fodder is the black-eye marrowfat, or some other pea with large vine; this variety should be sown early.

What is a Bushel?—"J. H. J.," Frankfort, Ohio, says that the rule given in the *Agriculturist* of April, 1872, for measuring corn in the crib has been pronounced incorrect by our readers in that neighborhood, and he asks why we take 2,750 inches for a bushel when 2,150 inches make a bushel all over the commercial world.—Our rule is correct. We take 2,750 inches for the simple reason that *corn-ears* are sold and measured by the heaped bushel, which is 2,750 cubic inches. 2,150 inches is a *struck* bushel, by which shelled grain is measured, and generally two bushels of corn-ears, of 2,750 inches each, make one bushel of grain of 2,150 inches. Corn, measured in the *crib*, of course is understood to be ears of corn, and the bushel in that connection is the heaped bushel.

Greasing Cog-Wheels.—C. Wade, Fairview, Ky., asks if it is necessary to grease or oil the cog-wheels of machinery, and if so, what is the best oil?—As there is considerable friction in the contact of cog-wheels, they should by all means be lubricated. The best lubricator is tallow and black-lead, rubbed together. In mowers, reapers, and thrashing-machines, this should always be attended to.

Bets.—We do not desire to be made a party to the decision of a question on which a bet is depending. Such disputes are never settled by such a decision, and the defeated party is never convinced of anything but that he is an injured individual. We desire to give information that may be useful to our readers, and are willing to respond to requests for such, but not to decide bets or even disputes.

Shares Harrow.—O. C. Gregg, Lyon Co., Minn., asks where a Shares harrow can be procured, and if we think them the best for prairie sod.—This harrow can be purchased of or ordered through any agricultural implement dealer. It is undoubtedly a very good harrow, if not the best, for mellowing plowed sod without turning it back.

Smut.—"Orion," Clarksville, Neb., complains of his spring wheat being smutty; not single grains, but the whole ear is a bunch of smut. What is the cause and the remedy?—This is only a bad case of ordinary smut, which is a fungus often appearing on grain of all kinds, and sometimes completely destroying it, as in this case. It is worse in hot damp seasons than in others. A remedy is to soak the seed in strong brine or a solution of blue vitriol for a few hours, drain, and dry with lime, air-slaked, in a state of fine powder, just before sowing.

How Can it be Done?—It is often asked, How can the Publishers possibly give so large a paper as this, with all its Engravings, etc., at \$1.50 to \$1 a year?—*Answer:* The circulation is so great, that the Thirty-odd Thousand Dollars laid out in engravings, getting information, proofing, electrotyping, office expenses, etc., amount to but a trifle for each subscriber. (If there were only 30,000 subscribers, this would cost over a dollar each.) But the publishers are satisfied if they get from subscribers just about the cost of white paper to print on, because the large circulation brings an income from good advertisers to pay other expenses and a living profit. The advertising pages are valuable to the reader, because only good advertisers are admitted, and they can go with confidence to these pages for business information. The reader will thus see why it is that so much can be given for a small amount of money. More subscribers bring more advertising money, which in turn enables the publishers to give a better paper, as well as premiums, and the extra numbers offered on page 328.

Ten Cents a Month, or 2½ Cents a Week, or ½ Cent a Day, will be the cost to any one of having himself and family supplied with the forty-four pages of good reading, of useful information, of fine pictures, etc., given in each number of the *American Agriculturist*—that is, to those who subscribe this month, and get the extra three months offered free. If four, or ten, or twenty or more persons club together, the cost will be even less than the above. See page 328.

Eggs at 12½ Cents a Dozen.—In New York they retail now at 35 to 45 cents a dozen, but at 12½ cents a dozen, a little more than two eggs a week would pay for the *American Agriculturist* during the next fifteen months, at the extra offer made to single new subscribers on page 323, with a further reduction to clubs of four, ten, or twenty. One good hen ought to yield this much. *Result:* Keeping one hen more will supply a family with the constant reading of this journal. Why, the \$15,000 worth of fine pictures given in every fifteen months are worth a hundred times as much as this.

How about the Four Millions?—There are probably about five million men in this country who are engaged in cultivating some portion of the soil, varying from a garden plot up to large farms. From four to five hundred thousand read the *American Agriculturist*, directly and indirectly, and enough more to make up one million read other journals devoted to practical cultivation, while some four millions plod on, using only their muscles and what knowledge they have picked up by experience and limited observation. Every man of them all ought to be observing, reading, and studying about his business—making his head help his hands. What would be the effect if, for one year only, every cultivator in the land should become a reader of books and papers devoted specially to his own pursuit, or even of only one such paper? We firmly believe it would add millions upon millions of dollars to the products of the country. It would give each one something more to think of during the hours and days and weeks of hard toil, and they would be so much happier and so much elevated above the animals whose muscular force they employ. It would dignify their calling, and make it more attractive to themselves and their sons. Suppose, now, that each of our present readers should induce one or more brother cultivator to become a reader also. Would it not be a grand contribution to the general good! We believe so, and invite each of our readers to do this much. *As an extra inducement to such non-readers, the Publishers propose to present to all new subscribers, who come in this month, a whole quarter-year's subscription; that is, any new subscriber coming in during September, will get the Agriculturist from now to the end of 1873 for a single year's subscription, as noted, page 328. Will our friends please make this offer known among their friends and neighbors at once?*

Weak Hoofs.—"M. E.," Walla Walla, W. T., wants something to prevent the hoofs of his horses and colts from breaking as they do in his dry climate. They are too dry, and if they are washed in water occasionally and then well rubbed with tar they will become tougher. It would be well in addition to keep the loose ragged parts pared off.

Curb.—T. B. Townsend, Washington Co., Maine, asks for information relative to curb in horses, and whether it is likely to cause permanent lameness. This is a disease of the tendon at the rear of the hock-joint and its sheath, resulting from a strain, and appears in the shape of a swelling immediately below the joint at the back of the leg. It does not affect the bone as a spavin does. It is curable by cooling applications and bandages on the parts, if curable at all. Blisters or firing irritate it and render it totally incurable.

Substitute for Wood-Ashes.—I. Little, Akron, Ohio, wants to know if there is a substitute for wood-ashes. The German salts, or kainit, and sulphate of potash are all sold as substitutes for wood-ashes, and have been used in England with success.

Fallows.—T. B. White, Sherburne, Mass., asks if fallowing will help light soils, and if a fallow is plowing land and keeping it for a year free from weeds.—Fallowing is not profitable on light soils unless they are excessively weedy, and then a hoed crop would be better. But on heavy clay soils which are very weedy, and have been severely cropped, a fallow, which consists of several plowings and harrowings and a complete mellowing and clearing of the soil from weeds, is very often highly beneficial.

Roots for Stock.—"C. B. J.," Bear Lake, Wis., is preparing land for roots, but is doubtful which sorts would be best to plant for cows and young heifers. There are no roots which exceed the ruta-baga and the sugar-beet for feeding purposes, and as a variety to some extent is desirable, it might be better to plant both of these kinds. For a good crop rich clean land is needed.

Milking Machine.—Ernest Beckert, Montana, asks if there is a milking-machine, and if so where it can be got. We do not know of any better machine, or one so good, as the ordinary one that sits on a three-legged stool and sings while it milks. The patent machines are merely curious failures.

Sweet-Corn Fodder.—A "Youthful Farmer" says he believes that sweet-corn fodder contains more nutriment than that from field corn, and he is cultivating six acres for his stock. Is he doing wisely?—This is a question which has two sides to it, as many others have. Sweet-corn fodder contains more sugar but is less bulky, and the yield is not more than half or one third that of common Western or Southern corn. However, the result of the experiment will test the question, and we should be glad to hear how it turns out.

Best Stump-Puller.—"R. S.," Cox's Mills, Ind. There are several kinds of these implements described in late numbers of the *Agriculturist*, which are useful in their way. There are several others made throughout the country which are patented, and which are said to be good machines, and which it would be for the general interest if they were advertised. We do not know the makers' names.

Ditching Machines.—We have several inquiries for ditching machines, also about their relative merits. We do not know the addresses of any of these makers, but we know there are machines which will do good work where there are no stones or roots to interfere with them. The best we have seen was at Duquoin, at the Illinois State Fair last year, but unfortunately can not give the address of the makers.

A Six-Acre Farm.—"A Constant Reader," Portage City, Wis., asks what shall he raise on six acres of light sandy soil to get the greatest revenue out of it when he can not attend personally to it? He suggests hops.—Hops thrive best on deep, strong loams or clays, and this light soil would not be suitable for them. Such crops as potatoes, cabbages, carrots, sweet-corn, and others, called market crops, would be most profitable on such a small tract near a town, if, as we may suppose, there is sale for them; or strawberries or small fruit might do. But the question is, How can these be profitably raised without personal attention? There is no resource here but to get a good market gardener to raise the crops on shares or on long rental.

Abortion in Cows.—"T. B.," Mass., says this complaint has got amongst his cows, and asks if it

will do good to allow them to go farrow a year. Generally, in such a case, it is found best to sell off the whole herd and buy a new stock. The loss of a year's profit would be too considerable, and would be far greater than thus changing. The change often results in bringing about a cure in the cows. Then the whole premises should be disinfected or cleaned, whitewashed, and renovated most thoroughly before the new stock is brought in. The nervous system of cows has more to do with this than is generally supposed, and once the trouble occurs by accident, as in this case, it spreads as by contagion. Then medicine and treatment are found of no avail, and dispersion is the simplest remedy.

Punctuation.—"C. L.," Portage City, Wis., wants to learn the rules of punctuation. "Wilson on Punctuation," which may be ordered through any bookseller, would be a useful work to study. The writing would be a fair business hand, with more care. The main thing in business writing is to write legibly.

The Cook Evaporator—Patent Extended.—The patents covering this machine—an invention that has proved of great value to the sorghum and sugar-cane interest—which expired on the 22d ult., have been extended seven years. These patents cover all channeled pans in which a cooling surface is used as a resting-place for the scum, and all pans which afford facilities, either by rockers, gate, or otherwise, for regulating the flow of the stream of juice on the bottom. As the entire control of the Cook patents has passed into the hands of one party, and prosecutions will be commenced against all parties infringing, it is important that those using, or about purchasing, an evaporator that infringes on these patents, should know that not only are the makers of such machines liable to heavy penalties, but the dealers and those using them also.

Condition Powders.—"M. Z. F.," Van Buren County, Mich., has some blooded pigs which he wants to grow rapidly and look well; he asks if condition powders will be good for them, and if fed in large quantities can harm result?—These powders have generally tonic and alterative properties, or are intended to have, and are supposed to increase the appetite. But it is not wise to depend on them to the neglect of good sufficient food and cleanly and healthy lodging. If given in excess, undoubtedly they would be harmful.

Danger of Choking by Turnips.—A. C. Knoxville, Tenn., asks if there is danger of cattle choking when feeding in a field of small turnips. Yes, more so than in any other way, and it should not be permitted. Better pull the turnips, and chop them up in a trough with a sharp spade, and feed them in the yard.

Disease of Poultry.—J. R. Williams, Raleigh, N. C., wants a remedy for his poultry, which have lost their appetite, keep their eyes shut, and hold their heads to the ground; their feathers fall off, and their bowels are costive; after twelve to thirty-six hours they die.—This seems most like pip, which affects the point of the tongue and prevents the bird from feeding, and results in fever and starvation. On examining the tongue, if a horny scale is seen on the point of it, remove it with the finger-nail, and give soft feed.

Gail Borden.—We are indebted to Mr. S. L. Goodale, Sec. Maine Board of Agriculture, for a very neat pamphlet, of which he is the author, giving an account of our friend Gail Borden's inventions in preparing condensed milk, concentrated meat, etc. The memoir has an excellent portrait of the "great condenser."

Col. Waring's \$100 Premium for 1872.—The annual premium of one hundred dollars, offered by Col. Waring, of Ogdon Farm, for the best Trophy Tomato raised this year from seed of his "head-quarters" stock will be awarded by the editors of this paper to the heaviest tomato, of perfect form and well ripened, that may be sent, express-paid and in good condition, to Messrs. Orange Judd & Co., 245 Broadway, New York, before October 1st. The specimens sent will be exhibited at this office, and will be well worth a visit. The Trophy has, from all accounts, and from our own observation of it, surpassed itself this year—especially in carliness of ripening and in profusion of bearing.

Grub in the Head.—A "Doctor," of Westfield, Mass., says that "grub in the head" in sheep may "be cured by pouring into the ear a table-spoonful of butter melted and mixed with a teaspoonful of spirits of turpentine."—Now this wise, or rather otherwisc doctor, seems not to know that the grub exists only in the nasal sinuses, and can only be reached through the nostrils, and how his physic is going to reach the grubs through the sheep's ear is a mystery which he ought to fully explain. We have tried all reasonable remedies,

but have found prevention by keeping the sheep's noses tarred to be much the best "cure." It is very rare that a sheep dies from the effects of these grubs; but turpentine in the ear would be far more injurious than a good many grubs in the head.

Irrigation.—"A Subscriber," Riceville, Tenn., writes that he is situated on a muddy stream, has an improved 25 horse-power, and 150 acres of land around the water-power, and from 30 to 60 feet above it; can he profitably use a pump to raise 1,000 gallons of water per minute to irrigate his 150 acres?—The way to figure this out is to take the weight of 1,000 gallons of water = 8,333 pounds, multiplied by the height it is to be raised, 60 feet, and divide by 33,000 = to the pounds raised by one horse-power per minute, which gives 15, the horse-power required to raise 1,000 gallons per minute 60 feet high. The power is thus seen to be ample. The only remaining question is, would the expense of raising and distributing the water be repaid by doubling the crops of grass, as this is the utmost result to be anticipated in all probability.

Shall he Farm?—"W. F. P.," Newark, N. J., writes us a letter which we like. He is a carriage-maker, but is strongly attracted towards farming, of which he knows considerable; is sober, careful, and industrious, and can rent a small farm near New York on favorable terms, and has eight hundred dollars cash. Though we do not profess to recognize character by handwriting, yet there is that in the tone of this letter which leads us to encourage W. F. P. in his desire, and gives us the belief that if any man can succeed he will.

The Boston Cattle Show.—The exhibition of cattle which the Massachusetts Society for Promoting Agriculture had proposed to hold this month in Boston, has been postponed until next year, because the only available ground for the purpose is occupied by the "Coliseum," in which the Jubilee was held, and arrangements for securing it could not be completed in time to give sufficient notice of the show. We trust that nothing will next year prevent the carrying out the very promising plans that had been formed.

Cucumber Catsup.—J. D. Boggs, Md. The item referred to should have said cucumber catsup instead of "salad." To make the catsup, gather the cucumbers when full grown, but before they turn yellow, peel and grate them. Let the pulp remain upon a colander until the juice drains off, then rub through a coarse sieve, to separate the seeds. Half-fill bottles with this pulp, fill up with vinegar, and keep well corked. This retains in a marked degree the odor and taste of fresh cucumbers, and is excellent with cold meats. When served upon the table, salt and pepper are added. We extemporised an efficient grater for this purpose by punching holes with a large nail in the cover of a superannated wash-boiler.

He goes Two and a Half Better.—"Subscriber," Symmes, Ohio, in reply to the inquiry made in *Agriculturist* of Augst, says a Durham cow, owned by John Gardiner of that place, had a calf on the 16th May, and on the 25th gave 104 gallons of milk (42 quarts), and the calf at nine weeks old weighed 326 lbs. This is the largest milking by 2½ qts. we have heard of, and is extraordinary. But is there no mistake?

West Virginia Farm Journal.—We find among our exchanges a new-comer, bearing the above name, which is a weekly, published at Union, Monroe Co., West Va. While especially devoted to the local farming interests, the editor has the good sense to let his readers know what is being done elsewhere, by means of judicious selections.

The Bushberg Catalogue.—Isidor Bush & Son, Bushberg, Mo., send us a wholesale catalogue of grape-vines and small fruits, which is noteworthy for the extent of the collection and the condensed descriptions. We notice that Mr. G. E. Meissner, formerly of Staten Island, is now with the Messrs. Bush.

Tree Seeds.—L. A. Gregg, Minn. It is better, when practicable, to sow all the seeds you mention in the fall. If they are to be kept through the winter, mix with sand, and keep in a cool place. If planted in the fall, they come up next spring; if in the spring, they should, if properly kept, come up the same season.

Breachy Cows.—W. F. Humphrey, Poultney, Vt., asks how he may prevent a cow from breaking down and jumping over fences. Sometimes a board hung from the horns over the face will do it. But if the cow is an old one she is most likely incorrigible, and the butcher would cure her of all her bad habits.

Wolf-Teeth in Horses.—W. D. Harry, Rockwood, Ill., asks, What is the truth about wolf-teeth in horses—do horses go blind if they are not removed?—There are some well-authenticated cases of relief to the eyes of horses having followed the drawing of what are called the wolf-teeth, but it is very doubtful that the teeth caused the trouble. They may have indirectly been the occasion of inflammation, and no harm can follow their removal, if not occurring naturally, when the horse is five years old. That they produce blindness is an error.

That Fruit-Wash.—If we were desirous that any writing of ours should live, we would put down something thoroughly absurd and nonsensical, for then we should be sure that it would be quoted every few years. An absurd tree-wash has a vitality that almost approaches immortality. The Country Gentleman has it this time through a corresponded. The wash is made by heating sal-soda until it becomes a dry powder, and then dissolving it in water. Will the Country Gentleman, or any one else, please tell us what is the use of heating the sal-soda before dissolving? If a wash of sal-soda is desirable—and we do not doubt its utility—why heat it first? The merest novice in chemistry knows that all the heating to which we can possibly subject sal-soda (carbonate of soda) will drive off nothing but water, which is immediately restored when a solution is made. Caustic soda can not, like caustic lime, be made from the carbonate by any amount of heat. Then why publish such nonsense?

The Northern Pacific Railroad.

This is one of the grand enterprises of our day, of so great interest not only to every American citizen, but to many millions in Europe, that it is worthy of the freest attention of the press, and of the careful study of every one who would be up with the times. Let the reader open a map of the United States, and follow its general line from Lake Superior westward through Minnesota, 252 miles (completed) from Duluth, on Lake Superior, to the Red River; thence 200 miles through Dakota to the Missouri River, near the entrance of the Jamez River, where it meets the fleet of thirty or more steamboats already plying the thousand miles of navigable waters of the Missouri above, up to Fort Benton in Montana, which is less than 400 miles from the constant steam navigation of the Columbia River in Oregon. The cars, now moving from Duluth west of the Red River, will next month reach the Missouri. From this point the line extends westward, 226 miles, to the crossing of the famous Yellowstone River in Montana, and thence on through an easy pass in the Rocky Mountains to Puget Sound on the Pacific, where track-laying eastward has already begun, with 65 miles about completed. We shall therefore have in October 517 miles of the road in operation, or an average of about a mile a day since the work began, despite all the preliminary examinations, surveys, gathering of materials, and other preparations. The track-laying is now approaching the Missouri at the rate of two miles a day or more. So much for the progress of the work, which will undoubtedly be carried on with all rapidity consistent with due economy.

In looking at the country traversed by the Northern Pacific Railroad, one must remember that the isothermal line (the line of equal temperatures) does not run with latitudinal lines—that is, directly east and west. Paris, in France, with the climate of Philadelphia, is about 200 miles further north than Montreal in Canada; while London is 15°, or a thousand miles, further north than New York, though subject to less of cold weather. The isothermal line running westward bends northward so much that Dakota and Montana are warmer than the northern New England States, while Washington Territory averages in temperature about the same as New York State, we believe.

The vast territory traversed by the Northern Pacific Railroad is, from all accounts, generally well adapted to agriculture, and untold millions of industrious people, from all parts of our own country, and especially from the whole northern half of Europe, will soon occupy this domain. The alternate sections of land owned by the Railroad, on either side, along the portions already completed, or nearly so, amount to some 10,000,000 acres—twice the size of the State of Massachusetts—and, with a wise enterprise, the Company is affording excellent facilities to promote its settlement. A Land Department is established, and a Bureau of Immigration with agencies in various parts of this country and Europe. Large, convenient Reception Houses have been built and furnished at each of several principal points on the road, to serve as temporary free homes for settlers and their families while engaged in selecting lands and preparing their own houses. The Bonds of the Road are taken at

ten per cent premium in payment for lands. The sale of lands not only cancels the indebtedness of the Company, but builds up a local business which must soon render the road a good paying enterprise, aside from any through business to the Pacific coast. The country being developed is so vast and so valuable, that the enterprise must continue for some time to come to occupy a large place in the public attention, and we will try to keep our readers informed of such items as are of public interest.

National Swine-Breeders' Convention.

Report of Committee appointed to prepare Work for the Adjourned Convention to be held at Indianapolis, Ind., November 20th, 1872.

The committee appointed by the National Swine-Breeders' Convention, held at Cooper Union, May 14th, to name committees to prepare reports upon the history, characteristics, and a scale of points for the respective breeds of swine, and upon the question, "What constitutes thorough-bred swine?" also to name the time and place for holding the adjourned meeting of the Convention, respectfully report to the swine-breeders of America:

1. The adjourned meeting will be held at Indianapolis, Ind., Wednesday, November 20th, 1872.

2. It will consist of one delegate, at large, from each State, and of one delegate from each State for each breed of swine raised therein.

3. These delegates shall be named by the State Swine-Breeders' Associations where such organizations exist. Where they do not exist it is recommended that the Executive Committees of the respective State Agricultural Societies, or the State Boards of Agriculture, call Conventions of the Swine-Breeders of their respective States at the time and place of the State Fairs, for the purpose of naming delegates to this Convention. In the absence of any such call, the Committee recommend that the exhibitors and breeders of swine at the State Fairs meet, name, and accredit such delegates. In case any States neglect to do this, breeders from such States present at Indianapolis will be recognized and received as delegates, so far as is necessary to secure just representation from each State.

4. The Committee think it proper to assert that the gentlemen named on the following committees are selected from lists of names furnished and recommended by prominent swine-breeders in the different States and Canada, with a view to securing the most impartial representation upon said committees and the most carefully and intelligently prepared reports upon the respective breeds to be submitted to the Convention for its action.

5. A circular letter was sent to the chairman of each of the committees named, asking whether he would accept the position and duty. Responses have not been received from all. Only two have declined, naming, however, men who would act in their respective places. These names have been substituted. The near approach of the Fairs renders it impracticable to delay this report longer in order to receive further responses. It is, therefore, recommended that the members of the respective committees place themselves in communication with each other, and act as they may mutually agree—or that each member prepare a written report prior to the Convention, and mail it to Alexander Heron, Secretary of the State Board of Agriculture of Indiana, at Indianapolis, Ind.

6. The Committee respectfully urge upon the swine-breeders of the country the importance to them of the work it is the object of this Convention to accomplish; and that since it is to be a delegated and, in a sense, a legislative body, their representatives should be their best posted, most intelligent, and impartial breeders; that if the work projected is well done, it will inaugurate a new era in swine-breeding, and help to protect both swine-breeders and buyers of swine in their mutual relations.

7. The following are the Committees named to report upon "What Constitutes Thorough-bred Swine?" and upon the history, characteristics, and a scale of points for the respective breeds:

On "What Constitutes Thorough-bred Swine?"—John P. Reynolds, Chicago, Ill.; Fred. Wm. Stone, Cinch, Ontario; S. L. Goodale, Augusta, Me.

On *Berkshires*.—A. B. Allen, P. O. Box 376, New York City; J. T. Hudson, Kansas City, Mo.; Daniel McMillan, Xenia, O.

On *Improved Cheshires*, or "Jefferson Co."—C. V. Maxon, Adams, N. Y.; J. H. Sanders, Sigourney, Iowa; J. J. De Forest, Duaneburg, N. Y.

On *Chester Whites*.—Thomas Wood, Doc Run, Pa.; Dr. Calvin Cutter, Warren, Mass.; W. W. Thrasher, Groves, Ind.

On *Essex*.—Joseph Harris, Rochester, N. Y.; Dr. A. C.

Stephenson, Greencastle, Ind.; George Roach, Hamilton, Ontario.

On *Neapolitan*.—M. W. Phillips, Memphis, Tenn.; F. D. Curtis, Charlton, Saratoga Co., N. Y.; Mason C. Weld, Closter, N. J.

On *Magie or Poland-China*.—John M. Millikin, Hamilton, Ohio; Rankin Baldrige, Hagerstown, Ind.; Shepard (of Shepard & Alexander), Charleston, Ill.

On *New Jersey Reds*.—David M. Brown, Windsor, N. J.; David Petit, Salem, N. J.; John C. Tatum, Woodbury, N. J.

On *Suffolks and Other Small White English Breeds*.—John Wentworth, Chicago, Ill.; John Snell, Edmondston, Ont.; T. L. Harrison, Moreley, N. Y.

On *Yorkshire and Other Large White English Breeds*.—O. P. Cobb, Aurora, Ind.; James Brodie, Rural Hill, N. Y.; M. H. Cochrane, Compton, Quebec.

On *Victorias*.—Charles Leland, Albany, N. Y.; W. S. King, Minneapolis, Minn.; George S. Lonsbury, Aiken, S. C.

Any inquiries with reference to this Convention or the Committees may be addressed to the Secretary of the Committee, CHAS. D. BRADGON, 5 Beekman street, New York City.

Committee { HENRY STEWART,
M. C. WELD,
FRANK D. CURTIS,
L. A. CHASE.

Prize Shorthorns.

At the last fair of the New York State Agricultural Society there were some notably fine Shorthorns exhibited. Our artist who was in attendance upon the fair made sketches of several of the prize-winning animals, three of which are given in the engraving upon our front page. The two heifers presented in the upper part of the engraving were shown by Messrs. Walcott & Campbell, of York Mills, N. Y., and well sustain the reputation of the celebrated herds of these gentlemen. These animals were justly admired by lovers of fine stock, and, if we mistake not, the lower of the two has been sold at a large price for shipment to England. The bull in the lower part of the picture is "Treble Gloster," 7331, the property of Geo. Butts, Esq., Manlius, N. Y., by whom it was reared. This bull is considered as a remarkable result of in-and-in breeding. It was calved March 31st, 1867, got by Apricot's Gloster, 2500—out of Spring Beauty, by Apricot's Gloster, 2500—Silkie, by Apricot's Gloster, 2500—as we are informed by the printed pedigree. It will be seen that this bull can find his father, grandfather, and great-grandfather in the same animal. He took the first prize for Shorthorn bulls against considerable competition.

Jersey Cattle, and Scales of Points.

BY GEORGE E. WARNO, JR., OF OGDEN FARM,
(Secretary of the American Jersey Cattle Club.)

The article from the London Field in the July *Agriculturist* suggests several questions which it will be well for intelligent breeders to consider with care.

The American Jersey Cattle Club recently appointed a committee to investigate the subject of a Scale of Points applicable to this breed. The chairman of the Committee (Mr. J. Milton Mackie, of Great Barrington, Mass.) made at the April meeting of the Club an elaborate report on the subject, in which he submitted a scale founded on an entirely different basis from that in use in the Island of Jersey. This is now before the Club for discussion, and may or may not be adopted at the next annual meeting. In the mean time it has no more force than any other expression of opinion, and no one will be more glad than Mr. Mackie himself to have it intelligently criticised. The scale adopted by the Society in the Island of Jersey

is given in the article above referred to. That suggested by Mr. Mackie is (for cows) as follows:

SCALE OF POINTS.

COWS AND HEIFERS.

Points.	Counts.
1. Head, small, fine, and rather long.....	4
2. Face, dished, broad between the eyes, and narrow between the horns, with receding forehead....	3
3. Cheek, small.....	1
4. Throat, clean.....	2
5. Muzzle, encircled by a light color.....	2
6. Nostrils, high and open.....	1
7. Horns, small, smooth, crumpled, tapering, yellow at the base and black at the tip.....	6
8. Ears, thin.....	2
9. Ears, of a deep orange color within.....	5
10. Eyes, full and placid.....	2
11. Neck, rather long, straight, thin, fine at junction with the head, and placed lightly on the shoulders.....	6
12. Chest, deep.....	3
13. Withers, thin, and not too high.....	2
14. Barrel, hooped, broad, and deep.....	10
15. Well-ribbed, having but little space between the last rib and the hip.....	1
16. Back, straight from the withers to the top of the hip.....	3
17. Back, straight from the top of the hip to the setting on of the tail; and the tail at right angles with the back.....	2
18. Hips, of good width between.....	3
19. Hips, long from point to end of hanch-bone.....	2
20. Tail, fine.....	3
21. Tail, hanging down to hocks, with switch reaching the ground.....	2
22. Hide, thin and movable, but not too loose.....	4
23. Hide, covered with fine soft hair.....	6
24. Hide, of a deep orange color where the hair is white.....	6
25. Fore-legs, short, straight, and fine.....	3
26. Fore-arm, swelling, and full above the knee.....	1
27. Hind-quarters, from the hock to the point of the rump, long, rather straight, and thin.....	3
28. Hind-legs, short, straight, and rather fine.....	2
29. Hind-legs, squarely placed, not too close together, and not to cross in walking.....	2
30. Hoofs, small.....	1
31. Udder, full in form—i. e., well in line with the belly, and not fleshy.....	25
32. Udder, well up behind, and not fleshy.....	25
33. Teats, large, squarely placed, and wide apart.....	25
34. Milk-veins, very prominent.....	25
35. Escutcheon, or milk-mirror, high and broad.....	100
36. Size, medium.....	1
37. Disposition, quiet and good-natured.....	5
38. Condition, medium.....	1
Perfection.....	300

The elaborate argument with which this schedule was submitted may be thus condensed: The present scale is defective, because it gives the same value to minor as to greater points, so that the nostrils or the tail may carry the day over the udder, a worthless cow being judged finer than a good one simply because she is prettier. The only way to remedy this fatal defect seems to be to construct a scale in which the relative values of the most important points shall be expressed by high numbers, and the values of the less important by lower ones. We know of no more correct principle than the adage, "Udder means dairy cow." If this be so, we may safely express the total values of the lacteal organs by the same number we fix upon for the values of the minor points (100). We thereby protect the lacteal organs from being outweighed in the scale by the less important organs—as they are in the scale of the Jersey Society. What number shall be assigned to the escutcheon, or milk-mirror? The only principle by which we can be rightly guided is, we think, this: *The escutcheon shows, as in a glass, the milk-giving capacity of the cow.* Its significance can not be truly expressed by the same number that is used to denote the value of a single one of the lacteal organs. It requires for its expression the sum total of the values of all the lacteal organs. If these be denoted by 100, that is the proper number to express the escut-

cheon. Let us give the escutcheon the place of honor which its significance deserves. We arrive thus at a Scale of Points in which perfection is indicated by 300—minor points counting 100, the lacteal points 100, and the escutcheon 100. Our knowledge of the value of the different points of an animal is not sufficient to enable us to express them with scientific accuracy. The most we can do is to frame a scale of comparative numbers which shall prove convenient and useful in judging of the value of animals. We can not wait for science to inform us of the exact worth of the head compared with the tail, but must accept such rules of judging as our present imperfect knowledge can give us.

In discussing the relative merits of these two standards by which to judge the breed, we find that the Jersey scale has the advantage of precedence; that it expresses the points of character under which these cattle in their native home have been greatly improved; and that it is of questionable promise to attempt to change a system which has produced such decided good results. Mr. Mackie's scale, on the other hand, while it has the disadvantage of being novel, applies its standard of excellence most emphatically to what we may justly consider *the more essential* qualities of any dairy animal. Without disregarding those points which give their ornamental value to the Jerseys, it subordinates them to the milking characteristics. The motive with which this is attempted no sensible farmer will question. The manner in which the motive is carried out meets with opposition from men whose judgment is worthy of much consideration. In my position as Secretary of the Jersey Club, I have received many letters on all sides of the subject, and have thus been led to give it more consideration than I otherwise should have done.

It is stated on one hand that the escutcheon or milk-mirror is an *ignis fatuus*—a chimerical creation—and a pack of nonsense; and, on the other, that except for the improvement of beef cattle any Scale of Points is worse than useless, because it must tend to encourage the development of the body rather than of the milk-producing tendency, and that the only standard should be a record of the yield of milk or butter. They are not few who claim that, as the Jersey breed has been brought to its present development by the aid of the existing Scale of Points, it would be extreme presumption for us (who know the breed only by adoption) to attempt to set it aside and raise a standard of our own.

The friends of the new scheme meet these objections thus: If the theory of the escutcheon is not a correct one, Guenon, its discoverer, must have had a superhuman insight into the character of the cows he examined, for in hundreds of test cases he gave an account of the amount of produce, the quality of the milk, and the duration of the flow during pregnancy, which agreed in all essential points with the statements of the owners, who were examined apart from him. Furthermore, it is claimed that his system is a real system, and capable of being taught to others, because in the trials which resulted in its approval by the French agricultural societies, he and his brother examined the same animals separately, and their estimates concerning them tallied exactly with each other, and with the records previously furnished by the owners. This system is not generally accepted in all its details, but very many, if not most, of the most skillful dairymen in this country and in Europe do pay much attention to its general features in buying and selling dairy cattle—believing the escutcheon to be a

valuable if not an unmistakable indication of milking tendency. It is not unlikely that those who object most strongly to the escutcheon, do so from lack of knowledge concerning it. Guenon did not claim that he who runs may read its record, only that it bears a record which he who understands the handwriting may decipher.

Concerning the necessary tendency of any Scale of Points to foster only the beef and fat-forming tendency, it is claimed (and with reason) that it depends entirely on what the scale is. If we say that no cow shall be considered perfect unless we can hang a hat on her hips, surely it can not be claimed that our standard tends to develop beefiness, and so it is with every point that comes under consideration; if we give value to all of the features that indicate great butter-making capacity, and to all that directly oppose the beef-producing quality, we shall encourage the development of a race eminently fitted for the dairy. If prizes are to be awarded according to the records of performance at the milk-pail or churn, who shall verify the records? The premiums would go to those who had the largest yield of brag and dishonesty in their milkers. We can not know whose figures are true and whose untrue, and we must judge of the cow by her pedigree, and by what we can learn from a personal examination of her. In order that we may judge wisely and fairly, we must have a judicious and an invariable standard or Scale of Points.

(TO BE CONTINUED.)

Ogden Farm Papers.—No. 32.

Inquiries are still made about the details of the "deep-can system," most of which are fully answered by previous papers of this series, and it would be unfair to old readers to occupy space with their repetition. The recent hot weather, however (hotter than Newport has often known), has given us a better opportunity of testing the plan than we have had before. For two or three weeks we had by spells intense heat, high winds, thick fogs, heavy thunder-storms, chilly nights, and, in fact, every variety of weather of which an American summer is capable. In all this time, our butter was absolutely uniform in quality, and as good as it is possible for butter to be.

The secret of this uniformity (which under the common system of setting milk in shallow pans on shelves would have been impossible in such weather) was that the milk was kept at a *uniform temperature*. The surface exposed to the air was very small, and the milk took its temperature from the water in which the cans were immersed. This water (pumped up by a windmill from a well 1,000 feet distant, and conveyed through wooden pipes three feet under ground) was not perceptibly affected by the heat of the atmosphere. It varied but little from 53°.

We hope to secure the same advantage in winter by heating the tank-room sufficiently to prevent the water from becoming too cold—which it occasionally did during the past winter—and by heating also the room in which the skimming, churning, and butter-working are done. To effect this heating by the use of common stoves would involve the necessity of keeping up two fires, and the certainty of occasionally having the air tainted by coal-gas. The plan decided on is to build a small hot-water furnace in an outer apartment, and to carry the water-pipes around each of the two rooms.

This will enable us to keep up a moderate heat with the least expenditure of labor, and with the total exclusion of the smoke and gas of the fire. The cost of construction will not exceed the value of two weeks' product, and the expense for fuel will not exceed two cents per pound on the amount of butter made. I am confident that my customers will cheerfully pay ten cents per pound extra for the certainty of *always* having their butter of first quality, while the new customers that the increased capacity of the dairy will require will be much more readily secured.

A neighbor, who also keeps Jersey cattle, recently bewailed his inability to get my prices, and ascribed his failure to the fact that he could not advertise his butter and "write it up" as I do. The reply to this was that my butter is never advertised at all, and that it is only "written up" in these Ogden Farm Papers, which, so far as I know and believe, are never seen by a single one of those who buy the butter. "Good wine needs no bush," and good butter is equally successful in making its own way. The reason why "O. F." butter sells for a better price than common butter is that it is better—made from the milk of better cows, by a better system, and (to give Frau Haubrich her well-earned share of the credit) by a better butter-maker. Any other farmer who will use the same means that we do will achieve a corresponding success; until so many of them do it as to make the supply of good butter equal to the demand for it—and that will not be in our day.

In an article in this number on Earth-Closet Manure I have alluded to the question of fallows—the "pet idea" of my friend who "Walks and Talks on the Farm." I shall not have the temerity to oppose any recommendation of so good a farmer as he is, especially when he is sustained by the recorded experience of many generations of good farmers who have preceded him, notably by Jethro Tull, who believed that the frequent and thorough stirring of the soil might be made to do away with the necessity for manure. At the same time, Dr. Voelcker's statement concerning the small amount of ammonia found in earth which had passed five times through the closet, confirms a suspicion that I have long had, and for which I have found some authority in my reading, that loose, dry earth (loose enough and dry enough to admit air freely into its pores) is a destroyer of the ammoniacal products of the decomposition of organic matter. Or, to be more precise, the air is the destroyer, and the earth condenses or concentrates the air, and makes it more rapidly active.

Investigations made in England with a view to determining the value of sewage-water as manure, and others to decide on its contaminating influence when mixed with the water of rivers, have shown that under the condition of exposure to the air to which the movement of the water subjects it, its organic impurities are after a certain distance traveled entirely annihilated. Not only are the original compounds of the sewage destroyed, but the resultant impurities of their decomposition, and even the ammonia, etc., into which these are finally resolved, are utterly consumed (or withdrawn) by the air after a certain amount of exposure, so that the water becomes safe to drink, and useless as manure. This effect is ascribed to the action of the oxygen of the air, which consumes, under favorable circumstances, all organic matters.

The ability of animal charcoal to disinfect large

volumes of foul gases is in like manner ascribed to the fact (or to the supposition) that it condenses within its pores much oxygen (or active ozone), which there exists under circumstances favorable to its powerful and repeated action—destroying and dissipating (not storing up) the products of organic decomposition with which it comes in contact. It seems to act like a mill, grinding all the foul grist it can receive, and ever ready for more.

In like manner, but in less degree, the earth used in an earth-closet does not store up all the ammonia that the decomposition of urine and solid feces supplies to it, but aids in its destruction and dissipation. Dr. Voelcker seems to have demonstrated the fact that a mass of dry earth, in the loosened condition in which it is used in the closet, is a poor storehouse for the ammoniacal parts of manure.

If this is true, then the same property of earth should exist in the soil of a cultivated field. Lying in a compact bed, it may retain animal manure indefinitely. Plowed and covered with a crop, it may be able to carry the decomposition of effete organic matter only to the point of preparing it for use before it is taken up by the roots of the crop. But in the naked fallow, which is opened to the admission of air to the fullest possible extent, I see no reason why the destructive conditions of the earth-closet manure should not be present in the most active degree. I have heard farmers say, "That land has been plowed to death; the manure has all been burned out of it," and I think the above possible explanation of the destructive action of disinfectants accounts in a way for the injury to which they refer.

There is no doubt that the naked fallow system—the fine comminution of the soil—is very beneficial in developing the latent mineral sources of fertility. That it does not lead to the dissipation of its organic sources of fertility we can hardly believe. This is not to be taken as a conclusive argument against fallows, only as a suggestion about them. They offer an excellent means for destroying weeds, and if these are allowed to grow nearly to maturity (flowering) before being plowed under, they secure a large and valuable addition of organic matter (green manuring).

If the suggestion made constitutes a real objection, it is one which will have more weight with those who adhere more strongly to the modern English idea of the supremacy of *nitrogen* in manure, than to the "mineral theory" of Liebig, which is still not without its defenders. My knowledge of the subject is not sufficient to give especial weight to my opinion that the fundamental and permanent fertility of the soil depends mainly on its mineral wealth, and but slightly on its content of nitrogen, and that, therefore, we shall be better off in the long run if we develop the mineral element even to the sacrifice of the ammonia. At the same time, I would hold very tenaciously to the crude organic matter on which the fertile *physical* condition of the soil (and the chemical condition too) so largely depends, and my fallows should always be "green fallows." Rag-weed or some other rapid grower should carry into the furrow a good supply of organic-matter at each plowing.

My relations with the Island of Jersey have brought me acquainted with a work on "The Varieties, Properties, and Classification of Wheat," written by Col. Le Couteur, who has long been known as a leading authority on Jersey cattle. This work on wheat contains the

results of thirty-five years of careful experiment and study in connection with the growth of wheat on a large scale and in experimental beds—results which can not fail to be of the greatest value to all practical cultivators of the great cereal. I call attention to it in this way because it is not a work that is likely to be reproduced for the American market, and many of the readers of the *Agriculturist* may be interested to know of it. It has determined me to attempt the cultivation of some suitable variety of wheat at Ogden Farm, although it is accepted by my neighbors as a fixed law that on the Island of Rhode Island, with its open winters and high winds, it is impossible to grow it at all. Col. Le Couteur's work encourages me to think that I may find a variety that, on our excellent wheat soil, will withstand our unfavorable climate. Whether its cultivation will pay, even if it is successful, is yet to be proven, but the chances are worth the trial.

Water Running into an Underdrain.

A subscriber to the *American Agriculturist* in Ulster Co., N. Y., writes: "I have a large ditch into which empty two or three springs, which form quite a large stream at some seasons of the year. It starts from a farm above me, and flows through 20 rods of my land. I want to cover it up. How shall I manage to run it no further up than my line, and yet not have it fill in at the head? I also want to have my branch underdrains to flow into it."

There is no difficulty in regard to the side underdrains discharging into the main covered drain, provided the main drain has sufficient capacity to carry off all the water. The real difficulty in the case is the water flowing from the open ditch into the covered drain. It is apt to carry sticks, weeds, grass, etc., into the drain, and stop it up. We have on our own farm a covered drain, four to five feet deep, and over one hundred rods long, laid with five-inch tiles at the upper end, and towards the lower end we have two five-inch tiles to carry off the increased volume of water that is discharged from the lateral drains. At the upper end there is more or less water coming from a ditch on the side of the highway which flows into this main underdrain, and the plan we adopted was this: For about eight or ten feet from the open ditch at the upper end of the underdrain, we cut the underdrain three or four feet wider and deeper than the other portion of the underdrain, and filled it in with stones up to the surface. These stones act as a kind of filter. The object of making it deeper than the tiles is to allow any sediment that may be in the water flowing from the open drain to settle. If our correspondent will adopt this plan, and do the work thoroughly, we apprehend he will experience no trouble from his underdrain filling up. On Mr. John Johnston's farm, which consists of high rolling land, and on which he has laid over fifty miles of underdrains, there are several places where a considerable body of surface water at certain seasons of the year flows into the underdrains from the highway, and the plan he adopted is substantially the same as the one described above. The drains have been laid for over twenty years, and none of them have ever stopped up, except one where the roots of an elm-tree grew into and choked up one of the tiles. There has been no trouble with the surface water flowing into the tiles from the road. The stone-filters exclude leaves and other matter suspended in the surface water.

The White Dorkings.

Some twenty years ago, more or less, when the memorable "hen fever" was on, the Dorkings were among the prime favorites. At that time, the now popular Asiatic breeds were scarcely known, save in the gigantic, grotesque, and altogether useless Shanghai. There are Gray, Fawn-colored, and even Black Dorkings, but these are all believed to have been produced by the crossing of the original White Dorking upon other breeds. How the Dorkings originated is not known, but all poultry authorities agree that they are a very old English breed, and that the standard plumage is white. The pure Dorkings are of a clear white, or it may be a slight cream-color throughout, the legs white, with perhaps a rosy tinge, and a rose comb, broad at the front, ending with a raised point behind, and no depression in the center. The breed in whatever color presents the extra or fifth toe, and in well-bred fowls this does not appear as a monstrosity, but is perfectly developed. The Dorkings are good layers when young, but not good winter layers. The great merit of the breed consists in the quality of the flesh. As a table bird the Dorking is excellent.

Belted Kingfisher.—(*Ceryle Alcyon*, Boie.)

BY ERNEST INGERSOLL.

The design of much of classic mythology seems to have been to account for the appearance of favorite animals upon the earth. Prominent among these, and one of the most beautiful, is the touching story of Alcyone, the fond wife, who, awaiting the return of her husband from his long voyage, one day beholds his dead body tossing in the surf. Overwhelmed with grief, she springs to catch him from the sea, but ere she touches the water she is changed into a Kingfisher, and with her husband, alike transformed, she glides away over the billows. Many a time after were they seen resting upon old Ocean's bosom, and whatever the violence of the storm, around their nest the sea was ever tranquil. What wonder that the mariners protected

and venerated Alcyone, the Kingfisher! But for these old fables we have no room. Over the winds and waves the humble Kingfisher of our day has no control. Its nest is neither constructed of glue nor fish-bones, nor is it thrown on the surface of the water to float

THE BELTED KING-FISHER.—(*Ceryle Alcyon*.)

about with its proprietor at random, but is snugly secured from the winds and the weather in the recesses of the earth. Nor, as of old, do even the most illiterate of our rustics or seamen believe its head or feathers a charm for love, a protection against witchcraft, or a security for fair weather. "It is neither venerated like the Kingfishers of the Society Isles, nor dreaded like those of some other countries; but is considered merely as a bird that feeds on fish, is generally fat, relished by some as good eating,

representatives elsewhere, particularly in Australia, where a common variety, styled by the colonists the "Laughing Jackass," makes the woods ring with his hoarse cackinations.

Our friend ranges all over the United States, from the Rio Grande to Labrador, and probably inhabits the Bahamas. In the northern portions of the Union he is migratory, flying away to the South on the approach of winter, and returning by easy stages in the spring as fast as the ice thaws in the rivers. Yet they do not altogether follow the river-courses, but often fly straight across the country thirty or forty miles, their flight consisting of a series of six or seven slopes, followed by a long slide on motionless wings. Thus progressing, they reach us by the first of April in ordinary seasons, and lose but little time before pairing. A mate is soon found, and together they seek out a soft, steep bank, at the base of which is a meadow brook or larger stream. They ask but two conditions—that the earth be easily worked, and that

water be near. In such a spot they dig a straight, sometimes winding hole, three or four inches in diameter, and from two to ten feet in depth, near the enlarged extremity of which a little carpeting of loose grass and feathers constitutes their nest. The eggs are usually six in number, nearly round, and of a most beautiful whiteness.

The Kingfisher ranks among the most brilliant of our birds, though his great head, short wings, stumpy tail, and little sparrow-like feet are sadly out of symmetry in their proportions.

We all know him, with his high, brave crest, blue coat, and chestnut vest, and admire him, too, as he shakes the glistening drops from his plumage, and looks sharply down from some high sycamore, ready for a new victim. See how sharply he glances, and woe to the luckless fish who swims under the range of his piercing eye! There! he sees one. And down he goes with a swift, circular plunge. Splash! into the water. Ah! he has it. But the shining scales glitter but an in-

WHITE DORKINGS—ROSE COMB.

and is now and then exposed for sale in our markets."

The Belted Kingfisher is one of two of its kind in North America, but the family has many

stant before they are gulped down, and he is eager for another. Mill-dams and cataracts are favorite resorts of the Kingfisher, and here you may see him in some out-of-the-way place, be-

neath the shade of the gray alders, sitting motionless as a statue upon a branch that projects over the stream, or catch his rattling note as he scuds along the surface of the water to some distant point.

I have not pointed out any practical utility in his character. Yet what need of it, if he ministers to our pleasure and teaches us to more closely observe and better love all the birds?

Walks and Talks on the Farm.—No. 105.

We finished haying this morning, July 18th, and shall commence cutting wheat to-morrow. There is a good deal of grass yet uncut, and it will have to stand until after wheat harvest. We have had "catching" weather in this section, and haying has been slow and tedious. I was determined to get my hay out of the way before we commenced cutting wheat. I started two mowing-machines, and kept them going without regard to the weather. I cut all one day in the rain, and the next morning it rained again, and I still kept on cutting. I tried to keep up my courage, but must confess that my faith commenced to waver. By ten o'clock the rain ceased, the sun came out, and there was a good drying wind, and we got all that was cut the previous day into cock, and the next day we drew in twenty-two acres of hay. It was not injured in the least.

Clover can not well be cut while wet, but timothy can be cut in the rain just as well as when dry. The Deacon came up to congratulate me. He is one of the cautious kind, and only cuts down a few acres at a time, and then stops the machine until he has got it all in. The result is he is not yet through haying, and what he has got in is in no better condition than mine. "But you have a large force," he says; while in point of fact I have no more men in proportion to the amount of hay than the Deacon has. In fact not so many. The only reason why I am ahead of the Deacon is because I regarded not the clouds. My theory is that so long as the grass is green rain does not hurt it. But whenever it is partially cured, then rain or dew is very injurious. If because it rains to-day it is less likely to rain to-morrow, it is better to cut in the rain, and get everything ready to put all hands to curing and getting in the hay to-morrow—or at any rate to get it into cock.

A tedding-machine is a grand implement for meadow or timothy hay, and may also be used to great advantage in a field of early-cut clover that is full of sap. We have the best climate in the world for curing hay, and our implements are about as nearly perfect as we can hope to get them. It is difficult to see how our mowers can be improved, unless it is in hardening and strengthening the parts most liable to wear out and break. My land is pretty rough and stony, but we did not break or injure a single thing about the machines this season. When I think of how much trouble we had with our old machine eight or ten years ago, I have a gratifying realization of the great improvements that have been gradually effected. What we want to do now is to grow larger and better crops of hay.

I have just read with much interest a paper in the last Journal of the Royal Agricultural Society of England on the Management of Grass Land, by H. S. Thompson, of Kirby Hall, Yorkshire. I do not know that it presents anything especially new, but as I grow older new

things have less attraction for me. I like to see old truths presented in a new light, and illustrated and enforced by practical experience. I never get tired of reading about a wet farm that has been drained, or a foul farm that has been cleaned, or a run-down farm that has been brought to a high state of fertility. Such accounts are always interesting and always useful. They encourage us to go ahead with our own farm improvements. We need line upon line and example after example. We need to have our faith in good farming strengthened. It does one a great deal of good to get a splendid crop, or even to hear of others getting it by the same processes that we are adopting. When I put a five-inch-pipe drain through the old swale in the corner adjoining the Deacon's west line, where we used to have a foot of water in June, I felt sure that it would "knock the bottom out" of the pond and give me good land, but it was none the less pleasant to see the water soak rapidly away, and the dry land appear early in the spring. And now when I stand by the fence that divides the two fields, and see forty bushels of Diehl wheat per acre on the old swale on the one side the fence, and a crop that will not yield eight bushels per acre on the other, I know there is nothing "new" in all this, but it is none the less encouraging and gratifying for all that. It is a result which all experience and observation would lead one to expect, but it is very pleasant and profitable to see it with one's own eyes.

There is one phrase in Mr. Thompson's essay that is new to me. When speaking of top-dressing grass land with barn-yard or artificial manures, he calls them "tillage" or "tillages." "All tillage," he says, "should be applied to strong land pastures early in winter." . . . "If the application of tillage be delayed until March or April, and a droughty spring follows, the application loses a great part of its effect for that season." I like this use of the word. It is very significant. It is a recognition of the fact that tillage is manure and manure is tillage. In other words, that plowing and working the land is, in a certain sense, equivalent to manuring it, and on the other hand that manuring the land is equivalent to working it.

In England, summer-fallowing as a means of enriching land has been pretty well abandoned. Land is high, and meat in great demand, and it pays better to keep a large amount of stock, and buy American oil-cake, cotton-seed cake, and corn to feed out, and make a great quantity of rich manure, than to adopt the slow method of enriching the land by fallowing. They have also another advantage over us. They can buy artificial manures at something like what they are worth. The time will come when we can do so here, and then we shall use them in enormous quantities. Mr. Thompson's favorite "tillage" for grass land is 1 cwt. of nitrate of soda, 2 cwt. mineral superphosphate, and 3 cwt. of kainit per acre. These manures cost about \$10 per acre. For mowing land, he would increase the quantity of nitrate to 1½ cwt. per acre.

Almost all English writers who have visited this country seem to be struck with the poor, brown, weedy, burnt-up look of our pastures. I have always believed that we can raise just as good grass here as in England. Who can doubt that we could if we should top-dress a field of good pasture land with ten or fifteen tons of well-rotted barn-yard manure per acre, and then feed off the grass to sheep which are allowed one pound of oil-cake each per day?

Then late in the fall sow \$10 worth of artificial manures per acre. The next fall top-dress again with barn-yard manure, and the next year repeat the artificial manures, and in the mean time feed off the grass with sheep eating cake or grain. If we took pains to mow down the weeds and coarse tufty grass, and harrowed and sowed a little grass seed occasionally, can any one doubt that we should have just as good a pasture as they have in England? I believe we should have better. Whether it would pay or not is a question I have not now time to answer. But I believe there are thousands of farms on which some such a system would prove very profitable.

The great defect with our permanent pastures now is that at the season of the year when we need the most grass we have the least. The pastures dry up and fail us at the critical point. We can afford to pay liberally for means to avoid this difficulty, and it is certain that top-dressing with manure will go far to prevent pastures from drying up during even our severest drouths.

A miller who resides in one of the dairy districts tells me that the farmers are buying more and more corn-meal and bran every year to feed their cows. They feed it not only in winter and spring, but during the summer and autumn while the cows are at grass. I was exceedingly glad to hear it. It is a very encouraging sign of agricultural improvement. I have thought for some time that the dairymen were improving faster than the grain-growing farmers. The cheese-factory system, contrary to my expectations, proves a great stimulus to liberal feeding. I thought that rich food would give rich milk, and that if the factory paid a uniform price per quart there would be far less encouragement to produce rich milk by liberal feeding than if the milk was made into cheese and butter at home. I am glad to learn that such is not the case. The milk is weighed every day, and a farmer soon finds out whether his cows are giving less or more milk than those of his neighbors. If I were a dairyman, I should not only feed all the grain and bran I could afford to buy, but I should keep a sharp lookout to see if a few tons of artificial manure could not sometimes be obtained at reasonable rates. Kainit (sulphate of potash) and nitrate of soda ought to be sold here for about the same price as in England, and I do not see why mineral superphosphate (from the Charleston phosphates) can not be manufactured at such a price that we can afford to use it.

The Blood Manure I put on my wheat last fall I have no doubt paid me well. But I have not yet thrashed. The wheat generally is miserable. Much of it was thin on the ground, full of weeds, late, rusty, and badly damaged by the midge.

But I must say no more about our failures. I have thought many times of the remark made by one of my correspondents, that, "judging from 'Walks and Talks,' you must live in a poor neighborhood"! It is not so. I live in the "Garden of the Empire State." There are no better farmers in the country than can be found within a few miles of me. But still it is nevertheless true that our system of agriculture, taken as a whole, is very far inferior to what it should be. And is it not so all over the country? The really good farmers are the exception rather than the rule. No one feels more keenly than I do the difficulties under which we labor in all our efforts to improve our farms. But

this does not prevent me from seeing and feeling that there is no real profit in working land unless we raise good crops. Many of us must turn over a new leaf. We must make our land cleaner, drier, and richer. We must get rid of stagnant water, kill the weeds, and mellow the soil. We must keep better stock, and feed it more liberally, and thus make more and better manure. We must grow more and better grass. Now, because I say all this, and have said it over and over again, do not imagine that I live in a section where good farmers are unknown.

O. M. Richards, of Wisconsin, writes that his farm contains 360 acres, 160 of which is in pasture and 200 under the plow. "I propose," he says, "to raise 140 acres of corn, 10 acres of wheat, 20 acres of oats, and 30 acres of clover, so that I shall have 30 acres of clover to plow under in July. I have for some years sowed ten pounds of clover-seed to the acre in all of my small grain, and usually plowed it under the following October. It generally makes a fine growth. By this process, and feeding all I grow, my land is constantly increasing in fertility. Now, the point I wish to be clear on is this: I want to feed off my corn on the ground without gathering it, so as to save that job, and also drawing so much manure. My plan is to first snap off the corn on 40 acres; then put a fence between that and the ungathered corn; turn my cattle into the ungathered corn once a day in the morning, and let them stay just long enough to get all the corn they will eat. Then turn them back into the field where the corn is gathered, where also will be my hogs, and so on until the crop is consumed. You will bear in mind that labor is dear and produce comparatively cheap, and that corn is the cheapest food that we can raise. With our improved tools, the labor of one man and team will plow, plant, and cultivate an acre of corn in one day's time or its equivalent. I will say that my corn crop seldom falls as low as 50 bushels per acre, thanks to manure, clover, and 'Walks and Talks.'"

I do not know that I fully understand the point. And at any rate I have had no experience in this kind of farming. So far as making manure is concerned, the manure dropped on the land will be just as valuable as if it was dropped in a yard and afterwards drawn out. But still I am inclined to think that it would pay far better to feed in yards or sheds where the cattle could be kept warm and comfortable. Mr. Richards, as I understand him, now adopts the latter plan, and proposes to change to the rougher and more primitive system. This is going back instead of forward. I am well aware that labor is high. But it is no higher with him than with us. I should aim to raise good grade Shorthorns, feed liberally, and crowd them forward rapidly to maturity. I think I should adopt a modification of Mr. Richards's plan: feed on the land as long as the weather was favorable, and then finish off in the yards. It can not be long before we have a good machine for cutting up and husking corn.

Sowing clover in the spring and plowing it under the same fall does not commend itself to my judgment. It seems to me that it would be better to let it grow until the following May, and then plow it under for corn. But I have had no experience. It is merely a theoretical opinion. I should aim to grow more clover and less corn. But how this can best be done will depend on the character of the land and

on the kind of stock kept, and the mode of feeding. I should want to keep more or less sheep. It seems to me if I raised such a large proportion of corn I should see if it could not be seeded down with clover after the last cultivating in July. I have seen a capital crop of clover obtained in this way.

"I have made up my mind on one point," says the Deacon; "it does not pay to sow wheat unless the ground is in good order, and rich enough to produce a good crop." Good for the Deacon! I think thousands of farmers have had this truth brought home to them by the results of the present wheat harvest. The difference in the crops on good and poor land was never more striking. I saw wheat to-day (July 24th) in a field planted with apple-trees. Some manure had been spread for two or three feet round each tree. Here the wheat was four or five feet high, the straw stiff and bright, and the heads well filled. On the rest of the field the wheat was not over eighteen inches high. It was thin on the ground, the straw flimsy, and the heads empty. It would not yield five bushels per acre, and the wheat would be good for nothing but chicken feed.

I have made up my mind to sow my wheat early this fall—say the first week in September—two bushels to the acre, and drilled in pretty deep. Then as soon as it is well out of the ground, I will harrow it with Thomas's harrow every three or four days, to see if I can not kill red-root and other weeds. Harrowing in the spring will not kill the red-root plants. But in the fall, just as the weed-seeds germinate, I see no reason why the harrow will not kill them. At any rate, I mean to give it a thorough trial, and I wish others would test the matter.

We must do something to destroy the weeds on our farms, and we should try every method that commends itself to our judgment. The great aim should be to kill them before they get to the surface, or as soon after as possible.

Pure Water.

A correspondent writes us that he has a well thirty feet deep, situated twenty feet from a cesspool, into which the refuse of a family is discharged. He asks us if there is any danger that the water in the well will become defiled when the well is cemented from top to bottom. This is an important question, as these circumstances are very common, and in very few cases is there even the partial protection of the cement coating given to the well to prevent the influx of drainage. It is quite common to see wells surrounded with slops from the kitchen, or drainings from barn-yards. Sometimes the immediate vicinity of the well is constantly visited by farm stock of all descriptions, and its condition in the spring when the winter's accumulations become thawed is disagreeable and unwholesome in the extreme. It is too commonly supposed that earth will defecate and render pure all liquids which may pass through it. While this is true to some extent, it is just as true that there is a point of saturation which is easily reached when the earth no longer exerts this purifying property. It has been found that when soil has been abundantly manured, although heavily cropped, liquid manure spread on the field causes the water passing off in the drains four feet beneath the surface to be colored with it. This shows how easily the point of saturation of the soil can be reached. Now, what must be the condition of the soil beneath

an old barn-yard and that adjacent to it, or to a long-used cesspool! The large quantity of liquid passing into these places, and that from the rains constantly falling upon and percolating through the soil around the well, have completely charged it with offensive matter which must eventually pass into the well; and although it may not color the water, nor give it a disagreeable taste or smell, it will exert a most injurious effect upon the health of persons using it. It is well known that many diseases have been traced to a cause similar to the one referred to, and that its removal has immediately restored the locality to a healthy state. The peculiar poison generated by decomposing animal refuse when taken into the system produces a class of fevers known as typhoid, which are often fatal, and always dangerous. As a matter of course, this poison affects all animal life more or less acutely, and it is worth while for those who have written us from several localities about the suffering of their stock from diseases of a typhoid character, to consider if they have not originated in some manner similar to this. Pure water is imperatively necessary to human health, and it is equally necessary to that of our animals, and the farmer who violates this law can not escape the consequences. It is only a matter of time how soon the unwholesome matter will reach the well; and even though it be protected by a cemented lining, a passage will sooner or later be found for it.

Irrigation—Storage of Water.

The two past summers have been so dry as to cause heavy losses in various crops throughout great portions of the United States. If the excess of rains not wanted for the spring crops could have been stored in ponds, and then carefully used for irrigation as required through July and August, millions upon millions would have been added to the wealth of the country. There are few farms on which suitable spots may not be found for ponds, into which the waste water may be conducted, to be stored up against a drouth. Where springs or rivulets prevail, across which dams can be constructed for the same purpose, artificial ponds may be dispensed with. These ponds would also be very convenient for watering the live-stock of the farm; in fact, in many places where springs or rivulets do not abound, they are essential.

A Mr. Brown, of Edinburgh, Scotland, has recently invented an apparatus by which a fine shower of water, like fine natural rain, may be applied to the surface of the land as required. This is found far superior to the usual method of irrigating by ditches, and it has the further advantage of dispensing with the digging of these and leveling the surface of the ground through which they conduct the water, thus saving a large outlay to begin with. It is of no consequence how rough or uneven the land is where Mr. Brown's apparatus is used. It is affirmed that two men with it can shower a thousand acres in a single night. The best manner to use the water is to apply about as much at night as is evaporated by day. This gives the largest and best quality of crop that it is possible to grow. Will some of our wealthy and enterprising farmers import a set of Mr. Brown's apparatus, and show what can be done with it on American soil? A.

[The above comes from an esteemed correspondent, but we think there must be an error in stating the number of acres that can be watered by the apparatus referred to.—ED.]

How to Catch Down an Ox-Cart Body.

There are a number of simple ways to fasten down the front end of the body of an ox-cart. We have never found one more simple and

FASTENING DOWN AN OX-CART BODY.

effective than that shown in the engraving—which is simply a short chain passing loosely under the tongue. It is long enough to allow an up-and-down play of five or six inches in the front end of the cart-body. This enables us to fasten the free end to the body with a long hook which can not rattle out of its place; and it prevents every little movement of the load from throwing up the tongue in the yoke-ring, thus avoiding a very serious annoyance to the team. The cart should be so loaded that it will bear but lightly on the yoke, and then it will play up and down without disturbing the pole.

A Simple Stump-Puller.

Mr. J. H. Morse, of Morse's Mills, Mo., has kindly sent us a sketch of a contrivance for pulling stumps, which he has successfully used to clear forty acres of land very cheaply. It consists of a hook, a chain of more or less links, as may be needed for large or small stumps, and a ring twelve inches inside diameter, made of the best and toughest iron. Mr. M. makes his ring of two-inch round-iron, and the links of one-and-three-quarter-inch iron, but as it is an axiom

A SIMPLE AND EFFECTIVE STUMP-PULLER.

in mechanics that the strength of a chain can not be greater than that of its weakest part, the ring need not be of any heavier material than the links. The hook should be flattened on the sides, at the bend, to resist as much as possible the tendency to straighten out when the strain is brought to bear upon it. To remove the stumps if they are large and green, the roots should be partly uncovered, and the hook placed on the strongest of them. The butt-end of a

passed through the ring, a team attached to its other end, and the stump twisted out by driving around it. With two yoke of oxen, white-oak stumps of three or four feet diameter may be taken out with ease. If the roots are very fresh and tough, a man with an ax should stand near by to sever with a blow any one of the roots which offers great resistance. One acre per day can be cleared with this machine, worked by two or three men and a pair of stout oxen or a heavy pair of mules. In case very large stumps are to be taken out, it would be better to leave them to the last, and bring an extra team to finish them.

Saving Corn-Fodder.

A ton of well-saved corn-fodder is worth, if well used, the price of a ton of hay; yet how rarely is it well saved or well spent! Exposed, after husking, to all the storms of October, it is tardily stacked or housed in November, and, musty and mildewed, washed and weather-beaten, it is not only the poorest fodder but absolutely injurious to stock, to which it is thrown in the roughest and most careless way in the barn-yard. Then it is trampled down in the snow and mire, and next spring is cursed as the greatest nuisance a farmer has to contend with. But let corn-stalks be shocked up carefully, spread well at the butts of the shock, and tied closely at the top until the corn is husked, and then put up in convenient bundles, and again

set up, so that the rain can not penetrate the shocks, and as soon as cured be carefully stacked or put away beneath a tight roof, and it becomes agreeable-looking, sweet-smelling, nutritious fodder, which will be readily eaten by all sorts of stock. If it is cut up with any one of the various fodder-cutters into short lengths, or even chopped up with an ax on the barn-floor, wetted

and sprinkled with a little salt and a handful of bran, it will be entirely consumed; and the manure pile in the spring will be altogether freed from the objectionable, unrotted, and tangled stalks, while it will be equally enriched by their fertilizing remains. In this way the supply of feed will be economized, often leaving hay to spare for sale or permitting the number of feeding stock to be doubled, and besides what is often a source of trouble and annoyance may be turned to good account and money made by it.

A Hay-Knife.

Where hay is stacked, much waste occurs in using it during the winter season. Generally the hay is removed from the top of the stack as it may be needed for feeding, and thus the stack is exposed to snow and rain, and much hay becomes damaged, to say nothing of what is lost by being thrown down, scattered, and trodden under foot. This may be partly avoided by

A HAY-KNIFE.

having room in the barn to stow away one stack at a time, but still loss occurs in the removal, and very often the needed space is not to be found. Then the use of the hay-knife, as figured on this page, comes in as a very convenient means of preventing any waste. It may be made of a worn-out cross-cut saw, cut to a proper length, four feet or thereabouts, fixed to a handle, and ground to a sharp edge and point. This is to be thrust into the stack with a downward motion, and slices of the hay cut off of one side, sufficient to supply the needs of the

HORSE FOR SHOCKING CORN.

stock for a day or two. The hay can then be removed in a compact state, and the stack gradually cut up and used without the waste of a pound. Like all other cutting tools, a hay-knife cuts very much better when kept sharp and bright than when dull and rusty; it should therefore not be left out, exposed to the weather, leaning against the stack, but be brought into the tool-room when out of use.

A Shocking Horse.

P. M. McClure, Minn., sends us his method of shocking up corn, which is, he says, the simplest and quickest method he knows of. He uses a horse made of a small pole three inches in diameter and ten feet long, furnished with a pair of legs to elevate the end sufficiently, as shown in the illustration. A hole an inch and a quarter in diameter is bored through the pole, and a rod four feet long is so fitted as to slip in and out easily. The horse is placed where a shock is to be set up, the corn is leaned against the pole and the rod by which it is sustained until the shock is bound, when the rod is slipped out, the end of the pole picked up, and the horse drawn along to where another shock is needed.

Fall Treatment of Grass Lands.

A fellow-feeling, as it were, teaches us that it is inconsistent with the comfort and well-being of our live-stock to permit them to go unprotected through the winter, and exposed to cold and frost and the rigors of the weather. But

we never or seldom thus think of our meadows, and they in a sense are live-stock, and suffer from want of protection as much as cows, colts, or calves. On the contrary, a mistaken economy tempts us to deprive them of the natural pro-

tection of the aftermath, and generally they are eaten bare and close throughout the fall months, and go into winter quarters with their tenderest parts exposed to the killing blasts and biting frosts. Then the roots are winter-killed or thrown out, and in the spring, instead of the living green, we see the dead sere brown, and the season gets the discredit, when it is the result of mismanagement only or chiefly. A good coat of decaying aftermath would furnish protection and future nutriment as well, and by all means meadows should be so managed as to secure all the aftermath, or at least a large portion of it, for this purpose. Young lambs or calves may be pastured if necessary, but it is a most costly economy to turn horses or cows on to newly-sown clover or grass or to newly-mown fields. But considering that the fields are in danger of becoming poached while sodden with rain by even the lightest hoofs, it will be found cheapest in the end to keep all stock off from the fields to be mown next season.

and streams. A new plantation should be kept cut closely every year, so as to force out a good annual growth of shoots from the stumps, and the osiers may be gathered after the second or third year. But osiers may also be

shaped like that shown in fig. 3. This is made of two half-inch iron rods, eighteen inches long, welded together at one end, and gradually separating like the prongs of a fork at the other end. A stem welded on serves to retain it in a hole bored to receive it. The osier is drawn through this instrument, which strips off the bark, and it is then laid on one side until a bunch is gathered, when they are tied up, and are ready to be sent to market.

Fig. 6.—BEGINNING OF BOTTOM.

These operations are shown in fig. 1. Some osiers for coarse work are used without being peeled, but none are sent thus to market for sale unless specially ordered.

The growth of osiers may be made a means of adding to the resources of many farms, as willows will grow wherever their roots can get plenty of moisture. The making of baskets might also furnish employment for stormy days or long, dull winter evenings, when otherwise there might be no profitable employment. Weaving osiers into various kinds of baskets is an art which may be easily learned, and once the rougher methods for coarse work, such as barn baskets, or market baskets, or hampers for packing bottles, which in themselves are considerable branches of trade, are well mastered, and facility in them is acquired, the finer sorts of work will come quite handy, and can be easily performed. The commencement of all basket-making consists in laying the foundation, and this is shown in figs. 4, 5, and 6. Figs. 4 and 5 show the frame for a round-bottomed basket with handle. Fig. 6 shows the frame for a flat or square-bottomed basket, which consists of three coarse osiers, laid crosswise of

Fig. 7.—WEAVING BOTTOM.

three other similar ones. The weaving commences by passing finer osiers round the coarse ones where they cross each other, and when they are secured together they are spread out until they radiate like the spokes of a wheel, as shown in fig. 7.

Fig. 8.—BOTTOM FINISHED.

Fig. 9.—WEAVING THE SIDES. The weaving commences by passing finer osiers round the coarse ones where they cross each other, and when they are secured together they are spread out until they radiate like the spokes of a wheel, as shown in fig. 7.

Fig. 9.—WEAVING THE SIDES.

Fig. 1.—PREPARING OSIERS FOR MARKET.

grown by cutting off the mature trees a few feet above ground, and thus causing them to throw out numerous small branches, as in fig. 2. This is called "pollarding," and a willow thus cut off is a pollard or pollarded willow. In one year these shoots will grow several feet in

length, and in the fall are cut off close to the tree, and laid away in heaps until the following spring, when at the commencement of the growing season they are placed in water until the buds swell. They are then trimmed and peeled. A boy or girl removes with a sharp

Figs. 4 and 5.—FOUNDATION OF ROUND BASKET.

knife all the twigs, and hands them over to the peeler. This operator sits on a bench or before a log or stump in which is fixed an instrument

Fig. 2.—POLLARD WILLOWS.

Willows and Baskets.

The culture and preparation of willows for market is sufficiently easy and profitable to make it worthy of being carried on more systematically than it is at present. Osiers at the present time bring ten cents per pound in the New York market, and good ones are always in demand. There are several varieties of willow which may be made to produce osiers—the common White Willow (*Salix alba*) and its variety the Yellow or Golden Willow, the twigs of which are used for coarse work, and generally without being peeled, and the Basket Willow (*Salix viminalis*), which furnishes osiers superior to any others in length, flexibility, smoothness, and whiteness, and fitness for the finest kinds of work. These willows are readily grown from cuttings on rich soils or on the banks of ponds

Fig. 3.

and streams. A new plantation should be kept cut closely every year, so as to force out a good annual growth of shoots from the stumps, and the osiers may be gathered after the second or third year. But osiers may also be

shaped like that shown in fig. 3. This is made of two half-inch iron rods, eighteen inches long, welded together at one end, and gradually separating like the prongs of a fork at the other end. A stem welded on serves to retain it in a hole bored to receive it. The osier is drawn through this instrument, which strips off the bark, and it is then laid on one side until a bunch is gathered, when they are tied up, and are ready to be sent to market.

The finer osiers are then woven in amongst them, and the filling goes on until the bottom (fig. 8) is finished, when the frame-pieces are bent upwards (fig. 9), or fresh osiers are inserted, to form

a foundation for the sides. When the sides are carried up sufficiently, the frame-pieces are bent down and woven in amongst the filling, so as to hold them securely in place for a short piece, when they are cut off, and the top of the basket finished off. Figs. 10 and 11 show how the filling and finishing are done. The last work of all is to sharpen off the last remaining osiers

Fig. 10.—MAKING HANDLE.

and thrust their ends through the frame in such a manner that they can not work out. The basket is trimmed inside, all ends sticking out are smoothly cut off, and the basket is done.

Fig. 11.—A FINISHED BASKET.

and thrust their ends through the frame in such a manner that they can not work out. The basket is trimmed inside, all ends sticking out are smoothly cut off, and the basket is done.

WOLF-TEETH.—In reply to numerous inquiries as to whether "wolf-teeth" in horses cause blindness, we explain this question somewhat fully, that our correspondents may see the matter in its true light. At the age of five years every horse has or has had what are called wolf-teeth. They are pointed teeth, situated at the sides of the jaws towards the front. These teeth are naturally shed soon after their appearance in most cases, but sometimes remain, during a lengthened period, and as they are followed by other teeth, it sometimes occurs that an interference is occasioned when they do not fall out, and they are crowded in the gums, and cause irritation. In cases when from cold or neglect the eyes of the horse are injuriously affected and at the same time there is trouble with these teeth, it is very probable that the irritation may sympathetically increase the trouble with the eyes. But it is altogether an indirect effect, and if the eyes are properly cared for, the teeth would never affect them. When the interference is noticed, the wolf-teeth should be drawn, not knocked out; when there is no interference, they may stay in their place, without inconvenience, until they drop out.

Moule's Earth-Closet System and the Manure it Produces.

BY GEORGE E. WARING, JR., OF OGDEN FARM.

Having taken an active part in the introduction of the earth-closet in this country, and having attached especial importance to the economical bearings of the question, I desire to say a word in reference to a new development concerning it recently made in England. Dr. Augustus Voelcker, the Chemist of the Royal Agricultural Society, has long been known as an able investigator whose conclusions have

been stated with so much clearness and moderation as to command the highest respect. In the last number of the Society's Journal he publishes the result of a careful investigation of the effect produced on the earth used in closets by the feces they receive, which must radically modify our previous conclusions. The substance of his paper, briefly stated, is that human feces are of less value, or rather that they amount to less, than has generally been supposed, and that the quantity of earth required to disinfect them is so large that they produce an almost inappreciable effect in increasing their content of ammonia, phosphates, and potash—the three important constituents of manure. This he states with such evidence as to settle the question definitely; but in doing so he bears the strongest testimony to the value of Moule's system as a domestic and sanitary convenience, and expresses the opinion that under suitable circumstances it is the most desirable. Dr. Voelcker's investigations were made upon earth that had been used five times, and, so far as the earth that he examined is concerned, the argument seems to be closed.

Of course he does not intend to gainsay an opinion which he must hold as firmly as any other scientific man in the world, that however little the feces produced by a single man may be worth, the feces produced by all mankind it is of vast importance to save. It would extend this article too much to repeat what has been so often stated before concerning the manurial constituents of the food of large populations—the item of phosphoric acid contained in the food of the inhabitants of New York City alone amounting to 7,000 tons per annum. It would be impossible to review Dr. Voelcker's whole paper without reopening the discussion of the entire subject. The point that it seems to me most important to make relates to the application of his argument. He claims that earth which has been used five times contains so small a proportion of the remains of the fecal addition as not to be worth as a manure the cost of handling that would attend its collection and transportation in the case of large towns. It seems to me that this is the very best argument that could be used in favor of the speedy adoption of Moule's system under these very circumstances. If the earth remains nearly pure after five uses, it is evidence (confirming my own observation) that the earth may be used much more than five times. Viewed in the light of his experiments, it seems evident that it may be used even twenty or fifty times over, and that with proper facilities for redrying (which may be of the simplest character), the adoption of the system will require but one fourth or one tenth of the quantity that has been supposed to be necessary. A few tons of prepared earth, used over and over again, would suffice for an ordinary family for some years. Not until the accumulated matters had so far increased as to make the earth a valuable manure would there be the least objection to it for use in the closets.

There is one branch of the subject of which Dr. Voelcker has omitted to speak—that is, the effect upon the earth itself of the decomposition of organic matter within it. Precisely what this effect may be is not known, but it is unquestionably true that inert, fertilizing ingredients of the soil are made useful and available by the action of decomposing manure on the compounds or on the particles in which they exist in the soil. I have now had constant experience of the use of earth-closet manure for four years—in the open ground in summer, and under glass in winter—and I can not be mis-

taken in my conviction that it is a very valuable fertilizer. Its effect has been especially marked in the growth of roses and celery, both of which require a very rich soil, and both of which I have grown to greater perfection with earth-closet manure than with any other. My experience has not been singular, but accords with that of many others whose results have come to my knowledge. Even supposing that the effect produced by these manures is not enough to repay the high cost of labor here and in England, we must not lose sight of the fact that the wonderful agriculture of China and Japan is based almost entirely upon the strictest economy and the most skillful use of human manure.

There is still another consideration suggested by the article in question that has a bearing on the question of fallows, to which I refer in my regular paper in this number.

DEEP MILK-CANS.—Captain H. E. Alvord, of Fairfax Co., Va., writes: "The system of deep-setting milk is very old here. On my farm we have a stone spring-house, with deep pools of flowing water, at a temperature of 55°. For seventy years pans have been unknown here. In their place we use deep, straight-sided 'milk-crocks' or stone jars, about six inches in diameter. These stand in the pools. The milk in them is from six inches to ten inches deep, and they are skimmed with a ladle." Verily there is nothing new under the sun.

Ox-Teams vs. Horses.

In this go-ahead age it is a dismal sight to see an able-bodied man toiling along the road at the slow pace of a pair of oxen, and we have probably had as much to say as any one in favor of the substitution of the faster horse or mule team.

We are bound to confess, however, that the picture has another side which is worthy of careful consideration. Ox-teams are slow, it is true, but they are effective, cheap, and convenient. Horses are a necessity for regular road-work and for many operations on the farm, but it is almost indispensable to have for occasions considerably more team-force than is needed regularly. If the extra work of plowing, harvesting, and hauling manure is to be done by horses, we may make up our minds to have them more than half the year eating off their heads in idleness, and to be in constant danger of loss from the thousand ills that horse-flesh is heir to. To state the case in a nutshell, an idle horse is idle capital, invested in an extra hazardous risk, without insurance, and consuming itself month after month.

Oxen, on the other hand, if properly treated, are a tolerably safe storehouse of working power. When not at work, they are laying on flesh which is worth so much per pound in a ready market if we choose to sell, or which may be taken out again in the form of hard work whenever we may call upon it. In case of accident we may realize the full amount of our investment at the hands of the nearest butcher. An idle ox is active capital, the investment is safe and well insured, and his fodder is pretty certain to get paid for, either in flesh or in work.

The difference in returns in the two cases is a very important one, and the extra cost of teamster in the use of the slower animals is probably well compensated for by the saving in saddlery bills. And after all, the question of speed is of less consequence than we often imagine it to be. We have lately had an opportunity to watch two

teams in use in our neighborhood, one of horses and one of oxen, both engaged in similar work (mainly on the road), and we have come to the conclusion, against our preconceived notions, that "slow and steady wins the race." The oxen seem to do more work in a week than the horses. They are three pairs of young cattle, growing thriftily, and so paying a profit on their keep when not overworked—costing less to buy and less to feed than the single pair of horses. When they are needed for work, they are taken up and fed enough grain to keep them hearty. When their work is finished, they are turned out to "eat, sleep, and grow fat." When each pair have got their growth, they are sold to the butcher, and a part of their price replaces them with younger ones.

Starting our farming life with a prejudice against the use of ox-teams, we have been induced gradually to substitute them for horses, until now we have only enough of the latter for our regular road-work, and depend on oxen for all emergencies. In work and in flesh we get a full equivalent for all the food they consume, and we save the heavy cost of keeping idle horses, the risk of a total loss of value by accident or death, and the certainty of depreciation by reason of old age.

Hints about Wheat.

It is a mistake to suppose that wheat is not a paying crop. Very often it is not profitably grown, but it is looked upon as a necessary evil, hardly to be avoided, for the reason that there is no other crop to be substituted for it in the rotation. Yet wheat is absolutely necessary for us, and it would be strange if a crop which the world can not do without could not be grown to a profit anywhere and everywhere. The competition with the easily cultivated and productive new lands at the extreme West need not necessarily be overwhelming to the more eastern cultivator, who on his side has an advantage in nearness to market, and cheaper tools and implements, and less waste and cost in harvesting. But the trouble lies in the small yield with which the Eastern farmers are contented, consequent on the generally careless and insufficient methods of preparing for and sowing the crop. Very rarely is the oat-stubble, which the wheat crop generally follows, plowed more than once, and very often the corn-stubble prepared in the most hurried manner by a simple harrowing is made to bear this crop, which is more than all others dependent for success on a well-prepared seed-bed. The consequence is, that the young wheat is smothered by the more vigorous oats which spring up thickly on the newly-plowed ground, and thus weakened is unable to stand the first heavy frost of the fall or winter, and is killed out. So on the harrowed corn-stubble there is no depth of root to sustain the plant in the hard-beaten soil, and it is in a worse condition in this case even than on the plowed oat-stubble. At present there is not sufficient vigor in the soil to enable the plant to make head against the difficulties it has to contend with, and it succumbs, and the crop either fails completely or is very unprofitable in its results. We must work on a different system. Old things have passed away, and if this crop is to succeed a new system must be adopted. The wheat crop must be the pivot on which our farming must hinge both in the East and West. The West, as we used to understand the term a few years ago, is now the East, and is in exactly the same circumstances as to condition of soil

and needs of cultivation as that part of the country we used to call the East. "Thorns and thistles" have taken possession of the soil, and the "virtue has gone out of it" by which it used to grow crops by merely scratching the surface. No fair wheat crop can now be got by merely harrowing a corn-stubble, or once plowing an oat-stubble; nor can we lay our fields down to grass with a poorly-grown wheat crop and hope to have a good catch or a good crop of clover or grass. Grass is often called our "pivotal crop," that on which the whole rotation depends; but wheat is the precursor of grass, and as it succeeds or fails, so will our clover and grass flourish or fail. Then it will no longer do to hurry it into the ground as we have done. A difference of ten bushels per acre depends on this alone, and this is sufficient to make a crop profitable or otherwise. Two plowings at least should be given, and unless a very fair allowance of fairly good manure can be afforded, some of the purchasable manures should be applied, and those rich in nitrogen or ammonia are preferable to the phosphates, or at least have shown themselves to be more effectual as a fall application. Then, again, there is much in the sowing. It is plain, as the rapidly accumulating result of experience of late, as the attention of farmers has been more closely drawn to this matter, that broadcast sowing must be abandoned as no longer profitable. It is too costly a method. Especially has the late hard winter shown this. Drill-sown wheat has escaped the evil effects of drouth, frost, and excess of wet, while broadcast-sown has been seen dead and cast upon the surface, with its roots all drawn from the soil, and no resource left to the farmer in the spring but to replant his bare fields with other crops. The difference here in the yield of the crop will be from five bushels per acre to the whole crop lost, so that, should farmers generally adopt this and the previously mentioned plans, it is probably safe to say that the yield of wheat would be doubled. Certainly, we have often seen, in fact we have grown, crops of wheat of twenty-five or thirty bushels per acre, which have been carefully put into the ground, which we are satisfied would not have yielded ten bushels had the old-fashioned system here pointed out been followed. In the one case, at least expenses were paid, if no great profit was made, and a good hay crop followed; in the other case, there would have been a serious loss both on the wheat and hay crop. Further, in selecting seed, it will pay to exercise care and judgment. None but the plumpest grain should be chosen. The wheat should be cleaned two or three times, and our experience has been that it will pay to steep the seed in a solution of copperas, which destroys smut, and helps to separate the light grains from those which are fit for seed. A crop sown in good season is to be preferred, but it is far better to delay a week to complete the preparation, and get the soil into the best condition, than to hurry over it and make more haste but less speed in the end.

How to Kill and Hang a Beef.

A farmer should of right be one of the most independent of men. When the need arises, he ought to know how to do himself everything that he may want done on the farm. Amongst other things which he will sometimes find it necessary or convenient to do, is to slaughter and dress a fat cow or ox for home use or for market.

For want of knowing how to do this, a farmer often sells a beast to a butcher for five cents a pound, and buys beef for fifteen cents, and it needs but little figuring to show it to be an unprofitable business.

On every farm there should be an out-house, with a plank floor, which can be washed off clean, for the purpose of killing and dressing sheep, hogs, or a beef. There should be also a stout beam above, on which to hang the carcasses; the window should have a close shutter,

Fig. 1.—RIGGING FOR HANGING A BEEF.

to keep the house close and dark, and the door should fit tightly. Then, when a carcass of beef is to be prepared, the animal is brought into the house. A rope around the horns should bring its head to a strong ring-bolt in the floor, and a well-dealt blow with an ax, delivered on the forehead, just above the eyes, will fell the beast to the floor, and render it insensible. The throat should then be cut and the blood drawn as rapidly as possible. As soon as life is extinct, the skin should be slit along the belly

Fig. 2.—BEEF WHEN HUNG.

and brisket up to the chin, also from the fore-knees down the inside of the forelegs to the brisket up to the first slit. In the same manner down the back of the hindlegs and thighs to the rump. It should then be stripped off the legs, brisket, and belly, and the carcass opened and the inside taken out and removed at once.

The carcass may then be turned over and the hide stripped off completely, the head and feet cut off, a strong gambrel stick placed through the hindlegs at the gambrel-joint, and the carcass hung up. This is generally the most difficult part of the work, but by using such a contrivance as is shown in fig. 1, it may easily be done. A rope is thrown around the beam as shown in the figure, with the ends of equal length hanging down; a short, stout bar is passed

through a knot at each end of the rope, and the ends of the gambrel-stick are laid in the angle formed by the rope and one end of each bar. The bar is then turned around the gambrel-stick, and the rope is wound up and the carcass is hoisted. When sufficiently high, hooks may be used to suspend the beef, or ropes may be used for the same purpose, or one end of each bar may be twisted so as to pass

on the open prairie, all ready for the plow, and who may be carried thither comfortably on the "cars," can have an idea of the straits through which many now wealthy farmers once passed when they made "ashes" on the land now covered by fields of wheat and orchards. Then, far removed from what is called civilization, they were buried in the woods, depending solely on themselves, or on the mutual assistance of

In many rocky, rough parts of the country these potash camps were moved from one point to another as the land was cleared of the timber, and abandoned as worthless for any other purpose, and thus large tracts of mountain lands were stripped of their woods and left to grow another crop. But in all these cases the work and the ways and means of doing it were the same, the labor was heavy and great and

Fig. 1.—LOGGING.

Fig. 2.—LEACHING AND BOILING DOWN.

beneath the beam, and then, resting against it, will prevent the rope from unwinding and keep the beef suspended, or a rod may be placed between the ropes and the bars, as shown in fig. 2, with the same effect. It should be remembered that beef as well as all other meat is always better flavored, and keeps better, when it is permitted to lose all its animal heat and become "set" and rigid before being cut up.

Potash-Making.

The manufacture of potash has heretofore been largely carried on in the heavily wooded parts of this country and Canada, but of late

one or two neighboring settlers situated just like themselves, for all they might require.

There slowly throughout the winter months the great trees were chopped down and cut into lengths of twelve or fourteen feet, and with the help of a "logging bee" rolled up into heaps ready for firing. Thus the land was cleared and prepared for the first crop of potatoes or wheat to be put in, without the plow, but by means of a rough harrow built of logs and armed with wooden teeth. These log heaps were in due time fired and burned down into ashes, which were gathered and protected from the rain by a rough shed roofed with bark or split slabs.

When the scanty crop was sown or planted, the leaches were made, the ashes run off, and

the profit small, and much hardship was endured. In the illustrations, our artist has shown the prominent parts of potash-making—the logging (fig. 1), which is the heaviest part of the business, and needs the assistance of the neighbors, who help each other in turn, and make "bees" for this purpose; the burning (fig. 3), which is done mostly at night, and is a very picturesque scene to outsiders who are not obliged to get black from head to foot with coal-dust, nor be blinded with smoke or sparks, nor have to stir up the heaps with a long pole or handspike to keep them burning, but who can enjoy from a prominent point of rock or a little hill all the beauties or romance of the scene without any of the hard realities; and then the leaching and boiling

Fig. 3.—BURNING THE LOG-HEAPS.

Fig. 4.—BREAKING AND PUTTING INTO CASKS.

years has greatly fallen off. While the manufacture is to be regretted, as it abstracts from the soil a vast amount of valuable fertilizing material, yet the peculiar position of a backwoods settler is such that he is forced to make the sacrifice, and rob his future farm to supply his present needs. Poor in everything but strength of muscle and endurance of hardship, the backwoodsman very often depends on a few barrels of potash as the source whence he can procure those things urgently needed by his wife and young children, and few now settling

the lye boiled down to dryness, and the heat increased until the mass melted. When cold, the potashes were turned out of the kettle, broken up, packed into barrels, and as soon as possible taken to market and exchanged for provisions, clothing, or groceries, and occasionally, though but very seldom indeed did this occur, a dollar or two in money was procured. In this way these hardy pioneers "got along" until their crops were harvested, when the tide of fortune turned for them, and thenceforward they thought themselves independent.

down (fig. 2), which also needs attention night and day until completed; and finally the packing into barrels (fig. 4), which no doubt, as it is the finishing operation, is the most pleasant, and is most cheerfully performed.

The localities in which potash-making is practicable or profitable are annually becoming fewer, and it is to be hoped that some of the many projects for obtaining potash from mineral sources will be attended with success, and that the necessity for robbing the land of this important element of fertility may cease.

Sweet Peas—Improved Varieties.

In our early gardening days we had Sweet Peas, and that was the end of it. There was then no thought of named varieties. The ori-

trellis, and one to which the pea-vines take very readily. To have Sweet Peas continue long in flower, the blossoms should be picked, and no seed allowed to form. We have been much troubled by some insect that eats por-

tenuated look, we cut them back, when they grew very busily and bloomed profusely. The objection to their use as an edging is their height, they being much better adapted to the second line of a border than for the front. At any rate,

VARIETIES OF THE SWEET PEA.

TALL BROWALLIA.—(*Browallia elata*.)

ginal Sweet Pea, *Lathyrus odoratus*, a native of Southern Europe, is one of the oldest of garden plants, and has justly been a favorite on account of its agreeable fragrance. Of late years our catalogues have contained named varieties, which, thanks to the efforts of English amateurs, are very fine and distinct. This spring we received from Messrs. B. K. Bliss & Sons an assortment of seeds of the newer varieties, the results from which have afforded us much pleasure. There was a pure white; a part white and part violet; a striped scarlet; striped purple; an Invincible Scarlet, a very rich color; a variety called black, which is only a very deep purple. In the engraving there is an attempt to represent these varieties as well as can be done in black and white. Sweet Peas, like other peas, do all the better if sown early and the seed covered rather deep. We were at first puzzled to fix a trellis for a row over twenty feet in length, but hit upon the following plan, which is very satisfactory: Strong stakes were driven down, and common shingle laths nailed to them. One lath was placed near the ground, and another at the height of about three feet. Pea-brush was then stuck close against the laths, and bound to the upper one by winding a twine over and over so as to catch the brush in the turns. After the twine was made fast, the tops of the brush were cut off even with the upper lath. This makes a very neat

tions of the flowers and destroys their beauty, but have not yet been able to discover to what insect we are indebted for this little annoyance.

The Tall Browallia (*Browallia elata*).

Several times we have had occasion to notice the fact that well-known and old-fashioned plants would be almost lost to cultivation, and then again would spring up as novelties. The Tall Browallia is an illustration of this. Those who recollect the flower-gardens of a couple of generations ago know that this Browallia was at one time a favorite, but of late years nothing has been seen of it. Two years ago several specimens were brought us to name; last year still more came in; and this spring some of our florists introduced it among the novelties.

So the old Browallia, which has been known for over a century, turns up as good as new, and a great deal better than many really new flowers. It is a vigorous-growing annual of a foot and a half in height, with an abundance of dark green foliage, and small flowers of an intense blue, which is rather lighter at the throat of the flower. Blue flowers are so rare that we are glad to see this old plant brought into favor again. We used as an edging to a bed a lot of plants that had been started under glass and were rather drawn. Dissatisfied with their at-

the plant, on account of its lively blue, is a pleasing one. The engraving shows a small stem of the natural size. There is a white variety which we have not seen. The plant is a native of Peru, and the genus received its name from Linnæus, in honor of a bishop named Browallius. In the greenhouse it is especially valuable, as it remains in flower a long time, and becomes almost a perennial. It belongs to the large Fig-wort Family (*Scrophulariaceæ*). The very small seeds may be sown in the open border, or under glass if plants are wanted early, taking care not to cover too deeply.

The Market-Gardens near London.

EUROPEAN CORRESPONDENCE, BY PETER HENDERSON.

For years I have been anxious to see and compare the market-gardens of London with those of New York, and have this week been able to do so.

The extent and thorough culture of these gardens is something wonderful. One of the best we saw was in the vicinity of Tottenham, owned by a Mr. Hollington. It comprised about a hundred acres, every foot of which was planted in close crop, and, as far as could be seen, it would have been difficult to have picked up a bushel of weeds on the whole of the hundred acres. Mr. Hollington's success in

twenty years equals, if it does not surpass, any of which we have record in America. When he took possession of these hundred acres, twenty years ago, he did so at a nominal rent, but without a lease, with the condition, however (a very unfortunate one for the owner), that the owner might enter upon possession at any time by *paying him the value of the crop upon it*. Mr. H., a man of great energy and shrewdness, at once saw his advantage, and took care that his grounds should at all seasons be cropped to the fullest extent—something which can be better done in England than with us. The result was that when the owner one day took it into his head to take possession, he discovered that he would have to pay more for the crop than the land was worth, and there was nothing for him to do but to sell to the tenant, or go on receiving the nominal sum for rent. The result was that Mr. H. bought the land, and is now perhaps the wealthiest market-gardener around London.

The next grounds we visited were those of George Steele & Sons, of Fulham, a point nearer to the City. These grounds were also models of order and neatness, although a week previous three fourths of the workmen had struck for higher wages, and had gone to hay-making, leaving the owners in a bad plight. The garden comprised fifty acres, and the full number of hands was seventy-five. Now there were less than twenty, and these second-rate.

Why, it may be asked, does it require seventy-five men for fifty acres? Simply because John Bull will not believe that land can be better dug with a plow and harrow than with a spade. I took some time to argue the point with Mr. Steele, and he declared that the morrow would see for the first time a plow in the market-gardens of Fulham. Once there, it will remain, for there is no one who has had practice with both methods but knows that no digging with a spade or fork can bring the soil to the mellow condition that the plow and harrow can. Upon grounds of the extent of Mr. Steele's the use of the plow will save full one third of labor.

Here, too, and at Mr. Hollington's, they were using another very primitive tool, which I did not venture to say anything about, for I thought I had trodden hard enough on John's conservative toes for one day. The tool in question was a planting-stick made out of a spade-handle, just such as was in use thirty years ago by the cottagers of England or Scotland to set out a few dozen cabbage or lettuce plants for their own use. Yet here, where millions on millions of plants had to be set out, no better implement had been thought of. The spade-handle dibber, even in the most experienced hands, is a waggling implement, and is hardly more to be compared in effectiveness to the pistol-handled dibber in use by the gardeners of New York than a sickle is to a cradle in a wheat-field.

This reminds me that I have not yet seen a single machine in the hay-fields in England either for cutting or raking; nothing but the ordinary scythe and hand-rake. No doubt machines are in use in some districts, but are certainly not common, for along the whole line of railroad from Liverpool to London we saw hundreds of mowers all using the scythe. Yet we must not plume ourselves on any particular smartness in the use of implements that lessen labor. The necessities of our condition force us to their use. When it is found that we have two men's work to do, and can only afford to pay the high price of one man to do it, then necessity becomes "the mother of invention," and means are found to accomplish the end.

I found one practice in Messrs. Steele's grounds which our market-gardeners might imitate with profit. The system is a very old one, and has been in use probably for fifty years, but it is certainly not much used, if at all, by market-gardeners in the vicinity of New York, Philadelphia, or Boston, where its advantages would be even greater than those around London. It is the common hand-glass, of a size about two feet on the side. These would cost with us probably about 75 cents or \$1 each. Messrs. Steele use these glasses in large numbers to forward cauliflower for heading. They are placed at distances of two feet apart, and three plants of cauliflower are planted under each. The hand-glasses are tilted up for ventilation in sunny weather—used, in fact, just as we use a hot-bed or cold-frame, and the cauliflowers are forwarded probably two weeks earlier than they would be in the open ground. Of course there is not room under the glasses for the three plants of cauliflower to form their heads there, but the object is to forward them so that they will be large enough to head in the open ground when the glasses are taken off—a most important matter with us, as we find the trouble always is that we can not get the cauliflowers large enough until they are checked by our hot and dry weather in June. Thus forwarded in New York, I think it safe to say they would readily bring \$1.50 for each hand-glass.

Variation in a Peach-Tree.

W. C. M., Barren Creek Springs, Md., writes: "I have a peach-tree, six years old, from the Ohio bud, on the south-east side of which is one small limb which branches into two; the lower one last year ripened its fruit much earlier than the other branches, and this year has on it peaches of fair size, now ripe, while the rest of the fruit is green and hard, scarcely colored. Is this not uncommon? Can it be accounted for? All the conditions of this limb are apparently the same as in the other limbs. Is it a 'sport'? Would buds from this limb bear as early fruit?"—This is an instance of what is now called "bud-variation," to distinguish it from another kind of sporting from seed. It is not very common, but there are a sufficient number of well-recorded instances to establish the fact that it occasionally happens, not only with the peach but with other fruit trees. Some branches of the peach have produced nectarines, and *vice versa*. A tree of the well-known peach *Grosse Mignonne* in France produced a branch with fruit so much later than the rest, that it was propagated as the *Grosse Mignonne tardive*, or Late *Grosse Mignonne*. Such cases have happened with cherries, plums, grapes, and other fruits. We can not account for the occurrence. The peach, as our other cultivated fruits, is in a condition far removed from its original one, and we only know that there is a tendency not only among our cultivated fruits, but with flowers and vegetables, to vary. Buds from the limb in question would no doubt propagate the peculiarity.

PEA-BUGS.—A correspondent says we may rid ourselves of Pea-bugs in two ways, provided we let none escape before applying the means, and provided our neighbors will all take the like pains. By one method we involve the peas and bugs in good soft-soap suds, stirring a little until the bugs rise, and then skim them off and burn them. Probably they might, after the sudsing, be safely planted with the peas, but it

is sure work to burn them. Another method is to pour scalding water with a quick dash over the peas, and almost instantly follow it with cold. This may seem to endanger peas as well as bugs; but we have used this process, losing very few if any peas. But using either process, there must be care to sow the peas quickly, or they will swell, and be in danger of splitting and damaging the germ. A few bugs may escape from not having opened their cells; but in the second year, repeating the means, scarcely a bug need be left to propagate its species. It is best to treat small quantities at a time.

A California Lawn-Sprinkler.

We have recently received from a friend in San Francisco an automatic sprinkler such as is much in use there, where it is necessary to produce an artificial rain to keep lawns green in summer. It is shown in fig. 1.

A light tripod, about three feet high, supports a revolving head, which consists of three arm-like tubes (shown in fig. 2) attached to a hollow washer that plays around the tube to which the

Fig. 1.—CALIFORNIA LAWN-SPRINKLER.

hose is attached, bringing water from a head. The arms are turned a little backward and upward, and the water as it flows out causes them to revolve, flinging a fine spray over a circle of from ten feet to thirty feet in diameter, according to the pressure of the water. We are using ours with a head of about fifteen feet, and it covers a diameter of twenty feet. When this area has been well watered, the machine is

Fig. 2.—TUBES OF SPRINKLER.

moved to new ground. It requires but little attention from a man working in its neighborhood, and is a very useful affair in dry weather. We are not aware that they are for sale in the Eastern States, but any plumber could make one (mainly of gas-pipe) without much expense.

MR. SISLEY'S GERANIUMS.—Mr. Jean Sisley, of Lyons, France, is well known as a horticultural amateur, and now and then he has con-

tributed valuable articles to our columns. He has enriched our collection of Cannas by many fine varieties, and has of late years turned his attention to producing double Pelargoniums or Geraniums. The varieties that he has propagated are highly praised by the French horticultural journals, and some have passed into the hands of the commercial florists. Mr. Sisley has sent us by the hands of a friend two of his best seedlings, "Charles Darwin" and "Emilio Castelar." They were weak when first received, but have recovered by good nursing, and we hope they will give a good account of themselves.

Notes from the Pines.

Correspondents write to ask what has become of "The Pines." When I commenced these Notes I had no idea of continuing them regularly, but chose this gossipy form of presenting from time to time such things as I did not care to put in a regular editorial.

PEGGED-DOWN ROSES.—A little bed of tender roses kept well through the last winter, severe as it was. They were protected after Mr. Henderson's plan, by covering them with sods. Not having been laid down by a careful hand, many of the stems were badly bent, and rather than cut them away, as they never would have come straight, I pegged all down flat upon the ground. This is a common method of growing roses in England, but I had never before tried it, and am much pleased with the result. The bloom has been most abundant, the new growth (also pegged down) remarkable, and I think that the plants have been freer from slugs and other insects than when they grew erect.

DOUBLE PORTULACAS.—What fine things these are when you do get double ones! Some seeds from Mr. Dreer produced almost all double flowers. I have a rock-work devoted to succulents, but wishing something that would make a show while these were getting established, the Portulacas were planted among them. Their flowers every bright day are really fine, as double as roses, and white, crimson, and golden yellow.

BUSH AND CORDON APPLE-TREES.—I wish something could be done to make these dwarf apple-trees better known. They cost but little, and if they were planted only as ornamental shrubs their flowers in spring would be quite as satisfying as those of many things grown for their flowers alone. Then they bear fruit, and it is very pleasant to pick a dozen or two of apples from a little tree. One of my cordons not three feet long ripened twenty-three fine Duchess of Oldenburgs. The apples were almost as close as they could stick. Mind, I don't recommend these trees for profit, but as affording pleasure in fruit-growing.

THAT POTATO.—I think that in an earlier note I mentioned having received for trial from B. K. Bliss & Sons a potato for which great claims were made as to earliness. I made two plantings side by side with Early Rose, and in both cases it was easily ten days ahead of that well-known early variety. I don't know that the potato has any name, nor have I tried it upon the table. I could not afford that, as the gentleman who raised it was offered at the rate of \$4,000 a bushel for his remaining half-peck. I planted one pound each of Early Rose and this new variety in such soil and with such treatment as one would give in ordinary field culture, the object being to make a fair com-

parison of the two without attempting to get the greatest possible yield. When dug, the yield from the pound of Early Rose was 35 lbs., and that from the pound of the new potato was 34 lbs. As several potatoes were taken from the last-named from time to time for the purpose of observing progress, it is probable that had these remained the yield of the two varieties would have been the same, and we are safe in saying that it yielded in this single test quite as well as the Early Rose.

MOORE'S CONCORD CORN.—Last year I gave an adverse report upon this variety, but spoke highly of the quality of Judson's Branching Sweet-Corn, though it did not branch a bit. I procured seeds of half-a-dozen varieties of corn at the same time, and the seedsman who served me is convinced that in putting them up the Moore's went into the bag labeled Judson's, and *vice versa*. This year's experience shows that he was right—or wrong, as you choose to have it. Moore's Concord has this year done well, and is apparently just what my Judson's of last year was. It makes a fine large ear, larger than any early variety with which I am acquainted, and of very good quality, though not so sweet as some smaller sorts. To one not brought up in Rhode Island, where sweet-corn was invented—to the Boston people for instance—Moore's will no doubt seem the perfection of sweet-corn. But put it by the side of Early Narragansett, and then you will see that (as between Rhode Island and Massachusetts) size is not the only quality to be looked for in either sweet corn or States.

STRIPED JAPANESE MAIZE.—This has been "out" these many years, but I never happened to grow it until this season. I planted it in a thicket of Castor-Oil Beans, Cannas, and other quick-growing stuff intended to serve as a screen, and am much pleased with it. I may have got hold of a very good strain (R. H. Allen & Co.); at all events every plant is well marked, and some individual ones are really beautiful.

TOMATOES.—I have usually grown a dozen or more kinds for comparison, but this year my main crop has been the Trophy. The only others I tried were Early Shipping, from Peter Henderson & Co., and the Peach, from a correspondent at the West. The Trophy was ahead of either of these in earliness, while in size and quality there is no comparison. The Early Shipping has a most peculiar foliage, and looks more like a potato than a tomato. The "Peach" is a medium-sized fruit of good flavor, very regular, and of a peculiar light crimson color.

Propagating by Budding.

A majority of the readers of the *Agriculturist* rely upon its pages as their sole source of information upon all subjects relating to agriculture and horticulture. It is easy to refer those who send us letters of inquiry to this or that book to answer their questions, but the fact is, and we are glad to know that it is so, our large circulation is among those in moderate circumstances—people to whom the cost of the paper is an important item, and who can not as a general thing afford to invest much in books. Our great usefulness has been in adapting our teachings to the masses, and if our friends who are skilled in horticulture find us, as in the present article, now and then treating of what seem to them mere elementary matters—first principles—they must bear in mind that to the great multitude of readers such things are new,

and that articles like this are called out by numerous letters.

We are asked by many to give directions for budding and inoculating trees. It is a great misfortune that the term *inoculation* is employed, as there is a confusion of ideas caused by its use. People know that *inoculation* is practiced to so affect the human system as to diminish or destroy the liability to an attack of small-pox. Many quite intelligent people think that the *inoculation* of a tree introduces something into it that will cause it to bear better fruit, and are not aware that budding or inoculation replaces a worthless tree by a valuable one. The mechanical operations of budding are easily learned, but to work intelligently the principles which govern them must be understood. The propagation of plants by cuttings is one of the most common ways of multiplying them. Almost every one has grown a plant from a cutting, or "slip" as it is often called. This cutting or slip is a twig from the parent plant, with usually several eyes or buds upon it.

This being put in the soil under favorable circumstances, roots are formed, the eyes or buds push and form branches, and we have a new plant precisely like the one from which the cut-

Fig. 2.—BUDDING KNIFE.

ting was taken—a part of it as it were. The number of buds upon the cutting will depend upon the kind of plants, some rooting so easily that a single bud is enough. But all the plants that we desire to propagate can not be readily started from cuttings, and notably among these are our most valued fruit trees. In case of these we resort to grafting and budding. In grafting, we take a cutting or slip with several buds, and instead of planting it in the soil, we cut

Fig. 8. Fig. 9.
TIES.

off and split a tree or a branch, and plant the cutting in the split. The wound soon heals, and the cutting or graft unites with the branch, and goes on and grows by means of the roots of the tree (stock), in which it is placed, just as readily as if it had made roots of its own. Grafting and budding are essentially the same in principle, though the mechanical operation

is different. It is rather unfortunate that we have two so distinct names for the operations. The French, who make a great many kinds of grafting, call budding "shield-grafting." In budding we have still nicer work than in grafting. Instead of taking a twig with several buds from one tree and planting (grafting) it into another, we take one single bud and plant it in another tree. The tree that is budded or grafted is called the *stock*, which is operated upon or *worked* when of small size. Peach-trees from stones planted in the spring are large enough to bud the fall of the same year. Apple, pear, and most other stocks require to grow two or more years before they are large enough to bud. But we have not space to discuss the subject of stocks. The next thing to consider is the buds, which must of course be taken from the variety that we wish to propagate. It may seem superfluous to state this, but it is not rare to find a person who thinks that there is some virtue in the mere act of budding, and does not seem to know that the future tree will be precisely like the one from which the buds are taken. To obtain buds, we cut twigs of the present season's growth on which the buds, at the angle where the leaf joins the stem, are well developed. The leaves upon this twig are cut away, leaving the leaf-stalk attached. This is called a *stick of buds* (fig. 1), which in damp moss or in a close tin box may be kept for several days. The stocks and buds being ready, then comes the mechanical operation, which can be readily learned by watching a budder, or by practicing a short while upon some worthless twigs or stocks. The time for the operation depends upon the kind of stock and upon the season, it beginning much earlier at the South than at the North. The stock must be in a growing condition, in order that the bark may part freely from the wood. The only implement required is a budding-knife (fig. 2), which is often made with a small ivory blade at one end for use in lifting the bark of the stock. Material for tying is needed, which is usually bass-matting or bass-bark prepared from our native tree. Corn-husks are used by some, as are cotton and woolen yarn, etc. The operation of removing the bud is shown in figure 3. The knife being placed

heres to the inside of the bud separates easily, it may be removed, otherwise it can be left. A smooth place being chosen upon the stock, and such leaves as are in the way removed, two cuts are made, one transverse and the other lengthwise, as in figure 4, the corners of the bark are lifted as in figure 5, and the bud put in

The Venetian Sumac or Smoke-Tree.

The Venetian Sumac or Smoke-tree, also called by some nurserymen the Purple-fringe Tree, is one of our best ornamental plants. It is useful when planted in groups, but shows to the best advantage when grown by itself in a position where it can develop without being crowded by its neighbors. One would hardly suppose it to belong to the same genus with our native Sumac, but such is the case, though it differs from our species in having simple leaves. Its botanical name is *Rhus Cotinus*; it is a native of Southern Europe, and in its wild state is to be considered rather as a bush than a tree. Under cultivation it will grow to the height of fifteen or twenty feet, and if properly managed will form a very symmetrical rounded head. The leaves are oval, very blunt at the apex, and of a rich green color. Indeed, the tree is well worth growing for its foliage alone, and this endures until the occurrence of very hard frosts, and often takes on a fine reddish yellow color late in the season. The flowers are small and greenish, and are succeeded by small fruits which are half-heart-shaped. Usually only a small portion of the panicle bears flowers, the rest of the cluster consisting of abortive flower-stalks, which after the flowering increase very much in size, and are clothed with long hairs. It is these large clusters of abortive flower-stalks that usually pass for flowers, and form the most ornamental portion of the tree. They usually occur in great profusion, their cloud-like masses often nearly concealing the foliage, and so light and feathery are they, that the name Smoke-tree is not inappropriate. When these clusters first appear, they are of a delicate purplish tinge, which afterwards changes to a yellowish green. We are sometimes asked by correspondents, what they shall do to make their Smoke-

VENETIAN SUMAC OR SMOKE-TREE.

its place as in figure 6. The top of the bark attached to the bud is cut off square, so that it may fit accurately to the transverse cut in the stock. The last operation is to tie. A strip of bass or other material is wound around in such a manner as to keep the cut edges of the bark from curling up, and to hold the bud in place, as shown in figure 7, when the tie is put around the stock both below and above the bud. The operation is performed by a skillful hand with great rapidity. In the peach-growing districts there are those who make a business of budding, and put in from fifteen hundred to three thousand buds as a day's work. They have a boy to go ahead and trim the stocks, and one to follow to tie. The peach-budders use a very simple tie, either that shown in fig. 8, where the knot is over the bud, or in fig. 9, where the knot is on the opposite side of the stock. In about two weeks after budding it can be determined if the buds have "taken;" if so, they will remain plump and green, and the leaf-stalk will have fallen. If the leaf-stalk dries and remains, and the buds look brown and shriveled, the operation has failed. As the stock grows the ties may strangle the bud, hence they are cut as soon as the bud has united. The bud remains dormant until the next spring, when the stock above it is cut away, and the bud pushes rapidly and makes a vigorous growth.

trees flower. The trouble is that they do flower, and in such a case the tree makes but little show. It is only when from some cause or other the great majority of the flowers are abortive that the clusters take on their ornamental appearance. We have two trees upon our lawn, but it is not

Fig. 3.—MANNER OF REMOVING THE BUD.

about half an inch above the bud, a cut is made so that it will come out about three fourths of an inch below it, removing the bud with an attached shield of bark and usually a small piece of wood. If this portion of wood which ad-

usual for both of them to be showy the same year. The engraving gives a very much reduced flower-cluster, and at one side some of the hairy abortive flower-stalks, with one much less hairy, bearing the fruit or berry.

THE HOUSEHOLD.

(For other Household Items, see "Basket" pages.)

Short Hair for Women and Children.

A fine head of hair is a beautiful thing. It forms a becoming background or setting for the human features. Other "little women" than Jo March have considered their long, abundant, glossy hair their "one beauty." Some of these same little women have found, however, that they were really better looking than before when they have had their long curls or heavy braids cut off.

It seemed "such a pity" to all their friends, and they felt themselves that it was a great risk to run, because they might not look half as well after the barbering as before, and they hadn't a bit of beauty to spare. But the deed is done, and the friends who remonstrated most earnestly are perhaps forced to confess that short hair can be made very becoming to some persons.

Long hair is often very unbecoming we all know. Thin coarse locks are no ornament. If cut short, and tossed up lightly about the face, they sometimes improve the personal appearance very much, as many have learned during the late frizzing days. Long hair is usually drawn away from the face, so as to afford less of a "setting" for its wearer than short locks give. It is called a covering for woman, but it is drawn up from the neck in such a way, at fashion's demand, that it covers less of the body than hair only two inches in length.

While not advocating the total abolition of long hair, let us see what good reasons may sometimes constrain a sensible woman to have her head shorn of its reputed "glory."

The long, thick hair considered so desirable has considerable weight, and it taxes the nervous power to carry it about. A pound of hair is as heavy as a pound of candles. Worn in braids or rolls over the top of the head, it will actually make depressions underneath the rolls or braids, quite perceptible when they are removed after a few hours' pressure. At the same time, such long hair produces considerable discomfort. One may become so accustomed to this as to pay little attention to it. Worn in a coil at the crown or back of the head, it disturbs the circulation and provokes disease, and it renders any comfortable resting of the weary head almost impossible. What misery there is in the use of hair-pins! What "ridiculousness" in the "rats," cushions, jute chignons, etc.! What an amount of time, and care, and life-power gets used up in dressing and arranging this weight of hair, especially if it must be put in curl-papers or frizzing-pins over night!

Does it pay? Every woman should answer the question for herself. Outward adorning is all right if it does not interfere with the more precious inward adorning of the mind. The adorning fashion ordains is often barbarous in the extreme, and why does not a cultivated taste rebel?

What relief it is to get the head into such a condition that it can be bathed and dressed and rested with ease! How pleasant it is to run the fingers through the hair when the head is tired and heated! What a comfort it is not to have one's hair in the way when hurried or when weary!

But there is an answer ready for all reasoning in favor of short hair: "Oh! I think long hair looks best for a woman." That settles it, of course, for most women. Here and there is a woman who considers health and comfort and convenience of more consequence than prettiness. There are women, too, who can not believe that anything is really beautiful or truly becoming which tends to injure health or destroy comfort. But most of us go from one fashion to its opposite, unmaking slaves of fashion as we are, and everything we are accustomed to is considered tasteful and proper. And then a few women have husbands who consider themselves sole arbiters in all matters concerning their wives' apparel, and such men are pretty sure to like to see women (those belonging

to themselves) looking like duchesses, in plaited hair and brodered apparel.

Little Girlie had long golden curls, and we loved them until we saw how it fretted her and her mamma every day when the task of unsnarling and re-curling had to be performed. And the curls were so warm on her neck and shoulders, and such a temptation for baby's pulling fingers! So they were cut off, and when the pretty head was "shingled" the child actually was prettier than before, and her mamma admires the golden curls laid away in the bureau-drawer more than when they grieved and tormented and cultivated vanity in her child.

RELL.

How to Make a Refrigerator or a Meat-Safe.

In compliance with a request, we give cuts of a refrigerator and a meat-safe, with the following directions for making them:

The refrigerator is a wooden box of suitable size, having a recessed lid. It may be divided into

Fig. 1.—HOME-MADE REFRIGERATOR.

chambers if desired, to keep various articles separately, as butter from vegetables, or meat from fruit or pies. A central chamber with a separate lid is made in the upper part of the box to receive the ice. This should be made of sheet-zinc, and have a pipe in the bottom to permit the water to drain away as the ice melts. The shelves which divide the upper and lower parts of the box should be placed where the dotted line is shown in the cut, and should be made of slats, and movable, so that the cool air will circulate all around, and that they may be taken out to be cleaned occasionally. The

Fig. 2.—HOME-MADE MEAT-SAFE.

box needs lining to retain the coldness communicated by the ice. This lining should be a good non-conductor of heat, and as good a one as any is thick woolen felt, of which two thicknesses may be used, tacked on to the inside of the box, and covered with sheet-zinc soldered closely at the corners. Where the felt can not easily be procured, double walls may be made, and the space between them filled with pounded charcoal. The box should set on feet, so that it is not in contact with the ground, and that the water may drain off.

A meat-safe may be constructed by making a frame of four upright pieces, with a close top, back, and bottom, and two or three shelves, with a frame door at front. Mosquito-net or wire-gauze may be nailed over the frame and door, and the articles kept in the safe will thus have plenty of air, but will be kept free from flies. On no account should any gauze be put on the top, or flies would drop their eggs through it. Fig. 2 shows a safe of this kind.

Home Topics.

BY FAITH ROCHESTER.

SOMETHING ABOUT EYES.—If the remarks I am about to make are not approved by the editor-in-chief, you, dear reader, will never see them. So, if they do appear upon the page for which they are written, you and I may feel additional confidence in these same opinions. I do not wish to imply that all my views put forth in these pages have been "indorsed" by any editor, but I make these opening remarks because I am less and less inclined to speak as one having authority, and because I am more and more distrustful of ignorant tampering with ourselves and our children.

Sight is one of our greatest blessings, and it is a pity that it should so often be lost or impaired through ignorance or carelessness. How often did my mother warn me that I was "trying" my eyes when I was leaning out of the window to read in the twilight, or beg me not to spoil my eyes by reading while riding! I wish she had taken the book away from me, and so I mean to do by my children (gently but firmly), if their fondness for reading overcomes their judgment. We had better try first to convince our children that the pleasure gained by a few minutes' close application of the eyes in a light so dim or unsteady as to make seeing extremely difficult, always "costs a great deal more than it comes to." It is like any other strain, and its repetition will constantly weaken the power of vision, and result in positive disease if continued. Reading while lying down always wearies and injures the eyes, and is one cause of serious disease, especially if such use of the eyes occurs when one is recovering from sickness. The power of sight is very easily weakened when the body is weak or weary. Mothers who are recovering from confinement, and who are conscious of many little stitches needed in the family raiment, are very apt to use their eyes for sewing before they can really spare any strength in that direction. Weak eyes from this source are very common among women.

I have been reading parts of Dr. H. W. Williams's "Diseases of the Eye" lately. I looked to see what he said about near-sightedness, or *myopia*. I knew so many cases of *myopia* among musicians, especially among piano-players, that I had wondered if the study of music, the close attention to the fine notes, was not often a cause of near-sightedness. There can be no doubt that it is often a cause of the rapid development of incipient and before unsuspected *myopia*. Any pursuit or employment that calls for a use of the eyes upon small or near objects has this effect. Children are often discovered to be near-sighted when they first begin to apply themselves earnestly to study, or when they undertake to learn some business in which a steady use of the eyes becomes necessary. *Myopia* is much more common among the educated classes than among the ignorant and unskilled, though a hereditary predisposition may exist equally in all classes. Dr. Williams says that it "results in most cases from anatomical conformation, and is often hereditary; and, except in the slighter cases, is capable of being scarcely, if at all, modified for the better by age or treatment."

Many parents have an idea that their myopic children may outgrow their nearness of vision, and they are unwilling to have them put on glasses for fear they may always have to wear them. Dr. Williams says: "It is evidently useless for persons affected with *myopia* to deprive themselves of the very great aid to be derived from the use of glasses, in the hope that with advancing years their vision may become normal." It is true that a slight

change for the better results as age advances, but is it not too bad to go for years and years without ever getting a clear view of anything not close before the eyes? We were all a good deal moved, many years ago, when a dear inmate of our family exclaimed on first putting on myopic glasses: "Why, how pretty everything is! Oh! I can see the edges of the green leaves!"

Speaking of old sight, or the change that usually takes place in eyes originally normal at about the age of forty-five years, Dr. Williams says: "When these symptoms of loss of adaptive power begin to be felt, the eyes should be aided by convex glasses of sufficient power to compensate for the deficiency; otherwise they are fatigued by futile efforts, and yet more serious disability may result. It is useless to postpone wearing glasses in the hope that the necessity for resorting to them may be overcome." He advises, for near sight and for old sight, the weakest glass which gives distinct vision at the desired distance.

Parents are often alarmed by the sudden appearance of "cross-eyes" (or strabismus) in young children. It is quite common, in a slight degree, when children are teething. This very morning I perceive that my baby's eyes are not exactly straight, and once before I have seen the same slight deviation, but without alarm. At both times a severe crying spell has preceded such a result, and I am only more than ever determined to be, as far as possible, her obedient servant until teething is over. This is a secret, however! I hope she will not find out that her will is law here (and this will not be the case exactly), but any nervous excitement must be warded off from a system already taxed with the great business of getting a mouthful of teeth. My first child looked cross-eyed a very little for many weeks when teething, and it gave me much anxiety. How or when it disappeared I never knew.

But real strabismus is a thing not to be lightly treated. It sometimes results from convulsions or from whooping-cough. An operation by a skillful surgeon or oculist is then of great importance, and Dr. Williams says: "It is impossible to insist too strongly upon the importance of an early operation for the relief of strabismus, and on the fallacy of the popular belief which thinks it probable that 'the child may outgrow it,' or considers it best to 'wait until the child is older' before having anything done. The sight, in thousands of eyes, has been sacrificed to these erroneous opinions."

When one member of a family is afflicted with inflamed eyes, or with any disease of the eyelids, the greatest care should be taken that no one else uses the same towel, as eye diseases are often communicated in this way.

A YOUNG WIFE.—A little note came to me the other day, inclosing a long letter to my sister, whose address the writer had lost. That little note came home to my heart as news from heaven. It said: "I am married now, and am very happy, for a better husband I could not have—one whose constant aim is to do right, to do what is for the welfare of all around him."

Perhaps you think she only felt like all young wives. All the better, if this were true—but I am afraid it is not. The ostentatious appearance of conjugal affection is very common I know, but love like M.'s one does not see every day. I had the pleasure of reading the long letter too, and it was clear as day that a pure and noble love had done a great work for M. in the way of womanly culture. She loves her husband for what is God-like in him. Idolatry is hardly possible in such a case. It is not his mere moral perfection, it is his aim, his motive, his spirit that she loves. Not a word did she say of his fondness for her, and she only mentioned incidentally that he is a farmer, and that they would have to live very economically for some years. She is all alive to learn and to grow, and wisdom and growth are sure to come to a soul that covets only the best gifts. Not for "his sake" simply does she aspire to learn and grow, but this love is to her true woman nature what the warmth of spring-time is to the slumbering earth. I don't believe the great Jubilee in Boston could give my soul such an

"outing" into the heavenly realms as that simple, sincere note and letter gave.

It is very possible that as years go by M. will find that her husband is not all that she believed him to be. One illusion after another may vanish away, until he may seem to her quite a commonplace man after all. Character and temperament are two very different things. M.'s love is based upon character, and yet she may be considerably mistaken in her husband's character. And then her husband's temperament and habits may not always harmonize with her own. If she has disappointments of this kind, I hope she will know how to make the best of them, summoning common-sense and conscience to help her through. For some years I have been watching some of those people who don't believe in living with a husband or wife who is not in all respects agreeable to their own disposition; people who change one "mate" for another by means of divorce, believing that marriage is good for nothing unless one finds one's exact "true mate." The last condition of such persons is almost sure to be worse than the first.

Of course, it is best to avoid mistakes in marrying, as far as one is able, and it is a step to be taken with very great caution. But there are very few persons who do not find some disappointment in marriage. Love throws such a halo around the beloved object; we love our ideal of perfect humanity, and human nature can not yet satisfy that ideal. But all is not gone when one wakes from this young dream. Better things remain for those whose aim is true.

"RYE GRAHAM."—Several weeks ago, Mr. R. brought home from the mill, along with other things, about twenty pounds of rye Graham, recommended as very good. I did not know how to use it, and felt some doubts whether we should like it. But now it is all gone, and it went pretty easily after all. First we tried

RYE LIGHT CAKES, baked in gem pans, and this is the recipe: One pint of milk, three eggs, a tablespoonful of sugar, and a salt-spoonful of salt. Rye flour enough for the thickness of griddle-cake batter. Bake half an hour.

RYE BREAD we made in this fashion: For mixing, take one quart of warm water and one quart of milk. Thicken this with a teacup of corn-meal, and rye-flour enough for a common bread-sponge. Stir in about $\frac{3}{4}$ teacupful of good yeast. Let it rise in a warm place, and when light knead it quite stiff with rye-flour. Let it rise again, and bake it well.

RYE GEMS we make like the Graham gems, mixing them a little stiffer, as rye is inclined to be sticky. I observed that these gems always "took" better at our table when they were made one third wheat Graham and two thirds rye; and then they were best when the whole was sifted with a coarse sieve, which removed the coarsest part of the bran.

RYE ROLLS we made in two ways, mixing them with sweet milk. 1. Make a dough with milk and flour, stiff enough to roll an inch in thickness. Cut in strips an inch wide, and bake on a buttered tin. 2. Mix your batter of flour and milk stiff enough to take up a large spoonful in your hands, previously flouring them to prevent sticking, and roll the dough with your hands into straight rolls about an inch and a half in thickness. If these are floured, the baking-pan need not be buttered.

RAIN-WATER BARRELS.—Where it is desirable to catch rain-water for washing, and there is no cistern for the purpose, kerosene barrels are very useful. You can buy them for seventy-five cents apiece. Light a match and apply it to the oily inside of the barrel, and it will burn away the oil and give you a clean whole barrel. Of course, none but an idiot would do this where the flames would endanger house, barn, or other property.

Mollie Wants to Know.

One of the Household sisters, who signs herself "Mollie," is in trouble. As Mollie lives away off in Oregon, we hope some housekeepers not so near

the setting sun will come to her help, and put her in the way to "suit George."

"I should like to ask how to make good tender doughnuts, raised with yeast; also how to make tip-top stuffing for chicken. I have tried every recipe I know of, but they have all failed to suit George."

Household Items.

BY MRS. F. H. R.

LAMP CHIMNEYS are most apt to crack after being washed. In my own experience, they are less apt to break if moistened with the breath and polished with a cloth or paper, and afterwards with a chamois-skin, which gives them a clear brilliancy.

TIN-WARE.—If a housekeeper is ambitious, and prides herself on shining tin-ware, let her use whitening. Wash the tin-ware clean and wipe dry, and then polish with a dry cloth and dry whitening. That article is cheap, and gives a new, bright look to everything it is used on. For the tea-kettle and large coffee-pot (which finds its way on to our breakfast-table, though there is a silver one in the house) nothing is so effective.

BREAKFAST BREADSTUFFS.—Has any one ever tried what I am pleased to call "corn-muffins"? I make them with buttermilk, corn-meal, a little flour, a little butter or lard, salt, and soda, and bake them in my muffin-irons. They are beautifully crisp and light. They need to be quite thick—almost like "Johnny-cake." They have a chance to bake thoroughly through in the shallow irons, and we are very fond of them. We use cannille a great deal, made into muffins or "gems," in the same way, leaving out the tablespoonful of butter or lard or sour cream.

A great many, in making wheaten pan-cakes, fritters, and pot-pie, use eggs. I think this is a mistake, and never use any in mine. They rarely ever fail of being light, though I use nothing but buttermilk or sour milk, flour, salt, and soda.

CREAM-CAKE.—A cheap and excellent cream-cake for every day is made in this way: Break two eggs into a cup, and fill the cup up with sour cream. Add one cup of sugar, one cup of flour (perhaps a very little more), salt, soda, and nutmeg. This can be used also for a jelly-cake.

Ham and other Omelets.

Half a pint of milk with two teaspoonfuls of flour carefully intermixed, and three spoonfuls of finely-powdered cracker, sifted; add six eggs, well-beaten; butter a griddle, stir the omelet mixture well together, and pour thinly and evenly enough to cover the griddle; then immediately scatter over the surface of the omelet a layer of finely-minced ham; then fold immediately half of the omelet over on to the other half; then fold once more, so that it will come off the griddle in the form of a quarter of a circle, four-double. Finely-shred onions and minced veal can be used in the same manner. This quantity will make enough for six persons. W.

To Pickle Martynias.—Pick white yet soft enough to be easily penetrated by the thumb-nail, and throw into brine made strong enough to bear an egg. They are ready for pickling in ten days, or may be kept in the brine longer. When wanted to pickle, they are taken from the brine, washed in cold water, and soaked in vinegar two or three days. Then add about two pounds of sugar to one gallon of vinegar, with cloves, allspice, or other spices to the taste; tie them in a bag, and let them soak in the vinegar until the strength is extracted; heat the vinegar to boiling and pour upon the Martynias, which should previously have been removed from the vinegar in which they were soaking, and placed in a cask or other suitable vessel. After a few days they are ready for use.

BOYS & GIRLS' COLUMNS.

What is It?—Our Guessing-School.

So many odd things come to me with the question "What is it?" that I think I must turn some of them over to the boys and girls, and keep a sort of *Guessing-School*. Guessing-school is not exactly the right name

SOMETHING FOR BOYS AND GIRLS TO PUZZLE OVER.

for it—perhaps "Intelligence Office" would be better, because we do not wish the answers to be mere guesses, but bits of positive information. Still, as we have called it so, we will let it go as "Guessing-School." Now, here is an engraving of a "What is it?" brought the other day by one of my associates who has taken up his summer residence by the sea-shore. He picked up this something on the beach, and brought it to find out what it was. As I was born and brought up alongside of salt-water, I knew it at once, but I thought it would be an interesting thing for you boys and girls to puzzle at—so here is the engraving. The drawing was made by one of "the boys," for you must know that we have boys who do drawing. The thing is shown of the real size. It is black, and very tough and leathery; it shows no signs of life. When found upon the beach, it may be in the position here shown, or it may be the other side up—just as the waves happen to throw it. Now then, who will find out and tell us what it is? The one who gives the best account of it—I don't care how it is found—shall have the *Agriculturist* put down for his or her name, or to whomsoever he or she may direct, for the year 1873. Send answers to The Doctor, 215 Broadway, New York—and to no one else. Time will be up October first. Now, then, go to work for
THE DOCTOR.

A Petrified Squash—Sea-Urchins.

Children, did you ever see a Petrified Squash? I never did; in fact, I never heard of one until the other day, when there came by mail a specimen from a gentleman in Salado, Texas, of what he said was there called a "Petrified Squash." I have mislaid the gentleman's name, but you will thank him nevertheless for sending the specimen which allows me to give you the engraving of it, of the natural size, in figure 1. Perhaps before we go any further we had better see if we all understand the meaning of the big word *petrified*. If I had you all before me, I should ask those who knew what was meant by petrified to hold up their hands. All the hands would not go up I am sure; so, for the benefit of those who do not know, we must explain a little. If you look into the

Fig. 1.—PETRIFIED SQUASH.

dictionary, you will find that the word petrify comes from the Greek word *petra*, a stone, and the Latin word *facio*, to make. So "to petrify" is to make into stone, and a petrified thing is something made into stone. In some waters, which have much mineral matter dissolved in them, wood and other things are gradually changed into stone. So our "petrified squash" would be a squash turned to stone, only it does not happen to be a squash—indeed, it is not a vegetable at all, but an animal which has ages ago been turned into stone, or petrified. An odd sort of animal you think—and so it is. It is the remains of an animal the relatives of which are well known

in the living state as Sea-Urchins. It is only those who live on the sea-coast that are likely to see living specimens of the Sea-Urchins, and they are very unlike any kind of animal you who live inland are likely to meet with. They belong to that division of the animal kingdom called *Radiates*. You know that most of the animals, including the fishes, reptiles, insects, etc., that you have ever seen, have a right-hand side and a left-hand side. Their parts are arranged in opposites. In the radiates

they are arranged around a center, just as the spokes of a wheel are placed around a hub, as you may have seen in dried specimens of what is called a Star-fish, which is like a five-pointed star. These Sea-Urchins have their parts arranged in five or some multiple of five, but they are more or less globular, or more like a flattened biscuit. They have an outer shell or covering which is not

Fig. 2.—PIPER URCHIN.

whole, but consists of plates joined together, and the mouth of the animal is on the flattened side at the bottom. The living Sea-Urchins have attached to their outer surface numerous spines, some kinds having them only a quarter of an inch long, while in others they are three or four inches in length. In figure 2 is given an engraving of a living Sea-Urchin, which is not much unlike the petrified one in figure 1. This living one is called the Piper Urchin, and is found in the waters of India. You will see that it has its spines attached. These spines are of substance somewhat like shell, and are of use in enabling the animal to move about on the bottom of the sea, and probably by their forbidding appearance they protect it from enemies. It was discovered by the missionaries in India that these spines make very good slate-pencils. Besides these spines, the Sea-Urchins have numerous feelers by which they are able to seize their food, and pass it from one to the other until it reaches the mouth. Most of the Sea-Urchins found upon our coast have many more spines, and shorter ones, than the one shown in figure 2. Indeed, the spines are so many and so close together as to hide the body of the animal itself, and it looks as bristly as a porcupine. So our "Squash" is after all a Sea-Urchin, which lived ages ago, when that part of Texas where it was found was covered by the sea. In the wonderful changes which have since gone on, the animal lost its spines, but the form of its body was preserved by being gradually converted into stone. When you get older, you will all of you, boys and girls, I hope, read something of geology, which teaches the wonderful changes that have gone on to make this earth fit for our dwelling-place. Not only will that tell you of the wonderful things that happened in the far-off past, but those which are taking place now. Sea-Urchins and hundreds of other animals are living and dying now, and it may be that years and years to come some one will find a curious thing, and send it to some future Doctor, which will only be a petrified Sea-Urchin that is living on the coast at the time I am writing this for my boys and girls.
THE DOCTOR.

An Ant and a Green Worm.

Here is an account of a remarkable display of both strength and intelligence by an ant. It was sent us by Mr. Thos. S. Collier, of New London, Ct. He intended it for the older people's department, but we think it will find more interested readers among the boys and girls. Watch the ants as you see them at work, and it may be

you will see something equally strange and worth telling about. Mr. C. writes:

Whilst standing under the arbor near my residence this morning, I was somewhat surprised and amused to see a combat between an ant and a green worm or caterpillar of some kind. The worm had either been migrating or fallen from the arbor, and whilst in the path been attacked by the ant.

For a while the contest was very fierce, the ant running along the body of its adversary, and stopping now and then to give a pinch or bite—at least, I concluded such was the case, as it seemed to gather itself together for some muscular work, and when it did so the worm writhed and twisted as if in great agony.

This lasted some three or four minutes, when the worm grew exhausted and became quiet, and then the ant proceeded to drag it along the walk. The worm gave two or three weak struggles after this, but made no strenuous resistance. After dragging the worm some three feet along a level space, the ant came to an inclivity of about an inch, and finding its strength insufficient to cope with the difficulty, it left the worm and proceeded toward its hole. When near the entrance it encountered another ant, and after the usual manner of interchanging communications, by the use of feelers, it returned to the worm, and was shortly joined by the ant it had met.

These two, by their united exertions, managed to drag the worm up the precipice, for such I suppose it was to them. Then they conveyed it through a patch of grass, winding in and out among the spears, as if treading the intricate labyrinths of a dense forest. Beyond the grass they came to a clear space, and here the ant that had come to the assistance of the conqueror of the worm departed on its own business, and the conqueror was left to drag its prize along alone. This it did, until it reached the entrance of the nest, when it and the worm disappeared.

Now I took the trouble to measure the worm and the ant. The worm was one inch long, with a circumference of three eighths of an inch; and the ant was one quarter of an inch long, and belonged to the common brown species. The total space that the worm was carried was eleven feet, and one not performed the greater part of the toil. This, however, is not as remarkable as the fact of the ant attacking the worm, and its sagacity in not leaving it until it was powerless to escape, and its search for and obtaining help when unable to accomplish a task that came in its way.

THE UNWELCOME VISITOR.—Drawn and Engraved for the American Agriculturist.

CHARADE.

My first, some grain, was from a farmer bought,
And on long credit its delivery sought;
But quite without his host the buyer reckoned,
For—answering loud and firmly with my second—
The farmer vowed he'd have my whole or naught.

TEMPY.

NUMERICAL ENIGMA.

I am composed of 10 letters.
My 8, 5, 6, is a metal.
My 3, 9, 10, is a relative.
My 10, 9, 1, is an adverb.
My 4, 2, 8, is an article of apparel.
My 7, 5, 6, is a dangerous medicine.
My whole is a well-known name.

HELEN.

DIAMOND PUZZLE.

1. One thousand. 2. A Portuguese coin. 3. A kind of wood. 4. One who rescues. 5. An ancient Greek. 6. Not insulting. 7. The theme of many poets. 8. A room. 9. Something essential to every one. 10. Not known. 11. An inhabitant of a certain classic country. 12. An animal. 13. A consonant. The center letters, horizontal and perpendicular, give an inland sea.

AUNT SUE'S NOTICES TO CORRESPONDENTS.

JERE PLUMER.—The answer to the numerical enigma in the April number is, "A stitch in time saves nine." How did it happen that that one puzzled you?

E. L. C.—Tell "Auntie" that enigmatical questions are frequent in the scriptures, and that all Eastern nations cultivated, more or less, this species of composition as an efficacious means of calling forth the speculations of the wise men upon the numerous and inexplicable mysteries hidden in religion, nature, and art.

CARRIE.—A little alcohol will remove the stains of violet ink from your fingers; cologne-water, which is chiefly alcohol, will answer the purpose.

I am waiting to report on the "OVEN" squares; it was hardly fair to ask you to puzzle over the *oven* in July, was it? Next summer we will take "snow."

Thanks for letters, puzzles, etc., to Willie S., Mary and Kate, Tom, Lena G., L. N., and Owego.

The Unwelcome Visitor.

Did you ever see a nestful of young owls? If not, you have an odd sight in store for you. There are a number of different kinds of owls in this country, and they differ in the manner of making their nests. Some build a rude nest upon the branch of a tree; some find a hollow tree in which to raise their young; and there is one droll little owl in the far West that makes use of the burrows of the Marmots, or Prairie-dogs as they are called, for its dwelling. Nothing is more comical in appearance than a baby-owl. The thing appears to be all head, and that head nearly all eyes. Such a wonderful amount of blinking and winking as they do! We suppose that, however droll the little owls appear to us, they are in the eyes of Mr. and Mrs. Owl perfect beauties. Years ago, when the writer was studying French, he read a fable, which as near as he can recollect ran something in this way: The Eagle and the Owl had for a long time been at war, but at length they concluded to make peace, and live ever after on friendly terms. So they talked the matter over—birds are said, you know, to have been able to talk in those days—and came to an agreement about various matters. One of the conditions of the treaty of peace was that neither should disturb or injure the young of the other. "But I have never seen your children," said the Eagle; "describe them to me, so that I shall know them." "Oh!" said the Owl, "you will know them at once by their great beauty; they have the most elegant form of any birds, and such beautiful eyes and sweet mouths!" In a day or two, the Eagle, while out hunting a dinner, came across the Owl's nest. "Hallo! what strange things have we here?" said the Eagle; "these can not be young owls, for they are little beauties," and thereupon he gobbled them up. Fables, you know, always have a "moral" attached, but I think every bright boy and girl will be able to see the point of this one without its being shown. The young owls in the picture are old enough to be out of the nest, and they are thrown into astonishment by the appearance of a strange creature, the like of which they have never seen before. The object that engages their attention is the caterpillar of the Royal Moth, which lives upon oak-trees. It is a very large and showy caterpillar, and its long curved horns give it a very formidable appearance. No wonder that the owlets are startled; we have known much larger youngsters, who did not wear feathers, to be frightened at it.

A Railroad Watch.

Travelers by Railroad frequently find their watches completely demoralized by the continuous jar of the train. To overcome this difficulty has long been a problem with watchmakers, and it is now successfully accomplished in the new grade made by the

American Watch Co. of Waltham.

This Watch is made in the most substantial manner, on the most approved principles, and combines all the recent improvements. It has a new micrometrical regulator, by which the slightest variation can be easily corrected. It is carefully adjusted, and may be entirely relied on to run accurately, wear well, and ENDURE THE HARDEST USAGE, without any derangement whatever. We confidently recommend this watch to the trade and the public as the **BEST WATCH FOR THE PRICE IN THIS MARKET.**

The full trade-mark engraved on the plate of each watch is "AMERICAN WATCH CO., CRESCENT ST., WALTHAM, MASS."

and it is distinctively known as the CRESCENT-ST. Watch. For sale by all leading Jewelers.

ROBBINS & APPLETON,
GENERAL AGENTS, 1 BOND ST., NEW YORK.

The Best WATER PIPE, also the cheapest, when strength and durability are considered, is the TIN-LINED LEAD PIPE, manufactured by the COLWELLS, SHAW & WILLARD M'FG Co., No. 213 Center street, New York. Price 15c. a pound for all sizes. Send for Circular.

We have never yet seen a Book of Testimonials containing more valuable evidence of real merit in the article spoken of than the little pamphlet entitled "What People say about the Blanchard Churn." Send to any dealer in dairy implements for one of them.

GUARANTEED BONDS.

Payable in New York City at prices that will pay **13 PER CENT** on the investment. Call or send for descriptive circular.

FOR FLOORS.
CARNKIRK VASES for Lawns and Gardens, Chimney Tops, etc.
MILLER & COATES, 279 Pearl st., New York.

Economy in the Kitchen.

Prudent housekeepers are ever on the alert to practice economy in the culinary department. In no way can this be done more effectually than in the use of a Baking Powder which combines **purity, strength, and reliability.** DOOLEY'S YEAST POWDER has attained the deserved reputation of being economical, convenient, and wholesome, besides which it will produce from a barrel of flour twenty-five to forty pounds more bread, rolls, etc., than by the old process of raising dough with bakers' or hop yeast. Here alone is a great saving, and authorizes the guarantee that it will give entire satisfaction.

The more intelligent a farmer is, and the more particular he is about everything connected with his dairy, the better he appreciates and likes the Blanchard Churn.

ASBESTOS ROOFING

FIRST PREMIUM (MEDAL) AWARDED IN 1870, AND INDORSED BY CERTIFICATE FROM THE AMERICAN INSTITUTE IN 1871, AS "THE BEST ARTICLE IN THE MARKET."

The "Asbestos Roofing" is a substantial and reliable material, which can be safely used in place of Tin, Slate, etc., on steep or flat roofs, in all climates, and can be easily and cheaply transported and applied. Also, Manufacturer of Asbestos Roof Coating, Roofing and Sheathing Felts, Silica and Paraffine Paints, Asbestos Boiler Felting, Fire, Water, and Acid-Proof Compositions, etc., and Dealer in Asbestos, Asphalium, etc. Asbestos Board—an entirely new article for Packing, Gaskets, and for covering Locomotive Boilers, etc. In sheets 1-16 to 1/4 inch thick.—Asbestos Paper for Linings, etc. Send for Descriptive Pamphlets, Price-lists, Terms to Dealers, etc., by mail. [Established in 1858.] H. W. JOHNS, 78 William st., New York. The Tribune Buildings have been covered several years with the Asbestos Roofing, which has proven entirely satisfactory. We prefer it to Tin.—Eds. N. Y. Weekly Tribune, May 8th, 1871. Johns's Asbestos Roofing is light, strong, and practically fire-proof; is kept in order at a very trifling expense, and will last many years.—Eds. American Agriculturist.

1872.

A BOOK FOR THE MILLION.

THE

YOUNG

HOUSEKEEPER'S FRIEND.

By **MRS. CORNELIUS.**

REVISED AND ENLARGED.

The aim of the writer of this work has been to furnish to young housekeepers the best aid that a book can give in the departments of which it treats. No printed guide can perfectly supply the place of that experience which is gained by early and habitual attention to domestic concerns. But the directions here given are so minute and practical, that the observance of them will prevent very many of the perplexities which most young people suffer during their first years of married life.

The recipes, with very few exceptions, are furnished from the author's own experience, or that of her immediate friends. An ample variety is given for furnishing the table of any American family; but especial reference has been had to those who have neither poverty nor riches; and such directions have been given as will enable a housekeeper to provide a good and healthful table, or, if desired, a handsome one, at a moderate expense.

How well the author has succeeded is manifest from the very great favor with which past editions, through a period of twenty-five years, have been received. And now, in this new edition, she has rendered the book more than ever worthy of patronage, by a thorough revision, the omission of a few recipes of least value, the addition of full directions for **Canning Fruits,** and more than **One Hundred and Fifty New Recipes** which have been tested by experienced housekeepers. While the lessons of economy taught by the late war have not been forgotten, the author has well met the demands of the present customs of society for a greater variety of dishes than used to be thought requisite for the ample supply of the family table.

PRICE, POST-PAID.....\$1.50.

FRUIT RECORDER AND COTTAGE GARDENER

A MONTHLY of 16 pages, at \$1.00 per year, edited by A. M. PURDY—a life-long fruit grower and flower fancier. Published under cultivation at Palmyra, N. Y., and contains two hundred acres of fruits alone. Biggally, it contains horticultural, politics, &c., and no room in it, as a "Fruit Recorder," devoted to FRUIT GROWING AND HOME'S ORNAMENT, its high moral tone and rich store of practical, original and copied matter (from some 50 exchanges) endears it to all. To see a copy is equivalent to subscribing. Specimen copies free, or an excursion trip of four months (Sept. to Dec.) for only 25 cents. Don't judge it to be of no account because printed in an inland town and the editor a working, practical fruit grower but try it four months, and be not set. Address,
A. M. PURDY, PALMYRA, N. Y.

SMALL FRUITS! SMALL FRUITS!

THE largest stock in the United States. Plants pure and unmix'd. Wholesale and Retail List free. Also, SMALL FRUIT INSTRUCTOR, a 64 page pamphlet—tells how to plant, grow and market all kinds of small fruit—price, post-paid, 25 cents. Private terms to Agents, or those desiring to sell locally, free to all applicants. Parties have realized \$100 to \$500 in one or two week's time selling our Fruits, while others have got their own plants freely selling a few to their neighbors. Address, A. M. PURDY, PALMYRA, N. Y./ or PURDY & HANCE, SOUTH BEND, Ind.

Pure White Winter-Wheat.

All things considered, and on good, clean, rich, dry land, the DIEHL is the best variety of WHITE Wheat now grown. The straw is very stiff, the head very plump and full, and the yield on good land eminently satisfactory. The greatest difficulty we have experienced with it is to get pure seed. It is almost impossible to find it unmixed with Mediterranean and other red varieties. For some years past, many readers of the *American Agriculturist* have written to me for seed, but I have never been able to get any that I thought pure. I have now, however, the pleasure of stating that I raised this year ten acres of DIEHL WHEAT that is the PUREST I have ever seen, and I can send it out with confidence.

I will send four pounds by mail, prepaid, to any address, on receipt of ONE DOLLAR.

I will send by express or as freight, at the following rates:
1/2 bushel..... \$3 00
1 bushel..... 5 00
2 bushels..... 9 00
6 bushels..... 25 00
10 bushels..... 40 00

Larger quantities at the same rate, or \$1 per bushel. The Wheat will be put in strong, new bags, carefully directed, and delivered at express office or freight-house without any extra charge.

Orders will be filled immediately. Address
JOSEPH HARRIS,
Moreton Farm,
Rochester, N. Y.

OF

EXCELLENT FARMING AND SPLENDID

Michigan Pine Lands FOR SALE,

On which are **ONE THOUSAND MILLIONS OF PINE TIMBER**, and inexhaustible quantities of Maple, Beech, Elm, Ash, Hemlock, Oak, etc.

The grant of lands to the Grand Rapids and Indianá Railroad Company, to build their Road from Fort Wayne, Ind., to Traverse Bay and Mackinaw, Michigan, comprises in its farming lands every variety of soil, from the *rich clay loam* to the light sandy, and they are found in that section of Michigan, north of the city of Grand Rapids, and contiguous to the great fruit belt on the eastern shores of Lake Michigan, now being rapidly developed by railroad and other enterprises.

Farming Lands are sold to actual settlers, on credit, one quarter down, balance in yearly payments, interest 7 per cent. Persons desirous of locations for farms will, on application at the **Office in Grand Rapids**, be furnished with **Tickets over the Road**, entitling them to **Return of Fares**, in the event of purchasing any of the Company's farming land. For information about the lands, prices, location, etc., etc., address

WM. A. HOWARD, Land Commissioner, Grand Rapids, Michigan. **TITLE PERFECT.**

BELLEVUE HOSPITAL MEDICAL COLLEGE.

CITY OF NEW YORK.

SESSIONS OF 1872-'73.

THE COLLEGIATE YEAR in this Institution embraces a Preliminary Autumnal Term, the Regular Winter Session, and a Summer Session.

THE PRELIMINARY AUTUMNAL TERM for 1872-'73 will commence on Wednesday, September 18, 1872, and continue until the opening of the Regular Session. During this term, instruction, consisting of didactic lectures on special subjects and daily clinical lectures, will be given, as heretofore, by the members of the Faculty. Students desirous of attending the Regular Session are strongly recommended to attend the Preliminary Term, but attendance during the latter is not required. During the Preliminary Term clinical and didactic lectures will be given in precisely the same number and order as in the Regular Session.

THE REGULAR SESSION will commence on Wednesday, October 16, 1872, and end about the 1st of March, 1873. For the Annual Circular and Catalogue, giving regulations for graduation and other information, address the Secretary of the College, Prof. AUSTIN FLINT, Jr., Bellevue Hospital Medical College.

NOTICE.

Buckeye Steamer, Drier, Baker, and Range. Most wonderful mechanical combination of the age! One hundred bushels of feed cooked in three hours! Froid dried in five hours without change of position. Apparatus made entirely of iron. Bakes equal to a brick oven. For full particulars, including an excellent essay upon the advantages of cooking food for domestic animals and a fine illustrated pamphlet, sent free of postage, address
ENGLE, KELLER & CO., Lancaster, Pa.

THE UPRIGHT PATENT TRUNK

Opens without removing from the wall. Instead of trays to lift out, it is arranged with drawers. It is stronger, as only a small portion opens, whereas in the old style the whole top comes off. Some room in the bottom of the Trunk for dresses as in the old style. Address
Upright Patent Trunk Co.,

"MAPLE-SHADE FLOCK."

THOROUGH-BRED COTSWOLD SHEEP.

This justly-celebrated flock was selected from the flocks of the most noted breeders in England, with reference to the best wool-producing and mutton qualities. It is pronounced by competent judges to be the finest flock in America; and some of the Rams and Ewes are believed to be equal to any that can be shown in any country.

The wool is long, fine, and lustrous, yielding from 8 to 20 pounds per head. They are full and square-bodied, very strong in the loins, and weigh from 200 to 300 pounds at maturity—sometimes exceeding even this weight. They are hardy and vigorous, and for breeding pure or crossing with other breeds, are believed to promise more profit than any other sheep. The wool is in good demand at remunerative prices, and the thorough-bred rams crossed with any other sheep, even Merinos, will produce a good combing wool, and lambs of such size as will bring a large price early in the season in market.

Every sheep at present in the "Maple-shade Flock" was either imported or bred direct from imported sire and dam, or has a perfect pedigree.

It will be the aim of the present proprietors to sustain the reputation of the "Maple-shade Flock," and, if possible, add to it; also to show the good results of different crosses with other sheep.

We offer for sale Choice Ewes, Rams, and Lambs.

THOROUGH - BRED STOCK.

Jersey Cows, Heifers, and 3 young Bulls.
Ayrshire Cows, Heifers, and 4 young Bulls.
1 Guernsey Bull, 2 yrs. old, very fine. 1 do., 7 months, do.
Cotswold Sheep. The famous "Maple-shade Flock," as fine as any in the country. Rams, Ewes, and Lambs.

THOROUGH-BRED PIGS.

Berkshire Pigs of the very best blood. My Berkshire Sow "Queen of the Realm" took Sweepstakes Prize for all breeds of pigs at the New England Fair in 1871.

Essex Pigs, equal to any in this country or any other. Splendid young boars and sows now ready for shipping. Prices reasonable. No extra charges for boxing and shipping. Safe arrival guaranteed.

Perfect pedigrees given with all thorough-bred stock, which may be seen at my farm (Herdsdale), Florence, Mass. Send communications to

L. A. CHASE,
245 Broadway, New York.

ESSEX PIGS.

ESSEX PIGS.

ESSEX PIGS.

Pure,

Well-Bred,

Very Choice.

Now is the Time to Order Fall Pigs.

The demand for this valuable breed of pigs is such that many who delay in sending their orders are disappointed. My rule is to enter orders on the receipt of five dollars in advance, and as soon as the pigs are ready, the orders are filled in rotation. My spring pigs, except a few choice sows and one boar, are all gone. I am now ready to enter orders for Fall Pigs, and I should be very glad if those wishing pigs would send on their orders as early as possible. I send out none but choice pigs, and they give good satisfaction. Read the following unsolicited testimonials:

AUGUSTA, MARION CO., IND., July 16th, 1872.

The Essex pig arrived safe and sound June 6th. He gained one pound per day for the first four weeks. Since then he has gained 10 lbs. in a week. He is admired by all my visitors. I think he is the best pig in "Hoosierdom."

A. P. WILEY.

COLUMBUS, OHIO, May 29th, 1872.

I am well pleased with the pig.

C. W. HESS.

NEW BRUNSWICK, N. J., June 8th, 1872.

He is a very fine pig. I am well satisfied.

C. H. NUE.

STEEPSVILLE, HOWARD CO., MD., June 20th, 1872.

I am very much pleased with the determination you have manifested to give me a good start with Essex pigs. The two sows arrived this morning in first-rate condition. The male pig [sent some weeks before], is growing very fast, and is the best looking pig I have ever seen.

JOSEPH BARLOW.

MONTON, IND., June 10th, 1872.

The pigs arrived May 10th. They have completely recovered from the trip, and are doing as well as any pigs I ever saw. I am well pleased with them.

WOODFORD BURE.

HANNIBAL, MO., December 22d, 1871.

The Essex pig I received from you has grown finely, and given perfect satisfaction. I have this fall slaughtered four grade Essex that averaged 303 lbs. each. One weighed 325 lbs. alive, and dressed 230 lbs., making 56 2-13 per cent of his live weight. They were eight months and eight days old the day they were slaughtered.

JAMES C. ASHMORE.

CLARESVILLE, OHIO, Jan. 15th, 1872.

The Essex pig I got from you is growing finely, and I am well pleased with him.

W. CLIMER.

MONMOUTH, ILL.

The Essex sow I got from you is doing splendidly. She is admired by all who see her. I think she is the handsomest pig I ever saw—and I have seen a great many.

IRVINE McCARTNEY.

ARCADIA, N. Y., May 10th, 1872.

The Essex pig arrived safe and in good order, and I am well pleased with him. He is all that I anticipated.

L. J. BENTON.

AUSTIN, TEXAS, Feb. 6th, 1872.

The pigs arrived yesterday, and look remarkably well. To say that I am thoroughly pleased is scarce enough. I am more than pleased, and you have my thanks for giving me more than my money's worth. I have two Scotchmen in my employ who were in ecstasies over them (for Scotchmen). I would not take \$150 for the pair of pigs.

D. R. TOWNSEND.

WHAT I CLAIM FOR THE ESSEX.

1st. Pork and hams of the choicest quality—sweet, tender, juicy, and fine flavor.

2d. The lard is remarkable for its whiteness and solidity.

3d. The pigs are entirely black, but when dressed are perfectly white.

4th. They are the largest of the small breeds.

5th. They are a thoroughly-established breed, and when pure-bred, and have been properly cared for, they have remarkable power in impressing their qualities on their offspring.

6th. They have fine bones and light offal.

7th. They are remarkably quiet and gentle.

8th. They are "easy keepers." They eat well, and then lie down and grow rapidly, and can be fattened at any age. No breed matures earlier or fattens more rapidly.

9th. They are good graziers. My breeding sows keep almost too fat on grass alone.

10th. A pure-bred Essex will improve any breed (for the butcher) with which he is crossed.

I have over One Hundred thorough-bred Essex pigs, and pay great attention to their improvement. I make their breeding a speciality, and believe I have as good Essex pigs as can be found in this country or in England. I shall have great pleasure in forwarding good pigs to any readers of the *American Agriculturist* or *Hearth and Home* who may favor me with their orders. My prices are reasonable. Order early, and you will be sure of getting choice pigs. They will be boxed, furnished with food for the journey, and delivered at express-office without extra charge, and I guarantee their safe arrival. Address

JOSEPH HARRIS,
Moreton Farm,
Rochester, N. Y.

Fairs 1872.

HARRIS ON THE PIG.

Breeding, Rearing, Management, and Improvement. With numerous Illustrations. By Joseph Harris. Price, \$1.50. This is the only American treatise upon the breeding, rearing, and management of swine, and is by one thoroughly familiar with the whole subject. The points of the various English and American breeds are thoroughly discussed, and the great advantage of using thorough-bred males clearly shown. The work is equally valuable to the farmer who keeps but few pigs, and to the breeder on an extensive scale. Sent post-paid on receipt of price by ORANGE JUDD & CO., 245 Broadway, New York.

Gardening for Profit

In the Market and Family Garden.

By Peter Henderson.

ILLUSTRATED.

NOTICES BY THE PRESS.

All the vegetables that thrive in the open air in our latitude are described, together with the best methods for growing them. The author also imparts practical instructions on the subjects of drainage, and the formation and management of hot-beds. Numerous well-executed wood-cuts tend to make clearer the instructions of the author.—*Philadelphia Inquirer*.

The author of this treatise is one of the best known and most successful of those gardeners who supply New York with green vegetables; and as he writes from long and dear-bought experience, the positive, dogmatic tone he often assumes is by no means unbecoming. The book itself is intended to be a guide for beginners embarking in the author's business, and gives full and explicit directions about all the operations connected with market-gardening, lists of varieties of the most profitable vegetables, and much sound advice on kindred topics. Though designed for a special class, it can not fail to be valuable to the amateur and private gardener, and unlucky experience has taught us that the information contained in a single chapter would have been worth to us the price of the book.—*Daily Mercury (New Bedford)*.

It is unquestionably the most thorough and the best work of its kind we have yet had from the pen of an American author. It is written in a clear, concise style, and thus made more comprehensive than works which smack more of the office than the farm or garden.

[*Daily Evening Times (Bangor, Me.)*]

Mr. Henderson writes from knowledge, and is not one of those amateur cultivators whose potatoes cost them ten dollars a bushel, and whose eggs ought to be as valuable as those of that other member of their family—the goose of golden-egg-laying memory—for they are all but priceless. No; he is a practical man, and he has the art of imparting the knowledge he possesses in a very agreeable manner; and he has brought together an extraordinary amount of useful matter in a small volume, which those who would "garden for profit" ought to study carefully.—*Evening Traveller (Boston)*.

These are marvels of transformation and rapid reproduction recorded therein, which might well shame the dull fancy of the author of Aladdin or of Kooloolah. There is no theory about it; a man who has made himself rich by market-gardening plainly tells our young men how they can get rich as easily as he did, and without wandering to California or Montana for it either.

[*HORACE GREELEY in the N. Y. Tribune.*]

We have devoted more space to this little work than we usually do to tomes much more pretentious. We have done so because of the rare merits of the book in its fund of information, useful to the farmer and market-gardener, and because of the dearth of that kind of knowledge. We earnestly advise that fraternity, for whom this work was written, to buy it and study it. If any among them have never yet read a book, let this be their primer, and we will vouch for the excellence and endurance of the priming. The work is profusely illustrated with wood-cuts.—*Louisville Daily Journal*.

Price, post-paid, \$1.50.

ORANGE JUDD & COMPANY,
245 BROADWAY, NEW YORK.

READ THE NEW BOOK ON Farm - Gardening AND SEED - GROWING.

BY FRANCIS BRILL.

NOTICES BY THE PRESS.

Orange Judd & Co. have added to their splendid catalogue of agricultural books "Farm-Gardening and Seed-Growing," by Francis Brill; it is practical, plain, complete, and satisfactory, so that for a small amount of money a great deal of desirable information can be obtained. If there is any firm anywhere which is to-day disseminating so much knowledge in regard to tilling of the soil as this same said firm of Orange Judd & Co., we will present a medal to our informer.—*Watchman and Reflector (Boston)*.

The want occasionally expressed to us of a work on the cognate subjects above named (Farm-Gardening and Seed-Growing), is now met in a book under this title from the pen of Mr. Francis Brill, formerly a market-gardener and seed-grower at Newark, N. J., and at present engaged in raising seeds at Mattituck, L. I. Its directions are concise and practical, covering those points on which a beginner is most likely to require information.—*Country Gentleman*.

Mr. Brill has had large experience, and derived his knowledge wholly from the school of actual tests.—*Chicago Evening Journal*.

We have in this volume the results of a practical man's experience in raising root crops and other vegetables in the market-garden. Not only the professional seed-grower and trucker, but the amateur gardener who has a little patch in his suburban home, will find many a valuable hint and direction in this full and comprehensive manual.—*Sunday-School Times*.

It seems to be a very sensible, practical work by a practical man. Mr. Brill's father was a gardener; and he himself has had an extensive experience, and he talks about what he knows, which is more than can be said of many authors of industrial works.—*Moore's Rural New Yorker*.

There can be no question that this farm-gardening can be made in many districts of the Southern Atlantic States, especially near the coast, far more profitable than growing the ordinary staple crops. In connection with producing the vegetables, the growing and saving their seeds receive minute attention.—*American Farmer (Baltimore)*.

A very useful hand-book, not merely for farmers and growers of seed on an extensive scale, but for all who, whether for recreation or for the purpose of supplying their own families with garden products, desire to know something about the adaptation of seed to soil and the mode of culture.—*Church Journal (New York)*.

This industry is now occupying the attention of many persons who sell their products to the great seed-houses, and novices who have the facilities, and wish to enter upon the business, will find in this book just the hints needed.—*Springfield Republican*.

Mr. Brill has been a successful farm-gardener and seed-grower for a number of years, and gives in a clear and concise form the knowledge he has gained. . . . It gives the best method of manuring, planting, and cultivating every vegetable sold in markets—in short, everything required to be known, plainly and fully—and should be in the hands of every one who cultivates so much as a rod of land, for family use, pleasure, or profit.—*Suffolk (L. I.) Times*.

The seal of Orange Judd & Co. upon an agricultural publication is sufficient guarantee of its worth. Francis Brill's book, published by them, is a very complete work, giving plain, minute instructions as to raising, taking care of, and bringing to market those vegetables which are most in demand in the large cities, and those seeds which are being called for throughout the country.—*N. Y. Evening Mail*.

The work of showing how this can be accomplished has fallen in good hands, and it has been done well. The book will well repay perusal, and we hope soon to see its good effects in a more intelligent direction of farm industry, and accompanied by more satisfactory pecuniary results.—*The Signal (L. I.)*

To the market-gardener, or even the owner of a small piece of tillable land, this book will be of great value. Qualities of soil required for the growth of different vegetables, how to plant, how to cultivate, to harvest, and preserve during winter.—*N. Y. Citizen and Round Table*.

Price, Post-paid, \$1.00.

ORANGE JUDD AND COMPANY,
245 BROADWAY, NEW YORK.

GARDENING FOR THE SOUTH;

OR, HOW TO GROW

VEGETABLES AND FRUITS.

BY THE LATE
WILLIAM N. WHITE.

OF ATHENS, GA.

WITH ADDITIONS BY MR. J. VAN BUREN AND
DR. JAS. CAMAK.

REVISED AND NEWLY STEROTYPED.

ILLUSTRATED.

NOTICES BY THE PRESS.

It supplies a place long vacant in Southern literature, and should be in the hands of every man or woman who cultivates a foot of ground. While it treats very freely of the vegetable garden, it devotes much space also to fruits, etc.—*Tribune (Mobile, Ala.)*

It is illustrated by a portrait of the author, and numerous engravings of subjects treated. It is a work of 450 pages, and is a complete manual of kitchen gardening and fruit culture.—*Telegraph (Macon, Ga.)*

Mr. White was prime authority in his specialty, and this volume is a complete manual for gardening for Southern latitudes. Besides the usual fruits and vegetables of Northern gardens, there are full instructions as to the culture of the almond, fig, orange, lemon, shaddock, olive, yam, ground-nut, Madeira nut, and pistachio. In view of the rising importance of "truck farming" in the South to supply Northern markets with early vegetables and fruit, this book is quite important to the gardeners of either section.—*Register (Wheeling, W. Va.)*

Coming from the pen of an experienced cultivator of Southern vegetables and fruits, the reader, whether of old or recent residence, is put in possession of facts relating to the soil, climate, and varieties of plants adapted to the South that would otherwise require much time and expense to acquire. The vineyard and orchard receive sufficient attention to furnish all the necessary information for the beginner. We regard the book as especially adapted for the private garden, and if a copy could be placed in the hands of every farmer, we might expect, on our visits to the country, to be regaled upon something else than "bacco and greens."—*Daily State Journal*.

The first edition of this work appeared in 1856, but the second, now just issued, is much enlarged, containing 441 pages. It embraces a much larger range of topics than the title indicates, and is one of the most valuable compilations of facts that we have anywhere seen in a single volume, relating to different kinds of soil, and their adaptation to different kinds of fruit and vegetables.—*Journal of Agriculture (St. Louis, Mo.)*

The book itself we can commend to our farmers and gardeners. Its author was formerly connected with the "Southern Agriculturist," a most excellent farmers' paper, and was thoroughly acquainted with the wants of the Southern people in respect to their farming and gardening operations.—*Gazette and Banner*.

A complete gardening book for the localities which it specifies. It is full and comprehensive, and written in a clear, perspicuous style. A volume of 441 pages, well printed and bound.—*Republican (St. Louis, Mo.)*

It is very comprehensive, embracing all the improved kinds of fruits and vegetables, and the modern modes and implements of tillage. Its arrangement is systematic, and entirely convenient for prompt reference. It is illustrated by a large number of drawings relating to garden and fruit cultivation, such as trailing, grafting, draining, transplanting, together with pictures of novel fruits and vegetables.—*Dispatch (Richmond, Va.)*

Price, post-paid, \$2.00.

The Great New Story,

The End of the World,

By EDWARD EGGLESTON,

Author of "The Hoosier School-Master," etc.

WITH

15 Fine Full-Page Engravings,
and Numerous Other
Illustrations.

The Publishers are happy to announce the early appearance, in book form, of the new story, "THE END OF THE WORLD." Its earlier chapters read like a Western Idyl; but Mr. Eggleston soon gets us into the grotesque scenes which he draws so strongly, and Gottlieb Wehle, the Backwoods Philosopher, the Steam-Doctor, Cynthia Ann, the "Hawk," the "Mad-Clerk," and, above all, Jonas Harrison, one of the most effective Western characters ever drawn, make a rare gallery of original portraits. The speeches of Gottlieb Wehle, Jonas, Cynthia Ann, and the Philosopher are full of a delightful humor, while the Night Adventure of August, the Moh Scene, the life-like description of gambling in the saloon of a Mississippi steamboat, are drawn most vividly. The interview at the Castle can hardly be read without tears, and the chapters entitled "The Last Day" and "The Midnight Alarm" contain pictures of religious excitement such as can not be found elsewhere in English literature, while the mob and "shiveree" scenes are pervaded by an irresistible spirit of fun, and the reader will fully appreciate Bill Day's longing for "somethin' ludikerous." The moral influence of the book is of the healthiest kind.

The leading critics assigned a very high place to the "Hoosier School-Master," and we feel sure that "The End of the World" will place its author in the front rank of American writers of fiction, and we predict for it a success unsurpassed by any American work that has yet been written.

Price, Post-paid, \$1.50.

ORANGE JUDD & CO.,

AGENTS Wanted.—Agents make more money at work for us than at anything else. Particulars free. **G. STINSON & CO. Fine Art Publishers, Portland, Maine.**

THE BICKFORD FAMILY KNITTING MACHINE.

The machine we this week bring before our readers is one which, in the accomplishment of varied results through the employment of the most simple means, has been rarely equalled. Those who have seen the complicated knitting machines at work in the large factories, which at present fill the American market with knit goods, have been accustomed to regard them as essentially and necessarily complex. The inventor of this machine has shown, however, that only a few parts are necessary to accomplish a great variety of work, and also that these parts may be of forms easily understood, put together, and operated by those unfamiliar with machinery.

We have taken great pleasure in personally inspecting and operating this machine, and have become convinced that it comprises all that is essential for family use.

It supplies a means of fabricating many articles of usefulness in every household. A great many ornamental kinds of work undertaken for the purpose of filling up leisure hours, but becoming tedious and burdensome before they can be completed by hand, can be begun and finished in an hour or two, in such a perfect manner and with such facility, that the delight in making them is not marred through prolonged labor. We can conceive of nothing more fascinating to a tasteful mind than the rapid production of forms of beauty and usefulness effected by this machine.

The merits justly claimed for it are: the variety of work it executes; its non-liability to get out of order by transportation or use; the perfect manner in which it is made; ease in working, and absence of noise in running; the little skill required to operate it, and its capacity to knit anything that the most expert operator can knit or crochet by hand, from a watch-cord to a bed-blanket. The machine, having no tension, does not wear or tear the yarn to pieces. It can, therefore, be traveled and knit over and over again. [Scientific American.]

PEACH CULTURE.

Illustrated. By **James Alexander Fulton.** Price, \$1.50.

Among the fruits, the Peach, if not the most, is one of the most important of all. It is so easily raised, comes into bearing so soon, and is so delicious, as well as beautiful, it is impossible that it should not be a favorite. Living in the very center of the peach-growing district; sharing the common interest felt in the subject; deeply impressed with its importance to the individual planters themselves, and also to the community at large; and believing that a lasting benefit could be done to both, the author has been induced to prepare this work on peach culture.

AGRICULTURAL CHEMICAL ANALYSIS.

After **E. Wolff, Fresenius, Krocker,** and others. Edited by **Prof. G. C. Caldwell,** of Cornell University. Price \$2.00.

In this work Professor Caldwell has brought together the processes of analysis which apply especially to soils, fertilizers, animals and plants, and their products. He has tested the methods of the best foreign authorities, and presented them in a compact hand-book. Such a work has long been needed by all who teach agricultural chemistry, and by analytical chemists generally. Professor Caldwell modestly calls himself the editor, but his book shows that he has not contented himself with editing the works of others, but has given much of his own experience.

Either of the above books sent post-paid on receipt of price by

**ORANGE JUDD AND COMPANY,

THE PRACTICAL POULTRY KEEPER.

A COMPLETE AND STANDARD GUIDE TO THE
MANAGEMENT OF POULTRY,
FOR DOMESTIC USE, THE MARKETS, OR
EXHIBITION.

Beautifully Illustrated.

By L. WRIGHT.

NOTICES BY THE PRESS.

This book is a valuable manual for everybody who feeds chickens or sells eggs. It enits at once the plain poultryer who must make the business pay, and the chicken fancier whose taste is for gay plumage, and strange, bright birds. The most valuable portion is the first section, extending through fifty-five pages. These were written with the intention of producing a manual so plain, minute, and practical, that any one could, by using it as a guide, with no previous experience with poultry, become at once successful in producing eggs, young chickens, and fat fowls for market. The author has not misaed his aim. The middle parts of Mr. Wright's Manual are taken up with minute directions for making show fowls for Fairs, a nice discussion of the good and bad points of the different breeds, and a brief sketch of such fancy stock as peafowl, pheasants, and water-fowl. Then follows a section on artificial hatching, and another, worth special attention, on large poultry yards. . . . A study of Mr. Wright's book will convince any farmer's wife that all she needs is to give a half hour each day, of intelligent and sagacious attention to her poultry, in order to obtain from them, not tape, and knitting needles, and buttons, and nutmegs merely, but the family supplies of sugar, shoes, and cloth. *New York Tribune.*

It is the most complete and valuable work on the matters of which it treats yet published. It will be found a plain and sufficient guide to any one in any circumstances likely to occur, and is illustrated with elegant engravings of many breeds of fowls. *Farmers' Cabinet.*

This is a reprint, with numerous wood engravings, of an English book, the object of which is to convey in plain language a great deal of practical information about the breeding and management of poultry, whether for domestic use, the markets, or exhibition. . . . The book is eminently practical, and we recommend it to farmers and others interested in breeding and selling poultry. *Philadelphia Press.*

It is a handsome volume, brought out in the best style, and enriched with nearly fifty illustrations. It is evidently the fruit of a thorough, practical experience and knowledge of fowls, and will be found a plain and sufficient guide in all the practical details of poultry management as a profitable business. *United Presbyterian.*

The subject is treated fully and ably by an experienced hand, and the volume will doubtless find a large sale among the growing class of poultry fanciers. It is embellished with numerous illustrative engravings. *New York Observer.*

The author has called to his aid all who were experienced in the subject whereof he writes, and the consequence is a volume of more than ordinary thoroughness and exhaustiveness. *Rochester Democrat.*

The book is a complete and standard guide to the management of poultry for domestic use, the market, and for exhibition. *Watchman and Reflector.*

THE BECKWITH \$10 SEWING MACHINE.

DESCRIPTION.—c, clamp holding machine upon edge of table; a, shield over wheels, with an opening to show the wheels; b, the crank-bar or picion-arm, by which b, the upper arm, is moved; d, the lower arm; f, cloth plate; n, needle; t, thumb-screw to hold the needle; r, presser foot spring; s, tension screw and disks; s, spool of thread; m moves the stitch-maker which can not be readily shown. It is very simple in form and sure.

A GREAT BOON. A Good Cheap Sewing-Machine at Last.

We have been offering as a Premium, for some months past, the **Beckwith new \$10 Sewing Machine**, which has been fully described in the *American Agriculturist* for March and April. We have already given and sold some hundreds of these machines, and testimonials of satisfaction are coming from every quarter.

Hundreds of letters have been received by us and by the Beckwith Sewing Machine Co., extracts from a few of which are given below.

VAN BUREN, ARK., May, 1872.

GENTLEMEN: We have just received from Orange Judd & Co. one of your machines. We are very much pleased with it, and write to know terms to agents.

Respectfully,
DECHERD BROS.

CONCORD, OHIO, April, 1872.

GENTLEMEN: I purchased one of your machines of Grange Judd & Co. My wife is learning to use it. We are much pleased with it thus far.

Yours truly,
R. BURR.

No. 3, A. & G. R.R., GEORGIA, April, 1872.

GENTLEMEN: Seeing your improved machine advertised in the *American Agriculturist*, and relying on Orange Judd & Co.'s statements, we sent to them and got one of your machines, with which we are much pleased. Have shown it to several friends, and I presume several orders will soon be sent to Orange Judd & Co. or to you.

Respectfully yours,
J. A. M. KING.

NEW YORK, May, 1872.

GENTLEMEN: It is due your laudable enterprise to state that, having had in my family one of the Beckwith Sewing Machines from its first appearance, its great merits are more apparent the longer we use it. My wife makes all her dresses on it with ease and perfect satisfaction, as well as everything else she desires to sew. She has recently made a heavy silk dress with it, and is now making a light summer dress. Having formerly been accustomed to the use

of first-class large machines, she greatly prefers the little Beckwith. Its ease of operation, its simplicity, and always being in perfect order, together with the great convenience of taking it with her wherever she goes, and of using it wherever she pleases, are considerations so greatly in its favor, that it must soon become the favorite of every household.

Yours respectfully,
LEANDER FOX, 26 Varick St., N. Y.

WASHINGTON, D. C., March, 1872.

GENTLEMEN: Received the machine and letter sent by you on the 8th inst. After an examination and trial of the former, sewing with it nearly the whole of several garments, including one of cloth, I can say that it gives entire satisfaction.

Very respectfully yours, etc.,
H. L. CLARK.

CHESTNUT CREEK, ALA., April, 1872.

GENTLEMEN: On the 30th day of March last, my wife, Mrs. E. A. Floyd, inclosed \$10 to the Beckwith Sewing Machine Co., and waiting several weeks she became very impatient, as women usually do, but she has received the Beckwith Sewing Machine in good order and complete in every part, and says she would not take fifty dollars for it if she could not get another like it. It does all you claim for it. Several persons have seen this machine at work, and are well pleased with it. If you would receive the money through the Express Co. on delivery, I would like to have one dozen of them sent immediately to this office. I am satisfied that I can sell one dozen per week easily. I am County Surveyor for Baker County, and mixing with the people daily.

Respectfully yours, etc.,
GEO. W. FLOYD.

KENANSVILLE, DUPLIN Co., N. C., April, 1872.

GENTLEMEN: The machine has been received, and works like a charm.

Yours respectfully,
H. H. BROWN.

BRUNSWICK, MAINE, March, 1872.

GENTLEMEN: Your machine was received in good order, and I think very highly of it, and they will find a ready sale. Should be very happy to take the agency or buy machines of you to sell again.

Yours truly,
B. L. DENNISON.

HAMILTON, LOUDOUN Co., Va.

GENTLEMEN: Please send me your terms to agents for the Beckwith Sewing Machine. We are much pleased with ours. I would like to have the agency of this county, if terms are satisfactory.

Very respectfully,
WM. H. BALL.

ANNA, UNION Co., ILL., March, 1872.

GENTLEMEN: Yours of late date to hand, and contents noted. Am glad to learn your demand is more than you can supply, and hope your every success possible. My machine came all right, and such a novelty you can imagine, and so surprising to do such work, is really astonishing! Have experienced considerably, and am well pleased, and think I will soon be an expert at the business.

Yours truly,
W. S. MORGAN.

SALISBURY, MD., March, 1872.

GENTLEMEN: The sewing machine came safely to hand, and on trial I find it complete. The dearest little machine ever was made. I am quite in love with it. A gentleman told me last night that he believed I could sell a hundred here in town, and urged me to write and get the agency.

Yours respectfully,
Miss SALLIE BUSH.

FOND DU LAC, WIS., March, 1872.

GENTLEMEN: I have received from the office of the *American Agriculturist* one of your \$10 sewing machines, and am so much pleased with it that I would like to know on what terms you supply agents, and what is required of them. An early reply will oblige

Mrs. EDWARD COLMAN.

COLUMBUS, GA., April, 1872.

GENTLEMEN: I purchased a sample of the "Beckwith Sewing-Machine" while in Savannah, Ga., for a lady friend. She has received it, and is perfectly satisfied with it. I am confident, from the merits of the machine, that many of them can be sold in the Southern country, from the fact that thousands would buy machines if they could get a cheap meritorious one.

Yours truly,
L. C. DUER.

LOWER MACON, CUMBERLAND Co., N. S., April, 1872.

GENTLEMEN: I received twice Beckwith Sewing-Machine a few days ago, and am perfectly satisfied with it. It exceeds my expectations, and those who have seen it pronounce it beautiful.

Very truly yours,
ISAAC HARRISON.

BEDFORD Co., VA., March, 1872.

GENTLEMEN: Some time since, I got for my wife one of your sewing-machines, and she and I are so well pleased with it, and think it comes up so nigh to what it promises, that I have determined to apply to you for an agency. I believe I can sell a good many of them, and can make a good thing of it both for yourselves and me. I do not know of there being another machine of the kind in the county. If you choose to entertain my proposition, I refer you (for my character) to our Circuit County Judge, or the Clerks of our County or Circuit Court, or any one you may happen to know in the County of Bedford, Va.

Yours very respectfully,
DR. JNO. S. MITCHELL,
Liberty, Bedford Co., Va.

We have contracted with the Beckwith Sewing Machine Company for a large number of them to supply our own friends, and as *Premiums*. Each machine is put in a neat, compact box, with *hemmer and guide, oil-can, bottle of oil, thread, different-sized needles, etc.*, with full Printed Directions for using, and delivered to any express office in this city, without extra charge above the \$10. As we buy the machines at wholesale price, we have decided to give our readers some advantage of this, and we therefore propose to make a present for himself or herself, or for any friend, of one copy of *Hearth and Home* or two copies of the *AMERICAN AGRICULTURIST for the balance of this year (1872)*, to those persons who send us \$10 for one of the machines while this offer is continued.

The New Sewing Machine as a Premium without Money.

To enable those to get this machine who can not raise even the \$10 to buy it, we make the following offer:

We will send the Machine free to any one who will collect and forward **SIX** subscribers for **HEARTH AND HOME** one year at \$3 each; or **TWELVE** subscribers to **AMERICAN AGRICULTURIST** for one year, at \$1.50 each.

Almost any lady can readily secure this small number of subscribers and get a machine free; or some friend can thus obtain it for her, as a present.

**THE
PERCHERON HORSE.**

TRANSLATED FROM THE FRENCH OF
CHARLES DU HAYS,

Author of the "Dictionary of the Pure Race;" "Trotters;"
"The Horse-Breeder's Guide;" etc.

FINELY ILLUSTRATED.

TABLE OF CONTENTS.

Production, Rearing, and Improvement of the Percheron
Horse.

PART FIRST.

Greatness and Decline of the Percherons. Glance at
Perche. Sketch of the Percheron Race. Origin of the Per-
cheron. Modifications of the Percheron Race. His First
Modification due to Contact with the Brittany Race. Con-
ditions under which they are Bred. Causes of the Degener-
acy of the Percheron Horse. Starting Point of this
Degeneration.

PART SECOND.

Of the Means of Regenerating the Percheron Horse. Re-
generation of the Percheron Breed. Regeneration of the
Breed through itself or by Selection. Consanguinity. Ought
the Gray Coat of the Percheron to be Inflexibly Maintained?
Preserve Pure, and without Intermixture, the Three Types
of the Percheron Race—the Light Horse, the Draft-Horse,
the Intermediate Horse. Improvement of the Breed by
Means of Foreign Crossings. The Arab Cross. The English
Cross. Improvement by Means of the Stud-Book. Re-
capitulation.

PART THIRD.

Information to Strangers Wishing to Buy Percheron
Horses. Food and Breeding. Trade. Glance at the most
Celebrated Breeding Districts. Speed and Bottom of the
Percheron Horse. Tests of Speed of the Percheron Horse.
Tests of Endurance of the Percheron Horse.

American Pomology.—Apples.....\$3.00

This volume has 744 pages, the first 375 of which are
devoted to the discussion of the general subjects of
propagation, nursery culture, selection and planting,
cultivation of orchards, care of fruit, insects, and the
like; the remainder is occupied with descriptions of
apples. With the richness of material at hand, the
trouble was to decide what to leave out. It contains
293 Illustrations. CONTENTS: I. Introductory.—II.
History of the Apple.—III. Propagation. Buds and
Cuttings—Grafting—Budding—The Nursery.—IV.
Dwarfing.—V. Diseases.—VI. The Site for an Orchard.
VII. Preparation of Soil for an Orchard.—VIII. Se-
lection and Planting.—IX. Culture, etc.—X. Philoso-
phy of Pruning.—XI. Thinning.—XII. Ripening and
Preserving Fruits.—XIII and XIV. Insects.—XV.
Characters of Fruits and their Value—Terms used.—
XVI. Classification. Necessity for—Basis of—Char-
acters—Shape—Its Regularity—Flavor—Color—Their
several Values, etc., Description of Apples.—XVII.
Fruit Lists—Catalogue and Index of Fruits. By Doct.

ty; Vice-President American Pomological Society
Cloth, 12mo., 744 pp.

HOW CROPS GROW.

A Treatise on the Chemical Composition, structure, and
Life of the Plant. With numerous Illustrations and tables
of analyses. By Prof. Samuel W. Johnson, of
Yale College. Price \$2.00.

This book is a guide to the knowledge of agricultural
plants, their composition, their structure, and modes of de-
velopment and growth; of the complex organization of
plants, and the uses of the parts; the germination of seeds,
and the food of plants obtained both from the air and the
soil. Very full and accurate tables of analyses are given,
and tables of the proportions existing between different
principles, oily, starchy, or nitrogenous, in the same and
different plants. The book is an invaluable one to all real
students of agriculture.

HOW CROPS FEED.

A Treatise on the Atmosphere, and the Soil as related to
the Nutrition of Agricultural Plants. Illustrated. By Prof.
Samuel W. Johnson, of Yale College. Price, \$2.00.

The work entitled "How Crops Grow" has been received
with very great favor, not only in America, but in Europe.
It has been republished in England under the joint Editor-
ship of Professors Church and Dyer, of the Royal Agricul-
tural College, at Cirencester, and a translation into German
has been published, at the instigation of Professor von Liebig.
The author, therefore, puts forth this volume—the com-
panion and complement to the former—with the hope that it
also will be welcomed by those who appreciate the scientific
aspects of Agriculture, and are persuaded that a true
Theory is the surest guide to a successful Practice.

Either of the above books sent post-paid on receipt of
price by

ORANGE JUDD AND COMPANY,
245 BROADWAY, NEW YORK.

PARSONS ON THE ROSE.

A Treatise on the Propagation, Culture, and History of
the Rose. Revised and newly electrotyped. Illustrated.
By Samuel B. Parsons. Price \$1.50.

The Rose is the only flower that can be said to have a his-
tory. It is popular now and was so centuries ago. In his
work upon the Rose, Mr. Parsons has gathered up the curi-
ous legends concerning the flower, and gives us an idea of
the esteem in which it was held in former times. A simple
garden classification has been adopted, and the leading vari-
eties under each class enumerated and briefly described.
The chapters on multiplication, cultivation, and training,
are very full, and the work is altogether the most complete
of any before the public.

THE ARABIAN STALLION "SAPPHIRE."—Drawn from Life and Engraved for the American Agriculturist.

This horse, of which we give an engraving, is a late importation direct from Morocco. He is of the pure Abda race, which is now bred only in that country in a district located at the foot of the Atlas Mountains. The exportation of these horses is permitted only by favor of the Sultan of Morocco, and in this special instance was a courtesy granted by the Sultan with the gift of the horse to Mr. P. W. Scott, the interpreter of the United States Consul at Tangiers. They are therefore very rare, and as their excellence is unsurpassed by any strain of Arabian

blood, an importation becomes a matter of great interest and value to American breeders. There are those who pretend that our best breeds of horses can not be improved by foreign blood, and that they have advanced beyond any need for its introduction; but we can not believe this, for as we owe to the Arabian horse much of the excellence of the American thorough-bred, it is consistent with all past experience in stock-breeding that new blood is occasionally needed to keep up the standard and prevent depreciation. If this is a correct view, then this horse

must prove a valuable addition to our stock. He is a dark iron-gray or black and gray, beautifully formed, with an eye indicative of intelligence and spirit. His temper is gentle, and he has been ridden by a lady. He is now in training at Flushing, L. I., and although never in harness until now, shows fine trotting action, and promises considerable speed. He is six years old, and stands 15½ hands high. His attendant, Selim, the Moor who accompanied him, has returned to Morocco. Sapphire is owned by Messrs. J. H. Drake and Edward Annan, of N. Y.

AMERICAN AGRICULTURIST.

NEW YORK, OCTOBER, 1872.

On our own farm we usually find October the busiest month in the year. There is not only more actual work to be done, but it is of a character that requires close personal supervision. A farmer needs to rise early, lay good plans, work himself, and make others work. He must look to the details, and see that every hoe, potato-hook, corn-cutter, basket, shovel, spade, fork, rake, scythe, chain, rope, ladder, plow, coultter, plow-point, harrow, cultivator, cart, wagon, wheelbarrow, crow-bar, hammer, nail, bolt, monkey-wrench, and auger is not only in good order, but is in its proper place where it can be found at any moment.

Farmers should not only attend the Agricultural Fairs themselves, but allow their men to go too. We know from experience that nothing so effectually disarms them of prejudice. We like to see a farmer and his boys and his hired men looking at improved stock and examining new implements. You will find it useful to take the addresses of exhibitors of good stock or of implements that you may sometime wish to purchase. All sensible manufacturers have circulars describing their machines; take one of them to read when you get home. It is a great mistake to confine your attention to new things. It is better to look after the improvements that may have been made in old implements and machines. Do not overlook the fruit, vegetable, grain, and dairy departments. A good Agricultural Fair is a grand means of improvement, but it is quite an art to know how to examine the articles to the best advantage. Go at it systematically. Finish one department before you go to another. Do not be in a hurry on the one hand,

or stop to loiter on the other. Do not waste your time and energy in finding fault with the officers. If you are not an exhibitor, look at the articles on exhibition, and see if you have nothing at home that would have taken a prize—and make up your mind to exhibit next year.

Hints about Work.

Cutting up Corn.—Unless it is intended to husk the corn from the standing rows, the work of cutting and stooking, if not already concluded, should be finished as early as possible.

Husking.—In our own case we find it far cheaper to have corn husked by the bushel than by the day. We usually pay from four to six cents a bushel of ears, depending on the quality of the corn. Last year we paid six cents. This year the corn is so much larger and better ripened that the husker can make more at five cents than he could last year at six cents. We say "he," but in point of fact this work is often done by women, or by a man who has a wife and children to help him. It is often with us cheaper to have it husked on shares. A correspondent of the Agriculturist in Wisconsin speaks of paying one third the crop for husking. We often get the work done for one seventh or one eighth. That is to say, the husker takes one bushel and leaves us seven. When corn is cheap it is generally better to have it husked on shares. See that the corn is husked clean, and that the stalks are tied up properly.

Cribbing Corn.—If the corn is sound, dry, and hard, it may be kept in a large crib, but if somewhat soft it will be necessary to take some pains to keep it from molding. The narrower the crib the better, and it is well to make some chimneys in the corn with boards. Soft corn should be spread out on a floor where it will dry, and be turned occasionally. Feed it out at once. It is better for cows and cattle than for fattening pigs.

Corn-Stalks.—Hay is likely to be scarce and high. Wheat-straw is with us of poor quality, and we shall need all our corn-stalks for fodder. Their value for fodder depends a great deal on how they are cured. Make the stooks upright and compact, so that they will shed the rain. Draw in as soon as they are cured, for at this season the weather is very uncertain. A little sap in the stalks is far less injurious than external moisture. Half the stalks in the country are seriously damaged by careless harvesting.

Potatoes.—Dig as soon as they are ripe. Fine weather is important, and there is nothing to be gained and everything to lose by delay. Unless you have every convenience for keeping, it is usually best to sell as fast as you dig them—drawing them from the field to market.

Small Potatoes are of far more value as food in the early spring than in the fall. They pay well for keeping, either in a barn-cellar or in pits.

Pits for Potatoes should be made on dry soil and where there is no danger of water standing in the spring. Our own plan is to make a deep dead-farrow with a plow, and then throw out the soil on each side so as to make the bottom of the pit about three feet wide. Cover the potatoes with four or five inches of straw, and then throw on a light coat of soil, about sufficient to cover the straw, leaving some ventilators at top. Just before winter sets in, put on another coat of straw and cover it with earth. This second coat of straw holds dead air between two layers of earth, and will keep out the severest frost.

Potato-Tops are well worth drawing to the yard to absorb the liquid manure. Allowing them to remain scattered over the field until spring is a very slovenly practice.

Weeds and Rubbish are best got rid of by setting fire to them. They burn better now than in the spring. Be careful that the fire does not spread to fences or the woods or mucky land.

Fall Plowing.—Unless the soil is very sandy and

TAKE NOTICE.

2 Months' Subscription Free, viz.

Every New Subscriber to the American Agriculturist for 1873, whose subscription comes to hand during October, will be presented with the paper the rest of this year without charge, if the name be marked new when sent in. Take Notice, that this offer extends to All New Subscribers, whether coming singly, or in Clubs, or otherwise. (This will help those who now begin to make up lists for Premiums—page 313—for they can offer to each new subscriber the new \$5 Picture—page 365—and a bonus of two months free, and still count these names in Premium Lists.)

N. B.—The German Edition is issued on the same terms as the English one, with the same privileges, and may form the whole or any part of any Club or Premium List.

liable to leach or wash away, you can not go amiss in keeping the teams busy at plowing land intended for spring crops. If possible, plow the corn-stubbles this fall. If there is not time for this, go over them with a two-horse cultivator. It will kill a good many weeds, and level down the hills, and leave the land in far better shape to plow in the spring. It will also do good by exposing the soil to the atmosphere, and thus develop plant-food. It will also cause a great many weed-seeds to germinate, and the young plants will be killed by plowing in the spring. We think so much of this work that we often cultivate between the stooks of corn as soon as the crop is cut. Try the plan. It will pay.

Ditches.—On low, moist land, the fall is a good time to cut new ditches and clean out and deepen old ones. Underdraining on upland is usually best done in the spring, or late in the fall or early winter, when the ground is saturated with water.

Wood.—If not already done, delay no longer in filling the wood-house with dry wood for winter.

Clean up.—Pieces of boards, broken rails, barrel-staves, etc., should be gathered up before they become saturated with the fall rains. A few hours' labor in straightening up would add much to the appearance of many a farm. Nothing pays better than neatness, system, and order.

Harrowing Wheat.—We hope our readers will try the effect of harrowing wheat this month. Let it be done while the weather and soil are dry, so that any weeds that are pulled up will die.

Horses that are kept at steady work should no longer be turned out to pasture. The nights are cold, and the horses are better in the stable. Horses that are only worked occasionally, and never very hard, may be still kept out at pasture during the day. They should be brought up on cold nights and stormy days. As a rule, it pays far better to stable the horses, feed well, and work steadily. But avoid working them on rainy days. If caught in a storm, rub dry when brought in.

Milk-Cows, if well fed, give very rich milk at this season. As the pastures fail, the cows should have plenty of food at night in the yards or stables, such as corn-fodder, hay, bran, soft corn or corn-meal, beet-tops, cabbage leaves, pumpkins, etc.

Steers intended for winter feeding should now be allowed a little grain, say two quarts per day. They should be pushed forward now as rapidly as possible before cold weather sets in.

Sheep.—If you intend to raise early lambs for the butcher, select out the largest and best common Merino ewes from the flock. Give them the best pasture and a little grain, say half a pound each per day. This will cause them to take the ram in a few days. Use a pure-bred ram—either Cotswold, Leicester or South-Down, as may be preferred.

Sheep for Fattening in Winter should now be selected and pushed forward rapidly. On good feed, with a little hay and grain, they will often gain more in the month of October than during the next six or eight weeks. It rarely pays to try to fatten Merinos, in winter until they are three years old.

Lambs should be kept in a flock by themselves, and have the best of care and feed. If not already done, they should be dipped in a solution of carbolic soap to kill ticks. This is especially necessary with the long-wooled sheep. In cold, stormy weather put all, and especially lambs, under cover.

Do not Sell the best Ewes or Lambs.—Sheep are scarce, and the butchers are picking up all the good sheep and lambs they can find. Never let a butcher go into your flock until you have first selected out all that you intend to keep.

Sheep-killing Dogs are apt to be around at this season. Put bells on two or three sheep in each flock. Keep a gun loaded ready for the dogs.

Poultry.—Feed well, and get such as you intend to sell or eat as fat as possible. Keep the hen-house clean. Do not allow the fowls or turkeys to roost in trees or on the implements. A little

attention for a few nights will teach them to go to their proper roost.

Swine.—Do not fall into the common mistake of neglecting these useful animals because pork is very low. A reaction is sure to come, and good pigs will be profitable stock.

Farrowing Sows should have a warm, dry pen, with a rail round the inside about twelve inches from the ground and six inches from the sides. For two or three days after farrowing give the sow warm slops, and gradually give richer food as the young pigs grow and require more milk. At three weeks old the little pigs should have some food in a small trough separate from the sow.

Spring Pigs if not in unusually good condition can probably be wintered over with profit. Pork can hardly fail to be much higher next year than now.

Fattening Pigs should be pushed forward as rapidly as possible this month. It is a great mistake to delay shutting them up to fatten until cold weather sets in.

Young Pigs, like all young, growing animals, should have abundance of food, and the best of care and treatment.

Work in the Horticultural Departments.

Nearly everything in the way of fruit and vegetables at the North will be harvested during this month, and many arrangements can be made for the next season, especially in planting trees and shrubs. As the days grow shorter, and fall work becomes less pressing, more time may be very profitably spent in reading, and in promoting sociability among neighbors and friends, especially those interested in similar pursuits. If no rural club is organized in the vicinity, a little exertion on the part of several live, wide-awake farmers and horticulturists can form one, and sustain an interest in such an organization.

Orchard and Nursery.

Picking the late varieties of fruit will be the main business of this month; the quickest way to gather the fruit from an orchard is to pick the tree clean, and not stop to sort it, but store in large bins, and afterwards assort it, making two qualities, and using those which can not be sold, for cider. The late sorts of apples make the best cider, and it will pay to take considerable pains in selecting the apples, so that no rotten ones are mixed with the others. Cider made in this way is excellent for bottling, or it may be put into good air-tight barrels, when it will keep nearly as well as in bottles.

Packing Fruit.—The great danger in barreling apples arises from their not being packed tight. Clean new barrels should be provided. When one is about half-full, shake the barrel gently, in order to settle the fruit; repeat this when the barrel is full, and then place a layer on the top, so that the apples will be at least one inch above the chime. The head is then put in position, and pressed down by means of a lever. Apples packed in this way can be carried a long distance without danger of bruising. Do not put any poor fruit with the first quality, as it will seriously affect the price. After the fruit is all barreled it should be stored in a cool place, where there is no danger from frost.

Pears.—Late fall and winter pears may be treated the same as apples, but the earlier ones should be placed on shelves, where they can be watched, and as soon as ready sold or used.

Pomace.—Should any seeds of apples be wanted for nursery stock, the pomace may be washed out; if considerable quantities are required, it is necessary to have a running stream of water; this is conducted into a box, containing the pomace, which is constantly stirred, and the lighter parts washed away, and the seed, which is heavier, remains. The seed is then dried, and stored in a cool, dry place.

Manure in the nursery and orchard is needed, in order to secure the best results, and the fall is a good time to haul and spread it upon the land.

Fruit Garden.

Planting may be done this month, when the weather is mild. Raspberries and Blackberries do better when planted in the fall, as the buds start early, and when set in the spring they are not apt to make as good growth.

Raspberries and Blackberries when planted should have the canes cut back to the ground, otherwise they are apt to fruit the first year, and this often injures the plants for future bearing. Set raspberries 4 to 6 feet apart, and blackberries 6 to 8 feet.

Gooseberries and Currants.—Prune when the leaves have fallen, removing enough of the old wood to admit the sun and air, and cut back the new growth one half or more, according to the strength of the branch. The prunings may be used for propagating; cut them into lengths of 6 inches, and plant in trenches, 4 inches apart, leaving the tops an inch above the surface of the ground. The soil should be pressed firmly around the cuttings, and when cold weather comes cover the bed with litter or leaves.

Grapes.—It is desirable to leave these upon the vines until there is danger of frost, as when perfectly ripe they are of better flavor. Before packing in boxes, allow them to remain on shelves a few days, after which they should be packed in boxes containing 5 or 10 pounds; store these boxes in a dry, cool place, and keep at an even temperature.

Kitchen Garden.

The harvesting of the late crops and the fall planting and preparation of the ground for next season will give the gardener enough to attend to during the present month. The soil should be plowed in the fall, as it can be done easier, and can be worked sooner in the spring.

Preserving Roots, etc.—In very cold localities roots will have to be stored this month, and everything ought to be in readiness to do the job if sudden cold weather should come on. When roots are stored in cellars, provide plenty of bins, boxes, or barrels. The best way, however, is to store them in pits in the open ground. A dry place should be selected, and a trench dug, $2\frac{1}{2}$ to 3 feet deep, 6 feet wide, and as long as needed. The roots should be packed in sections reaching across the pit, two feet long and as high as the surface of the ground. Six inches of earth are left between the sections, thus giving two feet of roots, and then six inches of earth alternately. A layer of straw is then placed on the top and covered with a foot of earth, having slant enough to allow the water to run off.

Asparagus.—When the tops begin to turn yellow, cut and burn, so as to destroy all the seeds. It becomes a bad weed in cultivated grounds, and very difficult to destroy when once established.

Beets.—Pull and store on the approach of frosts.

Cabbages and Cauliflowers.—These bear considerable frost, and should not be pulled until freezing weather. Prepare frames for small plants to be wintered. These should be one foot high at the back, and eight inches in front, wide enough for the sash, and as long as necessary. Set the plants $2\frac{1}{2}$ inches apart, and deep enough to cover the stems. The sash must not be put on until cold weather.

Celery.—Finish cutting up, banking the stalks nearly to the top of the leaves. Next month will be early enough in most places for storing it.

Lettuce.—Young plants are to be set in frames as directed for cabbages. In some situations, the more hardy kinds can be preserved in the open ground if covered with leaves or straw.

Horseradish may be left in the ground until it is ready to freeze up, when it should be dug and stored like other roots. Save the small side roots for setting next spring.

Rhubarb may be taken up, divided, and new beds made. Cut the roots so as to leave a bud on each piece. Apply plenty of good stable manure, in order to give it an early start in the spring.

Spinach.—Keep the late-sown crops free from weeds. Thin where needed, and use the thinnings.

Sweet-Potatoes are fit to be dug when the vines are

first touched by frost. Take care not to bruise when digging, as they are very liable to decay. Those that are to be kept should dry in the sun for a day, and then be packed in sand or cut-straw, only using that which is perfectly dry. Keep where the thermometer will not fall below 60°.

Flower-Garden and Lawn.

The cool weather of this month is well suited to laying out walks, drives, laying sods, etc.

Lawns.—The soil for a lawn should be deep and rich, with a good drainage. The quickest way to secure a good surface to a small lawn is to sod it, though sowing the grass seed is cheaper.

Dubs.—Purchase early, and plant in soil well enriched with cow-manure, adding sand if the soil is heavy. When the ground freezes, give a covering of litter.

House Plants which have been kept out of doors should be taken in before cold weather comes. Cut them back well, and they will make a finer growth and be of a better shape.

Chrysanthemums must be tied up to stakes, as high winds will break them down when they are loaded with blossoms. A few may be potted for house decoration after the buds are well formed.

Perennials succeed best when taken up and divided every three or four years. Fall is the best month in which to do this, as they will become established by spring, and flower better than when disturbed in spring.

Peonies seldom flower when moved in the spring. Take up early this month and divide, leaving one bud to a root, and plant in rich soil.

Tender Dubs like the Gladiolus should be taken up after the leaves are dead, dried, and stored in a dry place where they will not freeze.

Protection to half-hardy shrubs, etc., should not be given until quite cold weather, the object being to protect them from sudden changes rather than to prevent freezing.

Greenhouse and Window Plants.

The greenhouse should have been prepared before this for taking in the plants, but if it is not yet done, attend to it at once, as a sudden cold snap may do a great deal of damage.

Annuals.—Sow a plenty for winter flowering, and prick out as soon as large enough to handle.

Bulbs.—Pot those needed for winter flowering, and put them in a dark place until the pots are well filled with roots.

Insects.—Every plant should be washed and cleared of insects before it is taken into the greenhouse, as this will save much time and trouble.

Materials.—See that plenty of soil, manure, moss, etc., are provided for the winter.

Plants to be forced for winter flowering must be taken up, potted, and stored in a cold-frame until next February, when they may be brought into the greenhouse and forced.

Commercial Matters—Market Prices.

The following condensed, comprehensive tables, carefully prepared specially for the American Agriculturist, show at a glance the transactions for the month ending September 13, 1872, and for the corresponding month last year.

Table with multiple columns showing transactions at New York markets for various commodities like Flour, Wheat, Corn, Rye, Barley, Oats, and comparisons with the same period last year.

Stock of grain in store at New York. Table with columns for Wheat, Corn, Rye, Barley, Oats, and Malts, showing quantities in bushels for various dates from 1872 to 1871.

Current Wholesale Prices. Table with columns for Aug. 13 and Sept. 13, listing prices for various commodities such as Flour, Sugar, Coffee, Tea, and other goods.

Gold declined to 112 1/2, closing September 13th at 113 against 115 1/2 on the 13th of August. The Breadstuff trade has been quite active since our last, but prices have been variable, especially on Wheat and Corn, influenced mainly by the receipts and the foreign advices.

is a moderate call for desirable grades of stock, but the bids generally fall short of the views of holders, who do not appear disposed to make important concessions. Hence the actual dealings in most kinds are on a limited scale, and indicate considerable irregularity as to values.

New York Live-Stock Markets.

Table showing live stock markets for Beef Cattle, Sheep, Swine, and other animals, with columns for date and price.

Beef Cattle.—Taken as a whole, there has not been a great deal of variation in prices of good cattle, but the markets have been glutted with poor stock which sells lower. The average receipts of the past month are the greatest ever known, and it is surprising that prices do not go still lower.

Table showing the prices of the past 4 weeks for various live stock categories.

Milk Cows.—The cow trade is quite dependent, during the summer months, upon the state of the milk market, and that has been very irregular.

Sheep and Lambs.—With larger receipts the trade is dull just now, and sheep are scarcely as firm, while lambs have declined about 1c. per pound. Some of the butchers now prefer fat sheep to lambs.

Fodder-Cutter.—J. H. Snyder, Berks Co., Pa., wants a machine that cuts and crushes or grinds corn fodder at one operation. The horse-power fodder-cutters which feed by means of rollers, crush the stalks to a great extent, but we know of no machine which cuts and grinds, and doubt if there is an opening as yet for such a machine in the present state of our stock farming.

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Remitting Money: — Checks on New York City Banks or Bankers are best for large sums; make payable to the order of **Orange Judd & Co., Post-Office Money Orders**, for \$50 or less, are cheap and safe also. When these are not obtainable, register letters, affixing stamps for postage and registry; put in the money and seal the letter in the presence of the postmaster, and take his receipt for it. Money sent in the above three methods is safe against loss.

Postage: On American Agriculturist, 3 cents a quarter, in advance; on *Hearth and Home*, 5 cents per quarter. Double rates if not paid in advance at the office where the papers are received. For subscribers in British America, the postage must be sent to this office for prepayment here.

Bound Copies of Volume Thirty are now ready. Price, \$2, at our office; or \$2.50 each, if sent by mail. Any of the last fifteen volumes (16 to 30) will also be forwarded at same price. Sets of numbers sent to our office will be neatly bound in our regular style, at 75 cents per vol. (50 cents extra, if returned by mail.) Missing numbers supplied at 12 cents each.

Clubs can at any time be increased by remitting for each addition the price paid by the original members; or a small club may be increased to a larger one; thus a person having sent 10 subscribers and \$12, may afterward send 10 more subscribers with only \$8; making a club of 20 at \$1 each; and so of the other club rates.

Too Late.—We have a large batch of inquiries too late for this paper. Those who had the good sense to sign their names, will get replies by mail. Those who signed their initials, or "A Subscriber," etc., should remember that such letters do not often receive attention.

Can't Do without It.—"We can't get along without the *American Agriculturist*," is the substance of testimony that comes to us from multitudes of homes in all parts of the land, where this paper has long been a welcome visitor. No additional inducement is needed by such friends, to continue their subscriptions, although they will receive upon renewal the gift (the splendid picture) we promise to all. But will not each one of this host of friends invite at least one other to join our army of subscribers, and receive the *American Agriculturist* with all that we promise for the coming year? Take hold with us, friends, and you shall find you have lost nothing by helping to double the subscription list.

New England Fair.—The New England Agricultural Fair of 1872 may be said to have been a success. An attendance of seventy-five thousand people on the third day of the fair, with satisfactory attendance on the previous days, secured its success financially, while the exhibition of stock and agricultural products and implements was creditable even to New England. Amongst the horned stock a herd of Swiss cattle and another of Brittany cattle were particularly interesting as being something not often seen in the United States. The show of Herefords and Ayrshires was also worthy of note. The greatest attraction, however, was the exhibition of horses, which showed great improvement in this class of agricultural production to have taken place of late years in this section. Our visit was necessarily brief, and the immense crowd prevented anything like rapid movement. If asked what was the most wonderful thing we saw at the fair, we should answer, "the people." All seemed pleased and satisfied, and the fair closed with *éclat*.

A Question in Proportion.—"W. S." asks if cabbages at five cents per head will pay better than tobacco at twelve cents per pound. It is probable that cabbages would be the more profitable crop, on account of the less labor involved in harvesting; a good crop of cabbages at that price should bring nearly four hundred dollars per acre, and the cost of preparation of the ground and cultivation is about the same in either crop until ripe, when the cost of gathering would be in favor of the cabbages. It must be a very good crop of tobacco to bring four hundred dollars per acre.

About Hops.—"S. V. C.," Richland Co., Wis., writes that he has two acres of hops. Shall he sell early?—We can not advise "S. V. C.," or any other man, as to how or when he shall market his crops, for very ob-

vious reasons. The *Agriculturist* is not gifted with a prophetic vision, by which it can tell the price of hops next January. Hops promise to be a fair crop all over the world, and it is not likely there will be much fluctuation in prices. Our experience for some years has been that we have always done better by selling our crops as soon as they were ready for market, and taking current prices. We have speculated, and held for a rise, and have been disappointed and lost money. We do not remember ever making anything by it. Hops are now salable at fair prices, about 50 cents a pound, which may or may not advance, and hops are best marketed while new.

Diseases of the Horse.—"C. H. L.," M.D., Tarentum, Pa., asks if we can not give some information on the diseases of the horse and their treatment. The horse is subject to as many diseases as a man, and to treat of all of them in a satisfactory manner would require several volumes, and to treat of them otherwise would be worse than useless. It is worthy of suggestion whether or not it would be proper and advisable for country physicians to make this matter a subject of study and practice. We can see nothing derogatory in it to the character and position of a physician or surgeon, and our experience has been that no persons could more usefully make this a part of their business than such men, and so do away with an array of quacks who destroy more horses than they cure, if they ever cure any.

Gas-Lime for Cabbages.—"H. W.," Lafayette, Ind. Gas-lime should not be used for cabbages nor any other crop until it has been so long exposed to the air that it has no longer any sulphurous odor. It can then be used like any other lime.

Osage Orange Plants.—"J. N.," Normal, Ill. The size of plants will depend upon the season and thick or thin sowing. They range in size from that of an ordinary lead-pencil to that of one's little finger. They may be wintered out of doors by placing in a heap and covering with earth as you would potatoes, or by laying in trenches and covering. In either case a place where water will drain off must be chosen.

The Baldwin Apple.—In August last we published a gossipy article from a well-known literary lady, upon the Baldwin apple. This has called out several letters, controverting the statements there made, and as these letters do not at all agree with one another, we must decline to publish them. We have not space to give to such controversies. For the sake of peace we are willing to admit that Count Rumford was born in six different places, and that the Baldwin apple originated on as many different farms.

SUNDRY HUMBUGS.—Some persons have sent us the circulars of the so-called "Missouri State Lottery," and ask, "Is this a genuine Lottery?" Suppose it was, would the writers invest in it, and allow the managers to put \$3 of their money in their own pockets, and then give their dupes a chance to draw the remaining \$2? That's the way of all lotteries. But this Missouri State Lottery is not a State Lottery at all—that State has got above dabbling in such swindles. If the writers or any one else are foolish enough to send money to the individuals who call themselves "managers," they need not expect to ever get anything back. The "Sale of the Monat Florence Estate" is merely a lottery at best (or worst), and a poor one at that. If the lots be valuable, they will sell on their own merits, without the bewitchment of a prize, which only one person in a million can get. Wonder if Hon. Chancey M. Depew, Hon. Jas. W. Husted, and others, know how their names are used to bolster up this scheme? The so-called "N. Y. Loan Brokers' Union," offering to sell tickets for a little money, which tickets will tell you what big articles you can get for a little more money, is an old catch-penny. You must send all sums up to \$40 in advance, and 1/2 of all above that is to be C. O. D., which is just the same as if remitted in advance—and just the same as if thrown into the river at first—no, not the same, for in the latter case you might find it again. Wonder where "R. H. Lewis, Business Manager," keeps all that "over \$1,000,000 worth of unreclaimed articles, 67,590 in number"? Why not call it an even 67,600 while about it? We have been looking for Elias to turn up somewhere again, after he sold out those millions of dollars' worth of Geneva watches, and this Loan Brokers' Union looks very much as if he had got into "No. 4 Bond street." No Elias, no Lewis, or their stock was visible when we called there. A little sign on a little room on a top floor reads R. H. Lewis; nobody in at 11 1/2 A.M. And now comes the old Missionary, the very "Rev. Jasper Marx," who has spent 40 years or so, as a self-appointed missionary in Paraguay, S. A., where he learned from an 87-year-old woman how to make "Aya-Pana-Coca," and the "Nicaya," which are to banish all sorts of diseases, "to correct,

neutralize, and banish forever all evils" of the blood, etc., and this very Rev. old Jasper Marx has come home to sell his medicines to poor sick North Americans, through his "business agent" in Jersey City, State of New Jersey. Bah! We grieve to see geniuses that can invent so taking a story as that of "Rev. Jasper Marx" degraded to so low a business. Such a man ought to be in some higher grade of life, an ornament to society, and not a vender of quack medicines. Reader, pray do not be led to dosing yourself for imaginary diseases, or any other, by such pathetic stories as that of old Jasper Marx, the missionary, who never got into any worse heathen country than is to be found in "Jersey City." And after Marx comes 76-year-old "Aunt Lee," a good Methodist, of Glenmarthen, in Wales, who sang an "old-school Presbyterian" "into tears he had not shed in years," as "the good old soul burst into one of those wild refrains" of John Wesley's followers. She—to wit, "Aunt Lee"—had an "all-healing syrup," and being about to "shuffle off this mortal coil," sold the recipe to the aforesaid "old-school Presbyterian" for a "good round sum." He (not she), his "dear wife having long since departed to the promised land," and his "only child being married to a British officer in India," departed to make "the land of the setting sun the scene of his future operations," until it "shall please the Lord to call him" (which we hope will be very soon). In short, he erected "suitable buildings in the State of New Jersey," operated in the Southern States until he "drove out all unworthy competition in that direction," and now proposes to give the "West" a chance at his Aunt Lee's "life-restorer," salves, etc. He wants "agents." We have given the above two specimens of a vast amount of printed stuff sent through the country to beguile the ignorant masses into buying and swallowing the medicines (so called) under the impression that they are doctored by the divinely-sent prescriptions of some old semi-spiritual being. Is this whole quack-medicine business any better than sheer swindling? Beware of the fellows at the fairs and elsewhere who sell envelopes with numbers in them, the lucky numbers to draw prizes. They have their stool-pigeons who draw good prizes before your eyes, but these swindlers know how to get your money and keep it, and they'll surely cheat you out of your money if you invest with them. The fair managers or other good citizens should arrest them as lottery dealers, and give them a dose of "country justice." Among new names for operating the "Spanish Lottery" swindle are: S. W. Cone, 105 Bleeker st., alias Clark Fargo, 22 West 4th st., alias 16 South 5th avenue. The "Queer" or pretended counterfeit money-swindlers have the following new names: F. E. Morrell, 69 Fourth ave.; Arthur Debenham, 190 Broadway; O. Aragon & Co., 12 Broadway, alias J. B. Marlett, Sangerties, N. Y.; Geo. W. Lucas, alias Wade M. Jacobs, 105 Bleeker st., alias F. A. Newton, 34 Amity st.; R. J. Spragg, alias Wm. Layton, alias E. M. Wootz, 609 Broadway; Geo. D. Marshall, alias Wm. O. Paige, alias Col. M. A. Ennever, alias Harrison L. Felix, at 34 Amity st., alias Amos Wainwright, 170 Broadway, in Trenton, N. J., etc., etc. Most of the above use the same circulars—that is, they come from one operator—but new names are continually sent out to hoodwink the P. O. clerks.

Insects on Asters.—"J. N.," Ironton, Mo. The insect sent as the one destructive to your asters is one of the blistering beetles, *Lytta vittata*. It is also destructive to potato vines and other vegetation. It appears to have been unusually abundant this year. We set out a great many asters, and, so industrious were the insects, did not get a single perfect bloom. The only remedy we know of is to shake them off into a pan of water, but we were too short-handed to do this, and had to go without asters.

Hail Insurance.—In an article some months ago, Mr. Henderson alluded to the necessity for insurance against damage by hail. We learn that there is a Mutual Hail Insurance Co. in Milwaukee that commenced business in April, and up to July had issued 1096 policies and paid 19 losses.

Free Lands in Iowa.—John Brennan, Sioux City, Iowa, informs us that he will reply to any inquiries regarding government lands open to settlement under the homestead law.

Steam-Plows.—"C. F.," Abilene, Kan., asks if there are any thoroughly practical steam-plows now made in the United States which do not use tackle. The American steam-plow is as yet unperfected, and as there are in the way of the practical use of those engines which travel over the ground immediately in advance of the plows serious difficulties which have not yet been completely overcome, we have to wait further developments before we can say that we have a thoroughly practical steam-plow which does not use tackle.

An "Axiom."—"G. H." writes us in regard to a question which we consider settled, and therefore can not reopen. But lest he might think we treat him discourteously, we would say that he is as incorrect in his main idea as he is when he speaks of an "almost universally established axiom." An axiom is a self-evident truth, as that "the whole is greater than one of its parts," and therefore can not be said to be "almost universally established," or admit of any qualification at all.

Fall Treatment of Old Meadows.

—Old meadows which have partly run out, and which it is not convenient to plow up, may be renovated by tearing up the old sod and bare spots with a sharp-toothed heavy harrow driven rapidly over it. When the surface has become loosened, fresh seed may be scattered, and a rolling immediately afterwards would be a help. Some fine manure or other fertilizer should be applied, and a light dressing of lime or ashes would also be a great benefit.

Lombardy Poplar—The Other Side.

—"G. W. G.," Iroquois Co., Ill., gives his view of the Lombardy Poplar as follows: "I believe the *American Agriculturist* has proved itself a friend to that much-abused tree the Ailanthus, and now to have it turn around and abuse one of the most beautiful trees our broad prairies possess is beyond my comprehension. We have no tree better than the Lombardy Poplar to protect us from the winds that blow across our prairies. You may talk about your bean-pole Ailanthus and the other trees you speak of, but when it comes to the real facts, which we ought to know, living on the prairie, you will find the Lombardy Poplar supplies a place which very few trees can do, and at least none that you have mentioned. I can go on and tell scores of uses which the Lombardy Poplar can be put to, but will refrain from troubling you now. Please let me ask you to tell the Nebraska man to set a grove around his barn-yard, farm, or anywhere, four feet apart each way, and I can prove to him that there will be in time to come few groves more beautiful, none more useful, and no part or place of ground on his farm more valuable."—As our correspondent speaks of the Lombardy Poplar as "beautiful" and "useful," and the Ailanthus as a "bean-pole," we suspect that he does not know the Lombardy, and must be talking about some other tree.

Potatoes and the Potato-Bug.

—"A. W.," Phillipsburgh, Ohio, asks if the potatoes the vines of which have been defoliated by the bug and checked in growth, will be good to use.—No injury is likely to come to the potato by the work of the bugs upon the leaves. If the potatoes cook well, we should eat them.

Poor Yield of Crops.—The average yield of crops, according to the census returns, is only about fourteen dollars per acre for all the land in cultivation in the United States. This is a poor showing, and shows the great need for improvement in our agriculture.

The Crops of Illinois.—According to the census reports, the State of Illinois produces larger crops of grain than any other State, and in total products of all kinds she comes second only to New York.

Egyptian Beets.—"W. B. H.," Berea, Ky. The Egyptian is the best early beet when you can get it pure. Ours came up full half Bassanos, some rascally European seedsman having mixed them. It is likely that this year our dealers will have home-grown seed.

A Crank Churn.—Mrs. J. F. B., Martin Co., Minn. Try the Blanchard Churn, made by P. Blanchard's Sons, Concord, N. H. We are never over twenty minutes in churning. The butter can be almost entirely worked in the churn. If there is any better churn than this, we should like to know it.

Plums Rotting.—"E. P.," Indianapolis, Ind. The rotting just at the time of ripening is not an unusual thing with plums, especially in some seasons. We have heard much complaint this season. We have seen no satisfactory reason given. Good culture and thinning of the crop are the best advice we can give.

Melon Seeds—Lima Beans.—Mrs. C. R. M., Naples, Ill. The seeds sent are those of the Apple-seeded Watermelon, a good variety, which keeps well after it is ripe... The proper Large Lima bean is always white. There are mottled and purple varieties, which are but little grown.

Sawdust for Bedding.—"A. S. T.," of Center Co., Pa., writes that he has used sawdust to bed horses and cattle for fifteen years. "It is a good

bedding," he says, "but, except for trees, very poor manure. The manure 'firefangs' easily. I once lost a hundred dollars worth of good manure by using too much sawdust." By keeping the manure-heap moist enough, firefanging may be prevented, or the manure might be drawn out and spread on the land directly from the stable.

Draining Timbered Swamp-Land.

—A Pennsylvania lumberman writes: "It pays to drain swamps that are covered with trees for the benefit of the timber. I have seen much valuable timber die for want of draining."—There seems to be some difference of opinion on this subject, and we should be glad to hear from any who can furnish facts bearing on the point.

Farm and Household Help.

—Adrien Briggs. A letter sent to your address was returned as unclaimed. Its purport was that we know of no such facilities for obtaining help as you speak of, nor at the prices named. If you can find us a good woman to do housework who will agree to stay a year for \$100, we will give you \$25 for your trouble. If any Chinese laborers are seeking employment in New York, we have never heard of them. Those who come to the city daily have as much difficulty in finding help as you who live at a distance. You have been deceived by some one.

A Good Cow.

—H. E. Wright, of Meadville, Pa., writes us that he has a cow "the mother of which was part Devon and the father a thorough-bred Short-horn. She gives the richest of milk—none better except the Alderneys. The last time she calved (1871) she gave during the months of May and June 72 lbs. of milk each day, and one day 80 lbs. I milked her three times a day."

A Professor of Horticulture.

—Mr. Charles S. Sargent, of Brookline, Mass., has been appointed Professor of Horticulture in Bausy Institution, which is the "Farm School" of Harvard University. Mr. Sargent is well known to the readers of the *Agriculturist* as the maker of the highest-priced butter sold in America, and as the most successful grower of azaleas. He is still a young man, with much enthusiasm and more knowledge in horticultural matters, and he enters upon his work with a determination to make it practically useful. An important feature of his department is a commercial greenhouse and garden in which pupils can obtain not only practical instruction, but actual experience of the business of gardening. We know of no better opening for any young man who may desire to embark in the pleasant and profitable profession of commercial gardening than to place himself under Professor Sargent's tuition and guidance. Incidentally to the giving of instruction, it is proposed to grow and to distribute at a low price such of the choicest and more useful plants as are not easily to be obtained in the market. We are glad that Massachusetts has at last an institution where horticulture is taught, and shall watch the career of this new school with much interest, believing it well calculated to accomplish most useful work.

An Australian Catalogue.

—Those who are accustomed to regard Australia as a place quite out of the world would be surprised if told that horticulture is there in a most flourishing condition, and that the small cities are far ahead of New York in all horticultural matters. We have just received from Anderson, Hall & Co., Sydney, their seed and plant catalogue, which in mechanical appearance and illustrations, and the character of its contents, will compare favorably with those issued by the New York and London seed establishments. In looking over the seed lists, we find that most of the novelties in vegetables and flowers are offered. Conover's Colossal Asparagus finds a place, and the Early Rose potato is mentioned as of great promise, and just introduced. In looking over the list of fruits we find the varieties, as might be expected, mainly English. The many fine apples of our Southern States should be tried in Australia. The list of Australian seeds, the remarks on tree-growing—in fact, the whole catalogue we have perused with much interest.

Will It Pay to Raise Corn?

—A correspondent of the *Agriculturist*, at Wawatosa, Wis., writes: "As you are a practical farmer, I would like to ask if you think it will pay to raise corn where we give one third for husking, and raise 50 bushels per acre, and sell the pork it makes for five dollars per hundred?"—We do not see how it can pay the farmer. It would pay the man who does the husking very well indeed. He can well afford to sell pork at five dollars per hundred pounds. But the other two thirds, after paying for the rent of the land, the plowing, harrowing, planting, cultivating, and cutting up, shocking, and cribbing, will not leave much profit for the man who raises the crop. We must look for better prices. Staple articles like corn and pork can not long sell for less than the cost of production.

Potomac Fruit-Growers' Association.

—The annual exhibition was held last month, and compared well with the exhibitions of national conventions in quality, showing that we have about us as good a fruit-growing region as can be found. The collections of fruits consisted of some 175 samples of pears, 80 of apples, 60 of peaches, 90 of grapes, also almonds, paw-paws, etc. The principal contributors were John Saul, Washington, O. D. Munson, Va., C. Gillingham, Va., R. A. Phillips, Va., and J. B. Claggett, D. C. The Agricultural Department and the Maryland Agricultural College were also exhibitors.

Seeding Down in the Fall.

—"Inquirer" may seed down in the fall by plowing or harrowing the surface until it is sufficiently mellow to receive the seed, and sowing as early as possible. If clover can be well established before winter, or where the snow gives ample protection, it may be sown in the fall.

Among Railroad Bonds

we judge there can be few if any better or safer ones than those of the New Canada Southern R.R. Its directness between New York and Chicago, its good grade, and the character of the men engaged in it—men who never go into a poor enterprise—are all so many guarantees of its great success. A safe seven per cent gold interest bond, at ninety per cent, is "not a bad thing to take." We would like to have money enough to take the whole. See advt.

Soil for Compost.

—"T. A. O." asks: "In getting soil for compost, how do you keep from skimming the land or leaving the subsoil bare where the soil is not over twelve inches deep?"—In England, where composting is far more common than in this country, the usual plan is to select an old headland or fence-bottom or earth-bank, or soil that has been thrown out of ditches, or road scrapings. We have never known a farmer go into a field and dig up his ordinary soil to make compost with. He uses material that he wants to get rid of.

Bommer's Method of Making Manure.

—"I have just read this book," writes "T. A. O." "Do you fully indorse it?"—No. But it is worth reading. You must exercise your own judgment. Try and separate the chaff from the wheat. If there are any special points on which you want information we shall be happy to hear from you.

Langstroth's Hive.

—In answer to "M. F. N.," who wishes to know if the patent on the Langstroth hive is run out or renewed, Mr. Quiby writes: "In answer to the above, I would say that I believe that the second patent of L. L. Langstroth's hive expires in October, 1872. His patent was renewed in 1865 for seven years. As it could not be renewed again by the Commissioner, many bee-keepers were apprehensive that he would apply to Congress the past winter for an extension. Accordingly, many remonstrances were sent in against it. I believe, however, he made no application." Mr. Quiby must have made a mistake in his date, as Mr. L. advertises that his patent was renewed in 1866, and, this being the case, will not expire until October, 1873.

How many Bricks to a Cubic Foot?

—N. R. Fielding, Decatur, Ala., wants to know how many bricks there are in a cubic foot.—This depends on the size of the brick, for there are various sizes. Multiply the length, breadth, and thickness of the brick in inches together, and divide 1,728 by the amount. There are 1,728 cubic inches in a cubic foot.

Price of Clover-Huller.

—"G. B. L.," Bernard, Mo.—The price mentioned is that of one made by R. H. Allen & Co., Water street, New York.

An Ill-mannered Horse.

—"O. S. C.," Danville, N. H., wants a cure for a horse which keeps his tongue out of his mouth when traveling.—Fortunately we never owned a horse so badly brought up as this, and have no experience. Wearing a muzzle would probably prevent it. It may be that some of our readers can help "O. S. C." in his trouble.

Fall Work on Drains.

—"A Farmer" asks what he can do in the way of draining through the fall and winter.—The fall is the very best time to prepare for making drains, and the winter the best time for completing them. Now is the time to lay them out, staking the ground in the direction the drains should run, and as soon as frosts begin to occur the lines might be covered with coarse litter or swamp hay or stalks in bundles, which will prevent the ground from becoming frozen. During heavy frosts the digging should not advance faster than the drain can be completed.

Sawdust for Mulch.—“L. B. B.,” Lansing, Mich. We have never used sawdust as a mulch for strawberries. Complaint has been made, where it has been used in some Western nurseries as a mulch for young stock, that in its decay the sawdust produced a fungus which was injurious to the young trees. Leaves are the best of all material for mulch. We use marsh hay, as it is cheaper for us than anything else. Has any one any experience in the use of sawdust?

A Double White Zonal Pelargonium.—M. Jean Sisley, of Lyons, France, whose success in raising double Pelargoniums we noticed last month, informs us in a recent letter that he has at last succeeded in obtaining a pure double white from seed. An unsatisfactory double white had been in cultivation, a sport from a single white. Mr. Sisley is an enthusiastic and successful amateur to whom we are indebted for some of our finest Cannas and Pelargoniums, and knowing his experience and judgment in such matters, we look for something very fine in his new horticultural triumph.

Ailanthus-Trees for Posts.—“Reader,” N. Y., has some Ailanthus-trees which he wishes to cut off, and, as we understand him, use as posts for grapevines, where they stand. We do not know how he can prevent the trunks from sprouting. Better cut down the trees, season the posts, and then set them.

Pegging Down Roses.—“Uncle Edward,” The roses referred to were China and Tea Roses, but the Remontants or Hybrid Perpetuals may be so treated. The common garden roses are too robust to manage well. Peg down in the fall or spring, and as the new growth is formed, peg that down. We use hooked pegs, cut from brush. The use of one or several varieties in a bed is a matter of fancy; we have a dozen at least. We shall let our tender sorts remain in the bed, and when the ground freezes cover them with sods.

Bee Notes.—Owing to the illness of Mr. Quinby, the Bee Notes for last month and this were omitted. We are glad to learn that Mr. Q. is recovering, though but slowly.

Fruit in England.—The Gardener's Chronicle, in giving its customary annual report upon the fruit crop in the kingdom (including Ireland, Scotland, and Wales) presents a most melancholy account. That journal says: “Never before have we had occasion to report so complete and so general a failure.” Here we have a crop of almost unprecedented abundance, apples being so plenty that they hardly pay for sending to market.

A Farm Cyclopedia.—“Jas. M. G.,” Oakland Co., Mich., asks which is the best work on farming which treats of all branches, from clearing the ground up to planting, reaping, harvesting crops, and raising all sorts of stock. There is no one American book that treats fully of all these things. “Allen's New American Farm Book” is one of the best hand-books we know of. “Stevens's Book of the Farm” is the best English work, and a valuable help to a farmer.

Fodder-Cutter.—“J. McC.,” Berks Co., Pa., has planted some corn for fodder, and now wants a good fodder-cutter to cut for five or six cows. We have used “Gale's copper-strip” fodder-cutter, and found it one of the best machines of the kind.

Greenhouses.—“A. B.,” Concord, N. H. A reply was sent to your letter which was returned as “uncalled for.” The substance of our note was as follows: The cheapest house you can build is that described in February *Agriculturist* of this year—a lean-to. The cheapest method of heating is by a flue; full directions for building one are given in September, 1871. If you wish to build a span-roof, Henderson's Practical Floriculture is the best work to consult. Other things being equal a span-roof is best, but where expense is a consideration, the lean-to is much cheaper, and answers a good purpose. Henderson's book gives as much about management as you can get from books.

“Vindication of the Entomological and Museum Divisions of the Department of Agriculture” is the title of a small pamphlet by Prof. Townsend Glover. It is intended to show up the misrepresentations of one Swank, who as chief clerk of the Department has published a most uncalled-for pamphlet, “The Department of Agriculture, its History and Objects,” in which the Swank aforesaid, by implication, omission, and misstatement, reflects upon Prof. Glover, the man who of all others has made the Department what it is. It seems an unnecessary labor for a man like Prof. Glover to refute what a man like Swank may say. Those who have not given up all hope that the Agricultural De-

partment may yet be of use to the agricultural community, look in vain for any good results from its present management. The time will come, we sincerely hope, when, with abundant means and competent officers, the Department will take its proper place. In that hopefully looked-for day there will be neither Wattses nor Swanks to stand in the way.

Potatoes for a Hot Climate.—A Kentucky correspondent asks what are the best potatoes for a hot climate. A potato expert says, Early Rose for early, Garnet Chili for medium, Peachblow or Peerless for late. The Shaker Russet, also known as Dyrhight, N. J. Monitor, and by several other names, does well in Kentucky, but is very poor with us. In the far South the Peachblow is a very poor cropper.

Cutting Hay in Wet Weather.—Mr. H. C. Hallowell, of Maryland, writes: “Allow me to say that my experience fully indorses the remarks of Walks and Talks on the subject of cutting grass in wet and cloudy weather. I have for a number of years secured hay from about 100 acres, and generally with satisfaction to myself. My neighbors sometimes express surprise that I secure so much in such beautiful order. I think it is because I keep my Buckeye Jr. moving almost constantly, regardless of the clouds. If it is raining, there is the greater probability of clear weather afterwards. We must run some risks, and I prefer a possibility of some hay being wet, to the chance of its getting over-ripe. My experience fully confirms the remark that ‘as long as grass [and clover] is green, rain does not hurt it.’”

Winter Wheat in Massachusetts.—A. L. Clark & Son, of Hampshire Co., Mass., raised 29 bushels of winter wheat per acre, in 1871. Owing to the severe drouth the straw was not two feet high. The land was seeded down with the wheat, and this year the first crop of hay was estimated to yield 4 tons per acre, and a second crop well worth cutting. And this upon land that in 1864, when it came into their possession, yielded only a crop of white beans of six bushels per acre. The wheat was sown after tobacco. Mr. C. says, “We got our land clear from weeds with two crops of tobacco, and any crop does well after it. We have four acres of tobacco this season, and there is not half a bushel of weeds upon the whole.” Manure and clean culture is what our land needs to produce good wheat and grass.

Jerseys for Butter.—L. C. Flower, Onondaga Co., N. Y., sends us the following statement of the yield of butter from his Jersey cows, viz., Jenny Lind, 2 years old, in seven days in April last, from 94½ pounds of milk produced 10 lbs. 2 oz.; Victoria, 6 years old, in 28 days in June produced 80 pounds; Beauty, 4 years old, in the same period produced 72 pounds from an average of 30 pounds of milk per day. The heifer was fed on hay and oat-meal, the cows on grass alone. What can beat the Jerseys for butter and beauty?

Heeling In.—“E. H. M.,” Danbury, Ct. This term, or “laying in by the heels,” is used by gardeners to designate a kind of temporary planting. In the case of cabbage plants, they are laid closely together, and the roots covered with earth. This operation checks growth, and yet keeps the plants alive. It is often very convenient when one wishes to remove plants from a piece of ground, and the place where they are to go is not yet ready, to heel them in. Trees are often heeled in for the winter, they being taken up in autumn, and laid in trenches at an angle of 45°, taking care to fill in the earth so completely as to leave no spaces among the roots.

“Minnie B.'s” Inquiry.—If “Minnie B.” had sent her name, with her address, we should have replied to her question by mail. Others writing on purely personal matters will please take notice.

Sixth Report of the Connecticut Fish Commissioners.—Much has been accomplished in the Nutmeg State to make cheap fish. Thirty-seven ponds have been stocked with black bass by the Commissioners, and nearly as many more have been stocked by private enterprise. Nearly all the available ponds in the State are now supplied with this superb game fish, and they are known to be doing well. The policy of hatching shad at Hadley Falls is persistently followed. This, without doubt, is the best point in New England, if not in the whole country, for this business. After the public fishing ceases, on the 15th of June, all the fish in the river are compelled to stop at these falls, and fish fully ripe are taken in large numbers for about three weeks. Over sixty-three million ova were taken, and nearly all hatched and turned into the river at an expense of about five hundred dollars. All parties are now agreed that artificial propagation is a complete success. At a very small cost to the State every stream within its

borders may be made to swarm with this delicious fish. A million of shad-fry may be carried in five gallons of water a half-day's journey with very little loss. The Saugatuck, at Westport, and Great Brook, near New London, have been stocked by private enterprise. The Commissioners, united with other parties, formed a stock company, to take salmon spawn on the Penobscot, last fall. The enterprise was successful, and will be continued under more favorable circumstances the present season. About 25,000 salmon-fry were hatched at Poquonoc, and distributed mainly in the Saugatuck and Quinnchaug Rivers. A note from C. G. Atkins, at Bucksport, Me., who has charge of the salmon-spawn enterprise on the Penobscot, just received, informs us that he has already purchased 231 salmon of the fishermen, and has only lost 20 of the lot. The rest are in the reservoirs, doing well. Should he be as successful with the spawners of this year as he was the last, he will take at least a million of eggs, which will mark a new era in salmon breeding in New England. The great obstacle hitherto has been the extreme difficulty of procuring spawn.

A Prolific Sow.—“J. M., Jr.,” Wayne Co., Ind., makes the following statement about his sow: Late in July she produced three pigs, and three weeks later added eight more to her family. Two of the first and five of the latter litters are living and doing well. “J. M.” thinks this a strange freak on the part of his sow, and asks if there are more of her character.

A New Method of Churning.—“L. L. D.,” Wake Co., N. C., sends us a new method of churning, which he thinks an improvement on the old plan; it consists in forcing air through the cream by means of bellows and a system of pipes, contained in a cylindrical-shaped vessel. We doubt the success of this method, as it is necessary to the complete breaking up of the butter globules that a more powerful mechanical action should be produced than would be caused by the mere passage of currents of air. But let “L. L. D.” make a churn and try his method, by all means.

Power for one Run of Stone.—“W. P. S.,” Sidney, Ohio, asks what is the power of one run of stone. This depends on circumstances somewhat. Generally it will take one horse power to grind one bushel of wheat into fine flour, or two bushels of corn into meal, per hour. The less quantity of wheat is caused by the extra consumption of power by the bolts and smut machine. With old-fashioned or badly constructed wheels not more than half this work will be done, but with the best turbines it is often exceeded.

Saving in Feeding Cooked Corn-meal.—“W. A. T.,” Augusta, Ky., asks if it would pay to hire an extra hand to cook the corn for 32 hogs which he wishes to fatten. It would certainly pay to do so, as the saving in grinding corn and cooking the meal is equal to one fourth of the feed, at least, which in feeding 32 hogs would pay for the extra labor. The cooked meal should be fed cold, and in the shape of thick mush.

Boys and Girls—Special Notice.—All contributions intended for the Puzzle-Box should be addressed to Aunt Sue, Box 111, P. O., Brooklyn, N. Y. “The Doctor's” address is 245 Broadway, New York. Puzzlers will specify whether their contributions are for Hearth and Home or for the *American Agriculturist*.

Well-flavored Butter.—How can it be expected that butter of good flavor can be produced from pastures foul with every strong-flavored weed? From early spring, when garlic abounds, up to fall, when the Golden-rod and Ragweed cover the pastures and meadows, cows rarely get a bite of grass or clover free from admixture with weeds. And when it is known that these strong and often disagreeable flavors concentrate in the milk, and that every impurity in the milk seems to concentrate in the butter, how can it then be otherwise than that the great bulk of butter coming to market should be poor in quality, and poorer still in profitable returns to the farmers? Here is the strongest argument for clean pastures and meadows, and such farming as will raise feed and not weeds.

Egg-eating Hens.—“C. G. R.,” North Attleboro, Mass. The best preventive is to provide dark nests, to be approached by a covered passage just wide enough to admit the hen. When the egg is laid, the hen starts for the light and does not turn around to see the egg. So says one who has tried it.

Artificial Manures.—English farmers use yearly nearly a million tons of artificial and chemical manures, the materials for which are drawn from all quarters of the globe. It is thus they raise their heavy crops and keep their soil improving.

A PLEASANT
ANNOUNCEMENT.
—
A \$5.00 Present
To Every Subscriber
TO THE
AMERICAN AGRICULTURIST
For 1873,
Received on and after Oct. 1, 1872.

A Splendid Ornament for every Home.

The Publishers have received from the celebrated American Painter, Mr. B. F. REINHART, a fine Oil Painting, executed expressly for the *American Agriculturist* during the past summer, entitled "Mischief Brewing,"—a beautiful Rural Scene, for which they paid \$400.

This Painting has for sometime past been in the hands of the noted firm of Bencke & Scott, who are executing it in Chromo, on 16 stones (not on metal plates, or by any new uncertain process). From these stones each picture will receive at least 16 impressions in colors, thus producing a perfect copy of the original \$400.00 painting and scarcely to be distinguished from it by one person in a thousand.

At the usual charge for Chromos, the pictures will be worth fully \$5 each, and they will be sold at that price; while, taking into account the design, the character, and quality of the pictures, if valued at \$10 each, they would still be cheaper than most Chromos sold or given.

By arranging for 200,000 copies, so great economy is gained in the multiplication of these Pictures, that the Publishers will be able to present a perfect copy to each and every subscriber to the *American Agriculturist* for 1873 hereafter received. (It costs no more to put the picture on 16 stones for 200,000, than it would for 1,000 copies.) The Picture will give great pleasure to every one receiving it, and be a fine Ornament in every Household. It would be worth purchasing at \$5, or more, if it could not be obtained otherwise. It is a perfect Gem, 11 x 13 inches inside the frame.

The Picture will be given to every subscriber for 1873 (new or old), whether coming singly at \$1.50 each, or in Clubs of Four for \$5, or Clubs of Ten for \$1.20 each, or in Clubs of Twenty or more at \$1 each. Subscribers in Premium Clubs will also be entitled to it. It will be delivered at the Office, unmounted, free of charge, or if mounted, for 15 cents extra. If to go by mail, unmounted, 10 cents must be sent to cover cost of packing and postage.

It will be mounted on heavy binder's board, and Varnished, ready for use, even without any frame,

or for putting into a frame, for 15 cents extra—that is, for 25 cents it will be Mounted, Varnished, Packed, and sent Post-paid to subscribers (to this Journal for 1873 only), who come in now, or hereafter.

We advise all to have them mounted before leaving the office, as in the large quantities we put up, we are able to mount them for a quarter of the cost of doing it singly, and better than it can usually be done elsewhere.

We shall begin delivering the Pictures on Nov. 15th, in the order in which the names of subscribers are received, beginning with this date, Oct. 1st. All new subscribers for 1873 who have been received during September will also be presented with a copy on forwarding the 25 cents for mounting, packing, and mailing. We advise every one to send 25 cents and have it well mounted before it is sent out.

SEE HERE
EVERYBODY!

All Competition Distanced.

MANY DOLLARS For ONE.

The *American Agriculturist* has long excelled in circulation any and every other similar journal, or any half-dozen others. This has resulted from the fact that, taking into account its size, careful preparation, its very numerous fine Engravings, etc., it has been furnished far cheaper than any other journal in the world. [NOTE.—The printed surface of the *American Agriculturist* is nearly equal to most of the \$1 Magazines—the pages being 2½ to 3 times the size of ordinary magazine pages, while not more than one other magazine in the world gives as many costly engravings.]

BUT, the Publishers, warranted by the liberal patronage hitherto received, have resolved, for the coming year, to take

TWO STEPS FORWARD.

1 The former and present character, quality, and value of every number will be maintained, and material improvements be introduced during 1873.

2 A Splendid \$5 PICTURE will be presented to Every subscriber (as noted on this page).

MORE:—Every new subscription now received will be entered at once in the mail-books, and will be furnished with the paper from the time the name comes in until the end of 1873, at a single subscription price. (This applies to all new subscribers now received, whether singly at \$1.50 each, or in clubs of four at \$1.25 each, or in clubs of ten at \$1.20 each, or in clubs of twenty or

more at \$1 each. Those coming in during October will thus have the paper 14 months for a single subscription price.)

STILL MORE!—Very Valuable Premiums are offered (see page 393) to those who take the trouble to gather up and forward clubs of subscribers. These Premiums are 4 to pay for the time and trouble taken in gathering and forwarding the subscriptions (and good pay they are). The subscribers themselves will each get the \$5 picture, and new ones coming in now will get the extra numbers free.

How CAN it be Done?

Many will ask (as heretofore), "How CAN the Publishers afford to give so large a paper as the *Agriculturist*, so many engravings, etc., and also add pictures, premiums, etc.?" Answer: The average circulation of even good papers throughout the country is less than 5,000. It costs just as much to procure information, make engravings, set type, and electrotype, etc., for 100 or 1,000 or 5,000 subscribers as it does for 200,000 or more. When these matters are provided, the only further additions for subscribers is the cost of printing-paper, press-work, and mailing. In other words, the immense circulation of the *American Agriculturist* divides the cost of preparation, engraving, etc., among so many, that it amounts to but a trifle for each.—Again, the large circulation is so valuable to good advertisers, that they freely pay high rates; and any addition to the circulation increases the receipts for advertising. The truth is, the Publishers don't begin to charge the subscribers the actual cost of supplying the paper to them. The advertisers pay a large part of this, and enough more to pay for engravings, chromos, premiums, etc., and leave a living profit to the publishers. And this explains why our subscribers receive so much, and are to receive so much more this year than ever before. The large wholesale mode of doing things in this Office inures directly to the advantage of all our readers. If, for example, only a few thousand of the Chromos were made, they would cost from \$2 to \$5 each; whereas, by making 200,000 or more, the cost is so reduced that one can be presented to each subscriber without even increasing the subscription price.

How to Spend Election Days.

First: Vote right yourself—once.

Second: Get all your friends to vote right.

Third: Have with you a copy of this journal, and fill up all the spare moments in collecting names of subscribers for a premium club. You can thus secure, without cost, very valuable articles from the List on page 393. You have very strong "arguments," as you can not only promise every subscriber for 1873 a good paper, but also a splendid \$5 Picture, also the remaining numbers of this year—all for a single subscription price—a price so small that it merely covers the cost of the printing paper. See the offers on this page and page 393.

Fourth: You can get subscribers enough for one or more premiums before election day, by using evenings and rainy days. Begin to-day and try it.

Strong Arguments are much sought after among politicians just now. The Publishers of this journal are just now giving the strongest possible "arguments" to induce people to read—to wit: They offer not only a splendid paper at the bare cost of printing paper, but even offer to pay people to take it, by giving every subscriber a splendid \$5 Picture, and the bal-

ance of this year **Free**. They also present very **strong arguments** to those who get up clubs of subscribers—viz. the splendid Premiums on page 393.

A Good Paying Business— for Women as well as Men— Honorable and Useful.

Several persons of both sexes, in different parts of the country, devote their chief time to gathering subscribers to the *American Agriculturist* and to *Hearth and Home*, and to selling books on Agriculture, Horticulture, Gardening, Architecture, etc. (see list on third cover page, and notices of some of them in the advertising pages). For the subscribers obtained they take the Premium Articles offered on page 393, and sell them (as they are all very good, wanted generally, and are readily salable). These Premiums, obtained by the Publishers on special terms, are just as good as money, and give much better pay than could possibly be given in cash commissions. These canvassers, who work during the most favorable seasons, realize from \$300 to \$3,500 a year, according to their tact, experience, etc. Experience goes a great way. Some, who succeeded poorly at first, hardly paying their board, have by persevering practice come to be very successful. The success to be obtained is worthy of long practice. It is certainly quite as honorable and useful to engage in urging people to supply themselves with good reading and useful information, as it is to stand behind a counter and show up, and persuade people to buy silks, laces, or other goods, or to engage in any other work or business.

\$66.67 to \$100.00 worth of Engravings for ONE CENT.

At least \$10,000 will be expended in procuring pleasing and instructive *Engravings*, of fine quality, for the *American Agriculturist* during 1873. Every subscriber will have a neatly-printed copy of each of these in the pages of the paper, in addition to all the carefully prepared information given in the reading columns. This will give \$66.66 $\frac{2}{3}$ worth of engravings for every cent of cost at \$1.50 a year; or \$80 worth to those in clubs of four to nine at \$1.25 each; or \$83.33 $\frac{1}{3}$ to those in clubs of ten to nineteen at \$1.20 each; or \$100 worth for each *Cent*, to those in clubs of twenty or more at \$1 each. In addition, every subscriber will be presented with a perfect copy of Reinhart's beautiful \$400 painting, "*Mischief Breeding*," which will be a charming ornament in any home—a picture so much like the original oil painting that none but experienced artists will be able to detect the difference.

Hints to Manufacturers of Mowers, Rakes, etc.—Does it never occur to those who manufacture the various agricultural machines that a farmer's time is of value, and that he can not afford to spend it uselessly in trying to tighten a nut on a round bolt with a round head which turns in the hole? Now, if we can not have square holes and square bolts, at least we could have bolts with square heads by which they could be held while the nut is tightened. Farmers have much to complain of, too, in regard to the quality of the timber sometimes put into axle-trees and other important parts of machines, and in the use of cast-iron of a very brittle character in places where it should be of the very toughest kind or at least malleable iron.

Continued Experience in the use of the Averill Paint confirms the good opinion of it expressed in these columns a year or more since. It wears well—equally well or better—with the ordinary white-lead and oil paints. Messrs. Brown Brothers, the well-known bankers, who formerly used imported white lead to make sure of a good article, have, after fair trial, substituted the Averill paint for all their work. Being already mixed in all desirable shades, it is a great convenience to the many who can do their own painting.

Plants Named.—"Virginian Subscriber," Clifton, Va.—No. 1 is *Phalaris arundinacea*, or Reed

Canary Grass; there is a striped variety of this cultivated in gardens, known as Ribbon-Grass. No. 2. *Dactylis glomerata*, or Orchard-Grass. No. 3. *Festuca elatior*, var. *lolifolia*, Meadow Fescue. No. 4. *Agrostis alba*, White Beet Grass. No. 5. *Poa pratensis*, Kentucky Blue Grass. . . . J. H. Key, Leonardstown, Md.—The plant, very poor specimens of which you inclose, is *Chondrilla juncea*, a recent introduction from Europe; as it is a biennial, there need be but little difficulty in eradication, if it is not allowed to go to seed. . . . "A. A. L.," New Hampshire.—No. 1. *Geum rivale*, Purple or Water Avena, a plant with rather pretty maroon-colored flowers, inhabiting wet places. No. 2. *Saxifraga Pennsylvanica*, Swamp Saxifrage. No. 3. *Tiarella cordifolia*, False Mire-wort; does well when cultivated in the garden. No. 4. *Polygala pumila*, Fringed Polygala or Milkwort; a very beautiful plant, with large rose-colored or, as sometimes happens, pure white flowers. No. 5. *Myosotis palustris*, var. *laxa*, Forget-me-not. No. 6. *Muscari racemosum*, often cultivated in gardens, where it is known as Grape Hyacinth.

New Cocalias.—Mrs. M. Milburn sends us specimens of varieties of *Cacalia* which she claims are distinct in color from the old sorts. One, an orange scarlet, she says is valuable for dry bouquets.

Pigs for Packing.—A farmer in Boone Co., Mo., writes: "I have just finished reading 'Harris on the Pig,' with much pleasure and profit. I am satisfied, from my own experience, that he is right as to the advantages of crossing the Essex or Berkshire boar with the large sow, to get the right pig for the packing market."—We think there can be no doubt on this point.

Pickling Peaches.—"Mrs. A. M. B.," a Georgia lady, sends the following: For two gallons of peaches (when peeled) take 1 pt. vinegar, 3 lbs. white sugar, 2 oz. cinnamon, 2 oz. allspice, $\frac{1}{2}$ oz. cloves—the spices must be whole. Peel the peaches. Use a porcelain-lined kettle if possible. Dissolve the sugar in the vinegar, add the spices, and bring the syrup to a boil. Put in as many peaches as the liquid will cover, and let them cook until clear and tender. Take them out with a skimmer and put them into your jar. Repeat the operation with fresh peaches until all are done. Lastly, pour the hot syrup over them, and keep in a cool place. Peaches pickled without peeling are generally tough, while these will be found as tender as canned fruit.

Potatoes in England.—In addition to the almost total failure of the fruit crop, noted in another item, the English papers bring most unfavorable accounts of the potato crop. In almost every quarter rot is showing itself and spreading rapidly. The reports say that the mining localities where smelting is going on, and sulphurous and arsenical fumes are abundant, are nearly free from disease.

Alfalfa.—"Subscriber," New Jersey, asks if he can sow "Alfalfa grass" seed with oats in the spring, instead of timothy, with success.—Such a plan would certainly fail. Alfalfa is not a grass, but is related to clover. It is simply lucern, and needs to be sown as a crop by itself, with the best of care during its early growth until well established. It can not bear crowding with other crops or weeds. It is a question whether or not it would be best to prepare the ground for the lucern alone, in which case the oat crop would have to be abandoned, or sow the oats and timothy as proposed.

Young Rams.—Jas. Moore, Labette Co., Kansas, is buying rams for stock purposes, and asks if spring lambs, well grown, would do as well as yearlings. It would be more profitable to purchase yearlings, one of which would be equal to three spring lambs, and there would be more certainty in their use besides.

Practical Trout Culture, by J. H. Slack, M.D., Commissioner of Fisheries, N. J., etc. New York: Orange Judd & Co.—We were about to write a notice of this work, when a note from the father of fish culture in this country, Seth Green, came to hand. Mr. Green writes: "Your book on Trout Culture is received. I have read nearly all of it. . . . As far as I have gone, it is the best book on Trout Culture I have seen." The work can have no higher commendation than this, and we have only to add that it is abundantly illustrated, and sent by mail for \$1.50.

Protection to Native Industry.—New Hampshire has adopted a law for the protection of farmers against rapacious and dishonest manufacturers of artificial manures. Each manufacturer must file a bond for ten thousand dollars, payable to the State, to secure compliance with the law, which requires that all fertilizers offered for sale shall be accompanied by a statement of

the date of manufacture and the percentage of its valuable component parts, and that the article sold shall be identical in quality with this published statement. Besides, all dealers in fertilizers shall be licensed. A similar law should be made in each and every State.

The Magic Sifter.—We have an inquiry for the address of the patentee or manufacturer of the "Magic Sifter." If parties who make these things want them to become popular, why do they not make them known in a proper manner? We can not give the information needed.

Heavy Fleeces.—E. H. Worrall, Chester Hill, Ohio, sends us a statement of the shearing of a flock of Merinos, consisting of 20 bucks and 60 ewes. The wool, mostly unwashed, weighed 1080 pounds, and sold for \$36.80, averaging 13 $\frac{1}{2}$ pounds in weight and \$6.71 in money per fleece. The heaviest fleece was that of a two-year-old buck, viz., 24 $\frac{1}{2}$ pounds; the heaviest ewe's fleece was from a two-year-old, and weighed 21 $\frac{1}{2}$ pounds. One yearling buck sheared 19 $\frac{1}{2}$ pounds.

Carrots and Parsnips.—"W. S.," O., who has been vanquished as a potato-grower by the bugs, asks if carrots and parsnips pay to raise for market.—With the single exception of not being in such regular demand, we have found them a far more profitable and advantageous crop either to sell or feed than potatoes.

Salt-Meadow Muck.—"A Subscriber," Suffolk Co., L. I., asks what is the best use that can be made of salt-meadow muck. The best way to use it is to haul it into the barn-yard, and compost it with the manure in the proportion of one load clear manure to ten loads of muck. In the absence of the stable manure it may be composted with lime in the proportion of one bushel to the load, and used as a top dressing for grass or clover. It will be of very little use spread in a fresh state.

Summer Feed for Cows.—J. T. Gordon, Ashland, Va., wants to know what feed he shall give a cow which he is forced to keep in a dry lot, so that her milk will not fall off. He can get plenty of mill-feed and wild hay, but the green feed from the garden has given out.—This is a difficult business to manage. Milk can not be looked for, unless fresh succulent feed is given, and wild hay will not satisfy a cow which has been used to green fodder. But it might answer to ent the hay and mix it with feed and bran, and scald it, and feed it when cooled; there will be some fermentation, which will make it more palatable.

Use the Roller.—A coarse, lumpy soil is not favorable to a successful wheat crop. It requires a compact yet well-pulverized soil. This may be made to some extent by rolling; in fact, this is the only resource now, at this season of the year. A rolling given to the young wheat will compact the soil about the roots, and tend to give them a hold sufficient to resist a good deal of freezing and thawing.

Advertisements worth Reading.—Our newer readers may perhaps not understand that very great care is taken to exclude from the pages of the *American Agriculturist* all advertisers and all advertisements that will be likely to deceive the readers. No patent medicines are admitted on any terms. It is our constant aim to exclude all humbugs and all advertisements deceptive in form or substance. It is not enough that an advertiser pays for space. Our rules say: "Every advertiser unknown to the editors personally, or by good repute, must furnish satisfactory evidence that he has not only the *ability* but the *intention* to do what he promises to do in his advertisement." In short, we would not knowingly admit any advertiser to whom we would not ourselves send money in advance, with an order, if we happened to want the things advertised, and at the price asked for them. In this way we hope not only to make the advertising columns valuable to good business men, but also to guard the interest of our readers, and to make the advertising pages a valuable source of information—almost or quite as much so as even the reading columns. This strictness cuts us off from a large revenue, because the class rejected are just those who can and do pay the highest prices, as they can well afford to, because they give little of value in their medicines, wares, etc. But we feel well repaid for the loss, in the consciousness of doing an honorable business, and it is a source of satisfaction to have such testimony as that given by Messrs. Geo. P. Rowell & Co., the great Advertising Agents, who recently said to one of their customers: "It is very difficult to get an advertisement into the *Agriculturist*; probably no other journal in the land has laid down stricter rules or more persistently adhered to them through a long course of years."

Loss of Cattle.—The progress of the cattle disease in England has become a source of national alarm. The losses last year are estimated to amount to over thirty millions of dollars. American and Canadian importers of stock, fearful of the danger of introducing the disease here, are discontinuing their purchases.

Grubs in a Strawberry-Bed.—"O. M.," Ottumwa, Iowa. We doubt if any special manure or other application to the soil will be of use. In Europe, where a closely-related insect is a great pest, they find no relief save in plowing and picking up the grubs. The underground life of the common white grub extends over three years, and it eats whatever roots come in its way. When a plant is injured, dig it up, find the grub and kill it. This will save many other plants. Watch for the first appearance of wilting, and act promptly.

Lambs in Lincolnshire.—The productiveness of Lincoln sheep is shown by the fact of 107 ewes, the property of Joseph Baker, of Mortoo, Lincolnshire, having produced 209 lambs, which are all living and doing well.

How High Prices Come.—A butcher doing a large business has stated that the stock he buys generally passes through four or five hands before it reaches him and after it leaves the farmer or feeder. This will explain why the farmer gets five cents per pound, and the man who buys a steak pays twenty-five.

Another Duchess Gone.—Mr. Richard Gibson has returned from his late trip to England with an importation of sheep, and has since sent out another "Duchess," the 15th Duchess of Airdrie.

Materials for Tents.—"D. V.," Verden, Ill., asks what is the best material for a large tent, and who are the manufacturers or dealers in such materials. —The best material for a large tent is cotton sail-cloth, which can be procured at any of the large dry-goods stores in Chicago. Farwell & Co., or Field, Leiter & Co., both of Chicago, could supply it. It is probable that a second-hand army tent could be purchased which would exactly suit the purposes for which it is required.

Shad-Hatching in 1872.

So far as we know, the only rivers in which shad are hatched are the Connecticut, the Hudson, and the Merrimac, and this is the sixth season of the use of Seth Green's hatching-boxes—a discovery that is likely to do for the food supply of the nation what Whitney's cotton-gin did for its clothing. About 8,000,000 of shad-spawn were hatched in the Hudson last year, and we learn, unofficially, that the number is considerably exceeded this year. Of the number hatched, 230,000 were put into the river above the Troy dam, 80,000 into Lake Champlain, 20,000 in Lake Owasco, 50,000 in the Genesee River, 30,000 in the Alleghany River at Salamanca, and 25,000 in the Mississippi River, two miles below St. Paul. The remainder were turned into the river below Castleton. The operations began May 18th and ended July 2d.

The ova hatched in the Connecticut last year were over sixty millions. This year operations did not begin until the 24th of June, and ended on the 18th of July—less than four weeks. The fish were larger and finer than ever before, and the hatch of spawn was ninety-two million sixty-five thousand, a third more than was taken last year. The hot weather of the early part of July had such an effect upon the females, that the average number of ova from each one was greatly increased. Of this number 2,000,000 were sent to the Alleghany, White, and Platte Rivers, a half-million were distributed in Rhode Island waters, a half-million were sent to the Sangatuck, and about the same number to Great Brook, in Groton, Ct. All the rest were turned into the Connecticut, just below Hadley Falls. This enormous addition to the finny tribes was made at an expense to the State of Connecticut of about five hundred dollars. If the improvement of only two of our shad streams for five

years has resulted in the reduction of the wholesale price of shad in New York to \$3.50 per hundred, what may be expected when all the States turn their attention to this business, and Seth Green's hatching-boxes are in use upon every shad stream in the country? Is not cheap food for the coming millions a problem already solved?

SHEEP-KILLING DOGS.—"I would like to keep sheep on my hilly farm," writes a correspondent, "but am afraid of the dogs. Is there any remedy?"—There are three remedies: 1. If there is a tax on dogs in your State, see that it is enforced in your neighborhood. 2. If there is no dog law in the State, vote for no man who will not pledge himself to do all he can to have one enacted. 3. Let all the sheep men in the neighborhood form themselves into an association. Let nothing be done to gratify personal spite; but if a suspicious dog is found prowling about the farm, shoot him. Then, if the owner can prove damages, let the association pay them, and repeat the process. City and village dogs must be taught to stay at home. They are often abused and half-starved, and it would be a mercy to them to give them one good meal of mutton with a liberal allowance of strychnine in it. The neighbors might be told that this feast was provided solely for visitors, so that they can keep their dogs at home.

A good plan to adopt is, when a sheep dies, dress it and wash it with water containing a few table-spoonfuls of crude carbolic acid. It will preserve the meat for months. Cut it up into joints and hang it up, and you will always have a piece of mutton on hand for a hungry dog that may visit you from the city or village or swamp. If this work is done systematically and constantly, it will have a wholesome effect. It is rarely that a well-bred and well-fed dog attacks sheep, and it is not often that such dogs wander far from home at night. If there are any good dogs in the neighborhood, inform the owners of the fact that you have set a trap for the half-starved prowlers from the city, and that they had better fasten theirs up at night. In this way no harm is likely to be done.

LARGE ONIONS.—Within a year or two some varieties of onions have been introduced into England from the south of Europe which have produced bulbs of remarkable size. Mr. Peter Henderson writes that he saw at the rooms of the London Horticultural Society a specimen that weighed 4 lbs. 2 oz., and measured 24 inches in circumference. A dozen such specimens were exhibited, which the visitor claimed were of so mild a flavor that they "could be eaten like bread." The name of this variety was the *Early White Maggiojole*. Very large onions are raised in California and New Mexico, but seeds from them brought to the East produce nothing remarkable, and such we fear will be the case with these new European sorts. There are few vegetables more readily influenced by peculiarities of soil and climate than the onion.

CISTERNS.—Unless the house and barn have a permanent spring or water-course near by, they should always be furnished with a large tank or cistern into which all the rain-water that falls on their roofs can be conducted. In addition to these a good well is requisite. It would be better to dig the latter in a dry time, and keep on digging from one to three feet below where water is then found. This will insure a never-failing well. Our well became dry

the past autumn, when, after cleaning it out and sinking it one foot below the original depth, three feet of clear sweet water, or more, rose up in it within a few hours, and we do not think it will ever be dry again, unless outside material should get into it. One great advantage of saving rain-water in a cistern is, that it gives us an abundant supply of soft water for washing, and if it falls from a clean roof is always wholesome to drink. But if impurities get into it, the water is easily filtered, and thus rendered clear and sweet.—A.

KEEPING CABBAGES THROUGH THE WINTER.—"W. R. R.," of Michigan, writes: "You speak of raising cabbages for stock. How do you keep them through the winter? We have no difficulty in growing large crops here, but as yet have found no good way to keep them."—We make a deep and wide "dead furrow" with a plow, in dry, sandy soil; and then lay the cabbages in it, packed close together, with the stalks up. Then throw the earth back on to the cabbages. The cabbages should be dry and the weather cold, and care should be taken that the furrow left on the side of the row of cabbages should be cleaned out, so as to carry off the water. If no water gets to the cabbages, and the heads are sound, large, and hard when put in, we have never experienced any difficulty in keeping them perfectly until spring. And there is nothing that our sheep relish so much. The only trouble about raising cabbages for stock is that they usually command so much more in market than they are worth to feed out, that it is difficult to resist the temptation to sell them.

Husking and Cribbing Corn.

"The way we husk," writes one of our Illinois correspondents, "is to grasp the ear with the left hand, stripping one side with the right hand, then grasping the ear with the right hand and strip with the left, and break in a sort of combined movement, tossing into the wagon with the right hand. Sometimes a husk or silk adheres, but we let it go, for while you are taking it off you can husk another ear. It makes one third difference in the work, and no perceptible difference in the value of the corn to horses, cattle, sheep, or hogs, or to the buyers. Husk from the shock and throw directly into the wagon. It saves much labor. To prevent the corn from being thrown over the wagon, take a wide board as long as the box, nail strips on both sides, a few inches longer than the board is wide. Then place the board on top of one side of the wagon. The strips will hold it in place, making that side of the wagon higher than the other, and enabling the husker to toss in the corn without looking. If the corn must be sorted, throw the poor corn on the ground.

"To facilitate unloading, take a board, fifteen inches wide, three and a half feet long; nail a cleat across it on one end, and an inch from it nail another. Place this end on the tail-board of the box, and let the other end lie on bottom of the box. This will enable one to use a scoop-shovel at once, without the tediousness of hand-picking."—This latter plan was described in the *American Agriculturist* several years ago, and we have found it ourselves a great saving of time and labor. We do not husk into the wagon. If only one man was husking at a shock, it would not pay in our case to let a team stand idle. We would rather hire the corn husked by the bushel and set the team to fall plowing. But many of the writer's suggestions are good.

Ogden Farm Papers.—No. 33.

I have several times resolved to let the deep-can question rest on its own merits, and to take no part in the discussion concerning it which is wending its feeble and uncertain way through the columns of the agricultural papers; but I am called on every now and then to "state but the facts" in defense of my "pet theory"—to make a comparative trial of the two systems and to publish the result. This I would gladly do if I could afford it, but I can not. Butter-making is a *business* with us, and we have, happily, got through with our experimenting. At the same time, we have reached our present point by a very experimental way, and have lost many a large churn in attempting to find some means of making uniformly good butter by the old methods of creaming the milk. I have no favorite idea to advocate on this or any other subject, and I am entirely willing that every other dairymau in this free country should manage his work exactly as he likes. I merely say that I am entirely satisfied that I have hit on a plan that is more advantageous to me than any other I have been able to try, and when my advice is asked, I do not hesitate to recommend the deep-can system as sure to give good and uniform results. If the advice is not taken I am not at all offended, and if I am asked to prove the accuracy of my opinion I trust that my statement that I have no definite proof to offer will only induce those who doubt to experiment for themselves, and to leave me my own opinion.

But, while I have no definite proofs, I have general ones which may be worth considering. This has been the very worst summer for butter that I have ever known—at least so far as the climate is concerned. Intense heat, dense and long-continued fogs, and frequent thunderstorms have conspired to make it often impossible to make good butter from milk that has been subjected to atmospheric influences. Farmers generally have complained of the difficulty of making butter of satisfactory hardness, and customers have complained, still more, of the wretched quality of much of what they have received. "First-quality" fresh butter has ranged at about 30c. per pound, and much of it has been poor enough. Among those whom I know there has been great complaint of the quality of that which was bought for the best, and it has often been necessary to reduce the price to even 20c. to find a market. During all this time, the Ogden Farm butter has always been of the same excellent quality, and I have raised the price from 75c. to 90c. without eliciting a murmur. Of course, the fact that I have only Jersey cows has much to do with it, but with the same animals I was never able to prevent frequent changes in the quality until I withdrew the milk from the changing influence of the atmosphere, and subjected it to the uniform temperature of spring-water—avoiding the access of atmospheric influences almost entirely. I believe that I got more butter than I should get if I used shallow pans, and I have very good reasons for the belief. I am sure that I get more money from my dairy, and that is the sole object for which it is carried on.

I have several times been asked to give a detailed account of my herd and its product. I will premise by saying that it is essentially a breeding herd, and that butter, though an important, is a secondary object. We keep a good cow as long as she will produce fine calves, even though she may have ceased to be a good milker. Also, we turn the bull with the heifers

when they are from ten months to fifteen months old, that they may be made useful as breeders at the earliest possible moment, and that they may develop the milking tendency before they have time to form the other habit (most injurious to a butter cow) of taking on fat. The consequence is that we have always a good proportion of animals on the milking list which are of little account as compared with cows in their prime.

During the week ending August 10th we were milking 30 animals. Of these six had aborted at from four to seven months, and were giving very little milk. (Three of these had previously been the very best milkers in the herd, and had now become almost the worst.) Eleven were two-year-old heifers with their first calves, six were three year-olds with their second calves, and one was very nearly dry. They are therefore far from being an "abled-bodied" herd, nor are they heavy feeders. Yet they made, during this week, 153 lbs. of butter, worth, at 90c. per pound, \$137.70. It was about the hottest and most unfavorable week I ever knew.

One fact developed by the record of this week may surprise those who are not familiar with the Jersey breed. The average weekly yield of butter was (per cow) $5^{10}/_{100}$ lbs. The average daily yield of milk was $13^{21}/_{100}$ lbs. The largest daily yield from a single cow was $23^{70}/_{100}$ lbs. The total yield for the week was 2,774 lbs., and the weight of milk required to make a pound of butter (averaging the whole herd) was $18^{12}/_{100}$ lbs., or $8^{42}/_{100}$ quarts. This is not by guess, nor by "rule of thumb," but by actual weight taken at each milking, the cows being on green summer feed. The product has since fallen off somewhat, as an effect of the hot, close August weather, but the reduction has been more in the amount of milk than in the yield of butter.

The record would not be complete without an account of our manner of feeding, etc. The cows pass the night in the barn-yard. In the morning they receive an average of three quarts of wheat-bran and a good feed of corn-fodder. They then go to pasture, where they remain, on good feed, until 4 P.M. Then they are brought in, and have all they can eat of corn-fodder.

I think they would do better if "soiled" entirely with suitable fodder, but I have pasture land which must be used in this way, if at all, and the high price of winter forage tempts me to cure all I can of the soiling crops.

While on the subject of statistics, it may be of interest to say that I have sold since January 1st, 1872, fifteen bulls and bull calves, as follows: One two-year-old for \$200; seven yearlings for \$695; seven calves for \$350; in all fifteen head, at an average of \$83.

Formerly, my sales were almost entirely to breeders of thorough-breeds, but a very large proportion of this year's sales have been to dairy farmers who are desirous of improving the butter-making quality of their herds by an infusion of Jersey blood—indicating a growing appreciation of the value of this breed.

We made a mistake in our calculation about soiling this year, and it is very fortunate that the later growth of grass has been very good, and that we have been able to secure a good range. Last summer we planted fodder-corn until about August 10th, and the cold and drouth checked the growth of the later plantings, so that the crop was a failure, and our labor was lost. To be on the safe side, we this year planted all before July 20th—mostly before July 10th. The result is that all we now have left is

too far advanced to be readily eaten, and an experiment in feeding only this cut down the yield very materially, so that we have found the grass an indispensable resource. Of course, the corn now standing (about six acres) is very valuable for curing, so that there is no loss here; but it is clear that if we were to depend on this crop for the entire food of the cows we must run the risk of making one or two late plantings which might be of no use. This is a drawback to the system, but in spite of it I consider it a good system, and would on no account abandon it. Last year, in a severe drouth which cut the grass entirely short, we were making a fair amount of butter after our neighbors were very short indeed—simply because we had a good supply of corn-fodder. Whether soiling is adopted as the only reliance or not, it will pay every farmer who keeps cows (or swine) to secure himself against a grass famine by having a good field of corn-fodder. If it is not needed in this way, it will be worth many times its cost as winter forage.

When we commenced our operations we laid out a system of rotation of crops which was to keep most of the land always under the plow. The experience of the past two years has demonstrated the fact that Ogden Farm is "natural grass-land," and that for all other crops except corn-fodder and roots it is more or less unreliable. Such portions as have been put into good condition produce really remarkable crops of hay, and a simple top-dressing suffices to maintain the yield, while the soil is so heavy that for the successful growth of hoed crops it requires a large amount of manure to make it light and open enough. In time, when it is better stocked with the roots of grass (especially of clover) it will be improved in this respect, but now it is evident that grass pays much better than anything else. We are, therefore, seeding down all but about one fourth of the whole farm, hoping to raise on this fourth all the corn-fodder and roots that we shall need. An incidental advantage of this will be a decided reduction of the demand for labor in the field, and with a large herd of thorough-bred animals to clean and care for, the saving in this respect is very important. It is not pleasant to have to change plans which have been deliberately formed, but I confess that the labor question has conquered me, as it is pretty sure to do any farmer in this costly country, and I surrender at discretion. With as good facilities for getting labor as any one could wish, I find it the wisest plan to employ as little as possible, and to raise nothing that I can buy for less than the cost of raising it—as I nearly always can all kinds of grain. I can now safely calculate on a product of 100 tons of hay or its equivalent, 1,500 to 2,000 bushels of roots, and corn-fodder enough to furnish one half the summer feed for 40 head of cows and working animals. This is not a bad return from a 60-acre farm which five years ago would not produce the equivalent of 25 tons of hay, and was yearly growing poorer. It has been "a hard row to hoe," but it seems clear for the future, and under our system of cultivation the improvement can not fail to continue.

I am sometimes asked whether, if I were about to commence again, I would take such a worn-out and run-down farm. It would of course depend on circumstances. I would not do so unless (as in the present instance) the price of the land was very low, for it is far more costly to restore fertility than to preserve it. Other things being equal, I would rather pay \$200 per acre for land that can be depended on for two

tons of good hay at a single cutting, than \$100 for that which will produce only half a ton. The latter must remain unprofitable for some years, and will consume (in time and money and loss of profit) more than the difference of price before it will be as productive as the former.

There is a certain satisfaction in reclaiming worn-out land, but I am yearly more and more convinced that it pays better and gives much more satisfaction to farm land that does not need reclaiming. There are few soils now so rich that they will not make more improvement and pay better returns for the same amount of labor and manure than an exhausted and worthless one will. "The best first" is my motto. When the very best field of the farm has been so far improved that it will not pay for more improving, then go to the next best; but good land, like a good plow, is more profitable to work with than poor land, and should enjoy the concentration of our best efforts. When it is so rich and in such good condition that further outlay will not materially benefit it, then move on to another field; but don't spend money and time in draining and clearing a swamp for the sake of a half-crop, when the same expense will give a double crop on better land.

Jersey Cattle, and Scales of Points.

BY GEORGE E. WARING, JR., OF OGDEN FARM,
(Secretary of the American Jersey Cattle Club.)
(CONCLUSION.)

It is true that the Jersey breed has been made what it is under the influence of the Jersey Society's Scale of Points. It is by no means certain that if it is brought under the influence of a wiser scale it may not still farther improve. Opinions may fairly differ as to whether the Mackie scale is a wiser one, but it can not be assumed that perfection has already been reached, and that it is of no use to try for improvement. For my part, I think there are grave defects in the old scale, and that the fundamental theory of the new one is very good. If I hesitate to applaud its details, so far as I agree with them, it is because it seems the better course to invite further discussion, and to encourage all the suggestions that breeders may have to offer. It is surely safe to maintain that no perfect Scale of Points has yet been made, and that an intelligent discussion of the subject can only do good—never harm. It is therefore to be hoped that those who object to the Mackie scale will state not only the fact that they do object, but the reasons why they object. Only in this way can the best result be achieved.

Some of the reasons why I object to the old scale are as follows (for the sake of brevity, I give only the number of the article considered, following the list for cows on page 250 of the present volume): (4.) If "fine" means *small*, I doubt its fitness. I fancy the opposite, without knowing that it has any particular significance. (5.) This is not of sufficient consequence to count as much as (28) for instance. (7.) I think an examination of the best dairy cows would show that their ears are usually *large*, coarse, and hairy. (10.) Would prefer a "ewe" neck—hollowed out between the head and the shoulders. (11.) Not for a dairy cow; the thinner the better. (12.) Behind, yes, but not at the girth—the smaller the better there, if not out of proportion. (13.) This means beef rather than milk. (14.) Not essential, but comely. (15.) Beef, again, and rarely seen in a first-class Jersey butter-yielder. (16.) Doubtful, except for beef and beauty. (18.) Can it be too loose?

(22.) This generally accompanies large lungs, which a butter cow should not have. (23.) "Well-filled up" means *beef* again—the thinner and more delicate, the better for the dairy. (27.) Unimportant. These are some of the details. The worst fault of the scale is that the same value is given to non-essential as to essential points. It provides that a cow may be branded if she has 29 (out of 34) points, but not otherwise; consequently, a cow would not be disqualified for the highest honor if she was entirely defective in the items of udder, teats, and milk-veins, and had straight, coarse, thick horns; while a cow of the greatest excellence in these all-important particulars might be rejected simply because her cheek, muzzle, ears, eyes, tail, and hoofs were not up to the standard of beauty. It seems to me that this is an unanswerable argument in favor of a change in the scale. If Mr. Mackie's is not good enough to displace it, let us try again. I confess that I should be glad to have it adopted, at least so far as to secure its full discussion and improvement.

So much for the Scale of Points. The writer of the article under consideration says that what we know as "solid color" is popular in England "no doubt in consequence of its more aristocratic appearance." His arguments in favor of this coloring do not seem to be convincing. Aristocratic appearance does not depend on color nor on form, only on usage. If solid-colored animals are in fashion in England so are fat ones, and we can have no fault to find. What I especially desire is that, in this country, the aristocratic Jersey shall fill the niche—for which the breed is so admirably adapted—where the greatest beauty and the greatest utility shall go hand in hand. I have never seen a really good Jersey cow—a deep milker and a large butter-yielder—that was not also a beautiful cow. Those characteristics which indicate good dairy qualities—fine skin, silky coat, full placid eye, crumpled waxy horn, thin neck and shoulder, full flank, delicate limb, and fine udder—are beautiful in themselves, and are suggestive of a generous bounty of yield. Such a cow will attract admiration at first sight from every man or woman who ever fed on milk. It is sometimes necessary to have a *cultivated* taste to admire the aristocratic solid-colored cows whose black switches are flaunted in our faces as compensating for the heavy fore-quarters and light hind-quarters which such animals too often have. I have no sort of objection to the solid color, nor to the "black points," nor to any harmonious coloring that a cow may have. All I claim is that the fashion for these factitious distinctions has been started (in America at least) partly by men who are anything but practical breeders and dairymen, who are fledglings in the whole business of farming; and partly by cattle dealers who have sought to catch their fancy (and their fancy prices), and to encourage their fallacious notions, in order to palm off upon them animals which they have been able to buy at low prices here and in Jersey, because they had little else to recommend them but these "non-essential" qualifications. I have made a personal examination of a number of the "solid-colored" importations that have been sold at high prices on their arrival, and am convinced that if the arbitrary action of the Jersey Cattle Club had not placed a practical embargo on the traffic, the well-deserved and very promising popularity of the breed would have been utterly ruined in a very few years.

I repeat, and with emphasis, that I do not ob-

ject to the solid color. I only assert that most of the solid-colored animals that have been imported were imported because they were solid-colored, not because they were good cows; that neither in this country nor in Jersey do the best and most experienced breeders attach any considerable importance to the question of color; that the best cows (and the most beautiful) very rarely have the aristocratic marking; and that the cows which do have it are more often poor milkers than otherwise. Not because the color is detrimental, but because it has been sought, when sought at all, as a *primary* object, and the indispensable butter-producing properties have been relegated to a secondary position. It is not unlikely that many a bull which might have stamped a lasting improvement on this charming race has been slaughtered in his infancy because of white marks, to give place to a beefy, milkless brute who rejoiced his owner's eye with a black tuft at the end of his tail. Let us make our Jerseys as beautiful as we can, but, above all, let us not forget that "handsome is that handsome does," and seek first a full butter-tub, letting such other good things be added thereto as nature kindly sends us.

Tobacco Culture—The Harvest.

The reports that are now and then published of the large profits received from a crop of tobacco naturally excite in those farmers who are barely making a living a desire to engage in its culture. No one should undertake to grow this or any other special crop upon a large scale at first, as in the large majority of cases failure and loss are sure to follow. While it is true that growers have in certain localities made large profits by this crop, it must be borne in mind that there are few plants more directly affected by soil and climate than tobacco. The leaf raised in the Connecticut Valley is exceedingly poor stuff as tobacco, but it has a color and texture which adapt it to particular uses not found elsewhere. The Connecticut leaf is used for wrappers, on account of its fine, soft, and silky texture, while the body of the cigar is made from tobacco grown elsewhere, which, while altogether inferior in these qualities, is its superior in strength and flavor. Different sections of the valley only a few miles apart produce a leaf largely differing in quality and price. Besides these local influences that the novice must take into account, it must be remembered that there is no crop which demands more constant attention. From the day the plants are put into the field until the cured product is ready for market, it demands in every stage the greatest care, and the omission to do the right thing at the right time will result in the ruin or the great deterioration of the crop. If some tobacco-growers make money, it is only by unremitting attention to their business. As an illustration of some of the difficulties attendant upon the culture, we may state that one planter within our knowledge was obliged to set his field fifteen times before he could get a stand. Then comes a constant fight with weeds and insects, the last-named being often disastrously destructive.

One of our artists, who has been among the tobacco-growers of Connecticut, gives us some illustrations of the operations in the later cultivation and harvesting. The plant being grown solely for the leaf, it is treated in such a manner as to produce the greatest development of foliage. If left to itself, the plant, after having produced a certain number of leaves of a mod-

erate size, would throw up a flower-cluster, and prepare to produce seed. If allowed to do this, the leaves would be inferior in size and quality, so the moment the plant shows a "button," as

fully laying each plant upon the ground, the butts all one way, without breaking a leaf. When the tobacco is wilted it is then ready to be drawn to the barn where it is to be cured.

stick is pointed, to enter the socket of a sharp iron point, which serves as a needle with which to thread the tobacco upon the stick. The iron point is thrust through the large butts of the plants,

Fig. 1.—TOPPING TOBACCO.

Fig. 2.—SUCKERING TOBACCO.

the undeveloped flower-cluster is called, it is nipped off. This operation is called "topping" (fig. 1), and must be done with care not to injure the upper leaves. As the plants will not all be

Those who grow tobacco as a regular crop have barns erected for the express purpose of curing; these (fig. 5) are arranged with openings upon the sides and ventilators upon the roof, that can

which are shoved upon the stick one after another, until the stick is full. The number of plants put upon each lath will vary with their size, eight or nine being the usual number. This

Fig. 3.—CUTTING TOBACCO.

Fig. 4.—STRINGING AND LOADING.

in an equal state of forwardness, judgment is required as to the amount of top to be taken off. Being checked in its upward development by the topping, the buds in the axil of each leaf soon push and form shoots bearing small leaves, and these when the upper ones are three or four inches long are broken out, an operation which is called "suckering" (fig. 2). Being prevented from pushing upward by topping, and from producing side shoots by suckering, the whole energies of the plant are directed to the main leaves, which grow to a greater size than on plants that have not been subjected to these operations. In a few weeks the leaves attain their maturity, and are ready for harvesting. The precise time can only be determined by those familiar with the appearance and feeling of the leaf. Too early or too late cutting has an untoward effect upon the quality. Moreover, early frosts must be avoided, as a light frost will materially injure the crop and diminish its value. Cutting (fig. 3) is performed with a hatchet, the cutter beginning at the right of the row and working towards the left, care-

be opened or closed according to the weather or the condition of the contents. The internal arrangements depend upon the manner in which the tobacco is hung. There are several methods

operation is performed in the field (fig. 4), or the tobacco is loaded upon a cart, and carried to the barn, where it is put upon the laths. When it is done in the field, a cart is rigged for the purpose of carrying it, as shown in fig. 4. Supports are arranged within the barn, upon which the ends of the laths rest, and they are placed tier above tier until the barn is full. At first the laths are put far enough apart to allow sufficient circulation of air, and as the tobacco dries they are moved closer together, to make more room. The success of the curing will depend upon the weather and the proper management of the ventilation. After the tobacco is cured it is taken from the laths in a damp spell, and stripped; the leaves are assorted into different qualities and made up into bundles, called hands. The hands are then packed closely together in what is called bulk, when it undergoes a change or a

Fig. 5.—TOBACCO BARN.

of hanging, but we will describe the one most generally followed at present. A supply of strong oak laths or sticks is provided; these are about four feet long and three eighths of an inch thick and an inch and a half wide. One end of each

sort of fermentation, necessary to develop qualities which are not otherwise possessed by the leaf. After it has remained in bulk the proper time, it is put into boxes or casks for market, or, as is often the case, sold while in bulk.

Walks and Talks on the Farm.—No. 106.

Mr. Geddes has been to see me. He is almost as enthusiastic in regard to farming as our mutual friend John Johnston. It is a real pleasure to talk with such people. "When you get your south land drained," he said, "you will have one of the finest farms in the State." Thanks to the new drainage law, that will now soon be done. Nearly all opposition has ceased. Even the Deacon is now anxious to have the creek cleaned out and deepened and the low land drained. And Mr. Root has explained away his article, and says he had no intention of discouraging the drainage of swamps. He only thought it would not pay to *underdrain* them. He has a perfect right to his opinion in this respect. A farmer need not underdrain unless he likes. It hurts no one but himself. But opposing the opening or cleaning out of main ditches through swamps injures the whole neighborhood. One pig-headed farmer may completely block the efforts of a dozen enterprising men whose land lies above him. It is to meet such cases that our new drainage law was passed. It does no one an injustice. Those benefited by the work have to pay in proportion to the benefit; if any are injured they can recover damages. In our case, one man claims that we shall do him a great damage by draining five acres of his black-ash swamp. Another says that his land is now so dry in summer that the pasture burns up, and he thinks when the ditch is deepened it will produce nothing at all in a dry season!

Mr. Geddes was much interested in a tile-drain I am laying from five to six feet deep. The land on both sides is high and rolling, sloping down gradually to the drain. It has always been wet, and there was a shallow open ditch running through it. But while it carried off a large quantity of surface water in the spring and fall it did not dry the land. I have been gradually deepening this ditch, as I could get an outlet below. I also laid ten or a dozen lateral underdrains up into the higher land on each side. The ditch was a crooked one, and cut the field into a bad shape, and I finally determined to tile it and close it up. It has been a tough job. Many parts of the ditch were full of large stones that went down much deeper than I proposed to make the ditch. When these stones were got out we found water, and we cut the ditch deep enough to carry it off. To make a long story short, we found little or no water at four feet deep. The soil in some places was a tough clay. Underneath this we found, at the depth of five feet, a stratum of gravel, and the moment we struck it the water appeared. It was so full of little springs, that in a distance of eight or ten rods we found water enough *in July* to form a stream that would fill a two-inch pipe—and that requires more water than many people imagine. There was so much water that the men had to dam it up while working below, and in two hours it would flow over a dam eighteen inches high. This, mark you, was during a severe drouth, with the sun shining so hot in the ditch that the men could barely stand the heat. We put in the tiles and covered up the ditch, and the water continued to run through the tiles for two weeks, or until about the last of July.

The point that interested Mr. Geddes was this: At four feet deep we found no water, but when we got below the clay into the gravel we struck the springs. He thinks, and I quite agree

with him, that this one large, deep ditch will drain a great many acres of my farm, and do away with the necessity of laying so many lateral drains.

It is not exactly the Elkington system, because the drain itself is carried down below the clay into the porous and springy stratum. Elkington reached this stratum by digging a drain three or four feet deep, and then making holes with an augur down into the porous stratum—the water rising up through these holes into the drain. Elkington himself was wonderfully successful in draining extensive tracts of land in this way at a small expense, but since his day the system seems to have been pretty generally abandoned in favor of the "gridiron" plan of laying drains. So far as my farm is concerned, I do not think there is any necessity of laying down drains at regular distances apart. If I can get rid of springs and accumulated surface water (or water flowing from the high land into the valleys), I think there will be little necessity for drains to carry off the water that falls on the land in the form of rain. Of course, there are a great many farms where this is not the case. But I can not help thinking that many writers make a mistake in advocating a fixed system of laying down drains "two rods apart."

It was not a bad system in England, when the landlord found the tiles, and when it was thought better to create work for farm laborers at 25 to 30 cents a day rather than to force them "on the parish." But that day has passed, never I hope to return. In this country, at any rate, we can not afford to waste labor. We must exercise thought and good judgment in planning our drains. I have no sort of doubt that in England, and wherever the "gridiron" system of drainage is adopted, a pretty high percentage of the drains are useless.

I said Mr. Geddes is an enthusiastic farmer. He has faith in good farming.

"If I was ten years younger," he said, "I would go to Michigan and buy two thousand acres of good wheat land. I would hire men and clear it up, and make the necessary fences and improvements, just as I would build a railroad or make a canal."

"But would it pay?" I asked.

"There can be no doubt about it," he replied; and went into figures to show how he could make the interest on over one hundred dollars per acre. He would raise wheat and clover, and keep sheep. He thought land newly cleared, and with the stumps still standing, might be kept in grass and pastured with sheep, and pay the interest on one hundred dollars an acre.

For my part, I always distrust estimates in regard to the profits of farming, especially where the work has to be performed by hired men, but I was nevertheless pleased to know that Mr. Geddes had such faith in the profits of wheat and wool growing. A man who has lived all his life on the farm where he was born has a right to speak on such a subject. I felt quite cheered by his visit, and encouraged to go ahead with my improvements.

I spent last week in Canada. The winter-wheat was represented as a failure, but the spring-wheat, much of it (Aug. 15th) still in the field, is a capital crop. The straw was stiff and bright, and the heads well filled. With here and there an exception, I am not sure that the Canadians are any better farmers than we are. There, as here, many of the farms are evidently

running down. The weeds are getting possession of the land. The low price of produce and high wages are pleaded as an excuse for not employing the necessary labor to keep the crops clean. Turnips are much more extensively grown than with us. It is quite evident that there is nothing in the climate to prevent us from growing good root crops. One farmer who had a field of splendid mangels said the same land was in mangels last year, and would be put in mangels next year. He thought the crop, like onions, did better when grown year after year on the same land. This year he used no other manure except salt, ashes, and plaster. He has great faith in salt as a manure. He says he can put enough on the land to destroy the weeds without any injury to the mangels. He gets damaged salt for about \$4 per ton, and uses it freely on wheat and barley. He thinks it a sure preventive of rust on spring-wheat, sown broadcast at the rate of from three to four hundred pounds per acre.

Mr. Straub, of Hagerstown, Md., writes me that for the past two years the clover crop has proved almost a total failure, owing, he thinks, to the long-continued dry weather. "Now you will see at once," he says, "this leaves us in a bad shape for hay and pasture. For hay I shall rely largely on my oat and barley straw, which I find my stock quite fond of. I will also cut my corn-fodder with a horse-power and cutter, which makes it better suited for easy digestion, and the rejected portion passes into manure to better advantage." This is an excellent plan. If either wheat, barley, or oat straw is bright, and has not been exposed to wet weather, it makes excellent fodder for sheep; but they should have some grain with it, say from half a pound to one pound for each sheep per day. If bran or fine middlings can be obtained at reasonable rates it makes excellent food for sheep, and also valuable manure. Two bushels of cut straw (say 14 lbs.), a peck of bran, and six quarts of corn-meal per day is an economical and nutritious food for a horse. The corn-stalks are best for cows, but I would give each cow two to three quarts of corn-meal per day with them. To use up our straw and corn-fodder to the best advantage we must feed more or less grain. On farms where straw is abundant, grain and straw together are a cheaper and better food than hay.

"To meet the lack of clover," Mr. S. continues, "I will sow 20 acres of ground, now in corn, with rye, for the purpose of getting early pasture to carry the stock until my other grasses take its place; then let the rye grow until it is eighteen inches or two feet high, and then put a chain on the plow and turn the rye under for a wheat crop. What think you of the plan, and how does rye compare in value as a fertilizer with clover?" As a renovating crop, clover is far superior to rye. Rye is a good crop to grow for early pasture for sheep, but so far as my observation extends its growth and consumption on the land add little or nothing to the fertility of the soil. I should as soon think of growing wheat to turn under as a manure for wheat as to grow rye for this purpose. Still, I may be mistaken.

Mr. James M. Budd, of Cecil Co., Maryland, also writes me in regard to the failure of clover in that section. Such a drouth, he says, has never been known there before. "Wells all dry or deepened." The same thing is true here. I have had to drill three of my wells down into

the rock from 12 to 20 feet. Mr. B. says he sowed seven bushels clover-seed on 35 acres of wheat, but it did not catch, and he is now plowing the stubble to sow to wheat again. His wheat this year was badly injured by the Hessian-fly, but his crop nevertheless was two thirds of an average, or 15 bushels per acre. The weather was so dry that the wheat cut off by the fly filled as it lay on the ground without damage. One fourth of his crop was rakings. He got 160 bushels from the first raking, and 30 to 40 bushels the second time. "We ordinarily raise straw," he says, "five to six feet long, and get no wheat. This year the straw was not over three feet and well headed, and although very thin on the ground gave us two thirds of a crop. Tell us why it is so." On rich land wheat always does best in a dry season.

Mr. B. says he uses 60 bushels of slaked lime per acre every four years. He sows it on the clover after the wheat is harvested. He says he would pay 30 cents a bushel for the unslaked lime if he could not get it cheaper. It costs him 20 cents a bushel, which, as one bushel in slaking makes about two bushels, is equal to 10 cents a bushel of slaked lime, or \$6 per acre. "Try it," he adds, "it will pay you better than anything you have ever used." I have never used lime on clover, and the plan strikes me very favorably. Here, plaster (sulphate of lime) is quite cheap, and is our main dependence for increasing the growth of clover, and thus ultimately enriching the land for wheat.

J. A. Clark, Jefferson Co., Wis., writes: "We have always grown spring-wheat here, and are this year harvesting about *five bushels* per acre. Don't let the Reports from the Agricultural Department fool you. There never has been so poor a year for spring grain in Wisconsin as the present." I am very sorry to hear it. I know the winter-wheat is very generally a failure. In this section the wheat on thrashing turns out far worse than we expected—and we did not expect more than half a crop. I was in hopes that the spring-wheat would turn out well. If it does not, we shall see high prices for wheat before next harvest.

I do not believe the climate is changing, or that the seasons are any more unfavorable than formerly. I question if Western New York ever produced a better crop of peaches than this year. And I can imagine horticultural writers thirty years hence in the twentieth century telling what magnificent crops of peaches we used to grow here when they were young men. They will forget or say nothing about the many years when we have scarcely a peach.

A young friend of mine went to Illinois some years ago. He bought a farm for a few dollars per acre; put in forty or fifty acres of wheat the first year, and got 30 bushels per acre, and sold it for \$1.50 per bushel. "And that crop ruined me," he said. "How so?" I asked. "I have been trying to do the same thing again ever since, and this year scarcely got my seed back."

The truth is, there have always been good seasons and bad seasons, and will be until the end of time. He is the wise man who understands this, and acts accordingly. I should not like to go to sea with a captain who expected nothing but fair weather. I have little respect for any man who hopes to get good crops without labor. I do not think such a man

would succeed any better in a shop, or store, or factory. But be this as it may, he certainly can not make a good farmer until this kind of nonsense is driven out of him. Wet springs and dry summers, rust and insects, weedy land and poor wheat, floods and hail, milk-fever and floating cards, footrot in sheep and sickly lambs, colic in horses and hog-cholera—one or all will pay him a visit, and urge him to think, and work, and plan. If anything can make a man of him, it is farming. It can not be said, however, that farmers do not work hard enough. The great trouble is that we undertake to do too much. But I think this fact is now fully admitted by all intelligent farmers, and I feel confident that a great improvement in our agriculture will soon be apparent. The weeds, if nothing else, will compel us to cultivate the ground more thoroughly.

Peart, the butcher, was telling me to-day that this spring he bought two lots of grade lambs from two farmers, with the privilege of taking them "when fit." Both lots when he bought them were equally good, and both had good pasture; but one lot had constant access to water, and the other had not. The former grew finely and got fat, and by the middle of August weighed from 60 to 70 lbs. each. The latter only weighed from 40 to 45 lbs., and were so thin that he could not kill them. It seems passing strange that any one should expect cows to furnish milk for their lambs during our hot summer weather without water.

The people in England are holding meetings to see if nothing can be done to lower the price of meat. All we can do to help them is to send them plenty of cheese and pork. Our exports of bacon, hams, lard, and pork to Europe for the past few months have been and still are enormous, and must soon it would seem put up the price here to something near the cost of production. A year from this time the indications are that there will be a great falling off in the number of pigs.

I think the farmer who has fall pigs will do well to keep them and take good care of them. A year from now they will be wanted. I believe in the West it is thought that fall pigs are not as profitable as spring pigs. But with me I can make cheaper pork from *early* fall pigs than from spring pigs. The great point is to keep them well through the winter. If well wintered, they will keep fat on clover during the summer, and a very little corn in the fall will make them ready for market.

My plan is to give my young pigs all the cooked corn-meal, with a little bran, that they will eat and digest until they are four months old. After that I aim to keep them on cheaper and less concentrated food. There is nothing better than clover. In this way pork can be produced at a comparatively cheap rate.

The Hatching of Eggs.

There seems to have been something abnormal in the condition of the atmosphere or of the hens last spring that prevented successful incubation. The complaint of bad luck is very general, or the unlucky ones have reported more generally than usual. It comes not only from novices, but from poultrymen of orthodox standing, who could count their chickens, as they thought, before they were hatched. "Connecticut" thinks *the* trouble lies in the prevalent

custom of crowding hens into small yards, reserving nineteen reasons until this shall have been proved insufficient. "Ohio" thinks this can not be the cause, inasmuch as many hens in small yards hatch triumphantly, while some hens running at large make an entire failure. Another very plausible theory attributes the cause to the uncommon dryness of the month of May and the early spring. Some breeders who practice sprinkling the eggs every other day when the hen comes off to feed, succeeded as well this season as in any former year. It may be doubted whether this theory has any sound basis. The hen left to herself does not wet her feathers, and her eggs do not get wet during incubation. Her first impulse on leaving the nest is to roll in dry dust, and the drier the better. The thunder theory is no more reasonable. Hardly a season passes without thunder in the spring, and yet the eggs hatch. There was no unusual display of electricity this season. With all the shortcomings of the hens from whom we have heard, we suspect that the great majority of quiet non-cackling birds have had about the usual success in hatching, and that the price of poultry, except among the amateur breeders, will not be affected the value of one mill in the dollar by any peculiarity of the hatching season. As to the fancy breeds, we suspect there has always been a slight discrepancy between the chickens counted before and after hatching, and that narrow quarters is likely to increase this difficulty. *

Road Fences.

One of the admirable features of the landscape in the new States and Territories is the freedom from fences. In some of the prairie States they have begun right by compelling every man to take care of his cattle, and holding him responsible for all damage to his neighbor's crops. The fences mainly are on the boundary lines of farms, and these are often omitted. This gives full sweep to all the modern implements of husbandry—the cultivator, the horse mower and reaper, the tedder—and prepares the way for the steam-plow, which can not be far in the future. There is a great saving of time in the cultivation of large fields free from all obstructions. One great want of Eastern farms now is to get rid of the heavy walls that our fathers have built at so much expense. The two, three, and four-acre fields want to be thrown together, and the fields arranged with reference to the system of rotation to be pursued upon the farm. If it is a four-years course, quarter that part of the farm that is to be devoted to tillage, simply marking the corner bounds with permanent stakes or stones. What, then, is to be done with our cattle? On the frontier the neighborhood make one herd of their cattle, and a boy or herder takes care of them at so much per head. They are fed upon the public lands. In the older States pastures are already inclosed, and these need not be disturbed until the tillage land is arranged. In cases of radical reform the remedy is found in soiling. Arrange the barn with reference to keeping all the cattle in stalls the year round, and to making the largest amount of fertilizers possible. This is what we are coming to in the Eastern States. If we compete with the West successfully, we must put our fences out of the way, use more machinery, make more manure, and cultivate the products consumed in our own markets. A farmer should be able to tell what crops are grown at a profit, and what bring him in debt. C.

A Muzzle for Crib-biting Horses.

Crib-biting and wind-sucking are vices to which a great many horses are addicted, and

Fig. 1.—CRIB-BITER MUZZLED.

which are incurable by any means except mechanical ones. There must be either something to prevent the horse seizing the crib or post with his teeth, or everything must be removed from his reach by means of which he can exercise his vice. All the methods which have been tried heretofore, by rubbing acrid or distasteful matters on the crib, have not been successful, as they are rubbed off and are not permanent. But a muzzle such as we figure on this page is effectual if properly made and rightly fitted on to the head-stall. It is made

Fig. 2.—MUZZLE.

of quarter-inch galvanized iron wire, with interstices sufficiently large to allow the horse to reach his feed without difficulty, so that it may remain permanently attached to the head-stall and will be always in use. This is the greatest requisite to success in the way of cure. When the horse attempts to seize hold of anything with his teeth he is prevented from so doing by this muzzle, and after some few attempts he will abandon the labor as an unprofitable one.

How to Empty a Cesspool.

The cesspool is the great domestic difficulty; and to judge by the numerous inquiries which come to us as to how to manage them, the difficulty would seem to be a very general one.

It is one to be met and overcome, for by lapse of time the trouble increases. Probably the most serious part of the difficulty is that which is least observed, and consists in the danger to health and life in infecting the air we breathe and the water we drink with poisonous germs, which are imperceptible to any of our senses, and therefore the more seriously dangerous. Deodorizing is not always disinfecting, and the presence of the most destructive poison may be quite unsuspected in the atmosphere or in fair-looking and sweetly-tasting water, but yet it may be there. This matter is gradually becoming better understood, so that the peculiar class of diseases arising from the presence of contamination of this character is looked upon as avoidable and disgraceful, as much so as the cutaneous diseases caused by personal uncleanness which years ago carried no such significance with them. No cesspool can remain within a distance from a house or well that is convenient for its use without the greatest danger, or the certainty of disastrous effects sooner or later. It is time now that this old-fashioned and barbarous plan was abolished. No deep cesspools

should now be made, for we know better, and know, too, how to do without them. The closet and the receptacle should be altogether above ground, and should be arranged in such a manner that the deposits can be removed easily every few days. Such a closet may be built in the form illustrated on this page (fig. 1). The size or material of the closet may be whatever is convenient. The needed things are those appertaining to the system itself. These are the receptacle, which may be a box on wheels (as shown at *a*), the door (*b*), which closes in the space beneath the seat (*c*), and opens upwards to permit the removal of the box for the purpose of being emptied. The earth-chest (*d*), provided with a scoop, and which contains a supply of pulverized dry earth, to be filled in through the door (*e*), which opens on the outside. These parts are all that is necessary to the successful application of the new system, and in the majority of cases existing buildings could be modified to suit it.

Fig. 1.—EARTH-CLOSET.

But how to get rid of our present accumulations is the more serious question. Utilize them. And do so in the following way: Remove the building. Draw to the spot several loads of earth from a plowed and harrowed field. Throw into the vault a sufficient amount of this earth to solidify the upper part of the contents. Then with the scoop shown in fig. 2 take up the mixed soil and earth and deposit it in a heap or into the box of a sled, by which it may be immediately removed to a convenient spot for use as manure. Then throw in more earth, and repeat until the bottom is reached, when the old vault may be filled up with stone or gravel. The scoop is made of sheet-iron, bent into the shape of a double shovel, so that it may be operated at either end; it is suspended on to a common bail of stout iron rod, which

Fig. 2.—CLEANING OUT A CESSPOOL.

is affixed to the end of a pole or staff by a ring on which it oscillates. When it is thrust into

the earth and soil one edge engages with the handle (as is seen in fig. 2), and it works similarly to a shovel. As soon as it is drawn up, it swings suspended, and balances itself without spilling its contents. By this process this objectionable job may be performed without any unpleasant effects, and should the earth not sufficiently deodorize the soil of the cesspool, a few pailfuls of water in which 1 lb. of copperas to the pailful is dissolved, will effectually accomplish it.

To Make Cider-Vinegar Rapidly.

"J. B. W." writes that he has several casks of cider which he can not make into vinegar fast enough, and he asks how he can hasten the process. As there are probably many others just now in his predicament, we describe and illustrate a plan which has been found to decidedly hasten the production of vinegar from cider. It is to elevate the barrels upon a frame sufficiently high above ground to admit of a keg being placed under the faucet, with a frame of laths made in the shape of a funnel placed in it. The frame is loosely filled with beech or birch shavings, and a stream of cider is allowed to run out of the faucet into it and amongst the shavings. Here it is separated into a great many small streams and very thin sheets, and a large surface is thereby exposed to the air, and the process of souring is very much hastened. A further hastening is caused by putting into the barrels a piece of brown paper covered with brewer's yeast, and by proceeding in this manner vinegar can be made in warm weather

QUICK VINEGAR-MAKING.

in a few days. A faucet should be put into the keg about the middle, and as the keg becomes filled the cider should be drawn off and returned into the barrel. As a matter of course this requires attention, but a child is able to manage it, and if the keg is replaced by a tub or half-barrel, attention is only required twice a day. The bung-holes of the casks should be open, and should be covered with a piece of gauze or mosquito-net to keep out flies and moths. The whole arrangement is shown by the cut above.

Lap-Streak Boats.

To judge by the number of inquiries as to how to construct boats of various kinds, we should suspect that many farmers or farmers' boys do manage, in the midst of their hurried work of plowing, sowing, or harvesting, or so soon as it is over, to get some share of recreation. Those who have lately desired directions for building skiffs or boats for hunting in shallow water, will find them in full in the *American Agriculturist* for August, 1871, page 297. We now, in compliance with numerous requests, give directions for building lap-streak keel-boats, suitable

for rowing or sailing in deeper water, and which may be made of any suitable size. The proportions to be observed in building these boats is a length equal to four or five times the width; the greater width being adapted for boats to be used with a mast and sail. The first requisite is to lay the blocks, on which the boat has to be built, at a sufficient height to enable the work at the bottom to be done conveniently; the next to procure and lay the keel. This should be a piece of sound white oak, six

inches wide and two inches thick, perfectly true, and free from any twist or spring, and should be dressed down to an inch thick at the bottom, and be grooved at the top to receive the edge of the first streak or board. It should be clamped on to the blocks or trestles by side-clamps or

the boat in those parts. They will be somewhat of the shape shown in fig. 2, but will vary as the shape of the boat may vary. Possibly the first boat built may not have the most desirable lines or shape, but the next one can be brought

Fig. 1.—LAYING THE KEEL AND ATTACHING STEM AND STERN.

into more perfect form by making changes which will occur during the first experiment. It is not to be supposed that directions can be given here, sufficiently minute to enable any one to construct a perfectly handsome model of a boat at the first attempt, but if these directions are

followed out as nearly as may be, the probability is that the second attempt will be pretty satisfactory to any but a very fastidious boatman. With practice comes perfection. Then we proceed to the laying on of the streaks or boards. These should be of very good, clear stuff, free from shakes,

Fig. 2.—MOLD FOR BOAT.

pieces spiked to the blocks, and the keel-piece is firmly held by means of wedges which can be knocked out when the boat is finished, and the keel released. The stem of the boat may be of ash or elm, naturally crooked, or sawn out to a proper curve, and should be mortised into one end of the keel and fastened with two copper bolts, which will not rust. The stern should then be cut out of a piece of ash or yellow pine to a proper shape, and be firmly fixed on to the keel by means of a knee, as shown in figure 1. This engraving shows the blocks or trestles, the keel, and the method of mortising the stem and stern to it. In addition to the knee a metal strap may be used, to firmly unite the keel and stern together. All these joints should be made water-tight, by means of a piece of brown paper soaked in pine tar placed between them, and should be firmly secured by screws or screw-bolts and nuts. Then the mold should be made and fixed lightly to the keel, as it must afterwards be removed. This consists of three or four boards, as shown in fig. 2, cut to fit the shape and size of the boat, the center one being of the width the boat is desired to be. The width across the

and of the very best of soft white pine, or spruce, or cedar, for here is where strength and lightness are wanted. They should be sawn half an inch thick, and should be dressed down to three eighths. They need to be cut of a peculiar shape, to fit the curve of the boat, and this shape may be got by first clamping the streak into its place with the clamps shown in fig. 2, and marking with a pencil where the edge of the streak should come, and cutting sufficiently far away from the mark to allow for the lap, which should be at least half an inch, but not much over. The first streak should be made to fit closely in the groove in the keel, and be firmly nailed all along. There should be no nails driven into the mold, as they would leave holes to be afterwards filled up, and damage the boat. The boat is built up regularly on each side, and care must be taken that the mold is exactly the same on each side and the streaks are laid on of exactly the same width and thickness. The boards should be fastened with boat-nails, which are made so that they can be driven without splitting the boards,

Fig. 3.—BOAT COMPLETED.

center of the boat is called the beam, and the amount of beam desired regulates the size of the mold. The mold gradually tapers towards the stem and stern, to suit the shape of

and are of very soft metal, so that they may be clinched on the inside. The clinching should be done on the inside with a light hammer, a heavy one being held on to the head of the nail

outside, and if burrs are not used, the point of the nail should be turned and bent sideways, and made to enter the wood on the lap. If the boards are found difficult to bend into the abrupt curves at the head and stern, they may be greatly softened by steeping in boiling water, when they should be clamped in their place until dry, and when cold can be easily nailed and secured. When the sides are completed, the ribs may be put in. They should be made of tough white oak, and should be steeped in water until quite pliable, when they may be bent into their places and nails driven through the boards into them; here and there some longer nails should be passed right through and clinched. The ribs should be an inch square, or if the boat is heavy may be an inch and a half wide. There should be several short ribs, coming half-way up the sides of the boat, fastened between the other ribs, to strengthen the bottom and to furnish a place on which to rest the foot-boards. All these ribs should be firmly nailed or screwed to the keel. The thwarts or seats should rest on a narrow streak fastened inside the boat to the ribs, but if permanently fixed, might rest on small knees, made of the roots of small tamaracks or cedars, which are attached by small bolts to the ribs at a convenient height for the seats, or not less than ten inches. The gunwale is made by laying a streak two inches wide all around the inside of the boat at the upper edge, and it should rest on the ribs and be of the same thickness as they are. Another streak is laid around the outside, which may be ornamented with a molding. Any other fittings, as lockers, or boxes, or ring-bolts, may be put wherever they are desired, and the rowlocks are the same as in any other boat. The rudder for steering is hung on the center of the stern, and is worked either by means of cords, which is the most convenient, or by means of a tiller. The cords may be affixed to arms fastened to the rudder-head. If

Fig. 1.—DAM AND WASTE GATE.—(See next page.)

a mast is desired, it may be stepped into a piece of two-inch plank, fastened in the forward part of the boat to the keel, and in which is a hole to receive the foot of the mast; an iron strap which receives and embraces the mast, is affixed to the front of the forward thwart or seat. The cut of the complete boat (fig. 3) shows all these little details. It is advisable to brush over the inside of all the joints of the streaks with the stem and stern, before nailing them, with white lead, that they may be made water-tight.

Dams and Ponds.

The building of dams is a work that needs care and skill, or the labor is very often thrown away. The difficulty of making a simple and tight dam, often prevents the use of the water

of a stream for irrigation, or for ponds which might supply a stock of ice for a house or dairy, or for several of them. We are only now commencing to learn the value of the streams which traverse our farms, and which might be made to do duty as water-powers for churning or thrashing, for fertilizing meadows, for supplying ponds, for ornament, or for furnishing ice.

But before the streams can be thus used, it is necessary to build the dam. It is a rule in all sorts of engineering work, from the making of a simple pond-dam or a hill-side road, up to the building of railroad or other large embankments, that an old surface and fresh earth do not bind or adhere together well. A want of knowledge of this fact frequently leads to dams being leaky at the bottom and their early destruction. It becomes necessary, then, first to make the foundation by removing the surface, and more particularly so if the surface is sod, or rough swampy ground covered with tussocks or coarse grass. It is best therefore to excavate a narrow ditch where the center of the dam is to be, and throw the earth outside of it. If there are sods, they should be reserved to finish off the slope by planting fragments of it here and there, which by and by will spread until they meet and completely cover the surface. If musk-rats are to be feared, it will be necessary to drive stakes down in the center of the trench, and fasten to them hemlock boards or planks, which will prevent the animals from burrowing through the dam, and also will have the effect of greatly strengthening it. Then the trench should be filled with clay or stiff loam well tramped down, and packed by having water thrown on to it, until a ridge the height of the finished dam is made. Then on the inside (but not on the outside) fine brush may be laid and covered with earth well worked down, and two or three layers may thus be made. In case of a freshet or of water washing against the dam, this brush will tend very much to bind and strengthen it. The back of the dam may be built up of stone or coarse gravel, but nothing but the most closely-binding and compact materials should be used for the front and the center. Figure 2 shows a section of a dam thus built, the trench

Fig. 2.—SECTION OF DAM.

with the plank in the center, and the layers of brush worked into the front.

The weakest part of a dam is very apt to be where the waste-gate is built in, but if this is properly done there will be no trouble. There should be a framework made, consisting of two parts, one for each side of the gate. Each part consists of a post mortised into the mud-sill, and two braces mortised into the sill and the post, as in fig. 1 (page 377). The ends of this frame are boarded up on the inside. The boards rest against cleats, which are spiked to the sill and braces to prevent them from being forced inwards by the pressure of the earth. The sides of the gate are kept apart by means of the plate at the top of the posts and the planks at the bottom, on which the falling water is received to prevent washing out of the bed. The gate itself consists of planks cut to a length to fit the frame and to lie loosely against the up-

right posts, where they are held by the pressure of the water. They can be easily removed or lifted by means of a bar whenever the water is to be lowered or run off, and the water may be kept at any desired height by the arrangement of these boards. In setting the gate-frame, care must be taken to fill in around the bottom and the sills with clay, so that no water can escape.

The Lactometer.

The lactometer, or instrument by which the quality and value of milk may be measured,

Fig. 1.—RACK WITH TUBES.

should be used by every farmer who owns more than one cow. Where there are but two, it becomes a matter of interest and curiosity to know which one is the better, and where there are a dozen the probability is that there will be found one amongst the lot which is not worth keeping, and she can not easily be detected without experimenting on her milk with the lactometer. One of the first requisites to an improvement in our dairy stock is a simple means of detecting those which are unprofitable to keep, and by getting rid of them as soon as possible preventing the perpetuation of poor stock. It is only by breeding from our best cows by means of bulls descended from dams which excel in the quality of their milk that we can hope to improve our dairy stock; and that our stock needs and is susceptible of vast improvement is plain to those who know how poor is the average product of our cows. We very rarely think of the fact that the average yield of butter in the United States is only a quarter of a pound per cow per day, or of milk only four quarts. The discovery of these poor cows, by which the average is so much reduced, and their separation from our herds, depend on the use of some such instrument as is here proposed. It is simply and easily made. A frame consisting of a lower and an upper platform with supporting columns at the corners is made; holes to receive the glass tubes are bored through the upper platform, and the tubes are common glass test-tubes, which may be procured from or by any druggist. The tubes should be divided by marks made with a common file into ten spaces of equal size. The spaces or degrees may be one inch in length, in which case the tubes should be eleven inches long; or the divisions may be half an inch apart, in which case

the tube should be six inches in length. Fig. 2 shows the tube graduated into spaces.

When filled to the uppermost mark with milk free from air-bubbles or foam, the tubes are suspended in the frame, and are to be kept undisturbed for a determined length of time, and the amount of cream which has risen is then noted, when it may remain longer to note any further rise of cream, or the separation of the whey from the curd if it is desired to test the amount of whey or water or solid matter or curd in the milk. Those lactometers which test the quality of milk by its specific gravity are often incorrect and fallacious, as the richest milk is of the lightest specific gravity, and is not to be distinguished by such a test from watered milks.

The exact percentage of cream may be ascertained by dividing the upper spaces into tenths. Each tenth would represent one hundredth part or one per cent of the whole milk. Thus, if the cream occupies five of the small spaces, there is five per cent; if one large space, there is ten per cent; and if one large space and two small ones there would be twelve per cent; two large spaces would give twenty per cent of cream.

As one quart of pure cream will make a pound of butter, the value of each cow as a butter-producer is readily ascertained, for if she should yield 10 qts. of milk of which ten per cent or one tenth is cream, she may be expected to produce one pound of butter per day, and so on.

Editorial Correspondence.

[This letter from our associate should have appeared earlier, but its facts are as interesting at one time as another.—Ed.]

DENVER, COL., July 10th, 1872.

SLAUGHTERED BUFFALO.—Is it not about time that the indiscriminate slaughter of the buffalo was stopped? We counted in plain sight from the cars at Buffalo depot 125 carcasses and skeletons of buffaloes in various stages of decomposition. This station is about the center of the buffalo range, and for a long distance east and west on the railroad the work of destruction goes steadily on the year round. Here our royal guest Alexis came last winter, and is said to have slain forty of these animals. Sports from the Eastern cities, rich men's sons in search of new sensations, merchants and bankers on vacation trips, European travelers doing the Western Continent, stay over a few days on the plains to chase buffalo. Men who make a business of hunting live at the stations, and kill all of this game they can. They thoroughly understand the habits of the animal, know how to approach him, and just where to send the deadly bullet. They are by far the most destructive of any class that hunt buffalo. A large portion of the fresh meat consumed at these stations is furnished by them, and in the winter buffalo hind-quarters, with the skin on, are shipped in immense numbers to New York and other Eastern cities. The meat in its season is about as cheap as beef in these city markets. It is estimated that a hundred thousand buffalo are slain annually in this region. Since we were here last year a new traffic has sprung up of considerable importance. We saw at Bunker Hill, Fossil, and other stations, immense quantities of bones brought in from the adjacent prairies to be shipped East for the manufacture of bone-dust and phosphates. As they are found everywhere in abundance, and bring about twenty dollars a ton in market, it pays very well to gather them. Besides the meat sent off in

Fig. 2.—GRADUATED TUBE.

the fresh state, large quantities are dried and sent to market. The hams properly cured can hardly be distinguished from beef hams. At Grinnell there are two large turf houses built for drying buffalo meat. There is so little moisture in the atmosphere, that the meat keeps for several days, even in summer, and much less salt is needed than would be necessary at the East. We saw and tasted the sun-dried article at Buffalo. It was cut in thin slices, strung on small wands, and hung upon poles to cure. It is no doubt a wholesome and nutritious diet for hunters and Indians, but the civilized world, we apprehend, loses little in the entire absence of these flitches from its larder. The buffalo does good service upon the frontier in furnishing the settler with meat until he can raise domestic animals for himself. And it is for this reason mainly that we put in a plea for his prolonged existence. We have no sentimental admiration for the beast, no faith in his adaptation to civilized wants, or in the superiority of his robes to good woolen blankets, no craving for his flesh in comparison with good Shorthorn steaks. We have no confidence in the efforts made to cross him with our domestic animals, and believe the hybrids will be decidedly inferior to the breeds we already have, whether we breed for milk, butter, cheese, beef, or working cattle. We have no doubt that the buffalo, and the nomadic tribes that chase him over the plains, are doomed, but we need take no special pains to hasten the decree of Providence.

Our pioneers want meat in the first few years of their settlement, and there is no good reason why the idlers and the rich men from our Eastern cities should take it from their mouths. There should be a close time for the buffalo as there is for the deer and other large game—six months at least, including the breeding time—in which it shall not be lawful to kill them in any part of our territory. Our sporting clubs in the East could not do a better thing than to memorialize Congress upon this subject the coming session and secure the necessary legislation. As the general government has military stations as well as civil officers all through the buffalo country, it would be easy to enforce such game laws as are needed.

WINTER GRAZING.—We took a good deal of pains to ascertain the facts about the destruction of cattle in this region the past winter. It is admitted by all the drovers to have been a winter of unusual severity, and the losses have been above the average. The best evidence that these losses were greatly exaggerated in the reports made to the papers is the fact that the popular faith in the profit of keeping herds is not at all shaken. The fact is that the business of grazing was never more prosperous. The old herdsmen are steadily enlarging their herds, and new men are investing their money in Texas and other stock as if nothing had happened. Over 45,000 head of cattle, in herds of from 2,000 to 6,000, had arrived at Ellsworth as early as the first week in June. The herds are numerous near the railroad, and are said to be still more abundant in the river valleys a few miles back, where the grazing is better. In conversation with a gentleman yesterday, who had wintered his herd near the foot of Long's Peak, he admitted a loss of only three per cent. In Southern Colorado, where little snow fell, the cattle grew fat and the loss was insignificant. In Northern Colorado, where the snow fell in November, the loss was large, in some cases reaching three fourths of the herd. The loss also among sheep was very great. But the great fact remains, notwith-

standing these reverses, that the graziers are fully persuaded that they have the best sheep and cattle country in the world. The grass, though short, is exceedingly nutritious. The rains fall in the spring, the grass grows rapidly, and in the summer is cured upon the stalk. There are no rains to dissipate its juices. People were so accustomed to see their cattle go through the winter without fodder, that no provision was made for them last winter, and thousands perished. The calamity will lead the thrifty cattle-men to select good shelter for their stock, and to lay in hay for the future. That the lesson has been heeded, is evident from the mowing machines we saw at work on the journey hither. There is an unusual demand for hay in the territory. If the climate is undergoing a change, and more rain is to fall in the summer, it is not improbable that more snow will fall in winter, and the difficulty of winter grazing be increased. The cattle-men that we saw are not at all despondent. A very large capital is invested in the business, and it pays as well as any other pursuit in a territory where the average price of money is two per cent a month. W. C.

How Milk Gets Spoiled.

Mr. Willard, in his Ohio address, gives much weight to certain causes which effect a deterioration in the quality of milk—especially the presence of dirt and dust in the pail; the inhaling of foul odors by the cows, at pasture and elsewhere; and the drinking of putrid water.

Instances are cited, in which putrifying flesh (as of dead animals) has communicated a taint to the milk in the bag, by simply tainting the air breathed by the cow. Milk in the vat of a cheese factory during the heating of the curds gave off a smell like that of stagnant water. It was found that one of the patrons had allowed his cows to pass through a narrow slough, the mud of which adhered to their udders. Particles of dust thus got into the pail at milking, and thus introduced fungi from the slough, which multiplied in the milk, and spoiled the whole of it—giving it the odor of the foul water.

Prof. Law, of Cornell University, finding the cream on his milk to be rosy, examined it with a microscope, and found it infested with living organisms. On investigation he found that the herd from which his supply came, drank the water of "a stagnant pool, located in a muddy swale." The microscope developed organisms in this water of the same sort with those found in the milk. The same were also detected on a microscopic examination of the blood of the cows. That the cows were in a diseased condition was shown by the thermometer test—they being hot and feverish. A little of the same filthy water was introduced into milk which proper tests had shown to be pure, and in due time "the same filthy organisms multiplied and took possession of it in vast numbers, producing the same character of milk as that first noticed."

This investigation, made by a careful observer, proves conclusively that the germs of disease and of a milk-spoiling ferment can be introduced into the blood and into the udder, by simply allowing the cow to drink unsuitable water. It holds out the plainest possible practical lesson to the dairyman, and if he disregards it, and so misses his opportunity for making good cheese and butter, he has only himself to thank. It shows that the cleanliness of a dairy farm must be radical, thorough, and all-pervading. No filthy mud should be allowed to dry into a

dust that may foul the pail; no foul odors should taint the undrawn milk; and the drinking water should be free of the "little leaven that leaveneth the whole lump"—cow, milk, and all.

Churning Whole Milk.

Mr. Peter Mulks, of Slaterville, N. Y., in a communication to the Buffalo Live-Stock Journal, states that for twenty years or more he has churned all his milk. He thinks that, while it is possible to make fair butter by churning the cream alone, it is impossible to make strictly fine butter in this way. What he understands by "strictly fine" butter, we do not know—perhaps something better than we have any knowledge of, but it is certain that the Ogden Farm butter, which sells for 90c. per pound, Darlington's (Philadelphia), which sells for \$1.00, and Mr. Sargent's, which sells for \$1.15 (wholesale), are all very good, indeed. In fact, they are much better than most of the world knows anything about, and they are all made by churning the cream alone.

Mr. Mulks's argument is as follows: 1. The impurities of the air in the milk-room are absorbed entirely by the cream (this being on the surface), and if only this is put in the churn, these impurities are much more concentrated and affect the butter much more than if the whole of the milk is present to extract its proportion of them. 2. When only the cream is churned, the amount of buttermilk is so small, that the butter is more constantly acted upon by the dashers, and is made salvey and has its grain broken, while in churning the whole of the milk the butter is less in proportion, and it retreats out of the way, and does not get mashed fine, salved, and made greasy, as in churning the cream alone.

The following answers to these arguments naturally suggest themselves: 1. No well-regulated milk-room has any impure odors in it; and if it had it is not likely that they will confine themselves to the cream. They will probably permeate the entire contents of the vessel, cream and milk alike. 2. Practically, if the temperature of the churn is not higher than 62°, the butter will be hard enough for its "grain" to withstand not only the beating of the dasher, but also the subsequent much more trying manipulation of the working-table, while the latter would be equally necessary after the gathering of the whole milk-churning.

However, we are not inclined to gainsay the statements of one who has (after a trial of both systems) decided that whole-milk churning is the best, and has practiced it successfully for twenty years.

The general opinion, unfavorable to the whole-milk process, has, we fancy, been based on trials with new milk. Mr. Mulks allows his milk to stand, not only until the cream rises and becomes concentrated, but until it has turned loppered. It is a very good evidence of his success that he gets from 15 to 20 cents above the regular market price. Let us try it.

The Fall Treatment of Grass Lands.

"Old fog," as farmers call the fall growth of grass left to stand on the land during the winter, is wrongly charged with an injury to the land; and the mistaken notion that it does harm is made an argument in favor of the feeding off of the after-growth. Nothing could be more injurious to the condition of mowing lands than this custom.

[COPYRIGHT SECURED.]

THE MODERN TANTALUS.—*Drawn and Engraved for the American Agriculturist.*

Experience with forest trees, and every fact of vegetable physiology, point to the correctness of the opinion that the ability of roots to produce a good growth in the ensuing season depends on the extent to which they have been reinforced, after the ripening of the seed, by their autumn vegetation. If the fall growth is allowed to remain, to supply strength to the underground organs, the natural conditions for future growth are complied with, and, so long as the fertility of the soil is preserved, full crops may be expected. It will, of course, be necessary to apply manure, and the best time to do this is soon after harvest. The only real objection to the "old fog" is, that it may make the use of the mowing machine difficult. This is easily overcome by rolling early in the spring.

We are satisfied that any observing farmer will on trial find it an excellent rule to adopt (and to stick to), *never to let a hoof go on to the mowing fields, except for necessary work.*

Pasturing (as the animals take the materials of their growth and of their milk from the land) is an impoverishing process. The grass allowed to fall and decay on the ground, is worth much more than the manure of pasturing animals.

Neglect of Animals in Autumn.

If animals were endowed with speech they would often remonstrate with their owners about the neglect and carelessness with which they are occasionally treated. And though they can not speak, yet they have a certain mute eloquence in their look, and tell their tale with a force and point that are often more effectual than words. Very often the rough, sluggy, staring coat, the prominent ribs, drooping head, woe-begone countenance, and appealing eye tell a tale as plainly as if it were in print. It tells of hard work, poor feed, exposure to storm and tempest and keenly-biting winds. And yet there may be a tight, snug barn, and stacks of fodder still remaining in the field, while from very thoughtlessness the poor old faithful servant, who has plowed his master's fields year by year, is permitted to remain in an airy yard or in a barren pasture, with half-filled belly, and sniff with impatient appetite at the fodder just beyond his reach across the fence. The picture drawn by our artist may be taken as an example of what may be seen any time during the autumn months without traveling far. It is to

be hoped that it may attract the attention of those farmers who seem to think that the fresh air of our October nights and an occasional wetting with the cold fall rains are good for the health of their horses, colts, cows, or calves, and makes them hardy and vigorous. But this is all wrong. It is unprofitable as well as cruel. Animals exposed to the cold until they are chilled are stunted in their growth, and gather the seeds of future disease. Warmth saves feed. Cold wastes feed. Stock well housed keep in better condition on less food than those left outdoors in rail pens, damp yards, or exposed pastures. At this season no stock should be kept out at nights nor on stormy days, for the abrupt change from warm sunny days to cold storms of rain and sleet is too great a shock. Pine boards are in a sense excellent fodder, and a dry bed of straw the best of nutriment. Farmers who consult the comfort of their stock and their own profit will see to it that their stables and sheds are put in good order, loose boards nailed on, doors and roofs made tight, good dry straw furnished for bedding, and that their cattle are comfortably sheltered before the cold winds begin to blow and the first snow of the season flies.

Bee-Balm, or Oswego Tea.

The plant which we figure, and which is known as Bee-Balm, Oswego Tea, Crimson Balm, Horse-Mint, Bergamot, etc., is a very old inhabitant of our gardens. It is a native of the

of the careless cultivator is the Soapwort, which is found about door-yards, in neglected fence-corners, and by the road-side. A single specimen of the Soapwort is not inelegant. In its form and general habit it reminds one of its relative the Sweet-William; in color it is of a

BEE-BALM, OR OSWEGO TEA.

SOAPWORT, OR BOUNCING BET.

wooded banks of streams in the Northern States, and is one of the most showy of our wild flowers. Its botanical name is *Monarda didyma*. The *Monardas* or Horse-Mints generally abound in an aromatic oil, which is in some species more pungent than the one under consideration, and leads to all the species being more or less used in domestic medicine. It is, however, as an ornamental plant the Bee-Balm is chiefly valued. It produces compact heads of large scarlet flowers. These heads are closely surrounded by flower-leaves or bracts, which are also colored. We very frequently find, as shown in the figure, one flower-cluster growing from the center of another. The Bee-Balm is a plant of the easiest culture, requiring only division of the clumps where they have become too large, and though rather too weedy in its appearance to be called a first-class flower, it is useful to make a show in places where its brilliant color can be seen from a little distance.

The Soapwort (*Saponaria officinalis*).

Some plants have the singular peculiarity of hanging about dwellings, and are seldom found in any other position. Notably among these plants is the common Plantain, which seems to thrive all the better in a situation where it can be trodden upon. Another constant companion

slight blush or rose, and its fragrance is rather pleasant than otherwise. Still, notwithstanding these merits, it is in the mass nothing but a slovenly weed, and indicative of careless cultivation. The stems generally grow from one to two feet high, and bear clusters of flowers which are single or double. We are inclined to think that in this country the variety with double flowers is more common than the single. The plant is a native of Europe, and is said to have early been used as a substitute for soap, whence its generic name *Saponaria*. When the leaves are crushed and rubbed with water, a principle called saponine is liberated, which possesses the property of forming a lather with water and of cleansing fabrics. There are several vegetables used in various parts of the world as a substitute for soap. One which grows upon the Pacific coast is considerably used by both Spanish and American residents, under the name of Soap-plant. It, however, belongs to a very different family from the plant under consideration. An old English name for the Soapwort is Fuller's-herb, which has also reference to its detersive properties. One of the common names by which the plant is known in this country is Bouncing Bet. Some species of *Saponaria* are cultivated for ornament, and we have even seen the common Soapwort in old-fashioned gardens. It can, however, only be regarded as a weed, and one not very difficult to eradicate.

mer months is the wonderful diversity and beauty of the flowers cultivated in the windows and balconies of the houses. In some of the best streets hardly a house can be seen that is not so adorned, and even the most squalid abodes of vice and poverty are often relieved by a miniature flower-garden on the window-sill. The most common style is the window-box, made to fit the window, usually from four to five feet long and about six to eight inches wide and deep. It is made of every conceivable pattern, of terra-cotta, cork, and rustic design in endless variety. The plants used are not very numerous in variety, being selected of kinds suited to keep in bloom or to sustain their brightness of foliage. Now and then the ribbon-line system is adopted on the balconies; one very handsome in this style was composed first of Moneywort (*Lysimachia nummularia*), which formed a drooping curtain of four feet in length; half-way down on it drooped blue Lobelia; then upon the Lobelia fell a bright yellow Sedum (Stone-crop); then against the Sedum, for the top-line or background, a dwarf Zonale Geranium, a perfect blaze of scarlet. Hardly two of these window decorations were alike in the best streets, and varied from a simple box of Mignonette or Sweet Alyssum to cases filled with the rarest ferns or orchids. The effect as a whole is most pleasing, and one that can not fail to strike the most indifferent ob-

server as an agreeable change from the seemingly never-ending brick and stone of the city. The window-gardening is not confined to private dwellings, but all the leading hotels are so decorated. In the dining-room of the Langham Hotel (said to be the largest in England), some hundreds of well-grown specimens of plants are placed in the windows, and kept in perfect order during the entire summer. The selection of plants is made regardless of expense, and in looking around the dining-hall it is with some difficulty that you decide if you are not dining in the midst of a vast conservatory, so redolent is the air with the perfume of flowers. The same taste for window-gardening is displayed, more or less, in all the English towns and villages, and even the humblest thatched cottage of the peasant by the wayside is given a look of quiet happiness by the bower of flowers in the window. How different the look of these humble homes, where the occupant is receiving barely \$4 per week, to the squalid shanties in the suburbs of our great cities in America, where the "naturalized" American citizen is earning three times that amount!

Here let me deviate from my text, but to a kindred subject, and tell how the English cottager works his garden in some of the old towns, such as Colchester. To each cottage, renting for about \$50 per year, is attached a garden of something more than an eighth part of an acre in extent. In this little spot the tenant contrives to grow four to six kinds of vegetables, such as potatoes, cabbage, peas, turnips, etc., and of fruits, gooseberries, currants, raspberries, and strawberries. Every foot is made to produce something, and rarely a weed was seen in some scores that we saw ranged side by side. The heavy work is done by the man of the house, "before or after hours," on his own time. In the weeding and hoeing he is assisted by wife or children. There is great rivalry among the different owners of these cottage gardens, and in many places liberal prizes are given by the horticultural societies to those that are best cultivated.

Prizes are also offered for the best window-grown plants, and in Hull and some other towns plants are distributed and printed instructions given for culture to encourage the taste.—LONDON, August 10th.

Garden Experience.

BY C. M. A. BESS, JOHNSON CO., IND.

Can you find space in your columns for a little experience and a grumble from this hitherto unheard-of section?

I am fond of trying new sorts of vegetables and comparing them with established varieties. Here are some results.

Sowed peas, "Carter's First Crop," "McLean's Little Gem," and "Laxton's Alpha," on March 23d. They came into bearing, Carter's, May 22d; Little Gem, May 28th; and Alpha, June 2d. So much for earliness. The Alpha bears tremendously, but all at once, while Carter's gives two and sometimes three pickings; for delicate flavor the Little Gem is best of all, so my wife says, and on that account I shall sow a few each season, even though I don't think they pay in product for the ground occupied.

I economized space and swindled the bugs by sowing Little Gem peas with early potatoes. I used the King of the Earlies, and can speak well of them. They are earlier than the Early Rose—heretofore a standard in this section—and drier or mealier when gathered young; planted

March 23d, five inches deep, in gravelly soil, covered about three inches, then sowed the peas and covered level; had potatoes to eat (size of unhulled walnuts) on June 4th. The peas had quite a start before the potatoes came up, but there seemed room enough for all. Pulled the pea-vines out when done bearing, and left the potatoes, from which I gathered every day until July 4th. I was not troubled with bugs at all, although my neighbors had plenty.

Now for the growl. Why are we bound to receive, in ordering seeds, a certain percentage that is useless? I can count nine distinct total failures in one lot of twenty-four packets—is this not too large a percentage?—all from one house. Don't they sometimes give us seed a little too old to be good? Of course, there are allowances to be made. Aren't we advised in the catalogues that failures may occur? But so many in one firm's lot make me suspicious, and I shall not order from them again.

It is too provoking to sow a lot of seed, say parsnip for instance, and have none of them come up, besides losing the time. I had even worse luck, for I sowed cabbage seed enough to produce a thousand plants, and did not get fifty, and even they were stunted and deficient in vitality, while other varieties of cabbage seed, from another house, grew beautifully, in the same bed. Being intended for early cabbage plants, it was of course too late to sow again.

A Greenhouse Furnace and Flue.

BY EDWARD TATNALL.

[In September of last year (1871) we published an article, by Mr. James Hogg, giving full details for the construction of a furnace and flue for heating a greenhouse. At this season, when inquiries in regard to heating apparatus are

PLAN OF GREENHOUSE FURNACE.

numerous, we refer such correspondents as wish to use flues—the cheapest mode of heating—to the article referred to. Those who propose to heat by means of hot water will find useful suggestions in "Henderson's Practical Floriculture." As an improvement upon the ordinary furnace, Mr. Tatnall, of the Wawaset Nurseries, Wilmington, Del., gives a diagram and description of his manner of inclosing the furnace in an air-case, and thus economizing heat.—Ed.]

MESSRS. EDITORS: Allow me to make a few suggestions in addition to Mr. Hogg's directions for greenhouse furnaces in September number,

1871. Instead of using tile, form an arch of fire-brick made for the purpose, and set on edge. Leave a space of two inches next the furnace, and open to the inside of the house, on both sides of the furnace, above the level of the grate-bars, and a two-inch opening in the front wall on the same level to admit cold air. For the first eight or ten feet next the furnace lay the bricks on their sides, instead of on their edges, to prevent cracking of flues when great heat is required. Use terra-cotta pipe instead of sheet-iron for the rest of the flue—eight inches in diameter, and supported on single brick piers, with an occasional pipe having a side-opening for the purpose of cleaning when foul. The side-opening to be closed with sheet-iron mortared in. By all means have the throat or opening at the furnace one fourth less than the pipe or flue in area. With this provision, a gradual rise of flue from near the furnace to the upright flue or chimney, and a rise of 35° to 45° at the furnace, there need be little fear of poor draught. Thirty inches is a better depth than two feet, as the additional six inches does not necessitate a greater consumption, and the larger the body of coal the more easily is the fire kept alive when the draughts are off.

Horticultural Journals.

Journals calling themselves horticultural, give themselves such airs, that we are tempted to look back upon the field of journalism and refresh the memory of these novices. Among the first, if not the first of these journals was Hovey's Magazine. Excessively Bostonian it is true, but in its pages are embodied a vast amount of our horticultural literature, and whoever has a full set of that journal from the beginning has a most valuable mine of horticultural lore.

Then came the Horticulturist. When A. J. Downing edited it, it was truly the Horticulturist. It has had its ups and downs since then, now rising to importance under Barry, and then being just such as those who have had it in hand could make it. Then came the Gardener's Monthly, a journal with the peculiar crotchets of which we can not always agree, but which is edited with such a sincere purpose and such competent knowledge as to make it the only horticultural journal worthy of the name that we have in

the country. A few years ago a new light dawned upon us—The American Journal of Horticulture. It came ignoring the things that were behind, and promised a new era in horticultural journalism. All that fine paper, excellent engraving, and perfect press-work could do were done for this journal; but, in the language of Sir Charles Coldstream, "There was nothing in it." It absorbed Hovey's Magazine, but did not absorb Hovey, and got no better. Then the publisher, thinking perhaps the title not comprehensive enough, enlarged it to Tilton's

Journal of Horticulture; but even this did not save it, and it quietly retired, leaving no vacancy in the journalistic world. Not long ago we had the Western Gardener, published in Kansas, and the Western Pomologist made its appearance in Iowa. After a while these two periodicals coalesced, and formed the Western Pomologist and Gardener, which after a brief career has united with the Horticulturist. We leave out of our account the local Californian Horticulturist and a Southern journal or two. So far as these various publications have deserved well of the public, we have spoken well of them, and we should not now allude to the many disasters attendant upon the publication of horticultural journals did not some of these put on airs which demand a little plain speaking. When "Tilton's Journal" succumbed, the "Horticulturist," with a wisdom wonderful to behold, gave its views as to the reasons for the want of success of horticultural journals. It said:

"The agricultural journals of the present day have stepped over into the field of horticulture, and by engaging horticultural editors, writers, etc., draw away a great many from the patronage of the horticultural magazines."

Hear further the words of wisdom:

"In the older days of the Horticulturist this was not so. No agricultural papers were then treating specially on horticultural subjects, and every one looked to the Horticulturist, and nowhere else, for its appropriate information."

The "Western Pomologist," taking up the same theme in its dying issue, said:

"Public journals, assuming the title of agricultural or horticultural, should confine their teachings in accordance with the title by which they represent themselves to the world. * * * Agricultural papers, therefore, should never admit to their columns articles purely horticultural. * * * While agricultural journals may, with strict propriety, urge upon farmers to plant orchards, and even flowering bushes and plants, as home adornments, yet it is not expected, nor would it be within their legitimate province, to descant upon the particular varieties of the apple, the pear, the peach, or any other kind of fruit; to speak of their size, shape, color; their various times of ripening, their keeping qualities, the growth of the tree, whether it was hardy or tender. Or, in raising flowers, to point out the almost countless varieties and colors of the rose; whether they should be annuals or monthlies, with innumerable other matters belonging to the floral kingdom. These all properly belong to the horticulturists."

Now that the Western Pomologist and Horticulturist are united, we may look for a combined wall against those horrible agricultural journals. These good people do not consider that the attention given by agricultural journals to horticulture—a subdivision only of agriculture—have made purely horticultural journals possible. The Horticulturist was established in 1846. The oldest agricultural paper we have at hand as we write is a volume of the *Agriculturist* for 1842, in which we find that the "horticultural" articles bear about the same proportion to the other matter that they do in the issues of the present year. The whine of the Horticulturist and the expiring groan of the Western Pomologist will not deter the agricultural journals from supplying their readers with such material as they require. If the engagement of "horticultural editors" by the agricultural papers has drawn "away a great many from the patronage of the horticultural magazines," as the Horticulturist asserts, why on earth does not it engage a horticultural editor, and not be excelled in what it claims as its own specialty by the Country Gentleman, Rural New Yorker, Prairie Farmer, *American Agriculturist*, and several other agricultural journals? The whole history of journalism shows that the public will buy an article that they want, and no amount of scolding will

bring success to a periodical that people do not want, however it may be labeled. We are glad that the Western Pomologist and the Horticulturist are united, as it will give the Horticulturist an editor, which it has long needed. So long as it rests its claims upon its own merits we shall give it a good word, but when it tries to explain away its own want of success by the superior enterprise of the agricultural journals, we shall show up its folly by quoting its own words. We may just here remark that no one ever saw in the Gardener's Monthly any jealousy of other journals. It welcomes, and quotes, and criticises every earnest worker in the cause—a course which we commend to the Horticulturist in starting out under its new régime. When our neighbor gets out a patent on horticulture as an invention of his own, then he may prevent others from writing about it. Only we can't help thinking what funny horticulture it would be if it were only dispensed by a certain journal which we need not name.

Amaranths as Ornamental Plants.

Perhaps the most notable among the new plants of last spring was the Willow-leaved Amaranth, *Amarantus salicifolius*. It was extensively advertised and indorsed by English cultivators, and hundreds of our people who are on the lookout for novelties have made a trial of it. It has in some cases proved a complete failure, and in others a most gratifying success. The reason for this difference we will presently explain. Not quite so new, but still strongly commended, were *Amarantus tricolor giganteus*—an improved form of the old "Joseph's Coat"—and *Amarantus atropurpureus*, a variety of the old "Love-lies-bleeding." This last we may dispose of by saying that it is a miserable, coarse, weedy thing, that in the garden bears no more resemblance to the colored plates sent out from Germany than does the sleepy, half-dead boa-constrictor of Barnum's menagerie bear to the raving, ramping, and violently-twisting "serpent" upon the show-bills. The first two species, *salicifolius* and *tricolor giganteus*, are good or not, according to circumstances. Thorburn & Co., who kindly send us spring novelties, sent us seeds of all three kinds. These seeds were sown in boxes in a gentle hot-bed, and came up well, but the young plants seemed to make very little progress. Being very desirous of making a show of these new Amaranths, we assigned to them a large circle in the most conspicuous place in the lawn. Happening to call upon a florist-friend, we found that he had *salicifolius* and *tricolor giganteus* in pots, and several times larger than our own seedlings, and we arranged for a number of each. In planting the bed, we found we had not enough of the potted plants from the florist, and filled out of each sort from our own seed-boxes. Now for the result. The plants of *salicifolius* from the florist reached the height of eighteen inches and died, those of the *tricolor giganteus* grew about eight inches high and fell over dead, while those from our own sowing grew some four feet in height, and were still advancing, but the defection of the others left the bed so one-sided and ragged that the whole was cut away to make room for other plants. The plants which we procured from the florist had become pot-bound, and immediately stopped growing and began to produce seed, and in the act of providing for their perpetuation they exhausted themselves, and having fulfilled their career died. The plants from seed sown in

boxes had plenty of root-room, and after being transplanted went on growing, as they should do, and began to make a fine show, when, for appearance's sake, they occupying only a small part of a large circle, they had to be removed. Now, this experience teaches two things. First: Never allow ornamental annuals to become checked in their growth, but keep them pushing from the very start. Second: Do not decide upon the value of a plant from one trial. If we had only planted out the potted plants from the florist's we might have justly recorded our experience with these Amaranths as adverse. As it is, we think with proper management both the *salicifolius* and *tricolor giganteus* will prove valuable garden ornaments.

The Arnold Arboretum.

Mr. Arnold, who died a few years ago, at New Bedford, left a large bequest to Harvard University for the establishment of an Arboretum. It has finally been decided to locate this Arboretum on the Bussy farm, about ten miles south of Boston, where the School of Agriculture is already under way. The details of the work are to be under the immediate control of Professor Sargent, who is eminently well qualified for it. He proposes to lay out the ground (137 acres of well-diversified land) as a natural park, with drives and walks tastefully arranged, and leading from one family to another, in scientific order, of all the trees and shrubs hardy in this climate. It will be the work of more than a single lifetime to complete the arrangements contemplated, but it will not be long before the Arboretum will assume a useful form.

The ultimate result will be so important, whether we have regard to the pleasure or to the instruction of those who may be able to visit it, that we trust all who are interested in the advancement of scientific horticulture will give this beneficent enterprise the encouragement and assistance of their best efforts and sympathy.

Something about Corn.

This season we have had numerous samples sent us of corn in which the ordinary manner of growth is departed from. People in different parts of the country seem to have been more observant than usual, for we have rarely gone through a field of corn without finding some of these abnormal forms, and they are common enough to those who are on the lookout for such things. Some of the specimens come asking us to give an explanation and cause of the occurrence. It is very difficult to assign causes for the abnormal things we meet with, but perhaps we can throw a little light upon it. In the first place, we must premise that the structure of the flowers of Indian-corn is difficult to describe to those who are not quite familiar with the structure of grasses in general, for the Corn is only one of the large family of Grasses, and one too of a sub-family which is one of the most difficult to study. It will serve our purpose to say that the corn-plant has flowers of two kinds. Those in the tassel are staminate, or male, and their business is to produce the fertilizing powder or pollen. These flowers are produced in a loose terminal spike, along the branches of which they are arranged. The pistillate or female flowers are inclosed by leaves or husk, and the only visible part of these is the long styles, which protruding from the husk are popularly known as "silk." Each

thread of silk is connected with the pistil of a concealed flower, just as much a flower as the

of corn that have come into our possession. In figure 1 we have a tassel, but the central spike is developed as an ear;

produce flowers and perfect seed. This is the way all well-regulated beets do. It seems that

Fig. 1.—EAR-BEARING TASSEL.

we have the miniature kernels, the silk, and all that belongs to an ear of corn except the leafy envelope or husk. In this case we suppose that for some cause the abortive or suppressed pistils of the usually staminate flower were stimulated into developing, and instead of a spike of staminate flowers there is produced one of pistillate ones. It is not at all rare to find here and there a kernel of corn—sometimes many kernels—growing upon a tassel, in which case the development of suppressed pistils is less general than in the instance just referred to. In figure 2 we have just the opposite of what has happened in figure 1, and staminate flowers precisely like those of the tassel are produced within the husk. It would seem that in this case flowers that should have been pistillate only have changed their character entirely; the pistil has been suppressed, and the stamens have developed. This in a popular way is the best account we can give of these curious phenomena, and we trust that these illustrations and remarks may lead our corn-growing friends to notice their crops more closely. They will find almost every season some curious departures from the regular growth, and we have no doubt they will find

Fig. 2.—TASSEL-BEARING EAR.

more conspicuous ones of the tassel. The ends of the silk receive the pollen from the tassel flowers, the embryo is fertilized, and the grain enlarges very rapidly and soon outgrows the rest of the flower, the remains of which we only

the study of them a matter of some interest.

now and then one prefers a different course, as happened to Mr. J. H. Brightly, who sent the specimen from which we have had an engraving made to Mr. Jas. Fleming, the seedsman, with a letter from which we extract the following:

A Freak of a Beet.

Every one knows that when a beet has been

“Early this spring I brought up, from my cellar, about a bushel of Egyptian Beets. They had kept remarkably well, notwithstanding the croaking of some people, so I had no difficulty in selecting half a dozen for seed. I selected six of the most perfect out of the lot, and planted them as usual, covering the crowns about an inch deep. In a few days five of them started off in fine style, throwing up their seed-stems with great uniformity. But, to my surprise and disappointment, the sixth one ‘made no sign.’ After a time it produced a great bunch of foliage but no seed-stem. I was tempted many times to pitch it into the road, but as I hate a gap, I left it, with its bunch of leaves and the stake I had put there to support the stems that came not. A short time since I took the trouble to look at the monster and ascertain what was the matter. I was again in for a sensation on finding that, instead of producing seed, like a well-ordered and respectable root, it had employed its time and energies in forming three good-sized beets, as you will see.”

adheres there after the corn is shelled. We may regard an ear of corn as composed of branches united in pairs, the number of which differ with the variety. These branches are as if they were soldered together, and the flowers which grow along them are very much crowded, especially when the grain is mature, for then all semblance to flowers is lost. We then have in the tassel, flowers containing stamens but no pistil, and in the ear, flowers containing a pistil but no stamens. In most of the plants with which we are familiar the stamens and pistil or pistils are both in the same flower, but here we have them separated, one portion of the flowers performing one function and the others another. In these separated flowers, as they are called, we find that they are uni-sexual by the suppression of parts. In the staminate flowers we frequently find an abortive or suppressed pistil, very rudimentary it is true, but still something standing in the place the pistil would occupy. On the other hand, in pistillate flowers we often find abortive stamens, frequently reduced to mere little points, or “glands” as they are sometimes called, but still sufficient to show the places where the stamens would have been had the flower been a perfect one. We have figured two of the most striking of the abnormal specimens

A MULTIPLYING BEET.

carefully kept during the winter and is planted out in the spring, it is its business to go on and

in the usual way, it put out a lot of young offsets, after the manner of a multiplier onion.

THE HOUSEHOLD.

(For other Household Items, see "Basket" pages.)

Green-Corn—A Corn-Cutter.

Properly eaten, there is no more enjoyable or nutritious table vegetable than green-corn. It is our peculiar American vegetable, whether in the form of the sweet-corn of the best gardens, or the simple "roasting ears" taken from the field by those who know not the superiority of sweet-corn. The majority of persons eat the corn directly from the cob, an operation that can not be regarded as elegant, but custom sanctions it, and many think that the goodness of the corn can only be reached in this way. Children and those who have imper-

Fig. 1.—CORN-CUTTER.

fect teeth are apt, in eating the corn directly from the cob, to tear off whole kernels, which escape mastication, and pass into the stomach in an unbroken condition. Now, while a broken or masticated kernel of green-corn is nutritious, one that is completely inclosed in its natural hull or envelope is completely indigestible, and passes out of the system in just the same condition as it entered. It is in fact just as much a foreign body as a gravel-stone, and is likely to produce the bowel derangements that may be caused by any foreign indigestible substance. Knowing this, careful parents and those not blessed with teeth that can crush and grind every grain, slit the kernels by drawing a sharp knife along each row of the cob. When the corn is thus prepared, the digestible and nutritious contents of the kernels slip out, leaving the parchment-like hulls attached to the cob. In this way only can corn on the ear be safely intrusted

Fig. 2.—MANNER OF USING CORN-CUTTER.

to children. Some 'cute Yankee, having these things in mind, has invented what he calls a "Yankee Corn-cutter." We do not know who he is, and do not care how much good he may get from this "first-rate notice," for he has done a capital thing by inventing the simple implement with the above name. We procured ours of our neighbor Baldwin in Murray street, and we do not know of any investment of twenty-five cents that we ever made that has paid better. The apparatus, instrument, implement, contrivance, or whatever we may call it, is a half-cylinder of tin, with a handle by which to hold it. Across the half-cylinder there is a strip of tin with projecting teeth, and above this is soldered a wire, as seen in figure 1. The manner of using is shown in figure 2. The cutter is carried down the cob, being held in such a manner that the teeth will cut the kernels and the wire will press out their contents. Half a minute's practice will enable one to completely shell out the contents of

an ear, leaving nothing but the empty hulls upon the cob. For preparing corn for the table there is nothing equal to it, and then for corn-fritters! Oh! Perhaps our readers do not know the virtue of

CORN-FITTERS, and the season is not too late for those yet in ignorance to experience a new sensation. We boil more corn than is needed for dinner, scrape what is left with the corn-cutter, put it in the refrigerator until morning. Then for two coffee-cups full of the corn, a pint more or less, take three eggs well beaten, a small cupful of flour, salt, and enough milk or cream to make the batter drop readily from the spoon. Drop in spoonfuls into hot fat, and fry as other fritters. When these are on hand, we care for little else for breakfast. Some call these "corn-oysters," but they are not oysters, or anything else other than their own excellent selves.

Home Topics.

BY FAITH ROCHESTER.

VISITORS.—House and home keepers who expect visitors "at any time," and dare not get out of "company cake" for fear of getting caught in such a predicament, can not possibly realize the novelty of the sensation with which I welcomed my unexpected visitors a few weeks ago.

We heard them afar off, and knew perfectly well that the wagon coming would stop at our house, for it was on our own private road through the woods. An emigrant wagon! Who under the sun! We all went out to see—a fine team, a beautiful colt, a big watch-dog, and—who?

"Three cheers for Faith Rochester!" and the lady of the coming party swung her hat, and we all laughed, and were so astonished and rejoiced at our meeting that we none of us remembered to shake hands or do any formal greeting that night, but went right to talking as though only days had separated us instead of years.

When I spoke of going into the house, I was told that the wagon in which they came was their house in which they intended to sleep as long as they remained with us. After weeks of open-air life, they couldn't think of sleeping in shut-up rooms. As I was able to offer a "spare bed," with a netting canopy, in an unfinished chamber, where breezes from all quarters of the heavens had free access, my guests consented to lodge in our house, but they had served themselves with their last meal for the day at their last camping-place, so we had little to do but to talk together until bed-time.

Their style of traveling for health and pleasure delighted me. I thought "H. H." was having a pretty good time in her palace-car journey to the Pacific coast, but now I should sooner take the emigrant wagon of my friends, if pleasant and healthful traveling were my object in the journey—as it is theirs. Ruskin himself could find no reasonable objection to this method, I am sure. The wagon-box is large and deep, the seat is on springs, with an easy back, and the cloth roof is painted a light buff, and so is quite water-proof. A straw bed with bedding, a little table that folds up when not in use, two camp-stools, and a sheet-iron cook-stove that I can lift with one hand, and a small Kedzie's water-filter are the furniture of the establishment. The stove has two pot-holes, a good tin baker, a tin wash-boiler, and two or three kettles, stew-pans, etc. They had bags of meal and flour of various kinds stored away in the wagon, and dried fruit, Lima-beans, etc. Fresh fruit and vegetables they purchased as they needed and had opportunity.

Living on a new place, in a house not yet half-finished, with three babies and a half-sick husband, and with no hired girl, I had not meant to be "at home" to any visitors this summer. I told my guests this on the night of their arrival, while assuring them that I was truly very glad indeed to see them. (And so I was. No one but myself can understand how very "providential" their coming seemed!) They said they knew it very well, and so they had not given us a chance to forbid their

visit, but had arranged it all their own way, and were going to camp beside us awhile. They really meant to go to housekeeping for themselves after a day or two in their emigrant fashion. When their emigrant wagon "hove in sight" (about half-past six P.M.), paterfamilias was shelling a large pail of green peas for breakfast (of course I know that it is better to pick and shell peas just before cooking; I also know that if you need help you must take it when you can get it), while I, who, according to all the ancient notions of woman's sphere and duty, should have been shelling those peas, so that the "master of the house" might be reading his newspaper if no "manly occupation" employed his noble powers—I was only holding the baby with one hand as she dandled up and down trying to get the use of her fat legs and feet, while with the other hand I turned the pages of a Botany trying to satisfy my boy and myself as to the name of a plant which we have since proved to be Horse-Mint or Wild Bergamot.

As soon as our visitors came into the house they went to shelling peas, and next morning they took hold, naturally enough, of whatever work seemed necessary to be done, and before many days it actually seemed to be the opinion of all the mature members of the concern that the occupation of child's nurse was all I ought to attempt to fill! Only twice since that second day have I been allowed to wash the dishes.

Perhaps you remember what I said on that subject in the July *Agriculturist*. I remembered it, I assure you, and "kind o'" wished I had not given advice to visitors! My guests take the *Agriculturist*, but had not seen the July number. Our copy was mislaid, and I couldn't feel sorry that it kept out of sight several days. My lady guest was wiping the dishes one morning, when her husband came in and read aloud the advice given by F. R. to visitors about washing dishes! I blushed, but the dish-wiper said "amen" to the remarks read in our hearing.

The gentleman of the party, being an expert fisherman and a "good shot," supplies the family with fish and with wild game. Presently I will tell how the fish-are cooked. The gentlemen, including our little boy, go berrying sometimes, and keep us pretty well supplied with "small fruits."

These are our great occasions for talking—and what is the use of writing about visitors if you say nothing about the visiting? I can not report it, of course, but I can say that visiting of this kind—real soul-communion—is the greatest refreshment human life affords. Which of us felt the most need of it, and which of us two women gets the greatest enlargement from such communion, I can not say, and it is of no consequence so long as both are helped. I wish everybody knew how well it pays to brush away the surface jokes and commonplaces that conceal our real selves from each other, and compare our honest beliefs and true feelings with an earnest desire to get at the truth and the right. We can not do it everywhere—at least not yet. It hurts so cruelly when our precious pearls fall before swine and they turn and rend us! So the masks seem necessary to us in our weak estate—but don't you get dreadfully tired of them sometimes?

DIETETIC HABITS.—The gentleman of our visiting party is an invalid, and a carefully-prepared diet of the most wholesome materials, at regular hours, is one of the means of restoration to health most relied upon by his wifely nurse or nursing wife. They prefer only two meals a day, the last one not later than two o'clock. They supposed this would not chime in with our habits, and for that reason, among others, they proposed to camp beside us as neighbors. But we were eager to try their way of living. It was no difficult change for me, for I learned long ago that my head is clearer and the taste in my mouth more agreeable on waking after going to bed supperless, and more than half of the time (when I am not nursing a baby) I find the little ones their suppers without tasting a morsel myself. Paterfamilias has not had faith in this method. It has seemed to him a dreadful thing to have an

"empty stomach," and he would eat late at night sooner than go to bed without supper; and this he sometimes did in busy times, when neither of us had sufficient help about our work. Of course the weary system had a hard time digesting its late suppers, and the stomach had no chance to rest while he slept. He arose from a night's sleep unrefreshed, and could not wait for breakfast half so comfortably as I could. So his digestion was in a wretched state when Providence turned over this last new leaf in our family history. But he asked questions, and listened and thought for himself, and tried the two-meal system. So far the result is very satisfactory, and a courage and hope unknown for some months past come with a better digestion. We never thought of requiring the little chicks to conform to the new method, but after the first few days the baby and the three-year-old girl ceased to hint the least hunger between breakfast and dinner—a period of six and a half hours—and after a week more they cared so little for supper that on a few occasions it has been omitted without any protest from them; only I gave them all the warm milk they cared to drink, which was not much. The child of six, a boy who inherits a feeble digestive apparatus, was not so easily brought into the new order, but in each case the change of dietetic habits causes an improvement in the disposition. They eat heartily at the table now, and we have them take enough bread or other food slow (but not difficult) of digestion to "stand by" them a good while. I am not prepared to insist upon two meals a day even for our own family, much less for any other; but I see more clearly than ever that it is mainly a matter of habit whether one eats two or three meals a day, and that it is decidedly a *bad* habit to "lunch" between the regular meals.

Another thing which our visitors have led me to realize is this: the danger of giving children too much "sloppy" food. Toothless babies require liquid or semi-liquid food, of course, but children who have teeth should learn to chew their food thoroughly, mixing it well with saliva, before it enters the stomach. If the bread or potato is made soft with milk or gravy the child will be too apt to bolt it in a half-masticated condition or without any real chewing. That is the mischief played by the drinks used at table. They are used to moisten the food and wash it down, and the saliva which nature furnishes for an important part of the digestive process is hardly called into natural action. The children now come to their meals with so good an appetite that a Graham gem without butter or other "spread" seems as delicious to them as it does to me when I am hungry, and they chew it with considerable enjoyment. Much of their food is soft, or semi-fluid, but there was something morbid in the boy's desire to have nearly all his food swimming in milk.

As far as we can *reasonably*, I think we should consult our children's natural preferences in diet. Food that is eaten with a relish for it is more wholesome to the stomach usually than food (even more wholesome "in the abstract") which is distasteful to the palate. But we should discriminate between a natural relish and a morbid craving, and use our best judgment in respect to the child's permanent welfare in preparing its food. Here is something to be taken into the account too: no food will digest *well* that is taken by a person in an *unhappy frame of mind*. So this matter of feeding our families is quite a complicated one. As far as possible, we should "let them have their 'd ruther,'" as Cousin Kate pithily remarks. It is a poor plan to *ask* each child its preference. That is the way to introduce disorder at table. But we can easily learn their tastes, and show that we regard them in filling the little plates at each meal. Careful and sympathetic parents can often guess the real choice of their children better than the children can tell it. It is not well for young children to hear much discussion about the food set before them. The talk should be upon other subjects, and the wholesome fare should be eaten as unconsciously as is consistent with healthful propriety.

MODES OF COOKING FISH.—Most cooks are aware that mackerel and other kinds of salted fish are good freshened thoroughly and then baked and dressed with cream. But frying is the usual method of cooking the common kinds of fresh fish caught in our lakes and rivers. When our gentleman guest brought in his first mess of sunfish I wondered what our *guestess* would say about it. I was sure she must have a horror of scorched butter, and must abominate melted grease in any form as an article of diet. I know the French cooks are said to boil things in such a quantity of "oil," at just the right degree of heat, that no grease penetrates the food, but few of us can afford sufficient good butter to cover a half-dozen fishes while frying, and all the fried fish I have ever seen certainly were more or less "greasy" outside.

But our wise woman had a better way for cooking fish, as she has a "better way" for doing almost everything. This is the way she

BAKES FRESH FISH.—First the mode of dressing the fish preparatory to cooking. Our fisherman cuts the throat of each finny victim with his jack-knife as soon as he gets hold of it. He does not believe that any meat is as good when the victim is strangled or killed by any slow tormenting process as when quickly killed by letting the blood. As soon as possible the "inwards" are removed that they may not affect the flavor of the meat. Then the heads and fins are taken off (cutting around the fins and so taking them *out*) and buried in the earth somewhere, so that the air may not be tainted by them as they decay.

Our wise cook skins all kinds of fish. She says that the skin is good for nothing as meat, and as it is just an *excreting surface* for the animal she can't bear to eat it. It is easier and more agreeable to skin the fish than to scrape off the scales. Usually you pour boiling water over them, and the skin strips off quite easily. The sunfish have such thick skins that the hot water has little or no effect in loosening the skin unless first scaled, and it is as easy to skin them without scaling or scalding.

The best way to salt the fish is before cooking, if you have time, by letting them lie, already dressed, in a pan of salted water over night, or for an hour before dinner. Drain them from the salted water, or sprinkle salt over them if they have not been in salted water, and lay them in your clean dripping-pan, and put them in the oven. They need about half-an-hour's good baking, and then you may pour over them a cup of creamy milk and set them back in the oven for a few minutes. It is best to bake them in some baking-dish that will do to set upon the table just as it comes from the oven.

TO BOIL FISH.—Dress them as for baking. Wrap them altogether in a cloth, or, better still, put them in a clean bag (a salt bag if there are not too many), and put the bag into boiling water enough to cover it. Let them boil half an hour. Pour over them, when dished, cream-gravy or drawn butter.

I don't know which is best, baked or boiled fish, but no one but a dyspeptic whose tastes are all morbid, will be likely to prefer fish fried to either.

Bustles, Hoops, etc.

BY BELL.

The other day a young girl came into my room and said: "I wish you would write an article about bustles. I really think it might do good by setting some people to thinking. Folks praise the bustles because they keep the clothing away from the spine and hips, which are usually too much heated by a woman's style of dress, you know. But see this girl now," she said, lifting the overskirt of her sister who had just come into the room. "She puts her bustle on over all her clothes except the overskirt, which is never more than two thicknesses of cloth, and cloth too that never ought to be there in the first place, making so much unnecessary warmth. So her bustle makes her dress all the more unhealthy by pressing her petticoats and dress-skirt all the closer to her back. There is Hetty Atkinson, now, wears a bustle because her back is

weak, and she puts it under all her skirts, so that it does keep her spine cooler than it would be without one. But most girls only put the bustle under the overskirt and basque, unless they have made their dress skirts to accommodate bustles, or long enough behind to be elevated by the bustles without spoiling the 'hang' of the skirts. And poor girls can't afford to buy good, cool, wire bustles like this, so they make thick, warm ones of newspaper wadded together over a string, and those are a great nuisance. I do think it is wicked!"

Thus said the pretty maiden; and I replied: "The article about bustles shall be written."

I have given her earnest little lecture on the subject as nearly *verbatim* as possible, for I think many persons are not aware that there are girls just coming into the prime of their youth who have conscientious thoughts about the hygiene of dress.

The other day I read that a professor in a New York medical college deliberately stated that it is impossible at the present day to find a woman whose internal organs are in a healthy condition, and this because of the unhealthiness of woman's dress. I suppose no intelligent physician will deny—what most of them positively assert—that almost all of the "female weaknesses" are caused mainly by woman's unhealthy mode of dress. The weight of her clothing upon the hips, and its undue thickness and heat about the abdomen, are especially complained of. The weight presses the internal organs out of their proper place, and the heat (an excess of which is always enervating to any living thing or to any part so heated) weakens the action of the abdominal organs, and also destroys the natural power of the muscles and ligaments which hold them in place. The *unconscious suicide* going on among women is fearful to think of. And what chance is there for healthy sons and daughters to be born of these victims of Fashion?

If long, heavy skirts must be worn, the skeleton-skirt lessens their unhealthiness and discomfort, provided it is large enough (especially at the top) to afford some ventilation about the hips, and to allow of easy locomotion, and provided it does not hang upon the hips and bowels—for whatever hangs upon the hips also presses down upon the bowels.

Do you think it is any better to hang the skeleton skirt upon a stiff corset? It *feels* better, because the pressure is so much equalized, but it is in reality worse and worse. The most reasonable bustle and support for the skirts is a loose waist cut high enough upon the shoulders so as not to press upon the arms, and so as not to be dragged down by the skirt's weight. A gored or circling piece sewed around the bottom of this waist, with a long whalebone or large rattan run in the hem of it, forms the bustle and skirt-supporter. The size of the bustle is determined by the length of the whalebone and the width of the gored piece sewed on. It should not be gored or cut circling in front.

I recommend this simple bustle only as a mitigation of a nuisance—not at all from the artistic point of view. If the idea of woman's dress is not chiefly, as it ought to be, a comfortable and convenient covering for the body, but if it is chiefly *drapery* and barbaric ornamentation, then we must mitigate its inevitable evils as far as possible—so give us hoops and bustles.

Yesterday was the Sabbath. I took up the Christian Union, and read one of Mr. Beecher's "Lectures on Preaching," delivered to the theologues of Yale. Having determined to write this article, this sentence struck me as applying to the subject of woman's dress: "You can not long go right when it is the sense of beauty alone that you are appealing to."

A good deal of a sermon grew out of that sentence in my own mind. My sister, see if you can not preach one to yourself from the same text. "The sense of beauty" is what woman's dress professes to appeal to chiefly, and it is so long since woman's dress has gone right that the memory of man runneth not back to that time. And it never will go right until women are made intelligent about anatomy, physiology, and hygiene, and not until the conscience of woman is freed from its slavery to the "traditions of men," and taught to concern itself with the practical duties of daily life.

BOYS & GIRLS' COLUMNS.

One Less—One More.

Little did I think, when I began to talk to the children in my old-fashioned way, that I should get so attached to them. The nice letters that I get show that the children think quite as much of the "Doctor" as he does of them. It may be a fortunate thing that he has no children of his own, as he can now open his heart to those of other people, and right happy does it make him that not only the children but their parents come into his circle. I have written at the head, "One Less"—"One More." Before the prizes for the flower-lists were announced, one little girl, who was among the successful ones, was taken away. Our family of children has now "one less,"—"One more" has been added to that band of children who are spared the troubles and temptations of life, and whom the good God has taken to himself. I trust it is not wrong to give some extracts of a letter I received from the mother of the little girl:

"The copying of that list was the last work our darling did. You will remember, I told you in a note, that she was taken ill, and I had completed the copying for her. One week from that day she died. She seems fully to have expected the prize, and hequeathed the book when it should come, if it did, to her father. We wish to preserve the book as a memorial of L...L. had so many hours of enjoyment in searching for her flowers and preparing her list, that we are desirous of preserving the list in her own handwriting. The last work she ever did, the last word she ever wrote, the last time she signed her name, was on that paper...L. was a very lovely child, and an earnest, happy Christian, and met death without fear or dread, rejoicing in the knowledge that the dear Jesus she had so long loved, would take her to himself. We rejoice for her, while we mourn for ourselves."

Is not that lovely? And do you wonder that I rejoice over my relations with the children all over the broad land?

THE DOCTOR.

The Isle of Man.

It is a long while since we have had a bit of geographical talk. So let us have a few words about a curious place, the Isle of Man. It may be that you will be obliged to go to the atlas or geography to refresh your memory. When you do find it, it will be seen that it is in the Irish Sea, about midway between England and Ireland, and some thirty miles from either coast. The old Scandinavian name was *Man*, which means alone or isolated, and it is spoken of in poetry as *Mona*, but commonly called Man, and the people who live upon it are called *Manx*. The island is only about 30 miles long, and from 6 to 12

respect, save that they have no tails. Think how odd a rooster must look, strutting about without the fine tail-feathers which give our birds their principal beauty. Then a pussy without a tail! How can a cat be a cat, when she can not wave her graceful tail? To show you how queer they look, we give you an engraving of one of these Manx cats, which as well as the fowls are called *Rumpies*, and sometimes *Stubbins*. At the great cat-show held not long ago at the Crystal Palace, near London, the Manx cats attracted a great deal of attention, and the picture here given is from one of the animals exhibited there. There is a tradition that these tailless cats came from a ship that was wrecked upon the island years ago. That will do for our geography class at this time.

The Autumn Leaves.

Who does not admire the forests in autumn! What a glory of gold, and crimson, and richest brown the leaves present! The cool autumn mornings seem warm as we look upon their brilliant color. Many persons think that all this brilliancy is the work of the frost, while the fact is we have the finest coloring in those seasons in which the frost holds off the longest. The appearance of the color shows that the leaves are ripe. They have finished their work, and are just ready to pass into decay, just as the ripeness of fruit is the first step toward decay. The dying leaves are so beautiful that many gather them in the hope that they will retain their brilliant colors, and are disappointed in finding them turn in a few days to a dull brown. The colors can be preserved, but to do this you must arrest the process of decay, and this can only be done by drying as rapidly as possible. As soon as the leaves are gathered, place them between perfectly dry papers, old newspapers will do, and change the papers every day until the leaves are quite dry, which will be known by their becoming brittle. When the leaves are dry keep them between papers until you wish to use them for making wreaths and other decorations. To make the colors come out more brilliantly, the upper surface of the leaf should be lightly brushed over with boiled linseed-oil. The leaves may then be pasted or glued upon card-board to make wreaths or lamp-shades, or used in any other way that fancy may suggest.

AUNT SUE'S NOTICES TO CORRESPONDENTS.

I received very few "Oven" squares. "Jes" and "Owego" send the most. "JES" sends ten squares, but I must deduct the "obsolete words," "proper nouns," incorrect words, and abbreviations ("nesh," "erke," "Etna," "noil," and "necr"), which leaves six correct squares. "Owego" sends nine; from them I must expunge "ernc," "vire," and "necr." As both lists give evidence of diligence and perseverance, I shall be glad to send to the authors "rewards of merit" as tokens of my approbation, if they will send me their addresses. SOMEBODY who is "no longer juvenile" but "still

TAILLESS MANX CAT.

in width. It usually happens that people who live upon islands that do not have very frequent intercourse with the rest of the world, have many ways and customs peculiar to themselves. The Isle of Man is said to have a very mild and delightful climate, and the Manx men to be very kind and hospitable. Many old customs which have died out in England, are still preserved upon the island. No iron must be put into the fire on Friday. Mugwort is gathered on St. John's day, as a preventive against witchcraft; rushes are strewn upon the floors upon St. Bridget's day; on May-day, primroses, buttercups, and other flowers are placed before the house-doors to keep out the fairies, and a great many other strange and curious things are done by these singular Manx people. But even here these old notions are dying out, because a plenty of schools are coming in, and education drives away all such odd beliefs. One of the things that strike a visitor to this interesting place as strange, is the fact that most of the fowls and cats have no tails. The fowls are called *Rumpies*, and are very handsome in every

takes an interest in the puzzle department," wants to know if our puzzlers can make a column of words, using every letter of the alphabet once only. He (or she) sends six words which use up all the letters but three. In a few minutes' trial I have made six words, using all the letters of the alphabet but two. Who will do better?

Puzzlers will please refrain from sending enigmas upon their own names, or upon the names of our papers or editors, for reasons of taste.

I often receive letters from little invalids, telling me how much pleasure the PUZZLE-BOX has given them. To all such I return my heartfelt thanks for the assurance that, though distant from them, I have been able to cheer and comfort them.

Thanks for letters, puzzles, etc., to O. A. G., C. H. M., Frank B., G. W. S.

Trouble with a Big Bird.

The excellent collection of wild animals at Central Park in New York City has been mentioned several times. There one can see without charge one of the finest menageries in the country. Constant additions are being made to this collection, and beasts and birds from all parts of the world find their way here. One of our artists happened to be at the Park at a time when a new-comer was being introduced to the collection, and though the new scholar was nothing but a bird, it required a great deal of strength and no little tact to get him into the school-house. It is not at all unlikely that he did not fancy the looks of the other scholars already in their places, and that the long neck of Master Camel, the shaggy mane of

Master Leo, the Lion, and the antics of Master Ussus, known to his mates as the Bear, were sufficient to inspire the new-comer with dread. At all events, there was what a New York "Arab" would call a regular "muss," and the whole scene was so ludicrous that the artist thought he would sketch it, so that our Boys and Girls could see it as he saw it. Now, if asked what bird this is, you all will answer, without hesitation, "An ostrich," and if asked where it comes from, the answer will be "Africa." To the question, What does it live upon? it is very likely we shall get the reply, "Glass-bottles and tenpenny nails," and if we go still farther and ask, What does the Ostrich produce? you will say, "Big eggs and feathers." All of this is in the main true, for the geographies and other school-books have about as much of the history of the Ostrich as is given in the above answers. Now let us see what we can add to it to make the story complete. In the first place, the Ostrich is the largest and the strongest of all living birds. Bones of a larger bird, no longer living, are found in Australia, but as far as size goes we must regard the Ostrich as the very "cock of the walk." Well we may, for it is often seven or eight feet high and weighs something like eighty pounds. The first thing that would strike your attention should you see one of these birds, is the enormous length and strength of its legs, and, for the size of the bird, the smallness of its wings. Nature always makes up in one thing what is lacking in another. Those plants that rarely produce seed, multiply in some other way, and persons born blind have wonderfully acute hearing and touch. The Ostrich is poorly off for wings, and can not fly at all, but as for running—just look at its legs! Unlike most birds, the

Ostrich has only two toes, the inner one of which has a powerful claw. The way these legs can get over the ground is something astonishing, and it is said that it can even keep pace with the fleet Zebra, and that their strength is such that a large bird that has been properly trained can carry a couple of negroes on its back. That story we give to you on first-rate authority, but we don't believe it. There is evidently one negro too many. The food of the Ostrich is vegetable, but it seems to have a habit of "gobbling" almost anything that comes in its way, hence we have the story of its feeding on tenpenny nails and finishing off with broken glass by way of dessert. It no doubt takes indigestible things to help grind its food in its gizzard, just as our fowls take gravel, but it is doubtful if it has any preference for such food. But the feathers! How beautiful they are! Such softness and graceful curves are not to be found in the feathers of any other bird. The feathers are highly valued as ornaments, and bring a very high price. They come from the wings of the Ostrich, and those from the male birds are much the finest. Of late years the value of these feathers has induced people who live in Africa to make what are called "Ostrich farms," where the birds are kept in captivity for the sake of their feathers. The eggs of the Ostrich are very large—as large as a child's head. The bird sits upon them at night, but during the day leaves them to the heat of an African sun. The eggs are said to be very good eating, and so are the young birds also. We should prefer a well-fed turkey. In very old times, when emperors and other high dignitaries fed their guests on peacocks' tongues and all such extravagant luxuries, ostriches' brains used to be served as a rare dish.

Still in Advance!

The Smith American Organ Co.

Respectfully announce that they have now an additional large manufactory in operation, making a

Great Increase

In their weekly production of instruments.
At the same time, they have introduced a number of

ENTIRELY NEW STYLES,

With elegant cases, increased power of tone, and improved mechanism.

They ask the attention of musical people to the new styles—**ESPECIALLY TO THE QUALITY OF TONE**—believing that these instruments will be pronounced the finest now made in the world.

☞ New Red-Line Catalogues are now ready, and will be sent free on application.

Tremont St., opposite Waltham St.,
Boston, Mass.

A Railroad Watch.

Travelers by Railroad frequently find their watches completely demoralized by the continuous jar of the train. To overcome this difficulty has long been a problem with watchmakers, and it is now successfully accomplished in the new grade made by the

American Watch Co. of Waltham.

This Watch is made in the most substantial manner, on the most approved principles, and combines all the recent improvements. It has a new micrometrical regulator, by which the slightest variation can be easily corrected. It is carefully adjusted, and may be entirely relied on to run accurately, wear well, and **ENDURE THE HARDEST USAGE**, without any derangement whatever. We confidently recommend this watch to the trade and the public as the **BEST WATCH FOR THE PRICE IN THIS MARKET.**

The full trade-mark engraved on the plate of each watch is "AMERICAN WATCH CO., CRESCENT ST., WALTHAM, MASS."

and it is distinctively known as the CRESCENT-ST. Watch.
For sale by all leading Jewelers.

ROBBINS & APPLETON,
GENERAL AGENTS, 1 BOND ST., NEW YORK.

☞ All the first-class agricultural journals in the country give the Blanchard Churn as one of their premiums for a certain number of subscribers. This is a pretty good endorsement of the Churn, as they are in a position to know which is *the best*.

☞ Any lady who will give a small amount of attention to the task may soon become an expert operator upon the Willcox & Gibbs Silent Family Sewing-Machine, and with its help may save hundreds of dollars annually in the expenditures of a large family, without risking her health. It is impossible to do this with any double-thread machine. 658 Broadway, New York.

☞ Our sympathies would be given to the farmers who are wheedled into buying poor churns if we did not know that there is no need of their being deceived. Buy an article proved by twenty years' use to be just what it is represented. Buy the Blanchard Churn.

WANTED—A FARMER in every town as agent for the Collins Steel Plows. For terms, address **COLLINS & CO., 212 Water St., New York.**

LOOK OUT FOR IMPOSTORS.

The great demand for Tin-Lined Lead Pipe has excited the cupidity of certain parties who are attempting to palm upon the public a Lead Pipe merely washed with Tin, for Tin-Lined Lead Pipe. The cheat is easily detected. Our patent Tin-Lined Lead Pipe is a Block-Tin Pipe heavily coated with solid Lead. It may be distinguished from all other pipe by the four small ribbed lines running lengthwise, at equal quarter distances. Samples sent by mail free.

Tin-Washed Lead Pipe no more compares in value with Tin-Lined Lead Pipe than common Tin-ware, which rusts and wears out in a short time, does with Block-Tin-ware, which never rusts, and is almost imperishable. Tin-Washed Lead Pipe was made thirty years ago, and abandoned as utterly useless as a protection against Lead Poison.

COLWELLS, SHAW & WILLARD MFG CO., No. 213 Center St., New York, manufacturers of Tin-Lined Lead Pipe, Block-Tin Pipe, Sheet-Lead, Lead Pipe, Bar Tin, Solder, etc. Orders filled at sight. Tin-Lined Lead Pipe is 16 $\frac{1}{2}$ cts. a pound for all sizes.

GUARANTEED BONDS.

IT HAS PROVED ITSELF TO BE THE

Handsomest and Most Durable Exterior Paint Known.

COSTS LESS, AND WILL OUTWEAR THE BEST OF ANY OTHER.

TESTIMONIALS:

EX-GOV. SHORTER, Eufaula, Ala., writes: "I am highly pleased with the Averill Chemical Paint."
Rev. JOHN A. WOOD, Honesdale, writes: "The Averill Chemical Paint is splendid; everybody is admiring it."

Gen. G. R. SMITH, Sedalia, Mo., writes: "Two coats of 'Averill' covered better and looked finer than three coats of Lead and Oil, with a coat of Varnish thereon. I would not again use Lead and Oil were it given to me."

LEVI SHAW, Trustee of the Society of Quakers, Mt. Lebanon, writes: "The buildings painted with the Averill White Paint, some 3 $\frac{1}{2}$ years since, I have examined, and found it retains the gloss nearly if not quite as well as when first put on. It is the best Paint we have ever used."

MANUFACTURERS OF

Trellises, Nourse's Patent Folding Plant Stand, Wardian Cases, etc.

Our leading articles of Fall Trade are our *Folding Plant Stand* and *Wardian Case*. The Plant Stand is a half-circle in form, painted green, and has no equal in compactness for shipping. For sale by Implement Dealers, Seedsmen, and the Wooden Ware Trade.

The Wardian Case (or Fernery) is of Black Walnut, mounted on legs (which disconnect for packing), and has a glass top. It is finished in the best style, and is an ornament to any apartment.

Retail price in Boston and New York, \$25.00. Circulars sent upon application.

To Dairymen & Capitalists.

1000-Acre Dairy Farm for Sale, with Stock, Implement, etc.
PRICE, \$40,000.

The subscriber offers for sale Spring water Farm, consisting of 1,000 acres, situated on Senogor Island, Ontario County, Canada, and distant three miles from Fort Perry, the terminus of the Whitby and Port Perry Railway, and close to the water's edge of Senogor Lake, where there is an abundance of fish and game.

This Farm is specially adapted for dairy purposes, being watered with numerous springs—all the buildings being supplied with water from this source, conducted through pipes, as well as the cattle-yards, etc.

There are on the place twelve houses for workmen, five large barns, horse and cattle stables, sheds, pens, etc., and one large dairy building, through which a stream of water constantly runs.

The soil is first-class, never failing to produce heavy crops. There is a fine wood-land in connection with it, sufficient to meet the requirements of the place.

The Farm would be sold in one or two blocks of 500 acres each, the purchaser having the option to take the cattle, stock, horses, and implements, at a fair valuation made by disinterested parties.

Terms of sale for the land, \$10,000 down, balance on mortgage for from five to ten years, with interest at seven per cent per annum. For stock, implements, etc., \$5,000 down, balance in one year, without interest.

Parties desiring to see the place or to purchase, will please address

W. S. SEXTON,
Port Perry P.O., Ontario, Canada.

FOR RENT.—The valuable farm known as "RIVERSDALE," the property of the late Hon. Chas. B. Calvert, near Bladensburg, Prince George's Co., Md., about seven miles by rail, and good turnpike, from Washington, D. C. It contains about 300 acres, 200 of which are cleared and mainly in grass, and water in harbors. There are two good farm-houses, and commodious barns, with stabling for over 100 cows. The proximity of the National Capital renders this one of the best possible points for a dairy or truck-farm. The Washington branch B. & O. R.R. runs through the place, with two stations very convenient. For particulars, terms, etc., address the editors of THE AMERICAN FARMER, Baltimore, Md.

FISHER'S ISLAND, For Sale or to Lease.

This property, belonging to the Estate of R. B. Fox, deceased, and containing several thousand acres, elegantly situated in the Sound, opposite Stonington, Mystic, and New London, Ct., is, by executor's order, offered for sale or lease as a whole, or, as it is divided, in separate farms. It is unsurpassed for salubrity and coolness, and has great agricultural advantages, being capable of producing one thousand tons of hay annually, and affording rich pasturage for large herds of cattle. It is well provided with harbors, and is worthy the attention of yachtsmen and sportsmen.

The MANSION HOUSE is very large and roomy, and, with the adjacent buildings, can be readily fitted to accommodate one or two hundred boarders.

Application and further inquiries may be made by letter, addressed to J. S. BLANCHFORD, 5 Pemberton Sq., Boston.

PARTNER. with about \$2,000, wanted on a dairy farm, now making money. A rare chance. Working man preferred. Address with references,

CHARLES E. CARPENTER, Farmingdale, N. J.

OF

EXCELLENT FARMING
AND SPLENDID

Michigan Pine Lands FOR SALE,

On which are **ONE THOUSAND MILLIONS OF PINE TIMBER**, and inexhaustible quantities of Maple, Beech, Elm, Ash, Hemlock, Oak, etc.

The grant of lands to the Grand Rapids and Indiana Railroad Company, to build their Road from Fort Wayne, Ind., to Traverse Bay and Mackinaw, Michigan, comprises in its farming lands every variety of soil, from the rich clay loam to the light sandy, and they are found in that section of Michigan, north of the city of Grand Rapids, and contiguous to the great fruit belt on the eastern shores of Lake Michigan, now being rapidly developed by railroad and other enterprises.

Farming Lands are sold to actual settlers, on credit, one quarter down, balance in yearly payments, interest 7 per cent. Persons desirous of locations for farms will, on application at the **Office in Grand Rapids**, be furnished with Tickets over the Road, entitling them to Return of Fare, in the event of purchasing any of the Company's farming land. For information about the lands, prices, location, etc., etc., address

WM. A. HOWARD, Land Commissioner,
TITLE PERFECT. Grand Rapids, Michigan.

Prime Investment

LOW PRICE.

CHICAGO

Canada Southern

First Mortgage Sinking Fund 30 Years

7 PER CENT GOLD BONDS,

INTEREST PAYABLE APRIL AND OCTOBER, AT UNION TRUST COMPANY,

AT 90 AND ACCRUED INTEREST.

This road is the western link in the new AIR LINE from Buffalo to Chicago, and runs from the Detroit River to Chicago in nearly a straight line.

The road is a part of the same line as the Canada Southern, and is being built by the same men—viz.: Milton Courtright, John F. Tracy, David Dows, Wm. L. Scott, Henry Farnam, R. A. Forsyth, Juno M. Burke, M. L. Sykes, Jr., all directors either in the Chicago and North-West or the Chicago, Rock Island, and Pacific; George Oplyke, of the Midland Road; Sidney Dillon, Daniel Drew, John Ross, David Stewart, Samuel J. Tilden, Kenyon Cox, and other prominent railroad men.

The road, like the Canada Southern, will have steel rails (60 pounds to the yard) throughout; is practically straight and level; much shorter; and can be run with greater speed and safety than any other road connecting Buffalo and Chicago.

Twenty-five miles are finished and running; seventy-five miles more are so far advanced as to be finished by January 1st; and the entire road will be completed during the ensuing year. Steel rails and ties for one half the entire road have already been purchased.

The builders of the road count on enough of its Chicago feeders to obtain for it a profitable business from the start, having projected the line to accommodate existing business, and having seen the necessity for another trunk line between Chicago and the Atlantic seaboard, located expressly with the view of obtaining the cheapest transportation practicable.

The branch lines will make the shortest connections between Chicago and Toledo and Chicago and Detroit, as well as between all these points and Buffalo.

The Canada Southern Bonds, in every particular like these, were eagerly taken, the last of them several weeks ago, by the best class of investors, and were on the market a shorter time than any other railroad loan of like amount for years past.

The proceeds of these Bonds will complete the entire line, and we recommend them with the same confidence as we did the Canada Southern, and regard them as in every way a choice security.

ASBESTOS ROOFING

Rockford, September 7th, 1872.

C. L. RICE & CO., Chicago, Illinois:
DEAR SIR: Yours of yesterday asking for my experience with **H. W. JOHNS' PATENT ASBESTOS ROOFING** duly received. In answer, would say, I have used Mr. Johns' Roofing and Coating extensively for **TEN YEARS** past, and with great satisfaction; I have applied it to more than three hundred roofs in Rockford, Illinois, and adjacent country. I have roofs in Rockford that have been on **EIGHT YEARS** without repairs—they are sound and good, and by simply recoating will last as much longer. I have seen and tested many kinds of Composition Roofing during the past ten years. I have seen nothing that comes up to "Johns' Patent Asbestos."
Truly yours,
L. M. WEST.

THE IMPROVED

Universal Wringer

Excels all others in having

Rowell's Cog-Wheels,

With long and strong alternate teeth.

The Patent Stop,

To prevent the Cogs from disconnecting.

The Folding Clamp,

Which fits any thickness of round or square tub.

The Apron or Clothes Guide

To carry the clothes over the side of the tub.

A Perfect Water-Guide,

Which conducts all the water back to the tub.

Test it with any and all others, and
BUY THE BEST.

Sold by dealers generally.

Metropolitan Washing Machine Co.,
32 Cortlandt St., New York.

The Patent Mushroom Strainer,

For all kinds of Suction Pumps. Screws on bottom of pipe for wells and cisterns. Especially desirable where wells are low, as it will draw in 3/4 inches of water without disturbing the bottom, and in case the water is let out of suction pipe it clears strainer without stirring up the bottom. Can be applied to lead pipe with a soldering iron. Liberal terms to Plumbers and the Trade.

Sent as ordered on receipt of the money. Prices: 1-inch pipe, \$1; 1 1/2, \$1.25; 2, \$1.75; 2 1/2, \$2.25. Circulars sent on application. Larger sizes to order.

W. S. BLUNT,

Office of "The People's Force-Pumps,"
86 Beckman St., New York.
For sale at San Francisco by Conroy, O'Connor & Co.

EDWARD S. BROWN, 181 Broadway, New York,
Buyer and General Dealer, furnishes for cash anything that can be procured in the New York market. Perishable articles and goods contraband to good morals excepted. Correspondents solicited.

Butterwood Fruit Farm and Nursery,
LITTLETON, N. C.

S. G. BILYEU,

Propagator & Dealer in Fruits & Fruit Trees.

EARLY BEATRICE PEACH,

A GREAT ACQUISITION, fruited three years in my orchards. This season's shipments were large to New York and Philadelphia. Fruit of excellent quality, at least 14 days earlier than Hale's Early. Does not rot, and proves to be a great shipper. For reference and full particulars send for Catalogue. The Early Louise and Early Rivers Peaches have been fruited, but not in large quantities sufficient to determine their shipping value. Quality of fruit apparently good. The two latter and the Foster Peach will be fully tested next season.

Local agents wanted through the country. None need apply without satisfactory reference.

S. G. BILYEU, Littleton, N. C.

N. B.—60,000 Early Beatrice Trees for fall and spring now ready.

Containing Descriptions of **Hyacinths, Tulips, Crocuses, Lilies,** and other Hardy Bulbs for Fall Planting in the Garden, and for House Culture. Full instructions for Planting, Treatment, etc. Thirty-two pages, nicely illustrated. Sent free to all who apply. Address

JAMES VICK, Rochester, N. Y.

Bulbs, Seeds, and Plants,

For present sowing and planting.

Our two Catalogues mailed on application.

Peter Henderson & Co.

SEEDSMEN, 35 CORTLANDT ST., New York.

R. B. PARSONS & CO.,
FLUSHING, N. Y.,

Offer a fine stock of **CAMELLIAS, AZALIAS,** and **RARE EVERGREENS, RHODODENDRONS, ROSES,** and other Flowering Shrubs. **ORNAMENTAL and FRUIT TREES.**

The attention of large buyers is invited.

For Catalogues, address as above.

Read this! For a twenty-five cent stamp, we will send, post-paid, a house-furnishing article, with patented improvement, which is indispensable in every family. If you do not choose to purchase, the money will be refunded on return of article. We also send a price-list of superior articles, which will be delivered direct from factory without extra charge.
TOWNSEND MANUFACTURING CO.,
21 De Kalb Ave., Brooklyn, N. Y.

AMERICAN AGRICULTURIST.

ORANGE JUDD & Co., Publishers, 245 Broadway, N. Y. City.
 ANNUAL SUBSCRIPTION TERMS (always in advance): \$1.50 each for less than four copies: Four to nine copies, \$1.25 each: Ten to nineteen copies, \$1.00 each: Twenty copies and upward, \$1 each. Papers are addressed to each name.
 Either English or German Edition, at these prices.

HEARTH AND HOME: \$3 a year for less than four. Four to nine copies, \$2.50 each; 10 or more copies, \$2.30 each.

Hearth and Home (weekly) with American Agriculturist sent to one address for \$4 a year.

GOOD THINGS, Desirable, Wanted by All, Easily obtained Without Money, and with **Little Trouble.**

Special Attention is invited to the list of choice articles in the Table, and to the descriptions following. . . . These articles are **fully worth** the money value set against each, which is the regular price. Every thing in the list is **new, useful, and first-rate.**

These articles are offered as Premiums or Gifts to those persons who take the little time and trouble needed to collect subscriptions, new and old, for our papers. Over **14,000 persons** have secured one or more of them, and they have almost universally given *great satisfaction* to those receiving them.

They are **all just as good as money.** The assortment is so large, that every one will find something needed. See table and descriptions.

They may be easily obtained by **Farmers, Postmasters, Gardeners, Merchants, Nurserymen, Mechanics, Physicians, Lawyers, Ministers, Students, Teachers, Clerks, Conductors, Children, By ALL.**

Any person who chooses may collect a small or large list of subscribers and receive the premium. (See first article, page 369.) It is only necessary to show copies of the papers, explain

their value, promise the \$5 picture, and collect and forward names.

It has been done largely at Stores, Shops, Post-offices, etc., and by private individuals. By **Co-operation**, Ministers, Teachers, Churches, Sunday and week-day Scholars, have obtained Melodeons, Libraries, Dictionaries, etc., also Sewing Machines, etc., for poor widows and others. Many Professional men have made up good premium lists at their offices. Clerks in Stores and Post-offices have materially increased their salaries thus, while individuals in all classes have secured good things for themselves or for presents to others, *all without the use of working hours, and at no money cost.*

The *American Agriculturist* is everywhere known and approved. HEARTH AND HOME is now without a superior in the world as a splendidly illustrated Weekly Newspaper, for real value, cheapness, and adaptability to every home in America. The papers are *entirely different*. Taken together, they supply over **\$30,000** worth of fine engravings, and more good reading than can be found in fifty books costing one Dollar each.

Premium Clubs can be made up of subscribers to either paper, or partly of one and partly of the other, as noted over the Table. We call **especial attention** to the last column of figures, showing the small number of names required where both papers are taken, at the reduced price of \$4 a year.

You, Reader, can get a Premium. TRY IT.

Explanatory Notes.

N. B.
 Read and carefully Note the following items:
 (a) All subscribers sent by one person count, though from one or a dozen different Post-offices. But . . . (b) Tell us with each name or list of names sent, that it is for a premium. . . .
 (c) Send the names as fast as obtained, that the subscribers may begin to receive the paper at once. You can have any time, from one to six months, to fill up your list. . . . (d) Send the exact money with each list of names, so that there may be no confusion of money accounts. . . . (e) Old and new subscribers all count in premium clubs, but a portion, at least, should be new names; it is partly to get these that we offer premiums to canvassers. . . .
 (f) Specimen Numbers, Cards, and Show-bills will be supplied free as needed by canvassers, but they should be used carefully and economically, as they are very costly. . . . (g) Remit money in Checks on New York Banks or Bankers, payable to order of Orange Judd & Co., or send Post-office Money Orders. If neither of these is obtainable, Register Money Letters, affixing stamps both for the postage and registry; put in the money and seal the letter in the presence of the Postmaster, and take his receipt for it. Money sent in any of the above ways is at our risk; otherwise it is not.

[In the following table is given the price of each article, and the number of subscribers required to get it free, at the regular rates, \$1.50 a year for *American Agriculturist*, and \$3.00 a year for *Hearth and Home*; also at the club rates of \$1 and \$2.50; also at the rates of \$4 a year for both papers together.] **Descriptions of Premiums on next page.**

N. B.—In all Premium Clubs for either paper, TWO copies of *American Agriculturist* at \$1.50 each, and ONE copy of *Hearth and Home* at \$3.00, will count exactly the same. So also two copies of *American Agriculturist* at \$1 each, and one copy of *Hearth and Home* at \$2.50, will count exactly the same. In this way Premium Clubs can be made up from the 2nd and 4th columns, or from the 3d and 5th, or wholly from the 6th column.

Every Premium article is new and of the very best manufacture. No charge is made for packing or boxing any article in our Premium List. The Premiums, Nos. 5 to 9, 19 to 25, 28, 50 to 73, and 76 to 88 inclusive, will each be delivered FREE of all charges, by mail or express (at the Post-office or express office nearest the recipient), to any place in the United States or Territories.—(No. 27 mailed for 30 cents extra.) The other articles cost the recipient only the freight after leaving the manufactory of each, by any conveyance desired. See Description of Premiums on Next Page.

Descriptions of Premiums.

(For number of Subscribers required, see Table, page 393.)

Nos. 1, 2, 3.—American Table Cutlery.—We are glad to be able to offer really good articles of American manufacture, such as are competing successfully with the best foreign make. **Messrs. Patterson Bros., 27 Park Row,** who supply us with these articles, are also importers of English goods. They recommend these Knives, manufactured by the **Meriden Cutlery Co.,** as equal to any Cutlery in the market, and their recommendation is a guarantee, wherever they are known. We offer two kinds of Knives, and three sizes of each kind. No. 1 have Rubber Handles, which are actually boiling-water proof, so that, if they were accidentally to remain in it for several minutes, or even hours, they would not be injured. The Blades are of the best steel, and warranted. Dessert size, with Forks, sold at \$15. For 24 subscribers at \$1.50, or 80 at \$1, we will give either the medium size or the table size, sold at \$16.00. No. 2 have Ivory Handles, are selected with great care, have Steel Blades, and are beautiful goods. Dessert size, with Forks, sold at \$20.00. For 33 subscribers, at \$1.50, or 110 at \$1, we will send the medium size, sold at \$22.00. For 25 at \$1.50, or 116 at \$1, we will send the Table size, sold at \$23.00. The Forks, which accompany these Premiums, Nos. 1 and 2, are made of genuine Albata, and warranted *double-plated with coin-silver.* These Forks are furnished to us by Messrs. Patterson Bros. The Carving-Knife and Fork are made by **The Meriden Cutlery Co.,** with the best Ivory, balanced Handles.

No. 4.—French Cook's Knife, Fork, and Steel.—This is a long (10 in.) thin Knife, with Pat. Rubber Handle, made of the best steel, and for use rather than ornament; and it is really pleasing to see how easily it slips through a joint of beef. The fork and steel are made to match. It would save many wry faces, and perhaps hard words, were it in general use. Made by **The Meriden Cutlery Co.**

Nos. 5, 6, 7, 8.—Pocket Knives.—**HERE'S FOR THE BOYS AND GIRLS!**—These Premiums are among the most pleasing and useful that we have ever offered. Every boy, and girl too, wants a pocket knife. We give them an opportunity to obtain a most valuable one for merely a little effort. These knives are furnished by the **Meriden Cutlery Co., 49 Chambers St., New York,** whose work is equal to any done in this country or Europe. No. 5 is a neat, substantial Knife, with three blades and back-horn handle. No. 6 is a still finer article, with four blades and pearl handle. No. 7 is an elegant Knife, with five blades and shell handle. No. 8 is a Lady's Pocket Knife, a beautiful article, with four blades and shell handle.

No. 9.—Multum in Parvo Pocket Knife.—This is a most attractive as well as useful Premium, from the well-known manufacturers, **Miller Bro's Cutlery Co., West Meriden, Conn.** It comprises, in one knife-handle, a large and a small blade, a screw-driver, a saw, a strong hook, a nut-cracker, a brad-awl, a gimlet, a corkscrew, a pointer, a slim punch, tweezers, and, in addition to this, it can be used for various other purposes which will at once suggest themselves to any smart boy or man. It is a pocket-full of tools weighing but two ounces. The knives will be sent anywhere in our country, post-paid.

No. 10.—Cake Basket.—A new pattern, oval-shaped, or square, nicely chased—a very taking, useful, and beautiful table ornament. This, with other articles that follow, is made by the **Lucius Hart Manufacturing Co., of Nos. 4 and 6 Burling Slip, New York City,** and is warranted by them to be of the best triple plate. Mr. Hart, "the veteran Sunday-school man," was engaged in the same place and business for nearly a quarter of a century. We have known him and his work for many years, and have taken pleasure in commending and guaranteeing its value to be as represented. We believe the Company which bears his name is fully sustaining his reputation. The amount of silver upon plated ware depends wholly upon the will and integrity of the manufacturer. We could give nearly as good-looking plated ware for less than half the money.

No. 11.—Revolving Butter-Cooler.—This is a really good and useful article. It is so arranged that a very little ice in the holder under the plate will keep butter cool and fresh for a long time on the table, even in the hottest weather. The cover revolves underneath the plate for use, and over for protection. The whole is in four pieces, which can all be taken apart for washing. From same house as No. 10.

No. 12.—Card Receiver.—This is a beautiful ornament, as well as a useful article. It is finely

chased and gilt-lined, and, like the three preceding, is from the **Lucius Hart Manufacturing Co.**

No. 13.—Nut Picks and Crackers.—Here are twelve nut-picks, elegantly chased, of medalion pattern, with two handsome nut-crackers, in a morocco-covered case. From the same house as No. 10.

No. 14.—Half-Dozen Napkin-Rings.—These rings are beautifully chased, and in a morocco-covered case. From the same house as No. 10.

No. 15.—One Dozen Teaspoons.—**No. 16.—One Dozen Table-Spoons.**—These are "figured tips," Olive-leaf Pattern, all of the same metal, plating, etc., and from the same makers as No. 10. They are far cheaper than anything we have found at half the price, and are well worth working for.

No. 17.—One Dozen Table-Forks.—The same description and remarks apply to these as to No. 16. We select as premiums only such articles as we can warrant in quality and price. All these articles come from the **Lucius Hart Manufacturing Co.**

No. 18.—Child's Cup.—A beautiful gift for the little one-year-old. It is made by the **Lucius Hart Manufacturing Co.** Triple-plated on the outside and gilded on the inside. It never breaks, and will last for many years—indeed, be a life-keepsake.

Nos. 19, 20, 21.—Gold Pens; with ever-pointed Pencils, in extension, coin-silver cases.—Premium No. 19 contains the best No. 4 Gold Pen; and No. 20 the best No. 6 Gold Pen, which is the same style, but larger. No. 21 contains No. 7 Gold Pen, in Gold-tipped Ebony Holder. Each pen will be sent in a neat leather ease by mail, post-paid. These pens are made by **Geo. F. Hawkes, No. 66 Nassau St.,** and have obtained an excellent reputation. We have known the maker and his goods for many years, and can recommend them.

No. 22.—Ladies' Fine Gold Pen, in Rubber Case, Gold Mounted, with Screw Extension, and Gold Ever-pointed Pencil. A beautiful present for a lady teacher or friend. Same maker as No. 19.

Nos. 23, 24.—Paragon Patent Revolving Pencil.—This is a beautiful Pocket Pencil, which is extended or closed by pulling or pressing the head. They are made with great care, and every Pencil warranted to work perfectly. They are gold-plated, and will last for years. We offer two patterns, one for ladies, with ring for chain, at \$1.50 each, and one of heavier and firmer plate, at \$3.00. Same maker as No. 19.

No. 25.—Payson's Indelible Ink, and Briggs's Marking-Pen Combination.—Payson's Indelible Ink is too well known to need further commendation. It is almost indispensable in the family. Briggs's Marking-Pen has been before the public for fifteen years, and is justly celebrated for all kinds of marking, and particularly for writing upon coarse fabrics. The Pen and Ink are put up in a neat case, being thus portable, always ready for use, and protected from loss or injury by evaporation or breakage.

No. 26.—Moore's Floral Set.—This is a beautiful Premium—a complete set of Ladies' or Children's Garden Tools for the cultivation of flowers, consisting of a Floral Hoe, Spade, Fork, and Rake. They are made of the best steel and iron, with finely polished hard-wood handles, light, durable, and highly finished, and each set inclosed in a box. They will be found very convenient in the garden and greenhouse, and are pleasing toys for the little folks. Made by the **Moore Manufacturing Company, Kensington, Ct.**

No. 27.—Steam-Engine.—This is a veritable steam-engine; one that will GO; and a capital, intensely interesting, and instructive article for boys, and grown-up people too. Our eleven-year-old boy ran his engine an average of an hour or more a day for six months; he exhibited it in motion to many of his playmates, hitched on various toy machinery, and it appeared to go just as well as when first started.

No. 28.—Very Choice Garden Seeds and Flower Bulbs.—We have taken special pains to have prepared by **Messrs. B. K. Bliss & Sons, 23 Park Place and 20 Murray Street,** whose seed establishment is well known as one of the best in the country, a list of seeds and bulbs of the very choicest kinds, and the most useful varieties. Though some are rare (and costly), all have been tested

and found excellent. Here is an opportunity to obtain a valuable assortment of seeds, as this premium allows you to select from the list below any that may be desired, to the amount of **two dollars.** If more is wanted, it of course is only needful to secure two or more of the premiums, and select seeds accordingly. *All delivered free:* 1 Pkt. Early Wyman Cabbage, 25c.; Diocorea Batatas, or Chinese Potato, per doz. tublets, 25c.; Moore's Early Concord Corn, ½ pint pkt., 25c.; Laxton's Alpha Peas, ½ pint pkt., 25c.; Trophy Tomato, ¼ oz. pkt., 50c.; ½ oz. Marblehead Mammoth Cabbage, 50c.; ½ oz. Improved American Savoy, do., 25c.; ¼ oz. Improved Brunswick, do., 25c.; ½ oz. Premium Flat Dutch, do., 20c.; ½ oz. Improved Red Dutch, do., for pickling, 25c.; ½ lb. Bliss's Improved Long Orange Carrot, 50c.; 1 pkt. Perpetual Spinach Beet, 25c.; ½ oz. Boston Market Celery, 25c.; 2 oz. Dewing's Improved Early Turnip Beet, 25c.; 1 pint McLean's Little Gem Peas, 30c.; 1 pkt. New Black Pekin Egg-Plant, 25c.; 1 pint Crosby's Extra Early Sugar Corn, 25c.; 1 pkt. (ten seeds) General Grant Cucumber, 25c.; 1 oz. Boston Market Tomato, 50c.; 1 ounce Conover's Colossal Asparagus, 25c.; 1 pint New Dwarf Wax Beans, 50c.; 1 pkt. New Egyptian Blood Turnip Beet, 15c.; 1 pkt. Early White Erfurt Cauliflower, 25c.; 1 pkt. Early Simpson Lettuce, 25c.; 1 pkt. New Garnishing Kale, 25c.; 1 pkt. Latakia Tobacco, 25c.; 2 oz. Conn. Seed Leaf Tobacco, 50c.; 1 pkt. Early Paris Cauliflower, 25c.; 1 oz. Finest Cucumber Seed, for pickling, 25c.; 2 oz. Genuine Hubbard Squash, 50c.; 2 oz. True Boston Marrow, do., 50c.; 2 oz. Turban, do., 50c.; 1 Liliun auratum, or New Gold-banded Lily, from Japan, 50c.; 1 Liliun lancifolium rubrum, Japan Lily, red, 40c.; 1 Liliun lancifolium album, Japan Lily, white, 40c.; 1 doz. Gladioluses, fine mixed varieties, \$1.50; 1 doz. Mexican Tiger Flowers, \$1.25; 1 doz. Tuberoses, Double Italian, best, \$1.50; 1 doz. Hyacinths, double and single, in three colors, red, blue, and white (for fall planting), \$1.50; 4 doz. Tulips, double and single, early and late (for fall planting), \$2.00; 100 Crocuses, fine varieties (for fall), \$1.00.

Nos. 29, 30, 31.—Sewing Machines.—"A good Sewing Machine lightens the labor and promotes the health and happiness of those at home." We offer a choice of three of the best of the leading machines, all of which have been thoroughly tested in our own families, and give entire satisfaction. While all are valuable, each has some excellence peculiar to itself. The **Grover & Baker** Machine is remarkable for the *elasticity of its stitch*, which is at the same time very firm and durable. The structure of the seam is such that, though it be cut or broken at intervals of only a few stitches, it will neither open, run, nor ravel. It sews directly from two spools, without rewinding. The **Florence** Machine makes different stitches, each being alike on both sides of the fabric. One of its special advantages is that it has the *reversible feed motion*, which enables the operator, by simply turning a thumb-screw, to have the work run either to the right or left, to stay any part of the seam, or fasten the ends of seams without turning the fabric. The **Willeox & Gibbs** Machine excels in the exceeding *simplicity of its construction*. Very little instruction and ingenuity are required to understand the few parts of which it is composed, and their use; and there is no excuse for getting it out of order, until the parts are fairly worn out. One of its strongest recommendations is the *ease with which it is worked*, taxing the strength of the operator less than other machines. The new table and pedals are great improvements. All these machines have constantly increasing sales, showing the public estimate of their value. Either of them will prove a great treasure in any household—worth more than \$500. The \$500, at 7 per cent interest, would yield (less taxes) about \$32. Most families require at least four months of steady hand-sewing a year, costing, if all hired, not less than \$24 a month, board included, or \$96 a year. With a Sewing Machine, a woman can sew more in one month than in four months by hand. Here is a clear saving of \$72. But far above this—the everlasting "Stitch, stitch, stitch," the bending over the work, and the loss of sleep, have brought tens of thousands to early graves. We say to every man, Get your wife a Sewing Machine, even if you have to sell a favorite horse or an acre or two of land—get the Sewing Machine any way. If you can get one through our premium-list—well; but get the machine. —No charge for boxing the machines. They go safely as freight. Send for circulars, giving full instructions, to **Grover & Baker Mfg Co., 786 Broadway, N. Y. Florence Sewing M'ne Co., 39 Union Square. Willeox & Gibbs Mfg Co., 658 Broadway, N. Y.**

No. 32.—Beckwith \$10 Sewing-Machine.—While we advise buying a \$55 to \$65 Sewing-Machine, we have long been looking for one which, while brought by its low price within the reach of multitudes who can not afford the valuable higher cost machines, should be at the same time worthy of commendation. This we have found at last. The Beckwith Machine is well and strongly made, is simple, its use being quickly learned, is applicable to almost all kinds of family sewing, and has already been tested so thoroughly that hundreds of testimonials, from all quarters, have been given by those who are delighted with its work. Each machine is put in a neat, compact

box, with hemmer and guide, oil-can with oil, thread, different-sized needles, etc., with full printed directions for using. We offer these Machines on our Premium List. We will sell them to any who may wish to buy, for \$10 each, delivering to any express office in this city.

No. 33.—Bickford Family Knitting Machine.—This is a practical and efficient machine, simple in construction, works very easily, makes scarcely any noise, occupies but little space, can be attached to any common table, and be removed instantly by simply turning a thumb-screw. It can be worked by any person of ordinary intelligence, after a careful perusal of the accompanying book of instructions and a little patient practice. A great variety of articles have been made with this machine, and it is capable of producing many more and different kinds. A complete stocking, heel, toe, and all, can be knit in ten minutes by a skillful operator, and socks, sacks, hoods, skirts, mittens, undergarments, etc., in remarkably quick time. Send for circular to **Dana Bickford, General Agent, 689 Broadway, New York.** For 52 subscribers at \$1.50, or 162 at \$1.00, we will send the machine with black walnut table, price \$33.

No. 34.—Doty's Improved Clothes Washer, with the Metropolitan Balance Weight. Over seventy-five thousand families in the United States are using the Doty Washing Machine, and we believe the improved machine has no superior. The "help" use it and like it. Send for descriptive circulars to **R. C. Browning, 32 Corlandt St., New York,** or to **Metropolitan Washing Machine Co., Middlefield, Ct.** It goes cheaply by freight or Ex.

No. 35.—Universal Clothes Wringer.—A very useful, time-saving, strength-saving, clothes-saving implement, that should be in every family. The wringing of clothes by hand is hard upon the hands, arms, and chest, and the twisting stretches and breaks the fibers with lever power. With the Wringing Machine, the garments are passed rapidly between elastic rollers, which press the water out better than hand wringing, and as fast as one can pick up the articles. We have given thousands of these premiums, with almost universal satisfaction. They are made by the **Metropolitan Washing Machine Co., Middlefield, Ct. R. C. Browning, 32 Corlandt St., N. Y.**

Nos. 36, 37.—Melodeons.—These are excellent and desirable instruments, for the Home Circle, for small Churches, for Sunday-schools, for Day Schools, Academies, etc. Instrumental and Vocal Music in a school has a beneficial influence upon the pupils. We have seen the whole tone and character of a school improved by introducing a Melodeon.—Set the pupils to work and they will raise a club of subscribers for this premium. We offer the Melodeons made by Messrs. **Geo. A. Prince & Co., Buffalo, N. Y.,** for we know them to be good. A large one in our own Sunday-school room has been there *thirteen* years, and is to-day just as good as when first purchased, though used from time to time by a large number of persons.—Several clergymen have obtained this premium for themselves, their Churches, or Sunday-school rooms. The clubs of subscribers were quickly raised among the members of their parishes.—Many others can get a Melodeon for their home use. Send a postage-stamp to the makers and get their illustrated descriptive circular. These Melodeons will be shipped direct from the manufactory at Buffalo. They can go safely as freight or by express. If an Organ should be wanted instead of a Melodeon, we can supply it for an increased number of subscribers in proportion to the value.

No. 38.—Steinway Piano.—SEVEN OCTAVE ROSEWOOD CASE, SOLID ROSEWOOD DESK, LARGE FRONT, ROUND CORNERS; OVERSTRUNG BASE, FULL IRON FRAME, PATENT AGRAPPE TREBLE, CARVED LEGS, AND CARVED LYRE.—This is one of the most elegant Premiums ever offered; regular and only price \$650. That this magnificent instrument comes from the celebrated establishment of **Messrs. Steinway & Sons, Nos. 109 & 111 East 14th St.,** is enough to say; but it is due to these enterprising manufacturers to state that, while their pianos have repeatedly received the First Premiums, by the award of the most competent judges the world can produce, at the Universal Exposition, in Paris, they received the First Grand Gold Medal for American Pianos in all three styles exhibited, viz.: Grand, Square, and Upright. The following official certificate was signed by the President and the five members of the International Jury: "Paris, July 20th, 1867. I certify that the First Gold Medal for American Pianos has been unanimously awarded to Messrs. Steinway by the Jury of the International Exhibition. First on the List in Class X." The Society of Fine Arts in Paris unanimously awarded Steinway & Sons their only annual Testimonial Medal for 1867. The President of the Musical Department of that Society reports: "The pianos

of Messrs. Steinway appear to me, as well as to all the artists who have tried them, superior to all that have been made to this day in the entire world." The best judges in America say the same. We also speak from personal knowledge, as each of our partners has one at home and desires no better. This splendid premium may be secured by many persons. Only 625 subscribers are required to do it. Several have obtained this premium. It will pay for even a year's labor. Classes of young ladies at school might unite in canvassing, and obtain a present for a Teacher, or a Piano for their school-room. We shall be glad to give this premium to a large number. Send to **Messrs. Steinway & Sons, New York City,** for a free circular describing it.

No. 39.—A Good Watch.—The Watches made by the **American Watch Co., Waltham, Mass.,** have peculiarities of excellence which place them above all foreign rivalry. The substitution of machinery for hand labor has been followed not only by greater simplicity, but by a precision in detail, and accuracy and uniformity in their time-keeping qualities, which by the old method of manufacture are unattainable. A smoothness and certainty of movement are secured which proceed from the perfect adaptation of every piece to its place. The extent of the Waltham establishment, the combination of skilled labor, with machinery perfect and ample, enable them to offer watches at lower rates than any other manufacturers. Their annual manufacture is said to be double that of all other makers in this country combined, and much larger than the entire manufacture of England. The mechanical improvements and valuable inventions of the last fifteen years, whether home or foreign in their origin, have been brought to their aid, and the presence of over 400,000 Waltham Watches in the pockets of the people, is the best proof of the public approval. We offer a Silver watch, jeweled, with chronometer balance, warranted by this Company as made of the best materials in the best manner, and in pure coin-silver "hunting" case; weight 3 oz. This watch we offer as one of our Premiums, with the fullest confidence. Upon the movement of each of these watches will be engraved, "AMERICAN AGRICULTURIST. MADE BY THE AMERICAN WATCH CO., WALTHAM, MASS."

No. 40.—Ladies' Fine Gold Watch.—This elegant Premium will delight our friends who may receive it. Our arrangement with the **American Watch Co.** (see No. 39 above) includes these beautiful gold watches. They are full-jeweled, in 18-carat "hunting" cases, warranted to be made of the best materials, and possessing every requisite for a reliable Time-keeper. Upon the movement of each Premium Watch will be engraved "AM. AGRICULTURIST. MADE BY THE AM. WATCH CO., WALTHAM, MASS."

No. 41.—Breech-loading Pocket Rifle.—This remarkable little fire-arm weighs only eleven ounces, yet shoots with great accuracy and power from 30 to 100 yards, or more, and can be loaded and fired five times a minute. It can be carried in a side pocket, and is accompanied by an extension breech, so that it may be used either as a pistol or rifle. It is put up in a neat mahogany case, with 250 rounds of ammunition. The manufacturers are **Messrs. J. Stevens & Co., Chicopee Falls, Mass.,** and the rifles are sold at retail by **Messrs. COOPER, HARRIS & HODGKINS, No. 177 BROADWAY.** Without the mahogany case, we will give the weapon, all complete, with 100 cartridges, packed in a pasteboard box, on receipt of 18 subscribers, at \$1.50 each. For a full description see *American Agriculturist* for Jan. 1869, page 32.

No. 42.—Double-Barrel Gun; OR FOWLING PIECE.—These guns are the genuine London "Twist" barrel, Patent Breech, Bar Lock, ebony ramrod, and in all respects desirable. Their caliber and length of barrel vary, and may be ordered to suit the kind of shooting to be done. They are furnished for this Premium by **Messrs. Cooper, Harris & Hodgkins, 177 Broadway,** well known as one of the most reliable and best houses in their line of business, and they highly recommend this particular gun, and guarantee it in every respect. It is from one of the oldest and most favorably known English manufacturers. The price is not put on in fancy carving and plating for show, but in the gun itself. This Premium includes Gun, Powder-Flask, Shot-Pouch, and Wad-Cutter.

No. 43.—Charles Pratt's Astral Oil supplies a great Public Want for a Safe, Reliable Illuminating Oil. It is manufactured by him and packed only in the Guarantee Patent Cans, expressly for FAMILY USE. It has more body, and an equal quantity will burn longer and give more light than other oils. The constant recurrence of explosions, fires, devastation, and death resulting from the use of what is called Kerosene Oil—but really a mixture of Benzine, Naphtha, and other highly inflammable substances, the use or sale of which is an in-

fringement of United States Law—has induced us to place this article on our premium-list as a humanitarian as well as a useful act. The Board of Health of the city of New York have examined scores of samples of Oil obtained from as many different dealers in this city, and nearly all have been found far below the Government standard and entirely unfit for use. This "Astral Oil" is from the **House of Chas. Pratt, 103 Fulton St. Mr. P.,** a merchant of high reputation, will keep up the article to its present standard. It has been tested, and fully indorsed by the highest scientific authorities in the land. The Guaranty Cans are made of tin, and sealed so that none of the oil can be removed without breaking the seal, thus securing safety in transportation. The can is inclosed in a strong wooden case, and may be returned for refilling. For 19 subscribers at \$1.50, or 65 at \$1.00, we will send a case containing 12 one-gallon Guaranty Cans of Oil, which may be distributed among a club.

No. 44.—Comstock's New Horticultural Implements Combined.—*The Hand Cultivator and Onion Weeder* will do the work of six men with hoes. It pulls the weeds and thoroughly pulverizes the soil. It is as much superior to the hoe for all small drill culture, as the mowers and reapers are to the scythe and cradle. *The Seed Sower* is the most perfect small-seed drill we have seen. It sows Beet, Parsnip, and other difficult seeds with the greatest regularity, and it is specially adapted to sowing Onion seed at the rate of 4, 5, or 6 pounds to the acre. It is readily attached to the Cultivator. *The Strawberry Cutter* takes off the runners and at the same time cultivates between the rows. After another year's trial of these implements on our own grounds, and the entire satisfaction they have given to all who ordered them of us as premiums, we offer them again and recommend them as being all the inventor claims—"the best in the world." For 19 subscribers at \$1.50, or 65 at \$1.00, we will give the Cultivator and Weeder and Strawberry Cutter, price \$12.00.... For 22 at \$1.50, or 75 at \$1.00, we will send the Cultivator and Weeder and Seed Sower, price \$15.00.... For 27 at \$1.50, or 90 at \$1.00, we will send all these implements complete, price \$18.00. Manufactured by **Comstock Brothers, East Hartford, Ct.,** who furnish descriptive circulars to all applicants. See cuts in *American Agriculturist*, page 127, 1869, and page 118, 1870.

No. 45.—The American Submerged Pump.—Every family needs a reliable pump, capable of raising water easily and rapidly from the bottom of the well, be it deep or shallow—one that is durable, that will not get out of order, or be liable to injury from frost or gravel. When we add to these the qualities of a powerful force-pump, ability to throw water 60 or 70 feet from a hose-pipe, and a construction which renders freezing an impossibility, though it stand out of doors, we think we have a family and farm pump which we can conscientiously recommend. No. 1 will raise 29 gallons of water a minute. This is the pump offered in the list. No. 2, 30 to 35 gallons. No. 3 will raise two bbls. per minute from an ordinary well; and there are larger sizes. Either of these pumps will be furnished for the same number of subscribers required for other premiums of the same price. The pump is set in the well, and nothing but the perpendicular brake and spout appear above the platform. Send for Circulars, to the **Bridgeport Manufacturing Co., Bridgeport, Ct.,** or at **55 Chambers St., New York.**

No. 46.—Family Scales.—These scales, combining the advantages of counter and platform scales, are peculiarly adapted to household purposes. They weigh from ½ ounce to 240 lbs. They have a scoop, or pan, for weighing flour, sugar, or other house stores, and a platform for heavier articles, and are just such an apparatus as is needed for in-door or out-door use, occupying less than 2 feet square. These scales are manufactured by the well-known **Fairbanks & Co., No. 252 Broadway, New York,** whose weighing apparatus has long ranked as the standard in all parts of the country. Send to them for circulars, if desired.

No. 47.—Crandall's Improved Building Blocks furnish a most attractive amusement for children. Churches, Dwellings, Barns, Mills, Fences, Furniture, etc., in almost endless variety, can be built with them, and the structures remain so firm as to be carried about. For developing the ingenuity and taste of children they are unequalled. The Blocks are put up in neat boxes, accompanied by a large illustrated sheet giving various designs of buildings, etc. This is one of the most successful toys ever invented.

No. 48.—B. O. B.—The "Boy's Own Boat"—a Real Toy Steamboat, that will propel itself on the water for over half an hour. This beautiful toy is durably made, elegantly finished, and is just the thing for bath-tubs in winter and ponds and streams in summer. The boat is 18 inches long, and fitted with Ryder's Dollar Steam-Engine and Dodge's

Propeller. The engine has a perfect-working safety-valve, whereby any excess of steam passes off. It is one of the most pleasing and instructive toys ever produced. Printed directions for management accompany each boat.

No. 49.—The Great Dictionary.—WORCESTER'S LARGE PICTORIAL UNABRIDGED EDITION, containing 1854 three-column pages, with a multitude of illustrative engravings. (The work is a large quarto volume.) Most of the thoroughly educated men of the country consider this as by far the best Dictionary in the English Language. It gives the spelling and pronunciation of every word in the language with full explanations, and as a source of general information stands next to a Cyclopædia. The Dictionary can be called for at our office, or be sent by express or otherwise to any part of the country. It should be in every family. It is published by **Brewer & Tileston, Boston.**

Nos. 50 to 58.—Volumes of the American Agriculturist (Unbound).—These amount to a large and valuable Library on all matters pertaining to the Farm, Garden, and Household, and contain more varied information on these subjects than can be obtained in books costing three times as much. The price of the volumes is \$1.50 each, at the Office, or \$1.75 if sent by mail, as they must be post-paid.—They are profusely illustrated, the engravings used in them having alone cost at least \$100,000. Those obtaining premiums for less than fifteen volumes can select any volumes desired, from XVI to XXXI inclusive. For ordinary use, the sets of numbers unbound will answer.

Nos. 59 to 68.—Bound Volumes of the Agriculturist.—These are the same as Nos. 50 to 58 above, but are neatly bound in uniform style, and cost us more for binding and postage. Sent post-paid.

No. 69.—Farmer's Boy's Library.—A few dollars' worth of books pertaining to the farm will give the boys new ideas, set them to thinking and observing, and thus enable them to *make their heads help their hands*. One such book will, in the end, be of far more value to a youth than to have an extra acre of land on coming to manhood. Any smart boy can easily secure this Premium, and he will have two sterling works by a well-known, practical farmer. They are Allen's New American Farm Book, and Allen's American Cattle.

No. 70.—Farmer's Boy's Library.—Both the books in No. 69, and also Herbert's Hints to Horsekeepers, and Henderson's Gardening for Profit.

No. 71.—Farmer's Boy's Library.—The four books in No. 70, with the addition of Fuller's Strawberry Culture, Gregory on Squashes, Brill's Farm Gardening, and Harris on the Pig.

No. 72.—Farmer's Boy's Library.—The eight books in No. 71, with the addition of Thomas's Farm Implements, Tim Bunker Papers, and Waring's Draining for Profit.

No. 73.—Farmer's Boy's Library.—The eleven books in No. 72, with the addition of Fuller's Grape Culturist, Breck's New Book of Flowers, and Hunter and Trapper—in all 14 fine volumes.

Nos. 74, 75.—Bound Volumes of Hearth and Home.—These volumes are neatly and uniformly bound in cloth, with title in gilt on back and side. With their beautiful engravings, and abundance of useful and entertaining reading for all the members of a family, they will prove valuable additions to any library.

Nos. 76 to 87.—Good Libraries.—In these premiums, we offer a choice of Books for the **Farm, Garden, and Household.** The person entitled to any one of the premiums 76 to 87 may select any books desired from the list of our books published monthly in the *American Agriculturist*, to the amount of the premiums, and the books will be forwarded, Post or Express paid. Let the farmers of a neighborhood unite their efforts, and through these premiums get an agricultural library for general use. See Table List of Books in advertising columns.

No. 88.—General Book Premium.—Any one sending 25 or more names, may select books from our list to the amount of 10 cents for each subscriber sent at \$1; or 30 cents for each name sent at \$1.20; or 60 cents for each name at \$1.50. This offer is only for clubs of 25 or more. The books will be sent by mail or express, prepaid through, by us. See List as in No. 76.

A GREAT BOON. A Good Cheap Sewing-Machine at Last.

We have been offering as a Premium, for some months past, the **Beckwith new \$10 Sewing Machine**, which has been fully described in the *American Agriculturist* for March and April. We have already given and sold some hundreds of these machines, and testimonials of satisfaction are coming from every quarter.

See what the People Say.

Hundreds of letters have been received by us and by the Beckwith Sewing Machine Co., extracts from a few of which are given below.

VAN BUREN, ARK., May, 1872.

GENTLEMEN: We have just received from Orange Judd & Co. one of your machines. We are very much pleased with it, and write to know terms to agents.

Respectfully, DECHERD BROS.

CONCORD, OHIO, April, 1872.

GENTLEMEN: I purchased one of your machines of Orange Judd & Co. My wife is learning to use it. We are much pleased with it this far.

Yours truly, R. DURR.

No. 3. A. & G. R.R., GEORGIA, April, 1872.

GENTLEMEN: Seeing your improved machine advertised in the *American Agriculturist*, and relying on Orange Judd & Co.'s statements, we sent to them and got one of your machines, with which we are much pleased. Have shown it to several friends, and I presume several orders will soon be sent to Orange Judd & Co. or to you.

Respectfully yours, J. A. M. KING.

NEW YORK, May, 1872.

GENTLEMEN: It is due your laudable enterprise to state that, having had in my family one of the Beckwith Sewing Machines from its first appearance, its great merits are more apparent the longer we use it. My wife makes all her dresses on it with ease and perfect satisfaction, as well as everything else she desires to sew. She has recently made a heavy silk dress with it, and is now making a light summer dress. Having formerly been accustomed to the use of first-class large machines, she greatly prefers the little Beckwith. Its ease of operation, its simplicity, and always being in perfect order, together with the great convenience of taking it with her wherever she goes, and of using it wherever she pleases, are considerations so greatly in its favor, that it must soon become the favorite of every household. Yours respectfully,

LEANDER FOX, 35 Varick St., N. Y.

WASHINGTON, D. C., March, 1872.

GENTLEMEN: Received the machine and letter sent by you on the 8th inst. After an examination and trial of the former, sewing with it nearly the whole of several garments, including one of cloth, I can say that it gives entire satisfaction. Very respectfully yours, etc.,

H. L. CLARK.

CHESTNUT CREEK, ALA., April, 1872.

GENTLEMEN: On the 30th day of March last, my wife, Mrs. E. A. Floyd, inclosed \$10 to the Beckwith Sewing Machine Co., and waiting several weeks she became very impatient,

as women usually do, but she has received the Beckwith Sewing Machine in good order and complete in every part, and says she would not take fifty dollars for it if she could not get another like it. It does all you claim for it. Several persons have seen this machine at work, and are well pleased with it. If you would receive the money through the Express Co. on delivery, I would like to have one dozen of them sent immediately to this office. I am satisfied that I can sell one dozen per week easily. I am County Surveyor for Baker County, and mixing with the people daily.

Respectfully yours, etc., GEO. W. FLOYD.

KENANSVILLE, DUPLIN CO., N. C., April, 1872.

GENTLEMEN: The machine has been received, and works like a charm. Yours respectfully, R. H. BROWN.

BRUNSWICK, MAINE, March, 1872.

GENTLEMEN: Your machine was received in good order, and I think very highly of it, and they will find a ready sale. Should be very happy to take the agency or buy machines of you to sell again. Yours truly,

B. L. DENNISON.

HAMILTON, LOUDON CO., VA.

GENTLEMEN: Please send me your terms to agents for the Beckwith Sewing Machine. We are much pleased with ours. I would like to have the agency of this county, if terms are satisfactory.

Very respectfully, WM. H. BALL.

ANNA, UNION CO., ILL., March, 1872.

GENTLEMEN: Yours of late date to hand, and contents noted. Am glad to learn your demand is more than you can supply, and hope you every success possible. My machine came all right, and such a novelty you can imagine, and so surprising to do such work, is really astonishing! Have experimented considerably, and am well pleased, and think I will soon be an expert at the business.

Yours truly, W. S. MORGAN.

SALISBURY, MD., March, 1872.

GENTLEMEN: The sewing machine came safely to hand, and on trial I find it complete. The dearest little machine ever was made. I am quite in love with it. A gentleman told me last night that he believed I could sell a hundred here in town, and urged me to write and get the agency.

Yours respectfully, Miss SALLIE BUSH.

FOND DU LAC, WIS., March, 1872.

GENTLEMEN: I have received from the office of the *American Agriculturist* one of your \$10 sewing machines, and am so much pleased with it that I would like to know on what terms you supply agents, and what is required of them. An early reply will oblige

Mrs. EDWARD COLMAN.

We have contracted with the Beckwith Sewing Machine Company for a large number of them to supply our own friends, and as *Premiums*. Each machine is put in a neat, compact box, with *hemmer and guide, oil-can with oil, thread, different-sized needles, etc.*, with full Printed Directions for using, and delivered to any express office in this city, without extra charge above the \$10. As we buy the machines at wholesale price, we have decided to give our readers some advantage of this, and we therefore propose to make a present for himself or herself, or for any friend, of one copy of *Hearth and Home* or two copies of the *AMERICAN AGRICULTURIST* for the balance of this year (1872), to those persons who send us \$10 for one of the machines while this offer is continued.

The New Sewing Machine as a PREMIUM without Money.

To enable those to get this machine who can not raise even the \$10 to buy it, we make the following offer:

We will send the Machine free to any one who will collect and forward SIX subscribers for **HEARTH and HOME** one year at \$3 each; or **TWELVE** subscribers to **AMERICAN AGRICULTURIST** for one year, at \$1.50 each.

Almost any lady can readily secure this small number of subscribers and get a machine free; or some friend can thus obtain it for her, as a present.

GEORGE W. FISHER,
P. O. Box 233, Rochester, N. Y.

THE PRACTICAL POULTRY KEEPER.

A COMPLETE AND STANDARD GUIDE TO THE MANAGEMENT OF POULTRY, FOR DOMESTIC USE, THE MARKETS, OR EXHIBITION.

Beautifully Illustrated.

By L. WRIGHT.

NOTICES BY THE PRESS.

This book is a valuable manual for everybody who feeds chickens or sells eggs. It suits at once the plain poultryer who must make the business pay, and the chicken fancier whose taste is for gay plumage, and strange, bright birds.

It is the most complete and valuable work on the matters of which it treats yet published. It will be found a plain and sufficient guide to any one in any circumstances likely to occur, and is illustrated with elegant engravings of many breeds of fowls.

This is a reprint, with numerous wood engravings, of an English book, the object of which is to convey in plain language a great deal of practical information about the breeding and management of poultry, whether for domestic use, the markets, or exhibition.

It is a handsome volume, brought out in the best style, and enriched with nearly fifty illustrations. It is evidently the fruit of a thorough, practical experience and knowledge of fowls, and will be found a plain and sufficient guide in all the practical details of poultry management as a profitable business.

The subject is treated fully and ably by an experienced hand, and the volume will doubtless find a large sale among the growing class of poultry fanciers. It is embellished with numerous illustrative engravings.

The author has called to his aid all who were experienced in the subject whereof he writes, and the consequence is a volume of more than ordinary thoroughness and exhaustiveness.

The book is a complete and standard guide to the management of poultry for domestic use, the market, and for exhibition.

PRICE, POST-PAID, \$2.00.

ORANGE JUDD & CO., 245 Broadway, New York.

READ THE NEW BOOK ON Farm - Gardening AND SEED - GROWING.

BY FRANCIS BRILL.

NOTICES BY THE PRESS.

Orange Judd & Co. have added to their splendid catalogue of agricultural books "Farm-Gardening and Seed-Growing," by Francis Brill; it is practical, plain, complete, and satisfactory, so that for a small amount of money a great deal of desirable information can be obtained.

The want occasionally expressed to us of a work on the cognate subjects above named (Farm-Gardening and Seed-Growing), is now met in a book under this title from the pen of Mr. Francis Brill, formerly a market-gardener and seed-grower at Newark, N. J., and at present engaged in raising seeds at Mattituck, L. I.

Mr. Brill has had large experience, and derived his knowledge wholly from the school of actual tests.—Chicago Evening Journal.

We have in this volume the results of a practical man's experience in raising root crops and other vegetables in the market-garden. Not only the professional seed-grower and trucker, but the amateur gardener who has a little patch in his suburban home, will find many a valuable hint and direction in this full and comprehensive manual.—Sunday-School Times.

It seems to be a very sensible, practical work by a practical man. Mr. Brill's father was a gardener, and he himself has had an extensive experience, and he talks about what he knows, which is more than can be said of many authors of industrial works.—Moore's Rural New Yorker.

There can be no question that this farm-gardening can be made in many districts of the Southern Atlantic States, especially near the coast, far more profitable than growing the ordinary staple crops. In connection with producing the vegetables, the growing and saving their seeds receive minute attention.—American Farmer (Baltimore).

A very useful hand-book, not merely for farmers and growers of seed on an extensive scale, but for all who, whether for recreation or for the purpose of supplying their own families with garden products, desire to know something about the adaptation of seed to soil and the mode of culture.—Church Journal (New York).

This industry is now occupying the attention of many persons who sell their products to the great seed-houses, and novices who have the facilities, and wish to enter upon the business, will find in this book just the hints needed.—Springfield Republican.

Mr. Brill has been a successful farm-gardener and seed-grower for a number of years, and gives in a clear and concise form the knowledge he has gained. . . . It gives the best method of manuring, planting, and cultivating every vegetable sold in markets—in short, everything required to be known, plainly and fully—and should be in the hands of every one who cultivates so much as a rod of land, for family use, pleasure, or profit.—Suffolk (L. I.) Times.

The seal of Orange Judd & Co. upon an agricultural publication is sufficient guarantee of its worth. Francis Brill's book, published by them, is a very complete work, giving plain, minute instructions as to raising, taking care of, and bringing to market those vegetables which are most in demand in the large cities, and those seeds which are being called for throughout the country.—N. Y. Evening Mail.

The work of showing how this can be accomplished has fallen in good hands, and it has been done well. The book will well repay perusal, and we hope soon to see its good effects in a more intelligent direction of farm industry, and accompanied by more satisfactory pecuniary results.—The Signal (L. I.)

To the market-gardener, or even the owner of a small piece of tillable land, this book will be of great value. Qualities of soil required for the growth of different vegetables, how to plant, how to cultivate, to harvest, and preserve during winter.—N. Y. Citizen and Round Table.

Price, Post-paid, \$1.00.

ORANGE JUDD AND COMPANY, 245 BROADWAY, NEW YORK.

HARRIS ON THE PIG.

Breeding, Rearing, Management, AND Improvement.

With Numerous Illustrations.

By JOSEPH HARRIS,

OF MORETON FARM, ROCHESTER, N. Y.

NOTICES BY THE PRESS.

To say that this work on the pig is by Joseph Harris, that genial philosopher-farmer of Rochester, N. Y., who writes the "Walks and Talks upon the Farm" in the Agriculturist, is to insure for his book at once a large circle of delighted readers. He is just the man to lay down the gospel for the raising of pigs or any other domestic animal. If all breeders and farmers would follow Mr. Harris's directions, pork would be a very different article of food from what it is now, and could be eaten without any fears of the trichina.

[Springfield Republican.

The author discusses the pig—for he takes exception to the word hog as applied to the domesticated animal—with a view of showing how the most pork and lard can be produced from the smallest amount of feed. He gives elaborate descriptions of the different breeds of swine, showing the peculiarities of each, and the relative advantages to the producer.—[Prairie Farmer (Chicago).

The pig is doubtless one of the most valuable animals that a farmer can raise, and it is the laudable purpose of Mr. Harris to tell farmers how to treat their pigs so as to get the most profit from them, and what kind of pigs are best.—[Daily Evening Traveller (Boston).

It treats of breeding, rearing, managing, and improving swine; and what Mr. Harris don't know on these topics, is hardly worth knowing at all. The book is fully illustrated, and is very valuable to all who are interested in this branch of stock-raising.

[Lowell (Mass.) Daily Courier.

The author is a practical farmer, and has gathered the results of many experiments besides his own. The book is amply illustrated.

[Republican Statesman (Concord, N. H.).

Almost everything a farmer wants to know about the breeding, keeping, and fattening of pigs, is here put down in plain, common sense, and is mainly the result of the writer's own management.—[Maine Farmer.

This is an interesting, valuable, and a much-needed treatise on an important department of rural economy. It contains about 53 illustrations of pigs, piggeries, troughs, etc. We are heartily glad our old friend Harris was persuaded to prepare this useful Manual on the Pig—breeds, breeding, feeding, etc., comprising what farmers need know respecting this department of husbandry.

[Boston Cultivator.

This little book is profusely illustrated, and contains information in abundance, which every farmer ought to possess.—[Weekly Mail (St. Louis).

Here is a book written by a practical farmer, who has brought to the aid of his own large experience and observation the most extensive acquaintance with the science of breeding, and, as might reasonably be expected, we have from his pen the best book on the Pig ever written.—[Western Stock Journal.

Price, Post-paid, \$1.50.

ORANGE JUDD AND COMPANY, 245 BROADWAY, NEW YORK.

Standard Books on Architecture.

WARING'S BOOKS FOR FARMERS.

DRAINING FOR PROFIT AND DRAINING FOR HEALTH.

By GEO. E. WARING, JR.,
Engineer of the Drainage of Central Park, New York.

CONTENTS.

LAND TO BE DRAINED; HOW DRAINS ACT; HOW TO MAKE DRAINS; HOW TO TAKE CARE OF DRAINS; WHAT DRAINING COSTS; WILL IT PAY? HOW TO MAKE TILES; RECLAIMING SALT MARSHES; HOUSE AND TOWN DRAINAGE.

EXTRACTS FROM NOTICES BY THE PRESS.

He (the author) describes the action of draining upon the soil, the construction of single drains and systems of drains, the cost and the profit of thorough drainage, the making of tiles, and the reclaiming of salt marshes, treats sensibly of malarial diseases, and closes with a chapter which should be widely read, on house drainage and town sewerage in their relations to the public health.

[Portland (Me.) Press.

Nowhere does this book merit a wider circulation than in the West. Every year adds to the thousands of dollars lost to this State from want of proper surface drainage, to say nothing of the added gain to result from a complete system of under-drainage. This book will prove an aid to any farmer who may consult it.

[Chicago (Ill.) Republican.

A Book that ought to be in the hands of every Farmer.
SENT POST-PAID, - - - PRICE, \$1.50.

ELEMENTS OF AGRICULTURE.

A BOOK FOR YOUNG FARMERS,

By GEO. E. WARING, JR.,

Formerly Agricultural Engineer of the Central Park, in New York.

CAREFULLY REVISED.

CONTENTS.

THE PLANT; THE SOIL; MANURES; MECHANICAL CULTIVATION; ANALYSIS.

The foregoing subjects are all discussed in plain and simple language, that any farmer's boy may understand. The book is written by a successful *practical farmer*, and is full of information, good advice, and sound doctrine.

HORACE GREELEY says of it: "Though dealing with facts unfamiliar to many, there is no obscure sentence, and scarcely a hard word in the book; its 254 fair, open pages may be read in the course of two evenings and thoroughly studied in the leisure hours of a week; and we pity the man or boy, however old or young, who can find it dull reading. Hardly any one is so wise that he will not learn something of value from its perusal; no one is so ignorant or undeveloped that he cannot generally understand it; and no farmer or farmer's son can study it thoughtfully without being a better and more successful cultivator than before."

THOROUGH - BRED STOCK.

JERSEYS.—Three young Bulls, Cows, and Heifers.
AYRSHIRES.—Four young Bulls, Cows, and Heifers.
GUERNEYS.—One two-year-old Bull, one Bull calf.

THOROUGH-BRED PIGS.

BERKSHIRE PIGS of the very best blood. My Berkshire Sow "Queen of the Realm" took Sweepstakes Prize for all breeds of pigs at the New England Fair in 1871.

ESSEX PIGS, equal to any in this country or any other.

SPLENDID YOUNG BOARS AND SOWS now ready for shipping.

Prices reasonable. No extra charges for boxing and shipping. Safe arrival guaranteed.

Perfect pedigrees given with all thorough-bred stock, which may be seen at my farm (Hardsdale), Florence, Mass. Send communications to

PHASES OF THE MOON.

Table with columns for MOON, BOSTON, N. YORK, WASH'N, CHA'STON, CHICAGO.

AMERICAN AGRICULTURIST.

NEW YORK, NOVEMBER, 1872.

Winter is rapidly approaching. What we do must be done quickly. The days are getting shorter and shorter, and the weather colder and more uncertain. November on the farm seems to an outsider a dreary month. A city visitor wonders what pleasure we can find in such a life. He is glad to get back to the gas-lit streets and the warm and cosy rooms of his city home. Sitting in his comfortable chair, by a bright open fire, in a well-furnished library, reading the evening paper or talking with his friends, he may well be excused for congratulating himself that he is not a farmer. From his stand-point, farm-life seems dull, and dreary, and dirty! He forgets that the faithful performance of duty gives happiness. The farmer has plenty of work to do. And he finds pleasure in doing it. Digging potatoes and putting them in the cellar is dirty work. A farmer, with his pantaloons stuck in his boots, walking through a muddy bare-yard, or milking in the rain, is not an attractive picture. Carrying will to the pigs is not an ennobling occupation. It is no use to deny it. But we have known politicians to do dirtier work with less benefit to themselves and the country. Farmers should guard against plodding. Let us work when we work. Let us put spirit and force and energy and thought into all that we do. Let us study to economize labor—to apply it to the best advantage. Let us discipline ourselves. There is much in a farmer's life to call out all the best, highest, and noblest faculties of our nature. It has been truly said that no one can succeed as a breeder unless he is a gentleman. And it is no less true that to attain the highest success a farmer must be a man. The field that demands the most attention is himself. He should aim to root out every bad habit, and to develop every manly quality. He must be prompt, regular, systematic, thoughtful, energetic, industrious, orderly, kind, not easily provoked, temperate in all things, economical, hopeful, and patient. We are very sure that there is no occupation more useful and honorable than agriculture, and

none in which there are more frequent opportuni- ties for the cultivation of every noble faculty.

Hints about Work.

It is a good plan to write down a list of every- thing that has to be done before winter sets in on the farm, in the garden, in the orchard, in the wood lot, in the barns, sheds, horse and cow sta- bles, corn-house, piggery, hen-house, cellars, etc., etc. Consult with the members of your family and the hired help on the subject. Encourage them to give an opinion as to the best way of doing the work and how long it will take. Go as much as possible into details—especially in regard to the implements, tools, etc., that will be needed.

What to do first is an important question, and should have careful consideration. You must take the uncertainty of the weather into account, and aim to plan so that whether it is wet or dry, cold or warm, there shall be no loss of time and no loss of or injury to crops. It shows bad planning to husk corn in the barn during warm, dry weather, and afterwards to dig potatoes in a snow-storm.

The Most Important Work for the month is the care and management of animals. In our anxiety to push forward the labor of gathering and scen- ring the crops we too often neglect to give that daily attention to our live-stock, on which so much of the loss or profit of farming depends.

Horses.—Avoid as far as possible exposing horses to storms. When on a journey aim to feed at the regular hour. If nothing more can be done, take along some corn-meal and put a quart in a pail of water, and stir it up while the horse is drinking. It will greatly refresh and strengthen him. Many horses suffer from dyspepsia, and one great cause of it is irregularity in feeding and giving too much grain when the horse is fatigued. When a horse has been exposed to a storm, and comes home in an exhausted condition, give him a warm bran- mash. Put two or three quarts of bran in a pail, and pour on two or three quarts of boiling water and stir it up. Then add cold water sufficient to cool it to the temperature of new milk, and give it to the horse. Blanket the horse and rub his head, ears, and legs dry, and afterwards rub him dry all over. Many an attack of colic would be avoided by these means. We think many farmers err in not feeding their horses more grain. It would be better to work harder, or at least more constantly, and feed higher. Of one thing we are very sure: not one farmer in ten grooms his horses sufficiently. It is a shame to a man to leave a horse at night, after a hard day's work, until he has been rubbed clean, dry-bedded, and all his wants attended to.

Cows.—During storms cows are far better in a dry stable or shed than in the field. A little extra feed in the shape of corn-fodder, hay, bran, or corn- meal will prove very profitable. It is a good plan to flesh up a cow at this season. You will get it back again in milk next spring and summer.

Young Cattle should be liberally fed and pro- vided with comfortable quarters. It pays to give a growing animal all the food it can eat and digest.

Sheep.—There is nothing so essential to the health of sheep as dry land, shelter from storms, and fresh air. Low, wet land, dirty yards, and close, damp quarters are fatal to their health and vigor. In dry weather, no matter how cold it may be, sheep are better in the field, but during storms they should be brought into the yards, and kept dry. If they do not go under cover of their own accord, they should be driven in and shut up until the storm is over. Animals do not always know what is best for them. "Nature" is all very well, but reason, observation, and experience are far better. But we repeat that the shed or barn must be dry, clean, and well ventilated. At this season of the year grass is often too succulent and deficient in nutri- ment, and it is very desirable to give sheep access to good hay, and half a pint of grain each per day, or a pint of bran, can often be fed to great profit.

Long-wool and South-Down Sheep, which grow

rapidly and mature early, require liberal feeding while young, and will pay well for it.

Breeding Ewes should be selected with care. Draft out all that have lost their teeth, have bad udders, or are in any way defective. Select the ram with even still greater care. He ought to be pure-bred, and as near perfect as you can get him. A defect in a thorough-bred will be impressed more strongly on his offspring than the same defect in a ram of mixed blood, and so will his good qualities. Put but one ram in the flock at a time. It is well to remove him every evening and shut him up for the night, and give him a pint of oats and a pint of bran. It is also very desirable that the ewes have liberal feed for some time before and at the time the ram is with them. Salt regularly, and see that they do not want for water.

Lambs should be kept in a flock by themselves, and have the best of food and care. If any are affected with scours, give half a pint of milk porridge, made with wheat flour.

Ticks are often very troublesome in winter or early spring, especially on long-wool lambs. If not already done, dip all the lambs and sheep in a solution of carbolic soap. Use warm, soft water, and dip the sheep in all over, except the head. Select a dry, sunny day for the operation. Squeeze the wool as dry as possible with the hands, and the sheep will not be likely to take cold.

Swine.—Push forward the fattening pigs as rapidly as possible, and dispose of them as soon as ready. We shall be obliged to accept what we can get. Next year prices will probably be higher, and as corn is cheap, it may be well to keep over our spring pigs rather than fatten them now. Young pigs of this fall's litters should have good care and abundance of nutritious food. Keep them growing rapidly through the winter, and next summer they will thrive on clover, and a little corn will make them ready for the butcher early in the fall. Select good-sized sows for breeding, and secure a well-bred boar. Those who improve their stock of swine are sure of their reward.

Poultry.—Select out the best for breeding, and fatten and dispose of the rest.

Fall Plowing.—As long as the ground is dry enough to work we would keep the plows and cultivators going. Except on the lightest sands, which are liable to leach, there can be no doubt of the advantages of stirring and exposing the soil; and our springs are so short that we should aim to do as much work as possible in the autumn. Plow or cultivate corn stubble and potato ground.

Digging Potatoes.—Use every dry day in finishing this work. There is nothing to be gained by delay, and much to lose. See Hints for last month.

Harvesting Root Crops.—Mangel and other beets should be gathered at once, as they are liable to be injured by frosts. Swedes and other turnips are less liable to injury, but it is better to secure early all that are to be put in pits or in the cellar. It is hardly worth while trying to preserve the tops. Feed them out now, giving plenty of dry food, such as hay and bran, in connection with them. If mangels are kept in pits, be very careful to provide plenty of "chimneys" for ventilation. Our own plan is to put a board lengthwise of the pit on top of the straw, putting only dirt enough on it to prevent the wind from blowing it off. This will keep out the rain, and it can at any time be lifted with a crowbar and the heap examined. If the straw is wet and the roots warm, the heap needs ventilating. We kept 3,000 bushels of mangels in pits, last year, in this way, without loss. We need hardly say that a perfectly dry location is essential.

Carrots not needed until spring, are best kept in pits. Those put in the cellar should be "corded," and not thrown in a heap. The more soil there is mixed with them the better they will keep.

Parsnips are not injured by being left in the ground all winter, and if fed out early in the spring, before they commence to grow, this is much the better way to keep them.

Cabbages are best preserved by plowing a deep

"dead-furrow" in a dry soil, and then lay the cabbages with the roots up in the furrow, and cover the heads with soil. Be careful that no water gets to the heads. Do this in dry, cold weather.

Get Ready for Winter.—If stones are placed in large heaps, they can be drawn where they are wanted for fences or other purposes in winter while the snow is on the ground. Large stones should be lifted with a crowbar, and a small stone or piece of wood put under them, to keep them off the ground; otherwise they will freeze to the earth, and can not be removed without great labor.

Underdrains can be dug in winter, even in the Northern States, provided you make deep dead-furrows where the drains are to be cut before winter sets in. The snow blows into the dead-furrows and keeps out the frost.

Gravel for roads should be screened so as to remove the sand. It can then be drawn on sleighs in winter, and much labor will be saved. One load of screened gravel is worth three loads mixed with earth. There is dirt enough already on our roads.

Work in the Horticultural Departments.

The pleasant weather of October has given the gardener time to make everything in and around the garden snug and ready for winter. The harvests of vegetables and small fruits have been unusually large the past season, but unless continued exertions are made bountiful harvests will not be had. It is only by long and arduous labor that a gardener becomes successful, and through the use of improved methods and labor-saving implements. In the more southern latitudes, out-door work can be continued during the month, and it must be remembered that a man can do more labor in a day at this season than during the hot and sultry days of August and September, even though the number of working hours is less now than then. Everything in the way of rubbish should be cleared up, so that the grounds may look neat during the winter, and also to save much valuable time in the spring when work is pressing.

Orchard and Nursery.

Many of the operations mentioned in this department last month will hold good for the present, and a little careful thought will suggest others which we may fail to mention on account of space.

Planting done now will save a great deal of time in the spring, and trees are pretty sure to live in moderate climates if properly planted, and protected around the roots with a good mulch.

Seeds of trees for nursery stock may be planted now and subjected to the action of frost. Chestnuts, walnuts, acorns, peach-stones, etc., are much more likely to germinate than if allowed to dry until spring. Seedlings raised last spring will need mulching, and to be protected from cold winds by means of evergreen boughs or board fences.

Heeling-in.—When trees are not planted at once in the orchard, it is customary to lift them from the nursery rows and heel them in. When treated in this way they do not start until until two or three weeks after those left in the nursery. There is danger, however, that the work will not be done properly, and many do not advise it, but if the trees are carefully lifted, and no air-holes left around the roots when set in the trenches, the process is perfectly safe and reliable.

Ripening is the first step towards decay, and the more this process is retarded the longer the fruit remains in a sound condition. The fruit-room should be opened whenever the temperature will permit, or when it is not warmer outside than in.

Stocks for Root-grafting.—Take up, assort, and tie in convenient sized bundles, pack in boxes of sawdust or sand, and place in a cool cellar.

Fruit Garden.

Pears that have been carefully preserved will bring good prices now if put up neatly. The best method of marketing choice specimens is to pack

in shallow boxes containing a single layer of fruit each, wrapping each pear in soft white paper.

Covering plants, whether with earth or straw, should not be done too soon, nor left until too late. The best time is just as the ground is about to freeze; if covered before this, there is danger of the plants heating, and consequent decay.

Root-Cuttings of blackberries, raspberries, etc., are very easily made, and where a stock of any new or valuable variety is needed this is the readiest method of propagating. The roots are cut into pieces of two or three inches in length, and packed in a box containing earth; the box should be provided with holes to allow water to run off, and then buried in a dry place deep enough to be safe from frost; if the ground is naturally moist, provide a drain.

Cuttings of gooseberries, currants, and quinces may be planted now, taking care to press the soil firmly against the lower ends of the cuttings.

Grape-vines.—This is the best season in which to trim grape-vines, unless they can be pruned very early in the spring before the sap has commenced to flow. There have been so many methods given in previous numbers of the *Agriculturist*, that it will not be necessary to repeat them here; but whatever method is employed it is best to leave upon each cane one or two buds more than are necessary, in order to guard against winter-killing; the extra buds may be cut off early in the spring. Do not cut the cane off close to a bud, but leave about an inch of wood above each bud.

Grape Cuttings.—The wood cut off in pruning may be used for propagation. Cut into pieces of six or eight inches in length, and tie in convenient bundles and bury in sand, and place in a cool cellar.

Kitchen Garden.

Look over the directions given for last month concerning the preparations for the soil, etc. See that as much of the soil is spaded or plowed up as possible. Grass land intended for use next summer should be heavily manured and plowed. Put in drains where they are needed.

Asparagus.—After the frost has stopped the growth of the tops, cut them off and burn, and apply a heavy coating of manure.

Roots.—After digging what parsnips, salsify, and horseradish are needed for winter use, the remainder may be left in the ground over winter. If the other root crops have been harvested and stored, as recommended for last month, they may be covered with earth as soon as settled cold weather renders it necessary.

Manure.—Every means should be used to increase the stock of manure, and everything that can be converted into a fertilizer should be carefully saved. Plenty of dry earth should have been secured to use in the earth-closets. Save all house slops, provide a heap of soil through which are placed layers of leaves to receive them; it will become a valuable fertilizer next spring.

Rhubarb.—Better transplant for new beds now. Cover the old beds with plenty of manure.

Cold-Frames.—Cabbage and cauliflower plants wintered in a cold-frame often suffer from too much heat; they will bear considerable freezing without injury. Place the sashes on the frames at night only, unless the weather is unusually cold.

Celery may be stored in trenches now, or left until later in the ground banked up with earth. The trenches for storing it during the winter are to be made a foot wide, and as deep as necessary to admit the plants. The roots are to be set close together without any earth between, and when cold weather comes on covered with straw and boards to keep out the rain.

Cabbages.—Store as recommended for last month, but wait until the ground is about to freeze up before giving the final covering.

Spinach.—Apply a slight covering of hay or straw to protect it through the winter. In the warmer latitudes it may be thinned and sent to market.

Soil.—Prepare soil for use in hot-beds next spring.

If left until then, it is likely to be frozen so hard that it will be difficult to procure it. Store in some place convenient to the hot-bed, and cover with boards or sods.

Sweet-Potatoes.—Dig as soon as the frost has touched the vines, selecting a warm day. Put them in barrels after they have dried an hour or two in the sun; pack in dry, chopped straw, and place them where the temperature will not fall below 60°.

Flower-Garden and Lawn.

Comparatively little can be added to the notes given last month, most of which will answer for now. Always bear in mind that a day's work done in the fall will be so much saved in the spring.

Planting can still be done in some places this month, but all trees and shrubs planted now should be mulched thoroughly to prevent the roots being dried by cold winds.

Bulbs should have been planted last month, but if the ground is still open they may be put in now with good results. Cover all bulb-beds with a coating of leaves or straw.

Chrysanthemums.—Stake those which are now in flower. They are generally hardy, but keep better if the roots are taken up after they are done blooming and kept in a cool cellar.

Dahlia.—Take up those still in the ground, and after drying the tubers thoroughly, store in a cool cellar, or under the stage of a cool greenhouse.

Protection.—Those things which are to be covered should be attended to as soon as the weather gets very cold. Straw, evergreen boughs, and hay are all good substances to cover with.

Lawn.—If the lawn needs mauling, use fine, well-rotted stable-manure spread over the surface evenly, taking care to break all large lumps. In the spring this may be raked off, leaving the lawn in a good condition.

Greenhouse and Window Plants.

Look out for sudden changes in the weather. A sudden cold snap may do a large amount of damage to valuable plants if provision is not made for heating the greenhouse on short notice. The heating apparatus should be in good order, so that no delay need occur when it is wanted for use.

Insects.—If the plants were returned to the greenhouse properly cleansed, the few insects that make their appearance during the winter may be easily held in subjection.

Bulbs.—Some of those potted last month may now be brought into the greenhouse. In order to get flowers for the holidays, six weeks in the greenhouse will be sufficient.

Camellias.—Keep the plants in a cool place, so as to retard the flowering. A few for early blooming may be brought into heat now.

Propagation.—A stock of cuttings may be put in now for early spring flowering.

Climbers.—A greenhouse should be provided with plenty of climbers, in order to cover the posts and rafters as much as possible. Passion-flowers, Hoyas, etc., produce a good effect. If quick-growing plants are wanted, Tropæolums are valuable.

Window-Boxes will need refilling and arranging, so as to make a good show during the winter.

Hanging Baskets make very pleasing ornaments for a room, and if carefully arranged and tended they are a source of pleasure during the winter.

Commercial Matters—Market Prices.

Gold advanced to 115½ and declined to 112½, closing October 12th at 113 against 113 on the 13th of September. The movements in Breadstuffs, since our last, have been on a liberal scale, both in the way of receipts, sales, and shipments of the leading descriptions, with, however, a variable market as to prices, influenced to a considerable extent by the fluctuations in gold, the stringency in the money market, and the comparative scarcity of ocean freight room. Flour, Wheat, and Barley closed in

favor of buyers, while Corn, Rye, and Oats left off with more firmness. The Provision trade has been less satisfactory. Pork and Bacon have been irregular in values; Lard, much depressed; Beef, about steady; and the finer grades of Butter and Cheese held with more confidence. Wool has been quoted lower, and unusually dull, manufacturers purchasing very reservedly, and only to supply urgent wants. Cotton has been quite active, but cheaper, closing, however, rather buoyantly, as the offerings of stock fell off considerably. Hops receded rapidly under large receipts of new, but closed steady, on a moderate business, at the reduced figures. Hay, Hemp, and Seeds quiet. Tobacco in moderate demand, and quoted stronger in price.

The following condensed, comprehensive tables, carefully prepared specially for the American Agriculturist, show at a glance the transactions for the month ending October 14, 1872, and for the corresponding month last year.

Table with 5 main sections: 1. TRANSACTIONS AT THE NEW YORK MARKETS. 2. Comparison with same period at this time last year. 3. Exports from New York, Jan. 1 to Oct. 10. 4. Stock of grain in store at New York. 5. Receipts at head of tide-water at Albany each season to Oct. 7th.

CURRENT WHOLESALE PRICES.

Table listing prices for various commodities including Flour, Wheat, Corn, Rye, Barley, Oats, Beans, Peas, Eggs, etc., with columns for Sept. 13 and Oct. 11.

New York Live-Stock Markets.

Table showing live stock market data: WEEK ENDING, Receipts, Cows, Calves, Sheep, Swine, etc., for Sept. 16th, 23rd, 30th, and Oct. 7th.

Beef Cattle.—The features of the market for the last four weeks have been much the same as for the month ending September 9th. Good cattle have been comparatively scarce, and with slight fluctuations, prime native steers have ruled steady and firm at full prices; but the market has been over-supplied, sometimes absolutely glutted with Texans, Cherokees, and immature rough native, and for all grades below fair prices have ruled low, and the trade has been dull and unsatisfactory. Common to fair Texas cattle have been generally sold at 7½¢. @ 8½¢ per pound, to dress 55 lbs. to the gross cwt.; fair to fat Cherokees at 8½¢ @ 10½¢; and common to strictly prime native steers at 9½¢ @ 13½¢ per pound to dress 56 lbs. and 60 lbs. to the gross cwt., some very common mixed lots of State steers and heifers falling to 8¢ @ 9¢, and a few extra and premium bullocks rising to 14¢ @ 15¢. To September 30th last 342,505 Texans passed eastward through Kansas, by the Chisholm Trail, against 411,341 to the same date last year, a falling off of 98,839; but the number received at this point has been larger than for any previous season.

Table showing prices of the past 4 weeks for various live stock categories like Range, Large Sales, and Averages.

Milk Cows.—The receipts for the month exceeded the arrivals during the previous month by an average of 15 per week, and the demand has been barely equal to the supply. Good cows have been quickly sold at satisfactory figures, ranging from \$55 to \$75; and extra large, fleshy cows, with evident fine milking qualities, were taken by private parties at \$85 to \$95, and one at \$105, but poor trash, culled from dairy herds, had to be sold at bayers' own figures—\$25 to \$35. Calves.—With no important change in the numbers received weekly, the market has been unusually steady; and for fat, milk-fed veals, prices have ruled high and firm. Common to good milk-fed could be sold on almost any day at 7¢ @ 10¢ per pound, and grassers at \$5.50 @ \$12 per head, chiefly at \$6 @ \$8. Sheep and Lambs.—The market has been fair, with no very large or sudden fluctuations in prices, but shippers have complained of the slim margin for profit, and often of considerable losses. Towards the close of the month the receipts were heavier than the immediate demand called for, and most of the advance which had been gradually made during the previous three weeks, was lost, the latest transactions being at 6½¢ @ 6¾¢ per pound for common to prime sheep, in lots; and 6½¢ @ 8½¢ for lambs—a few of the best sheep going at 6¾¢ @ 7¢, and choicest State lambs at 9¢. Swine.—The total for the month shows a large increase, and the demand has more than kept even pace with the increased supply, so that a slight advance has been made in prices, with a decidedly active trade at the close. Dressed hogs readily sell at 6¾¢ @ 7½¢ per pound; pigs at 7½¢ @ 7¾¢, and live hogs at 5½¢ @ 5¾¢. Jersey pigs, dressed, are selling at 8½¢ @ 9½¢ per pound.

containing a great variety of items, including many good Bibles and Suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Remitting Money: — Checks on New York City Banks or Bankers are best for large sums; make payable to the order of Orange Judd & Co. Post-Office Money Orders, for \$50 or less, are cheap and safe also. When these are not obtainable, register letters, affixing stamps for postage and registry; put in the money and seal the letter in the presence of the postmaster, and take his receipt for it. Money sent in the above three methods is safe against loss.

Postage: On American Agriculturist, 3 cents a quarter, in advance; on Hearth and Home, 5 cents per quarter. Double rates if not paid in advance at the office where the papers are received. For subscribers in British America, the postage must be sent to this office for prepayment here.

Bound Copies of Volume Thirty are now ready. Price, \$2, at our office; or \$2.50

each, if sent by mail. Any of the last fifteen volumes (16 to 30) will also be forwarded at same price. Sets of numbers sent to our office will be neatly bound in our regular style, at 75 cents per vol. (50 cents extra, if returned by mail.) Missing numbers supplied at 12 cents each.

Clubs can at any time be increased by remitting for each addition the price paid by the original members; or a small club may be increased to a larger one; thus: a person having sent 10 subscribers and \$12, may afterward send 10 more subscribers with only \$8; making a club of 20 at \$1 each; and so of the other club rates.

Other Items for which there was not room in the "Basket" will be found on page 437.

Steel Engravings and Lithographs of a single color are very common and very cheap now, as it costs but a penny or two to strike off copies, after a single plate or stone is prepared, even though of very large size. Good steel engravings will always hold a high place, as they are valued by many, but the demand runs largely to oil-paintings in lively colors, and the perfect copies of them now made by the chromo-lithograph process, which are by far the most popular as well as the most pleasing.

No more Stamps.—Since the first of October last, no stamps are required on receipts or legal documents, as deeds, mortgages, or bonds; only bank-checks now require stamps.

Gather Leaves.—There is no more valuable waste product of those farms which possess wood lots than forest leaves. They make excellent bedding for all stock, are one of the best absorbents, decay very rapidly, possess valuable fertilizing properties, and cost nothing but labor to gather them. They should be raked up before snow falls, gathered into heaps, loaded by means of large barn-baskets into hay-racks with the open sides closed up by light boards, and stored in a shed for use during winter.

Blunt's Mushroom Strainer.—We have examined this very ingenious device for straining the water entering the suction-pipe of any kind of pump. We take pleasure in recommending it as an improvement on all the strainers we have hitherto seen. While it will work perfectly in only three inches of water, it is better than the usual form for deep water, as when the water is let out of the suction-pipe it can not rattle the well by its action on the bottom. Any one having a strainer that is not entirely satisfactory would find this one to be all they could desire.

Taylor's Horse and Cattle Food.—"G. E. W.," Millin Co., Pa., asks whether Taylor's Horse and Cattle Food, advertised in *American Agriculturist*, would be any help to him in keeping his stock in good health.—We believe it would. We have investigated this article, and one of our associates has tried it with good results. We find that it is favorably thought of by the superintendents of several horse-car companies, and used regularly by them. It is quite certain that cattle and horses need some condiment given with their feed, regularly, to keep them in good health, and we believe this "vegetable food" is as good as any in the market.

Conventions of Stock Breeders.—The National Convention of Short-horn Breeders is appointed to meet at Indianapolis on the 27th November. Delegates have been appointed from many of the States, of which we have been advised, and it is to be hoped that no State will fail to be represented at this Convention. The Swine Breeders' Convention is appointed to meet at the same place, immediately on the close of the Short-horn Breeders' meeting, and as important matters are to be then and there considered, those interested would do well to make a point of attending. Delegates from each State and Canada will be in attendance.

A German Almanac.—The *Illustrirter Farmerfreund*, 1873, an agricultural almanac edited by H. Nicholas Jarchow, is just published by Orange Judd & Co. It contains besides a calendar hints about work, followed by several valuable agricultural articles. This Almanac is beautifully illustrated. 12mo, 144 pages. Price 35 cents.

Records of the Weather.—The Annual Report of the Meteorological Observatory of Central Park, New York, is received. This is a valuable contribution to the general mass of information by which the apparently unstable operations of the weather are reduced to tables of averages, from which laws may be deduced. Dr. Draper shows conclusively in his report that the climate has undergone no change, so far as can be ascer-

tained by the records available, which date from so far back as 1750. On the contrary, certain periods, into which the whole time may be divided, show that the average temperature of each agrees very nearly with that of the others, showing that the changes in the physical condition of the surface of the country—the removal of the forests and the breaking up of the surface for cultivation—has had no disturbing effect, on the whole, either on the temperature or the amount of rainfall. But our own observation in the course of years goes to show that while the rainfall and temperature may remain the same, yet the evaporation from the soil and the rapid disappearance of the rainfall from the surface and the instability of streams are much augmented by the rapid clearing of formerly wooded countries; and as these effects are very noticeable to ordinary observers, it is easy to see how the popular idea is created that our climate is seriously affected, while to a scientific observer no such results are apparent. And yet, practically, to the farmer there is a marked difference, which interferes to some extent with his operations.

A Novel Directory.—We have before us a neat volume of 500 pages, entitled the "Tobacco Trade Directory," giving some 60,000 names and locations of tobacco manufacturers and dealers in various parts of the world, comprised in five parts: 1st. Tobacco manufacturers in the United States; 2d. Cigar manufacturers in the United States; 3d. Dealers in tobacco and cigars in the United States; 4th. Manufacturers and dealers in foreign countries; 5th. General index for every town in the United States. Such a work must have cost a great amount of labor, and will be useful to all interested in this branch of business. The work is issued by the "Tobacco Leaf Publishing Company" of this city, and supplied at \$5 per copy.

Many Matters.—"A Subscriber," Baltimore Co., Md., sends the following inquiries: 1. Will apples eaten by a cow injure the milk, in taste, or any other way? 2. Will Lima beans succeed in the same ground, year after year, if it is well manured? 3. Is it well to manure and plow the ground in the fall for a corn crop next spring? 4. Will plaster have as good effect on grass when spread in the fall as when spread in the spring?—Replies. 1. No.... 2. Yes.... 3. No. Corn loves fresh manure and is a rank feeder.... 4. No.

An Old Discovery.—"J. C. G.," East Tenn., has discovered a plan by which 1½ gallon of syrup can be extracted from a bushel of corn-meal, and asks if it would do to take out a patent.—By no means. There are doubtless several patents referring to these processes now in existence, and several more expired, for the discovery is very old. It would be more profitable to make good sweet pork or beef out of this meal than to make a poor substitute for cane-syrup.

Mushroom Culture.—"A. J. R.," Saratoga Co., N. Y. Henderson's Gardening for Profit gives a chapter on mushroom culture. The most thorough work upon the subject is by W. Robinson, Esq. Price, \$3.

Live-for-Ever.—"S. S. D.," Sullivan Co., N. Y., has some of his land "literally thatched" with "Live-for-ever," and wants to know how he shall get rid of it.—This plant, *Sedum Telephium*, is a nuisance, and needs close attention and constant work to get rid of it. The best method would be to mow it as closely as possible, carefully raking up and burning the stems, and by plowing the ground and harrowing turn out the roots, which should be gathered up and destroyed. The ground may be cropped with potatoes and corn, and hoed carefully, until free from the weed. Clear the headlands.

Aylesbury Ducks.—"J. G. McR.," Adairsville, Ga., has purchased some Aylesbury ducks, the majority of the progeny of which have black spots on their heads; he fears he has been imposed upon.—This is questionable. Very often it is found that pure-bred poultry do not breed true to feather, and it is very rare, if ever, that a brood of young are all perfectly marked. It is necessary to mate only perfect birds, and keep weeding out the imperfect ones.

New Jersey State Fair.—The annual fair of the New Jersey State Agricultural Society for 1872, held at Waverley, was well attended, more especially that portion of the grounds which commanded a view of the race-course. The show of implements was very meager, the fruits and vegetables, at least those grown in the State, were not such as should satisfy the requirements from such a State as New Jersey, while the stock—with the exception of the horses, which were kept carefully preserved from view in close stalls, and of which nothing can therefore be said—was very deficient

in quantity and of a very low standard. Is it that the interest in these things is falling away in New Jersey, or what is the matter?

The North Pacific R.R.—The collection of agricultural productions from the Territories opened up by the North Pacific Railroad, now exhibited at the American Institute Fair, is very remarkable as showing the immense fertility of the soil and the favorable climate of those regions. Wheat and oats are shown, both in the straw and grain, which are simply magnificent. The wheat is readily seen by the samples in the straw to yield the amounts stated—viz., 40 bushels per acre of grain weighing 60 to 66 pounds per bushel. Oats yielding 60 bushels, weighing 45 pounds per bushel; timothy sufficiently heavy to ent three tons of hay per acre; several varieties of corn, roots of monstrous size and perfect shape, fruit of fine appearance, specimens of timber, coal, and other minerals—all these go to show that there is no production of the soil wanting to make these North-western regions the homes of millions of successful and wealthy farmers and equally successful and independent artisans. The exhibition is one of the most striking and interesting features of the Fair.

Diseased Potatoes.—"C. G.," Cornwallis, Nova Scotia, asks if it will injure cows to feed diseased potatoes to them. If fed raw they will cause dangerous diarrhoea, but if cooked no harm will occur.

See Page 437 for various items that were crowded out of these pages.

SUNDRY HUMBUGS.—A Tennessee subscriber, referring to our September showing up of the so-called "Rev. Edward Wilson," says his advertisement is in nearly every one of the Southern newspapers, and nearly every place in all that section has one or more of his patients (dupes we should say). One of our correspondent's neighbors took the precaution to write to a Williamsburgh friend about the "Rev.," and received the following terse reply: "First, there is no such a man at the number indicated. Secondly, He is a woman. Thirdly, it is a vile humbug."... An Egyptian corn and "Chion" swindler calls himself G. W. Cornwellie. His name is not in the New York Directory, nor is the name of any one of the bankers, etc., whom he gives as references—one of whom he locates at 449 Wall street, while there are only 120 numbers in that street! His whole story is a humbug, yet so plausibly told that probably he will catch a good many farmers, and get the \$3 out of them which they could not afford to pay for this paper for a couple of years. When they get nothing for their money, they may become wiser and join those who enjoy the benefit of these columns. ... And now comes another "Old Mother Noble"—viz., old Mrs. Abbie M. Cole, a soldier's widow of course, and she wants people to dose themselves with "Old Jonas Appleby's" Sore Medicines, which, according to his daughter (Mrs. A. M. Cole), is a cure-all for nearly all the ills that flesh is heir to. Well, "it takes all kinds of people to make up an assortment," and we suppose there are many of the species that swallow what Mrs. (Mr.?) Cole tells them and sells them—especially the *self*. ... Hoorah! The temperance lecturers can hang up their violins and retire. Druggists had better lay in a very small allowance of opium, for the price will soon fall tricenarily. "Cause why?" Why, one Dr. Beers (not birer, nor beer, nor bear) has discovered a cure for drunkenness—says he has permanently cured over 10,000 inebriates already, and he also advertises a cure for opium-eating. He says there are 100,000 opium-eaters in the U. S. and as all these want to be cured, and he can do it, won't the opium trade have a wonderful decline! Nonsense. See report of our Libel Suit—Dr. Byn's—who advertised a cure also, (in *Heath and Home*, Vol. IV, No. 16.) We charge nothing for the following "prescriptions," which are similar to several we have known of being sold at high prices, and ours is just as effective, and we will merely add that our prescriptions are infallible if "taken according to directions," and here they are: First, To cure your drunkenness, stop drinking liquor. Second, To cure opium-eating, stop eating opium.—N. S. "Marriage Guides," etc. We have a dozen, more or less, of books on matrimony, marriage, and the like, probably all that have been advertised by circulars and otherwise, and we pronounce every book of this kind a humbug. They are got up to advertise the maker or sellers, and draw customers for medicines. Don't read or touch one of them, if you would be safe. The latest one, pretending to tell you a great many things you ought to know, is made to appear to be written by a distinguished physician, and he is said to be connected with a college which does not exist. The pretended "medical institutes," colleges, etc., in Boston, New York, Philadelphia, and elsewhere, including the "Howard Associations," etc., which advertise medicines, and to send prescriptions, are not

to be trusted. These names (medical colleges, etc.) are fictitious assumptions put forth by quack-doctors, who combine in their own person the whole "faculty." There is not a single medical institution that advertises medicines and practice which is trustworthy. . . . The circular of the Albany "Dr. Pardee" contains within itself enough to tell all sensible readers of it whether to send money to him or not, and as others are not likely to read the *American Agriculturist*, we save the room and disgust of treating of him here. This applies to sundry other "medical" pamphlets, "marriage guides," etc., now before us. . . . Every perambulating doctor going through the country with marvelous pretensions, and pretending to be connected with some New York, or London, or Glasgow, or Dublin, or Philadelphia hospital or college, is a thorough quack and humbug. Pray don't put your lives, health, and money at the mercy of these swindlers. This is to answer many special inquiries from Connecticut, Maine, Ohio, Georgia, Minnesota, Tennessee, etc. . . . Newspaper subscription agencies, with great promises, are now located in various parts of the country. Some of these are good and trustworthy, and some are not. We can not yet answer about those that are particularly inquired about. . . . The "Queer" or pretended counterfeit money operator at 609 Broadway, New York, pockets all money sent him, and sends to those ordering, by express, boxes of "sawdust" and old papers with large hills, "C. O. D."—that is, pay the bill before you take your box from the express company, and in a secret place find out what it contains. To blind the letter-carriers, he adopts a great variety of names. We have a large number of his confidential circulars sent to us from all over the country. On these we find the following names sent to different parties with practically the same circular: Stewart R. Parks; Melrose L. Weston; Dr. Chas. F. Tucker; Morton T. Philips; C. W. Clute; Chas. Ring; Geo. W. Ball; Col. Henry Frost; Wm. H. Becket; L. S. McIntyre; L. M. Henderson; Wm. Barteman; Wm. H. Anderson; Geo. W. Bal; W. L. Wholley; B. F. Haller, etc. Others (or the same man) operate at 34 Amity street and 193 Broadway, under the names of Dr. James Meares, G. H. Geery, Anthony Debenham, etc., and as Amos Wainwright, at 170 Broadway, Trenton, N. J. . . . The "Spanish Polley" swindle is carried on ostensibly at 105 Bleeker street, under the name of M. O. Godwin, etc. . . . Circulars and tickets for a Sham Lottery in aid of Cuba have been scattered with a fine show of printer's ink. . . . A swindling chap in Newark, N. J., offers, among a lot of other trash, oroid watches, and unblinking prints letters from agents who relate how they pass those off as gold watches all over the South and elsewhere, selling them for \$50 to \$30 each, though they cost the seller \$9, and are not worth \$1. The same chap sells transparent cards with pictures so lowly that they must not be shown to respectable people. . . . Wells's Lottery (*alias* "Grand Distribution"), at Bridgeport, Ct., is being pushed vigorously. We thought lotteries were prohibited in the "Land of Steady Habits." It is, how! this one tolerated, for no casuistry can make this anything else than a lottery. . . . Our note in reference to B. Fox & Co., in June last year, has been construed by some as a *quasi* indorsement of them. If so understood, we take it back. The catalogue recently sent out by B. Fox & Co. contain advertisements of pictures, etc., etc., that should not be furnished by any respectable party. One parcel of our money sent to their address from a country post-office (through a friend) received no answer, and on his calling about it nearly three weeks afterwards, he was told it had not arrived. Our representative called *incoq.*, and examined some of the pictures, etc., set forth in their circular catalogue in such a way as to catch the lascivious imaginations of young men, and found them of quite a different character from the impression given of them in the circulars—they were of a character so modest as to be safe to sell. Of their value we let the purchasers judge. Of the fairness of advertising them in the colors set forth we have a decided opinion. We regret having been led—by the persuasion and special pleading of one of the firm, and by a desire to avoid even the slightest injustice—to give even the *quasi* indorsement in June last, which has made necessary further investigation and this explanatory note

Ozone and Plants.—Only a little while ago we were gratified to learn that flowers of strong perfume gave off the useful ozone. Now one M. Cloiz has clearly proved that they do nothing of the kind, and the beautiful talk that has been had about health-dispensing flowers was written all for naught.

A String of Questions.—"M. N.," Annapolis, Ill., propounds the following: 1. Are horses subject to distemper more than once? 2. Will the seed of grafted or budded peaches or cherries grow and bring the same kind of fruit they come out of? 3. How to prevent the bitter rot in apples? 4. Will wheat turn to chess or cheat? 5. Will the seed of weeds lie in the

ground longer than one season, and grow?—Answer 1. Yes. . . . 2. No. . . . 3. We do not know, and would like to learn. . . . 4. This question is altogether too old. There is no proof that it will. . . . 5. Yes, some seeds will remain for centuries, if buried deep enough.

Destroying the Turnip-Fly.—The Journal of Horticulture states that the market-gardeners around London have used with great success spent hops strewn between the rows of turnips. This either kills or drives off the flies. This is well worth trying; spent hops as a fertilizer are equal to stable manure.

A Fine White Rose.—"Madame Planter" is probably the best of the white roses. Not only is it a profuse bloomer, but it has fine foliage, and the plant is as hardy as a common brier.

Persian Walnuts.—"A. T.," Tipton, Iowa. We do not know where seeds can be had.

Again.—If persons choose to write to us upon matters of importance only to themselves, and withhold their names, their letters will find the most direct way to the waste-basket.

White Blackberries.—"R. H. C.," Lenke Co., Miss. These turn up every year in different parts of the country. Some have been named, and are cultivated by the curious, but none have become popular.

Mahaleb Cherry.—"G. R." This cherry will bear when the seedlings get old enough.

A Variegated Ice-Plant.—Mr. Peter Henderson informs us that one of the finest "foliage plants" for bedding purposes that he saw abroad, was *Mesembryanthemum cordifolium variegatum*, which name we might as well shorten at once to Variegated Ice-plant.

An Agreeable Fly-Antidote.—A writer in the Bulletin d'Agriciculture says that flies are so disgusted with the perfume of the Golden-banded Lily (*Lilium auratum*) that they will at once disappear from a room in which a flower of it is placed. We wish this were true—but we can all try it.

The Death of J. C. Thompson, of Staten Island, occurred early last month. Mr. T. was not only a public-spirited and highly-esteemed citizen, but a most successful horticultural and poultry amateur. Our back volumes contain several articles from his pen. He brought to his favorite pursuits not only enthusiasm, but a great deal of ingenuity and common-sense. Such men are too rare to allow their departure to go unmarked by a brief token of respect.

Wants a Mulberry-tree.—"S. K.," Woodbury, Pa.—For shade, either the white or black mulberry would answer; for fruit, Downing's Everbearing is best.

Double Fruits.—It seems to us that double fruits have been more than abundant this year. United cucumbers are of very common occurrence. We saw at Newburgh a plateful of double plums. Several apples, apparently two fused into one, have been brought to us. We have not heard of a doubled pear—save Père Hyacinth.

Potato Disease.—The English papers are amusing just now. The potato disease has appeared again, and almost every gardener who ever grew a potato feels called upon to "say his say." As a consequence a vast amount of nonsense finds its way into print. We have looked over much of this rubbish, and find but one practical suggestion, viz.: Plant early varieties, and plant early, as the disease only appears late in the season.

Road and Farm Engines.—Chas. Frankish, Abilene, Kan., wants a steam-engine for plowing, that does not use tackle, and is a perfectly practical machine.—Whether there is such a machine in existence or not is doubtful. There are engines perfectly capable of moving and drawing loads or plows over dry or solid ground, but it is a matter for experiment as yet whether they can be made to succeed under all the varied circumstances incident to plowing or cultivating the soil.

A Practical Concrete Builder.—A "Subscriber" who wished to correspond with a concrete builder, and whose address we have mislaid, by sending his address will be referred to the party desired.

Grass for Wet Meadow.—S. W. Jacobson, Otter Tail County, Minn., wants to know what grass-seed to sow on "a drained wet piece of land" the soil of which is soft and black. This land has probably

been only partly drained by open ditches, and in that case we would recommend Red-top (*Agrostis vulgaris*), to be sown at the rate of two bushels per acre.

Blackberries as a Substitute.—The Gardeners' Chronicle suggests, that when ordinary fruit is scarce we begin to look about for "available substitutes," and recommends the Blackberry. We infer from this that the Blackberry is not an "ordinary fruit" in England. Then the Chronicle recommends the poorest of all Blackberries, the Parsley-leaved, better known among us as the Cat-leaved. If they could have a fair chance at our Kittatinnies or Wilsons, they would throw away the miserable Parsley-leaved, and at once establish the Blackberry as an "ordinary fruit."

Plants Named.—"H. C. B.," Ellenville, N. Y., sends specimens of *Spiranthes cernua*, or Ladies' Tresses; a very pretty plant, bearing white fragrant flowers; described in the *Agriculturist* for Nov. 1871. *Caladiums*: see item on page 423. . . . "I. V.," Fairport, Mich. Your plant with fragrant white flowers is *Valeriana sylvatica*, commonly known as Valerian. . . . Susan King, no State. *Tilia Europæa*, or European Linden. . . . E. B. Coles, Opelousas, La. The specimen sent is *Physostegia Virginiana*; its common name at the North is False Dragon-head. E. B. C. writes that in Louisiana it is known as "Lady of the Lake," on account of its growing near the water. . . . "J. P. A.," Pine Bluff, Ark., sends *Vaccinium arboreum*, or Farkleberry. We never heard of cattle being poisoned by eating the leaves; it belongs to the genus containing the cranberries, blueberries, etc. . . . "Glades," Virginia, sends the same plant as the above in fruit; the berries are mealy and insipid, and ripen late in the fall. . . . R. Sharpe, Eckley, Pa. The climbing plant with pea-shaped pods is *Amphicarpæa monoica*, or Hog Peanut; a very pretty vine, with small clusters of purplish flowers, and has pods underground.

The Vienna Exposition.—Our associate editor, Col. Waring, has been appointed a member of the Advisory Committee to aid the U. S. Commissioner and Chairman of the sub-committee having charge of the items of Agriculture, Horticulture, and Forestry of the American contribution to the great exhibition at Vienna. All who are interested in this department of the exhibition may obtain fuller information by addressing Col. George E. Waring at Newport, R. I.

English Persistence.—Because some one named the California big trees Wellingtonias, most English writers as a matter of national pride stick to the name, although it has long been known that the tree belongs to the old genus Sequoia, and that there was no need of a new name for it. The admirable address of Prof. Asa Gray as President of T. A. A. F. T. A. of Science was upon "Sequoia, and its History," and under this title was published by its author. A recent Gardeners' Chronicle reprints this address, but entitles it "Genealogy of the Wellingtonias, etc." We regard this as a violation both of science and courtesy. While the Chronicle is about it, we wish it would tell us how many "Wellingtonias" there are.

Now for Congress.—Formerly, packages of seeds, plants, etc., could go at a low rate of postage in quantities not over four pounds. In enlarging the parcel-post facilities so as to admit samples of merchandise the limit was fixed at twelve ounces. The post-office authorities construe the law to limit the seed and plant parcels to this amount. We received a few days ago a parcel of strawberry plants on which double letter-postage was charged on all over twelve ounces. The postage amounted to \$3.20. This change has made great trouble to the seedsmen and florists, but this is a small matter compared with the annoyance to the people at large. The former liberal postal arrangements were of the greatest benefit, especially to those who live aside from the ordinary lines of transportation, and the farthest backwoods dweller was made practically near the nurseries and florists' establishments. There is no remedy but in Congress. Let the people insist that the former law shall be restored, and if the mails need relief stop the sending of the useless Pa. Docs.

Cow Leaking Milk.—"H. L. W.," asks what is the reason for cows leaking their milk.—As nearly as we can get at it, it seems to be caused by a laxity of the muscles which surround the glands of the udder, and which so soon as the weight of the milk causes a strain on them give way and open the passage for its escape. Nothing but some mechanical means of supporting the muscles or closing the orifice will avail. Last month we recommended the application of collodion. Possibly an India-rubber ring fitting only close enough to exert a slight pressure might be of use, or at least be worth trying.

The New Rules of the Jersey Cattle Club.—It has been decided that applications for the entry in the Herd-Register of animals whose pedigrees need investigation, shall not be received after December 31, 1872. After that no applications will be considered, except of animals whose ancestors are already recorded, or which have been imported from the Island of Jersey, with the record of their Island pedigrees duly certified. Over three years have now been spent in tracing the history of the animals already in the country, and it is believed that most of the authentic pedigrees are recorded. All having stock whose pedigrees they think may be traced, must, if they wish to have them entered, submit them before the end of this year. Those not applied for before that time will, with their progeny, be permanently excluded from the Register. The total number of entries thus far made is about 3,400—constituting a very full record of all the principal herds in the United States and Canada. A circular, containing full instructions for submitting pedigrees, may be had by applying to the Secretary of the Club at Newport, R. I.

Horse Education.—“A Young Subscriber” asks if the works on the education of horses are of any use to a young man.—Some of them contain useful hints as to the management of a horse, but it would not do to expect to become a horse-tamer by reading one of them. That depends very much on the disposition or character of the man as well as that of the horse.

Potato-Bug Destroyer.—A correspondent from Oregon writes us that he has found out a process to destroy the potato-bug, and asks, do we think it advisable to sell the receipt for 25 cents; if so, he will advertise it in the *Agriculturist*.—If he has got a really effective method of destroying this pest, he could not do better than to make it known freely through the *Agriculturist*. For he should remember that all through his life he has been receiving benefits from others, directly and indirectly, and it is a small business to ask 25 cents for information by which he may benefit others in return.

Willow Poles for Rafters.—“Rustic,” Dubois Co., Mich., asks if willow and poplar poles from four to six inches in diameter will answer for barn rafters.—No, they will be too weak and brittle to safely bear up a roof that may be occasionally loaded with an extra weight of snow. Sawed in four pieces, lengthwise, they would make very good hurdles for fencing sheep-pastures, or sawed in halves would do for a light fence, in place of boards, or to make panels of a portable fence.

Bone-Dust for Meadow.—“W. C. W.,” Hanover C. H., Va., desires to enrich a timothy meadow, and in the absence of stable manure asks if bone-dust would make a substitute, and how it should be applied.—Meadows need potash, which bone-dust does not furnish, but if 200 pounds of bone-dust and 10 bushels of wood-ashes could be applied per acre, early in spring, the meadow would be greatly benefited. 100 pounds of ground gypsum per acre would be also a help to the bone and ash.

Regarding Butter.—Mrs. “F. H. R.,” Iowa, sends us her experience in butter-making, more especially as regards the difficulty of getting the butter to “come” in warm weather. She has avoided this by taking pains to separate the cream from the milk, and by preventing the milk from becoming lopped by frequent stirring. Before churning she has permitted the cream to stand a day or a night after the last stirring, pouring off the watery matter which collects at the bottom of the pan in which the cream has been “set,” and generally has then had no trouble in getting butter.

Light Brahmas and Heavy Eggs.—“T. S.,” Juno, Ripley Co., Ind., reports the feats of his light Brahmas in the way of laying large eggs. Seven eggs weighed 2¼ ounces; the heaviest one weighed 4 ounces, and measured 7¾ inches one way and 6¾ inches the other.

Poultry-Houses.—“E. V.,” wants plans of a first-class hen-house and the best book on poultry.—There are many plans of houses for fowls, and much excellent information and advice on poultry matters generally, in the volumes of the *American Agriculturist* for 1870 and 1871, as well as the present volume.

Cracked Hoof.—“A. T. D.,” Kendallville, Ind., has a horse whose hoof is cracked from toe to coronet, so that it bleeds. What shall he do for it?—The horse must be laid up from work, if possible. The shoe must be removed. The edges of the crack must be pared away at the upper part, so that a distinct separation is made between the crack and the coronet, or between the old horn of the hoof and the substance from which the new

horn grows. No union can ever be formed of the parts separated by the old crack, so that a new start must be had. Blistering ointment may be applied to the coronet, to encourage the new growth, and the hoof should be smeared with tar and bound up, to prevent injury by blows or accidents.

Comfrey.—“E. M. G.,” Oneida Co., N. Y., has half an acre of ground covered with Comfrey, which has become worse by having been plowed. He asks, What shall he do?—There is no remedy but perseverance in cultivating the weed to death, picking up every root after the plow and harrow, and giving it no rest. The roots, being perennial, will submit to no other treatment.

To Dry a Cow.—“D. M.,” Tioga Co., N. Y., has a cow which has been farrow for two years, but which he can not dry up, as she leaks her milk.—The only plan which occurs to us is to feed her on dry feed altogether, such as hay and corn-meal, and fatten her as rapidly as possible. She should have only a small allowance of water, say four quarts three times a day, until dry.

To Prepare for Soiling.—“D.,” Kendallville, Ind., wants full directions for soiling. As in other things, full directions for managing this business can never be full enough; something must be expected from the common-sense or smartness of the farmer himself. When we say that just now a piece of grass and clover should be abundantly top-dressed for use in spring to follow a piece of rye to be sown now for the first feeding, and that a piece of ground should be generously prepared for oats and peas, to be sown as early as possible in the spring, and that one and a quarter or more acres per head should be appropriated for each cow, and a constant succession of crops be made on that ground, the whole tale is told, to be applied as well as may be.

Hops in England and the United States.—There are about sixty-five thousand acres of land in hop-gardens in England, which are estimated to produce about a thousand pounds of hops per acre, or a total of sixty-five millions of pounds. In 1870 the United States produced twenty-five million pounds, of which New York produced seventeen millions and Wisconsin nearly five millions. At the same estimated amount of crop there would be only twenty-five thousand acres in hop-gardens, which would not seem to be overdoing the thing in this country.

Bronchitis, or Inflammation of the Air-Passages.—“E. M. A.,” has a favorite horse which pants and breathes with difficulty, does not sweat, and will not eat freely. A neighbor says it is because he was foaled in August. Is it so, or what is it?—It certainly is not caused by his being foaled in August. The symptoms are those of bronchitis, or inflammation of the air-passages, and may have been caused by overheating and sudden cooling. He must be tempted to eat by scalding his feed, and giving bran and crushed oats with cut hay. A blanket may be strapped around his chest and shoulders, and he should be kept in a stable where no currents of air can blow upon him. Care and good nursing is about all that can be done without the advice of a proper veterinary surgeon. No bleeding or physic is needed.

How to Use Lime.—“E. M. A.,” Forsyth Co., N. C., has 300 bushels of lime, and wants to know how to use it.—If it is air-slaked, as is probably the case, spread it evenly upon the plowed ground or grass, at the rate of 30 bushels per acre. If fresh, slake it, so that it is fine and dry, and spread it.

Farmers' Clubs.—G. A. Boyce, Prospect Depot, Prince Edwards Co., Va., wishes to form a Farmers' Club, and requests secretaries of similar institutions to send him copies of constitutions and rules that may aid in forming such a useful association.

A Despondent Farmer.—“G. W. K.,” Quincy, Minn., is despondent, and quack-grass is the cause of his despair. His farm is covered with it, and he is tempted to sell it and “go West.”—Let him not do anything of the kind, for where can he go to avoid weeds? He must fight them. Plow and harrow, and cultivate the ground, and as the roots are plowed up, gather and burn them, and cultivate the young plants out of existence while they are weak. Quack of course propagates by seed as well as by the root, and the prevention of seeding and careful and clean cultivation will keep it down, and nothing else will. A summer fallow, properly managed, may help him, if other means are not strong enough, but it must be thorough, or it will be useless.

Rotation of Crops.—“Fauquier,” Fauquier Co., Va., is dissatisfied with the present usual rotation of crops, viz., clover, corn, oats, and wheat, for the

reason that there is not sufficient time to properly prepare the oat stubble for the following wheat crop. He suggests wheat on clover sod, corn, wheat, as a better rotation. Very many good farmers besides “Fauquier” entertain the same ideas, and are trying to overcome the difficulty, but the proposed remedy will have the same difficulty in following corn with wheat, when large fields have to be prepared; in fact, the difficulty will be increased, as the time for plowing is shortened by a month at least, by the lateness of the corn crop. We once tried the following rotation with benefit, and see no reason why it should not be successfully brought in, at least in part, viz., clover, corn, oats, clover, wheat. This lengthened the rotation one year, the clover did very well with the oats, and after an early mowing could be very well prepared for wheat. There was the advantage of only two grain crops coming together in place of three, and the exhaustion following the oat crop was recovered. Suppose “Fauquier” should try this. Our experience has been that corn should by all means, if possible, follow a sod.

Orchard Grass and Clover.—“S. D. M.,” Warren Co., N. J., says he read lately in a newspaper that orchard grass and clover seeds should be mixed in equal parts for sowing, and as he wishes to sow some orchard grass and clover, and doubts the correctness of the above directions, he wants further light on the subject.—This fact illustrates the danger of taking directions from newspapers or other journals not devoted to agriculture as a specialty, as to the methods of conducting farm work. Orchard grass seed is always procured in the chaff, and is very light, weighing but fourteen pounds to the bushel, therefore two bushels of it is considered moderate seeding for an acre. Generally such a seeding will give a crop of coarse hay, and if fine hay is desired, three bushels will not be found too heavy seeding when sown alone. When sown with clover, one bushel and a half is a proper quantity, with six quarts of clover seed. If possible, orchard grass should be sown on ground not occupied by any other crop, early in spring, on rich, well-mellowed soil. It is of rapid growth, and makes an excellent pasture grass, especially for orchards or shaded pastures.

Power for Irrigating.—“F. A. O.,” Marion Co., Ill. There is nothing to prevent the use of as common railway horse-power to pump water from a creek or stream to irrigate a field. This question is of sufficient importance to occupy more attention than we can give it this moment, and we shall endeavor to return to it before long in another article, with illustrations and estimates as desired.

Summer Fallows.—“Young Farmer,” Chambersburgh, Pa., asks if we recommend summer fallows as a regular part of the farm work.—Not by any means. He will see by reference to the *Agriculturist* that we have favored summer fallows, all along, only as a means of ridding very foul land of persistent and destructive weeds. Otherwise all the benefits to be derived from fallowing may be secured by a well-cultivated hoed crop, and in the mean time the land is producing a crop.

Disease of a Horse's Foot.—“From the West,” Alleghany Co., Pa., has a mare, lame in the foot; there is no swelling, but tenderness when the frog is pressed or when she steps on a stone, and when in the stable she “points” with the fore-foot.—In such countries as Alleghany Co., Pa., where the roads are hilly and rough, this is a common trouble, and is doubtless caused by disease of that part of the foot which centers around the navicular bone (a small bone in the center of the foot), and is caused by constant and irritating jars upon this highly sensitive part. To the cutting of the frog and the removal of that elastic cushion, provided by nature for the protection of these delicate parts, is due the prevalence of this disease, which unfortunately is rarely curable. An unerring symptom is the throwing forward of the foot by the horse when in the stable, or pointing, as it is called, mentioned as belonging to this case. Absolute rest, with good feed, cooling bandages to the leg, stuffing the hoof with cow dung, making a soft bed of wet clay for the fore-foot to rest in, and rubbing the hoof with glycerine to soften and cool the crust, are the best remedial measures. It is a mistake to suppose the horse's foot is a solid mass of horn; if one is dissected, it will be found a very different thing, indeed, and it should be treated accordingly.

Bridgeman's Gardener's Assistant.—The Virginia Ruralist devotes several columns to a review of this book and criticises it with much severity. The work was in its time an excellent one, by a most competent and respected gardener, but on an unlucky day it was revised and edited by a man conspicuously incompetent to the task. Instead of being brought up to the present time, as it might have been, it is now a singular combination of very good old and very poor new matter.

A \$5 PRESENT

(WORTH \$10)

To Every Subscriber

TO THE

American Agriculturist

For 1873,

Received Now and Hereafter.

(Those subscribing now get the rest of this year Free.)

A Splendid Ornament for every Home.

The Publishers have received from the celebrated American Painter, Mr. B. F. REINHART, a fine Oil Painting, executed expressly for the *American Agriculturist* during the past summer, entitled "**Mischief Brewing**"—a beautiful Rural Scene, for which they paid **\$400.**

This Painting has for some time past been in the hands of the noted firm of Bencke & Scott, who are executing it in Chromo, on 16 stones (not on metal plates, or by any new uncertain process). From these stones each picture will receive at least **16 impressions in colors**, thus producing a *perfect copy of the original \$400.00 painting, and scarcely to be distinguished from it by one person in a thousand.*

At the usual charge for Chromos, the pictures will be worth fully **\$5 each**, and they will be sold at that price; while, taking into account the design, the character, and *quality* of the pictures, if valued at \$10 each, they would still be cheaper than most Chromos sold or given.

By arranging for **200,000 copies**, so great economy is gained in the multiplication of these Pictures, that the Publishers will be able to **present a perfect copy to each and every subscriber to the American Agriculturist for 1873** hereafter received. (It costs no more to put the picture on 16 stones for 200,000, than it would for 1,000 copies.) **The Picture will give great pleasure to every one receiving it, and be a fine Ornament in every Household. It would be worth purchasing at \$5, or more, if it could not be obtained otherwise.** It is a perfect Gem, 11x13 inches inside the frame.

The Picture will be given to every subscriber for 1873 (new or old), whether coming singly at \$1.50 each, or in Clubs of Four for \$5, or Clubs of Ten at \$1.20 each, or in Clubs of Twenty or more at \$1 each. Subscribers in

Premium Clubs will also be entitled to it. It will be delivered at the Office, unmounted, free of charge, or if mounted, for 15 cents extra. If to go by mail, unmounted, 10 cents must be sent to cover cost of packing and postage.

It will be mounted on heavy binder's board, and Varnished, ready for use, even without any frame, or for putting into a frame, for 15 cents extra—that is, for 25 cents it will be Mounted, Varnished, Packed, and sent Post-paid to subscribers (to this Journal for 1873 only), who come in now, or hereafter.

N. B.—The Chromo will be delivered: At the Office, **Unmounted, Free.**
" " " **Mounted, 15 cents extra.**
Sent by Mail, **Unmounted, 10 cents extra.**
" " " **Mounted, 25 cents extra.**

We advise all to have them mounted before leaving the office, as in the large quantities we put up, we are able to mount them for a quarter of the cost of doing it singly, and better than it can usually be done elsewhere.

We shall begin delivering the Pictures in November, in the order in which the names of subscribers are received, beginning with Oct. 1st. All new subscribers for 1873 whose names were received during September will also be presented with a copy if they forward 25 cents for mounting, packing, and mailing.

MANY DOLLARS For ONE.

The *American Agriculturist* has long excelled in circulation any and every other similar journal, or any half-dozen others. This has resulted from the fact that, taking into account its size, *careful preparation*, its very numerous fine Engravings, etc., it has been furnished **far cheaper than any other journal in the world.** [NOTE.—The printed surface of the *American Agriculturist* is nearly equal to most of the \$4 Magazines—the pages being 2½ to 3 times the size of ordinary magazine pages, while not more than one other magazine in the country gives as many costly engravings.]

The former and present character, quality, and value of every number will be maintained, and material improvements be introduced during 1873.

A Splendid \$5 PICTURE will be presented to Every subscriber.

Every new subscription now received will be entered at once in the mail-books, and will be furnished with the paper from the time the name comes in until the end of 1873, at a single subscription price. (This applies to all new subscribers now received, whether singly at \$1.50 each, or in clubs of four at \$1.25

each, or in clubs of ten at \$1.20 each, or in clubs of twenty or more at \$1 each.

Very Valuable Premiums are offered (see page 433) to those who take the trouble to gather up and forward clubs of subscribers. These Premiums are to pay for the time and trouble taken in gathering and forwarding the subscriptions (and good pay they are). The subscribers themselves will each get the \$5 picture, and new ones coming in now will get the extra numbers free.

A Good Paying Business—

for Women as well as Men—

Honorable and Useful.

Several persons of both sexes, in different parts of the country, devote their chief time to gathering subscribers to the *American Agriculturist* and to *Hearth and Home*, and to selling books on Agriculture, Horticulture, Gardening, Architecture, etc. (see list on third cover page, and notices of some of them in the advertising pages). For the subscribers obtained they take the Premium Articles offered on page 433, and sell them as they are all very good, wanted generally, and are readily salable. These Premiums, obtained by the Publishers on special terms, are just as good as money, and give much better pay than could possibly be given in cash commissions. These canvassers, who work during the most favorable seasons, realize from \$300 to \$3,500 a year, according to their tact, experience, etc. Experience goes a great way. Some, who succeeded poorly at first, hardly paying their board, have by persevering practice come to be very successful. The success to be obtained is worthy of long practice. It is certainly quite as honorable and useful to engage in urging people to supply themselves with good reading and useful information, as it is to stand behind a counter and show up, and persuade people to buy, silks, laces, or other goods, or to engage in any other work or business.

\$66.67 to \$100.00 worth of Engravings for ONE CENT.

At least \$10,000 will be expended in procuring pleasing and instructive *Engravings*, of fine quality, for the *American Agriculturist* during 1873. Every subscriber will have a neatly-printed copy of each of these in the pages of the paper, in addition to all the carefully prepared information given in the reading columns. This will give \$66.66½ worth of engravings for every cent of cost at \$1.50 a year; or \$80 worth to those in clubs of four to nine at \$1.25 each; or \$83.33¼ to those in clubs of ten to nineteen at \$1.20 each; or \$100 worth for each Cent, to those in clubs of twenty or more at \$1 each. In addition, every subscriber will be presented with a perfect copy of Reinhart's beautiful \$400 painting, "*Mischief Brewing*," which will be a charming ornament in any home—a picture so much like the original oil painting that none but experienced artists will be able to detect the difference.

Crude Carbolic Acid to Kill Sheep Ticks.—"C. A. L.," Shelburne, Vt., asks where he can get the crude carbolic acid, recommended by "Walks and Talks," to kill sheep ticks.—If your druggist does not keep it and will not order it, your cheapest and best plan is to use carbolic soap. In careless hands the crude acid is dangerous, but carbolic soap is perfectly safe, and if the solution is strong enough, equally effective.

Fall or Spring Planting of Grapes.—"A. L. & Co.," New Hampshire, ask if it is best to transplant grapes in September or April.—Under most circumstances we prefer to plant in spring rather than fall, but in sheltered positions, with dry and warm soils, early fall planting may have advantages over spring. What is meant by early fall planting, is planting done at least a month before frost becomes severe enough to reach to the roots of the newly-set vine or tree. If planting has been done so late in fall that freezing can not be avoided, success would be more likely to follow if the surface is covered with 4 or 5 inches of leaves or straw, to prevent early frosts reaching the roots.

The Jersey Herd-Book, Vol. II.—The second volume of the Herd Register of the Jersey Cattle Club is now in press, and will be ready for delivery in November. It will contain nearly 1,500 new entries. The edition will consist of but 500 copies, and it will be sold, for the same price, with the first volume (\$5), postage additional. Orders may be sent to Col. Geo. E. Waring, Jr., Secretary, Newport, R. I.

Hand-Glasses.—"R. D.," Lloyd, Wis. In this wooden country the bars of hand-glasses are usually made of wood. They are extensively used by many of our market gardeners, made of glass set in light wooden bars, and have a conical top. Many, however, use a frame of wood, about 13 inches in width and breadth—a miniature hot-bed frame, with a miniature sash for covering. This is the cheapest kind of protection for early spring vegetables, such as cauliflower, cucumbers, melons, etc. We know of no one who makes the metallic bar to which you refer as having seen in England.

Will Guano Injure Seed or Young Plants?—Phosphatic guanos will not; Peruvian guano, if of good quality, will. The former may be drilled in with the seed, the latter should be sown broadcast, and harrowed in, or mixed with the soil before sowing.

How to Remove Nuts from Rusty Bolts.—"G. R.," complains of the difficulty he often has in starting a nut on old bolts. Every farmer has experienced the same trouble. We can do little to help him. He must exercise patience and ingenuity. If the bolt turns in the wood, and has a round head, we should nick it with a sharp cold-chisel, and drive a nail by the side of it in such a way as to hold the bolt, or cut the head square with the chisel, and then hold it with pliers. Pour a little kerosene or other oil on to the nut and let it have time to penetrate. Try the nut both ways. If it can be moved at all, the battle is half-won. Keep moving it as far as possible; put on oil, and then turn it back again, and repeat again and again. If a hot iron can be placed on the nut, so as to expand it without expanding the bolt, the nut can often be started. Hammering the nut will sometimes heat it sufficiently to have the same effect.

Cattle Disease in England.—In one single county in England, that of Norfolk, there were in August last at one time, according to a statement in the Farmers Chronicle, ten thousand cases of disease in cattle and fifty thousand cases of similar disease in sheep, and the sheep are found to be equally subject to this complaint (*epizootic aphtha*) as horned stock.

The Flower-Garden.—This is a combined catalogue and journal published by C. L. Allen & Co., Brooklyn, N. Y. These gentlemen are the largest bulb-growers in the country, and the catalogue is mainly devoted to bulbs. Original and judiciously selected articles furnish a good quantity of reading-matter. We are surprised that a person of such good sense as Mr. Allen should devote several pages of his otherwise creditable magazine to such an unprofitable balderdash as that called the "Language of Flowers." If there is a demand for such nonsense it is another proof that the fools are not all dead yet. The subscription price, \$1 a year, is refunded to the subscriber in bulbs or seeds.

Slobbering in Horses.—"H. A. B.," Iowa City, writes that while the *Agriculturist* is good authority, yet he thinks we are mistaken in saying that it is Lobelia and St. John's-wort that causes slobbering in horses, and not the clover, for no horses can be induced to eat these herbs. But "H. A. B." states his case too broadly, and therein falls into an error, for we made the

statement on absolute personal knowledge that it was these herbs caused the slobbering in the case we referred to, and not the clover, for we detected the weeds in the clover which was fed to the horses, and the slobbering ceased when clover from another field in which there were no weeds was fed. There is a diversity of opinion on this matter, but we know that horses will eat both these weeds, both in pasture and in the stable, when they are mingled with the clover; and we know they are sufficient to cause severe slobbering. "H. A. B." rightly says that bran or other dry feed given will cure the slobbering very quickly.

Apiculturist and Floral Guide is the title of a new monthly published at Mexico, Mo., by W. G. Church. The only number that has come to our notice seems to be quite up to the times.

Plowing Twice for Wheat.—"An Ohio Farmer" writes us that last season, having tried twice plowing part of his oat stubble, he found that the yield of the part twice plowed was more than double that of the other, the difference being at the rate of nearly twelve bushels per acre. This year he has hired the plowing of what land he could not plow twice himself, being assured of the profit of the practice.

Lemon and Orange Trees.—"M. W. H.," New York. These trees may be kept through the winter in a room where the temperature does not go below 35°, and it need not be at any time higher than 55° or 60°. They will winter very well in a light cellar or basement. Water only when needed, as they are more likely to suffer from too much than too little. It is impossible to tell when a seedling tree will bear fruit, and on account of this uncertainty, as well as to get a valuable kind, the trees are budded or grafted.

A Green Zinnia.—Anna M. Brown, Carroll Co., Md., sends us a specimen of a double Zinnia in which the rays are mostly green. We have not seen a green Zinnia before, though most of the white ones have a greenish tinge. It is not remarkable that the petals should be green, as they are but modified leaves, and sometimes return to the condition of a leaf.

Extra Value of Choice Cattle.—E. Burr, of New Hampshire, has sold a pair of steers which weighed, dressed, 1,380 pounds each, at 11½ cents per pound. At the same market there were some poorer stock, weighing 900 pounds each, sold for nine cents, and some poorer still which brought six cents only; and yet some farmers think there is no profit in good stock.

A Giant Puff-Ball.—A fine specimen of this fungus was brought us last month from the farm of C. Van Horn, Lafayette, N. J. It weighed 3 lbs. 4 oz., and measured 33 inches in its largest circumference.

Steam Farming and Crops.—In England is a farm of 375 acres, on which for several years the crops have been sold standing, to be removed by the purchaser. This year the crops—a 1/2 grain of various kinds—realized from \$40 to \$75 per acre as they stood. There is no stock fed upon this farm, no manure made, and the plowing and cultivation have been done by steam for many years. Another farm of 600 acres, cultivated on the same plan, had grain, grass, and root crops sold, all of which were removed by the purchasers bodily. What would be said of such farming here?

How to Preserve his Sheep.—"J. C.," Atlanta, Ga., asks if he should pen some cows with his sheep whether they would prevent the dogs attacking his flock or not.—Such a course is not advisable, as cows seem to have a great antipathy to sheep, and very often kill or seriously injure them by hooking. The best plan would be to pen the sheep by themselves, and destroy all marauding dogs in some way.

Keeping Cider Sweet.—"J. M. S.," It is very difficult to keep early-made cider sweet in barrels for a long time. Sulphite of lime (not sulphate) will do it, but this is to many objectionable. Sweet cider may be kept by bringing it to a boil, bottling while hot, and corking and sealing securely. The vinegar question has been answered.

What is a Horse-Power?—"S.," Sidney, Ohio, asks, What constitutes a horse-power? A nominal horse-power is equal to the raising of 33,000 pounds one foot high per minute, and theoretically the force of a falling body of that weight through that space in that time would yield one horse-power. Thus, if 31,000 pounds of water fall one foot in one minute, or 1000 pounds fall 33 feet, or any multiple of feet or pounds that

will amount to the given sum of 33,000 (which is called "foot-pounds"), there will be one horse-power, theoretically, or about three quarters practically. If the number of feet passed over by a stream in a minute be multiplied by the number of square feet in its cross section, and by 62½ (equal to the weight of a foot of water), the result will be the weight passing over a dam in that stream per minute; and this divided by 33,000, of course gives the horse-power. It depends on the kind of water-wheel used, what proportion of this power (from 50 to 80 per cent.) may be utilized.

Hickory-Nuts and Chestnuts.—"A Subscriber" in Connecticut planted a few quarts of nuts by "striking the corner of his hoe a few inches into the sod, dropping in a nut, and then covering"—covered with the sod we suppose, and we are not surprised at the result—"one of the seed came up." Very few seedlings have the strength to force their way through a pasture sod. While the hickory and chestnut are robust as trees, they are while seedlings as delicate as any other plants. Our friend would not expect to get a crop of Lima beans by putting the seed under the sod. If he would succeed with tree seedlings, he must give them a good seed-bed.

Upright Strawberries.—"W. H. K.," Franklin Co., Iowa. The Bush Alpines make few or no runners, and a large plant may, as the nurseryman said, produce a quart of fruit in a season. The fruit is liked by some people, but is to our taste much inferior to other kinds. . . . In your cold climate we would advise planting fruit trees in spring.

Date Seed.—Some one whose signature we can not make out, asks where he can get date seed "in the green state, before it is preserved and sugared."—We were not aware that dates were sugared or preserved in any other way than by drying. If he wishes the seeds for planting, those taken from the dates of the shops will grow readily.

Horse and Cattle Powder.—"Young Farmer" asks if Taylor's Horse and Cattle Powder, advertised in August *Agriculturist*, is a humbug or is it reliable.—No humbugs can be advertised in the *Agriculturist*, as pains are taken to avoid such things. We believe it to be as represented.

White Browallia.—"O. S. D.," Westmoreland Co., Pa., sends us the white variety of Browallia.

Apple Seed.—"Mrs. J. G.," Nobles Co., Miss. Sow in spring as early as the soil can be prepared. If the seed has been well kept it needs no preparation. If very dry and dull-looking, mix it with twice its bulk of damp—not wet—sand for a week or two before sowing. Stir this occasionally, to prevent heating. This will cause the seeds, if good, to become plump, and even sprout if kept long enough. The sand may be sifted out or sown with the seeds.

Kerosene Oil and Lamps.—"R. H. G.," Miss. If the best quality of oil is used—and none other should be—it makes but little difference which of the ordinary lamps are used. We burn the German Students' and House & Perkins' lamps, and like both. As to safety, we look out for that in the oil.

"Death in the Pot"—especially if the pot contains cabbage, according to the Ithaca Daily Leader. Some one sends a quotation from a sheet of that name, but does not say what State. We hope it is not the Ithaca where Mr. Cornell has his University. The worms have been at the cabbage, and it is rank "pizen." Read: "A woman in Newfield died last week from eating cabbage. The report is that a part of the same cabbage that is said to have killed the woman was given to a cow, and, after eating it, the animal died also. Another report is to the effect that a woman in Lansing either died or came near dying from the same poisonous food. Do not put down any 'sauerkraut' this year, and let corn-beef and cabbage cease to be an article of food upon your tables. There is death in cabbage."—This very worm has been at work upon the cabbages of Europe for years, if not for centuries—but it took this Ithaca man to find out the deadly qualities of the cabbages upon which it had fed. It is now about time to trot out the old scares; and some one ought to die from the sting of a locust—and also for that lady to be bitten on the finger by a tomato-worm, and all the rest of it. In the mean time, let those who will, eat cabbage—with or without the worms, as they may prefer.

A Pink Katydid.—"J. P. T.," New Haven, Ct. Thanks for the Katydid of a lively pink color. We have seen the same thing once or twice before.

What is a Chromo?

The liberal offer by the publishers of a fine Chromo to each subscriber for 1873 has led some of our friends who have not kept pace with art matters to ask, "What is a chromo?" Chromo is a convenient abbreviation of chromo-lithograph, or a lithograph in colors. To explain what it is, we must first briefly describe the plain lithograph. Of the various prints or engravings, there are those printed from steel and copper plates and from wood-cuts, but the great majority, both fine and coarse, are lithographs, printed from stone. The stone used is a peculiar limestone, capable of receiving a polish, and yet absorbent of water. To print a lithograph, the stone is first polished, and then whatever design is required is drawn upon it with a pencil made for the purpose, and which contains some greasy matter. Let us suppose that the artist draws a picture, or, what is simpler, prints out the words "American Agriculturist." The stone is then wetted, and the water sinks into the pores everywhere except the place where the greasy ink formed the words. Ink, or paint, is then applied to the whole stone with a roller just as it is to types. This ink does not adhere to the stone where it is wet, but to the words drawn with the greasy pencil the ink will stick. Then a sheet of paper is laid over the stone, and the whole passed under a press; when the paper is lifted off, it will be found to have taken up the ink left adhering to the words upon the stone. This process can be repeated over and over indefinitely by inking the stone and keeping it properly wet. Now, let us suppose that we wish the word "American" printed in black and the word "Agriculturist" in red ink. The lithographer would take two stones, one for each word, and print the black ink with one stone and the red ink with another. He will take care to have the word on each stone in such a position, and to put his paper upon the second stone in such a manner, that the words will be in their proper places. Now, let us suppose that we wish the word "American" in black and yellow instead of all black, and "Agriculturist" red, as before. This will require three stones. The artist will draw with his greasy pencil, *A-a-a* upon the stone for the black, and *n-r-c-n* upon the stone for the yellow, taking care to leave such spaces between the letters, that when the black is printed, and the paper placed on the stone for the yellow, the letters will be in their proper places. This is a very simple case, but it will enable us to understand how the chromos are made. An artist paints a picture, using the colors, and blending them in such a way as will produce the effect he desires. It is the business of the chromo-lithographer to take this picture and reproduce a copy by means of printing in the manner we have described. There must be as many stones as there are colors and tints in the picture. One stone must have all the red parts drawn on it, another all the blue, another all the brown parts of the picture, and so on. Sometimes one color is printed over another in order to get the proper shade, so that, to reproduce the picture, the chromo has to be printed a color and a bit at a time, on from ten to twenty or more stones, every touch of the painter being faithfully copied. When the chromo picture has received 16 or 18 printings, on so many different stones, so that it is shaded every way like the original, it is finally pressed upon a clean stone, which has been cut in grooves like the threads of canvas, and it now has all the appearance of being a real painting on canvas. The reader will see that it is an immense work to prepare the different stones at first, so that each shall have some part of the picture in just the right place and color. It takes three to six months to prepare a set of stones for one picture, even if but one copy was to be printed. But after the stones are once prepared, copies can be transferred to other stones in a few minutes, and after that they can go on and print as many thousands, or tens of thousands, as are desired. Good artists at chromo-printing—such as make our pictures—do their work with such faithful minuteness that not only persons in general, but even the artist himself, would be puzzled to distinguish the copy from the original painting without the closest examination. So the beautiful chromo of "Mischief Brewing," which is being prepared for our subscribers, is, for all purposes of household adornment, fully equal to the picture for which we paid \$400. Truly this is a beautiful process which enables those who have a love for art to enjoy pictures which have heretofore been beyond the reach of all but the wealthy.

MOUNTING CHROMOS.

The chromos are necessarily printed on thick but pliable plate-paper. They can be framed under glass in this form; but it is far better to turn them over to another class of artists, who dampen and paste them on the back, and then spread them very carefully upon thick, strong binder's-board (a kind of paper), and put them in a powerful press to dry. After this, they cover the whole face of the picture with a pure, transparent varnish,

which does not injure the colors, but rather makes them stand out more beautifully, and they can then be cleaned, at any time, of dust or fly-specks, with a damp cloth, and will be very durable. When thus "mounted," they can be set upon a mantel or shelf, or hung up without a frame, or be set into a frame without needing a glass over them. This process requires skill and care, and increases the weight and postage; but in mounting a great number the publishers are able to get it done, and pay the extra postage of picture and packing, for 25 cents each, and they know the pictures will give much greater satisfaction than if sent unmounted.

Who We Are and what We Do.

We are so accustomed to have our statements accepted as the result of actual experience that the subjoined came with a refreshing coolness. It was dated at Syracuse, N. Y., and we give it as written, withholding the name only:

"As a practical farmer I am interested in the contents of your journal, but would it not be much more highly prized by its thousands of country readers, if the articles contained in it were the result of actual experiment, and not the theories of a doctor, colonel, and other professional men? Of course the hints given are often valuable, yet I should feel safer in following its advice if I knew that 'Ogden Farm' and 'Hookertown' had a locality. Even with this uncertainty I prefer the *Agriculturist* to any other farm paper."

We seldom say much about the individuals who make up our editorial staff, but as it may gratify our doubting correspondent, as well as the many new subscribers that come to us at this season, to know that our teachings are those of experience, we give the names of our associates, and what they are doing.

HENRY STEWART is the Office Agricultural Editor. He has long been a successful farmer in Pennsylvania, though for domestic reasons he has been for a year away from his farm. His familiarity with agriculture at home and abroad, and his experience in mining and engineering, and his thorough acquaintance with mechanical matters, make his services most valuable to our readers.

JOSEPH HARRIS is well known as the author of "Walks and Talks," but these are by no means his only contributions. His residence, Moreton Farm, is near Rochester, N. Y., and contains about 300 acres. There is no one in the country better qualified, by preparatory education and subsequent practice as an agricultural teacher, than Mr. Harris.

COL. GEO. E. WARING, JR., lives at Newport, R. I. His Ogden Farm Papers give an account of matters at a farm which he superintends. He is largely engaged in market-gardening, and writes upon many subjects other than those to which his name is affixed. Upon draining and farm engineering, Col. W. is considered the standard authority in the country.

WM. CLIFF has a large farm as well as a successful fish-breeding establishment near Mystic, Ct. It is now no secret that this gentleman is the author of the popular Tim Bunker Papers. Hookertown may not be found upon the map, but Hookertowns exist all over the country. At all events, Squire Bunker is a reality, and as has a specimen of a farmer as we know of.

PETER HENDERSON is known all over the Union as a successful market-gardener, who has by his writings added largely to the wealth of the country. He is now one of the largest, if not the largest, commercial florist in the country.

Besides these, one of our publishers, Mr. L. A. Chase, has a farm of 350 acres, upon which are to be found some of the finest thoroughbred cattle and sheep in the country. His experience and results are always at the service of the editors.

We may add that the Managing Editor, who supervises and harmonizes all the rest, takes the special charge of the Horticultural Department. His large garden, or small farm of ten acres, allows him to test all horticultural novelties for the benefit of our readers. He is assisted by George C. Woolson, who would have been a graduate of the Massachusetts Agricultural College but for the eminent bad faith of that very promising institution.

We submit that the *Agriculturist* is through its editorial corps thoroughly and intimately attached to the soil, and that its teachings are far from being the "theories of a Doctor, Colonel," or any one else. Unless the authority of some other person is given, every statement rests upon the actual experience of some member of our editorial corps, although, instead of giving the name of the particular individual furnishing it, we use the convenient editorial "we."

That our efforts to present a live, practical agricultural paper are appreciated, every mail brings abundant proof, not only in new subscribers, but in letters of commendation from those who have been upon our books for years.

We might fill a whole paper with these, coming from every part of this country, from Australia, Japan, and even from Africa. One at hand from Kentucky says:

"I find your paper very valuable, so much so that I could not afford to do without it. Every number brings me hints which are worth more than the cost for a year."

The following comes from Jonesburg, Mo.:

"GENTLEMEN: I hand you \$1.75 for *Agriculturist* and chromo mounted. Although I am in the lumber business only, I can not do without the *Agriculturist*. This is the sixteenth year I have taken it, and I have made money enough from hints taken from it to pay for one copy five hundred years in advance. You sent it to me twelve years at Salem, Marion County, Ill., one year St. Louis, Mo., two years Jonesburg, Mo., and this will make the sixteenth year. I shall try and make up a list."

From Franklin Co., O., comes the following:

"I have done my best to extend the circulation of the *Agriculturist*, not that I expected to ask a favor, but because I always feel grateful for the information I have received from it. I was born and raised in Philadelphia, and knew nothing about gardening when I moved here (1856), but, thanks to the *Agriculturist*, have one of the best gardens around."

Then from Bowdoinham, Maine, comes this:

"A hint in the *Agriculturist* about using air-slaked lime to prevent the ravages of the cabbage-worm, has been of more benefit to me than the price of the paper for ten years, as it has saved our crop. Don't think I shall be able to do without it now."

A short time ago a merchant called upon us and informed us that he had recently visited the famous Yosemite Valley in California. In the valley he became acquainted with Mr. Lemon, who had been there for thirteen years. For the first two winters he was the only man in the valley, and had no neighbors nearer than ten miles. His house is surrounded with the greatest abundance of fruit-trees of all kinds, with strawberries and other small fruits in profusion. The merchant, in congratulating Mr. L. upon his success, remarked that it must have resulted from great experience. Mr. L. stated that all that he knew about fruit-growing he had learned from the *American Agriculturist*, and that his first budding and grafting were done by following its instructions. Learning that his visitor was from New York, Mr. Lemon requested him to call in at our office and thank us in his name for the great service the paper has been to him in his garden and orchard.

Two Jersey Bulls.—(See First Page.)

The engraving on the first page of this paper represents two Jersey bulls, and probably two as fine of their kind as there are in the United States. Each is a representative animal, and may be taken as a type of the excellence of its special class of Jersey stock.

"Beacon Comet," the upper animal, belongs to that style of Jerseys known as fawn and white with light points. His color is a bright fawn, gradually shaded into lighter tints, which can hardly be called white and yet is not fawn—possibly cream-color would better describe the tint. He is eight years old, and the progenitor of eight later Comets, one of which, "Beacon Comet 8th," took two first premiums, one for the best two-year bull, and another with three cows in the first Jersey herd premium at the last New York State Fair at Elmira. This prize was taken in competition with a herd imported directly from the farm of Queen Victoria.

"Beacon Comet" has been the recipient of first premiums also wherever he has been a competitor. It is unnecessary to describe him more particularly. The engraving is an excellent portrait, and exhibits his points very accurately. He is the property of William Crozier, Esq., of Beacon Stock Farm, near Northport, L. I.

The bull "Wachusett" is a magnificent animal of that class distinguished by black points; the points of the horns, tongue, muzzle, and switch being black, and he has the light ring around the muzzle strongly marked. His figure is extremely fine; the horns are small and fine; the neck is tapering; and the head, handsomely put on, is very delicate, and in fine proportion with the neck and body. He has but very little dewlap, and the tail is extremely slender, with a switch that sweeps the ground. He was awarded the first prize at the New England Fair in 1871, and would be difficult to beat anywhere. His age is five years, his weight about 1,600 pounds, and he is the property of L. A. Chase, Esq., of Herdsdale, Florence, Mass.

Both these bulls are represented in their ordinary condition, and not as gotten up for show. Their owners are breeders who believe in thus keeping up their stock, both bulls and cows, and not in the idea, unfortunately too prevalent, that Jerseys make a better appearance, and are better performers at the pail and the churn, by being kept in poor condition and made to show too much bone and too much belly.

Two Cents a Quart for Milk.

Mr. George Geddes, in a communication to the Tribune, says that farmers generally would do better to sell their milk, as they first strain it, for two cents per quart than to make it into butter and cheese; that when they do so convert it they get only that price, losing their labor in the dairy. It is bad enough to say this, but Mr. Geddes clinches the nail by proving it—which is worse. These are his figures: It takes 14 quarts of milk to make a pound of butter, and a pound of butter is worth, in New York, only an average price of less than 22 cents per pound; 14 quarts of milk make three pounds of cheese, worth at the present an average price of 93 cents per pound. This is not a cheerful computation, but it is one which the "average farmer" must needs accept, and it indicates very clearly that if he hopes for any brilliant success he must in some way get above the average, and a good deal above it.

It is estimated by Mr. Willard that the average annual produce of the dairy cows of America

is either 100 lbs. of butter or 360 lbs. of cheese, representing an average annual produce of say about 1,500 quarts of milk, bringing, at 2c. per quart, \$30. So low an average as this must cover an enormous number of very poor cows, kept by farmers who are, in intelligence and enterprise, very far below those who support agricultural papers, and it would be unfair to address any argument to the readers of the *Agriculturist* based on the practice of this class.

So far as we can judge, those who are known by their neighbors as good farmers—who are very much above the average of their locality—usually get a yearly yield, taking one cow with another, of about 2,250 quarts of milk. This, if made into butter, brings in \$45, and the skimmed milk and buttermilk are worth enough to pay a fair compensation for the labor of the dairy. As they are kept, probably 1½ acre of meadow and two acres of pasture will support the cow throughout the year. The return, then, is equal to \$12.85 per acre. It enables a thrifty man (with a 100-acre farm), who raises his own supply of meat and vegetables, to maintain a family decently, to lay by a trifle each year, and to die with the soothing consciousness that he has done his duty. He has worked hard, has kept the wolf from the door, has educated his family better than he was educated himself, has sent two strapping boys into the world to be something else than farmers, and has settled the duller one on the farm, where he, in his turn, will pass an industrious and faithful life in making both ends meet—or lap by just a little.

If any one thinks that agriculture is to be made an attractive occupation by reason of the examples that such men set, he is vastly mistaken. So long as fidelity, industry, and thrift can secure only this meager share of the rewards of faithful labor, so long will the more intelligent sons carry their labor to fields which promise the bare possibility of something better—where, if failure is probable, success is at least possible. Every well-organized American boy is ambitious, and no youthful ambition is going to be satisfied with \$12.85 per acre. Unless we can make a much better showing than that, we may as well give it up at once.

But we can. Dairying is as good a branch of farming as we can adopt. Let us stick to it. Brilliant success in its prosecution demands three conditions: 1st, a high price for butter (or cheese); 2d, a fair yield of milk from each and every cow; 3d, a large percentage of butter from a given quantity of milk. Never mind "average" men now—we are talking about *brilliant* men, men whose success will be worth more in helping others to improve than would all the preaching we could do in a lifetime. We base our proposition on the fact that *really* fine butter will never lack a market at an extra price. Not fine this week and week after next, and pretty good at some other time, but sure to be A 1 fifty-two weeks of the year. No influence that can be brought to bear will secure an increase of this sort of butter so rapid as the increase of the demand for it. Any dairy with a fixed reputation for such butter is *sure* of at least 44c. per pound over all expenses of sale. This raises the price of the milk to four cents per quart instead of two, and the yield to \$25.70 per acre. How much better than this may be done depends on the man. Ogdén Farm gets 90c., Darlington gets \$1, Sargent gets \$1.15—and every one of these earns it by the quality and the *uniformity* of his product. A hundred women who read this will say their butter is as good as either of the above can produce. To ninety-nine of them we say: "You are entirely

mistaken; you have no idea what really good butter is, and until you find out you must not wonder at your poor returns."

The yield of milk per cow is no less important than the method of manufacture. It takes so many pounds of food to maintain the life of so many pounds of cow—whether she gives five quarts or twenty-five. The profit comes from her ability to use still more pounds of food and convert it into milk. Any man who has a *genius* for dairying will go through his herd and draft out all the second-class cows he has, and sell them for the best price he can get—and then buy as many *first-class* cows as he can afford. If any one of our readers fails to see the point of this without argument, he is not the stuff from which the brilliant dairyman is to be made; he will have to wait until some brighter neighbor sets him an example—by establishing a herd that will produce 3,000 quarts per head, and raise the average returns to \$33.93 per acre. Then will follow the attention to quality as well as to quantity. Instead of 14 quarts of milk to the pound of butter, a careful selection of cows for butter production will secure a pound of butter from 10 quarts of milk—averaging from his whole herd 300 lbs. of butter, bringing a return (at 44c.) of \$132 per cow, or \$37.71 per acre.

In support of the above, we would state that we know now a herd of under-sized cows which produce, in butter alone, an annual average of over \$150, and what has been done once can be done again.

Ogdén Farm Papers.—No. 34.

Mr. W. H. Scarboro, of Payson, Ill., writes to ask several questions of general interest.

Referring to my statement that if it will not pay to buy hay to feed, it will not pay to feed what we raise, he wants a clearer explanation, saying: "If you raise hay and it costs you \$8 per ton, and you feed it out and make \$16 per ton out of it, you have a clear profit of \$8, while it might not be worth \$16 in the market. But if you have to buy hay at \$16, you get no profit from its consumption."—The answer to this is that profit from hay and profit from feeding are not the same thing. If you raise hay at \$8 and sell it at \$16, you make just as much profit as though you fed it to cows and got your \$16 in that way. If it is only worth \$10 in the market, and is worth \$16 to feed, then you can afford to buy it. The principle is simply this: The hay in the barn is worth the market price—what it will fetch, or what it could be replaced for—without reference to where it came from. If you have animals you must feed, or if you have no other way to make needed manure, then you must feed out your own hay, though you might sell it for more than your cows will return, or, if your supply is short, you must buy at whatever is the market price. It seems clear to me that my original statement is quite right, that, if I can't afford to feed out hay that I buy, I can't afford to feed out hay that I raise. In feeding my own hay I have the advantage of having a good customer, and I escape the annoyance of having to buy and pay ready money, but if it is not worth so much to feed as it is to sell (not worth the market price of hay) I shall really lose as much money as though I had bought it—instead of only refraining from selling it. Of course it is understood that a part of the profit in feeding is returned in the form of manure, and manure from purchased hay is worth as much (if from as good hay) as from that raised on the farm.

The next question is: "Can I as well afford to buy all the corn I feed to my hogs as to raise it?"—Probably not, because you can not spare the ready money to buy it with, because you have land that you can most profitably use for corn-growing, and because if you are well situated for the business you have implements and teams that you can most profitably apply to its cultivation. At the same time, if you can make pork at a profit by feeding them with corn you could sell for 50c. per bushel, you can make the same profit by feeding them with corn you buy for 50c. per bushel.

He also asks: "If shoats are to be fattened at 18 months old, will it pay to feed them during the first winter all the corn they will eat, or would you give just enough to keep them growing?"—Feed them not only all they will eat if they have a liberal supply, but all you can induce them to eat, by stimulating their appetite with a variety of other food. The more grain any store animal eats in the winter, the more profit will it make from the green fodder of the following summer. Feed your young shoats all the corn you can, and then look to see them thrive like weeds on their cheaper summer feed. Of course, to get the full benefit you should properly house the pigs, and the corn should be ground, if practicable, and in any case it should be soaked or cooked.

On reading over the above, I am reminded that it is odd business, this answering of questions by unknown correspondents. I do not know Mr. Scarboro, nor his farm, nor his market, nor his qualifications for feeding hay or corn, nor any of the circumstances on which a reliable answer must be based, and there are always ten chances to one that if I did know them, the answers would be very much modified. On the other hand, to withhold an answer would seem ill-natured, and the best any of us can do is to reply to all inquiries according to such light as the letters containing them may give, and to hope that if the answer is not useful to the questioner it may be so to other readers.

The question of abortion in cows has interested me very much, since I have lost half a dozen thorough-bred calves (and to a greater or less extent the use of their dams as milkers), but all my investigation has failed to throw much light on the subject. The first case was that of a cow I had bought over a month before in Massachusetts, and was keeping on a farm a mile away. After she had been there more than a month she aborted with a seven-months heifer-calf. This was the first case in the neighborhood. Soon after this I traded for a common cow, which I found had calved too early, and she came direct to Ogden Farm. Then the ball opened, and within the next two months we had lost eight more calves, some from common cows.

There would be two or three abortions within as many days, and then not another case for a fortnight; then it would break out again, and two or three more would go. Sometimes it would be animals standing side by side, and then in remote corners of the stable (100 ft. x 40 ft.). It took all ages alike, from 2 years old to 12 years old. Some families, of which I had three or four, would lose one, and in another family all three aborted. The Massachusetts cow was with very few other animals, and was fed exclusively on dry hay and a little corn meal and bran. The others were (most of them) kept on steamed food.

Some with whom I have discussed the matter say that abortion is caused by "slinkweed" in the hay, but they have failed to convince me that we have any weed in our meadows which has this effect. I have lately seen it stated that the difficulty is the effect of an insect which penetrates to the womb, creating an irritation that leads to the expulsion of the fetus; the cleanings of the cow contain these insects, whose germs float in the air, find entrance to the parts of other cows, and there develop into perfect insects, and cause them to abort. Concerning this theory we can only say, "Not proven," and even if it were well established, it would suggest nothing in the way of prevention that we do not already follow—the isolation of the cow, and the immediate removal and burial of the fetus and after-birth. Yet, in spite of these precautions, the disease seems to follow its own fitful course.

It is a well-known medical fact, that *ergot of rye* (spurred rye) stimulates the action of the womb and hastens birth. Many cases are cited where cows have aborted very soon after having eaten the heads of rye straw, and it surely would be unwise under any circumstances to allow an in-calf cow to have access to any form of ripe rye. Yet this theory does not satisfy all the conditions of my case, for the Massachusetts cow did not see a spear of rye for over a month before she lost her calf. The animals at Ogden Farm were fed more or less on early cut rye, and it was steamed before it was given to them. However, I shall not take even this chance again. Possibly some of the usual meadow grasses may be subject to the same disease with rye, and ergot is formed upon them.

The foregoing is a statement of my not very lucid opinions and conjectures, and of the meager help I have thus far been able to get from books, all of which is very far from teaching us how to prevent abortion. My friend, Mr. Samuel J. Sharpless—one of our oldest breeders of Jerseys—sends me the following "prescription which is highly recommended as a tonic to prevent abortion. I always keep it on hand, and when a cow or calf seems out of condition, I give it for a week or more, and always with good results":

- 2 oz. Sulphate of Iron, powdered,
- 8 " ground Ginger.
- 8 " ground Fenugreek.
- 8 " ground Caraway.
- 4 " ground Gentian.

Dose.—Half a table-spoonful of the mixture daily, with bran or other feed. It is best to commence with a teaspoonful, until the animals become accustomed to the taste and smell.

I have no doubt this tonic is a capital thing to keep on hand to give in all cases of low condition, and it is quite likely that a low condition always precedes abortion, whether we recognize it or not.

Mr. Charles Sharpless, who has had some experience with aborting cows, gives a sensible-looking hint concerning their after-treatment. In the case of common cows there is no question that the correct thing will be to fatten the animal for the butcher, and to have no more of her. But C. S.'s advice should be followed with valuable thorough-breds. It is, not to let the cow take the bull until at least five or six months after her abortion, and in no case, even if you lose a year, before the month of November. He thinks that in six months' time the cow will be fully "healed," and that if she does not take the bull until November, she will be safely out at grass before the dangerous period arrives. This is usually at about seven months, but I

have had two cases much younger than this. I fancy December would be even safer than November.

If a cow commences to spring bag before her full time, or if she gives any other indication of premature calving, she should be at once removed as far as possible from all other pregnant animals, and kept away from them fully a month after the dropping.

As the season progresses I am more and more satisfied with the condition of the only field that was finally laid down to grass a year ago last spring. We had two good crops of hay and one of soiling grass over very nearly the whole field, and much of it is now (Sept. 27th) ready to be cut again, if it were necessary. Those parts which are the least good, are now dressed with the scrapings of the barn-yard, and the whole tract will have a coating of one ton of fish-guano and one cord of coarse stable manure per acre. By the time the growth ceases, there will be a thick mat of grass for winter protection, and if we don't get 30 tons of good hay (in two cuttings) as the crop of 1873, from 9½ acres, I will agree to be honest about it and own up. I don't want to be too hopeful and claim more for the farm than it can fulfill, but from present indications it will cut enough hay in 1874 to satisfy any hopes I have ever entertained for it.

I do not care to extend a general invitation to visitors to come to Ogden Farm, for the double reason that I am so constantly occupied with various duties, and so much away from home, that I am unable to give them much personal attention, and that it really offers little entertainment to repay the cost and trouble of a visit. 50 acres of grass—most of it newly seeded—and ten acres of corn-fodder and roots are all that are to be seen in the fields. The barn is large and good, and it contains a fine herd of Jerseys, and some useful machinery and fixtures. The dairy is original, and may be interesting to butter-makers. At the same time, I think that most of those who come here are disappointed to find it a very plain, every-day, working farm, with nothing about it in any way ornamental or elaborate. At the same time it may not be amiss to say to all who do come, that I shall be absent, in Europe, until the middle of January, and that when I am here they had better call first at my office, in the city, instead of driving directly to the farm.

One word, too, to correspondents. I suppose I ought to be glad to write long letters to all inquirers, and I should be if I had the time for it, but what with my writing for the *Agriculturist*, my paid services as an agricultural engineer, and the management of my business as a farmer and gardener, I find it simply impossible to do much gratuitous work; and when an enthusiastic and ambitious young farmer asks me, as one does to-day, to "answer my request in full," which is, "I have a farm of 70 acres, and I will ask you how I shall farm it to keep the most stock and make the most money, and at the same time keep improving my farm in value and richness," I can only advise him to take as many back numbers of the *Agriculturist* as he can find time properly to read during the coming winter, to gain such wisdom as he may find from their perusal, and then to add to it the vast fund of information that can be obtained only from well-considered experience; and I hope he will be in no wise offended by my inability to aid him further.

Chinese Pigs.

The steamer *Glengartney* lately arrived at New York direct from China, by way of the Suez Canal, having on board several China pigs. As China pigs directly imported are somewhat rare, and as it is interesting to compare these latest arrivals with those pigs we know as the Chinese breed in the United States, our artist has taken the portraits of a pair which fairly represent the whole shipment. It will be seen that our so-called China pigs possess very many of the characteristics of the parent breed, while they have certainly gained in size. In color, marking, fineness of bone, precocity in fattening, and depth of carcass, our China pigs have lost nothing by their emigration or by their acclimation, as compared with the specimens here illustrated. It will

be observed that there is a marked difference between the two pigs, especially in the form of the ear, one having erect and the other lopped ears. We could not learn whether these pigs had been selected especially for breeding purposes or not, but if they were, we should judge that they were not carefully selected, although something must be allowed for the ill effects of a long sea-voyage, which always unfavorably affects live-stock. It is

not generally known that we, as well as the English breeders, owe to the Chinese pig a considerable share of the improvement which has taken place in the Berkshire breed. The improved Berkshire owes some of its best points to the infusion of Chinese blood into that of the old Berkshire. In addition, the so-called Poland-China or Magie breed, the common hog of the Western States, owes a great portion of its excellence to the China blood contained in it. And

while it is doubtful if the Chinese pig in its pure state would be a valuable addition to our present varieties of swine, or if we have not by its admixture with native blood surpassed the pure animal in the most essential

points, yet we owe a debt to it much greater than is generally recognized. Comparing the portraits of the pure Chinese pigs here given with specimens of those breeds which contain more or less of Chinese blood, it is seen how much the descendants surpass in all important and valuable points the original progenitors, and how much the course of judicious selection

IMPORTED CHINESE PIGS.

and careful culture undertaken by our breeders results in a general improvement of the stock which comes into their hands. This is shown not only in the case of this breed, but in all those which have come under treatment not only of swine but of other species of stock. While we have abundant room for congratulation in this respect, it is still to be regretted that farmers generally can not see it to be to their best interests to avail themselves of the success-

EAST INDIAN AND GIBRALTAR SHEEP.

East Indian and Gibraltar Sheep.

We give above engravings of some foreign sheep brought to New York by the steamer *Glengartney*, mentioned in another article. One of these sheep, that with black wool, is from Calcutta, in the East Indies, and shows what can be done in the way of wool and mut-

ton-growing in that hot climate. It will be seen that the East Indian sheep are not calculated for mutton-producers, nor are they very good wool-bearers, the wool being short and coarse, as might be expected. The white-wooled sheep are from Gibraltar, a district in the south-western part of Spain, which is in the possession of Great Britain, and consists mainly of barren rocks, held only for military purposes. These sheep have a good frame, with long, coarse, straight wool almost like hair, and

have the reputation of being very hardy, and subsisting on the poorest fodder. They are not much superior to our poorest native sheep, and are interesting only as a variety which we very seldom have an opportunity of examining.

Keeping Pigs on Hotel Refuse.

A correspondent in Jersey City writes that he has read "Harris on the Pig" with much interest, but can find nothing said in regard to whether pigs can be successfully and profitably raised upon the refuse of hotels, restaurants, and private residences. "Such refuse," he says, "contains very rich food, such as pieces of cooked meat, soups, stale bread, potato parings, and vegetable refuse of all sorts. The breeding and raising of pork for packing in the above manner has been a hobby with me for several years, but whether I can ever make it practically successful or not remains to be seen. I am strongly inclined to make the experiment. I consulted with an Irishman who has already demonstrated the thing in a small way, and he was very enthusiastic on the subject, saying that he

ful labors of the professional breeders, and by incorporating the improved stock with their own native and comparatively unprofitable animals, add much to their own personal wealth, as well as to that of the country at large.

put four or five hundred dollars in his pocket every year with little or no expense other than the labor of collecting the refuse. He gets feed enough and to spare to feed 25 pigs by going three times a week after his work is done to one hotel and three or four private houses. He says if he only had money enough to buy the stock he would do nothing else. His pigs are in excellent condition, and one sow with fourteen pigs six weeks old was actually fat. May I ask your opinion on the subject, and as to whether pork so raised is healthy? The Irishman referred to says there is no objection made by the packers here to taking his pork."

The most profitable way of using this refuse would be to keep breeding sows and young pigs. If the pigs are fed for the last six or eight weeks on corn-meal, we do not see why the pork would not be healthy. We feed our own pigs all the refuse of the house and dairy, and never thought there was anything deleterious in such food. A well-known and extensive pig breeder in Canada has two large railroad eating-houses. He keeps and breeds large numbers of thorough-bred pigs, and ships them at high prices to all parts of the United States. His pigs are fed almost exclusively on the refuse of the restaurants.

We would advise our correspondent to go into the matter on a small scale at first, and enlarge as he gains experience. Or he might go into partnership with the Irishman, and do business on a large scale. There are many little details to be attended to that can only be learned by actual trial. But we see no reason why the plan might not be very profitably carried out. Pigs may be made very useful scavengers, but unless they are kept in dry, well-ventilated, and properly constructed pens, with due regard to cleanliness, they ought not to be tolerated in a city. A dirty pig-pen is a sore nuisance.

Walks and Talks on the Farm.—No. 107.

The Deacon and I have been to see Mr. Dewey's drilled corn. I have for some years been in favor of drilling in corn, *provided* the land was rich and clean. The Deacon has been steadfastly opposed to the plan. He plants his corn in hills 3½ feet apart, four seeds in a hill. I drill in my corn with a bean-planter. The rows are 3½ feet apart, and the corn is dropped, from two to three kernels at a time, every 18 inches apart. Mr. Dewey drills in his corn with an ordinary grain-drill. The rows are 35 inches apart, and the plants stand from 8 to 15 inches apart in the rows. Mr. Dewey's son drilled in 17 acres in one day. The field was not marked, but the rows are tolerably straight and equi-distant. Three rows are sown at a time. These are at equal distances apart, but the next row varies somewhat, and it is necessary in cultivating to go twice in a row.

It is rarely that one sees such a magnificent field of corn. There is a dense growth of stalks, and many of the stalks have two perfectly matured ears of corn on them, and nearly all of them have one large ear. I should estimate the yield at 140 bushels of sound ears of corn per acre.

"How long have you drilled in your corn?" asked the Deacon. "Well," said Mr. Dewey, "during the war we did not know what was going to become of us. We could not get men to plant the corn, and I had the rheumatiz. I had read about drilling in corn, and so I thought I would try it. It was the only thing I could

do. It was rather rough work, but I had a good crop, and have drilled in my corn ever since."

The truth is, however, that it is not the drilling that gives Mr. Dewey such good corn. He is a *good farmer*. He does not practice "high farming" in the sense in which I use that term. His is a good example of what I call "slow farming." He raises large crops, but comparatively few of them. His first purchase, where he now lives, was 92 acres at \$50 per acre. "And," said he, "I thought I should never be able to pay for it." He has, however, found means somehow to buy land adjoining, until he has now a splendid farm of some 300 acres, that would sell probably for \$125 or \$150 per acre. On this farm he raised this season 40 acres of wheat, 17 acres of corn, and 15 acres of barley and oats. The corn, oats, straw, hay, and stalks are all fed out on the farm, and converted into manure. He has no fixed rotation. He breaks up and sows and plants about as much land as he thinks he can attend to. The land he intends to plant to corn next year has been in grass for seven years. He will put pretty much all his manure on this land. After corn, it will be sown to oats or barley; then sown to wheat, and seeded down again. It will then lie in grass three, four, five, six, or seven years, until he needs it again for corn, etc. This is "slow farming," but it is also good farming—that is to say, it gives large yields per acre, and a good return for the labor expended.

The soil of this farm is richer to-day in *available* plant-food than when first cleared. It produces larger crops per acre. Mr. D. called our attention to a fact that establishes this point. An old fence that had occupied the ground for many years was removed some years since, and the two fields thrown into one. Every time this field is in crops it is easy to see where the old fence was by the short straw and poor growth on this strip as compared with the land on each side which had been cultivated for years.

This is precisely the result that I should have expected. If Mr. D. was a poor farmer—if he cropped his land frequently, did not more than half-cultivate it, sold everything he raised, and drew back no manure—I think the old fence-strip would have given the best crops.

I have great faith in the benefits of thorough tillage—or, in other words, of breaking up, pulverizing, and exposing the soil to the decomposing action of the atmosphere. I look upon a good, strong soil as a kind of storehouse of plant-food. But it is not an easy matter to render this plant-food soluble. If it were any less soluble than it is it would have all leached out of the land centuries ago. Turning over and fining a manure-heap, if other conditions are favorable, cause rapid fermentation with the formation of carbonate of ammonia and other soluble salts. Many of our soils, to the depth of eight or ten inches, contain enough nitrogenous matter in an acre to produce two or three thousand pounds of ammonia. By stirring the soil and exposing it to the atmosphere, a small portion of this nitrogen becomes annually available, and is taken up by the growing crops. And it is so with the other elements of plant-food. Stirring the soil, then, is the basis of agriculture. It has been said that we must return to the soil as much plant-food as we take from it. If this were true, nothing could be sold from the farm. What we should aim to do is to develop as much as possible of the plant-food that lies latent in the soil, and not to sell in the form of crops, cheese, wool, or ani-

mals, any more of this plant-food than we annually develop from the soil. In this way the "condition" of the soil would remain the same. If we sell *less* than we develop, the condition of the soil will improve.

By "condition," I mean the amount of *available* plant-food in the soil. The strip of land on which the old fence stood in Mr. Dewey's field contained *more* plant-food than the soil on either side of it. But it was not available. It was not developed. It was latent, inert, insoluble, crude, and undecomposed. It was so much dead capital. The land on either side which had been cultivated for years produced better crops. Why? Simply because the stirring of the soil had developed *more* plant-food than had been removed by the crops. If the stirring of the soil developed 100 lbs. of plant-food a year, and only 75 lbs. were carried off in the crops—25 lbs. being left on the land in the form of roots, stubble, etc.—the land at the expiration of 40 years would contain, provided none of it was lost, 1,000 lbs. more *available* plant-food than the uncultivated strip. On the other hand, the latter would contain 3,000 lbs. more actual plant-food per acre than the land which had been cultivated—but it is in an unavailable condition. It is dead capital.

I do not know that I make myself understood, though I would like to do so, because I am sure there is no point in scientific farming of greater importance. Mr. Geddes calls grass the "pivot crop" of American agriculture. He deserves our thanks for the word and the idea connected with it. But I am inclined to think the *pivot* on which our agriculture stands and rotates lies deeper than this. The grass crop creates nothing—develops nothing. The untilled and unmanured grass lands of Herkimer County are no richer to-day than they were 50 years ago. The pastures of Cheshire, except those that have been top-dressed with bones or other manures, are no more productive than they were centuries back. Grass alone will not make rich land. It is a good "savings-bank." It gathers up and saves plant-food from running to waste. It pays a good interest, and is a capital institution. But the real source of fertility must be looked for in the stores of plant-food lying dormant in the soil. Tillage, underdraining, and thorough cultivation are the means by which we develop and render this plant-food available. Grass, clover, peas, or any other crop which is consumed on the farm merely affords us the means of saving this plant-food and making it pay a good interest.

Mr. Dewey adopts the so-called summer-fallow of this section. Looking at a fine field of 30 acres of wheat, I asked if it was after barley or oats. "No," he replied, "it is a summer-fallow."

"How many times do you plow in summer-fallowing?" I asked. He and the Deacon exchanged looks. They both take the *Agriculturist*, and know my views on the subject. "Sometimes I plow once," he replied, "sometimes three times, and I have plowed *four* times. Here is a field that was overrun with thistles. I broke it up and planted corn. After the corn was off we plowed it in the fall, and the next year I summer-fallowed it, plowing three times, and cultivating and harrowing when necessary. Then sowed it to wheat and seeded down."

Now, *that* is what I call summer-fallowing. It killed every thistle, and the land will not forget such thorough tillage for years.

"But this thirty-acre field that you summer-fallowed this year, how many times was it plowed?"—"Only once. I broke it up in June with a jointer-plow. I have an Englishman who is a capital plowman. He plowed the field in fourteen days, and made a complete job of it. Afterwards it was harrowed and cultivated, and drilled in with Diehl wheat the first week in September."

This is certainly a cheap and to a certain extent a very effective way of summer-fallowing. The land was plowed full seven inches deep, and the "jointer" or skim-plow threw the sod to the bottom of the furrow, where it was completely covered with four or five inches of loose, mellow earth. There can be no doubt that this plan is becoming more and more popular. Said one of the best and most successful farmers in this section: "I would not let you plow my summer-fallow twice, if you would plow it for nothing."

It may well be that turning up this partly-rotted sod, full of weed-seeds, would do more harm than good. So far as the wheat crop is concerned, it would be better to let these foul seeds lie dormant until the next plowing, three or four years hence. But I still contend that, if we summer-fallow at all, it is better to break up early in the spring (or, better still, if the land is a tenacious clay, the fall previous), and then cross-plow as soon as the sod is sufficiently rotted. Then harrow, cultivate, and roll, and make the soil as fine and mellow as possible in order to induce the weeds to grow. Then plow again, and thus destroy the weeds. After the wheat is up, harrow again, to kill the small weeds while in the seed-leaf.

I am expecting to hear that the readers of the *Agriculturist* are getting tired with my repeated talk about weeds. I have more than once made up my mind not to say another word on the subject. But the truth is I can not help it. It seems to me that there can be neither pleasure nor profit in farming until we get the upper hand of the weeds. I have had a hard fight with them on my own farm, but have succeeded far better than I expected.

The Deacon says he never saw the weeds so numerous as they are this season. He thinks it must be owing to the unusually dry weather that we have had for two or three years. There may be something in this, so far as low, wet land is concerned, but I tell him that it is more likely to be owing to our better plows and better cultivators, harrows, and other implements for breaking up and pulverizing the soil. We use them enough to cause a greater number of weed-seeds to germinate, and to distribute the roots of thistles, quack, wire-grass, etc., but not enough to kill them.

For the first time during the last eight or ten years the midge, or so-called "weevil," injured our wheat the past season. Wherever the crop was late the straw rusted and the grain shriveled up, and there was also more or less midge. But, in the same field, where the wheat grew strong and ripened at the proper season, there was no rust and, so far as I could see, no midge. The past year was the worst season for wheat we have had for a quarter of a century or more, and I see no reason why we should feel alarmed at the appearance of the midge. But I am told that many of our farmers were afraid to sow white wheat, and have sown Mediterranean. Others have sown a mixture of red and white wheat together, thinking that if the midge de-

stroys the white wheat the Mediterranean will escape. The trouble is that the millers will pay little if any more for the mixed white and red wheat than they will for the red alone.

Mr. Peart, the butcher, who went to England last year on a visit, brought me some red wheat that he says yielded 92 bushels per acre. I have sown it, but do not suppose it will be of any value here. Our own varieties are better than our culture. No matter what variety we sow, we can not expect a large crop unless the land is rich, dry, and in good condition.

It would be a great blessing to the country if we should have a good wheat crop next year. The wheat crop of Great Britain this year is unquestionably far below the average, and much of it has been more or less injured by the wet harvest weather. Good, sound American wheat will be wanted, but I fear we shall find that we have not much to spare. Wheat is likely to bring a high price next summer, and there will be an active demand for our next crop, and we could sell immediately after harvest to good advantage. Let us hope for a good crop.

Mr. S. C. Gordon, of Ohio, writes: "What you say in regard to weeds—'cause as many of the seeds to germinate as possible, and then kill them'—is the correct doctrine. But being single-handed, and having rather an old farm pretty well stocked with weed-seed, it is an uphill business."—No doubt about that. But stick to it. Every year the land will become cleaner, and the thorough working of the soil will make it richer.

In regard to the latter point I have no sort of doubt, except in the case of a very light sand. On clays and clay loam, the more you stir the soil the more plant-food will you develop. But it takes time. The Deacon and I used to have a good deal of discussion on this point. He thought it a very bad thing to "sun-burn" the land. But I believe I have convinced him, not so much by argument as by actual experiment, that there is no danger in exposing land to the hottest sun, provided it is frequently stirred. A wet clay soil will bake and perhaps "burn" in the sun; but drain it and reduce it to a fine tilth by repeated plowings and harrowings, and it certainly will not sun-burn. We all know that a good summer-fallow retains far more moisture than land that has been "shaded" with a crop of oats, barley, or peas.

Mr. Smith, of Virginia, writes that he tried to grow some mustard, but that "it was a complete failure, probably on account of the dry season." I did my best to discourage every one from sowing either mustard, rape, or turnips unless the land was in the very best condition. It should be made as fine and mellow as a garden.

Mr. S. adds: "Suffering and loss from drouth seem to be the rule here—or, at any rate, more the rule than the exception. I think this section, however, is on the whole good for sheep husbandry, and with good management I think it would be a good wheat section. I have this year over 20 bushels to the acre on a field of summer-fallow, and I have heard of one man in the neighborhood of Alexandria who had 30 bushels per acre."

"This," he adds, "is certainly not very discreditable to old Virginia, more especially as it has been stated at the New York Farmers' Club that five bushels was considered a good crop in

Virginia. I think those men whose remarks are so widely circulated ought to be more careful in their statements."—I think so too.

"What we want here," continues Mr. S., "is a little more ammonia, and then, so far as I see, there will be no great difficulty in growing wheat. I intend to make that and mutton and wool the chief products of my farm."—Mr. S. has hit the nail right on the head. When I first read his letter, I thought he meant to say: "What we need is a little more money." But he means precisely what he says—"a little more ammonia." He goes to the root of the matter. If you can get ammonia you can get large crops of wheat, and if you can get large wheat crops you can make money. How to get ammonia at the cheapest rate is the great question of scientific agriculture. Keeping sheep, and raising clover, rape, mustard, peas, turnips, and other highly nitrogenous crops to feed them on, and buying some bran, oilcake, etc., in addition, is as good a plan in Mr. Smith's case as I can suggest.

The great trouble is that we do not get money enough for our meat. The consumers in our cities have to pay enough for it, but the money does not seem to find its way into the farmers' pockets. If I want a beefsteak, the butcher will charge me eighteen cents a pound for it, and it is not unfrequently very poor stuff at that. If I want to sell a carcass of beef, I should probably get not to exceed seven cents a pound.

I do not say that the butchers make exorbitant profits. One would think there is competition enough to prevent this. I suppose one trouble is that our beef is not as good as it should be. There is too much bone, tallow, and inferior parts of the carcass in proportion to the choice cuts. We want better bred animals.

One of my neighbors has some thrifty two-year-old steers. "I am overstocked," said he, "and want to sell them, and all that those rascally butchers will offer me is \$35 per head." I presume they offer him about what they are worth to kill. But why kill them? To make them into really good beef they want twelve months of good feeding. Many farmers in this section seem to have come to the conclusion that it does not pay to feed cattle, and are selling off everything that the butchers will take. The consequence is that the meat-market is flooded with inferior beef that must be sold at a low price—and is dear at that. It seems to me that those who have good young animals should hold on to them, and give them good feed. But ill-bred, inferior animals may as well be sold as not. It is impossible to fatten them in winter or keep them over to good advantage.

Turnip Flavor in Milk and Butter.

Col. Thos. S. Strobecor, of Venango Co., Pa., says he has been repaid "many times over" for his subscription to the *Agriculturist* by the simple benefit derived from Ogden Farm's information that if turnips are fed only immediately after milking their taste will not be communicated to the contents of the udder. He states that last winter he fed turnips to five cows until the milk and butter became so strong that it could not be used. He then tried Col. Waring's plan, and found that "there was not a particle of turnip flavor in the milk or butter." After a time the taste returned. On investigation, he found that one of the cows was nearly dry, and was milked only once a day, while she was fed with turnips twice a day. She gave but a pint of milk per day, so that when fed in the morn-

ing she could have had but about half a pint of milk in her bag; yet this received so much taste from the turnips that it spoiled the milk of four other cows in full flow. To make the test complete, he had her milked twice a day, when the difficulty at once ceased, and did not recur.

Evidently a very small amount of milk in the udder will suffice to do the mischief, and if drying-off cows are milked only once a day while on turnip feed their milk should not be mixed with that from the rest of the herd.

A Lock for Sleds.

The engraving below shows a simple and effectual lock, or drag, or hold-back for a sled. There are many cases in which such an attachment to the sled would be a saving of labor to both teams and driver, who in descending hills

LOCK FOR SLEDS.

are worried and tired by efforts to hold back the sled and load. Many serious accidents might be averted by the use of them. They should be made of good iron, and consist of a lever pivoted to the hinder post of the sled-frame, which when raised by means of the handle at the forward extremity, or a cord attached thereto to be used when a tall load is being drawn, depresses the tooth or catch, which is pivoted to the hinder arm of the lever, below the level of the runner, and causes the sled to drag in the snow, and so enables a team to make the descent of a steep hill quite safely.

Movable Manger for Stalls or Stables.

When it is desirable that the inside of a stall or stable should present no projecting points or furniture—a very necessary thing where valuable stock is kept, and a very neat and useful arrange-

A ROCKING MANGER.

ment at all times—the manger and hay-rack may be made movable on the principle shown in the annexed engraving. It represents a manger for a horse-stable, so arranged that it may be swung into the feed passage and fastened there when not in use, leaving the front of the stall inside with a smooth flush surface, and when needed for use may be filled and swung into the stall. The partition between the stall and the passage is represented at *a*, the hooks (*b*, *b*) hold the manger in place, and *c* shows the position of the manger when in use inside of the stall. A

break in the partition shows the position inside. On the same principle the mangers for cows or other stock might be constructed; also hay-racks where long hay is fed, as well as troughs for pig-pens. The manger vibrates on pins, either of wood or iron, let into the ends at the lower part and into the frame of the stall.

Winter-Feeding of Sheep.

We are requested by many of our readers to give them information respecting the fall and winter out-door feeding of sheep. Most of these inquiries come from Virginia, where the climate—as in many other of the Southern States—is well adapted to this method of sheep culture. It is a favorable sign of an improving condition of agriculture when the desire is becoming prevalent to raise crops to be eaten off the ground by sheep folded thereon. It is one of the more advanced arts of agriculture, which so far has been considered—but erroneously so—as not adapted to our climate. It is, wherever practicable, a great economy of

labor, both in harvesting and storing the crops eaten, and in caring for and hauling and spreading the manure made. Sheep are better spreaders of manure than most farmers or farm hands, and very easily accommodate themselves to and readily understand the system of folding.

The crops which may be eaten off the ground by lambs or sheep are of considerable variety. Clover, blue-grass which has been kept for winter pasture, rape, mustard, turnips, or any other roots may be used. The roots may be gathered and sliced and fed in troughs or scattered on the ground, or if shallow-rooted, as the white or yellow turnips or the ruta-baga, may be fed as they grow in the drills. The means of inclosing the sheep are the main difficulty, but it is easily met. Where small timber abounds, light hurdles may be made as described and figured in the *Agriculturist* of November, 1871, page 418. Where this is not readily available, nearly as cheap a material may be procured in the tarred twine or cocoanut-fiber netting, which may be purchased ready-made by machinery, or the twine may be purchased and made up into the netting at home during the long winter evenings or stormy winter days. The nets should be three feet in width, and may be made or procured in rolls of any length desired. Two rolls of a hundred and ten yards each would stretch across a square field of ten acres, and such a field might be fed off in strips by using two such rolls. Or the same lengths of netting would inclose a space of seventy yards by forty, which would be more than half an acre, and sufficient for a small flock of sheep. The nets should be hung on stakes driven into the ground, hooks being driven into the stakes, the lower edge of the net being six inches above the ground, and if the sheep are wild, and need more restraint, a No. 9 wire may be stretched a foot above the net, and will effectually inclose any flock, however inclined to rove. In a few days, sheep thus inclosed in a net hurdle become habituated to it, and of themselves come into the inclosure as soon as it is made ready for them.

We give the following directions for making the net. If the peculiar stitch by which fish-nets are

made is known, there is nothing easier than to weave the nets in that manner, but as in inland localities this is rarely understood, and it is almost impossible to describe it in print, we give a substitute, which answers the purpose in every way, and is much easier to make. It is made as follows: The material is stout hempen or cocoanut-fiber twine, about one eighth of an inch thick, which can be purchased at twenty cents per pound. A cord of thrice this thickness is used for the border of the net, and the meshes are attached to it by means of a still finer twine, which is twisted or knotted two or three times at the corner of each mesh by means of the needle shown at *a*, fig. 1. This needle

Fig. 1.—MAKING A NET.

is whittled out of a piece of maple or oak wood, one eighth of an inch thick and an inch and a quarter broad. On this needle the knotting thread is wound. The square piece of wood shown at *b* is held against the rope, the netting twine is passed around it and fastened by two or three turns of the knotting thread, and a fast knot is made. The thread is cut, the block withdrawn, and replaced in position to make another mesh, and so the work proceeds until finished. In fig. 1 is shown this method of knotting the meshes. When a sufficient length of net is made, it should, before it is used,

Fig. 2.—THE NET PUT UP.

receive a thorough soaking with pine-tar, which will add very much to its durability.

The stakes should be five feet long, about four inches thick, pointed at the foot, and are to be driven in the ground with a wooden mallet. Fig. 2 shows the net hooked on to the stake.

If the ground is hard, a short pointed iron bar may be used to make the holes for the stakes. The stakes should be loaded in a cart, driven along the place where the fence is to be erected, and one dropped about every eight feet. The net should be neatly rolled, and may be unrolled on the ground, and hooked on to the stakes as it is unrolled, and altogether the fence may be erected very rapidly by using method in doing it. It is very much to be hoped that this system will be undertaken as widely as may be practicable where the climate admits of it.

Cement Pipes and Tiles.

We have received several communications on the subject of cement pipes for conveying water, and cement tiles for draining land. The difficulties which seem to have occurred with our correspondents in the use of cement pipes are supposed excessive cost, leakage where they should be tight, and imperviousness to water where they are desired to be porous; besides a general want of information as to the use of the cement and how to construct the tile. Cement pipe, when it is properly constructed, has some advantages for conveying water over any other kind of pipe. In cost it should be cheaper than any other pipe. If one barrel of cement is sufficient for 600 feet of 1 1/2-inch pipe strong enough to resist a pressure of 20 lbs. to the square

to allow for a thickness of material sufficient to resist the pressure of the water; where there is but a few feet head one inch of well-spread and properly mixed material will be sufficient; where the head of water is greater, the thickness may be increased at about the rate of a quarter of an inch for every twenty feet of increase in the head. When the ditch has been dug free from sudden curves, and of an even grade, or so slightly or suddenly uneven as not to present any difficulties in laying the pipe, the trough or bed in the bottom of the ditch should be covered with the cement, by means of a trowel, to a thickness as near as may be to that required. A core (shown in fig. 1), which is a smooth rod of wood 6 or 8 feet in length, and of the exact thickness to

match the desired caliber of the pipe, and made with a very small taper from front to rear, is laid and bedded down in the cement; the core is then covered with it, commencing at the rear end, and compactly plastering it over to the proper thickness until the core is covered except a few inches at the front. The cement should have been properly prepared by mixture of one barrel of Rosendale cement, or any other of equal quality, with three barrels of fine, clean, sharp sand. The strength and tightness of the pipe depend in a great measure on the quality of the sand, and also on the use of a proper quantity of water. Only sufficient water should be used to render the cement plastic; if it is flooded with water the pipe will be porous. The cement and sand should be carefully and evenly mixed together in a barn

or out-house, and taken in a dry state to the place where it is to be used, and mixed with water only in small quantities as it is required; as it rapidly "sets" or becomes stiff. Two persons are required to do the work expeditiously, one to mix the cement for the pipe-layer, and to hand it to him as he needs it, and to cover the pipe carefully when the core is ready to be drawn ahead, with soil free from stones to a depth of a few inches. This soil is to be tamped down carefully, evenly, and solidly. When a foot or two of that first laid is thus covered and tamped, the core is drawn ahead to a corresponding distance, but no more, and the cement laid around it, thus adding a foot or two to the length of the pipe. Care must be taken to make a compact and tight joint, or the pipe will leak. It is well to add a little thickness to the pipe at the joints to secure

perfection in them. While the pipe-layer is doing this, the assistant is busy covering up an equal length with earth in the manner before described, and thus proceeding foot by foot two ordinarily smart hands will lay one foot per

Fig. 2.—MOLDS FOR PIPES AND COLLARS.

minute with ease—or at least two such have done so. A pipe thus laid is practically everlasting; it is stone, it can not decay, in course of time it becomes harder and stronger, it adds no impurity to the water, and neither worms nor rust corrupt it, as in wood or iron pipes. Its advantages when thus laid, over earthen pipes or tiles laid in short lengths cemented together, is that the pipe is one homogeneous whole, as though it were a leaden one; while these jointed pipes can not be made tight at the joints, and in course of time leak, and in addition are perishable and fail.

Figure 1 shows the process described above, the form of the ditch, the shape of the completed pipe, and the form of the core. The bed for the reception of the pipe at the bottom of the ditch should be round and not square, as it is accidentally made in the engraving, and only large enough to receive the pipe without any waste of cement.

Cement drain-tiles may be made in the above manner by laying the cement in shorter or longer sections, with joints between, or they may be made in molds, which would be preferable, although more labor is required.

Figure 2 shows the process of making the tiles and collars; *a* is the core which molds the interior of the tile, *b* is the mold itself, *c* the finished tile, *d* the core for molding the inside of the caps or collars, *e* the mold in which they are shaped, and *f* the finished cap. The preparation of the cement is similar to that pre-

Fig. 1.—MAKING CONCRETE PIPE.

inch, equal to a column of water of more than 100 feet head, and the cost of making the pipe comparatively inconsiderable, it must be by far the cheapest pipe that can be used. If it is properly constructed, with a view to the special purpose required, it may be made either watertight or porous, this depending on the proportion of sand used in the mixture. In laying pipe for conveying water on the plan here described, the excavation should be made deep enough to preserve the pipes from frost, as indeed should be done for any pipe. Three or four feet would be sufficient, except under exceptional circumstances when frost would penetrate deeper than any practicable depth at which pipe might be laid. The constant passage of a current of spring-water through the pipes would almost always prevent freezing, even when the surrounding ground might be frozen.

The ditch should be scooped out at the bottom with a drain-scoop, so as to make a semi-circular bed for the pipe, in which it may be laid evenly and without waste of material. On this greatly depends the economy of the plan. The bed or trough should be made large enough

Fig. 3.—PIPES AND COLLARS LAID IN DRAIN.

viously described, excepting that a much larger proportion of sand may be used, and much coarser sand, or, indeed, coarse sifted coal-ashes, will answer in the place of sand. As there is no pressure of water to provide against, and as the more porous they are the better, the

proportion of ingredients is varied, so as to give them just sufficient tenacity and strength to hold together and resist collapse by pressure of the earth above them. When the material is mixed, the mold (b) is filled with it, the core (a) is forced down upon the cement, which is mixed with sufficient water to render it quite soft, until it touches the flanges seen at each end of the mold, and thus the tile receives an even, square shape at the ends. The core is then covered with cement, and the top part of the mold is turned down over it, and the excess of material squeezed out. The mold with the contained tile is pushed on one side, and another filled in the same manner, sufficient molds being needed to work with until the cement has set enough to be turned out. The number required of course depends on the rapidity of the workman. The caps or collars are made in exactly the same manner; the mold, however, is provided with flanges placed so far apart as to cut the collars into the sizes required, three inches in length being about a proper size. The mold (c) is single, no upper portion being required, as the collars are much better in the shape of half-circles than whole ones. They are placed with greater facility when in this shape, and where the ground is solid, as in clay soil, and the bottom of the drain properly shaped to receive the tiles, no collars are needed under them, only caps over the joints being required.

Figure 3 shows the position of the tiles and caps in the drain as they are to be laid. Farmers intending to drain their fields who are situated at a distance from tile manufactories or from railroad stations, can very conveniently and profitably make use of the method above described. The great loss incident to the carriage of fragile articles such as drain-tiles is avoided and much expense of freight saved, the carriage of the cement alone having to be met, which is only a small portion of the material used, the greater bulk being sand, sifted coal-ashes, or finely-broken brick, etc., where coarse sand can not easily be procured.

Why Thorough-bred Bulls are Vicious.

We rarely hear of a common or scrub bull being vicious, and almost as rarely do we hear of a thorough-bred bull that is not so. In our judgment, this is due not at all to the difference of blood, but to the difference of treatment.

The common bull is generally kept in the same field and in the same stable with the cows, and is in all respects treated in the same way. He is accustomed to the presence of man, and to all the sights and sounds of the farm and the road. The thorough-bred, on the other hand, is usually expected to be vicious, and everything is done to make him so. He is confined in a box-stall (usually a dark one), and takes his exercise in a yard that is surrounded by a high fence, with no opportunity to become familiar with anything but his single keeper. Too often he is chained by his neck and by his nose-ring, and sees only his attendant—who usually goes to him armed with a club or a whip, and who makes it evident that he is afraid for his life while in his presence. This is enough to make a bull, or a horse, or a man cross and cantankerous, and we have no right to expect a different result from such management.

We have had practical experience of the opposite mode of treatment in the cases of a number of Jersey bulls, and always with good effect. We are now using one nearly six years old. When we first got him, four years ago, he

was showing the effect of previous mismanagement, and was ready to bellow and paw the ground in preparation for a fight at the sight of every man who went into the stable or field. Since he has been in our possession, he has been treated exactly as he would have been if he had been the tamest of scrubs. Tied by his nose-ring in the same line of stalls with the cows, fed in the same way, patted and spoken to by all who passed, he has become as docile and quiet as an ox, and strangers go into the open barn-yard with him without even attracting his notice. If this were a single case, the result might be ascribed to the temper of this particular animal, but we have had the same experience with a dozen others, and we have never seen a bull so treated that was vicious—nor one kept in solitary confinement that was not so.

A Farm Level.

T. S. Strobecer, Venango Co., Pa., sends us a model of a farmer's level, from which we

A SIMPLE FARM LEVEL.

make an engraving. He thus describes it: It consists of a board about eight feet long, both edges being straight and parallel, with sights attached to the upper edge. An upright piece about three feet long is dovetailed into the board, or otherwise firmly affixed, at right-angles to it. A cord and plummet is attached to the upright piece, and in its center a crease is made, also at right angles to the upper edge of the board carrying the sights. It can be rested on blocks on a staff, which may be pivoted so that the level may be used on ground that is rough or uneven. The upright piece is handy to plumb walls; attached to the board it is useful to level foundations or cellars. When mounted on a staff, it may be used for many purposes as a substitute for a surveyor's level, and it costs only a little ingenuity to make it.

SMALL ARTIFICIAL PONDS FOR FISH.—"S. L." Fairfield, Iowa, asks if a small half-acre pond can be utilized for raising fish, and what kinds of fish can be raised in it. The pond is six feet deep. If the pond is fed by springs, and the water does not get above 70° in the summer, trout can be raised in it. If there is a good stream running through, or if it is kept uniformly six feet deep, the smaller kinds of fresh-water fish will live in it, even if it is much warmer. If it is wanted merely for ornament, gold-fish may be put in, and it may be planted with water-lilies, to make shelter for them. If fish for food and sport are wanted, black bass would live in such a pond, but they would need to be fed occasionally in summer

to make them grow rapidly. The best feed is small live fish and insects. Beef-lights run through a sausage-meat cutter make good food. A few loads of coarse gravel should be put into the pond in water three or four feet deep for spawning-beds, unless the bottom is gravel. Of course, in so small a pond, not a great many fish can be raised. The growth will depend upon the liberality with which they are fed.

Old Pastures, or New?

There are two opinions about pastures. One is that it is more profitable to feed only newly-seeded land, using it not more than two years before plowing it up for a reseeded; and the other to let it remain for many years, allowing the surface to become fully occupied by the native grasses, these being supposed to be best adapted to develop its power of production.

If we consider this question according to the general practice of farming communities in this country, we can not hesitate to decide that the greatest profit will follow the first-named method, for there is no disputing the proposition that timothy, red-top, orchard grass, and red clover, newly sown on a well-prepared and well-manned soil, will produce much more forage (and of a highly nutritious kind) than will a close turf of blue-grass, white clover, etc., which has for many years had full possession of the ground, and has had no artificial stimulation. The difference in amount will be much more than enough to repay the cost of breaking up, manuring, and seeding.

It is not now a question whether the cows will do better on one kind of pasture than on the other, only which will produce the largest money profit. If a single cow were allowed to roam over ten acres of short old pasture, picking up her whole living in white clover and the tender sprouts of blue-grass, there is no denying that she would give more milk, more butter, and more cheese than she would if feeding, however abundantly, on the coarser grasses of an artificial pasture. But our purpose in farming is not to get the largest possible yield from our cows, but to get the largest possible yield from our land. The cows are only implements for converting the products of the field into the salable products of the dairy.

An average first-class cow coming in in May will make 200 lbs. of butter in the season on good natural pasture, but she will require at least three acres of land for her exclusive use. At 30c. per lb., the season's produce will be \$60—or \$20 per acre. On a good artificial pasture she may give only 180 lbs., worth \$54, but she will be fully supported by the produce of a single acre. Supposing that one third of the produce is consumed by the interest on the extra number of cows, and by the cost of keeping up the pastures—which is surely a very liberal allowance—we shall have \$36 instead of \$20 as the return per acre. In addition to this, we shall make ourselves much more independent of variations of the seasons, for a well-worked rich meadow is far less injured by excessive drouth than any natural pasture on the same soil could be. This, of itself, will often equal the drawback we have allowed for extra cost.

To put the proposition in another form, we may expect, from the foregoing calculation, as large a cash profit from ten acres of artificial as from eighteen acres of natural pasture, and there would be far less risk of loss from unusual drouth. It is not proposed, of course, that rough or waste lands should be used for arti-

cial pastures (they would not repay the cost), only that such fields as are susceptible of profitable sucthion should not be left wild.

How nearly natural pastures may be made equal to artificial ones by the use of the harrow and liberal top-dressings is a proposition not considered above. The cost would generally be less than that of reseeded, and the result equally good. In any case, no pasture—old or new—should ever be over-stocked.

Our Forests.

What we are to do for wood and timber in the next generation is becoming a very serious question. It is estimated that eight millions of acres are stripped of their forests every year to supply the wants of our present population. If these eight millions were left to grow up to wood again, or if as large a territory were planted every year, the fall of the forests would excite no alarm. But this is not the case. There is absolutely no system in our preservation of forests, and almost every land-owner follows the impulse of immediate profit. A very large proportion of our farming population use wood for fuel, and the destruction of forests from this source is immense. On almost every cultivated farm the breadth of forest is steadily waning. If there be any exception to this rule it is in the older States, where the agricultural population does not increase. Our railroads consume large quantities for fuel, and the draft for ties is very large. Every mile of railroad calls for two thousand ties, and these do not last more than seven or eight years. One only needs to visit the lumber regions in any of the States to comprehend the rapid disappearance of forests from those large tracts put down in the census returns as uncultivated lands. The steady advance in the price of lumber in all the older States is probably the best measure we have of the extent of the evil. Concerning the influence of this destruction of the forests upon the rainfall and the climate there is much discussion and some difference of opinion. There can be no doubt that climate is softened by the shelter which woodlands afford. A belt of evergreens inclosing a garden in any of our Northern States will virtually remove it three hundred miles south. The ground is not frozen so deep in winter, the snow disappears earlier, and fruits and flowers can be grown with certainty that can not be raised outside. The advantages of shelter are conceded by our best cultivators. The rainfall may or may not be increased by the forests. It is conceded by all that the rain which does come is more evenly distributed, and that there is much less liability of damage from floods or drouth. It is pretty well settled in European countries that the welfare of the farming interest demands that at least one fifth of the whole surface of a country should be kept in forest. More crops, and of better quality, can be drawn from four fifths of the land with this protection than from the whole without it.

In the prairie States something has been done from necessity to meet the want of fuel and of shelter. Wood grows with great rapidity, and plantations only six or eight years old yield steady supplies of fencing and fuel. Illinois has much more wood than when the State was first settled, and belts of timber are rapidly increasing. This is true of the States further west. Kansas, with a wise forecast, has begun to legislate for this interest, and offers special privileges to all those who will plant trees for ten years to

come. California has just appointed a State Arboriculturist at a salary of \$15,000 per annum. The Kansas Pacific Railroad employs an industrial agent, who devotes special attention to the planting of various kinds of trees on that part of the road which has been known as the Great American Desert, and where it was formerly supposed neither farm crops nor trees would grow. The experiments of R. S. Elliott are so encouraging, that there is little doubt of the capacity of the soil and climate to grow timber in all this region. The care of our forests demands immediate attention in all the States. Eventually we shall have to come to the European system, and have commissioners appointed by the legislatures who shall have power to regulate the cutting of forests, and to encourage plantations in districts where there is not sufficient shelter. It would be better indeed if the end could be accomplished by private enterprise, but thus far nothing has been done to correct the evil. There are large tracts in almost every township in the older States turned out to pasture that do not pay the taxes laid upon them. The public good, as well as the interest of the owners, requires that these tracts should be planted with forest trees.

Fish-Scrap or Guano.

We have received from a correspondent the following questions touching fish-scrap:

1. What is the quantity of fish-scrap obtainable?
2. What is the cost of the article?
3. What is the loss of weight in drying?
4. Cost of manipulation?
5. Cost of freight?
6. What is the market price of the manufactured article?

As these questions interest all farmers who buy fertilizers, we answer them.

1. The quantity of fish-scrap turned out from the fish-oil factories is not far from 30,000 tons, annually. The business is prosecuted from the capes of Virginia to the coast of Maine. A great improvement has taken place in the process of manufacture within the last twenty years. The principal fish captured are the *Alosa menhaden*, known among the fishermen as the Bony Fish, White Fish, and Menhaden. They swarm all along our coast from April until October, and are taken in greatest numbers in the bays and estuaries of our large rivers. They are mostly taken at a distance from the shore, in large purse-nets. They are loaded into boats, and carried immediately to the factories, cooked by steam in large vessels, put into hydraulic presses, which squeeze out the oil and water, and leave the scrap-cake quite dry, though it still contains a large percentage of water. It is used by farmers in the immediate vicinity of the oil works in this crude state, either taken in bulk or bagged and barreled. The great objection to its use at distant points is the cost of transportation, and its offensive smell. Various devices are resorted to, to meet these objections. The scrap is sometimes treated with sulphuric acid, or mixed with dried peat or with plaster. But this makes a manure of uncertain value, and the farmer does not know just what he is buying. The great desideratum is some economical process of drying and pulverizing, by which we can have a concentrated fertilizer of uniform value, that can be used in drills, or sown broadcast, evenly, over the land. Several claim to have found this process, and are about to put

the article upon the market. We presume it will soon be advertised. We have no doubt a fine dust can be made from fish-scrap, worth at least two thirds as much as Peruvian guano, by analysis, and which can very likely be sold for forty to forty-five dollars per ton.

2. The cost of the raw material varies with the abundance of fish, and the demand for concentrated fertilizers. Three years ago fish-scrap was selling at \$25 per ton, because there was a great demand for it by the manufacturers of superphosphate of lime. There was so much adulteration and cheating in this article, that fish-scrap has been declining for the last two years, and can now be bought at the factories for about \$10 per ton. 3. The loss in drying should be about 40 per cent, if the fish have been subjected to powerful pressure. It will lose nearly this, dried upon a platform in the summer sun. 4. The cost of manipulation will depend upon the process used. The cheapest we know of, costs about five dollars a ton for the dry article. Of course every inventor thinks his own machine the most economical. 5. The freight on the raw material is of the lowest class, as the factories are all upon tide-water, and sail-vessels can be used. The manufactured article is inodorous, or nearly so, and can be put up in bags or barrels, and shipped at the same cost as other articles. 6. The market price of the fish-dust must depend mainly upon the amount of ammonia, phosphoric acid, and potash it contains. Farmers want a good article, and are willing to pay a fair price for it.

JERUSALEM ARTICHOKE.—Mr. W. L. Heuser, of New York, noticing the statement in a recent Ogdens Farm Paper concerning the difficulty of eradicating the roots of this plant from a soil on which it has been grown as a crop, states that the following plan is adopted in Germany, where the plant is cultivated over considerable tracts; it has its place in rotation before winter grain. After the crop has been removed, sheep are tethered on the land with long ropes (or turned loose if there are fences). They eat off the young sprouts as fast as they appear, and the plant dies for want of the support which it can only receive from leaves. By the time the summer-fallow is to be broken up for the grain the artichokes will have disappeared.

The Thanksgiving Turkey.

Some one has said that our national bird is not the Eagle, but the Turkey. This present month of November brings Thanksgiving-day, and the most interesting period of the turkey's life—its death. Thanksgiving has become a national holiday, and what is Thanksgiving without turkey? It must be a poor family, indeed, that does not find a turkey on its dinner-table. The general demand for turkeys on this holiday is anticipated by the breeders, who late in October begin to fatten for the market. The best turkeys that come to the markets of New York and other Eastern cities are raised along the shores of Connecticut and Rhode Island, where the returns from the turkey flock form no small part of a farmer's income. The great bulk of the fowls sold in New York comes from the West, where not so much pains is taken in fattening as in the localities referred to, and on account of the long travel the birds do not come to market in such good order (especially if the weather is mild) as do those raised near at hand.

[COPYRIGHT SECURED.]

THE THANKSGIVING TURKEY.—Drawn and Engraved for the American Agriculturist.

One of our artists, who lives in the turkey-raising portion of Connecticut, has sent us a Thanksgiving picture which shows various scenes in this branch of farming. Turkeys are usually regarded as difficult to raise, and the scene entitled "Young Turkeys" shows one of the methods adopted to secure success. The broods of young are placed in simple board-pens a foot or more high, and kept there until they become large and strong enough to get over the barrier. This prevents the mortality that attends young birds that are allowed to wander with the old ones in wet grass.

The scene of roosting shows the primitive and general way in which turkeys dispose of themselves for the night. If left to their own instincts, they will select as a roosting-place the limbs of a tree, the peak of a building, or other lofty spot. If taught when they first begin to roost, they may soon be made to go regularly to roosts prepared for them under the shelter of a shed. This is a matter of no little importance when fattening time comes, as they take on fat more rapidly when under cover than when exposed to chilly and stormy nights, as they are if they roost upon trees, etc. Fattening com-

mences about six weeks before killing-time. During the summer the birds have picked up a good share of their own living as they roamed far and wide. At this time they need an abundance of fattening food, and to be kept as quiet as possible. In order that the change of diet may not be too sudden, it is the custom of the most successful raisers to begin with a mixture of oats and buckwheat. At the end of a week corn is substituted for the oats, and after another week the buckwheat is stopped, and the birds are fed upon corn altogether. They are fed as much as they will eat, the corn being supplied always at one place, and scattered upon the ground or grass that they may feed slowly.

Most of those who raise turkeys kill for the Thanksgiving sales. The birds will grow larger and weigh more if kept until Christmas, but the profit is not found to be so great. The birds are fed nothing upon the morning of killing. The flock is driven into a dark barn, and the birds brought out one by one with as little disturbance as possible. The most common way of killing is to sever the head by a blow with a sharp hatchet, and hold the bird until its struggles cease. Sometimes the bird is thrust into a

barrel, as shown in the engraving, until it is through bleeding. The picking should be done at once before the body is cold. The tail-feathers and wing-feathers, except those of the extreme joint, are first pulled out, and then the feathers of the body are removed, beginning at the breast. Great care is taken in picking not to tear the skin, as any blemish of this kind diminishes the market price. After the principal feathers are off, the removal of pin-feathers is usually done by women. Western poultry, which has to go a long distance to market, is always sent without being drawn, as it is found to keep better if no air is admitted to the cavity of the body. The turkeys raised in New England are generally drawn. A circular cut is made around the vent by means of a sharp pen-knife, and the entrails carefully pulled out through the opening. The turkeys are laid upon their backs and allowed to cool; the skin is pulled over the neck and tied securely. When thoroughly cooled the birds are ready for packing, which should be done in clean boxes. Many tons are shipped each November from the agricultural towns along the coasts of Long Island Sound and Narragansett Bay.

Lyon's Turtle-head (*Chelone Lyoni*).

The common Turtle-head, Snake-head, or Balmomy (*Chelone glabra*) is very frequent in wet and swampy places, where its clusters of white or rose-colored flowers are quite conspi-

splendens compacta alba. That is a good deal of a name, and none but a very fine plant could carry it. We have seen only a small pot-plant, but have no doubt that it will be found very effective when used in contrast with the well-known brilliant scarlet one. Mr. Chitty exhib-

Backwheat Family, one which contains the Persicaries, Knot-weeds, Smart-weeds, and other well-known aggressive plants. This species, as its name indicates, came from the East; and is said to have been introduced into Europe by Tournefort, who found it at the base of

LYON'S TURTLE-HEAD.—(*Chelone Lyoni*.)

ORIENTAL POLYGONUM.—(*Polygonum orientale*.)

uous during the late summer and the autumn months. Last spring we received from Hoopes, Bro. & Thomas, of West Chester, Pa., a specimen of another species, which is much showier than the one just referred to, and which possesses sufficient beauty to entitle it to a place in our herbaceous borders. This species, *Chelone Lyoni*, which we may call Lyon's Turtle-head, is found in the mountains of North Carolina. The stem, which in favorable soil grows three feet or more in height, is more or less branched, and produces its flowers in dense spikes at the ends of the branches. The flowers, which are rather smaller and more erect than in our Northern species, are of a bright purple color, and these, together with the ample foliage and a pleasing habit, make the plant a very desirable one in a collection of herbaceous perennials.

A WHITE "SCARLET" SAGE.—While our garden was all aglow with the brilliant flowers of the Scarlet or Mexican Sage, *Salvia splendens*, in one of its several garden forms, we were much pleased to receive from Mr. H. E. Chitty, of the Bellevue Gardens, Paterson, N. J., a flowering plant of a variety of the same Sage with pure white flowers. To call it a white "scarlet" sage is rather a contradictory nomenclature, but we prefer it to that given it by the European florist who originated it—*Salvia*

bited the plant at the recent annual exhibition of the Massachusetts Horticultural Society, where it attracted much attention, and received from the society a first-class certificate.

The Oriental Polygonum, or Prince's Feather.

Some of the old-fashioned plants that were formerly very common are now becoming quite rare. Some of these old plants we would not willingly spare, while we are glad to see the places of others occupied by more pleasing ones. Sun-flowers, Love-lies-bleeding, the large yellow Marigold, and the Prince's Feather are in our minds associated with tumbled-down fences and neglected front-yards, and where these are the extent of the attempt at flower culture we expect to see the missing window-panes supplied by an old hat or a bunch of rags. Those who do not thus associate the Prince's Feather with poverty-stricken dwellings may find in it something of a certain coarse kind of beauty. A good specimen has a strong stem six feet or more high, large leaves, each of which has at its base a sheath surrounding the stem, and long spikes of bright rose-colored flowers. The botanical name for the plant is *Polygonum orientale*, and it belongs to the

Mount Ararat. Besides the name Prince's Feather, it is also called "Ragged Sailor" and "Kiss-me-over-the-garden-gate." The plant comes readily from self-sown seeds, but does not show much tendency to spread and become a troublesome weed, though it is sometimes found naturalized in waste places near towns.

The Willow-leaved Amaranth.

In an article upon Amaranths, we gave last month an account of our experience with three species or varieties, and the reasons for our lack of satisfactory results. Since then, we have seen in the grounds of others specimens so fine as to make us feel that for once a plant has fully warranted the extravagant descriptions given it abroad. Indeed, as our climate is much more favorable for such plants than that of England, we have no doubt that the Willow-leaved Amaranth (*Amarantus salicifolius*) attains greater perfection here than there. The finest specimen we have seen was at Woodnethe, the country-seat of H. W. Sargent, Esq., at Fishkill Landing, N. Y. He has several specimens, but one in particular is full ten feet high, with branches of proportionate length. The leaves at the top of the main stem and the branches are of a most brilliant carmine color. This plant was indeed a fine sight, whether seen

at a distance or from a near point of view, and its size much exceeds that of any we have seen recorded. Mr. Peter Henderson has been very successful with this plant at Jersey City, as has Mr. Chitty at Paterson. Both these gentlemen made the mistake of following the recommendation of the English growers, and planting it in masses, while Mr. Sargent's is a single plant, standing against a background of green.

The Willow-leaved Amaranth is destined to become very popular now that this year's experience has shown the conditions of success and failure. It should be always grown in single specimens, and, as suggested in a former article, never be checked in any manner in its growth.

Notes from the Pines.

MELONS.—The past season has been an unfavorable one for melons. There was not so much trouble from insects as usual, but the frequent rains about the time of ripening prevented them from acquiring proper sweetness. Of a dozen or more varieties that were tried, Ward's Nectar was by far the best. I thought this could not be excelled, but

JAMES VICK sent me a basket of fruit from Rochester that quite took the conceit out of me. It is a variety which he has cultivated for twenty years without a name. We might express its excellence, and in a manner associate the grower's name with it, by calling it *Vic(t)tor*.

STRAWBERRIES have during the past summer been sadly injured by the white grub. The vines were mulched, and the Ogden Farmer, who was here one day, thought that the mulch attracted the grub. I can't see why, as they often attack vines that never were mulched.

CENTAUREA CLEMENTII, of which I received a specimen from Mr. H. E. Chitty, of Bellevue Nursery, Paterson, N. J., promises to be very effective in garden decoration. It has not such finely-cut leaves as *C. gymnocarpa*, but it is whiter, and of a remarkably graceful habit. It is fine for baskets and vases.

BRACKETS are useful things where one wishes to train vines of any kind against the house. It is bad for both vines and house to nail directly to the siding. I use iron brackets which project about four inches. One being placed above and the other below, a wire is stretched between them, and the climber tied to the wire. In this way the plant is kept from contact with the building, and has a free circulation all around it. The brackets may be had at the hardware stores, at wholesale, for five or six cents each. They are also very convenient for stretching wires horizontally.

ARUNDO DONAX, the variegated form, has grown taller with me this season than I have before seen it. Quite ten feet high, and flowering. A large clump of it, surrounded by a row of *Caladium esculentum*, made an odd combination, but an exceedingly effective bed.

SOWING SEEDS of herbaceous perennials is done at last. It was near the end of September before I could find time, and would have been rather late had I not sown in boxes which are put into a cold-frame. Those who have tried sowing flower-seeds in shallow boxes will not sow many in the open ground. A shallow box two or three inches deep is used. A grocer's soap-box will make two or three. The box can be placed on the work-bench, and the sowing done much more carefully and neatly than when one is obliged to stoop—to say nothing of

avoiding the backache. In weeding and removing the plants for pricking out, the box can be taken to any convenient place, and the work done more expeditiously and more at ease than when the young plants are in the open border.

A **SOWING BOARD** is very convenient with scarce and valuable seeds. I do not know who first proposed it, but I am much obliged to him for the hint. It is a strip of any thin smooth board that will just go across the box. With seeds so rare that one wishes to make every one tell, they are laid upon the board and moved one by one towards the edge at regular distances apart. When the seeds are placed just as it is desired to have them in the soil, they are carefully pushed off one by one into a little drill previously made for them. It does not take half so long to do it as it does to describe it.

MAKING DRILLS for small seeds is best done by pressing the edge of a lath or thin board into the previously-smoothed soil. This makes a drill that is perfectly smooth at the bottom—where the seeds can be distinctly seen, and if the sowing is not properly even it can be made so, which can not well be done in a rough drill made by scratching the soil.

THAT CHOYOTE.—Last spring there was introduced at the Farmers' Club, under the absurd name of "Mexican Bread-fruit," and as a new discovery, a member of the Squash family, the Chocho or Choyote, *Sechium edule*. It is a very common plant in the West Indies and other tropical countries, and has been known and grown for ages. It has succeeded in some of the Gulf States, but is entirely useless with us. I obtained a plant through the kindness of the gentleman who brought it before the Club, and planted it out. It was carefully protected by glass until hot weather came, and barely remained alive for several weeks. When it started to run, how it did go! It was said to require an area of 18 feet—better say 180. Wishing to give it every opportunity to do its best, I checked it but very little. If frost does not come pretty soon I shall have to give up the whole place to it. It runs worse than a member of Congress. It is on the tomato trellises, it is in the pear-trees, it covers the pig-pen, it drapes a high rail-fence, and is invading my neighbor's premises. One branch is headed straight for New York, where it may arrive if the season is long enough. It is now the first week in October, and as no flower has yet shown itself, the prospect of fruit can not be regarded as encouraging.

GRAPES have on the whole done well with me this year, and I will give my experience with some of the important varieties, but as this article is rather long the grape talk had better go in a separate one.

Grapes at the Pines.

Geography.—About ten miles north-west of New York. **Topography.**—The banks of a fresh-water river, and about 25 feet above it. **Soil.**—A very light sandy loam. **Climate.**—Much mixed, especially last winter. This is the third year of most of the vines of my little vineyard, though I have a few old vines.

Concord has been better than usual, which I attribute to the fact that there have been so few insects to injure the foliage.

Martha.—"You want Martha." Perhaps "you" do, but I do not. Its only claim to popularity is its being white; for the rest, it is a

very sweet, pasty, bad-flavored fruit. It bore well, and half the crop was left on the vines as not worth the trouble of picking, when there were so many better grapes.

Black Hawk.—I have had this vine for five years, and have at last succeeded in seeing the fruit. Why was this variety ever sent out? It is a fox, of the poorest kind, without a single good quality, except very robust foliage.

Wilder.—This is one of the Rogers hybrids (No. 4), and like all of that set is a most rampant grower. The fruit with me has been very fine, both bunch and berry of good size, and the quality satisfactory. I think that this variety will contest with the Concord for popularity. It seems to have all the good qualities of that variety while it is of finer appearance.

Barry (which is Rogers's No. 43) set a good crop of fruit, but it began to drop before it was fairly ripe.

Essex.—A great bearer of large brownish berries, with no especial quality to commend them.

Salem does not seem disposed to fruit with me. I have vines three and six years old, and not a good bunch upon either.

Ives set a full crop, but not a berry ripened; they all cracked and rotted just when they should begin to color. I was surprised at this, as it has been considered the surest of grapes. Mr. S. B. Parsons raises it in great perfection at Flushing. It is popular at the West as a wine grape, and some value it for the table, but in my estimation it is inferior to the Concord.

Creveling has the disadvantage of not making a good bunch, but aside from this it has hardly a fault. The fruit ripens early, is of excellent quality, and keeps well upon the vine. Its straggling bunch unfits it for a market grape, but for home use it has few superiors.

Eumelan mildews worse than any variety I have. There are some twenty vines, three years old, which lost their leaves before the small crop was ripe. A vine, six years old, gave a fair crop. It often makes a poor bunch, but those on my old vine were sufficiently full. Quality fine.

Senasqua and Croton were both badly cut back by the winter, but the first-named bore a small crop. It is earlier than I supposed, and as to quality I consider it the best black grape in the market.

Walter set a few bunches, but the leaves mildewed.

Delaware.—This needs a rich soil, but it will do well on a poor one after the vine gets large. It is so good that it is worth waiting for.

The Potato-Rot.

The disastrous effects of the potato-rot this year in England—three fourths of the crop being destroyed—will awaken an interest in the matter in this country. Probably few of the active cultivators of the present day recollect the former visitation of this scourge and the descriptions then given of it. In view of the possible appearance of this destructive disease among us—for the last time its advent here followed close upon that in Europe—we will endeavor to briefly state what it is.

The potato-rot is caused by a minute fungus—*Peronospora infestans*—a statement which conveys but little information, and we are at once met by the difficulty of explaining it to the average reader who has not studied the form of vegetation to which the fungus belongs. The fungus affects the potato leaf, stem, and tuber. Let us assume that these, as are all other vegetables, are made up of cells, small closed

cavities of microscopic size, roundish or long, according to the part of the plant in which they may be. A cross-cut of either the leaf, stem, or tuber would appear under the microscope much like a honeycomb, it being, like that, made up of cells. This being in brief the structure of the plant infested, let us consider the fungus. The potato-rot fungus is a minute, microscopic plant, but a plant for all that as much as the potato itself is. We are familiar enough with the larger fungi, the mushrooms and toadstools, which show on a large scale much the same manner of growth as the small fungi. When a gardener wishes to raise mushrooms he puts some spawn in a bed of manure. Soon the spawn begins "to run," and the manure is filled with whitish cobwebby threads, visible to the naked eye. After some weeks, mushrooms appear above the surface of the bed. To compare the vegetation of the mushroom with our common plants, the white threads of the spawn (*mycelium* of the botanists) may be compared to, as they serve the purpose of, the roots, stem,

and needs no leaves, while the smallest portion of it will go on and grow and rapidly multiply, and the fungus is propagated in this way just as we multiply a plant of a higher order by cutting of the root or stem. The rust, blight, or rot, as it appears above the surface of the stem or leaf, is, when examined by the microscope, a collection of club-shaped threads (fig. 1), which ultimately produce an exceedingly minute dust or spores (fig. 2), which in the fungus answer the purpose of seeds. These spores are so small that they can be carried about in the air, or be transported unobserved while lodged on other bodies. From what has been said, it will be seen that in the potato-rot fungus we have to deal with an exceedingly subtle enemy. It can, in the first place, work great damage inside of the tissues of the plant before its ravages are apparent, and it is propagated by spores or dust so minute as to escape detection. This being a brief history of the fungus, which science has made out in much greater detail, it will be asked, What remedy has science to offer? We are sorry to

This season we devoted a bed that was last year occupied by Cannas to other plants, and were much annoyed by the appearance of an abundance of seedling Cannas. Job's Tears (*Cola Lachryma*), a very tender tropical grass, has become almost a weed with us. So with the ornamental *Amaranthus*; they make themselves at home, and we should not be surprised to find that in a few years the now rare *Amaranthus salicifolius* had become a common weed.

Preserving Roots.

Market-gardeners and those who have a considerable quantity of vegetable roots to keep for winter use will of course pack them in trenches, but the family supply is usually kept in the cellar. When put loosely into bins and barrels, the roots, if the cellar be a dry one, become shriveled and injured before spring. This difficulty is avoided by packing in dry sandy earth—the sandier the better. We scrape off a cart-load of soil from a piece that has been recently harrowed, and use this for the roots. Beets, carrots, salsify, parsnips, horseradish, etc., are laid in boxes or barrels, as may be most convenient, with plenty of earth distributed among them. In this manner the roots are preserved perfectly fresh, and should any chance to decay, which is rarely the case, all odors are prevented from escaping by the earth.

Flower-roots, such as dahlias, caladiums, and cannas, may be successfully preserved by the use of earth, which for them may be quite dry. These tropical roots not only need to be kept dry, but warm, and if the cellar is a damp one they can hardly be preserved. A spare closet in a part of the house where there is no danger of freezing is preferable to a cellar for these.

Thawing and Freezing of Cold-Frames.

BY PETER HENDERSON.

A. Leavens & Co. ask the question, "How much freezing and thawing plants of lettuce, cabbages, etc., will stand without being destroyed?" In former articles I have taken the ground that the thawing, instead of being injurious, is a necessity for their safety. In doing so I know I run in direct opposition to a large majority of my brethren, but the experience of nearly a quarter of a century, yearly increasing in extent, confirms me that I am correct, and I am further assured in my opinion by knowing that there is not a market-gardener in this vicinity but whose practice in the management of cold-frames is the same as my own, though if the question was asked some of them if thawing and freezing did not injure plants, the answer might be in the affirmative, so universally has the dogma been accepted.

The gentlemen also ask: "How long can frozen plants be kept from the light under shutters?"—Much would depend on atmospheric conditions. If the temperature ranged at night from 25° to 32°—merely sufficient to mildly freeze the plants—they might remain in good condition for four or five weeks, but if subjected to a zero atmosphere, without change, as many days might prove injurious. A very common practice with cold-frames in this vicinity is, if the plants are frozen in the frames previous to a snow-storm, we allow them to be covered up by the snow often for two or three weeks, provided that it is deep enough to protect the plants from severe frosts, as in that condition the plants, though excluded from light, are subjected only to a temperature of from probably

THE FUNGUS OF THE POTATO-ROT.—*Peronospora infestans*.)

Fig. 1. The fungus as it appears on stems (a) and leaves (b). Fig. 2. Spores in different states. Fig. 3. Zoospores. The two figures at the right, marked b and c, show the mycelium penetrating the cells of the plant.

and leaves of ordinary plants, and the mushrooms, which alone appear above the surface of the bed, represent flowers and fruit. The mushrooms only appear when the mycelium or spawn which is running and branching in the manure attains sufficient strength to reproduce itself by means of the above-ground portion. Now, the potato fungus has a similar manner of growth, but its mycelium or spawn, instead of reveling in a bed of manure, finds its home in the substance of the plant. It lives in the cells already mentioned, and runs from one to the other, being nourished by their contents and substance. After a while, the mycelium having become sufficiently strong, it throws up reproductive organs, corresponding to, though unlike in appearance to, mushrooms, and this is the visible mold or rot that is seen in the stem and leaf of the potato. The fungus has two ways of propagating. First, by the mycelium or spawn, which branches and spreads in the tissues of the potato, just as the root of quack-grass or Canada thistle will spread through the soil. It lives on the already prepared food in the plant,

be obliged to reply, None. Some varieties are less liable to attack than others, and it is gratifying to know that our American varieties, notably those raised by Mr. Goodrich and their descendants, are especially exempt. It would be well that the importation of foreign seed-potatoes were stopped. At all events, we advise no one to plant an English potato as long as the present trouble continues. Secondly, should the disease break out on any farm, no potatoes should be sent out from it under any circumstances. This will not absolutely prevent the disease from spreading, but will do much to prevent it.

THE HARDINESS OF TROPICAL SEEDS.—Some of the tropical plants of our gardens are killed by the slightest frost, and one would suppose that their seeds would have their vitality destroyed by the cold of our winters. That such is not the case is shown by the Tomato, as it is a matter of common observation that this comes readily from self-sown seeds.

25° to 32°, which simply keeps them dormant. But if, on the other hand, the plants are not frozen when snow covers the glass, it becomes necessary to remove the snow in three or four days after falling, else the plants will become

they are smooth on the upper surface and somewhat downy below; they are much finer on the plants that grow upon the beach than upon those found inland. The fruit is from half an inch to an inch in diameter, globular, and varying in color from crimson to dark purple, and having a fine bloom. The shrub flowers in May and June, and ripens its fruit in September. The fruit varies in different plants, not only in color and size, but in quality—some specimens being quite pleasant to the taste, and others very harsh and acerb. It is highly prized by those who live near the shore for making preserves, and it is often seen offered for sale in the markets of seaport towns. As this fruit presents so great a tendency to vary in its wild state, we are surprised that no attempts have been made to improve it by cultivation. If a good variety could be produced it would be valuable. The wild plant is very ornamental when in fruit; the specimen from which the fragment was taken for the engraving was loaded with fruit, which in different stages of ripeness, and with its fine bloom, was an attractive shrub. Our principal object in calling attention to this plum is the promise it holds out of being useful as a stock on which to bud or graft the cultivated varieties. It would flourish upon the poorest soils, and it is very likely that it would prove a dwarfing stock.

tender, melting, juicy, of a sweet, high, aromatic flavor. August 15th to September 10th. Native of Ohio. We find it perfectly hardy here, and a great grower. And it is probably well adapted to a much more northern locality."

Fig. 1.—MUSKINGUM PEAR.

blanched, and made so tender that they will be unable to resist severe weather that may follow.

The Beach or Sand Plum.

There grows along our coast, from Maine to the Gulf, a species of plum which does not seem to have received much attention from cultivators. It is the Beach Plum, *Prunus maritima*, and is called in some localities the Sand Plum. It is found growing close to the sea among the blowing sands of the beach, and often at a distance of twenty miles inland. When found at a distance from the sea it is so much changed in appearance by the difference of soil and situation that it has been taken for distinct species, and the plant has been described by botanists under half a dozen or more different names. The tree, or rather shrub, is seldom more than five feet high, oftener only two or three, and has numerous stout branches, which are usually prostrate, and more or less covered by the shifting sand. The color of the stem is a very dark purple, almost black, and the young shoots are brown, dotted with orange. The shape of the leaves is shown in the engraving;

THE BEACH PLUM.

specimen of medium size, entire and in section. Cole describes the fruit thus: "Rather large; roundish to obovate; greenish yellow, with many dark specks, and much russet, seldom a brownish blush; stem long, medial, in a narrow cavity; calyx slight, open, in a slight or with no depression; flesh yellowish white, very fine,

market cultivation. It is very fair, remarkably solid, and cooks well.

CONNECTICUT.

[We seldom publish an article like the above without receiving many letters of inquiry, and we would say that the Muskingum Pear is to be found in the catalogues of all large nurseries, and that we have no trees for sale.—Ed.]

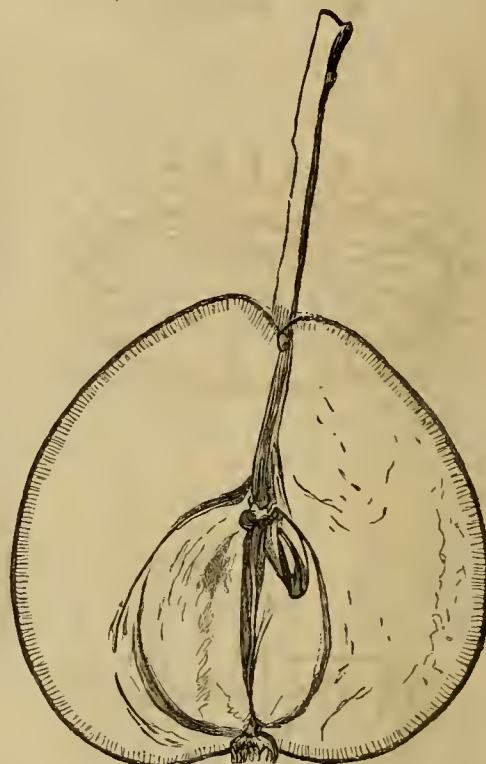

Fig. 2.—SECTION OF MUSKINGUM PEAR.

The Muskingum Pear.
We have in our garden six trees of this admirable variety of pears, and have watched their bearing for four years. It has more good qualities to recommend it for general cultivation, as an early fruit, than any pear of its season with which we are acquainted. The tree is a vigorous grower, makes a handsome head, and in good soil bears uniformly large crops every year. The illustrations (figures 1 and 2) give a very good idea of the appearance of a

In Southern Connecticut the fruit begins to ripen early in August, and lasts through the month. It holds on to the tree with great tenacity, and will rot upon the stem if it is not picked in season. If the fruit is picked just before it begins to turn yellow, there is no tendency to rot at the core. It ripens throughout at the same time, and is as nice eating as an epicure could

desire. It is in season for four weeks, coming in just after the Madeleine and lapping on to the Bartlett's. It might well be substituted for the Bloodgood, which is a much smaller fruit, with a shorter season, and, in our yard, of inferior quality. The wood also is diseased, and this we believe is a common fault of this much lauded variety. It also might take the place of the Dearborn's Seedling, which, though an excellent fruit, is of small size. The Muskingum bears so abundantly every year, that we think it would make an excellent variety for

THE HOUSEHOLD.

(For other Household Items, see "Basket" pages.)

White Wire-Ware.

Every one can not have table articles in silver of beautiful form and workmanship. We see no reason why beauty of form should belong only to costly materials. The French are much in advance

Fig. 1.—TEAPOT STAND.

of us in this respect, as with them nearly as much taste is displayed in the fashioning of articles of tin, iron, and copper as in the more costly metals. Persons of moderate means have as lively a love of the beautiful as those who are wealthy, and we welcome every attempt that brings pleasing and artistic things within their means. Recently there have appeared in our furnishing stores articles made

Fig. 2.—FRUIT-BASKET.

of tinned twisted wire, of which many are not only graceful in form, but useful articles of table furniture. To be sure, they are only of tinned wire, but if kept properly rubbed up they may well pass for silver, and the cost is very moderate.

We can not enumerate the various articles made in this ware, but give a few selected from the large stock kept by our friend Baldwin, 38 Murray street.

Fig. 3.—PICKLE-CASTER.

Fig. 1 shows a stand for a coffee or tea pot. In fig. 2 we have a fruit-basket, which is really handsome, and when filled with fruit would grace any table. Figure 3 shows a stand for a pickle-jar; these are made double, to hold two jars, and casters are made of the same material. A bouquet or flower-holder is shown in figure 4. It is a gracefully-shaped tapering glass, supported in a frame

of the twisted wire. Toast-racks, comb and brush-holders, paper-receivers, and a great variety of other conveniences are made in the same material.

Home Topics.

BY FAITH ROCHESTER.

A LITTLE REST.—Miss Peabody, in speaking of establishing kindergartens, says: "No one person could possibly endure such absorption of life in labor unrelieved, and consequently two or three should unite in the undertaking, in order to be able to relieve each other from the enormous strain on life."

Then think of the mothers. I know very well that there are mothers of large families (even in our day when children are born with natures that demand greater care and finer culture than their ancestors did) who feel very little concern for their children except to feed and clothe them and send them to the schools provided for their religious and secular education. But some of us realize that the demand made upon mothers by the enlightened spirit of our day is greater than mothers with our present poor preparation of health and culture can endure.

It is not so much what we do as what we see ourselves unable to do that is driving us mothers distracted nowadays. The kindergarten solves the difficulty, only some of us must do the best we can without its aid, it is so slow in coming.

Of course the minister must have his annual vacation, and teachers must have their holidays, but where and when shall a mother find rest?

This question, to which I could find no possible answer, was summarily settled for me by "our visitors," of whom mention has heretofore been made. I was told to pack up my things and go home to "mother's" for a visit of four weeks. I suggested two weeks, and we compromised on three. All the lions I saw in the way were removed, and I went—much more for the children's sakes than for my own. The eldest and the second child remained at home in the care of my lady visitor—a most motherly woman and an educated physician. I feared she was undertaking too great a task—to keep house for her husband and mine and our two children, with no assistance. But it was her own plan, and was cordially advised; and when I came home she was not sorry that she had undertaken the task. Neither was I. More good results came of it than were dreamed of in our planning.

Children need some variety in their care and education. A wise friend told me two years ago that what seemed to him at the time a great and irreparable calamity to his children had really seemed to prove the best thing for their development. They were early left motherless, and since then there have been several changes in their home and management—always pretty good care, but not invariable. The other day he wrote me: "I am glad you do not worry yourself to death about the disagreeable peculiarities of your children. I did that almost literally, and it incapacitated her for doing her best by them. And now they are almost model children, and it has not been accomplished by repression either, or only in a slight degree." Then he gave us two pages of happy father-talk about his children, now nine and seven years old.

The more thoroughly a woman is a mother, in heart and soul as well as in name, the more does she need opportunities of rest and assistance in her labors. No individual assistance can do for mothers and for children what the kindergarten is destined yet to do.

Madam Kriege says: "It is the mother's mission

to enter into the child's nature, to live its life, to understand its impulses, to feel its needs; to bring her love, her sympathy, her wisdom, to this work of leading the child along the dark path of early life, and to make it acquainted with its relations to nature, to its fellows, and through these to bring it into a conscious relationship to its Heavenly Father."

I think there is not a nobler mission on earth than that. But if this mother who ought to do all that for her babe, and who longs to do it, is the mother also of two or three more young children scarcely yet amenable to reason, with all the mischiefs and necessities of childhood; if she has to be not only their wise guide and tender friend, but also their seamstress, cook, and washerwoman; and if she must also have the ordering of an establishment, and is expected to follow the fashions in dress even afar off—then, I say, it is no wonder that insane asylums are so well filled, and that so many men are looking for their second and third and fourth wives; and it is no wonder that children have so poor home training. Let us accept all lawful means of refreshment, and all possible aids in our work.

Fig. 4.—FLOWER-HOLDER.

GOOD BOOKS FOR MOTHERS.—First let me mention Madam Matilda H. Kriege's new book, from which I have just quoted. I found this awaiting me on my return from my visit, and it was the book of books I most desired to see just then, having read Heath and Home's commendatory notice or welcome. The Christian Union seems to think that the "average parent" will not be able to get much from the book, while it commends it to the careful reading of the "professional educator and the profounder student." But it seems to be written for parents, especially for mothers. It is a philosophical book, but exceedingly interesting. It gives the philosophy underlying the Kindergarten. Madam Kriege and her daughter are the leading kindergarten educators in this country. This book, "The Child; its Nature and Relations," treats particularly of very young children, and is altogether the best book I know of about the education of babies from the first dawn of intelligence. If women's minds were not kept feeble by the poor, trashy literature too many of them feed upon, and belittled by such constant consideration of dress-trimming and other trivialities, this book would find many more readers among mothers than it can hope to find at present.

But here is Miss Alcott, who gives a deal of wisdom in a very fascinating form. I have only lately read her "Little Women," "Little Men," and "Old-fashioned Girl." All are useful books for mothers to read. We shall understand the little men and women under our care all the better if we get acquainted with the life-like ones Miss Alcott shows us, and it will help us to keep up courage and faith while we wait for the upspringing and fruitage of the good seed we are trying to sow patiently and cheerfully.

UNDER-CLOTHING FOR COLD WEATHER.—I have written on this subject before, but there seems to be need of precept upon precept. Of late I have been learning better ways than I knew before.

For children of three years and over there is nothing better, perhaps, than an under-garment clothing the body from the neck and wrists to the heels, much like the night-drawers children wear. They may be made with a plain, easy, high-necked waist, with long, straight sleeves, and with open drawers sewed to the waist. The drawers should be rather full at the top, but small enough at the lower part of the leg to go inside the stocking, reaching to the heel, or leaving no gap above the shoe. "Doctors disagree" about the material of this under-garment, some recommending woolen and some cotton. Taking into account the difficulty of washing woolen without shrinking it, and the disagreeable sensation many skins experience in wearing it, probably the best way in most cases is to have this under-garment made either of cotton-flannel or of thin cotton-cloth, with a similar garment of warm woolen material over it. Buttons at the waist support the other under-clothing.

There are many sensible ladies in these United States now wearing under-garments similar to those just described. Among them the preference is usually given to thin cotton material for the suit next the body, with a suit made of woolen (white flannel, gray ladies'-cloth, or red firemen's-flannel) in the same fashion worn over the cotton suit in winter weather. With two such woolen suits for frequent changes, to give opportunity for thorough airing and sunning of the woolens, they require very little washing. The cotton next the body takes up the perspiration, etc., and this gets the good weekly washing. The woolen suit when taken off weekly for a change need only be exposed to pure air and sunlight for a day or two to purify it properly, washing it only when it visibly requires it.

If men wear cotton under their woolen shirts, the woolen may be treated in the same way, and men who are not engaged in dirty work can wear their woolen shirts all winter with very little washing, purifying them by air and sunshine each week when changes are made. Ladies' cloth shirts shrink less than common flannel.

SQUIRREL STEWS.—I was told long ago that common red squirrels make very good food, but our first and second attempts at cooking them were not very successful. Perhaps a part of the fault was in the dressing, but now I know that I did not cook them long enough. In the region where we live red squirrels are so thick (or were until the late "dispensation" overtook them) that they do a deal of mischief to corn, etc. Half-a-dozen of these marauders make a nice dish to set before as many grown-up people who relish fresh meat for dinner. The squirrel lives upon the best of food, and lives a free, active life, but its very activity gives it muscles a tendency to toughness. This can be overcome by sufficient boiling. In the first place, it must be carefully skinned and dressed while yet warm. If the entrails are left in the animal until the body is cold they will injure the flavor of the meat more or less. Put them in cold water enough to cover them, and skin the pot carefully when it comes to boiling (this always in boiling or stewing meat or in making soup). Two hours' gentle boiling is not too much for young squirrels, and three hours for old ones. Never season them until they are done tender, and then you will add salt and cream, or a bit of butter, according to your judgment. A little thickening (a table-spoonful of flour stirred smooth in half a cup of milk or water) stirred in while the pot is boiling will make a nice gravy. Pour the whole over slices of bread or split gems. The strong flavor of squirrels comes from the fat. Cut this all away carefully before cooking.

I suppose everybody knows that gray squirrels are good eating. Red ones are just as good when well cooked, only they are smaller.

Chicken Stuffing.

"MOLLIE WANTS TO KNOW" how to make good chicken stuffing, does she? Well, I don't profess to know much about cooking; I'll fix your puzzles, paint your pictures, write your letters, and eat your dinners for you while you do the cooking; but if there be one article of culinary construction which I do understand it is chicken stuffing, and this is how I make it (that is, if I have to make it by reason of being without a cook. "Oh! yes, 'm, indade I'll have to lave; the docther says it's the debility I got, an' that I haven't a bit of muscle in my whole body." Of course, then I have to go into the kitchen on my muscle, and this is how I make the chicken stuffing): Three teaspoonfuls of grated bread-crumbs rubbed through a colander (don't let a drop of water come near those crumbs, and take out every bit of crust); one teaspoonful of very finely-chopped beef-suet; two thirds of a teaspoonful of chopped parsley; a good pinch of sweet marjoram and summer-savory; the grated rind of one lemon; some grated nutmeg, pepper, and salt. Now bind all these ingredients together with one or two beaten eggs, stuff your chickens,

boil or roast them, and invite me to dinner that I may see you enjoy that stuffing. AUNT SUE.

How shall we Keep Thanksgiving-Day?

The poor, poor stomach! What crimes against digestion are committed in the name of Thanksgiving! Our customs smack somewhat of heathenism, or would if the overloading of the stomach done on Thanksgiving-day were really done in the name of religion.

Don't I believe in Thanksgiving festivals? Indeed I do. But "enough is as good as a feast," and a great deal better than too much. What I wish to enter my protest against is the great variety of food offered at a single meal, and the indigestibility of most of it. The pie-crust alone which is eaten on that day adds much to the ill health of individuals, and greatly increases the sum total of our national dyspepsia. I speak feelingly, for I was wretched for two days after last Thanksgiving-day in consequence of the very small amount of pie-crust I ate that day. I was away from home, and in a part of the country where fresh apple-pie was a rarity. I left upon my plates as much of the chicken pie-crust and of the crust of fruit pie as I dared and pay any regard to good manners—but, oh! the lard! I understood then for the first time why such a cry is made about the indigestibility of pie-crust, for I was not brought up on anything like that. Now, pie-crust can be made very nice and palatable and wholesome—not "puff paste," but sensible crust for good fruit-pies. Use much less than the usual recipe of shortening, and eschew lard totally. Good sweet butter or cream are the only kinds of shortening hygiene allows. Many people who abhor pork use lard for shortening, but it is a distinction without any real difference.

But to the pie-crust. A little baking-powder (at the rate of a tea-spoonful to a quart of flour) will insure lightness. If you are afraid of the "neutral salts" left in bread or crust after the acid and alkali unite and effervesce, and dare not put your faith in Horsford's bread-preparation, use good cream, either sour or sweet, without any soda. Let your oven be waning in heat when you set the pies in, but hot at that moment, and set the pies upon the bottom. This do for the sake of baking the bottom crust before it gets soaked with the fruit juice.

How can an intelligent Christian woman set mince-pies before her family? If you make them so plain that they will not hurt anybody, who cares to eat them? They only taste good when they are so spiced that no stomach but the strongest can digest them without suffering, and such things finally break down the strongest stomach.

To make such conglomerations as mince-pie, pound-cake, old-fashioned fruit-cake, and the regulation plum-pudding, and expend the thankfulness of our hearts over food prepared in the most health-destroying manner, is—well, isn't it blasphemous? For just see! Here we have the most delicious fruits sweetened and flavored all ready for the eating, and such an abundance of beautiful and nutritious vegetables which need only the simple preparation of cleaning and softening with heat and water to be made fit to set before any creature with unvitiated tastes. And shall we ordain our Thanksgiving-day, and then set all God's bounteous autumn store in the background while we weary and heat ourselves making artificial preparations which tickle the depraved palate, but do injury to the whole body?

It is a good time to have those particular goodies which are too rare or scarce for every-day use. For most people roast turkey comes under that head. That is my idea of a feast—to choose a few delicious viands and spread a bountiful table with those. I would have plenty of these feasts, too—one for Thanksgiving, one for Christmas, one for New-Year, one for Fourth of July, one for each child's and each parent's birthday, and one for each family anniversary. A particular kind of choice fruit, or game, or good (but not dyspeptic) cake or pie, or nuts, or ice-cream, might celebrate each anniver-

sary. One special good thing is enough, with other wholesome every-day fare, but more than one "goody" is admissible, if there is harmony in the flavors, and no "death in the pot" in the way of unwholesomeness. It used to be thought that you must cook a little of everything you had in the house, but we are outgrowing that childishness I trust, as we are learning more about harmonies of flavor and more about the stomach's requirements and powers of endurance. And persons once seemed to feel obliged to eat a little of everything upon the table. Jean Macé tells of a man who died suffocated from excess of food after one of the great public dinners, and "his stomach was found so distended that it alone occupied more than one half his inside." Beware of a similar fate!

Of course eating is not the only event of Thanksgiving-day. A thankful heart is the great thing! And that we should have every day of our lives, for there is no life so bare and hard that it has no cause of thankfulness. RELI.

Chopped Pickle.

What we call Chopped Pickle goes also under the name of Chow-Chow, Picklette, Higdum, etc. It is liked by most persons, is readily made, and admits of the use of a number of articles. There is no particular rule for making it, and the basis may be of whatever pickle-making material is most abundant. We have just put up our winter stock, and this time made it as follows. Green tomatoes furnished the largest share, then there were nearly ripe cucumbers with the seeds removed, cabbage, onions, and green peppers. These were chopped in a chopping-machine and mixed, sprinkled freely with salt, and allowed to stand until the next day. The abundant juice was then thoroughly drained off, and enough spiced vinegar prepared to cover the material. No rule can be given for the spice, which may be according to taste. Whole pepper, cloves, mustard-seed, broken cinnamon, or whatever spice is fancied, may be boiled in the vinegar. We prefer it with the addition of sugar. Some mix up mustard and add to the pickle when cold, and others boil turmeric in the vinegar to give it a uniform yellow color. It is a pickle that can be made according to fancy rather than according to rule. In winter, cabbage, celery, and onions treated in the same way make a very fine pickle. As with other pickles, the vinegar should be poured off, and boiled, at intervals of a few days, two or three times before it is put away for the winter.

To Clean Smoky Paper-Hangings.

Take a piece of wood of the shape of a scrubbing-brush, nail a handle on the back, then upon the face nail a piece of dried sheepskin with the wool upon it, or flax or tow will do, or cotton-flannel of several thicknesses will answer very well. Dip this brush into dry whiting, and rub the smoke lightly with the brush, on the upper parts of the room first—protecting the carpet with matting or newspapers, as the whiting-dust is hard to sweep off a carpet. The whiting that remains on the wall is easily brushed off with a soft cloth attached to a stick. It is very effectual if the room is not damp and the whiting is dry. W.

To Wash Straw Matting.—Take a pail half-full of hot water, a perfectly clean long-handled mop, and a dish of dry, unsifted Indian-meal. Sweep all dust off the matting, then scatter the dry meal evenly over the room. Wring the mop so dry that it will not drip at all, and rub hard, one breadth at a time, always lengthwise of the straw, and use clean water for each breadth. When the matting is dry, the meal can be swept off easily; it should always be done on a dry day.—W.

Roots.—If these are stored in a cellar under the dwelling rooms, have them covered with dry earth, which will prevent disagreeable and unhealthy odors from coming into the apartments.

BOYS & GIRLS' COLUMNS.

Our Guessing School.

In September last I gave an engraving of a curious thing, and asked, "What is it?" A copy of the *Agriculturist* for next year was offered to the one who would give the "best account of it." I have received within a few of a hundred answers—more than I expected, as it is not a very well-known thing.

Of these answers thirty-one give the correct name, and several have sent well-written accounts of the thing, which is the egg of the Skate or Sting-Ray, called by the

WHAT IS IT? NO. 2.

fishermen Stinger. Indeed, two or three of the best were so near alike that I find it difficult to choose between them, but the one that is upon the whole the best, is printed below, and the writer of that takes the prize. Some of the answers were very wide of the mark, a great many were quite sure that the "What is it" was the egg of a shark, and they were very near the truth, but the shark's egg is not black, and the horns or projections at the corners are different. Several say that it is a piece of sea-weed; and others, that it is the dried and cracked open pod of a *Martynia*, to which it bears a slight resemblance. Two or three send the name of the *Nautilus* or Portuguese Man-of-war, which is far away from right; another calls it a "Sea-Bean;" another, that it is the egg of a King Crab; another, that it is a species of mussel, and still another calls it "The Ink Flying-fish," and so on.

As this has proved a useful exercise to many, I will give you another thing to work at. The "What is it?" engraved on this page is a piece of something that I picked up on the sea-shore many years ago. It is shown of the natural size, except in length, which is often two feet or more. It is of about the color of horn. Now, the conditions will be the same as before—the *Agriculturist* for 1873 for the correct name and best description, only we restrict the competition to young people of 18 and under.

What I Know about Skates.

BY SALLIE C. GERARD, POUGHKEEPSIE, N. Y.

Think of my surprise when, on opening the paper this month, I was confronted by the familiar form of an old acquaintance! I say old acquaintance, indeed I may say a tried one, for I certainly tried hard enough to find out what it was, the first time I found it at the sea-shore. Everybody has his or her "hobby," and mine happens to be Natural History, so it is no wonder that on finding, at the sea-side, my first specimen of the object your artist has so well illustrated, I did not rest until I had discovered what it was and learned all about it. You ask your young readers to give some account of this "What is it?"—this great big spider-like looking thing. And this brings me to my subject, so I will say "What I know about Skates."

One of the orders into which naturalists have divided the fishes is called by them "*Plagiotomi*" (I copied this name out of a book!), and includes such families as the *Sharks* (those terrible cannibals!), the *Skates*, the *Rays*, etc. Both the families of *Sharks* and *Skates* contain some species that give birth to living young, and others

that follow the general rule among fishes of "laying eggs." But the eggs of these are larger and fewer than those of the commoner kinds of fish, and they have this peculiarity: each egg is inclosed in a leathery, oblong, four-angled case. Each corner or angle of these egg-cases is drawn out into a long, tapering, tubular appendage. As far as I can find out, the egg-cases of the shark differ from those of the skate in these particulars: those of the former are horny, transparent, and yellowish, and the tips of the appendages are curled like tendrils—a wise provision of the Creator for the preservation of the inclosed fish, for these tendrils become entangled among seaweeds, and the cases are thus safely moored and prevented from being harmed by the rough waves of winter (the season in which the eggs are deposited). The egg-cases of the skate are of a dark-brown color, about two inches long, and one inch wide; the appendages are straight, and not curled, as in those of the sharks. What you figure, then, is the egg-case of a skate. These empty egg-cases may be frequently found on the sea-shore where they have been cast up by the tide, and are commonly known as "*Skates' Barrows*," "*Pery Purses*," "*Mermaids' Purses*," "*Fairy Purses*," and also "*Sailors' Purses*"—a joke on poor Jack, as they are most always empty! And now as to these singular spiny appendages. What are they for? Of what possible use can they be? These are questions that I many a time pondered over and long endeavored to find out. It is well known that they serve to admit and eject water for purposes of respiration to the inclosed young fish, but as water could just as well be admitted through little holes in each corner of the egg-case it seems to me that these formidable horns must serve some other purpose. The number of eggs deposited by each individual of the shark tribe is much fewer than in other fishes; may it not be that these tubes serve as a protection against the many voracious monsters of the ocean, in order that the race be not exterminated? But here, while I am speculating on this subject, the young imprisoned fish has matured and wants to get out! Let us see how he accomplishes it. While the egg-case was still in the body of the parent fish, it was open at one end like a bag, and into this the egg descended, the mouth of the bag closed, and then the egg was "hid." Now that the egg has floated about a proper length of time, the slit again opens, through the efforts of the prisoner, and the fish emerges and swims off. For a short time the yolk is attached to him for his nourishment, but when this is absorbed into his body, he is ready to take his chances with his fellows of the finny tribe in the "struggle for existence," and I will now leave him to his fate.

Are You Ready for Winter?

When this question is asked in the farmers' pages, it has reference to barns, cellars, hay, root crops, and all that sort of thing, but when we ask it of boys and girls, we have specially in mind skates and sleds. Were the skates last spring left anywhere that it was most convenient to drop them, so that you will now have to hunt them, one at a time? or were they carefully tied together, the irons first rubbed over with oil, to prevent rusting, and hung in a dry place where the leathers would not mold? The sled too, or cutter, as some call it, has it been left out where the sun has so shrunken it that its joints are shaky, and the irons so covered with rust that you can not tell whether they are iron or not? If you neglected these things last spring, you will find it so much trouble to repair damages, that next time you will take more care. It is now November, and to some boys and girls skating and sledding have already come, and to others it will soon be the season for these healthful winter amusements, so we ask if you are all ready for them. If not, get ready, for ice and snow may be at hand at any time. If the skates are rusty, oil them and let them stand for a few days; then rub the rusty spots with oil and emery. If you can not get fine emery, scouring-brick or coal ashes will do, but it will take more rubbing. Then, if the leather straps have become stiff, as they will for want of use, wash them with castile-soap and water, and while they are still damp, rub them over with neat-foot oil, such as is used on harness. So with the sled. See that the rope is strong, and if any joint is loose drive in a wedge, and if need be, get some one to give it a coat of paint, if you can not do it yourself. Then do not forget to put the things that have gone out of use where you can put your hand on them at any time. The tops, balls, hats, croquet set, and all that will be wanted in a few months, and it is much easier to find them and care for them now than it will be at the time they are wanted.

Making Shadows.

These boys are having a fine time with making shadow-pictures upon the wall. A great deal of amusement can be made in this way, not only to divert young children, who are always pleased by these shadow-pictures, but older ones can get much entertainment from them. Almost every one knows how to arrange his fingers to form the shadow of a rabbit, a fighting cock, and a bleating calf, but these are not by any means all the pleasing shadows that can be made. In order to have the shadows show to the best advantage there must be a white wall, or in absence of this a white cloth pinned against the wall. Then there must be but one light in the room, and the shadow will be all the more distinct if this is a strong one. You must recollect that in shadows it is only the outline that shows, and in forming them with the hands it makes no difference how the rest of the fingers are fixed if those engaged in producing the shadow are in their proper places. Also, the nearer the hands are held to the wall

the sharper will be the shadow. A closed fist with the fingers in the proper position will give a very amusing outline of a negro's head, and by the clever arrangement of a handkerchief a characteristic turban can be made for the head. A little ingenuity and patience will enable one by the use of one hand or both to produce very amusing shadows. Still more pleasing are what are called Chinese shadows. A sheet is hung across a door between two rooms; the spectators are in one room, in which there is no light, and the shadow-makers are in the other, in which there is a very strong light. The lower half of the door has a blanket or other screen, through which the light can not pass, across it, and the performer is hidden below this. When he lifts his hands above the screen the shadow falls upon the sheet. But Chinese shadows are not usually made by the hands; figures cut from stiff paper or pasteboard are used and operated from below. As an outline only is required, the joints and all other parts may be made very rough. Any ingenious boy or girl can get up figures of men, women, and animals, to make these shadows, and cause them to have life-like movements, taking care that the hands operating them are carefully concealed below the dark screen. The exhibition of Chinese shadows can be made more amusing if a dialogue is kept up as if it came from the figures. It would not be difficult to illustrate some story or dialogue in this way, and thus furnish a pleasant entertainment.

Still in Advance!

The Smith American Organ Co.

Respectfully announce that they have now an additional large manufactory in operation, making a

Great Increase

In their weekly production of instruments.

At the same time, they have introduced a number of

ENTIRELY NEW STYLES,

With elegant cases, increased power of tone, and improved mechanism.

They ask the attention of musical people to the new styles—**ESPECIALLY TO THE QUALITY OF TONE**—believing that these instruments will be pronounced the finest now made in the world.

"A beautiful diamond edition also has been prepared with clear type, new and beautiful engravings, and containing nearly all the styles in demand."

DOWNING'S FRUITS AND FRUIT TREES OF AMERICA.

By A. J. Downing. Newly Revised and Greatly Enlarged by Chas. Downing. 8vo., 1122 pages. Price \$5.00.

The original work of the late A. J. Downing appeared in 1815. Some years after it was revised and much enlarged by his brother, Charles Downing, who has again completed the work of a second revision. Charles Downing is upon all hands acknowledged as one of our highest pomological authorities. He writes but seldom, but whatever bears his name is accepted as the judgment of one who is entirely interested, as far as the commercial aspects of pomology are concerned. The present edition contains the results of many years' labor and experience which have been devoted to testing the value of fruits and acquiring a knowledge of them that should benefit others. When we compare this edition with the modest one which first appeared, we can see to what extent the subject has grown. If only a small proportion of the new varieties that have been added prove valuable, we shall have reason to be proud of our progress. This elegant and valuable work will be an indispensable requisite in every library, and to all interested in Fruits or Fruit Culture.

Either of the above books sent post-paid on receipt of price by

ORANGE JUDD AND COMPANY,

RICHARD LAUER, 52 Cedar St., New York, Sole Agent for the United States of the celebrated Nurserymen, Messrs. L. Van Waveren & Co., Holland, is now ready with his own Fall Importations from these eminent Florists, whose productions are unsurpassed for beauty. These goods, coming from a reliable source, are offered at importers' prices by the assorted case or otherwise. Catalogues furnished upon application by letter.

Great Change of Business Location.

Owing to our rapid increase of business all over the United States and Territories, we were compelled to get a more central location near New York. We therefore have removed between Newark and Elizabeth, N. J., only 1/2 hour's ride from New York City, where trains leave every half-hour each way. Letters and business communications should be addressed to

OLM BROTHERS, Newark, N. J.

To Dairymen & Capitalists,

1000-Acre Dairy Farm for Sale, with Stock, Implements, etc.

PRICE, \$40,000

The subscriber offers for sale Springwater Farm, consisting of 1,000 acres, situated on Senegor Island, Ontario County, Canada, and about seven miles from Port Perry, the terminus of the Whitby and Port Perry Railway, and close to the water's edge of Senegor Lake, where there is an abundance of fish and game.

This Farm is specially adapted for dairy purposes, being watered with numerous springs—all the buildings being supplied with water from this source, conducted through pipes, as well as the cattle-yards, etc.

There are on the place twelve houses for workmen, five large barns, horse and cattle stables, sheds, pens, etc., and one large dairy building, through which a stream of water constantly runs.

The soil is first-class, never failing to produce heavy crops. There is a reserve of wood-land in connection with it, sufficient to meet the requirements of the place.

The Farm would be sold in one or two blocks of 500 acres each, the purchaser having the option to take the cattle, stock, horse, and implements, at a fair valuation made by disinterested parties.

Terms of sale for the land, \$10,000 down, balance on mortgage for from five to ten years, with interest at seven per cent per annum. For stock, implements, etc., \$5,000 down, balance in one year, without interest.

Parties desiring to see the place or to purchase, will please address

W. S. SEXTON, Port Perry P.O., Ontario, Canada.

FOR RENT.—The valuable farm known as

"KIVERSDALE," the property of the late Hon. Chas. B. Calvert, near Badensburg, Prince George's Co., Md., about seven miles by rail, and good turpicks, from Washington, D. C. It contains about 300 acres, 200 of which are cleared and mainly in grass, with water in every field. There are two good farm-houses, and commodious barns, with stabling for over 100 cows. The proximity of the National Capital renders this one of the best possible points for a dairy or truck-farm. The Washington branch B. & O. R.R. runs through the place, with two stations very convenient. For particulars, terms, etc., address the editors of **THE AMERICAN FARMER, Baltimore, Md.**

900,000 ACRES

OF

EXCELLENT FARMING
AND SPLENDID

Michigan Pine Lands

FOR SALE,

On which are ONE THOUSAND MILLIONS OF PINE TIMBER, and inexhaustible quantities of Maple, Beech, Elm, Ash, Hemlock, Oak, etc.

The grant of lands to the Grand Rapids and Indiana Railroad Company, to build their Road from Fort Wayne, Ind., to Traverse Bay and Mackinaw, Michigan, comprises in its farming lands every variety of soil, from the rich clay loam to the light sandy, and they are found in that section of Michigan, north of the city of Grand Rapids, and contiguous to the great fruit belt on the eastern shores of Lake Michigan, now being rapidly developed by railroad and other enterprises.

Farming Lands are sold to actual settlers, on credit, one quarter down, balance in yearly payments, interest 7 per cent. Persons desirous of locations for farms will, on application at the Office in Grand Rapids, be furnished with Tickets over the Road, entitling them to Return of Fare, in the event of purchasing any of the Company's farming land. For information about the lands, prices, location, etc., etc., address

WM. A. HOWARD, Land Commissioner,
Grand Rapids, Michigan.

BEAUTIFYING COUNTRY HOMES.

AN ELEGANT QUARTO VOLUME.

By J. WEIDENMANN.

This magnificent work is illustrated not only with numerous fine wood-engravings, but also with seventeen full-page and seven double-page colored lithographs of places already improved. It embodies the results of a long practice in landscape architecture and rural adornment, and while its teachings are in accordance with the received rules of art, they are thoroughly practical in their character. It is one of the most elegant, and ought to prove one of the most useful works ever issued in the country. The work, both in its letter-press and colored lithographs, is beautifully printed, and it is elegantly bound in beveled boards.

PRICE, POST-PAID, \$15.00.

ORANGE JUDD & COMPANY,
245 BROADWAY, NEW YORK.

OVER 12,000,000 SQUARE FEET NOW IN USE.

FIRST PREMIUM (MEDAL) AWARDED IN 1870, AND INDORSED BY CERTIFICATE FROM THE AMERICAN INSTITUTE IN 1871, AS "The Best Article in the Market."

ROCKFORD, September 7th, 1872.

C. L. RICE & CO., Chicago, Ill.:

DEAR SIR:—Yours of yesterday asking for my experience with H. W. Johns' Patent Asbestos Roofing duly received. In answer, would say, I have used Mr. Johns' Roofing and Coating extensively for Ten Years past, and with great satisfaction. I have applied it to more than three hundred roofs in Rockford, Ill., and adjacent country. I have roofs in Rockford that have been on Eight Years without Repairs—they are sound and good, and by simply recoating will last as much longer. I have seen and tested many kinds of Composition Roofing during the past ten years. I have seen nothing that comes up to "Johns' Patent Asbestos." Truly yours, L. M. WEST.

The "Asbestos Roofing" is adapted for steep or flat roofs, in all climates, and can be easily and cheaply transported and applied.

Send for Sample, Descriptive Pamphlets, Price-Lists, Terms to Dealers, etc.

Established in 1858. H. W. JOHNS, 78 William St., New York.

The WESTERN TRADE supplied by C. L. RICE & CO., CHICAGO.

The TEXAS TRADE supplied by B. S. PARSONS, GALVESTON.

The CANADA TRADE supplied by R. J. SHORT, MONTREAL.

Important to Farmers & Stock-Owners.

TAYLOR'S HORSE AND CATTLE FOOD is used with great success in fattening horses, cattle, and swine. It gives a good appetite, acts on the kidneys, destroys worms, and gives a glossy coat. Stage proprietors, dairymen, farmers, stock dealers, and other reliable gentlemen have given it a thorough trial, and say it is the best article they have ever used for putting and for keeping stock in a good, healthy condition. It is also good for coughs and colds in animals, and is pronounced a very superior cure for cholera among poultry.

Diplomas have just been awarded to it by the Queens Co. and Suffolk Co. Fairs, Long Island.

It is manufactured exclusively by the

MANHATTAN FEED MILL CO.,

N. B. TAYLOR, President. 508 W. 26th St., New York.

ANNUAL SUBSCRIPTION TERMS (always in advance): \$1.50 each for less than four copies; Four to nine copies, \$1.25 each; Ten to nineteen copies, \$1.00 each; Twenty copies and upward, \$1 each. Papers are addressed to each name.

HEARTH AND HOME: \$3 a year for less than four. Four to nine copies, \$2.75 each; 10 or more copies, \$2.50 each.

Hearth and Home (weekly) with American Agriculturist sent to one address for \$4 a year.

Read this Carefully.

GOOD THINGS, Desirable, Wanted by All, Easily obtained Without Money, and with Little Trouble.

Special Attention is invited to the list of choice articles in the Table, and to the descriptions following. . . . These articles are fully worth the money value set against each, which is the regular price. Everything in the list is new, useful, and first-rate.

These articles are offered as Premiums or Gifts to those persons who take the little time and trouble needed to collect subscriptions, new and old, for our papers. Over 14,000 persons have secured one or more of them, and they have almost universally given great satisfaction to those receiving them.

They are all just as good as money. The assortment is so large, that every one will find something needed. See table and descriptions.

They may be easily obtained by Farmers, Postmasters, Gardeners, Merchants, Nurserymen, Mechanics, Physicians, Lawyers, Ministers, Students, Teachers, Clerks, Ladies, Conductors, Children, By ALL.

Any person who chooses may collect a small or large list of subscribers and receive the premium. (See articles on page 408.) It is only necessary to show copies of the papers, explain

their value, promise the \$5 picture, and collect and forward names.

It has been done largely at Stores, Shops, Post-offices, etc., and by private individuals. By Co-operation, Ministers, Teachers, Churches, Sunday and week-day Scholars, have obtained Melodeons, Libraries, Dictionaries, etc., also Sewing Machines, etc., for poor widows and others. Many Professional men have made up good premium lists at their offices. Clerks in Stores and Post-offices have materially increased their salaries thus, while individuals in all classes have secured good things for themselves or for presents to others, all without the use of working hours, and at no money cost.

The American Agriculturist is everywhere known and approved. HEARTH AND HOME is now without a superior in the world as a splendidly illustrated Weekly Newspaper, for real value, cheapness, and adaptability to every home in America. The papers are entirely different. Taken together, they supply over \$30,000 worth of fine engravings, and more good reading than can be found in fifty books costing one Dollar each.

Premium Clubs can be made up of subscribers to either paper, or partly of one and partly of the other, as noted over the Table. We call especial attention to the last column of figures, showing the small number of names required where both papers are taken, at the reduced price of \$4 a year.

You, Reader, can get a Premium. TRY IT.

Explanatory Notes. N. B.

Read and carefully Note the following Items: (a) All subscribers sent by one person count, though from one or a dozen different Post-offices. But... (b) Tell us with each name or list of names sent, that it is for a premium.... (c) Send the names as fast as obtained, that the subscribers may begin to receive the paper at once. You can have any time, from one to six months, to fill up your list.... (d) Send the exact money with each list of names, so that there may be no confusion of money accounts.... (e) Old and new subscribers all count in premium clubs, but a portion, at least, should be new names; it is partly to get these that we offer premiums to canvassers.... (f) Specimen Numbers, Cards, and Show-bills will be supplied free as needed by canvassers, but they should be used carefully and economically, as they are very costly.... (g) Remit money in Checks on New York Banks or Bankers, payable to order of Orange Judd & Co., or send Post-office Money Orders. If neither of these is obtainable, Register Money Letters, affixing stamps both for the postage and registry; put in the money and seal the letter in the presence of the Postmaster, and take his receipt for it. Money sent in any of the above ways is at our risk; otherwise it is not.

[In the following table is given the price of each article, and the number of subscribers required to get it free, at the regular rates, \$1.50 a year for American Agriculturist, and \$3.00 a year for Hearth and Home; also at the club rates of \$1 and \$2.50: also at the rates of \$4 a year for both papers together.] Descriptions of Premiums on next page.

N. B.—In all Premium Clubs for either paper, TWO copies of American Agriculturist at \$1.50 each, and ONE copy of Hearth and Home at \$3.00, will count exactly the same. So also two copies of American Agriculturist at \$1 each, and one copy of Hearth and Home at \$2.50, will count exactly the same. In this way Premium Clubs can be made up from the 2d and 4th columns, or from the 3d and 5th, or wholly from the 6th column.

Table of Premiums and Terms, for American Agriculturist, and for Hearth and Home, for the Year 1873. Open to all—No Competition.

Table with columns: No., Names of Premium Articles, Price of Premiums, (1) American Agriculturist, (2) Or (3) Hearth and Home, (4) Or (5) Both Papers together, Or (6) Both Papers together. Lists items like Knives and Forks, Revolving Butter Cooler, Card Beater, etc.

Every Premium article is new and of the very best manufacture. No charge is made for packing or boxing any article in our Premium List. The Premiums, Nos. 5 to 9, 19 to 25, 28, 50 to 73, and 76 to 88 inclusive, will each be delivered FREE of all charges, by mail or express (at the Post-office or express office nearest the recipient), to any place in the United States or Territories.—(No. 27 mailed for 30 cents extra.) The other articles cost the recipient only the freight after leaving the manufactory of each, by any conveyance desired. See Description of Premiums on Next Page.

Descriptions of Premiums.

(For number of Subscribers required, see Table, page 433.)

Nos. 1, 2, 3.—American Table Cutlery.—We are glad to be able to offer really good articles of American manufacture, such as are competing successfully with the best foreign make. Messrs. Patterson Bros., 27 Park Row, who supply us with these articles, are also importers of English goods. They recommend these Knives, manufactured by the Meriden Cutlery Co., as equal to any Cutlery in the market, and their recommendation is a guarantee, wherever they are known. We offer two kinds of Knives, and three sizes of each kind. No. 1 have Rubber Handles, which are actually boiling-water proof, so that, if they were accidentally to remain in it for several minutes, or even hours, they would not be injured. The Blades are of the best steel, and warranted. Dessert size, with Forks, sold at \$15. For 24 subscribers at \$1.50, or 80 at \$1, we will give either the medium size or the table size, sold at \$16.00. No. 2 have Ivory Handles, are selected with great care, have Steel Blades, and are beautiful goods. Dessert size, with Forks, sold at \$30.00. For 33 subscribers, at \$1.50, or 110 at \$1, we will send the medium size, sold at \$22.00. For 35 at \$1.50, or 116 at \$1, we will send the Table size, sold at \$23.00. The Forks, which accompany these Premiums, Nos. 1 and 2, are made of genuine Albata, and warranted double-plated with coin-silver. These Forks are furnished to us by Messrs. Patterson Bros. The Carving-Knife and Fork are made by The Meriden Cutlery Co., with the best Ivory, balanced Handles.

No. 4.—French Cook's Knife, Fork, and Steel.—This is a long (10 in.) thin Knife, with Pat. Rubber Handle, made of the best steel, and for use rather than ornament; and it is really pleasing to see how easily it slips through a joint of beef. The fork and steel are made to match. It would save many wry faces, and perhaps hard words, were it in general use. Made by the Meriden Cutlery Co.

Nos. 5, 6, 7, 8.—Pocket Knives.—HERE'S FOR THE BOYS AND GIRLS!—These Premiums are among the most pleasing and useful that we have ever offered. Every boy, and girl too, wants a pocket knife. We give them an opportunity to obtain a most valuable one for merely a little effort. These knives are furnished by the Meriden Cutlery Co., 49 Chambers st., New York, whose work is equal to any done in this country or Europe. No. 5 is a neat, substantial Knife, with three blades and back-horn handle. No. 6 is a still finer article, with four blades and pearl handle. No. 7 is an elegant Knife, with five blades and shell handle. No. 8 is a Lady's Pocket Knife, a beautiful article, with four blades and shell handle.

No. 9.—Multum in Parvo Pocket Knife.—This is a most attractive as well as useful Premium, from the well-known manufacturers, Miller Bro's Cutlery Co., West Meriden, Conn. It comprises, in one knife-handle, a large and a small blade, a screw-driver, a saw, a strong hook, a nut-cracker, a brad-awl, a gimlet, a corkscrew, a pointer, a slim punch, tweezers, and, in addition to this, it can be used for various other purposes which will at once suggest themselves to any smart boy or man. It is a pocketful of tools weighing but two ounces. The knives will be sent anywhere in our country, post-paid.

No. 10.—Cake Basket.—A new pattern, oval-shaped, or square, nicely chased—a very taking, useful, and beautiful table ornament. This, with other articles that follow, is made by the Lucius Hart Manufacturing Co., of Nos. 4 and 6 Burling Slip, New York City, and is warranted by them to be of the best triple plate. Mr. Hart, "the veteran Sunday-school man," was engaged to the same place and business for nearly a quarter of a century. We have known him and his work for many years, and have taken pleasure in commending and guaranteeing its value to be as represented. We believe the Company which bears his name is fully sustaining his reputation. The amount of silver upon plated ware depends wholly upon the will and integrity of the manufacturer. We could give nearly as good-looking plated ware for less than half the money.

No. 11.—Revolving Butter-Cooler.—This is a really good and useful article. It is so arranged that a very little ice in the holder under the plate will keep butter cool and fresh for a long time on the table, even in the hottest weather. The cover revolves underneath the plate for use, and over for protection. The whole is in four pieces, which can all be taken apart for washing. From same house as No. 10.

No. 12.—Card Receiver.—This is a beautiful ornament, as well as a useful article. It is finely chased and gilt-lined, and like the three preceding, is from the Lucius Hart Manufacturing Co.

No. 13.—Nut Picks and Crackers.—Here are twelve nut-picks, elegantly chased, of medalion pattern, with two handsome nut-crackers, in a morocco-covered case. From the same house as No. 10.

No. 14.—Half-Dozen Napkin-Rings.—These rings are beautifully chased, and in a morocco-covered case. From the same house as No. 10.

No. 15.—One Dozen Teaspoons.—**No. 16.—One Dozen Table-Spoons.**—These are "figured tips," Olive-leaf Pattern, all of the same metal, plating, etc., and from the same makers as No. 10. They are far cheaper than anything we have found at half the price, and are well worth working for.

No. 17.—One Dozen Table-Forks.—The same description and remarks apply to these as to No. 16. We select as premiums only such articles as we can warrant in quality and price. All these articles come from the Lucius Hart Manufacturing Co.

No. 18.—Child's Cup.—A beautiful gift for the little one-year-old. It is made by the Lucius Hart Manufacturing Co. Triple-plated on the outside and gilded on the inside. It never breaks, and will last for many years—indeed, be a life-keepsake.

Nos. 19, 20, 21.—Gold Pens; with ever-pointed Pencils, in extension, coin-silver cases.—Premium No. 19 contains the best No. 4 Gold Pen; and No. 20 the best No. 6 Gold Pen, which is the same style, but larger. No. 21 contains No. 7 Gold Pen, in Gold-tipped Ebony Holder. Each pen will be sent in a neat leather case by mail, post-paid. These pens are made by Geo. F. Hawkes, No. 66 Nassau St., and have obtained an excellent reputation. We have known the maker and his goods for many years, and can recommend them.

No. 22.—Ladies' Fine Gold Pen, in Rubber Case, Gold Mounted, with Screw Extension, and Gold Ever-pointed Pencil. A beautiful present for a lady teacher or friend. Same maker as No. 19.

Nos. 23, 24.—Paragon Patent Revolving Pencil.—This is a beautiful Pocket Pencil, which is extended or closed by pulling or pressing the head. They are made with great care, and every Pencil warranted to work perfectly. They are gold-plated, and will last for years. We offer two patterns, one for ladies, with ring for chain, at \$1.50 each, and one of heavier and finer plate, at \$3.00. Same maker as No. 19.

No. 25.—Payson's Indelible Ink, and Briggs's Marking-Pen Combination.—Payson's Indelible Ink is too well known to need further commendation. It is almost indispensable in the family. Briggs's Marking-Pen has been before the public for fifteen years, and is justly celebrated for all kinds of marking, and particularly for writing upon coarse fabrics. The Pen and Ink are put up in a neat case, being thus portable, always ready for use, and protected from loss or injury by evaporation or breakage.

No. 26.—Moore's Floral Set.—This is a beautiful Premium—a complete set of Ladies' or Children's Garden Tools for the cultivation of flowers, consisting of a Floral Hoe, Spade, Fork, and Rake. They are made of the best steel and iron, with finely polished hard-wood handles, light, durable, and highly finished, and each set inclosed in a box. They will be found very convenient in the garden and greenhouse, and are pleasing toys for the little folks. Made by the Moore Manufacturing Company, Kensington, Ct.

No. 27.—Steam-Engine.—This is a veritable steam-engine; one that will GO; and a capital, intensely interesting, and instructive article for boys, and grown-up people too. Our eleven-year-old boy ran his engine an average of an hour or more a day for six months; he exhibited it in motion to many of his playmates, hitched on various toy machinery, and it appeared to go just as well as when first started.

No. 28.—Very Choice Garden Seeds and Flower Bulbs.—We have taken special pains to have prepared by Messrs. B. K. Bliss & Sons, 23 Park Place and 20 Murray Street, whose seed establishment is well known as one of the best in the country, a list of seeds and bulbs of the very choicest kinds, and the most useful varieties. Though some are rare (and costly), all have been tested and found excellent. Here is an opportunity to obtain a valuable assortment of seeds, as this premium allows you to select from the list below any that may be desired, to the amount of two dollars. If more is wanted, it of course is only needful to secure two or more of the premiums, and select seeds accordingly. All delivered free: 1 Pkt. Early Wyman Cabbages, 25c.; Dioscorea Batatas, or Chinese Potato, per doz. bnbllets, 25c.;

Moore's Early Concord Corn, ½ pint pkt., 25c.; Laxton's Alpha Peas, ½ pint pkt., 25c.; Trophy Tomato, ¼ oz. pkt., 50c.; ½ oz. Marblehead Mammoth Cabbage, 50c.; ½ oz. Improved American Savoy, do., 25c.; ¼ oz. Improved Branswick, do., 25c.; ½ oz. Premium Flat Dutch, do., 20c.; ½ oz. Improved Red Dutch, do., for pickling, 25c.; ¼ lb. Bliss's Improved Long Orange Carrot, 50c.; 1 pkt. Perpetual Spinach Beet, 25c.; ½ oz. Boston Market Celery, 25c.; 2 oz. Dewing's Improved Early Turnip Beet, 25c.; 1 pint McLean's Little Gem Peas, 30c.; 1 pkt. New Black Pekin Egg-Plant, 25c.; 1 pint Crosby's Extra Early Sugar Corn, 25c.; 1 pkt. (ten seeds) General Grant Cucumber, 25c.; 1 oz. Boston Market Tomato, 50c.; 1 ounce Conover's Colossal Asparagus, 25c.; 1 pint New Dwarf Wax Beans, 50c.; 1 pkt. New Egyptian Blood Turnip Beet, 15c.; 1 pkt. Early White Erfurt Cauliflower, 25c.; 1 pkt. Early Simpson Lettuce, 25c.; 1 pkt. New Garnishing Kale, 25c.; 1 pkt. Latakia Tobacco, 25c.; 2 oz. Conn. Seed Leaf Tobacco, 50c.; 1 pkt. Early Paris Cauliflower, 25c.; 1 oz. Finest Cucumber Seed, for pickling, 25c.; 2 oz. Genuine Hubbard Squash, 50c.; 2 oz. True Boston Marrow, do., 50c.; 2 oz. Turban, do., 50c.; 1 Lillium auratum, or New Gold-banded Lily, from Japan, 50c.; 1 Lillium lancifolium rubrum, Japan Lily, red, 40c.; 1 Lillium lancifolium album, Japan Lily, white, 40c.; 1 doz. Gladioluses, fine mixed varieties, \$1.50; 1 doz. Mexican Tiger Flowers, \$1.25; 1 doz. Tuberoses, Double Italian, best, \$1.50; 1 doz. Hyacinths, double and single, in three colors, red, blue, and white (for fall planting), \$1.50; 4 doz. Tulips, double and single, early and late (for fall planting), \$2.00; 100 Crocuses, fine varieties (for fall), \$1.00.

Nos. 29, 30, 31.—Sewing Machines.—“A good Sewing Machine lightens the labor and promotes the health and happiness of those at home.” We offer a choice of three of the best of the leading machines, all of which have been thoroughly tested in our own families, and give entire satisfaction. While all are valuable, each has some excellence peculiar to itself. The Grover & Baker Machine is remarkable for the elasticity of its stitch, which is at the same time very firm and durable. The structure of the seam is such that, though it be cut or broken at intervals of only a few stitches, it will neither open, run, nor ravel. It sews directly from two spools, without rewinding. The Florence Machine makes different stitches, each being alike on both sides of the fabric. One of its special advantages is that it has the reversible feed motion, which enables the operator, by simply turning a thumb-screw, to have the work run either to the right or left, to stay any part of the seam, or fasten the ends of seams without turning the fabric. The Willcox & Gibbs Machine excels in the exceeding simplicity of its construction. Very little instruction and ingenuity are required to understand the few parts of which it is composed, and their use; and there is no expense for getting it out of order, until the parts are fairly worn out. One of its strongest recommendations is the ease with which it is worked, taxing the strength of the operator less than other machines. The new table and pedals are great improvements. All these machines have constantly increasing sales, showing the public estimate of their value. Either of them will prove a great treasure in any household—worth more than \$500. The \$300, at 7 per cent interest, would yield (less taxes) about \$32. Most families require at least four months of steady hand-sewing a year, costing, if all hired, not less than \$24 a month, board included, or \$96 a year. With a Sewing Machine, a woman can sew more in one month than in four months by hand. Here is a clear saving of \$73. But far above this—the everlasting “Stitch, stitch, stitch,” the bending over the work, and the loss of sleep, have brought tens of thousands to early graves. We say to every man, Get your wife a Sewing Machine, even if you have to sell a favorite horse or an acre or two of land—get the Sewing Machine any way. If you can get one through our premium-list—well; but get the machine. —No charge for boxing the machines. They go safely as freight. Send for circulars, giving full instructions, to Grover & Baker M'g Co., 736 Broadway, N. Y. Florence Sewing M'ne Co., 30 Union Square. Willcox & Gibbs M'g Co., 658 Broadway, N. Y.

No. 32.—Beckwith \$10 Sewing-Machine.—While we advise buying a \$55 to \$65 Sewing-Machine, we have long been looking for one which, while brought by its low price within the reach of multitudes who can not afford the valuable higher cost machines, should be at the same time worthy of commendation. This we have found at last. The Beckwith Machine is well and strongly made, is simple, its use being quickly learned, is applicable to almost all kinds of family sewing, and has already been tested so thoroughly that hundreds of testimonials, from all quarters, have been given by those who are delighted with its work. Each machine is put in a neat, compact box, with hemmer and guide, oil-can with oil, thread, different-sized needles, etc., with full printed directions for using. We offer these Machines on our Premium List. We will sell them to any who may wish to buy, for \$10 each, delivering to any express office in this city.

No. 33.—Bickford Family Knitting Machine.—This is a practical and efficient

machine, simple in construction, works very easily, makes scarcely any noise, occupies but little space, can be attached to any common table, and be removed instantly by simply turning a thumb-screw. It can be worked by any person of ordinary intelligence, after a careful perusal of the accompanying book of instructions and a little patient practice. A great variety of articles have been made with this machine, and it is capable of producing many more and different kinds. A complete stocking, heel, toe, and all, can be knit in ten minutes by a skillful operator, and socks, sacks, hoods, skirts, mittens, undergarments, etc., in remarkably quick time. Send for circular to **Dana Bickford, General Agent, 689 Broadway, New York.** For 52 subscribers at \$1.50, or 162 at \$1.00, we will send the machine with black walnut table, price \$33.

No. 34.—Doty's Improved Clothes Washer, with the Metropolitan Balance Weight. Over seventy-five thousand families in the United States are using the Doty Washing Machine, and we believe the improved machine has no superior. The "help" use it and like it. Send for descriptive circulars to **R. C. Browning, 32 Cortlandt St., New York,** or to **Metropolitan Washing Machine Co., Middlefield, Ct.** It goes cheaply by freight or Ex.

No. 35.—Universal Clothes Wringer.—A very useful, time-saving, strength-saving, clothes-saving implement, that should be in every family. The wringing of clothes by hand is hard upon the hands, arms, and chest, and the twisting stretches and breaks the fibers with lever power. With the Wringing Machine, the garments are passed rapidly between elastic rollers, which press the water out better than hand wringing, and as fast as one can pick up the articles. We have given thousands of these premiums, with almost universal satisfaction. They are made by the **Metropolitan Washing Machine Co., Middlefield, Ct. R. C. Browning, 32 Cortlandt St., N. Y.**

Nos. 36, 37.—Melodeons.—These are excellent and desirable instruments, for the *Home Circle*, for small Churches, for Sunday-schools, for Day Schools, Academies, etc. Instrumental and Vocal Music in a school has a beneficial influence upon the pupils. We have seen the whole tone and character of a school improved by introducing a Melodeon.—Set the pupils to work and they will raise a club of subscribers for this premium. We offer the Melodeons made by Messrs. **Geo. A. Prince & Co., Buffalo, N. Y.,** for we know them to be good. A large one in our own Sunday-school room has been there *thirteen* years, and is to-day just as good as when first purchased, though used from time to time by a large number of persons.—Several clergymen have obtained this premium for themselves, their Churches, or Sunday-school rooms. The clubs of subscribers were quickly raised among the members of their parishes.—Many others can get a Melodeon for their *home* use. Send a postage-stamp to the makers and get their illustrated descriptive circular. These Melodeons will be shipped direct from the manufactory at Buffalo. They can go safely as freight or by express. If an Organ should be wanted instead of a Melodeon, we can supply it for an increased number of subscribers in proportion to the value.

No. 38.—Steinway Piano.—SEVEN OCTAVE ROSEWOOD CASE, SOLID ROSEWOOD DESK, LARGE FRONT, ROUND CORNERS; OVERSTRUNG BASE, FULL IRON FRAME, PATENT AORAFFE TREBLE, CARVED LEOP, AND CARVED LYRE.—This is one of the most elegant Premiums ever offered; regular and only price \$650. That this magnificent instrument comes from the celebrated establishment of Messrs. **Steinway & Sons, Nos. 109 & 111 East 14th St.,** is enough to say; but it is due to these enterprising manufacturers to state that, while their pianos have repeatedly received the FIRST PREMIUMS, by the award of the most competent judges the world can produce, at the Universal Exposition, in Paris, they received the FIRST GRAND GOLD MEDAL for American Pianos in all three styles exhibited, viz.: Grand, Square, and Upright. The following official certificate was signed by the President and the five members of the International Jury: "Paris, July 20th, 1867. I certify that the First Gold Medal for American Pianos has been unanimously awarded to Messrs. Steinway by the Jury of the International Exhibition. First on the List in Class X." The Society of Fine Arts in Paris unanimously awarded Steinway & Sons their *only* annual Testimonial Medal for 1867. The President of the Musical Department of that Society reports: "The pianos of Messrs. Steinway appear to me, as well as to all the artists who have tried them, superior to all that have been made to this day in the entire world." The best judges in America say the same. We also speak from personal knowledge, as each of our partners has one at home and desires no better. This splendid premium may be secured by many persons. Only 625 subscribers are required to do it. Several have obtained this premium. It will pay for even a year's labor. Classes of young ladies at school might unite in canvassing, and obtain a present for a Teacher, or a Piano for their

school-room. We shall be glad to give this premium to a large number. Send to Messrs. **Steinway & Sons, New York City,** for a free circular describing it.

No. 39.—A Good Watch.—The Watches made by the **American Watch Co., Waltham, Mass.,** have peculiarities of excellence which place them above all foreign rivalry. The substitution of machinery for hand labor has been followed not only by greater simplicity, but by a precision in detail, and accuracy and uniformity in their time-keeping qualities, which by the old method of manufacture are unattainable. A smoothness and certainty of movement are secured which proceed from the perfect adaptation of every piece to its place. The extent of the Waltham establishment, the combination of skilled labor, with machinery perfect and ample, enable them to offer watches at lower rates than any other manufacturers. Their annual manufacture is said to be double that of all other makers in the country combined, and much larger than the entire manufacture of England. The mechanical improvements and valuable inventions of the last fifteen years, whether home or foreign in their origin, have been brought to their aid, and the presence of over 400,000 Waltham Watches in the pockets of the people, is the best proof of the public approval. We offer a Silver watch, jeweled, with chronometer balance, warranted by this Company as made of the best materials in the best manner, and in pure coin-silver "hunting" case; weight 3 oz. This watch we offer as one of our Premiums, with the fullest confidence. Upon the movement of each of these watches will be engraved, "AMERICAN AGRICULTURIST. MADE BY THE AMERICAN WATCH CO., WALTHAM, MASS."

No. 40.—Ladies' Fine Gold Watch.—This elegant Premium will delight our friends who may receive it. Our arrangement with the **American Watch Co.** (see No. 39 above) includes these beautiful gold watches. They are full-jeweled, in 18-carat "hunting" cases, warranted to be made of the best materials, and possessing every requisite for a reliable Time-Keeper. Upon the movement of each Premium Watch will be engraved "AM. AGRICULTURIST. MADE BY THE AM. WATCH CO., WALTHAM, MASS."

No. 41.—Breech-loading Pocket Rifle.—This remarkable little fire-arm weighs only eleven ounces, yet shoots with great accuracy and power from 30 to 100 yards, or more, and can be loaded and fired five times a minute. It can be carried in a side pocket, and is accompanied by an extension breech, so that it may be used either as a pistol or rifle. It is put up in a neat mahogany case, with 250 rounds of ammunition. The manufacturers are Messrs. **J. Stevens & Co., Chicopee Falls, Mass.,** and the rifles are sold at retail by Messrs. **Cooper, Harris & Hodgkins, No. 177 Broadway.** Without the mahogany case, we will give the weapon, all complete, with 100 cartridges, packed in a pasteboard box, on receipt of 18 subscribers, at \$1.50 each. For a full description see *American Agriculturist* for Jan. 1869, page 32.

No. 42.—Double-Barrel Gun; OR FOWLING PIECE.—These guns are the genuine London "Twist" barrel, Patent Breech, Bar Lock, ebony ramrod, and in all respects desirable. Their caliber and length of barrel vary, and may be ordered to suit the kind of shooting to be done. They are furnished for this Premium by Messrs. **Cooper, Harris & Hodgkins, 177 Broadway,** well known as one of the most reliable and best houses in their line of business, and they highly recommend this particular gun, and guarantee it in every respect. It is from one of the oldest and most favorably known English manufacturers. The price is not put on in fancy carving and plating for show, but in the gun itself. This Premium includes Gun, Powder-Flask, Shot-Pouch, and Wad-Cutter.

No. 43.—Charles Pratt's Astral Oil supplies a great Public Want for a Safe, Reliable Illuminating Oil. It is manufactured by him and packed only in the Guarantee Patent Cans, expressly for FAMILY USE. It has more body, and an equal quantity will burn longer and give more light than other oils. The constant recurrence of explosions, fires, devastation, and death resulting from the use of what is called Kerosene Oil—but really a mixture of Benzine, Naphtha, and other highly inflammable substances, the use or sale of which is an infringement of United States Law—has induced us to place this article on our premium-list as a humanitarian as well as a useful act. The Board of Health of the city of New York have examined scores of samples of Oil obtained from as many different dealers in this city, and nearly all have been found far below the Government standard and entirely unfit for use. This "Astral Oil" is from the House of **Chas. Pratt, 103 Fulton St. Mr. P.,** a merchant of high reputation, will keep up the article to its present standard. It has been tested, and fully indorsed by the highest scientific authorities in the land. The Guaranty Cans are made of tin, and sealed so that none of the oil can be removed without breaking the

seal, thus securing safety in transportation. The cans is inclosed in a strong wooden case, and may be returned for refilling. For 19 subscribers at \$1.50, or 63 at \$1.00, we will send a case containing 12 one-gallon Guaranty Cans of Oil, which may be distributed among a club.

No. 44.—Comstock's New Horticultural Implements Combined.—The *Hand Cultivator and Onion Weeder* will do the work of six men with hoes. It pulls the weeds and thoroughly pulverizes the soil. It is as much superior to the hoe for all small drill culture, as the mowers and reapers are to the scythe and cradle. The *Seed Sower* is the most perfect small-seed drill we have seen. It sows Beet, Parsnip, and other difficult seeds with the greatest regularity, and it is specially adapted to sowing Onion seed at the rate of 4, 5, or 6 pounds to the acre. It is readily attached to the Cultivator. The *Strawberry Cutter* takes off the runners and at the same time cultivates between the rows. After another year's trial of these implements on our own grounds, and the entire satisfaction they have given to all who ordered them as premiums, we offer them again and recommend them as being all the inventor claims—"the best in the world." For 19 subscribers at \$1.50, or 63 at \$1.00, we will give the Cultivator and Weeder and Strawberry Cutter, price \$12.00. For 22 at \$1.50, or 75 at \$1.00, we will send the Cultivator and Weeder and Seed Sower, price \$15.00. For 27 at \$1.50, or 90 at \$1.00, we will send all these implements complete, price \$18.00. Manufactured by **Comstock Brothers, East Hartford, Ct.,** who furnish descriptive circulars to all applicants. See cuts in *American Agriculturist*, page 127, 1869, and page 118, 1870.

No. 45.—The American Submerged Pump.—Every family needs a reliable pump, capable of raising water easily and rapidly from the bottom of the well, be it deep or shallow—one that is durable, that will not get out of order, or be liable to injury from frost or gravel. When we add to these the qualities of a powerful force-pump, ability to throw water 60 or 70 feet from a hose-pipe, and a construction which renders freezing an impossibility, though it stand out of doors, we think we have a family and farm pump which we can conscientiously recommend. No. 1 will raise 20 gallons of water a minute. This is the pump offered in the list. No. 2, 30 to 35 gallons. No. 3 will raise two bbls. per minute from an ordinary well; and there are larger sizes. Either of these pumps will be furnished for the same number of subscribers required for other premiums of the same price. The pump is set in the well, and nothing but the perpendicular brake and spout appear above the platform. Send for Circulars, to the **Bridgeport Manufacturing Co., Bridgeport, Ct.,** or at **55 Chambers St., New York.**

No. 46.—Family Scales.—These scales, combining the advantages of counter and platform scales, are peculiarly adapted to household purposes. They weigh from 1/2 ounce to 240 lbs. They have a scoop, or pan, for weighing flour, sugar, or other house stores, and a platform for heavier articles, and are just such an apparatus as is needed for in-door or out-door use, occupying less than 2 feet square. These scales are manufactured by the well-known **Fairbanks & Co., No. 252 Broadway, New York,** whose weighing apparatus has long ranked as the standard in all parts of the country. Send to them for circulars, if desired.

No. 47.—Crandall's Improved Building Blocks furnish a most attractive amusement for children. Churches, Dwellings, Barns, Mills, Fences, Furniture, etc., in almost endless variety, can be built with them, and the structure remain so firm as to be carried about. For developing the ingenuity and taste of children they are unequalled. The Blocks are put up in neat boxes, accompanied by a large illustrated sheet giving various designs of buildings, etc. This is one of the most successful toys ever invented.

No. 48.—B. O. B.—The "Boy's Own Boat"—a Real Toy Steamboat, that will propel itself on the water for over half an hour. This beautiful toy is durably made, elegantly finished, and is just the thing for bath-tubs in winter and ponds and streams in summer. The boat is 18 inches long, and fitted with Ryder's Dollar Steam-Engine and Dodge's Propeller. The engine has a perfect-working safety-valve, whereby any excess of steam passes off. It is one of the most pleasing and instructive toys ever produced. Printed directions for management accompany each boat.

No. 49.—The Great Dictionary.—WONCESTER'S LARGE PICTORIAL UNABRIDGED EDITION, containing 1854 three-column pages, with a multitude of illustrative engravings. (The work is a large quarto volume.) Most of the thoroughly educated men of the country consider this as by far the best Dictionary in the English Language. It gives the spelling and pronunciation of every word in the language with full explanations, and as a source of general information stands next to a Cyclopædia. The Dictionary can be called for at our office, or be sent by express or otherwise to any

part of the country. It should be in every family. It is published by **Brewer & Tilleston, Boston.**

Nos. 50 to 58.—Volumes of the American Agriculturist (Unbound).—These amount to a large and valuable Library on all matters pertaining to the Farm, Garden, and Household, and contain more varied information on these subjects than can be obtained in books costing three times as much. The price of the volumes is \$1.50 each, at the Office, or \$1.75 if sent by mail, as they must be post-paid.—They are profusely illustrated, the engravings used in them having alone cost at least \$100,000. Those obtaining premiums for less than fifteen volumes can select any volumes desired, from XVI to XXXI inclusive. For ordinary use, the sets of numbers unbound will answer.

Nos. 59 to 68.—Bound Volumes of the Agriculturist.—These are the same as Nos. 50 to 58 above, but are neatly bound in uniform style, and cost us more for binding and postage. Sent post-paid.

No. 69.—Farmer's Boy's Library.—A few dollars' worth of books pertaining to the farm will give the boys new ideas, set them to thinking and observing, and thus enable them to *make their heads help their hands*. One such book will, in the end, be of far more value to a youth than to have an extra acre of land on coming to manhood. Any smart boy can easily secure this Premium, and he will have two sterling works by a well-known, practical farmer. They are Allen's New American Farm Book, and Allen's American Cattle.

No. 70.—Farmer's Boy's Library.—Both the books in No. 69, and also Herbert's Hints to Horsekeepers, and Henderson's Gardening for Profit.

No. 71.—Farmer's Boy's Library.—The four books in No. 70, with the addition of Fuller's Strawberry Culture, Gregory on Squashes, Brill's Farm Gardening, and Harris on the Pig.

No. 72.—Farmer's Boy's Library.—The eight books in No. 71, with the addition of Thomas's Farm Implements, Tim Bunker Papers, and Waring's Draining for Profit.

No. 73.—Farmer's Boy's Library.—The eleven books in No. 72, with the addition of Fuller's Grape Culturist, Breck's New Book of Flowers, and Hunter and Trapper—in all 14 fine volumes.

Nos. 74, 75.—Bound Volumes of Hearth and Home.—These volumes are neatly and uniformly bound in cloth, with title in gilt on back and side. With their beautiful engravings, and abundance of useful and entertaining reading for all the members of a family, they will prove valuable additions to any library.

Nos. 76 to 87.—Good Libraries.—In these premiums, we offer a choice of Books for the Farm, Garden, and Household. The person entitled to any one of the premiums 76 to 87 may select any books desired from the list of our books published monthly in the *American Agriculturist*, to the amount of the premiums, and the books will be forwarded, Post or Express paid. Let the farmers of a neighborhood unite their efforts, and through these premiums get an agricultural library for general use. See Table List of Books in advertising columns.

No. 88.—General Book Premium.—Any one sending 25 or more names, may select books from our list to the amount of 10 cents for each subscriber sent at \$1; or 30 cents for each name sent at \$1.20; or 60 cents for each name at \$1.50. This offer is only for clubs of 25 or more. The books will be sent by mail or express, prepaid through, by us. See List as in No. 76.

No. 89.—Remington's Breech-loading, Single-Barrel Shot-Gun.—This gun has the best quality barrel, 32-in. gauge. No. 16, weight 6½ lbs., using "Draper's" patent brass shells, which can be reloaded over and over again, and will last nearly as long as the gun. Ordinary gun-caps and wads used in loading. Breech system same as the celebrated Remington's military and sporting guns. This Premium includes gun, with varnished stock, one shell and loader. Price of cartridge shells, \$3.00 per dozen extra. These guns are manufactured by the noted firm of **E. Remington & Sons, Nos. 281 and 283 Broadway, New York**, whose reputation is world-wide, and who stand in the front rank of manufacturers of fire-arms.

No. 90.—Remington's Single-Barrel, Muzzle-loading Shot-Gun. IMPROVED.—This very serviceable, low-priced gun has gained a wide reputation, and we doubt not that many of our boy-readers, who are old enough to handle a gun, will be glad to secure one. It is of good material and fine workmanship, and by the same makers as No. 89.

A GREAT BOON. A Good Cheap Sewing-Machine at Last.

We have been offering as a Premium, for some months past, the **Beckwith new \$10 Sewing Machine**, which has been fully described in the *American Agriculturist* for March and April, 1872. We have already given and sold some hundreds of these machines, and testimonials of satisfaction are coming from every quarter.

See what the People Say.

Hundreds of letters have been received by us and by the Beckwith Sewing Machine Co., extracts from a few of which are given below.

SHERMAN, CHAUTAQUA Co., N. Y., Aug. 15th, 1872.

GENTLEMEN: Having seen a notice of your machine in the *Am. Agriculturist*, and placing great confidence in whatever that journal recommends, I was induced to send for one. We never saw the machine until it came by express, and had no instruction except what came with it, and in less than half an hour after it was received my daughter was making a dress with it, with perfect success, which she completely made with the machine. Other members of the family used it at once with equal success. I consider this, the Beckwith Sewing Machine, a most useful family machine, which I cheerfully recommend to all.

H. W. SPERRY.

WEST CHESTER, August 15th, 1872.

GENTLEMEN: In answer to inquiry about Beckwith Sewing Machine, I can say that it has proved satisfactory. Our physician having forbidden a treadle machine to come into the house, for fear of my wife, who is in delicate health, being tempted to use it, I was induced to order a Beckwith. My wife, besides making up female wear of different materials, recently finished for me, in a most workmanlike manner, on the Beckwith, a whole suit, coat, vest, and pants, of French habit-cloth, which is equal, if not superior, to any I have had made in your city or elsewhere. It, like all other machines, requires some common-sense application, and a little patience, until one fully understands it, and then there is little or no trouble. My wife, without any other guide than a careful observation of the rules contained in the lid of the box, has been able to run it successfully. We value it highly.

W. P. TOWNSEND.

WELDON, FLA., September 20th, 1872.

GENTLEMEN: The sewing-machine came safely to hand, and on trial I find it complete. My wife says it is the dearest little machine that ever was made, and she would rather sew on it than to eat—would not take \$50 for it if she could not get another.

Respectfully yours, W. CLAY MALLORY.

LUDLOW, MASS., August 26th, 1872.

GENTLEMEN: I received your machine in good order, and after using it four months, trying it on all goods, I can say that it far exceeds my expectation. To say that I am well pleased with it would be but saying little. I am satisfied, and think the \$10 well spent.

Yours truly, Mrs. A. L. BENNETT.

LOOKOUT, W. TENN., August 3d, 1872.

GENTLEMEN: We received the Beckwith Machine safely the evening of August 1st, and, as this is probably the highest testimonial you will ever receive, we have duly felt the responsibility of writing to you how the little wonder works "above the clouds." We have taken two days to test its

powers, and are most agreeably surprised. We expected nothing half so small, so pretty, or so useful.

Your friend, MARY J. CHAPMAN.

DEFIANCE, OHIO, September 7th, 1872.

SIR: We received your letter and machine in good time. We are perfectly satisfied. They will give universal satisfaction. I am a German; I landed in New York in 1832; been in Defiance County sixteen years.

Yours respectfully, JOHN HEILSHORN.

PLYMOUTH, SHEBOYGAN Co., Wis., June 10th, 1872.

MR. BARLOW: We thought this the greatest invention for its inches in the world. It has become a family necessity.

Yours truly, Mrs. C. B. WILLEY.

MANSFIELD, TIOGA Co., Pa., September 27th, 1872.

GENTLEMEN: Your machine is the most perfect piece of simplicity that I ever saw, and ours works, as those say who run it, "splendidly."

Yours truly, JOHN H. PUTNAM.

FREMONT, DONOR Co., NEB., September 21st, 1872.

GENTLEMEN: I received the \$10 Beckwith Sewing Machine August 17th, since which time I have sewed garments from a French lawn to a cloth, and it gives entire satisfaction.

Respectfully, ANNA C. WATT.

No. 3, A. & G. R.L., GEORGIA, April, 1872.

GENTLEMEN: Seeing your improved machine advertised in the *American Agriculturist*, and relying on Orange Judd & Co.'s statements, we sent to them and got one of your machines, with which we are much pleased. Have shown it to several friends, and I presume several orders will soon be sent to Orange Judd & Co. or to you.

Respectfully yours, J. A. M. KING.

NEW YORK, May, 1872.

GENTLEMEN: It is due your laudable enterprise to state that, having had in my family one of the Beckwith Sewing Machines from its first appearance, its great merits are more apparent the longer we use it. My wife makes all her dresses on it with ease and perfect satisfaction, as well as everything else she desires to sew. She has recently made a heavy silk dress with it, and is now making a light summer dress. Having formerly been accustomed to the use of first-class large machines, she greatly prefers the little Beckwith. Its ease of operation, its simplicity, and always being in perfect order, together with the great convenience of taking it with her wherever she goes, and of using it wherever she pleases, are considerations so greatly in its favor, that it must soon become the favorite of every household.

Yours respectfully, LEANDER FOX, 26 Varick St., N. Y.

KENANSVILLE, DUPLIN Co., N. C., April, 1872.

GENTLEMEN: The machine has been received, and works like a charm.

Yours respectfully, R. H. BROWN.

We have contracted with the Beckwith Sewing Machine Company for a large number of them to supply our own friends, and as Premiums. Each machine is put in a neat, compact box, with hemmer and guide, oil-can with oil, thread, different-sized needles, etc., with full Printed Directions for using, and delivered to any express office in this city, without extra charge above the \$10. As we buy the machines at wholesale price, we have decided to give our readers some advantage of this, and we therefore propose to make a present for himself or herself, or for any friend, of one copy of *Hearth and Home* for six months, or one copy of the *AMERICAN AGRICULTURIST* for one year, to those persons who send us \$10 for one of the machines while this offer is continued.

The New Sewing Machine as a PREMIUM without Money.

To enable those to get this machine who can not raise even the \$10 to buy it, we make the following offer:

We will send the Machine free to any one who will collect and forward SIX subscribers for *HEARTH AND HOME* one year at \$3 each; or TWELVE subscribers to *AMERICAN AGRICULTURIST* for one year, at \$1.50 each.

Almost any lady can readily secure this small number of subscribers and get a machine free; or some friend can thus obtain it for her, as a present.

Address

ORANGE JUDD & CO., 245 Broadway, N. Y.

The Newburgh Bay Horticultural Society

Held its annual exhibition at Newburgh, on September 25-29. A taste for horticulture is widely diffused and firmly implanted in the vicinity of Newburgh—the home of the Downings—and though we had heard much of their annual shows we have not until this season been able to visit them. We are informed that the recent exhibition was not equal to that of former years—apples and pears especially being so abundant that less interest was taken in presenting them than in years of smaller crops. Whatever may have been the previous displays, that presented this year was one of which a much larger city might have been proud. Indeed, outside of Boston and Philadelphia, we doubt if it can be equaled. Every fruit in season was represented by fine and abundant specimens, excepting grapes, which, in a neighborhood usually producing largely, were so poor as to almost amount to a failure. We can not give the names of exhibitors, save to mention that a most extensive collection of pears was from the orchard established by Charles Downing, and now in the possession of Mr. A. Bridgeman. We must not omit to mention the hybrid grapes of Mr. J. A. Ricketts, of Newburgh, whose efforts at hybridizing the foreign and native grapes have been attended with marked success. When these vines are put in the market, cultivators will experience a new revelation in the way of native grapes.

The exhibition of vegetables was very fair, and that of flowers—mainly of bouquets and designs—while not large was creditable. We were surprised at the lack of specimen pot-plants in a locality where we should look for them in perfection. The executive management at this exhibition is worthy of commendation. To judge of fruits is usually a laborious task, but so well were the specimens arranged, and so competent the attendance upon the committees, that the work was easy.

Fodder-Cutters.—Numerous inquiries come constantly for fodder-cutters, and a dozen at least are now before us, to all of which we say: That there is but little difference, if any, in the value of any of the many cutters advertised in our columns, and parties desiring them can hardly go wrong whichever one they may happen to procure. Every man who owns one horse or one cow would find the use of one a great convenience and a great economy.

Blasting Stumps.—The Greenfield farmer who endeavored to get rid of his stumps by blasting them, was so successful that he threw several summer-sets, got outside of most of his clothes, and burned his hair out by the roots. It was his first and is his last blast.

Another Patent Fence.—A correspondent from Richfield, Pa., who omitted to affix his name to his letter, asks if certain men who are trying to dispose of rights to use a "patent fence," which consists of a sill in which are fixed two upright posts, to hold the rails, and of two braces, which cross the fence and sustain a top rail or rider, are worthy of notice, or if they are frauds.—The claim to a patent on such a fence is certainly a fraud, as the arrangement is about as old as rail fences themselves, and it is in use in hundreds of places. Whether the men themselves are honest or not, we can not say; they may be.

Teeth for Shares' Harrow.—"R. F. C.," Rhea County, Tenn., can procure teeth for Shares' harrow from R. H. Allen & Co., Water st., New York, or any of their agents.

Value of Large and Small Pictures.—Persons of uncultivated eye and taste are apt to value a picture by the square feet it covers, while real artists and persons of refined taste judge of the skillful arrangement of colors, and the genius displayed in grouping, position, light and shade, etc. We have stood at a sale, and seen oil-paintings covering several square yards, allowed to go off at \$10 to \$50 each, while there would be intense excitement and spirited bidding on another picture only 7 by 10 inches, and its price run up to \$500, \$1000, or even \$1500—and it was the cheapest picture sold even at the last-named price. When salesmen in New York have a stock of these large unartistic pictures, they advertise them among the uncultivated masses, who buy by the yard, as they would purchase wall paper.

Improved Sorts of Wheat.—"C.," Sulphur Springs, East Tenn., wants light thrown on the subject of the Fultz and other improved varieties of wheat and the special manures most suitable for that crop. The Fultz wheat is said to have originated in Mifflin County, Pa., in 1862. It is a red wheat, and after several years of experiment has become somewhat popular in

its native locality. It is said to stand the winter exceedingly well, to be free from damage by the weevil, to have good straw, and to yield well. We have had no opportunity of testing its merits, and should advise caution in trying this or any other new variety. The Touzelle is a French wheat lately introduced, and also highly spoken of by some who have tried it. Guano and superphosphate of lime are the best special manures for this crop.

Concerning Milk.—"George A. K.," Leavenworth, Kansas, asks how soon after calving the cow's milk is fit for use, and if it is customary to milk the cow immediately after the birth of the calf.—After four days the milk regains its ordinary quality, and during that time it should be fed to the calf as drawn from the cow. If left to itself the calf will often suck within a few minutes after its birth, and if it is taken from the cow the milk should be drawn as soon as possible and given to it. This is generally, if not always practiced.

Starch Factories.—"Wm. D.," Morgantown, W. Va., asks if it would pay to buy potatoes at 50 cents per bushel, to manufacture them into starch, and how much it would cost to start a starch factory.—Fifty cents a bushel could not be paid for potatoes in this business. Twenty-five cents would be about the most. A starch factory costs from three thousand dollars upwards. Doubtless a saving in this cost could be made if the party is a mechanic and builds his own factory.

Agricultural Labor.—A student at the Agricultural College of Pa. states as an illustration of the amount of labor performed by the students, that they hauled one thousand cart-loads of stone this season.

Catarrh in Sheep.—F. Koch, Mississippi, wants a remedy for a running at the nose or catarrh in sheep.—Tarring the nose is often of use; the sheep lick some of the tar and swallow it, which seems to act as a cure. Close penning of sheep or keeping them in a warm place often produces catarrh, and turning them into a roomy, airy, or out-door pen, where they have plenty of fresh air, and are kept quite dry, will often cause an immediate cure.

Farming on Ten Acres.—A "Subscriber," who gives neither name nor address, proposes to farm ten acres of land, two acres of which will be in market vegetables, and a portion, after appropriating hay and pasture for two cows and two horses, in tobacco. He asks for "some idea" as to the probable result. This depends very much on the management given, and the amount of manure which can be purchased, as four or more acres in such crops as vegetables and tobacco will use up a hundred tons of manure annually, and all that can be made from the stock mentioned, with a few hogs and fowls in addition, will be absorbed by the meadow and pasture. Unless the manure can be purchased and judiciously used, we should apprehend a failure.

Clydesdale Horses.—F. P. Clark, of Minneapolis, Minn., recently purchased two thorough-bred Clydesdale mares, three and five years old, for \$1000 gold. Their weights were 1600 and 1700 pounds, respectively.

New York State Fair.—This fair, held at Elmira, October 1st to 4th, was a marked improvement on that previously held at the same place. The State Agricultural Society have secured extensive grounds, on which permanent and convenient buildings have been erected, and the course of improvement undertaken on the property, when completed, will add very much to the future convenience and pleasure of both exhibitors and visitors. The exhibition was very successful in showing that several thousand persons could be induced on one day to attend an agricultural fair for its own special attractions, without the usual additional ones of the trotting course. Consequently it was an agreeable thing to exhibitors, and to those who, like ourselves, take pleasure in observing this, to see crowds of farmers and their wives around the stockpens, closely examining and discussing the merits of the stock, questioning the owners and attendants, and criticizing the awards of the judges. This is just as it should be, and is gratifying to notice. There was a good selection of stock, although not by any means so large a one as could be gathered together in this State if all the choice flocks and herds had been represented. Comparatively the best show of cattle was of Jerseys. The Shorthorns were only fair; there are better ones in the State than were on exhibition. A few good Ayrshires were also there, and those exhibitors who brought out their stock well deserve the premiums they earned by their enterprise. The poultry was far from first-rate in appearance, and did not show well in the low coops, which had a tendency to apparently dwarf their size, although the comfort of the poultry was increased by

being on the ground. Strangely, in this great dairy State, where cheese and butter factories exist by hundreds, there was no cheese found worthy of a premium, and the butter has been often surpassed in quantity by many a county fair where dairying was not a specialty. Another very remarkable want was apparent, viz., the absence of the least thing which could specially interest the young folks, who are certainly worthy of more consideration than to be left to be amused by the miscrably poor "merry-go-rounds" and side-shows, fit only for babes or idiots. If we must "keep the boys on the farm," it seems only reasonable that they should have a department appropriated to them in the recreations as well as the labors of the farm, in which they could be exhibitors and compete for premiums in the things in which they take an interest. Why could there not be a department for colts, calves, steers, pigs, and poultry owned and cared for by the young folks, both boys and girls? It is to be regretted that the receipts of the exhibition did not pay expenses, but there are several substantial reasons for this other than any fault on the part of the managers, whose efforts deserved success.

Apple or Quince.—M. Butler. The specimen sent is undoubtedly apple.

University of Mississippi.—We have received a prospectus of this institution which has a department devoted to agriculture and the mechanic arts. Dr. E. W. Hilgard is the professor of agricultural chemistry, and Dr. M. W. Phillips of practical agriculture. The University has secured a farm for the practical instruction of the students, on which if they desire they may work for the customary compensation. It is to be hoped that the efforts promised by this institution for the spread of agricultural information in this State may be crowned with the success that all such efforts deserve. Thomas E. B. Pegues, Oxford, Miss., Secretary of the University, will furnish all desired information.

Wanted, an Agricultural Paper.—"E. M. W.," Georgetown, Va., is about to take charge of his father's farm, and writes to know what agricultural paper would be of most use to him in learning when to plant seeds, and how to prepare the ground and take care of the crops. He thinks with this help he can succeed.—To give a simple, unprejudiced reply to this question would be to say that the *American Agriculturist* exactly meets the case of "E. M. W.," or any other man, whether he knows little or much of farming, for though he may know much, there are new views of things, new methods, and new appliances continually coming up, which are discussed or made known in its columns, while if he knows little, there is no branch of his business in which he may not be instructed by it.

Salt as a Fertilizer.—"Subscriber," Putnam, Ohio, asks the best method of using salt for grass or grain.—It should be spread early in spring, either on grass or grain, at the rate of one to three bushels per acre. As it has no direct effect on vegetation, but only indirectly by its supposed action on the mineral constituents of the soil, it is not always that its application is productive of any marked results. The writer has used it regularly on grass and wheat with the effect of considerably increasing the hay crop, and of preventing the wheat crop from lodging, and these are mainly the results anywhere obtained by its use. As a destroyer of grubs and insects we have no confidence in it, unless used in such quantities as would destroy vegetation.

What is the Matter?—"A. N. G.," Greenwood Co., Kansas, has something the matter with his cow and his corn. The cow "mumbles" with her mouth and slobbers as though she were choked; and the corn, which was planted on buckwheat ground, looks badly, as though the buckwheat had injured the ground. He asks, Is this crop injurious to the soil?—The cow probably suffers from toothache, which causes exactly such symptoms as these; if so, she will gradually get over it. Buckwheat does not injure the soil, notwithstanding there is a popular opinion in some places that it does. It only affects the soil by exhaustion, which is counteracted in some degree by the mellow condition in which it leaves the ground.

Wheat or Oat Chaff.—"G. H. B.," Ashland County, Ohio, asks if wheat or oat chaff will dry up cows, and if chaff is equal to straw for fodder.—We have never fed wheat chaff, but having found accidentally that oat chaff increased the flow of milk, have always saved and fed it, and believe it to be better feed than oat straw. Chaff has no direct effect in drying up the milk, or otherwise than as not furnishing the nourishment required, and acts just as straw would do when fed. No man expects milk from straw alone, nor without a quantity of bran or other grain feed larger than when hay is fed.

SUPERIOR STANDARD WORKS.

Published by **ORANGE JUDD AND COMPANY.**

THE HORSE.

**FRANK FORESTER'S
HORSE & HORSEMANSHIP
OF AMERICA.**

By **HENRY WM. HERBERT.**

Revised, corrected, enlarged, and continued to 1871,
By **S. D. and B. G. BRUCE.**

Always an **ACKNOWLEDGED STANDARD**, and now
the most **COMPLETE** and **AUTHENTIC** Work on the
HORSE. With steel-engraved portraits of Thirty
of the most famous

REPRESENTATIVE HORSES,
including pedigrees, histories, and performances.
Two superb royal octavo volumes of upward of 1800 pages.

Post-Paid, Fifteen Dollars.

WALLACE'S

American Trotting Register.

CONTAINING ALL THAT IS KNOWN OF THE

PEDIGREES OF TROTTING HORSES,
their ancestors and descendants, with a record of
All published performances in which a mile
was trotted or paced in 2.40 or less,
from the earliest dates until the close of 1863, and
a full record of the performances of 1869 and 1870.
Giving complete Summaries of over 6,000 Contests.

With an **INTRODUCTORY ESSAY** on the true
origin of the American Trotter. And a set of Rules
for the government of all trials of speed. By **J.
H. WALLACE**, compiler of Wallace's American
Stud-Book. Royal octavo.

Post-paid, Five Dollars.

WALLACE'S AMERICAN STUD-BOOK.

The Cultivation of the Native Grape and Manufacture
of American Wine. By **Geo. Husmann**, of Missouri.
Post-paid, \$1.50.

Elliott's Lawn and Shade Trees.

For Planting Parks, Gardens, Cemeteries, Private
Grounds, and Avenues. Fully Illustrated and described.
Post-paid, \$1.50.

Fuller's Forest Tree Cultnrst.

The Cultivation of Forest Trees for Shade, for Shelter,
for Fuel, for Timber, and for Profit. Illustrated. Post-
paid, \$1.50.

ORANGE JUDD & CO., 245 Broadway, New York.

THE PRACTICAL POULTRY KEEPER.

A COMPLETE AND STANDARD GUIDE TO THE

MANAGEMENT OF POULTRY,

FOR DOMESTIC USE, THE MARKETS, OR
EXHIBITION.

Beautifully Illustrated.

By **L. WRIGHT.**

NOTICES BY THE PRESS.

This book is a valuable manual for everybody who
feeds chickens or sells eggs. It suits at once the plain
poulterer who must make the business pay, and the chick-
en fancier whose taste is for gay plumage, and strange,
bright birds. The most valuable portion is the first sec-
tion, extending through fifty-five pages. These were writ-
ten with the intention of producing a manual so plain,
minute, and practical, that any one could, by using it as a
guide, with no previous experience with poultry, become
at once successful in producing eggs, young chickens, and
fat fowls for market. The author has not missed his aim.
The middle parts of Mr. Wright's Manual are taken up
with minute directions for making show fowls for Fairs,
a nice discussion of the good and bad points of the dif-
ferent breeds, and a brief sketch of such fancy stock as
peafowl, pheasants, and water-fowl. Then follows a
section on artificial hatching, and another, worth special
attention, on large poultry yards. A study of Mr.
Wright's book will convince any farmer's wife that all
she needs is to give a half hour each day, of intelligent
and sagacious attention to her poultry, in order to obtain
from them, not tape, and knitting needles, and buttons,
and nutmegs merely, but the family supplies of sugar,
shoes, and cloth. *New York Tribune.*

It is the most complete and valuable work on the mat-
ters of which it treats yet published. It will be found a
plain and sufficient guide to any one in any circumstances
likely to occur, and is illustrated with elegant engravings
of many breeds of fowls. *Farmers' Cabinet.*

This is a reprint, with numerous wood engravings, of
an English book, the object of which is to convey in
plain language a great deal of practical information about
the breeding and management of poultry, whether for
domestic use, the markets, or exhibition. The book is
eminently practical, and we recommend it to farmers and
others interested in breeding and selling poultry.
Philadelphia Press.

It is a handsome volume, brought out in the best style,
and enriched with nearly fifty illustrations. It is evidently
the fruit of a thorough, practical experience and knowl-
edge of fowls, and will be found a plain and sufficient
guide in all the practical details of poultry management
as a profitable business. *United Presbyterian.*

The subject is treated fully and ably by an experienced
hand, and the volume will doubtless find a large sale
among the growing class of poultry fanciers. It is em-
bellished with numerous illustrative engravings.
New York Observer.

The author has called to his aid all who were experi-
enced in the subject whereof he writes, and the conse-
quence is a volume of more than ordinary thoroughness
and exhaustiveness. *Rochester Democrat.*

The book is a complete and standard guide to the man-
agement of poultry for domestic use, the market, and
for exhibition. *Watchman and Reflector.*

PRICE, POST-PAID, \$3.00.

ORANGE JUDD & CO.,
245 Broadway, New York.

ONE OF THE BEST BOOKS ON VILLAGE BUILDING.
BICKNELL'S
VILLAGE BUILDER AND SUPPLEMENT

BOUND IN ONE LARGE HANDSOME VOL., 77 PLATES. PRICE, POST-PAID, \$12.

THE VILLAGE BUILDER

(REVISED EDITION, 1872)

Gardening for Profit

In the Market and Family Garden.

By Peter Henderson.

ILLUSTRATED.

NOTICES BY THE PRESS.

All the vegetables that thrive in the open air in our latitude are described, together with the best methods for growing them. The author also imparts practical instructions on the subjects of drainage, and the formation and management of hot-beds. Numerous well-executed wood-cuts tend to make clearer the instructions of the author.—*Philadelphia Inquirer*.

The author of this treatise is one of the best known and most successful of those gardeners who supply New York with green vegetables; and as he writes from long and dear-bought experience, the positive, dogmatic tone he often assumes is by no means unbecoming. The book itself is intended to be a guide for beginners embarking in the author's business, and gives full and explicit directions about all the operations connected with market-gardening, lists of varieties of the most profitable vegetables, and much sound advice on kindred topics. Though designed for a special class, it can not fail to be valuable to the amateur and private gardener, and unlucky experience has taught us that the information contained in a single chapter would have been worth to us the price of the book.—*Daily Mercury* (New Bedford).

It is unquestionably the most thorough and the best work of its kind we have yet had from the pen of an American author. It is written in a clear, concise style, and thus made more comprehensive than works which smack more of the office than the farm or garden.

[*Daily Evening Times* (Bangor, Me.).

Mr. Henderson writes from knowledge, and is not one of those amateur cultivators whose potatoes cost them ten dollars a bushel, and whose eggs ought to be as valuable as those of that other member of their family—the goose of golden-egg-laying memory—for they are all but priceless. No; he is a practical man, and he has the art of imparting the knowledge he possesses in a very agreeable manner; and he has brought together an extraordinary amount of useful matter in a small volume, which those who would "garden for profit" ought to study carefully.—*Evening Traveller* (Boston).

There are marvels of transformation and rapid reproduction recorded therein, which might well shame the dull fancy of the author of Aladdin or of Kaloolah. There is no theory about it; a man who has made himself rich by market-gardening plainly tells our young men how they can get rich as easily as he did, and without wandering to California or Montana for it either.

[HONORABLE GREELEY in the *N. Y. Tribune*.

We have devoted more space to this little work than we usually do to tomes much more pretentious. We have done so because of the rare merits of the book in its fund of information, useful to the farmer and market-gardener, and because of the dearth of that kind of knowledge. We earnestly advise that fraternity, for whom this work was written, to buy it and study it. If any among them have never yet read a book, let this be their primer, and we will vouch for the excellence and endurance of the printing. The work is profusely illustrated with wood-cuts.—*Louisville Daily Journal*.

THE BICKFORD FAMILY KNITTING MACHINE.

SANTA CRUZ, CALIFORNIA, }
 April 15th, 1872.

DANA BICKFORD, Esq.—*Sir*: The Machine is giving the greatest satisfaction. Every one is highly pleased with the beautiful work made upon it. There are two families here who will send for two Nos. 3—like this one—as soon as possible.

Very respectfully yours,
 MRS. KATE HOUSE.

WESTPORT, CT.

DANA BICKFORD, Esq.—*Sir*: I have used one of your machines only five weeks; yet five weeks is long enough to convince me that it should find a place in every household in the land, both old and young finding unending enjoyment in its use. Knitting-work is very well for the grandmothers to pass away the twilight hours with, but a machine such as you invented reduces the time of fabricating articles to moments, instead of hours, and also puts in the power of any person, male or female, the means to earn a livelihood.

You are at liberty to use the above as you wish.

I am very respectfully yours,
 E. B. ADAMS, JR.

The recent improvements on this machine make it one of the most perfect pieces of mechanism in the world. Every house-keeper in the country should see it, and judge for themselves, since it is now guaranteed to meet every need of the household.

Any machine at this price that will knit 20,000 stitches, or 2½ inches perfect work, per minute—either in flat web, hollow tube, or circular form, in any plain or fancy stitch that can be done by hand—will certainly be found more useful and convenient in a family than a sewing-machine can possibly be. It is very simple in its operation, and knits any kind of yarn, cotton, linen, silk, or woolen, in plain or fancy stitch of Knitted, Crochet, or Afghan work.

Price \$25 to \$75.

AFTER THE GREAT SNOW-STORM.—*Drawn and Engraved for the American Agriculturist.*

In many parts of the Northern States the scene depicted by our artist in the above engraving happens yearly. Not uncommonly the winter opens with a heavy fall of snow, sometimes equal to two feet on a level, and this, when driven into heaps and banks by the north wind, makes it necessary for backwoods-men to turn out and "break roads." Then the neighbors come out each with a yoke of cattle—for horses would be useless for this work—and one mounted on snow-shoes leads the way, followed by the oxen, who waddle through the deep snow slowly and clumsily; but they beat down the snow with their great limbs, and when five or six or more yoke follow each other, a

broad track is soon made. So they proceed, stopping now and then that a great tree, overloaded and broken down with snow and fallen across the road, may be cut out. By and by a drift is reached, into which the leading oxen plunge until nothing but their noses, elevated as much as possible, and the tips of their horns, can be seen. But the snow settles down over their backs as they wallow through the deepest part, and then as they emerge they look as though they swam in a sea of the purest foam, which rolls down the side of the drift in little ripples, and drops off their great sides. The others follow, and the "beautiful snow" that has been woven by the fingers of the north wind into

a fringe of purest white and most delicate pattern around the edge of the woods, is all broken down and soiled, and its beauty all gone. This is the way some look at it, but those whose business it is to battle with snow, and beat it down, making roads through it, or chopping down trees and making logs in it, or wading through it to get to their barns to feed their hungry cows, and shovel it away from their stable-doors, or hunt beneath it for the ax or what-not, carelessly left out to be snowed under—why, they vote it a nuisance, without considering how they would do their work in the woods, or haul their great loads, or go sleigh-riding, if it were not for a great snow-storm.

AMERICAN AGRICULTURIST.

NEW YORK, DECEMBER, 1872.

We are beginning to look back on the year 1872 and forward to the year 1873. December is a half-year house, a breathing spot. It is neutral ground. The labor of the past year are nearly ended; those of the new hardly commenced. The days are short, and during the long evenings we shall think over the past, and lay plans for the future.

We greatly mistake the signs of the times if we are not about to introduce a better system of agriculture, better breeds of animals, and a higher condition of farm-life. But the first improvement must be in ourselves. We must think more and work to better advantage. Never allow yourself to say "I have not time" to do anything that you ought to do.

little to sell, and that little not worth in market the cost of production. There is no remedy except to hope and to work. To a man who does not work times are never good. To one who does, there are fair prospects ahead—we think never better or brighter.

Hints about Work.

Evening Work.—We do not believe in "all work and no play." We believe in working with a will when we do work, and then resting. We work that we may rest, and rest that we may work. We can often rest ourselves more by changing the character of our employment than by absolute idleness. A farmer with the right kind of head and heart can not sit down at night with much comfort if he knows his horses are covered with mud and sweat in the barn, or if he knows there is no kindling-wood to start the fire in the morning, or that there is a pane out of one of the windows in the cellar.

Be Clean in the House.—There is much dirty work to be done on the farm, and a farmer should dress appropriately to his work. But there is no reason when his work is done for the day why he should sit down in the evening with his pantaloons stuck in his boots. We cordially dislike foppishness, but cleanliness is one of the cardinal virtues. The farmer or the farmer's son who does not make himself and his clothes clean before he sits down at night has something yet to learn in regard to the pleasures and advantages of a quiet country life.

Animals.—Next to himself and his family, a farmer's thought and attention should be turned to his animals. If we look upon them as machines for the conversion of straw, stalks, roots, hay, and grain into beef, mutton, wool, milk, pork, eggs, etc., we should never forget that they differ very materially from ordinary machines, that we can start and stop when we please, and stow them away when not in use. The animal machine is always running, winter and summer, night and day, and a farmer's first care should be to see that it is always running to some good purpose.

Horses.—If possible, work the horses moderately during the winter, and let them have grain enough to keep them in good condition. A horse that has been over-worked and surfeited with grain may be the better for a winter's run at a straw stack. But this is not the usual condition of farm horses. As a rule, it would be better to keep them in the stable and work them regularly. Labor is comparatively cheap in winter, and there is much work that can be done with advantage, especially if it has been prepared in advance. Gravel may be drawn for the roads; stones or rails may be drawn for

Disease in Poultry.—"Mrs. L. H. B.," Postville, Iowa, finds that the feathers fall off the breasts of her fowls, and that the toes gradually decay until only stumps are left, and that this complaint spreads amongst her fowls. She asks what is it? and what is the remedy?—It is probably not contagious, as supposed, but spreads because the cause is general. The cause is very likely unclean roosts and floors in their houses, not sufficient variety of food, and want of an alternative as medicine. Their quarters should be well cleansed with lime, some rusty iron with sulphur should be kept in their drinking water, and they should have some cabbage or raw potatoes chopped given regularly to them.

fences; manure may be drawn out and spread on the fields; plaster can be drawn from the mill; apple-trees can be pruned and the branches drawn off at the time and not left on the ground; grain can be taken to the mill and be ground, not merely as it is wanted, but enough for the whole year. Draining-tiles may be procured, lumber drawn, wood brought to the house and sawn; straw, hay, and corn-stalks may be cut into chaff with a horse-power machine. In many places hay may be drawn to market, and a load of manure brought back with profit and advantage. These are only a few things that may be done. We are sure that farmers, by a little planning in advance, can very generally keep nearly all their teams moderately at work all winter.

Cows.—Where hay is scarce and straw and stalks abundant, it will pay well to chaff the latter for cows and mix mill-feed and corn-meal with it. Keep the cows in a moderately warm, well-ventilated stable, clean it out every day, and turn out the cows twice a day to water, and let them stay out an hour or two when the weather is favorable. But avoid letting them get chilled in storms.

Sheep.—The best way to feed hay to sheep is to cut it into chaff by horse-power. It is little trouble to feed, and there is little or no waste. And we are not sure that it is not better to cut up straw and stalks also, and feed them with a little meal as we do cattle. The first point in the management of sheep is to provide *dry* quarters; 2d, To avoid overcrowding; 3d, To litter lightly and regularly every day; and 4th, To guard against any fermentation of the manure under the sheep. Give fresh water every day, and salt regularly. Feed liberally *before sundown*. Let there be straw or other food in the racks for the sheep to eat during the night.

Swine.—Where corn is worth less than 40 cents per bushel it will *pay well*, even at the present low price of pork, to make the hogs *fat* before selling them. Packers want small, fine-boned pigs, but they want them well-fattened. Store pigs should be kept growing rapidly. The prospects are favorable for an advance in pork another year, and farmers, especially in the West, should feed their young stock liberally. Breeding sows should have as much exercise as you can make them take in searching for food. But, at the same time, they should be able to find as much as they need to keep them in vigorous health and good condition. For thoroughbred sows, which keep easily, and are apt to get too fat, the food should be of a rather bulky nature, such as bran, turnips, etc. Sows go sixteen weeks. If you have a number of sows, and are short of breeding-pens, it will be well to push forward a few sows and keep back the others. This can be done by giving those you wish served first a little extra corn for a week or ten days. Provide dry, well-ventilated quarters, and see that they are kept clean and well littered. Do not allow young and old pigs to run together. The young, growing pigs should have all the food they will eat and digest. If they are of the right kind, that mature early, they must have good food, and plenty of it, while young, or they will not be healthy.

Poultry.—Select out the hens and cocks you intend to keep, and fatten the rest. If you wish eggs in winter, provide warm quarters, and feed more or less animal food. Keep the hen-house clean, and see that the hens do not want for water.

As Long as the Ground is not Frozen keep at work getting ready for winter. Finish the fall plowing. Plow the garden. If you have any large stones to draw off, raise them up a few inches now, and put a small stone or piece of wood under them to prevent their being frozen to the ground. They can then easily be loaded on to a sleigh or stone-boat in winter and drawn off easily. Bank up the cellars. If potatoes are pitted, and have only one coat of straw and earth on them, put on another thin layer of straw and cover it with a few inches of earth. This is the great secret of keeping out frost. The layer of straw between two layers of earth holds dead-air, which is the cheapest and best of non-conductors. Go over the farm during or immediately after a heavy rain with a hoe and spade, and see that the water has a chance to flow off freely.

This is very important, not only for wheat, but for land intended to be plowed in spring.

Work in the Horticultural Departments.

There is seldom a month in which something can not be done towards advancing the spring work. There are many mild days when things which were neglected in the fall can be attended to. There is now plenty of time for reading, and no good gardener will fail to provide himself with suitable books and papers to employ his mind during the long evenings. New horticultural books are published from time to time, upon different subjects, most of which contain some items of interest, and are worthy of a careful perusal. During mild days, rubbish, which often collects around the barn and out-buildings, may be taken away, thus making the house and grounds look as if they were properly cared for.

Kitchen Garden.

Cold-Frames.—Do not close the sashes entirely, except at night, and when the weather is above freezing remove them entirely.

Pits in which roots are stored, should not be covered until really freezing weather comes, and then gradually, just enough to keep out frost.

Roots fresh from the ground are the best. The season of digging may be prolonged by covering the beds with litter, to prevent the ground from freezing. Store a quantity in dry earth in the cellar, to use while those outside are not accessible.

Spinach, Lettuce, etc., which are to remain in the open ground during the winter, should be covered with leaves, hay, or other litter.

Rubbish.—If there is no snow upon the ground, the dry weeds, old vines, and everything which will prevent the easy working of the plow, may be burned, and the ashes saved for use the next season.

Bean-Poles.—Do not allow these to remain exposed to the weather. With shelter they may be made to do service for several seasons. Pen-brush seldom lasts more than one season, though occasionally, with care, it will do the second spring.

Seeds.—Thrash out and clean all that remain, and see that each variety is supplied with a proper label and date. Keep in a cool room, where mice will not trouble them.

Orchard and Nursery.

Trees.—Young trees need care at this season, whether newly set or not, as there is great danger from mice and stray cattle. The gates and fences should be properly secured, and when a light snow falls, it should be firmly trodden down around each tree, to keep the mice from gnawing the bark. It is a good practice to raise a mound of earth, a foot high, around the trunk of newly-set trees, as a support for them during the high winds, as well as a security against mice.

Rabbits are prevented from injuring the trees by sprinkling blood upon them, or wrapping them with tarred paper; the former is, however, the best.

Pruning.—If any pruning is to be done, it is better to select mild days during early winter than to delay until spring. Where large limbs are removed, the wounds should be covered with a varnish of gum-shellac, or with melted grafting-wax.

Cions.—When the trees are not frozen, cions may be cut, labeled, tied in small bundles, and stored in earth or sawdust. Grafting is a very easy method of stocking an orchard with good varieties of fruit, and the operation has often been explained.

Water.—Should any water stand upon the surface of the orchard, surface drains should be opened.

Root-grafting.—This can be done indoors, when the weather is too cold to admit of working outside. The varieties should be kept separate; place the grafted roots in boxes with earth or sand.

Seeds of stone-fruits must be buried, if not already done, in order to expose them to the action of the frost. If the quantity is small, they may be buried

in boxes in the open ground, where they are subjected to alternate thawings and freezings.

Fruit Garden.

Raspberries.—Bend down the canes of the tender varieties, and cover with earth before the ground freezes.

Strawberry Beds.—These should receive a covering of straw, or bog-hay, or leaves, two or three inches thick. A little earth or some brush will be necessary to prevent the leaves from blowing away. Care should be used not to cover too deeply, as the object is to prevent sudden changes of heat and cold, and not to prevent freezing.

Grape-Vines.—These ought to have been pruned last month, but advantage may be taken of any mild days to prune now. Young vines, whether tender or hardy, do best if laid down.

Wood for trellises and stakes may be prepared ready for setting in the spring. Chestnut and locust posts are very durable, and are best where it is necessary to have wood in contact with the ground.

Flower-Garden and Lawn.

Protection.—The same rules apply here for the protection of half-hardy shrubs and trees, as given for strawberries, etc. Tender roses are best treated by laying down and covering with sods.

Climbers which are not entirely hardy at the North, should be taken down from their trellises, and covered with earth.

Pits.—Plants kept in pits and frames, must be kept dormant, and take care not to keep them too wet. Plants stored in the cellar do best when surrounded by dry earth, and kept without water.

Trellises, etc.—Put all movable wooden trellises and seats under cover. Unpainted ones will last longer if a good coat of petroleum is applied to them.

Evergreens.—Protect the young trees by surrounding them with evergreen boughs; this slight protection will often save trees which when older will prove perfectly hardy.

Greenhouse and Window Plants.

Air is one of the necessary elements of success in plant-growing, whether in the house or greenhouse. Open the ventilators every day when the weather is not freezing, opening only those on the opposite side from which the wind is blowing.

Water.—Give only when the plants are dry; if watered too much, the soil becomes so thoroughly saturated that it is impossible for the roots to grow well. Sprinkle or shower the plants as often as convenient, except in the coldest weather.

House Plants usually suffer more from dust and a dry atmosphere than from any other cause, and the only remedy is to shower often, and to occasionally sponge the foliage of the smooth-leaved plants, such as Camellia, Ivy, etc.

Commercial Matters—Market Prices.

Gold declined to 111 $\frac{3}{4}$ and advanced to 114 $\frac{1}{2}$, closing November 12th at 113 $\frac{3}{4}$ against 113 on the 12th of October. The disease among the horses in this city and vicinity has very seriously checked business in the Produce line, by retarding the forwarding movement. Breadstuffs have been less active, and variable as to values, but close with some show of firmness in the instances of Flour, Wheat, Oats, and Barley, which are now offered less freely. Corn leaves off easier, on a liberal supply. The export inquiry has been less confident. . . . Provisions have been generally quoted stronger in price, on a good demand, but close less buoyantly. An extraordinarily large sale of Beef, embracing 6500 tcs. and 300 bbls., product of a single Western packing house, was reported on the 12th of November. . . . Wool has been in more demand and on the advance, closing buoyantly, in view of the reported destruction of a large proportion of the stock of Domestic in Boston, by the great fire in that city. . . . Cotton has been active, but irregular, closing weak. . . . Hay, Hemp, and Seeds, quiet, but about steady. . . . Hops and Tobacco in good demand at steadier rates. . . . Apples have been purchased with unusual freedom, for export to Liverpool, Glasgow, London, and the German ports, and close higher.

The following condensed, comprehensive tables, carefully prepared specially for the American Agriculturist, show the transactions for the month ending November 12, 1873, and for the corresponding month last year.

TRANSACTIONS AT THE NEW YORK MARKETS.

RECEIPTS. Flour, Wheat, Corn, Rye, Barley, Oats. 24 d's last m'th 3,846,000 2,817,000 3,569,000 26,000 1,111,000 895,000

SALES. Flour, Wheat, Corn, Rye, Barley, Oats. 24 d's this m'th 3,113,000 2,438,500 3,597,000 41,000 416,000 1,196,000

Comparison with same period at this time last year.

RECEIPTS. Flour, Wheat, Corn, Rye, Barley, Oats. 21 days 1872. 348,000 2,817,000 3,569,000 26,000 1,111,000 895,000

SALES. Flour, Wheat, Corn, Rye, Barley, Oats. 24 d's 1872. 313,000 2,438,500 3,597,000 41,000 416,000 1,196,000

Exports from New York, Jan. 1 to Nov. 6.

1872. Flour, Wheat, Corn, Rye, Barley, Oats. 1872. 931,176 10,351,411 23,102,108 660,588 22,656 20,824

Stock of grain in store at New York.

1872. Wheat, Corn, Rye, Barley, Oats, Malt. November 6. 429,760 4,733,426 31,374 376,750 2,191,362 250,930

Receipts at head of tide-water at Albany each season to Nov. 1st.

Flour, Wheat, Corn, Rye, Barley, Oats. 1872. 104,100 7,901,400 25,484,800 357,300 2,119,000 3,075,300

CURRENT WHOLESALE PRICES.

PRICE OF GOLD. 113. FLOUR—Super to Extra State \$5 75 @ 7 75. Extra Western 6 75 @ 12 00. Extra Genesee 7 80 @ 10 00.

New York Live-Stock Markets.

WEEK ENDING. Bees, Cows, Calves, Sheep, Swine, Total. October 14th. 1,236 71 2,415 29,816 44,680 83,748

Beef Cattle.

The above figures show a decrease of 1500 bnlocks per week, as compared with the previous month. Fat native steers have been scarce, while a better grade of Texans have largely taken their place. We

usually expect the largest ran of cattle from Illinois, but during the past week Texas has led off. Where this kind of cattle has been improved by the introduction of native bulls, the progeny is very much better. For the most part our markets have been rather tame and inactive, but the close is very firm, with an advance of more than 1/2c for the week. Appearances point to high prices for prime stock the coming winter. The late horse disease made quite a call for work oxen, and when well-matched pairs could be picked out of lots, they brought much more for work than for beef.

The prices of the past 5 weeks were:

Range. Large Sales. Aeer. Oct. 14. 7 @ 14 c. 8 @ 11 1/2 c. 11 c.

Milk Cows.

Receipts have been light of late, and the market has improved, milk itself advancing with the cool weather. Very few good cows are now sent to market, farmers preferring to keep them over. The prices are \$25 @ \$50 each for very ordinary to thinish cows of small size; \$60 @ \$75 for fair to good milkers, and \$80 @ \$85 for prime to extra large cows. Calves.—As cold weather comes on these are sent in dressed instead of alive, the transportation being less. Live calves are both scarce and high, while hog-dressed sell well. They are in quick demand just now. Quotations for live, \$6 @ \$11 each for grass-calves; \$8 @ \$11 for ordinary to prime milk-veals; 6c. @ 9c. for hog-dressed grass-calves, and 12c. @ 16c. for poor to fat milk-veals. Sheep and Lambs.—Now that most of the lambs are in, the receipts are lighter. The only variation in prices from the previous month is that a class of stock has been sent in from frosted pastures which were worth very little there, and still less here. Some of these scallawag sheep and lambs have been sold at \$1.75 @ \$2.25 each. White choice stock, both sheep and lambs, continue in good request, thin flocks move slowly. The quotations are: for sheep, 4 1/2c. @ 5 1/2c. for poor to medium, and 5 1/2c. @ 6 1/2c. for fair to choice, a few extras going at 7c. Lambs take the wide range of 6c. @ 7 1/2c. for mean to thinish lots, and 8c. @ 9c. for medium to extra. Swine.—These show quite a gain in point of numbers, and there is no decrease in prices, the demand running very large at present. Being cheaper than beef, there is always an increased call for fresh pork as soon as cold weather sets in. Many dressed hogs are being sent in from the surrounding country. Quotations of live hogs, 5 1/2c. @ 5 1/2c.; city-dressed Western, 6 1/2c. @ 7c. for heavy to medium, and 7 1/2c. @ 7 1/2c. for light. State and Jersey pigs sell at 8c. @ 9c., the latter price for those of less than 100 lbs. weight.

The New York College of Veterinary Surgeons.

The recently prevalent horse-disease has done at least some good, as it has called the attention of the public to the need of educated veterinary surgeons. We were quite surprised to read in a paper so generally well informed as the New York Tribune the following: "There ought to be an Academy of Veterinary Science, and all that concerns the treatment of that inestimable animal in sickness and in health should be the subject of study as methodical, as patient, and as accurate as that which is exacted by the College of Surgeons or the medical schools of France and Germany." Now, this is what we have had for years. The New York College of Veterinary Surgeons, on Lexington avenue, has an able corps of professors, and offers admirable facilities for a veterinary education, and we wonder that young men should in such numbers enter the already overcrowded medical profession while there is a demand in every community for skilled veterinarians. It is not too much to say that the prompt and constant labors of Drs. Liantard, Large, and others of the college did much to abate the fatality attending the recent horse epidemic.

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Remitting Money: — Checks on New York City Banks or Bankers are best for large sums; make payable to the order of Orange Judd & Co. Post-Office Money Orders, for \$50 or less, are cheap and safe also. When these are not obtainable, register letters, affixing stamps for postage and registry; put in the money and seal the letter in the presence of the postmaster, and take his receipt for it. Money sent in the above three methods is safe against loss.

Postage: On American Agriculturist, 3 cents a quarter, in advance; on Health and Home, 5 cents per quarter. Double rates if not paid in advance at the office where the papers are received. For subscribers in British America, the postage must be sent to this office for prepayment here.

Bound Copies of Volume Thirty are now ready. Price, \$2, at our office; or \$2.50 each, if sent by mail. Any of the last fifteen volumes (16 to 30) will also be forwarded at same price. Sets of numbers sent to our office will be neatly bound in our regular style, at 75 cents per vol. (50 cents extra, if returned by mail.) Missing numbers supplied at 12 cents each.

Clubs can at any time be increased by remitting for each addition the price paid by the original members; or a small club may be increased to a larger one; thus: a person having sent 10 subscribers and \$12, may afterward send 10 more subscribers with only \$8; making a club of 20 at \$1 each; and so of the other club rates.

Immigrant Laborers.—"E. T.," Mobile, asks where he can procure families of immigrants for farm laborers and to do housework. A vast number of persons would like to know this, ourselves included; but there are difficulties in the way which seem insuperable. Immigrants may be procured, but in almost every case which has come to our knowledge, either they don't know anything at all, or shoemakers or townspeople who don't know a cow from an ox happen to be gotten, or women perfectly helpless in a house, or if they are good for anything, many have not sufficient honesty to work out the money advanced for their passage, and leave as soon as they find a place where they can get higher wages. We see no help but in organized action of those interested to send an agent and procure the right sort of immigrants, and pay them on their arrival as much wages as they can get elsewhere.

The New York Weekly Tribune has long been an institution. As a record of news, as an exponent of progress in the various departments of science and industry, and as an index of current literature it has no equal among papers of its class. While its circulation is already enormous, the publishers take the proper means to increase it by setting forth its claims in our advertising columns.

Mr. Sisley's Pelargonium.

Since our announcement of Mr. Sisley's good fortune in obtaining a double white Pelargonium, Aline Sisley, persons have written him from this country in relation to it. Mr. S. is an amateur, and does not deal in plants. He has placed his stock of the double white and some other fine doubles in the hands of M. Alegatiere, Horticulteur, Lyons, who sends us a catalogue of prices.

The New York Weekly Tribune

has long been an institution. As a record of news, as an exponent of progress in the various departments of science and industry, and as an index of current literature it has no equal among papers of its class. While its circulation is already enormous, the publishers take the proper means to increase it by setting forth its claims in our advertising columns.

and other short items is four pages less than usual. To give the index upon an extra sheet would increase the weight of the paper beyond the proper limit. Fortunately, the questions at this season of the year are not generally pressing, and the large amount of Basket matter that we have in type will be as timely next month as it would be were we able to publish it now.

Read It Over.

After writing a letter read it over, at least sufficiently to be sure that you have given Post-office, State, and signature. One or all of these are sometimes omitted. Always date from your post-office, and not from "Home," "Pleasant Valley," "Prospect Hill," or any other local name.

Costly Pictures.

Some people estimate the value of pictures as they do land—viz., by the acre, or rather by the number of square feet they cover. Hence, large pictures, as a rule, command a high price. Those of cultivated tastes look more to the subject and its artistic execution, as well as to the reputation of the painter. Thus, at Mr. Belmont's sale, Nov. 12th, a painting, by Meyer von Bremen, of two children looking at their sleeping brother, sold for \$1,900. It is about the size of our American Agriculturist Chromo, and by the mass of people would be considered of little more value. Another painting, by Jean Louis Ernest Meissonier, of Paris, entitled the Cavalier awaiting an Audience, sold for \$6,050! Yet this is only about the size of the Hearth and Home chromo, and probably the majority of people would choose the latter as the more interesting of the two.

The New York College of Veterinary Surgeons.

The recently prevalent horse-disease has done at least some good, as it has called the attention of the public to the need of educated veterinary surgeons. We were quite surprised to read in a paper so generally well informed as the New York Tribune the following: "There ought to be an Academy of Veterinary Science, and all that concerns the treatment of that inestimable animal in sickness and in health should be the subject of study as methodical, as patient, and as accurate as that which is exacted by the College of Surgeons or the medical schools of France and Germany." Now, this is what we have had for years. The New York College of Veterinary Surgeons, on Lexington avenue, has an able corps of professors, and offers admirable facilities for a veterinary education, and we wonder that young men should in such numbers enter the already overcrowded medical profession while there is a demand in every community for skilled veterinarians. It is not too much to say that the prompt and constant labors of Drs. Liantard, Large, and others of the college did much to abate the fatality attending the recent horse epidemic.

Mr. Sisley's Pelargonium.

Since our announcement of Mr. Sisley's good fortune in obtaining a double white Pelargonium, Aline Sisley, persons have written him from this country in relation to it. Mr. S. is an amateur, and does not deal in plants. He has placed his stock of the double white and some other fine doubles in the hands of M. Alegatiere, Horticulteur, Lyons, who sends us a catalogue of prices.

The New York Weekly Tribune

has long been an institution. As a record of news, as an exponent of progress in the various departments of science and industry, and as an index of current literature it has no equal among papers of its class. While its circulation is already enormous, the publishers take the proper means to increase it by setting forth its claims in our advertising columns.

Michigan Agricultural College.

This, the oldest, and in many respects the best of our agricultural colleges, sends us its catalogue, which indicates that the institution is enjoying a well-deserved prosperity. For information, address Richard Haigh, Jr., Sec'y, or Prof. T. C. Abbott, Pres't, Lansing, Mich.

Canada Queries.

A correspondent at Montreal, whose name we can not make out, asks if it would pay for him to plant an orchard. For this we must refer him to local experience. It is difficult to give lists of apples for a particular locality. Among the hardiest varieties are Red Astrachan, Sops of Wine, Duchess of Oldenburg, Early Joe, Tollman Sweet, Famense, St. Lawrence, Wagener, Pomme Gris, Golden Russet, and Northern Spy. Trees usually come into profitable bearing in 6 or 7 years. Stable manure, at "reasonable rates," is better for nearly all purposes than concentrated manures.

The California Vintage.

The circular of J. M. Curtis informs us that owing to the late cold spring and severe frosts in April, the vintage may be set down as fully twenty per cent less than the average.

Wire Fence.

A. Hance & Son, Monmouth Co., N. J., writes us of what they know of wire fences as follows: As to fence wire, we would advise, after a very satisfactory experience of twenty years, No. 8 annealed. One pound will measure fifteen feet. We use five strands for cattle, and use No. 7 for the middle strand; posts six feet apart, end post well braced and secured; wires tightened whenever required by a cheap apparatus similar to that used in cording a bedstead.

Smutty Wheat.

"Mrs. M. L. B.," Montana. Smutty wheat is not wholesome food for fowls nor for any other animal. Boiling might prevent injurious results.

Feeding Fowls.

"W. N. T.," wants to know how much corn would feed 500 fowls for one day, and if it would pay to keep fowls for eggs alone.—The allowance of grain is a quarter of a pint per day per fowl. If they have a good run, where they can get grass and insects, one bushel per head per year is a proper allowance. Our experience has been that fowls kept for eggs alone will not always pay, but when chickens are raised, the eggs pay expenses, and the chickens yield a good profit. But there must be tact and experience.

Management of Horses and Cattle.—Subscriber will find Allen's American Cattle and McClure's Diseases of Horses, Cattle, and Sheep valuable books to put in the hands of a manager of a stock-farm.

Corn-Stalks.—"J. F. P.," Fredericksburgh, Va., has 100 tons of corn-stalks; hitherto he has burned them, but is ashamed to confess it; now what can he do to avoid this waste?—No one should be ashamed to confess his faults, but confess, repent, and learn better. There is a better way which has been frequently pointed out by the *Agriculturist*, which is to cure them and feed them to stock. This may be done by throwing them to the cattle in a yard or pen, when the finer portions are eaten, and the rest trampled down into manure; or, which is far better, cutting them up, wetting and sprinkling them with bran or mill-feed, when they will be eaten up clean. Horses, cows, and oxen will eat and thrive upon such food, if the stalks are well cured.

We repeat, that no one is bound to notice a letter which has no proper signature. We also repeat that we never print a name when the writer indicates that he would not like to have us do so. Sign letters whatever you please, but give us also the real name and place if you expect us to attend to your requests.

About West Point.—In reply to "J. R. W.," Portland, Me., candidates for admission to West Point must be between the ages of 13 and 21. They should be prepared for examination in the ordinary branches of English education, preparatory mathematics, and United States history. Appointments are made one from each Senatorial district and ten at large. The course is five years, and appointments are made as vacancies occur. Inquiries as to vacancies, etc., should be made of the Senator from your district.

Plants Named.—"G. A.," Stanhope, Prince Edward Island. Your plant is *Sonchus arvensis*, or Field Sow-Thistle. It is one of the weeds introduced into the United States and Canada with grass and other field seeds sent from Europe. The plant is best eradicated by plowing the land in the fall, thoroughly harrowing it, and putting in some crop which requires careful cultivation; or the land may be allowed to remain idle during

the summer, and plowed and harrowed at least once a week during the season. . . . A. E. Treadway, Havre de Grace, Md. No. 1. is *Triosteum perfoliatum*, commonly known as Feverwort, or Horse Gentian; No. 2, *Euphorbia polygonifolia*, or Shore Spurge, a very common plant along the Atlantic coast. . . . "H. B.," Pleasant Green, Va. It is impossible to name grasses from leaves alone; either send them in flower, or with ripe seeds. Your other plant is a species of Aster, probably *Aster Tradescanti*. It is necessary to send the whole plant, or at least the flowers and root leaves, in order to determine asters accurately, as there are upwards of fifty species in the Northern States.

Agricultural Schools.—The general failure of the efforts to make agricultural colleges what they were designed to be, seems to have turned the ideas of private parties towards attempting something which may take the place intended for them, or at least do their work. We understand that Thomas Judd, a wealthy farmer of Illinois, has about completed arrangements for opening an industrial agricultural college, in which practical and scientific studies shall be open to young men and women. A farm of 160 acres of land will be attached to the college. Competition is said to be the life of business; it may also help our agricultural colleges.

The "Eternal Corn."—A highly intelligent lady who has a somewhat rare knowledge—for a lady—of stock and other agricultural matters, made use of this expression in a conversation with us the other day. It was an apt expression. Our corn crop has become so immense that the inquiry, What will we do with it? becomes exceedingly apropos. Corn is worth ten cents a bushel in the far West. At such a price it had been better not to have raised it, for there is no profit in it. But what shall we do about it? Feed it! is a general recommendation. And this, though at present in most cases impracticable, must at some time be done. How to do it must be studied out, and the way learned as soon as possible, for it won't do to raise corn to burn always.

The Bluffton (Mo.) Vineyards., established in 1867 by a stock company, under the direction of Mr. Hasmann, of Missouri, with some 1,500 acres of land, and many buildings and other improvements, which have cost over one hundred thousand dollars, have been sold lately under mortgage. The present owners now offer the entire property for rent for a long term of years. These lands are known to be very superior for grape and fruit-growing.

Chickens without a Mother.—"J. W. B.," Carlisle, Mass., is troubled with lice on his young chickens, and asks: Can chickens be taken from the hen as soon as hatched, and reared successfully? And if so, how?—There is but little difficulty in hatching chickens artificially, but the trouble begins when it is undertaken to rear the brood. Our correspondent had better get rid of the lice, and leave his chicks with their mother. Sprinkle the nest freely with sulphur, and give the hen herself a dusting two or three times during her sitting.

How to Get Early Clover.—Top-dress it with manure in the fall. It would have been better earlier, but may yet be done. The manure protects the plants and enriches them at the same time.

How many Rows on an Ear of corn?—"E. N. H.," asks what is the largest number of rows of corn on an ear we have seen or know of.—We have raised corn with 32 rows on an ear, but believe we have heard of more. Have any of our readers?

No Milk.—"S. T.," Morrilstown, has a young Alderney cow, with her second calf, which has no milk. With her first calf, she gave bloody milk out of one teat, and dried up in two months. He thinks this is an unusual case, and asks if she would be likely to milk if she had another calf. We never met with so bad a case, in a cow at least, and fear that she would never be worth keeping. Can any one advise him what to do?

How to Renovate an Old Apple Orchard without Plowing.—We have only space to answer this question briefly. Prune judiciously, and manure heavily. Do not put the manure round the trunks of the trees, but spread it all over the ground. Ashes, leached or unleached, are excellent; so is lime or bone-dust. But superphosphate and nitrate of soda would probably act quicker than any other application.

The Cotton States Association Fair.—The Cotton States Association comprises some of the most active business men in Augusta, Ga., and vicinity. It has near the beautiful city of Augusta ample grounds, which are well arranged and tastefully orna-

mented, and offer every facility to exhibitors and spectators. Its fair was held in October last, but as the weather was adverse, the result was a pecuniary loss. There were many interesting things exhibited, and though some departments were less full than usual, the show of stock was remarkably fine. Some animals exhibited by A. B. Allen & Co., and by Wm. Crozier, both from New York, attracted much attention. The Brahmin cattle, both pure and grade, shown by Mr. Peters, were among the novelties. Of fruit there was a most meager display, but Floral Hall was made attractive by the abundant and tastefully arranged contributions of the President, Mr. P. J. Berckmans. The Association did everything to deserve success, some of the most prominent business men giving their whole time and personal attention to the different departments. We hope that another season fairer skies and a more abundant attendance of both exhibitors and visitors will reward the efforts of the courteous officers.

"PATENT MEDICINES."—Recipe for Getting Rich: Get from the medical dispensaries, or elsewhere, any simple stimulating compound or tonic, or take cheap whiskey and color it, adding any cheap stuff to give it a medicinal taste. Adopt any name you choose, the more nonsensical or mysterious the better—one having an Indian, or Japanese, or Turkish sound will be all the better. Employ the glass-blower, or printer, or both, to get up fanciful bottles, or boxes, or labels. Look out that the package, contents included, don't cost over 5 to 8 cents. Assume for yourself a name, as near that of some noted physician as you dare go, and add to the end of it M.D., F.R.S., D.M.D., etc., etc. Write a long story about your great age, experience, and success abroad. Invent 50 to 100 or 1,000 wonderful cures wrought by your medicines, giving names in full, with residences, date, etc., but be careful to not blunder into giving any real name of any person living in the same place. (An improvement is to refer specially to one or two persons, and have an ally at the place, to receive letters of inquiry, and write false letters confirming the story you tell of their being cured.) If you connect with your medicine a touching story about some old mythical person, or Indian, or South American, all the better. These matters arranged, advertise your medicines largely. Print and scatter circulars, pamphlets, and pictures by the ton. Call for agents, and let them give away samples of your medicine, to be paid for if it does good. You may begin in a small way with a few hundred dollars (printing is cheap now), but five or ten thousand dollars or more will make a more brilliant show, and produce large proportional returns. **Result.**—You will reach a multitude of weak, nervous, ignorant people who are slightly ailing, or think they are. They will take your stimulating or tonic preparations, and "feel better" right away. They will believe they have escaped or been cured of some terrible disease (the symptoms of which you should take good care to set forth vividly in your circulars). Henceforth, you have not only a regular customer, but one who will sign your certificates of cure as strong as you can write them, and who will talk up the wonderful virtues of your medicines to others. A dozen of your bottles or packages, costing you less than a dollar for the whole, if given away in any neighborhood, will find you one or two ardent customers, and thenceforth you may depend upon the annual sale of a hundred bottles or parcels, at \$1, \$2, or \$3 each—the price to depend upon the skill you use (or buy of some penny-a-liner) in writing up the medicines. The druggist of the town, as your "agent," will of course help scatter the medicine if you give a liberal profit. If you set aside three quarters of the receipts to cover cost of bottles, advertising, commissions to retailers or agents, etc., you will still have a net profit of say \$50 a year from each town where your medicine is well introduced. If you only secure 1,000 such towns in the whole country, you still get the modest income of \$50,000 a year! Do you ask, "Is this all true?" We answer, that **this is a fair history of the patent-medicine business**—with the variations of pills which give relief to some cases, and opiates which under the name of soothing syrups, etc., give quiet to young and old babies at the expense of future health. We have several other recipes in reserve to give.

SUNDRY HUMBUGS.—Our newer readers keep inquiring about the trustworthiness of this, that, and the other doctor for various diseases. We answer, that every so-called physician, every medical institute, or college, or association that advertises medicines or medical advice, by circular or otherwise, is a quack—in short, a swindle. The whole tribe of those who advertise "marriage guides," "female medicines," "advice to the young," "errors of youth," "eye doctors," "ear doctors," "consumption-curers," "cancer doctors or medicines," etc., etc., are positively quacks and impostors, to whom it is unsafe to address even a letter of inquiry. . . . A lot

of letters from various places in Texas show that the quack Dr. F. E. Andrews, of Lexington avenue N. Y., alias Albany, N. Y., is just now vigorously operating in that State with his humbugs, his "Good Samaritan," "American College of Health," etc., etc. "Dr. H. M. Brown," of Albany, N. Y., may be Andrews under another name, or a brother quack. Let them both alone, and burn all their circulars that are thrust into your hands. Five hundred letters of commendation will not whitewash "Rev. Edward Wilson" into anything less than an old swindler. The "Golden Remedies," inquired about by several, are nonsensical quackery. Our Hamburg Drawer for this month contains 43 different names of swindlers. The "363 Lottery of the Free City of Hamburg" is a swindle, at least so far as any agency in the U. S. is concerned. The "N. Y. Loan Brokers' Union," R. H. Lewis, manager, 4 Bond street, N. Y., is a humbug, as before stated. Pardee, of Binghamton, N. Y., was still selling his humbug tickets, etc., as late as October 23d. Why don't the good people of Binghamton drive this nuisance out of their midst? They are in danger of getting as had a reputation as New York. Don't be humbugged into sending money for watches to any but well-known, reputable parties. A large share of that sent to our large cities in answer to circulars is never heard of again, and so much of it as is heard from is poorly recompensed. The stories about falling firms, etc., etc., is all humbug. Good watches, like good gold coin, never go begging customers at half-price. No decent person of common sense will give the slightest heed to the circulars of C. Sheldon & Co., Hohoken, N. J., or any one of his class who pretend to be such great friends to the married and inferentially, to the vicious unmarried. To T. E., of Pennsylvania, and others: These various eye-doctors, eye-sight restorers, etc., are merely advertisers of cheap spectacles. Go to the nearest village, and you can try and be fitted with glasses every way as good, at a quarter of the cost, and with more certainty. We are tired of chasing up every advertising swindle of this kind after having looked into merits of a score or more of them, and find them all *de-merits*. To E. H. M., New York: No circular was inclosed. The syrup is doubtless quackery. The swindling fraternity have, in one way and another, got the P. O. address of most persons in the U. S. They sell and "swap" lists of these names among themselves and with quack-doctors, etc. The "Queer" or "Sawdust" swindlers are brisk at work, adopting a great variety of names to deceive the P. O. people, who try to keep letters from those known or believed to be cheats. The fellow operating in this line sends out, among others, the following names as his address: At 34 *Amity street*, N. Y.—H. L. Barnard; K. P. Douglass; Geo. Savory; L. F. Harness; M. L. Keiley; N. L. Werner; F. H. Park; L. P. Benchley; H. J. Keane; Chas. W. Young; K. G. Pott; H. W. Elston; E. S. Hale; L. F. Stark; Elbert Putnam; G. E. Starkevaut; F. P. Walters; G. L. Demey; Ben. L. Crowe, at 609 Broadway.—Col. James Warlow; Thos. Jackson; E. C. Catlin; Otis T. Bengor; S. W. Westervelt; K. M. Walters; Isaac S. Lewis; Edwin Virgil; Arthur Debenham, 190 Broadway. Also Reid, Delafeld & Co., 88 Broadway, N. Y., and New Haven, Ct.; David W. Coles, 357 3d ave.; Myron F. Brittle & Co., 30 Bond st.; W. H. Malcolm, 63 4th ave., etc., etc. All the above use essentially the same circulars. We have not room for a lot more of humbugs on hand, but will renew the war upon them in the next volume, and, as hitherto, we expect to shield at least all our readers from swindlers, and through them many other people.

Parsnip Seed.—"C. C. M." Leave the roots in the ground until spring, then dig. Select the best, and set them out to bear seed. If there are wild parsnips in the neighborhood, there is danger that they will cross with the cultivated ones, and deteriorate the seed. This may have been the cause of your trouble.

Evergreen-Trees from the Woods.—W. Oldfield, Canada. Evergreens from the woods need care the first year. Take them up and set them in rows close together, and put over a rough shelter—a rail plat form, covered with boughs, and a foot or two above the trees, will answer. Those that survive a season under this treatment, may be set out the next year, and be quite sure to live. You can judge whether it would be cheaper for you to take this trouble, or to purchase trees at the price named.

Cannas.—"L. A. G." Vernon, N. Y. The roots should be dug before the stems are fairly cut down by frost. When the stems are subjected to hard frost, the roots soon decay. We find that the roots do not keep well in the cellar, and shall try them in a drier place.

Borers.—"J. K. B." We doubt the efficacy of any external application after the borer has entered

the tree. They may be of use, at the proper season, to prevent the deposition of eggs. Remove the earth around the base of the trees, and search for the holes. Often they may be cut out with a knife, but if they have entered too deeply, a wire-probe must be used. Sometimes it is necessary to cut the wood away with a gouge, before the grub is reached, but the cutting will not be equal in injury to that done by the borer. Well-rotted stable manure, ashes, or lime are best manures.

Ground-Vinery.—"W. O.," Quebec. We do not know of any one who has tried to grow exotic grapes in ground-vineries so far north, but we think the probabilities are in favor of success. We figured the ground-vinery in June, 1866.

Vinegar Eels.—"H. L. D.," Oswego, N. Y. The so-called eels are worms, and are called by naturalists *Anguillula aceti*. There are several species, some being found in vinegar, some in porter and other fermented liquors, and others in wet moss and moist earth. The only way that we know of, to get rid of them, is to heat the vinegar to the boiling point, but it is not likely that this will prevent others from breeding after a while. The manner of the production and reproduction of low forms of animal life related to these vinegar eels is a subject of scientific controversy, and one too wide for our limits.

Peaches for Canada.—"W. O.," Quebec. Probably no variety of peach will endure your winters, no matter how well protected by evergreens. When the mercury goes 12° below zero, the fruit buds are usually destroyed. You can grow peaches in boxes or tubs, and remove them to the cellar in winter. We can not answer the other question.

Spreading Manure.—"J. C.," Ridgway, Minn., asks if it is best to spread manure direct from the wagon in the fall of the year for plowing in for corn, or let it lie in heaps.—Don't by any means let it lie in heaps, but spread direct from the wagon. It saves labor, and the ground is more equally fertilized.

Cross-Harrowing.—"M. B.," Brush Valley, Pa., sends us a method by which he cross-harrowed his field with only half as much turning of the team as by the usual method. He commenced at one corner and crossed the field diagonally to the opposite corner, turned to the left and returned, then turned at right angles until he reached the edge of the field at his left hand, then returned alongside of his first stroke to the end of it, then turned at right angles until he reached the fence at his left hand again, and so on, going continually round the field diagonally, when he finished at a corner, and the ground had been passed over twice and no hoof-marks were left on the field.

Cord-wood Sticks for Hay.—Those Northern farmers who put sixty pounds of wood in the bales of hay sent to Texas, which the Texan planters think not so kind treatment as they might naturally be led to expect, should remember that though such conduct may be profitable, it is not neighborly.

Lolling of the Tongue.—"L. W. W.," Defiance Co., Ohio, informs "O. C. S." how to cure a horse that carries his tongue out—viz.: Rivet a section of a knife from a mowing-machine on his bit; dull the edges, and make everything smooth. The knife running up in his mouth prevents him from drawing his tongue far enough back to get it over the bit. Carelessness in breaking colts is the cause of it. He has just finished breaking a colt that had this habit. He broke him by taking a strong rubber tape, sewing a buckle on one end, and running it through the rings in the bit and over his nose, tight enough to hold the bit up against the roof of his mouth. He thinks the rubber would not cure an old horse of the habit, although he never tried it; but the knife will prevent it as long as it is used.

Houdan Fowls.—"An Old Subscriber" asks if Houdan fowls have muffs in front of the neck as shown in the illustration of a trio in the *Agriculturist* of March, 1871.—This is indispensable in pure-bred fowls.

Sundry Questions.—"Wm. T. O.," Buncumbe Co., N. C., asks as follows—viz.: 1st. What is the difference in value between leached and unleached wood-ashes on a wheat crop? 2d. What is the best way of reducing bones to fine dust where there is no bone-mill? 3d. Is not \$20 per ton sufficient freight on fertilizers for 1,000 miles? 4th. What is the best and cheapest way, and what is the cost, of transporting a mare from Liverpool to North Carolina? 5th. What is the cost of a good drill to sow seeds and fertilizers at the same time? 6th. What is the chemical operation of burnt clay used as a manure for turnips? 7th. What is the rate of import

duty on English farm implements, new or second-hand?—Replies: 1st. Unleached are worth double the leached. 2d. There is no ready way. 3d. If they could be carried in bulk in large quantities. Yes; if not, No. 4th. By steamer to New York, thence by steamer to Wilmington, N. C. The passage costs from \$55, gold, upwards, with fare of attendant, \$80, and feed additional; total, probably not less than \$200, gold, if not more. 5th \$90. 6th. Potash is released and rendered soluble. 7th. Forty per cent *ad valorem*.

Question for Decision.—"J. D. H." asks the following question: At an agricultural fair a premium is offered for the "best coop of chickens, not less than three varieties, and three of each." The only coop on the ground that contained three fowls of each of three varieties was one with five light Brahmas, four dark Brahmas, and three half-bred Houdans. Was this coop entitled to the premium?—We should say it was, unless the judges, as they sometimes do, reserved the right to refuse a premium when in their opinion the specimens exhibited are unworthy. But unless this is expressly declared and understood, it leads to dissatisfaction and ill-feeling, which should be avoided.

Crushing Bones.—"Wm. A.," Gainesville, Va., wants to know all about crushing and reducing bones for manure, and if a two-horse railway power is sufficient to run a bone-mill.—There was a crusher figured in the *Agriculturist* of November, 1871, which could be run by such a power if the number of stamps were reduced to two or three. The ordinary bone-mills require five-horse power to run them. The methods of reducing bones with sulphuric acid or with alkalis have been so often described that almost any back number of the *Agriculturist* contains one or other equally effective method.

How to Manage a Lot of Calves.—"Young Farmer" has a lot of yearlings, which he wants to feed as cheaply as possible on corn-stalks and corn. He wants information on the subject.—We once fed twenty-four head of calves and yearlings in the following manner: A shed, fifty feet long, was furnished with a feeding trough to which access could be had from the front. The trough was divided into partitions, so that the animals could not crowd each other, and each had a feeding place from which it could not be ejected by the others. Corn-stalks were cut and wetted and mixed with corn-meal and wheat-bran, ground together in equal parts, and salted; and half a bushel per head was fed twice a day. Each animal had two quarts per day of the meal and bran. Plenty of straw was thrown into the shed, and none removed until spring, when there was three feet in depth of well-rotted manure which had not frozen at all, taken out, and which paid for all the feed the calves consumed. Regular currying, and exercise in the yard through the day when they wished, kept them in good health. We know of no better plan.

Books Received.

The Polytechnic and The Athenaeum are both new collections of music, the first containing selections for schools, and the other part-songs for female voices. J. W. Schermerhorn & Co. \$1.25 each.

Object-teaching Aids. J. W. Schermerhorn & Co., New York, send a catalogue of a great number of curious and useful appliances for the instruction of children.

Monteith's Comprehensive Geography. A. S. Barnes & Co. send us a copy of this new school-book, which has much to commend it to teacher- and others.

Hobbs's Architecture. by Isaac H. Hobbs & Sen. Lippincott & Co., Philadelphia. A handsome volume, containing a large number of designs in various styles of architecture. It will be found useful to architects and those who intend to build.

Dick's Encyclopedia of Practical Receipts. by William B. Dick, published by Dick & Fitzgerald. This is a compilation of over 6,000 receipts or recipes, covering every branch of art. The value of such a work, like that of a dictionary, can only be ascertained from actual use. The contents seem to be carefully classified, and to be obtained from the best sources, and the whole is presented in a handsome volume of 607 pages.

The Independent Child's Speller. A juvenile book, which teaches a child to spell by the use of script, or writing letters, which allows writing to be taught with spelling. A. S. Barnes & Co. 25c ms.

The Constitution of the United States, with a concordance and classified index. This seems to be a most carefully prepared and useful work. The index allows reference to be readily made to any article or section. The author is Charles W. Stearns, M.D. Published by Mason, Baker & Pratt, New York.

Trapping the Fox.—The article on page 451 was sent us by a correspondent whose name we have lost. He promises us other articles, and we shall be glad to hear from him.

"I find Three Papers enough."—So says one who is fortunately able to supply himself with as many as three newspapers. "I take my religious paper, for of course everybody wants to read about the work of his own denomination; and my local paper, for who wouldn't patronize that? and the *American Agriculturist*, for I must have that, sure. And I find three papers enough."—We commend our friend's selection.

Steaming Food.—"R. W. B.," St. Louis, Mo., says he keeps 1 horse, 2 cows, and 100 hens, and asks what is the best plan of steaming food for them.—We would not steam at all. It will not pay for such a small stock. If thought desirable to cook the food, we would pour boiling-hot water on the chopped hay or straw, and cover it up tight for a few hours. The simplest way to cook meal is to boil the water, and then, while it is still boiling on the fire, stir in the meal, gradually, a little at a time, and let it boil until it is well cooked and converted into pudding.

How to Make Ten Acres Pay.—"R. W. B.," who asks about steaming, also says: "I do business in the city, and live about 10 miles out on a railroad, and am trying desperately hard to make my place of ten acres pay part of my family expenses, but have not had much encouragement yet."—We do not think steaming food for your small stock will help matters. Food is much cheaper than labor. Better devote the time and labor to making the land clean, rich, and highly productive. As a rule, a man can not do business in the city, and carry on a farm or market-garden to advantage at the same time.

The Report of the Department of Agriculture for October contains the usual crop statistics, but these fall into insignificance by the side of an article by the Commissioner himself, upon the "Cultivation and Hybridization of Wheat." The profundity of the physiological knowledge there displayed would amaze us, were we not blinded by the dazzling brilliancy of the style in which it is conveyed. We at home expect nothing better, but what most scientific men abroad think of such stuff as this in an official document? The chemist tells us about zinc tree-labels, written upon with a copper solution, which may be new to him, though not to others. The microscopist informs us that, when weeds and brushwood are burned, "caustic potash" is liberated. Then there is an account of Prussian experiments in crossing the Zebu or Brahmin cattle upon European stock. The Department does not seem to be aware that such crosses were made in this country years ago, and that grades are still being raised which are highly valued. The Prussian account, allowed to pass without comment, would give the reader an impression that the grades were nearly worthless. But this is a wonderful Department.

A Dry Well.—"J. M. S.," Yonkers, has a well run dry for the first time; what shall he do with it?—Dig it deeper; this is the best season for doing it. Put a wooden curb inside the stone-work, and wedge it tight. Dig the new well of a diameter equal to the lining of the old well until water is reached, when it should be stoned up a foot or two higher than the old bottom. The curb should be removed as soon as the new lining reaches it. It is not probable that the water will fall again.

Pumping by "Clock-Work."—"L.," Brooklyn, Ct., asks if there is any machine of half or a whole horse-power, that could be wound up by a horse, and that would saw wood or pump water or cut feed.—Such a thing is impracticable, for the reason that no power is absolutely gained by employing machinery, and a horse-power would require a horse constantly working to keep it in motion. If power is to be stored up, as in "clock-work," by elevating weights quickly, to run down slowly, it would take 10 horses working one hour to make one horse-power for ten hours, to say nothing of the power lost by friction, so that no gain is made, except in time only. A boy with a taste for mechanics might use clock-work to churn with, for amusement, but for practical use it will "cost more than it comes to."

To Kill Moss on Fruit-Trees.—There is nothing better than carbolic soap and lye. We have used it on apple, pear, peach, and cherry trees with manifest advantage. It will kill every particle of moss or parasitic growth of any kind that it touches. Apply it at any time. Lye alone will answer, but we prefer to add carbolic soap to it. The lye need not be so strong. The poorest soft-wood ashes will answer for making the leach. We use the lye simply as we would water to dis-

solve the carbolic soap—say half a pound of soap to a three-gallon pail of boiling lye. It may be applied to the trunks of old trees while holling-hot. Use a swab or a large paint-brush. Go over the trunk and all the large branches. It will kill the eggs and larvae of insects as well as the moss, and will greatly improve the appearance of the trees. Try it.

Poll-Evil.—"C. F. K.," St. Joe, Mo., wants a remedy for poll-evil in a young mare.—Apply a poultice of linseed-meal or boiled carrots to the tumor until it suppurates, when it should be washed often with a solution of one dram of chloride of zinc in a quart of water until it heals. It is sometimes necessary to use the knife, but this is unsafe in unpracticed hands. A cloth dipped in tar should be kept over the wound, and a breast-strap should be used instead of a collar.

Feeding Pigs and Poultry on House Refuse.—In reference to an article in regard to feeding pigs on city swill, which appeared recently in the *Agriculturist*, a correspondent at Philadelphia suggests that it might be more profitable to feed it to poultry. Probably the better plan would be to keep both pigs and poultry. In Philadelphia he says there are several parties who do nothing else but collect swill and feed hogs, some to the number of several hundred, and the pork is sold in market at as high a price, and gives as good satisfaction, as any other.

Several Questions.—"Is old plaster as good as that freshly ground?"—There is a very general opinion that it is not. There is no chemical change, and we believe it is just as good, provided it is kept dry and does not adhere together in lumps. "Is salt a valuable manure?"—Sometimes it has a wonderful effect on wheat and barley, and, when cheap, is well worth experimenting with. It is generally beneficial on mangel-wurzel. Average quantity, four to five bushels per acre, sown broadcast. "Is it well to mix salt with guano?"—If salt is cheap, Yes—say 200 lbs. ammoniacal guano and 100 lbs. salt per acre. "Is nitrate of soda as good as nitrate of potash?"—No; but it is far cheaper, and better in proportion to cost.

Water in Turnips and other Roots.—When fresh from the field, common white turnips (the bulbs) contain about 94 per cent of water; Aberdeens, 92 per cent; ruta-bagas, 90 per cent, and mangel-wurzel, 88 per cent. The amount varies somewhat, according to the rapidity of growth, size, etc., but the above figures are not far from the average when these roots are growing in the field or are in a fresh state. After they have been gathered and exposed for some time, they may contain one or two per cent less.

Price of Pure Cotswold Sheep.—A gentleman in Pennsylvania complains of the high prices asked for thorough-bred Cotswold sheep by some of the breeders who advertise in the *American Agriculturist*. He says: "I am asked \$50 for a good ram, and yet two years ago I bought a good one, direct from Canada, for \$25, and will now sell him for \$15. I can only get from \$8 to \$10 for yearling rams."—That may well be. A sheep "direct from Canada," no matter how good he might appear to be, would, in all probability, be at best only a grade, and would be dear at \$25. There are very few breeders of pure animals either in England, Canada, or the United States. What our correspondent wants is a ram "direct" from a responsible breeder, and not from Canada or elsewhere. Fifty dollars is quite a reasonable price for a good, thorough-bred Cotswold ram. Our correspondent would smile to hear a Canadian say he got a Chester White pig direct from Pennsylvania.

Sowing Plaster in the Winter.—When plaster is cheap and the mill is a considerable distance from the farm, and you have no convenient place to stow away the plaster, it is a good plan to draw it in the winter and sow it on the clover at once. If there is not too much snow on the land this can easily be done. Our own plan is to put a boy to drive, and a man on each side the wagon-box, and one behind, and scatter the plaster with a free hand as the horses walk along. We sow two to three bushels per acre. A little of the plaster may be carried off by the melting snow in spring, or blown to the fences with the drifting snow, but not enough to occasion any serious loss. And it is certainly a great convenience to draw plaster on a sleigh rather than in the spring, when the roads are almost impassable, and the fields so soft that you can not take a team on to them without injury.

Lice on Dogs.—Our young farmer friend Harmon, of Ogden, N. Y., who reads the *Agriculturist* and believes in it, is in trouble, and thinks we can help him. He has a valuable and favorite shepherd dog that has had

the distemper, and is now troubled with lice. He wants to know how to kill them. Nothing is easier. Get some carbolic soap and dissolve quarter of a pound in a gallon of boiling soft water, and when cool enough to bear the hands in, wash the dog all over with it. Put on some old clothes, get a sponge, and make a thorough job of it, wetting every part of the dog, and rubbing it into the hair. If the work is well done one dressing will kill all the lice, but if after three or four days any lice are found on the dog, wash him again. This is a far better and safer remedy than mercurial ointment.

White Wire-Work.—The useful and ingenious articles made of white wire, described last month on page 425, are made by Woods, Sherwood & Co., Lowell, Mass., who have a patent for the process. As in the article referred to, it was mentioned that the French make articles beautiful in form of comparatively cheap materials, some have inferred that the wire-work was of foreign origin. It is due to Messrs. W. S. & Co. to say that the manufacture is a purely American one, and instead of being imported large quantities of the goods are sent abroad.

Fine Fruit.—The collections of apples and pears from Ellwanger & Barry, Rochester, N. Y., have formed an attractive feature at many of the fall fairs. Messrs. E. & B. not only raise fine trees, but large quantities of fruit of a perfection of form and beauty of color and bloom not often seen at exhibitions. That the beauty of the fruit is more than skin-deep we can attest, having received some samples sent to convince us of the same.

Painting Implements and Machines.—We know of nothing so cheap and so easily applied as crude petroleum. Put on all the wood will absorb. Cover the whole implement or machine with it—wood and iron both. It will keep the iron from rusting. Do not mix anything with it. If you prefer to use a paint, you can get it ready for use at the painter's. Give it time to dry.

Best Food for a Young Pig.—"A. R." There is nothing better than fresh skimmed milk and cooked corn-meal. Stir the hot corn-pudding into the milk, and feed warm, but be careful that the pudding is well broken up and mixed with the milk, so that there shall be no lumps or balls of hot pudding to scald the pig.

Chip Manure.—The chips themselves are worth little or nothing for manure. Better rake them out and burn them. The finer particles are good to spread on the grass in an apple orchard, or it may be used as mulch. We are afraid to use chip manure about pear-trees, as it favors the growth of fungus.

How to Keep Cider Sweet.—A correspondent says: Use only sound apples. Make the cider when the weather is almost cold enough to freeze the apples. Expose the cider during freezing weather, and stir it till the whole of it is reduced as near the freezing point as possible without freezing. Then barrel it, bung up tight, and place it in a cellar kept nearly down to the freezing point. As long as you can keep it cold enough it will not ferment, and as long as it does not ferment it will remain sweet.

What Roots to Feed First.—The White Strap-leaved turnip and similar varieties should be fed first, then such kinds as the Yellow Aberdeen. The different varieties of Swede turnip or ruta-bagas should not be fed until after the former kinds are gone. They are in their prime from February to April. Mangel-wurzel and other beets should be reserved to the last.

Bean Straw.—If well-cured and free from mildew, the pods and leaves of bean straw make excellent fodder for sheep and cows. If you have only a little bean straw do not feed it all out at once, but reserve it to feed occasionally, by way of a change.

A New Agricultural Implement House.—Mr. George W. Carr and Mr. J. W. Hobson, for a long time with R. H. Allen & Co., have established the firm of Carr & Hobson, for the purpose of carrying on the agricultural implement business at 56 Beckman st.

Christmas-Tree Rosettes.—There are several devices for decorating Christmas trees, and none prettier than these rosettes. By ingenious combinations of brilliant-colored papers and exceedingly neat workmanship, a very pleasing and ornamental effect is produced, and more cheaply than by most other decorations.

Your Subscription Expires NOW

(unless you have recently renewed it for 1873, or chance to be among the few whose time runs over into next year, of which fact you will be cognizant, without any personal notice from the Publishers).

PLEASE RENEW AT ONCE,

For the following Reasons:

1st.—You will have an early place on the list of those receiving the Splendid Pictures, which are sent out strictly in the order the names have been received.

2d.—If the subscriptions for 1873 are sent in the first week in December, it will greatly assist the Publishers in getting the names carefully and systematically upon the mail-books, without calling in additional inexperienced clerks, so that the January number can be mailed promptly before the Holidays.

3d.—It will take no more time to attend to renewing to-day, than will be required next week or next month.

4th.—The American Agriculturist for 1873 (Vol. XXXII) will in many respects be superior to any previous volume—in engravings, in useful and interesting reading matter, etc.—for all classes.

5th.—Please invite your neighbors to join you in taking the paper. Tell them about the beautiful picture given to each subscriber. See next column.

6th.—If you have German friends, or neighbors, or workmen, please let them know that the American Agriculturist is printed in German also, with the same illustrations, the more important reading matter, etc., besides a Special German Department by Hon. Frederick Münch, of Missouri, and that the German edition is furnished at the same rates, single and club, as the English edition.

7th.—NOW is the best time to renew your subscription for 1873.

Free.

A MOST BEAUTIFUL CHROMO

Richly worth Ten Dollars; A Perfect Copy of an Original \$400 Painting, by B. F. Reinhart, entitled "Mischief Brewing,"

PRESENTED

To Every Subscriber to the American Agriculturist for 1873.

A Splendid Ornament for every Home.

The above fine gift is completed, and is being supplied as fast as they can be worked (about 5,000 a week), to subscribers in the order the names have been received for 1873. It is a beautiful ornament that will greatly please everybody. It is printed in 16 colors, which give the exact shading of the original painting, so perfectly that it is just as good for all practical purposes, and few persons can tell the copy from the original. The last printing gives a canvas impression so perfectly that the Chromo has all the appearance of an oil painting on canvas.

The cost of putting this on 16 stones has been large, but this being done, by printing 200,000 copies, the Publishers are able to present a copy to every subscriber for 1873. It is a perfect Gem, 11 by 13 inches inside the frame.

The Picture will be given to every subscriber for 1873 (new or old), whether coming singly at \$1.50 each, or in Clubs of Four for \$5, or Clubs of Ten at \$1.20 each, or in Clubs of Twenty or more at \$1 each. Subscribers in Premium Clubs will also be entitled to it. Any and every subscriber for all of 1873, whenever received, will be entitled to this picture, on remitting the 25 cents to pay for mounting, packing, and postage. The picture will be delivered at the Office, unmounted, free of charge, or if mounted, for 15 cents extra. If to go by mail, unmounted, 10 cents must be sent to cover cost of packing and postage.

It will be mounted on heavy binder's-board, and Varnished, ready for use, even without any frame, or for putting into a frame, for 15 cents extra—that is, for 25 cents it will be Mounted, Varnished, Packed, and sent Post-paid to subscribers for 1873 only.

N. B.—The American Agriculturist Chromo will be delivered:

- At the Office, Unmounted, Free.
" " " Mounted, 15 cents extra.
Sent by Mail, Unmounted, 10 cents extra.
" " " Mounted, 25 cents extra.

We advise all to have them mounted before leaving the office, as in the large quantities we put up, we are able to mount them for

a quarter of the cost of doing it singly, and better than it can usually be done elsewhere.

GET The CHROMO By EXPRESS.

While we can mail the Chromo put up in extra pasteboard cases with safety, it will be better where half a dozen or more go to the same place to have them put in one parcel and sent by express, one person receiving the package and distributing them to others. The cost to each will seldom be more than the postage (10 cents each), and where there are large clubs, the express charges will amount to only a few cents each. Where this is done, only the 15 cents for Mounting will be required.

Hearth and Home

And Its Beautiful

FREE CHROMO.

READ THIS.

While the old American Agriculturist is their "first and best love," as it has been for many years past, and while it will still continue to receive the most earnest attention and care of the Publishers, they are, in addition to this, in conjunction with an able corps of assistants, supplying in HEARTH AND HOME a first-class Weekly Journal, entirely different from the American Agriculturist. It is beautifully Illustrated, and filled with a high order of useful and interesting reading matter for all classes, including a special department for HOUSE-KEEPERS, and a most entertaining, instructive CHILDREN'S Department, filling two Illustrated pages or more, and which in its extent and quality stands unrivaled, and forms a distinctive feature of HEARTH AND HOME. (This is under the special care of Mrs. Mary E. Mapes Dodge, the authoress of "Hans Brinker," etc., and one of the most popular writers of the time.) That the Publishers are meeting a public want is evidenced by the fact that HEARTH AND HOME has already risen to a circulation equaled by very few other Weekly Journals in the entire country, and it has for some time past increased more than twice as fast as at any previous period—and this, too, in the midst of the absorbing presidential campaign.

Edward Eggleston, whose American Stories of the "Hoosier School-Master" and "The End of the World" have been so popular that tens of thousands of copies in book form have been demanded by the public, has a New American Story far advanced, the first chapters of which will appear in HEARTH AND HOME the first of this month (December), and be continued in that Journal. It promises to far surpass Mr. Eggleston's previous popular stories. It is founded on facts, and its scene is laid in one of the newer North-western States, during the Immigration fever and Land Speculation of a dozen years ago, and aptly illustrates Western life and society in some of its striking phases.—It will be finely Illustrated.

But, while HEARTH AND HOME itself, as large, valuable, and as finely Illustrated as it is, is supplied at the low rate of \$3 a year, the Publishers are

happy to announce that they will have the pleasure of presenting to Every Subscriber for 1873 a most beautiful and artistic copy of a large, CHARMING PAINTING, which is every way equal to the European copies sold for \$20 GOLD, each. (Those happening near the Office are invited to call and see the picture.) It will be a most beautiful Ornament for Every Home. The two Chromos supplied with the *American Agriculturist* and HEARTH AND HOME will not only give great pleasure, but they will be more ornamental to every dwelling containing them than many Oil Paintings which have cost Hundreds of Dollars. Yet \$4 pays for both Journals from now to January 1st, 1874, including both Chromos. All new subscribers to HEARTH AND HOME for 1873 arriving early in December will receive the remaining numbers of that Journal for this year, including the first chapters of Edward Eggleston's New Story, without extra charge.

The HEARTH AND HOME Chromo will be delivered at the office free of charge, beginning some time this month, in the order in which subscriptions have been received for 1873. If to be sent by mail, unmounted, 20 cents will be required for packing and postage. It will be carefully Mounted on strong Binder's Board, and Varnished, ready for use with or without a frame, for 30 cents. We repeat: HEARTH AND HOME Chromo will be delivered

At the office, **Unmounted**,.....Free.
 " " **Mounted**,.....30 cents extra.
 If sent by mail, **Unmounted**,.....20 cents extra.
 " " **Mounted**,.....50 cents extra.

We advise all to have them mounted before leaving the office, as in large quantities we are able to have them mounted for a quarter of the cost of doing it singly, and better than usually done elsewhere.

Wherever practicable, it is best to have the Chromos mounted at the office, and then have them go by EXPRESS. If several persons unite and have all their Chromos sent in an express parcel to one of their number, they will save the 20 cents postage, as the cost by express will be but a few cents each, depending upon the number that go to one place; and pictures of this size ought to go by Express whenever convenient.

Worthy of Everybody's Attention.

The fine Premiums offered on page 469 are well worth looking into. Over 14,000 Persons in all parts of this country, in British America, in Australia, in the Sandwich Islands, in South Africa, and elsewhere, have each obtained one or more of these valuable articles, with little trouble, by simply collecting a list of subscribers. This has been done by many Children, by many men in all pursuits and professions, and by a large number of Ladies. See "A Good Paying Business," on page 468.

A GOOD HOLIDAY PRESENT

for your wife, or your best friend, will be easily obtained by collecting at once a club of subscribers, and thus securing a desired article from the Premium List on page 469. Hundreds have done this annually for many years past.

\$66.67 to \$100.00 worth of Engravings for One Cent.—At least \$10,000 will be expended in procuring pleasing and instructive Engravings, of fine quality, for the *American Agriculturist* during 1873. Every subscriber will have a neatly-printed copy of each of these, in the pages of the paper, in addition to all the carefully prepared information given in the reading columns. This will give \$66.66 $\frac{2}{3}$ worth of engravings for every cent of cost at \$1.50 a year; or \$30 worth to those in clubs of four to nine at \$1.25 each; or \$33.33 $\frac{1}{3}$ to those in clubs of ten to nineteen at \$1.30 each; or \$100 worth for each Cent, to those in clubs of twenty or more at \$1 each. In addition, every subscriber will be presented with a perfect copy of Reinhar's beautiful \$400 painting, "Mischief Brewing," which will be a charming ornament in any home—a picture so much like the original oil painting that none but experienced artists will be able to detect the difference.

Bee Notes for December. — By M. Quinby.

We have a little more anxiety about wintering our bees than heretofore. If the lesson of last winter is not lost, instead of a calamity, we may yet be able to call it a blessing. We shall investigate closer than before, and if we get a correct idea, we can expect to ward off all fatal consequences. It was thought that we were pretty well acquainted with all the phases of winter management. But we find that a season like the last will affect bees as they have not been before in forty years. It was not the extreme cold so much as the length of time it was continued. The strong wind blew through every crack. The fatal dysentery was attributed to various causes. Probably there was not one case produced in the absence of protracted cold. With the experience of the last season in view, we can make preparation for winter with confidence that all will be right. Watch the weather a little closer. Arrange so that the bees may be warmed at any time, if occasion requires. Everything should be in readiness to put the bees into winter quarters the first severe weather. If put in the house, and if the number of stocks is less than fifty, even in a small room, they will hardly, in a winter like the last, keep each other warm, unless adjoining a room with a fire, or in a cellar, under a room with fire. They would hardly keep up the requisite heat of themselves with less than 100 stocks. A large number of box-hives in a room should be inverted—movable-comb hive should stand right side up—as it is possible to get up too much heat as well as not enough. Let the room be perfectly dark.

The number disposed to keep bees in the open air, will be much less than heretofore. But last winter taught us that housed bees were not safe without artificial heat. Many, with a few bees, can not afford the expense of a special room or cellar for winter quarters, and would like to know how best to dispose of them, with the least trouble compatible with safety outdoors. I examined some apiaries last spring, that had been in the open air, that were in comparatively good condition. The hives were brought together and a row placed near the ground, and straw packed between the hives, under the bottom and on the top. The second and third rows were packed on these, and a good thick packing on the back of them. The place was sheltered by surrounding hills. The front side of the hives was exposed to the sun, that occasionally warmed them a little. When they can be sheltered from the cold winds, such a situation is a good one. If the sun is warm enough to melt the snow, allow the bees to fly; otherwise keep just the entrance shaded, allowing the sun to shine on the other part of the hive. The weather must be very mild when third, and even second-rate stocks can stand safely out of doors. Bees not housed need frequent attention, to keep the ice from closing the entrance. The moisture from them that condenses on the side of the hive in frost, may pass off through holes in the top, slowly, without freezing, if the cap is filled with some absorbent material. With a proper degree of heat, the liquid portion of their food probably passes off in the form of vapor, leaving the more solid part as feces, which can be retained until occasion offers for flying out and voiding them. But when the colony is kept a long time in a cold state, the warmth of the bees is insufficient to drive off the liquid portion, which accumulates in the form of feces so rapidly that the bees can not retain, and they leave the cluster in the hive, during severe weather, to void it, very often besmearing each other and the combs. When bees and combs are badly soiled, the bees become greatly reduced, and are seldom worth anything. This state of things must be prevented by keeping them warm occasionally, if not continually. It may be necessary to bring them to a warm, dark room for a few hours. If the hives in the open air have any passages large enough for mice to enter, cover with wire-cloth, leaving

room for only one bee to pass at once. Set traps for mice. About twenty-five pounds of honey will be required to keep a strong colony of bees until May 1st. If there are doubts about the weight of honey, the stock should be weighed, and subtract the weight of hive, bees, etc. It is too late to feed to best advantage, such as are short of the required weight now. Ten pounds will probably last a colony until the first of March. After that time—if healthy—they will require more. Bees, when fed in cold weather, must be kept warm. Let them be so warm that a bee can leave the cluster and take after the feed, without becoming chilled. For feeding, make a syrup of four pounds coffee-crushed sugar and one quart of water, and one teaspoonful of cream of tartar, or its equivalent in vinegar, to prevent graining; scald and skin. If disposed, the feeding may be done now, but the room in which they are fed, should be kept warm.

The Great Wheat Region.

One of the most notable discoveries relating to the economic value of the "Great West" is that of the existence of an immense territory, including the head-waters of the Missouri, specially adapted, by characteristics of soil and climate, to the growth of wheat. This territory stretches from Minnesota westward to the Pacific Ocean, with here and there an intruding, intervening strip of mountain range. Northward it extends far into the territory of the Dominion of Canada. Part of this immense tract of country has been known for many years as a wheat country, and has been well settled, principally by Scotch and Canadian farmers. Their settlements, generally known as the Red River settlements, have been thrifty and successful, although heretofore far removed from what we have been used to call civilization. The country south of these settlements, alike rich and fertile, enjoys a climate equally salubrious but more genial, and lies within our own boundaries. It is now rapidly settling by farmers who find their way thither by means of the Northern Pacific Railroad, by which all this vast tract is being made available to the settler. Wheat is the great staple of this portion of the country, although other crops usual in the West are raised successfully. But wheat is the crop most easily raised. The samples brought hither of last year's harvest are excellent. They show a splendid head, with grains of extraordinary size and weight. Crops of 40 bushels per acre, of grain weighing 66 pounds per bushel, are said to be of ordinary occurrence, and this is not doubtful, after seeing the quality of the grain. The climate and soil are also well adapted to roots, and we know from personal experience that this is a perfect grass country. Having wheat, roots, and grass, cattle and sheep, dairy products, meat, and wool inevitably follow. There needs but population to bring about the fullest fruitfulness of result, and this is rendered possible and desirable by the rapid completion of the railroad, which will cause all this hitherto silent and neglected territory to soon hum with a diversified industry.

Tim Bunker on Self-sucking Cows.

"What ye gwine to dit with that 'ere keow," asked Seth Twigg, as he poked his head over the wall where Jake Frink was busy tying the cow's head to a bar-post.

"I'm jist gwine to put the confounded critter into a bag to see if I can't keep her from stealin' her own milk. Never had sich a beast afore in all my life. I bot her of Kier Funk, up in the White Oaks, and ought to have known better, for he allers cheats me in hoss trades. The slippery skunk told me that she was a cosset

cow raised by his wife, and would give her weight in milk every month, and keep fat on't. The knavish scamp wern't fur from right—for she sucks herself dry every chance she can git, and Polly has been on the keen jump ever sence I bo't her to git a drop for tea. If I keep her head in the stanchions I can get the milk, but ye see if I turn her out she does her own milkin'. A mighty ekernomical ceow that!"

"A ceow in a bag!" exclaimed Seth, as he knocked the ashes from his pipe and drew out

Fig. 1.—UNCLE JOTHAM'S POKE.

his tobacco-pouch to load again. "I have heern of a pig in a poke, but a ceow in a bag is the latest fashuun."

"Jes so," said Jake. "Ye see, it is one of Polly's contrivansis to save the milk."

Jake tried this plan of curing the White Oaker's cow for a week, and all Hookertown came to see the cow in a bag. It was a big piece of sacking tied on just back of the fore-shoulders and under the belly, covering the cow's bag, and leaving the rump and tail free. But Polly's contrivance did not work well. The cow would sometimes get her nose through the canvas, and when she failed to do this, she would lie down and double the canvas over the teat, and suck herself through the strainer.

"Take that thing off," said Uncle Jotham Sparrowgrass one morning as he came up the street. "I've got suthin' they used to use over on the Island forty years ago, and it was never known to fail. It is kill or cure, I assure you."

Uncle Jotham's poke was fig. 1: Two frames of white-oak, armed with half-inch iron rods sharpened like hatchet-teeth. The frames bound upon each side of the neck of the cow with ropes.

Jake tried this establishment for a couple of weeks. It saved the milk effectually, but it drew blood. If the cow attempted to get her head toward the tail, it pricked her severely.

Fig. 2.—O. W. TUCKER'S POKE.

The flies were troublesome, and every time she threw her head round to drive them off she wounded the skin. Polly said this thing would not answer in Hookertown, even if it did on the Island. She thought Long Island folks must be heathen if they tortured their cows in that way.

George Washington Tucker was the next doctor to prescribe for Jake's cow.

"You see, Jake," said Tucker, "that are thing is agin Scripture, for 'it's hard to kick agin the pricks,' and the ceow won't give milk long that is goaded in that way. I can fix you a poke in about an hour that will keep her from sucking jest as well as them spikes, and not hurt her a bit."

So Tucker took Jake's saw and auger, and from some slabs and a pair of worn-out ox-bows he constructed fig. 2. The top frame slips off easily, and the uprights are fastened in place by a wooden peg or bow-pin. The cow's head is fastened in this frame, and the side-pieces come just back of the fore-shoulder, so that if she attempts to get at her bag she gets a smart punch in the ribs, without breaking the skin.

"Now," said Tucker, after he had put on his machine, "that is what I call a persuader of a merciful sort. Tell Polly I'll pay for all the milk that 'ere ceow sucks after this."

This thing worked well, and Jake had peace until Benjamin Franklin Jones came along one morning, and hailed Jake: "Are ye gwine into the lumber business, Mr. Frink?" looking at the poke as if he saw a lumber-yard.

"Wal, neow," said Jake, "I'll allow there's considerable wood about the machine, but then it duz the work, and 'handsome is that handsome duz.'"

Seth Twiggs happened along at this juncture, and seeing by the smoke which way the wind blew, asked: "Have ye got plenty of fencin' stuff, neighbor? I've got a stack that wants a yard round it, and rails is skase on my farm."

Jake Frink grew restive under these pleasantries of his neighbors, and had about made up his mind to drive the cow back to the White Oaks, when Deacon Smith dropped in, and said

Fig. 3.—THE DEACON'S JEWEL.

he thought he could help him out of his trouble. He had a contrivance that he never knew to fail. He said it was much used up in Berkshire County, and it was the cheapest and best remedy he had ever seen.

So the Deacon took out his pencil, and made a picture like fig 3, and told Jake to go down to the tinman's and have a jewel made just like it. When it hangs in the cow's nose it looks like fig. 4. It is simply a piece of tin cut out in half-moon shape, and bound on the edge with a wire. The wire is cut and bent over at the two ends for the purpose of slipping it into the nostrils of the cow. If she attempts to suck, the bit of tin is always in the way. She can not get her tongue over nor under the tin. It is not in the way of feeding, for the ground raises the lower edge of the tin and it slides along before the cow's nose. This is a sure remedy, and is much better than carrying a lumber-yard upon the neck, or the barbarous practice of slitting the tongue. It is a very convenient article to put upon a calf's nose when he is weaned, and turned out to grass with the herd. He is about as effectually cut off from his mother's milk as if he was in a separate pasture. They may be made of sheet-iron, tin, or zinc. They cost but little, and it is but a moment's work to put on the jewel or take it off.

I am surprised to see by your last paper that there is one man left who does not know where Hookertown is, and thinks you may have been

gassing people for the last twenty years. This is the biggest joke you have printed in a year. Sally burst out laughing when she read it, and said she thought the school-master hadn't been around where that man lived. For his benefit, I want to say that there isn't a five-year-old boy in any of our schools but could tell him just where the place is. It is just five miles south of the White Oaks, and there are three

Fig. 4.—THE COW ORNAMENTED.

guide-boards at the cross-roads on the way. It is two miles east of Shadtown, and there is but one turn out, and there you keep the main travel.

Yours to command,
TIMOTHY BUNKER, Esq.
Hookertown, Ct., Nov. 10th, 1872.

The Striped Bass (*Labrax lineatus*).

The great value of the Striped Bass as a food fish, and its high price in winter, have led to some experiments for growing it in confined waters where it could be taken at pleasure and marketed. In summer, when the fish bites freely, and is taken in our rivers in seines and nets, it is sold at wholesale quite cheap, so that the fishermen do not average more than six cents a pound. In winter, the price goes up to twenty-five cents, and the market would take a much larger quantity if they could be furnished. The spawn has never been taken, that we are aware of, but the young fish, weighing from a few ounces to a pound, are caught in pound-nets in immense quantities along the coast wherever these destructive engines are not interdicted by law. The small fish are not desirable for market, and are sold cheap. These fish, from a half-pound upwards, can be bought for five

SCREEN FOR BASS POUND.

cents a pound or less, and put into an inclosure that admits the tide, and there fed regularly until they are fit for market. This inclosure may be of any size that suits the convenience of the fish-grower. The only essential things about it are that it should admit the tide-water with its abundance of sea food, and shut in the bass. It should be near the house, that it may be protected from poachers. Any small bay of a half-acre or more, or the mouth of a small brook that runs into tide-water that can be easily

dammed and screened, will serve. Almost every estuary furnishes a multitude of little bays that could be used as pounds for raising this fish. A bulkhead of stones or plank is made across the narrowest part, leaving a channel three or four feet wide for the water. The channel should be filled up to low-water mark, or a little above, and a screen made of strong iron rods be put in the channel, as shown on p. 450. This screen consists of a frame of 2×3 joists, three feet long and two feet high. The iron rods are five eighths of an inch in diameter, and the space between them is three eighths of an inch. It is desirable that the water should be eight or ten feet deep in some parts of the pound, and that there should be a regular flow of the tide, both to admit food and to keep the water cool in

summer. If the water is shoal, and the tide does not come in, the fish will suffer from heat, and some of them will die. If the water is kept fresh and cool, a large number of fish may be kept in a comparatively small inclosure. They may be fed with any kind of fish or fish offal, daily, or two or three times a week.

Along the shore where the menhaden fishery is prosecuted, this fish makes the favorite food. Bass eat voraciously from May to October, and then go into winter quarters. They grow quite rapidly in these pounds if well fed, and growth is mainly a question of food. A four-pound bass will in three years reach the weight of eighteen pounds. Every one can see that this industry must be exceedingly profitable in the shore towns, where there are the requisite facilities for making the inclosures and procuring the young bass and their food. There is not only the profit of the growth of the fish, but of the increase of price, which is not infrequently quadrupled in winter. The menhaden can be bought at the fish-works and from the boats for from one to two dollars a thousand, weighing from five hundred to a thousand pounds, according to condition. This cheap, unmerchanted fish is

transmuted by the bass into a table luxury that sells readily in winter at twenty-five cents a pound. The business is not yet organized or transacted on a large scale, but enough has been done to demonstrate its feasibility. Nothing as yet has been done for the protection

of this fish. It is hunted by all methods and at all seasons of the year, and its numbers are greatly reduced. There ought to be laws passed in all the sea-board States prohibiting its capture in rivers during the spawning season—say from June 1st to July 15th. If they could have

unlucky woodchuck from its tenement, which is enlarged to a size that will admit his body.

He is the cunning thief who makes such havoc among the inmates of the poultry-yard.

In ancient times the Fox was represented in prose and poetry as a model of craft and cunning,

and at the present day he fully sustains the reputation for sagacity that was accorded to him of old. His sense of hearing is so acute, his sense of smell so delicate, that to take him in the hunt or catch him in a trap requires considerable skill and knowledge of his habits. So instinctively cautious is this animal that it is with difficulty he can be induced to approach a trap, even when baited with the choicest morsels. It is smell more than any other faculty which seems to guide him, and so

excessively keen is this sense that he will detect the work of the human hand unless skillful efforts have been made to hide its presence.

The method adopted by the most successful fox-hunters is to set the trap in some spring or small rill, thus covering up or washing out with water the traces which are the occasion of so much caution on the part of this sagacious and highly-sensitive animal. Taking a hoe, the trapper proceeds to some small stream, ascends it, walking in the water, to find a convenient place to commence his work. A place is selected as

near as possible to where the fountain springs from the earth; it will be less liable to freeze on the approach of cold weather, and will be less affected by the rise and fall of water. With the hoe the banks of the stream are excavated, making a pool some four feet in diameter, and from three to five inches in depth. No more earth is removed in digging than is absolutely necessary; all turfs and clods are pushed beneath the water, and the whole made to assume an appearance as natural as possible. This pool is called by trappers "a bed." If made several days before wanted for use, so much the better.

Returning in the stream for a distance of five

or six rods, in the same manner as the bed was approached, the trapper prepares for setting the trap. First the bait is carried between forked sticks, and placed in the center of the bed, a third part or more remaining above the surface of the water. The trap should have a small

STRIPED BASS.

six weeks' close time they would rapidly multiply and soon be restored to their former abundance.

Trapping the Fox.

The well-known Fox belongs to the genus *Vulpes*, of which there are several species, differing but little in their habits and characteristics.

The Red Fox of America (*Vulpes fulvus*) is the common fox of this country. This species is widely distributed, and in some localities quite numerous. The fox burrows in the ground,

FOX-TRAP.

where the young are born in early spring, some four to six in number. The remains of birds and animals killed by the mother-fox are often found scattered near the entrance.

These burrows are seldom dug by the fox himself, his usual practice being to eject some

clog of heavy wood attached to it by a chain, twenty inches in length; when set, a dry brittle weed-stalk is placed beneath the pad, with the ends resting on the jaws for a support. It should then require a weight of about two pounds to spring the trap. When ready, the trap is placed between the bait and the adjacent bank of the bed; the clog is stowed away as most convenient. Both, however, must be entirely covered with water.

Now comes the most difficult part of the whole process—to cut a turf of a diameter a little less than the distance across the trap, and of a thickness equal to the depth of water over the pad. It must be cut from firm sod, circular in form, where the grass is short. It will not do to touch it with the hands, but proceed in the same manner as directed for bait. When placed evenly on the pad, the work will be complete.

A fox coming near, scents the bait; he walks around the bed, but can not reach the coveted treasure from the bank; and as he dislikes to step into mud or water, he steps upon the turf so cunningly arranged to aid him in his efforts, seizes the bait, and the next moment has a foot fast between the jaws of the trap.

If skillfully set, the first fox that comes along will be taken; sometimes several days will elapse before there is a capture. A heavy rain does much towards washing out any traces left by bungling hands. The skillful trapper is very particular about his bait. In selecting this important requisite, it should be borne in mind that the fox is as fastidious in his tastes as any epicure, though sometimes driven by hunger to coarser fare. Poultry of all kinds is his special delight, and he will run the greatest risk to obtain it. The carcass of the muskrat is to him a great rarity, and from its musky odor is probably the best bait known. He has also a remarkable fondness for a cat, the body of which is often used for bait by trappers. Choice pieces of any kind of meat may be used in the absence of other bait.

Mice are caught by the fox, and eaten with avidity. A few grains of strychnine inserted in the body of a mouse placed near the haunts of the fox, is the usual mode of poisoning—a dangerous and objectionable method of taking game. No animal intended for bait should come in contact with the naked hand after life is extinct. Cut into pieces of two or three pounds' weight with an ax, it should then be carried between forked sticks.

Walks and Talks on the Farm.—No. 108.

"I tell you," says the Deacon, "farmers have worked cheap this year."

"I suppose," replied the Doctor, who, though city-born, has had charge of a country church for some years, and knows something of the trials of farm life, "I suppose you can not get up a strike! I have often thought that farmers work harder and for less compensation than any other class with the same amount of capital and of equal intelligence."

This is probably true. But it should not be forgotten that we run no risk with our capital. We get a low rate of interest, but our principal is safely invested, and is steadily rising in value. In the mean time, we have a home and many of the comforts of life. Let us be thankful. It is no use complaining. We can not strike for higher prices. It would do no sort of good. And hard as we have to work, and poor as is our pay, I can not but admit that American

farmers, as a whole, are as well off as any farmers in the world.

"We are fortunate in one thing," said the Deacon. "Apples bring nothing this year, and we have none to sell!"

One thing is certain—we can not get extravagantly high profits from any one product for any length of time. It soon gets understood, and enough people will embark in the business to bring down prices to their proper level—and generally as much below the level as they rose above it. A well-managed apple-orchard has been more profitable for some years past than any other farm crop. I have no doubt apples will always be a good, paying crop in this section, but it is not to be expected that they shall be so very much more profitable than other products. The fruit-growers that will make the money are the men who set out the best varieties, and give their orchards the best care and treatment. There is no error so wide-spread and so pernicious as the idea that *easily-grown* crops are the most profitable. From the very constitution of things this can not be true. Were I a young man, and about to set out an orchard, I would select the choicest variety I could find, and the one which required the highest culture. And I would aim to carry this same principle into the selection and management of all the crops and animals on the farm.

"I have had bad luck with my Bates stock," said a young Shorthorn breeder to me a few days since; and he went on to give me the particulars. This cow would not breed, and the calf of another was sick, and another died, etc., etc. This is precisely what I should expect. It is absurd to expect that an animal bred for rapidity of growth and early maturity should be as hardy and breed as readily as an animal that has no other object in life but to propagate its species. I wish this matter was understood. It is no argument *against the breed*. If I offer to sell you a barrel of choice Northern Spy apples for \$5, you might say: "I do not want them. They cost too much. I can buy Baldwins and Greenings cheaper."

But it would show a sad confusion of ideas if you should say: "I do not want them. They are very difficult to raise. The trees are a long time in coming into bearing. They need much pruning, and the land must be deeply drained and made very rich, the bark kept free from moss or the apples will be specked; and when the trees *do* commence to bear, they bear too much, and the fruit is small, insipid, and poor. To get good specimens, you have not only to give the trees the highest culture, but you must thin out the fruit, and take special pains in picking and packing the apples to avoid bruising their delicate skin."

You would say to such a man: "Here are the apples—large, fully matured, high-colored, free from specks, and of the choicest and highest quality. Eat one. It is the best apple in the world. What you say may be a good reason for not buying Northern Spy trees, but is no argument against buying Northern Spy apples."

And so it is with high-bred Duchess Shorthorns. If they are difficult to raise, that may be a reason why you should not engage in breeding them. But it is no reason for not buying them. If you could show that they were of little use after you had bought them, that would be a good reason. But the evidence is all the other way. The Duchess Shorthorns are kept for the purpose of improving other tribes of Shorthorns, and these in their turn are used for the purpose of improving common cattle. Universal experience sanctions their

use for this purpose and proves their value. This principle applies to all our thorough-bred animals. No one should engage in their breeding unless he is prepared to bestow more time, thought, care, and labor on their management than on common animals. If faithfully, honestly, intelligently, skillfully, and perseveringly carried on, there is money, pleasure, reputation, and honor in the business of raising thorough-bred stock. But where one man succeeds ten fail. And I believe it is owing in a good degree to a misapprehension of the principles here alluded to. Paying high prices for choice animals and then leaving them to the care of common hired men will not insure success. And it is to me one of the most encouraging features of our agriculture that so many young American farmers are turning their attention to this matter. I get a great many letters worded somewhat as follows: "I am a young farmer of limited means, but I read the *Agriculturist* and other papers attentively, and am satisfied that we need better stock, and I would like to know what I can get a pair of choice thorough-bred animals for?" Depend upon it, that "young farmer with limited means," but with unlimited energy, will be heard from. He will attend to the stock himself, study the principles of breeding, and bestow the necessary care and attention, and in a very few years he will carry off the ribbons at the County and State Fairs.

The Deacon smiles at this kind of talk. He is clear-headed, and is prepared to accept the truth when he sees it, but he is as yet only half-convinced. I have great hopes of him, but it is not an easy matter to drive new ideas into an old head!

Perhaps I ought not to say it—perhaps I am not free from blame myself; but it seems to me that agricultural writers do not discriminate as closely as they should. We have too many *half-truths* in our agricultural literature. I know two or three popular writers who are great sinners in this respect. They have not the patience necessary to a thorough examination of a subject, but content themselves with presenting crude, undigested, one-sided notions. They dabble in science, but quote scientific men only so far as they agree or seem to agree with their own preconceived opinions. They allude to "practical experience" in the same spirit. They have great respect for it as long as it favors their views, but utterly ignore any facts that are opposed to them.

While I was at the State Fair three dogs killed two of my Merino sheep and one thorough-bred Cotswold. One of my neighbors took his gun and followed the dogs home, and shot all three of them. The owners of the dogs threaten to commence an action-at-law to recover the value of their property. In the mean time, I propose to sue the owners of the dogs for the value of the sheep killed. If I can recover anything like what the sheep were worth, it will have a good effect. It will, I hope, convince some of my good neighbors that keeping a lot of half-starved dogs in the vicinity of a valuable flock of sheep may be an expensive luxury.

"Can you tell me," writes a correspondent at Camden, Miss., "why spring pigs are more subject to disease than fall or winter pigs? Such seems to be the fact, not only in my own experience, but also of others in this neighborhood." Perhaps it may be that the spring pigs do not get old enough and strong enough to stand the

hot weather or the system of summer management at the South. In my own experience I have never observed any difference, except that we usually lose more young pigs in the spring than in the fall. This is attributable to the fact that the weather is colder in the spring than in the fall, and the little pigs are more likely to get chilled. At the West, farmers who let their hogs follow the cattle in the cornfields object to fall pigs as not being strong enough to stand exposure to cold storms, etc. The breeders of the large Butler County hogs in Ohio do not, I am told, let their sows have pigs in the fall. They only allow them to have one litter a year, and that in the spring. This is one reason why they raise such large hogs.

But the butchers and packers do not want large, coarse hogs. Provided they are fat enough, they will pay the most for a fine-boned, small pig that does not weigh over 350 or 400 lbs. There is a great demand for bacon to send to England, and for this purpose especially pigs should be fat, but not too large and coarse. If our pork and bacon commanded as high a price abroad as the English and Irish bacon, we should now be reaping a rich harvest. With our cheap corn, we ought to beat the world in the production of choice hams, bacon, pork, and lard—and we shall yet do it. But we must give up talking about "big" hogs, and aim to raise those of the finest and best quality.

The last number of the Irish Farmers' Gazette, in its report of the Dublin market, says: "There was a fair supply of bacon and hams; demand fair; old cleared out. Fritch bacon, new, 73s. to 76s.; Middles, new, 80s. to 82s.; American, 40s. to 46s." How do you like the figures? The Irish bacon, if I understand aright, is quoted at double the price of the American. The American sells for less than nine cents and the Irish for over seventeen cents per pound in gold. And you must recollect that if our bacon advanced eight cents per pound in Dublin it ought to advance eight cents per pound in Iowa or Kansas. This additional eight cents per pound is worth striving for. We talk and think a good deal about the demand in England for American wheat, but the demand for and price of our pork attract little attention from farmers. We have exported so far this season over 250,000,000 lbs. of bacon, pork, and lard.

A Western farmer asks me: "Why is it that farmers as a class have no price for their goods, like merchants, mechanics, lawyers, cobblers, etc.?" They have. A farmer sells his corn for the market price, just as a grocer sells his sugar. He can not get more, and need not take less. A lawyer, after years of hard study and much patient waiting, gains a great and deserved reputation, and can command his own price. So a farmer who has spent years in improving a breed of cattle, sheep, or swine is often able to fix his own price. Think of an American-bred Shorthorn bull being sold in Great Britain the other day at auction for 1,650 guineas, or, with gold at 113, \$9,397 in American currency!

"Why," he continues, "should the sons of the soil be the ignorant dupes they so often are, and be subject to the 'tricks of the trade,' and why should traders live more expensively than farmers? Is there no balm in Gilead?" If farmers are "ignorant," that is a sufficient answer to the questions. I know a good many that are not ignorant. An average farmer is as intelligent as the average merchant. There are rascals in the city who will cheat if they can, and farmers sometimes are their dupes. But all the cheating is not confined to the city. I

have known farmers to tie up dirt in their wool, and put wet or damaged hay in the middle of the load. I know a farmer who lost over fifty dollars last year from putting wind falls in his barrels of winter apples. When I first moved on to this farm, although I am farmer-bred and farmer-born, and have lived on a farm nearly all my life, yet it was known that I had been editing an agricultural paper for some years in the city, and was consequently supposed to be "green," and a fit subject of the tricks of country sharpers. Every horse within a dozen miles that was spavined, or broken-winded, or blind, or balky was trotted out for me to buy. If a cow kicked, or had lost a teat, or was a poor milker, the owner, though half-a-dozen miles off, would think that she was just the cow to sell to me. If a flock of sheep had the footrot, it was thought desirable to give me a chance to cure them—without, however, telling me what the trouble was. Every blacksmith, carpenter, wheelwright, mason, and stone-wall builder in the neighborhood deliberately cheated me, and then made his boast of it to a crowd of admiring listeners at the country tavern. I never go to an auction sale, because I know the auctioneer, himself a farmer, will bid against me on the sly, and cheat me if he can.

I do not wish to say hard things about my neighbors. Nine tenths of them are as honest, intelligent, industrious, sober, peaceful, respectable, kind-hearted people as any to be found in the world; but among the other tenth you will find men who, according to their ability and opportunity, are as thorough-paced scoundrels as you will find in Wall street. There is amongst them as much low-bred cunning, as much vulgar shrewdness, as much lying and profanity, as I have ever happened to meet with in the city.

As to "why traders live more expensively than farmers," I know of no good reason except that they have more ready money and spend it more freely. Poor men as a rule are more extravagant than rich men. A farmer with a farm and stock worth \$20,000 may not have more than \$2,000 pass through his hands in a year, while his brother in the city, an enterprising man that enjoys a good reputation, but with no more actual capital, may, by the aid of discounts, indorsers, and credit, use more than one hundred thousand dollars a year in his business. He takes greater risks, and may sooner or later lose everything, but in the mean time he makes larger profits and lives more expensively than his brother in the country. To make great profits you must run great risks. The farmer runs little or no risk, and makes comparatively little profit. For my part, I prefer to be a farmer; if you would rather engage in other business, I have no sort of objection.

Farmers are making small profits. There is no doubt about that. But it is useless to complain. It seems hard for a farmer in Illinois to be obliged to pay 45 cents for sending a bushel of corn to New York, and then sell it for 65 cents. But there is no law to compel him to send it. He had far better convert it into pork, or beef, or mutton, or wool, or cheese. It would be better for him, and better for us poor farmers at the East who have corn to sell, and who can not get as much for our corn as it costs us to raise it, owing to the market being flooded with Western corn. Our policy at the East should be to buy all the corn we can use to advantage, while the policy of the Western farmer should be to sell as little as possible.

The one central fact that deserves the thoughtful consideration of farmers everywhere is the

advance of wages throughout the world. It means an enormous increase in the consumption of cheese, butter, beef, mutton, and pork. The first effect of this increased demand for meat will be felt here in the cheese and pork market, because cheese and pork can be shipped to any part of the world. But it will also cause an increased demand for beef and mutton. Our aim must be to produce the best quality of meat, and then it seems to me there will be no limit to the demand. We must introduce better breeds, and feed more liberally.

Corn to-day is the cheapest food in the market. I think many farmers are making a great mistake in selling cows at such low prices. They are making a still greater mistake in wintering them on such poor, innutritious food. Why not give them four or five pounds of corn per day? Less hay, and more corn and straw, is my motto for the present winter.

This summer my horses got badly run down. We fed them liberally, but they did not eat well. They had no appetite, no digestion, and no strength and spirit. They came home at noon and night fagged out, and their night's rest did not refresh them. I sawed a barrel in two, and placed the ends on the platform of the pump. These are for watering the horses. Into one of them we put a pailful of corn-meal and mixed it with the water. The horses at first did not like it, and would only drink a little when very thirsty. After they had drunk what they would they were allowed pure water. In a very few days, however, they drank this corn-meal soup with a relish, and in less than a week there was a decided change for the better in the appearance of all the horses. We do not let them eat the meal, but merely let them drink the milky water. I have no doubt it is as good for them as a plate of good soup is for a tired and hungry man before dinner. It seems to stimulate the appetite and aid digestion.

It is a capital thing for cows as well as horses, but it is not so easy a matter to give it to the cows, as they soon learn to stick their heads in the water almost up to their horns to get the meal that settles at the bottom. It is necessary to have a large trough with a false bottom.

This is my last Walk and Talk with the readers of the *American Agriculturist* for the year 1872, and there are a great many things I want to say, but have not time.

I want it understood, however, that my faith in good farming and my respect for good farmers grow stronger and stronger every year. I still believe in summer-fallowing on clay land, and am satisfied that fall-fallowing is a good thing. I believe that weeds can be killed, and am making considerable headway against them. My corn is the best and my corn-stubble the cleanest I have ever had—better and cleaner than the Deacon's! I think we plow too much land, and do not plow our land enough. We must have cleaner land. We must raise bigger crops, or there is no profit in farming. We must keep better stock, and feed more liberally. We must make more manure, and what is still more important, we must make better manure. And we must take care of what we do make.

HAVE YOU PURE WATER?—Water is as necessary to the comfort and health of stock in the winter as feed; and if they are to be kept free from disease an ample supply of it, free from ice, snow, or filth, must be furnished them.

A Barn for Mixed Farming.

"J. F. G., Highland Co., Ohio, says: "I want a barn for mixed farming, for storing hay and

Fig. 1.—ELEVATION OF BARN AND STABLE.

grain, and for keeping stock; I want all the labor-saving improvements, and also a root-cellar in a convenient place, and a yard for manure." This is a general want, and the importance of a well-arranged barn to the comfort of the farmer as well as to the comfort and well-being of the stock is very great. We give on this page an engraving of a barn which has been found very convenient by the writer for his own use, with all the plans necessary for laying out the stables, sheds, and other accessories. Its cost will be from \$1500 to \$2500, according to price of materials and the amount of finish put upon

cellar, which should be two or three feet below the surface, to fill in the ascending road-way. The stable-floor is thus on a level with the ground, and windows on each side furnish ample light and ventilation. The foundation-walls are of stone, sunk three feet below the surface. Drains from the bottom of the foundation would be found of great use in keeping the stables perfectly dry at all seasons. Below the ground the walls may be built of dry work, but above the surface the best of mortar should be used in the building. Much of the solidity and durability of a building depends upon the excellence of the mortar. The stable-walls are built so that the barn overhangs the entrance-ways six feet, which

gives protection against rain or snow, as well as prevents drifting of either into the open upper half of the doors or windows, thus permitting ventilation in stormy weather, and allowing comfortable access from one door to another. The plan shown in figure 2 gives the arrangement of stalls and passages. *AB* is the horse-stable, with two double stalls and a loose box for a mare and colt. *CC* is the cow-stable, with stalls for 22 cows, arranged so that the animals' heads in each row are towards each other, with a central feed-passage between. *DD* are ventilators and straw-shoots, which carry off through the cupolas on the top of the building all the effluvia from the stables, and by which straw for bedding is thrown down from the mows or barn-floor above. *EF* are compartments for calves or a few ewes with early lambs which may require extra care and protection. *G* is the root-cellar, entered from the feeding-room, which also communicates directly with each compartment. *H* is the cistern, sunk twelve feet beneath the floor of the root-cellar, and which receives the whole of the water shed from all the roofs. It is prevented from overflowing by an outlet into the drain, which runs beneath the stable-floor. *I* is the pump in the feed-passage, *J* the shoot by which cut hay or fodder is thrown down from the barn-floor. *L* is the feed-mixing box, or steam-chest, if steaming is practiced, and *M* the stairs to the barn-floor above. On this floor are four bays for hay, straw, or fodder, a spacious thrashing-floor, with a cross-hall for cutting machine, and shoot (*O*) to pass the cut feed below. A door in this cross-hall opens into the barn-yard, by which straw may be thrown out for litter. A door at the rear of the thrashing-floor opens into the upper part of the open shed, where hay, straw, or fodder may be stored. The cutting machine is shown at *K*. *NNN* are grain bins or boxes for feed. *PP* are bays, *Q* the thrashing-floor; *RR* hay-shoots and ventilators, which are carried up level with the plates, doors being made, through which to pass the hay either from the barn-floor or the mows. *S* is the straw-shed, with open traps to pass straw or fodder into the racks shown beneath in fig. 1.

Fig. 1 shows the elevation of the barn, the arrangement of the barn-yard, the doors and windows of the stables and root-cellar. The

shoots for discharging roots into the cellar, and for ventilation, are seen at each side of the barn-door. The open shed seen in the rear of the barn-yard is for the purpose of airing stock in stormy weather, and is furnished with a straw-rack for feeding them. This barn is calculated for a farm of 100 to 200 acres. Exactly such a barn was built for a farm of 90 acres, on which soiling in summer and steaming food in winter were practiced, and was found ample to meet every want for the stock it was made to accommodate. A cart-load of green fodder hauled to the stable was unloaded into a small feed-truck through the window of the feed-passage, between the cows' stalls, and was distributed to 22 head in fifteen minutes. The same number of cows could be fed from the steam-chest, by means of

Fig. 3.—SECOND STORY OF BARN.

the same truck, in even less time, if necessary. Such conveniences as this make a comparatively costly barn much the cheapest in the end.

Butter-Molds

In reply to many inquiries made by some of our readers, who can not procure the butter-molds which we described in a former number of the *Agriculturist*, we give directions for making them at home. The difficulty lies in getting the stamp made. Any one who can work a foot-lathe, can turn the mold and the plain stamp with the handle, but the device which ornaments the stamp troubles them. To make this, take a

Fig. 1.—BUTTER-MOLD.

piece of wood free from grain—a piece of soft maple or birch-root is very good—and have it turned or dressed the proper size, and a smooth face made on it. Then either draw on the face, the wrong way (as shown in figures 1 and 2), or cut out letters from a printed bill or newspaper,

Fig. 2.—PLAN OF MAIN FLOOR OF BARN.

the work. In most places where stone for the lower story and lumber can be procured cheaply, \$1500 will be sufficient to build a barn fifty feet square, including everything needed. This is not a basement-barn. It is not built in a hill-side. Partly underground stables are not generally desirable, on account of dampness, too much warmth in winter, and want of ventilation. But a slight rise of ground which may be availed of for an easy ascent to the barn-floor is a convenience, although not at all necessary. This may be easily made by using the earth from the root-

and paste them on to the face of the mold, *the wrong way*, and make a border to suit the fancy, in the same manner. Then take a small, sharp gouge, like the one shown in fig. 2, not larger

Fig. 2.—BUTTER-MOLD.

than a quarter of an inch in diameter, and smoothly cut away the wood beneath the letters, making them deep enough to show well when printed on the butter. About a quarter of an inch would be right. The depression should be neatly smoothed out, so as to make a neat, smooth print. A pretty border for a mold is a quantity of clover leaves; they may be pasted on, and the wood then cut out as before described, or any other leaves would answer.

Corn-Planter.

W. C. Detweiler, Northampton Co., Pa., writes as follows: "In 1872, May number of the *Agriculturist*, you give a representation of a corn-planter, and state that by widening the machine it might be made to plant 2 or 3 rows. I have used your drawing as a guide from which to construct one that will plant 3 rows. You will notice by examining the drawing that I dispense with the wheelbarrow frame, substituting

AN IMPROVED CORN-PLANTER.

therefor a frame of oak (or other hard wood) planks, say 2 inches thick and 1 foot wide, also causing the driving wheels to serve the purpose of the pulleys, thus saving labor in constructing the machine, and the annoyance of slipping of the strap. The wheels I think should be 1 foot in diameter, thus causing a spread between the hills of 3 feet by each revolution. (By putting 2 holes in the receiving cups, the wheels might be made 2 feet high, and so on, but I should prefer to have them low, so as to prevent strain on the plows and scrapers.) The plows and scrapers are to be attached to wooden bars, which may be elevated or lowered, and fixed with a pin, so as to plant deep or shallow. I think that we could, with such a machine, by putting several more holes in the revolving cups, plant beans, peas, fodder-corn, etc., and by removing the plows, and attaching them to a cultivator, save extra ones for that purpose.

"I am no farmer at present, but do intend to be one shortly, and as I never intend to patent

anything, I would ask of you to suggest such improvements as you see fit."

We give an engraving of the sketch sent by our correspondent, which has some very good points. The implement can be made by almost any one who can use tools, and will be found useful where corn is planted in large fields. Eight acres per day could be planted by such a machine. The addition of a roller, to follow the scraper, which covers the corn, would be an improvement, as would also be the enlargement of the wheels to 3 feet in diameter, and the making of three holes or cups in the seed-dropper. If the corn is to be dropped three feet apart, one cup in the seed-dropper will be needed for each foot in diameter of the wheels. The construction is easily seen in the engraving. The hopper for the seed is shown at *a*, the scraper which covers the seed at *b*, the plow which opens the furrow at *c*. A separate figure of the plow is also given, which shows its construction, with the pin-holes by which the depth of furrow is regulated. The revolving cups and the shaft which carries them are shown at *d*, the wheels, made from plank, at *e*, and the frame plank (which is cut away in one place, to show the part of the hopper in which the seed-cups revolve) is shown at *f*. The hoppers should be separated at such a distance from each other, as will bring the rows in the desired position, either 3 feet or 4 feet apart, as the case may be.

Milk-Tester.

An instrument for testing the quality of milk by its density has been used in Germany, and is of sufficient value to be introduced here amongst those whose business makes it desirable to use such a test. It consists of a small table of wood, with raised sides, one of which is marked with a scale of degrees for ascertaining the comparative densities of different samples. Within the raised sides a wooden frame, carrying two plates of glass, separated a quarter of an inch apart, is moved back and forth. The glass

plates are cemented into the frame with shellac, so as to be water-tight. A spring, which holds a piece of candle of a certain size, is affixed to one end of the table. When pure milk is poured into the space between the glass plates, the frame holding them is pushed into such a position that the light of the candle can just be distinguished through the liquid. It is evident that if the milk should be diluted with water, it will be less opaque, and the in-

MILK-TESTER.

creased distance to which the frame must be moved to render the flame barely visible will

become the comparative measure of the adulteration. If foreign matter is suspended in the milk, its opacity becomes increased, and the lessened distance between the light and the frame made necessary to permit the light to be seen, shows the comparative impurity. Now that the milk question has become one of the leading problems waiting solution, it will be of interest to those whom it may concern to make for themselves one of these simple milk-testers. It is obvious that the candle used in these tests should be always of the same size and power. A piece of wax candle is preferable.

Barn-Stairs.

Barns and granaries are generally so much curtailed of available space, that it is an object

BARN-STAIRS.

to save as much as possible. Stairs are wasteful of this needed space, and inconvenient and unsafe ladders and other substitutes are very often used in place of them. We give an illustration of stairs for a barn or similar building, which occupy only half the space of common ones. It is seen that the steps are alternate; and while each has only the ordinary rise of say nine inches, yet each step, in perpendicular height, rises double this distance. A great saving of space is thus gained.

Composting Sods.

Being lately in Orange County, New York,

Fig. 1.—SOD-HOE.

we saw a farmer busy doing valuable work, which might at this season be very profitably

Fig. 2.—COMPOST HEAP.

done by thousands of farmers throughout the country. He was making manure. With the tool shown in fig. 1, he was cutting sods in a very rough, boggy meadow, covered with tussocks and coarse grass and weeds. These he was piling up in heaps, with weeds gathered seemingly from his fields and fence-rows, and all arranged in layers, with lime between them as shown in fig. 2. This is quite a common plan in several European countries, and we should judge this farmer was an "adopted citizen," paying for the privilege of his citizenship by giving some new ideas to his neighbors.

At any rate, it is a very useful thing to do, and by spring these heaps will be all rotted down into fine, rich mold, which will make an excellent top-dressing to grass lands or young wheat.

Large Cows, or Small Ones?

It is a question much discussed whether large or small cows are the more profitable, and experiments on the subject have not thus far sufficed to decide it. It must depend very much on the purpose for which the animal is kept. Mr. Leander Wetherell publishes the result of Villero's experiments, as follows:

Holland cows (Holsteins?)	gave	28.92	quarts	per	100	lbs.	of	hay	consumed.
Yorkshire	gave	27.45	quarts	per	100	lbs.	of	hay	consumed.
Devons	"	19.13	"	"	"	"	"	"	"
Herefords	"	15.97	"	"	"	"	"	"	"
Jerseys	"	26.33	"	"	"	"	"	"	"

And he concludes that it has been clearly demonstrated, by careful experiments made at the agricultural schools on the continent of Europe, that the large breeds of cows are more profitable than the small breeds.

Surely the table given above does not establish this conclusion. The Jersey is much smaller than the Devon and Hereford, yet it gives more milk from the same amount of food.

Then, again, if it is the purpose to sell milk only, the test given will do very well; but if butter or cheese is the object, it will all depend on the quality of the milk. For instance: Mr. C. M. Beach, of Hartford, Ct., made a careful experiment which showed that (the condition of the cows being the same, as to pregnancy, feed, etc.) he required to make one pound of butter $6\frac{1}{2}$ quarts of Jersey milk, and 11 quarts of "native" milk. By this test, 100 lbs. of hay fed to a Jersey cow would (according to Villero's estimate) produce 4.16 lbs. butter, while if fed to a Yorkshire (supposing her milk to correspond to that of our "native") it would produce but 2.49 lbs. Probably the Yorkshire would weigh fully fifty per cent more than the Jersey. In like manner the amount of cheese would depend less on the amount of milk produced than on the proportion of casein it contained.

The fact is that there is no rule by which we can judge from the size of the animal as to the economy of different breeds or of different individuals of the same breed for any purpose. It will depend on the character of the animal and on the purpose for which it is kept. The best, almost the only standard of comparison will be the actual performance at the pail, at the churn, and at the cheese-vat, and in practice the decision will be most safely made by an experienced dairyman according to the appearance of the cow, and his trained observation of her consumption of food and of her actual production.

△ Farmer's Savings-Bank; or, How to Manage Manure.

There is a very decided advantage in fermenting manure, provided it is done without loss. It converts the woody fiber of the straw into ulmic and humic acid and the nitrogenous matter into ammonia. In other words, it decomposes the manure and renders it soluble or available. Chemistry and experience agree on this point. Farmers and gardeners know that well-rotted manure acts more quickly than fresh manure; chemistry tells us why, and also teaches us that there need be no loss of ammonia during the process of fermentation.

It is undoubtedly true that there is often

great loss in keeping manure. This arises principally from leaching. The rain washes out the soluble matter. If the liquid was run on to a meadow or otherwise applied to the land, there would be little loss. But when it runs off into drains or ditches, we unquestionably lose much of the best plant-food of the manure.

The first thing to be done is to spout all the barns, buildings, sheds, etc., and carry off the water where none of it can come in contact with the manure. Some farmers seem to like a wet barn-yard. They think more manure is made. If the object is merely to wet as much straw as possible, there is some truth in the idea. But straw alone makes very poor manure, and letting straw lie saturated with water is not the best way to rot it. We have, moreover, rarely been on a farm where all the straw could not be used up to advantage in bedding the cattle, horses, sheep, and pigs.

NOW FOR THE MANURE.—And we wish we could get all the farm boys that read the *American Agriculturist* to try the plan we have to recommend. We have two boys who "boss" the job on our own farm—and do nearly all the work themselves—and they soon feel a real interest in what we call our "Savings-Bank."

We have in the center of the barn-yard a basin, or hole, with sloping sides. Into this basin the old-fashioned plan was to throw the manure, promiscuously, anywhere, just as it happened, and the result was that for several weeks or months it would form only a thin layer, spread out all over the bottom of the basin. It was too thin to ferment, and had a slovenly appearance. Our plan now is to wheel or cart the manure into one corner of this basin, making a kind of hot-bed of it. Make it four or five feet high, and as you get more manure, increase the length and width of the heap, but always keeping it in a compact mass. It soon begins to ferment and to get warm and throw off steam. This pleases the boys, and we, too, like to see it fermenting, because we know, if the heap is properly managed, there is no loss of ammonia. That is an exploded notion. There is water in the form of steam or vapor escaping, mixed with a trace of volatile oils and carbonic acid, but these are of no manurial value.

This little fermenting heap is the "nest-egg." It has an attraction for the boys. They seem to like to clean out the pig-pens and the cow-stables, in order to get manure to add to the heap. They have a horse and cart, and if they can find anything that will make manure, it is drawn to the savings-bank and deposited.

Now, is not this better than having a heap of horse-litter at the stable-door, where it gets so dry and hot as to "fire-fang"? or better than having another heap or heaps on the side of the cow-sheds, where the drippings from the caves wash out much of the best substance from the manure? or than having the pig-sties reeking with filth? or the sheep-yard so foul and damp that there is great risk of the foot-rot, and no possibility of the sheep doing well?

The great point is to get the heap started. Many a rich man dates his wealth from his first deposit in the Savings-Bank. Once get a little manure into the heap and start the fermentation, and it will keep growing bigger and bigger. Manure scattered about the premises is soon frozen solid, and remains in a crude state until spring. But this snug little heap will not only keep itself warm, but, like yeast, will induce fermentation in the fresh manure that is daily added to it. It will, as we can state from

actual experience, keep fermenting slowly during the coldest weather in winter. But it would not commence in such cold weather; hence the importance of starting the heap now. What we gain by this fermentation, we will tell the boys at some future time.

The Shad in Mississippi Waters.

The stocking of the rivers that empty into the Mississippi and into the Gulf of Mexico has ceased to be a problem. We have received a photograph of a shad which was taken from the Ouachita River, near Hot Springs, Ark., April 18th, 1872. It measured 19½ inches in length, and 12 inches in circumference around the dorsal fin. No one acquainted with the fish, we think, can doubt that it is a genuine *Alosa præstabilis*. Dr. Geo. W. Lawrence, of Hot Springs, informs us "that shad were first taken in this stream, so far as he knows, in 1860. Three were caught during the month of April, 1860, in a small wooden trap, erected in the middle of the stream, a few rods below Farr's mill-dam. This dam obstructs the river about eight miles west of Hot Springs. It is the first obstruction found between the mouth of the Mississippi and this place, a navigable distance of over 1000 miles. The Ouachita River empties into Black River, the Black into Red, and Red River into the Mississippi about the eastern center of the State of Louisiana. Farr's dam is at least 60 miles above steam navigation. The trap was built for the purpose of supplying Hot Springs market daily with fresh fish and soft-shelled turtle. Above Rockport the river has a rocky bed and barriers, and is protected in this mountainous part by forest margins. The Ouachita affords shelter and good feeding surface for all kinds of fish. The shad are as delicate and fine-flavored as any that can be found in the Susquehanna River, or elsewhere in the Eastern States. The first fish-trap was destroyed in 1862, and was not rebuilt until after the war. The number of shad taken in the trap has annually greatly increased. The present year shad commenced running early. The abundant rains that fell in April and May, about 7 inches in each month, kept a good volume of water in the river during that period. I was supplied with shad this year from April 5th until May 12th. Wagon-loads of these large, fine fish were brought into the village of Hot Springs, to supply visitors to our famed resort with the luxury of shad from the Ouachita River."

How did this fish find its way into the Ouachita River? It will be recollected by those who have followed the progress of fish-culture in this country, that Dr. Daniells, of Savannah, Ga., transplanted shad spawn from the Savannah to the head-waters of the Alabama in 1848, and that these fish were taken for the first time in the Alabama three years afterward, and that the Alabama and its tributaries are now abundantly stocked. They are also found in large numbers in the tributaries of the Escambia, the first large stream east of Mobile Bay, having, without much doubt, gone into that stream from the Alabama. It is highly probable that the shad of the Ouachita are a delegation from the Alabama. Their complete success in that stream is about as good evidence as we can have that the shad will flourish in all the tributaries of the Mississippi. If they will go a thousand miles through muddy water to reach their spawning-grounds, why will they not go two or three thousand? If they reach Hot Springs in perfect condition, why may they not reach Pitts-

burgh, St. Paul, or Denver? Their distribution by natural methods is extremely slow, as this case shows. By the artificial process it can be greatly hastened, as has been demonstrated in the Connecticut. If Congress will furnish the funds there is very little doubt that all the people of the Mississippi Valley will be eating fresh shad in less than five years.

The Labor Question in American Agriculture.

Indeed we need not confine our discussion to the agriculture of America alone, for the same causes which are threatening the stability of labor in this country, are operating in Europe as well. Their operation is natural, and the causes themselves are to be encouraged and sustained—which makes the problem a very difficult one. The growing prosperity of the world and the more active demand for labor in manufactures and kindred employments, are sufficient to account for much of the scarcity of farm hands, but this might be to a great extent met by an advance in wages, to draw out the idle men from towns, which, though serious, would be of secondary importance, compared to the need of going without sufficient labor at any price.

The real causes of the revolution that is slowly but very surely undermining the supply of farm hands, are the cheap newspaper and the common school. Formerly the man who was contented to work, year in and year out, as hired man on a farm, and had plenty of competitors for his place—the horizon of his life and thought was the "*pays bleu*," the blue country that bounded on every side the outlook from his township's hills—and he sought his soundest wisdom at the corner store, and his only suggestion of fancy in the staid sermons at the country church. The few strangers who came at odd times across his vision were too infrequent and too different from his standard of excellence, to awaken any emotion but curiosity or contempt. The district school had taught him only the 3 Rs, and even they had been allowed to fall into much disuse. He knew nothing better than his life, and he wanted nothing better. He was a steady, honest, hard worker, with the sort and amount of common-sense that are needed to enable a man to trundle along through the uneventful life of a country neighborhood; with no knowledge of and no respect for any further intelligence. He was exactly the stuff for a good farm laborer. If he was Irish, he seemed not more disposed to roam nor to dissipate his usefulness in foolish ventures than if he was "native and to the manner born." Most of us can remember when such hands were plenty, when they were glad to get a good place, and zealous to keep it. Those were good times for the employers, but we shall never see them again.

The later generations of the race have been inoculated with the poison of unrest. The scales have dropped from their eyes, and they have learned the great lesson that the world does not revolve around their own small village, and that there are better men than they in the world, and better opportunities to achieve success and happiness than their fathers dreamed of.

It would be idle to discuss the advantage or disadvantage to the world of this wide diffusion of intelligence—our duty is only to consider its effect on agriculture. It has broken up or is breaking up, in all the civilized world, the old, reliable system of farm labor. Men who take and read a newspaper, and have their

minds stimulated to an interest in the affairs of the world at large, gravitate toward each other, by a natural law, and the towns grow at the cost of the country. Pages might be written about the why and the wherefore of this tendency of men into whose minds the dawn of the new day has broken, but we could not change the fact. Our old race of farm laborers is going to drop away from us, and we must bestir ourselves to meet the new state of things—gradually, of course, as the change will come.

The extension of the use of machinery and artificial power will help us more than we now imagine, and, for one or two generations, we may find our relief in the employment of Chinese, but if we care for the interests of posterity, we must consider some reorganization of our system of agriculture which will allow of a concentration of the workmen into communities where they can enjoy the advantages they crave.

Straw for Bedding.

In some parts of the country straw is so abundant that it is left in the fields where thrashed and set fire to. Even in the wheat-growing sections of this State there are many farms where straw is scattered about the yards all winter for the mere purpose of rotting it into manure. In other parts of the State it is so scarce that the cattle must lie on the bare boards, or be bedded with sawdust or shavings.

We believe there are few farms where straw need be wasted. We propose to say nothing in regard to the demand which exists for it to make paper or for bedding in the cities, except to remark that in some cases it might be more profitable to sell the straw and buy bran or grain rather than to waste the straw at home.

Some farmers seem to suppose that they *must* get rid of their straw during the winter. We know many farms where straw is thrown a foot deep at a time about the yards in winter and early spring, where not a handful of straw could be found in June! We hope all the readers of the *Agriculturist* will avoid this mistake. There is not a week in the year when straw can not be used to advantage on a farm.

Where straw is fed to horses, cows, or sheep, we would not be sparing of it. Put enough into the racks for them to pick out the best, and use what they leave each day for litter. What we object to is scattering a great layer of straw about the yards two or three times during the winter. Better litter the yards every day where it is necessary. In the case of sheep, there is nothing more injurious than to compel them to lie on a mass of fermenting straw. Sheep are very fond of having a clean bed of straw to lie down upon. We have often observed sheep in winter standing about uneasily, and when a little clean straw was spread under the shed or about the yard they would very soon lie down and chew the cud of contentment.

The great point in littering sheep, then, is to give little and often—the less the better, provided it keeps the sheep out of the mud, and gives them a dry, clean bed to lie upon. A sheep must be very tired before it will lie on a dirty bed. Another point to be observed is either to change the position of the racks occasionally, or to be careful every day to scatter the straw that is pulled out. Unless this is done, there will soon be a thick layer of straw on the side of the rack, which will be liable to ferment.

It is sometimes a great convenience, and we think economical, to cut the straw into chaff, not only to feed, but for litter. We think it

absorbs more liquid, and the soiled portions can be removed more readily from the rest of the bedding, or at any rate with less waste of straw.

Wintering Cows.

An ordinary-sized cow will eat about 200 lbs. of hay per week. In the dairy districts of this State it is estimated that it requires two tons of hay to winter a cow. Where hay is worth \$20 per ton at the barn, as it is where we reside, the expense of wintering a herd of cows take a large slice out of the profits of the dairy. But with us, while hay is comparatively high, grain is cheap, and corn-stalks and straw abundant and of good average quality. Cows also sell for an unusually low price. We do not advise those of our readers similarly situated to buy cows and winter them in hopes of making a good thing out of it by selling them at a high price in the spring. They may or they may not make money by the operation. But we think we are perfectly safe in recommending those farmers who have plenty of straw and stalks not to *sell* their cows; and if they will need more cows next summer, we think they can buy now and winter them over to good advantage.

A cow will eat say three bushels of chaffed hay per day. So far as *bulk* is concerned, we must not vary much from this standard. In our own case, however, we would feed 2½ bushels of chaffed straw and stalks, half a peck of bran, and half a peck of corn-meal per day. We think a cow can be wintered better and (with us) far cheaper than on hay alone. If you have plenty of clover-hay it may take the place of the bran. But do not try to winter the cows on straw and stalks alone. It is very poor economy.

A New Sensation.—Horse Disease.

If, two months ago, any one had predicted that the streets of New York, Boston, and other cities were to echo to the cry of the ox-driver, and that horses would be for a time removed from the streets, he would have been received with contempt. But nevertheless, in 1872 the unwonted sound has been heard, and the strange sight has been exhibited of express and other wagons slowly moving behind ox-teams, which were urged along by the usual noisy epithets and maledictions of their drivers. A strange disease had suddenly stricken down the greater part of the horses and rendered them unfit for work. It originated in Canada, and in a few days had spread as far as New York and Philadelphia, and it may, before these lines can reach the readers of the *Agriculturist*, have spread south and west over the whole country. If the conditions are favorable, not only is this highly probable, but other stock may be affected also. But it is quite needless that serious apprehension should be felt. Fortunately the disease, although so sudden in its attack and so widely spreading, is comparatively harmless if rightly treated.

Its first appearance is made known by the following symptoms: A depressed condition of the animal, roughness of the coat, drooping head, watery eyes, and disinclination to exertion. On the first appearance of these symptoms, the animal should be cared for, kept dry, warm, and well bedded and blanketed, and fed with slightly-warm bran-mashes, scalded oats, and chopped and moistened hay. A little sweet spirits of niter, or a light dose, say a teaspoonful, of powdered saltpeter, may be given. Some

SCENES IN NEW YORK DURING THE PREVALENCE OF THE HORSE-DISEASE.—Drawn and Engraved for the American Agriculturist.

of the usual condiments or prepared cattle-feed will be found useful with slightly-warm flaxseed tea or thin bran or oat-meal gruel. If these simple remedies are used at once, the attack will generally pass off in a few days. If, however, through inadvertence or otherwise, the symptoms are allowed to increase in severity, and a copious discharge from the nostrils occurs, with sore throat, cough, and falling off from the feed, cold feet and legs, and fever, more active remedies must be applied in addition to the above-mentioned treatment. The nostrils should be washed often with warm water, in which a little vinegar has been mixed; the head steamed by means of a bag of scalded bran, hung beneath the nose; the feet and legs, after bathing in hot water, should be rubbed dry with woolen cloths; let the whole body be thus rubbed and then immediately blanketed from head to tail, and the patient kept free from drafts in a thoroughly ventilated, dry

stable. Tar should be burned in the stable for a disinfectant; take a small quantity in an iron pot and stir it with a red-hot iron, and allow the smoke to penetrate all through the building. The soreness of the throat may be relieved by rubbing externally with mustard, mixed in milk-warm water, as for the table, and also by placing on the back of the tongue a spoonful of molasses or of honey and vinegar, made as thick as possible. No medicine should be poured down the throat under any circumstances, and no bleeding should be allowed. On fine days gentle exercise is to be given, but no work should be permitted, nor exposure to damp or rain allowed. Rapid recovery should not be injudiciously attempted, nor should work or high feed be hastily resumed, but ample time given for complete restoration to health, before these precautions cease. With them there will be no fear of anything more serious occurring than a few days' idleness.

Our artist has engraved some of the scenes which have been common during the course of this disease in New York and other large cities. The lightning express has owed its slower motion to ox-teams, and the accumulation of all sorts of freight would have been greater than it has been had it not been for their needed help. Street-cars have been overloaded until car and horses have both broken down under the excessive loads, and occasionally a poor horse died, not from the disease, but from overwork when feeble and sick. On one occasion a horse-car has been drawn by men at increased rates of fare, and loaded wagons have also been thus drawn along. In the middle of the picture the methods of treating the complaint are illustrated; and on the whole, the scenes depicted—not exaggerated in the least—go to show to what straits we should be brought if we should suddenly be deprived of our patient and absolutely indispensable beasts of burden.

The Maiden-hair Rue-Anemone.

We have several species of Rue-Anemone, commonly known as Meadow-Rue, botanically *Thalictrum*. All of these have very much divided or compound leaves, and flowers without petals, but very showy stamens. The foliage of none of our native species is equal in beauty to that of the European smaller Meadow-Rue, *Thalictrum minus*. This species is found all over Europe and Russian Asia, and is so exceedingly variable that it is not surprising that we find various forms of it in the catalogues under different names. Last spring we received from W. C. Strong & Co., Brighton, Mass., a variety under the name of *Thalictrum adiantoides*, or Maiden-hair Rue-Anemone, so called from the resemblance of its foliage to the fronds of the Maiden-hair Fern. Messrs. Strong & Co. have introduced this as a plant to furnish foliage for bouquets. The leaves have all the delicacy and grace of a fern, while they are much more lasting and much more easily produced. The engraving gives an idea of the form, but well-developed leaves are several times larger than the one from which the illustration was taken. Certainly nothing can be finer for bouquets or other ornamental work than these beautifully dissected leaves. Being a hardy herbaceous perennial, it should be treated like other plants of its class. We grew ours in the open air during summer, and potted it on the approach of frost. It will be kept in a cold-pit until February, and having had a season of rest it will be brought into heat and forced like other plants of similar nature. The flowers of this species are not at all showy, and to get the best developed leaves the flower-stems unless it is desired to produce seeds should be removed as soon as they appear.

MAIDEN-HAIR RUE-ANEMONE.

The Glut in the Fruit Market.

The year 1872 will long be remembered as the abundant fruit year in all parts of the country. The rains have been abundant, and almost

have been so abundant that the larger part of the crop has rotted upon the bushes. The vineyards in the West have been loaded with grapes, and the growers have found it difficult to market

have jumped to the conclusion that there is no profit in fruit-growing, and that we may as well cut down our orchards. Certainly, we ought not to plant more fruit-trees. This is a hasty conclusion. There is just as good reason for planting orchards, especially of winter fruit, as there has been for the last twenty years. For some years past there have been serious doubts among intelligent men about the possibility of raising apples in sufficient quantity to make them pay. The trees would not bear. The crop of this year must have dissipated all doubt of this kind. The soil has not lost its fertility. The climate is not unfriendly to fruit. It is much to have our faith restored by the bountiful yield of this year. It is also a great good to have fruit so cheap that the poorest families in city and country can enjoy it. It has been so dear, in most years, that laboring men, in cities especially, have felt that they could not afford it. Apples at five dollars a barrel, and grapes at twenty-five cents a pound, were beyond their reach. A great many families have come into the full enjoyment of fruit this year, and will be good customers of the fruit-grower henceforth, as long as they can afford it. There can be no doubt that the market for fruit has been greatly enlarged by the bounty of this year, and the losses of the fruit-growers, so far as they have made them, may be regarded as so much capital invested for future operations. Every market in the country will take more fruit next year at paying prices, in consequence of the abundance of this. Those who have large orchards of winter fruit, of popular varieties, and plenty of storage room, will not lose money even this year. Apples will not be a drug in the market

next spring. The man who does not take pains to save his fruit will be sorry when he hears the cheerful prices of the late-keeping apples.

next spring. The man who does not take pains to save his fruit will be sorry when he hears the cheerful prices of the late-keeping apples.

The Mexico Apple.

The illustration shows the Mexico Apple of the natural size of a selected specimen. It

they have orchards, that immense quantities of summer fruit have rotted upon the ground. Trees in old pastures that have been barren for years have hung full. Dusty cider-mills, and presses unused for years, have been put in order, and the familiar squeak of the grinding apples has been heard in almost every rural district. The prophetic symbol of agricultural prosperity has been realized in all parts of the land. The presses have burst

without exception every kind of fruit has done well. The wild fruits, grapes, strawberries, whortleberries, blackberries, raspberries, plums,

out with new wine and cider. What is to be done with all this abundance, and what is the true policy for the future? Some

originated in the town of Canterbury, Ct., and was widely disseminated from the nursery of the Messrs. Dyer all through Eastern Connecticut.

cut. It is a fruit of great excellence, and ought to be more generally cultivated. It is the best apple of its season we have ever found. The tree is hardy, a good grower, and, on good soil, very productive. The fruit is of medium size, round, regular; surface bright crimson red, striped darker; dots, numerous, yellow-green. The basin is shallow, regular; eye medium, closed. Cavity acute, regular; stem long or medium, slender. The core is large, open, meeting the eye; seeds numerous, angular, pointed. The flesh is white, tender, fine-grained, and juicy. Flavor, sub-acid. Quality, best; season, August and September. It is a superb dessert apple, worthy of a place in any small collection or fruit-yard.

The Canker-Worm.

The wingless female moth that lays the eggs of the Canker-worm must ascend the tree by climbing up the trunk. All the methods of prevention oppose some obstacle to her ascent, or catch her in the act of climbing. One great difficulty with all these preventives is that they are not put upon the tree early enough. It has been found that the insects ascend very early, even during the warm spells that we often have in February, and that the only safety in sections where they are abundant is to keep the protecting material always ready. Tar has been used, but the following, from our correspondent "Bay State," is much better. He writes:

"Having had some twenty years' experience with the Canker-worm, and during that time having either tried or witnessed the results of the experiments of others, with all the various methods, patented and otherwise, to prevent the female from ascending the trees, I feel that the right thing has been hit upon at last. It consists simply of bands of sheathing-paper, 6 or 8 inches wide, tacked around the trees (same as for the old tar process), and an application of refuse printer's-ink. The ink is now manufactured for the purpose and costs 12½c. per pound. This remedy has been used in Massachusetts three years, and gives general satisfaction. Two to four applications a year are sufficient, and an orchard averaging from four to twelve-inch trees can be protected for an annual sum of *ten cents* per tree. As some evidently know but little of the persistency of the Canker-worm, I thought the above item might be useful."

Hints about Cheap Greenhouses.

BY PETER HENDERSON.

I find so many inquiries coming in at this season of the year about the heating and general construction of cheap greenhouses, that I am compelled to give instructions which are known now to nearly every one in and around our large cities. Yet, simple though the matter may be to us who see so much of it, it is evidently perplexing enough, when they come to construct, for those who have nothing to copy from. Those of us who write on such subjects too often take for granted that those for whom we write know something about the matter, when for the most part they really know nothing.

The cheapest kind of construction is a lean-to (already described by me in the *Agriculturist* for February, 1872)—that is, where there is anything to lean it against, such as the gable of house or barn. But if the greenhouse has to be constructed entirely new, I think the ordinary span-roof is best—see end-section. The walls

are four feet high, formed of locust or cedar posts. To the outside of these are nailed boards—rough hemlock will do, if appearances are not considered. To the boards is tacked the ordinary tarred paper used by roofers—a cheap article, and an excellent non-conductor of heat. Against the paper is again nailed the outer or weather boarding. This makes really a better wall for greenhouse purposes than an 8-inch one of brick, as we find that the extremes of temperature of the greenhouse—inside at 50°, and perhaps 10° below zero outside—very soon destroy an 8-inch *solid* brick wall, particularly if exposed to the north or west. A wall of wood constructed as above will last for twenty years, and be as good a protection as one of 8-inch brick. So much for the construction of the frame. The roof is formed by the ordinary sashes, six feet in length by three feet in width, which can be bought ready made, or easily be made by a carpenter or any one handy with tools.

Such a house, if cheapness is an object, should be heated with a flue. It should not be

END-SECTION OF GREENHOUSES.—C, Furnace; D, Flue; K, Walk; I, Gutter.

more than 60 and not less than 30 feet in length; if more, the flue would not heat it enough, and if less it would be likely to get too much heat. About 50 feet by 11 is we think the best size of a greenhouse to heat with a flue. The flue should run all around the house—that is, it should start along under one bench, cross the end, and return under the other bench to the end where it begins, making the length of flue in a greenhouse of 50 feet about 110 feet long. It should have a "rise" in this length from the furnace of at least 18 inches, to secure a free draft. For the first 25 feet of flue nearest the furnace it should be built of brick, forming an air-space inside of about 7 by 7 inches. From this point (25 feet from the fire) the flue should be formed of the ordinary drain-pipe cement or terra-cotta. The former is to be preferred, and that of 7 or 8 inches diameter is best. The drain-pipe for flues is now almost exclusively in use here wherever flues are used, and it is found not only to be much cheaper, but better for rapid radiation than brick. The cost of a plain greenhouse so built, complete, in this section, is about \$6 per running foot—that is, one 50 feet long by 11 feet wide costs about \$300.

The use of tarred paper for the walls or drain-pipe for the flues of greenhouses is not given in my "Practical Floriculture."

Hints on Pot Plants for Winter—Cheap and Effective Manure.

People who live in the country have no excuse for being without good food for pot plants. Dead leaves and earth or mold from the woods are always attainable. My advice is mainly for dwellers in cities.

First, make your calculations a year ahead. You who have not been accustomed to make plans for gardening, in-doors or out, for a month ahead, need not be discouraged at this. The amateur and professional florist make their plans for a much longer time. There are very few cities where a bushel or two of dead leaves can

not be gathered in the fall from the many trees that line some streets, or adorn your own or your neighbors' yards; but don't be afraid of getting too many. The older and more thoroughly rotted the manure is, the more valuable, and a bushel or two of leaves will go very far—much farther than you think. Put the leaves in a sheltered place, say against your back wall or fence, and put a board or two over the heap, to shed rain. Then to a bushel of leaves add a peck of loam or garden soil (sods are best), and a half-peck of common sand. Every washing day empty a pail of hot suds on the heap, and stir it as often as possible with a garden fork, hoe, or shovel, or anything else that will mix it up well. Of course, it will freeze up solid many times during the winter, unless kept where it does not freeze, but if you begin now, and stir as often as you can, by next fall you will have the whole thoroughly rotted down. Oak leaves do not rot as quickly as some others, maple, for instance. My heap was begun last October, and you can not now distinguish the least form of a leaf in

the mass. Although out of sight, under a flight of steps at the back door, it is perfectly odorless, and is springy and spongy—just what is needed.

To recapitulate: A bushel of leaves, a peck of loam or sods, a half-peck of sand are all the important ingredients.

Whatever you can add in the way of stray bunches of moss, or bones burned in the kitchen fire and powdered, is so much gain.

When ready for use, sift through your coal-sieve (let it be a coarse one), and take one third of the manure and two thirds of the best garden soil you can get, and make your heap for potting. With very few exceptions all plants will thrive in this mixture, and your courage will not be damped by the formidable array of soils paraded as necessary in most works on flowers. Through the winter you will have flowers that will be the envy of your less energetic neighbors—Geraniums that are Geraniums, Bouvardias and Primroses that no greenhouse need be ashamed of—especially if you have a sunny window. It is of no use to attempt to have winter flowers without some system. Better have none at all than the sickly specimens that disgrace so many windows from November to April.

I do not find in my horticultural reading much said about Geraniums for winter-flowering; yet they will be much more satisfactory, if some of the better varieties are tried, than many other plants chosen. Two years ago I gave a lady friend, living in the country, two cuttings of Geranium—one a bicolor (salmon pink, shaded with white) and the other pure white. She has a little winter sitting-room, about nine feet square, with a window each to the south and west. The south one is devoted to flowers, and it isn't worth while to boast of Geraniums unless you could see hers. The first winter they were less than a foot high, the leaves so thickly set that the stalks were not visible, and the horse-shoe or zone on each leaf almost black. They each threw up one cluster of buds, then another, and another, until finally through the greater part of the winter there were always from one to four clusters of blossoms. And such clusters! Nearly as big as your fist, and each floret as large as an old-fashioned cent. The shape of the cluster was such that the flowers seemed to grow in trusses, like the Hyacinth, and hid the stem entirely. The difference between the summer and winter blooming of the same plants was very marked. Out of doors they bloomed like

nearly all Zonal Geraniums; one half the florets faded before the other half came out. In the window each cluster would keep about three weeks; if one floret dropped, another came out in its place, or the rest pressed together and filled up the gap. Cuttings from these did equally well last winter. They stood on the window-sill, close to the glass. The room had only a wood-fire, and was never very hot—which last item, by the way, is a very important one for your own health as well as for that of your plants. Don't let the thermometer get above 65° or 70° at the most, going down not lower than 45° at night if possible. You can easily accustom yourself to the temperature, and will be all the better for it.

PROVIDENCE, R. I.

G. H. B.

Seedling Pelargoniums.

BY JEAN SISLEY, OF LYONS, FRANCE.

Mr. Sisley, well known as the originator of several choice varieties of double Zonale Pelargoniums, writes to the editor as follows:

LYONS, 16th October, 1872.

Editor of *American Agriculturist*, New York:

You have asked me how I proceeded to obtain the new double-flowered Zonale Pelargoniums, and since then I have received many applications for information from Belgian, English, and French horticulturists, particularly since my friend Carrière, speaking of my double White Zonale in the *Revue Horticole* of 1st October, says that it is the result of scientific combinations. I must decline to accept this encomium, but am very willing to let the horticultural world know my very simple practice, which I have never kept secret. It is not necessary to discuss here the process of artificial impregnation; one familiar with horticulture knows how it is practiced. I will therefore at once inform your readers of my proceedings.

When, six years ago, I began the artificial impregnation of Zonale Pelargoniums, I first procured about fifty of the best varieties of single-flowered Zonale Pelargoniums, selected from the various colorings, and about two hundred plants of the then existing double-flowered varieties. And until 1870 I continued to buy all the new double varieties that were brought out, and all the single-flowered varieties which were of different shades from those in my collection.

Without any preconceived theory I impregnated all the single-flowered with the pollen of the double ones which had stamens.

For three years I did not obtain a seedling worth mentioning, and I was on the eve of giving up artificial fecundation, when in 1869 I obtained Victoire de Lyon and Clémence Royer, which, although not perfect in form, were very different in color from any double Zonale Pelargonium until then produced. This led me to continue my efforts. Since the first year I had kept my seedlings that were alike in shape and color to those in my collection, and rejected the old ones. I proceeded in the same way with the double-flowered, and rejected principally all those that had few or no stamens as useless to me. I had been led to this selection by the idea that single flowers obtained from single flowers impregnated by double ones, might perhaps be more disposed to produce double flowers than the old sorts.

This selection is the only scientific combination I have used, and although I can not affirm that this proceeding is the cause of my success, I recommend this method to those who may be disposed to practice artificial fecundation with

other species of plants. Nevertheless I have not learned by my practice anything that can be called a theory, because among my seedlings coming from the same mother and the same father I have found them all differing from one another. My double White is the produce of a single White (one of my seedlings second or third generation) by a double Red; but four other seedlings from the same fecundation are either white, pink, or red, and all single flowers.

And there is nothing astonishing in this. Why should the laws of nature vary and act differently in the vegetable world from what they do in the animal world? Nature and science have not yet taught us why the offsprings of the same father and the same mother are *always* different from one another, notwithstanding their family likeness. And it is very likely that man will always be ignorant of this and many other laws of nature. The only thing I know, and every horticulturist knows, is that to obtain double flowers, single flowers must be impregnated by double ones.

Measuring the Hight of Trees.

It is often desirable to determine the hight of a tree, if not with mathematical correctness, with something approaching to accuracy. There are instruments made for the purpose of measuring with great precision, but there are several methods by which the hight can be

MEASURING THE HIGHT OF A TREE.

ascertained without expensive appliances. By measuring the shadow of a rod or other object of a known length and the shadow of the tree, a simple sum will give the hight. Suppose that we measure the shadow of a perpendicular rod six feet long, or that of a man of the same hight, and find it to measure eight feet, and then measure the shadow of the tree and find it to be 132 feet; then

$$\text{as } 8 \text{ ft.} : 6 \text{ ft.} :: 132 \text{ ft.} : 99 \text{ ft.}$$

The Gardeners' Chronicle figures a simple quadrant for tree-measuring which we here reproduce. A quarter of a circle is made of some light wood, and a small plumb-bob is suspended from what would be the center of the circle, and a mark made just half-way of the curved side of the quadrant. Two small eyes for sights attached to one of the straight edges make the implement complete. The quadrant is held as in the diagram, the operator moving backward or forwards until he can see the top of the tree through both sights, the plumb-line at the same time hanging over the mark. The distance of the observer from the tree, when he

can see the top of it in this manner, will be the hight of the tree. Allowance must be made for the hight of the eye from the ground, and for any difference in the level of the ground between the tree and the observer.

Yuccas and Insects.

At the last meeting of the Association "with a name," Mr. Riley stated as a discovery of Dr. Engelmann, that our American Yuccas could be fertilized only by means of some artificial agency, and that an insect was engaged in the work. This insect, a moth, was described by Mr. Riley as one hitherto unknown to entomologists, and one by its structure well calculated for its work. The insect collects the pollen which would not otherwise reach the pistil, and places it upon that organ and lays her eggs. The young larva after hatching eats its way into the developing fruit, lives on the maturing Yucca seeds, and by the time the seed-pod is ripe the full-grown larva leaves the capsule and enters the ground, where it undergoes its transformation, and comes out the following spring as a moth to repeat the work. Mr. Riley is quoted as saying, "In the more northern portions of the United States and in Europe where Yuccas have been introduced and are cultivated for their showy blossoms, the insect does not exist, and consequently the Yuccas never produce seed there," and suggests that the insect be

captured in the chrysalis state and sent to those countries where it is lacking. Three large plants of the Adam's-Needle, or Bear-grass (*Yucca filamentosa*), in our garden near New York, produced fine clusters of capsules this autumn; upon examining them we found that apparently every seed-vessel either contained an insect, or had a hole showing where one had escaped. The capsule of this Yucca consists of three cells, and generally but one of them was inhabited by the larva, which destroyed the seeds in that, while the contents of the other two cells were untouched. All the capsules were one-sided or contorted, owing to the presence of the caterpillar. The fact is an interesting addition to our rapidly-accumulating knowledge of the relations between plants and insects, but it is a question if all Yuccas require this insect aid in order that they may produce seed, or that it is always necessary, even with our commonest species, *Yucca filamentosa*. A very observing friend who made extensive experiments with seedling Yuccas in the hope of obtaining some new varieties, is quite sure that he has obtained crops of seed without any of the distortion of the capsule to which we have referred. A recent Gardener's Chronicle, alluding to the statement that Yuccas do not fruit in Europe, cites two cases in which *Y. filamentosa* produced seeds, which would show either that the moth in question is in Europe, that some other insect does the same work, or that the presence of an insect is not always required. During a recent visit to Georgia we found *Yucca gloriosa* in fruit. The fruit of *Y. filamentosa* is a dry capsule, while that of *Y. gloriosa* is pulpy, and when quite ripe is as soft as a banana. We examined a number of fruits of *Y. gloriosa*, and failed to find any distortion, perforation, or other indication that an insect had entered or made its exit. We hope that those who live where this and other species fruit will continue the investigation begun by Dr. Engelmann and Mr. Riley.

Vegetation in the "Pine Barrens."

There is no more interesting section of country than that extending from Ocean County to

YELLOW MILKWORT.

Cape May, New Jersey, commonly known as the Jersey "Pine Barrens." Here it is that many of our rarest plants are found, some species of which are not known in any other locality. There are the dry and the swampy "Pine Barrens." The former consist of large tracts of dry sand, covered with a growth of scrub oaks and pines; the latter, which border the coast, support a dense growth of Magnolias, Rhododendrons, etc. Many of the plants found here are very beautiful, while others are interesting on account of their rarity. We here figure two species which came from the swampy "Pine Barrens" in the vicinity of Tom's River. The *Gentiana angustifolia*, or Narrow-leaved Gentian, though having a wide range, is not often found growing in any considerable numbers in one place. The plant grows from six to twelve inches high, and bears one to three flowers; these are two inches long, of a beautiful azure blue, with the inside of the corolla striped with white. There are nine species

of Gentian found in the Northern States, all of which produce handsome flowers. One of these, *Gentiana Andreinii*, or Closed Gentian, was figured in the *Agriculturist* for December, 1870.

Very little attention has been paid to the cultivation of Gentians in this country, owing to the supposed difficulty in growing them. When, as is usually the case, the plants are taken up from the fields, they seldom do well under cultivation, but if the seeds are sown as soon as ripe, they vegetate freely, and may be easily transplanted, though it requires several years before they become well established. The other plant we figure is the *Polygala lutea*, or Yellow Milkwort. The leaves are thick and fleshy, mostly clustered at the surface of the ground. From this cluster of leaves rises the flower-stalk, six to twelve inches high, usually bearing a solitary head of showy orange flowers. As it is a biennial, it can only be grown from seeds. We do not know that any attempt has ever been made to grow this plant, but it is worthy of a trial. Besides the plants mentioned there are many others which are interesting, though they generally have no common name, owing to their local character. One of the earliest found is *Pyxidanthera barbulate*. This is a prostrate evergreen plant, producing numerous white or rose colored flowers, which appear early in April, with the Trailing Arbutus. Following the *Pyxidanthera* is the Sand Myrtle, *Leiophyllum buxifolium*, a low, branching evergreen with terminal clusters of small, white flowers. Next follow *Helonius bullata*, bearing fragrant purple flowers, in a dense raceme, two or three inches in length, upon a stalk fifteen to eighteen inches in height, and *Xerophyllum asphodeloides*, a plant resembling somewhat an Asphodel, which produces a raceme of showy white flowers in June. The last two did well with us this year under cultivation in common garden soil.

The Pinneo Pear.

This pear, represented in figs. 1 and 2, was brought to the notice of the horticultural world by Mr. Hovey, of Boston, some years ago, and was by him called the Boston. It is an old variety, cultivated and quite extensively disse-

years ago, on the farm of Esquire Pinneo. It is a chance seedling which he found in an outlot where he was cutting brush. He transplanted it to a place near the house, thinking to graft it, but finally concluded to let it stand and mature the natural fruit. The pear was so good that

NARROW-LEAVED GENTIAN.

he never wished to change it, and his neighbors were so far of his mind that they came to him for grafts. It was scattered all through the northern part of New London County, and finally found its way to the Hartford and Boston markets. Mr. Hovey was so well pleased

with it that he propagated it, and sent it out extensively among horticulturists. There is no longer any doubt about the identity of the pears bearing these names of Pinneo and Boston. The tree is vigorous and productive, the young wood brownish red. The fruit is below medium size, obovate, inclining to conic, remotely pyriform. Skin yellow, with numerous small green or gray dots, and patches of russet all over the fruit, but much more upon one side than upon the other. The stem is rather long, and inserted in a slight depression, and sometimes a little upon one side. Calyx set in a broad, shallow basin. The flesh is white, tolerably juicy, with a pleasant, sweet, somewhat aromatic flavor. CONNECTICUT.

minated in Eastern Connecticut. It originated in the town of Columbia, more than a hundred

September.

THE HOUSEHOLD.

(For other Household Items, see "Basket" pages.)

Chopping and Choppers.

Chopping or mincing is one of the frequent mechanical operations of the kitchen. Where any special apparatus is used for the purpose it is the old-fashioned chopping-knife, fig. 1, made with a curved cutting edge if a round or oval bowl is used, and with a straight one if a flat-bottomed tray is to hold the material to be chopped. Chop-

Fig. 1.—CHOPPING-KNIFE.

ping in this way is tedious work, not on account of the strength required, as this is but little, provided the knife be sharp, but from the many blows or cuts necessary to reduce the material to the desired fineness. Sometimes the common knife is made with two blades, and this with some materials facilitates the work, while with others it is apt to clog. In fig. 2 is given a French chopping-knife, which is made of two blades a foot or more in length. The material to be minced is spread upon a chopping-board, and the knife is worked

Fig. 2.—FRENCH CHOPPER.

with a rocking motion. The German butchers, who often chop meat for their customers, use two heavy cleavers, one in each hand; these play upon the meat alternately, and chop it rapidly, though at an unnecessary expense of strength. Chopping machines of various kinds have been devised, and have met with more or less success. One of the earliest of these was a cylinder in which the blades, placed on an axis in a spiral form, revolved against other blades attached to the interior of the cylinder. This, however, tore rather than cut the meat, and

Fig. 3.—THE AMERICAN CHOPPER.

is now much less used than formerly. The latest chopping machine is called the "American Meat and Vegetable Chopper." It is made of several sizes, one of which is shown in figure 3. The knife is moved up and down in a cylinder which turns a short distance around with each movement of the knife, and thus exposes a fresh place to the

cutting edge. The motion is communicated by a crank, and by means of multiplying wheels is very rapid. The machine is much more simple than it appears to be, is easily cleaned and kept in order, and does its work in a very satisfactory manner.

New Heels in Old Socks.

I like to darn stockings, but sometimes the heels of my husband's socks gave way before his rough boots in such a shocking manner that I had no heart to undertake their repair, and was fain to provide new socks instead. The heels of these I lined with strong cloth. Once, before the use in our family of farmer's "stoga" boots, I thought it enough to run the heels with doubled yarn like the socks. In spite of even the linings, the heels would wear out all too soon, and a day came when my stocking-bag was no longer a pleasure, but just a reproach to me, and I dreaded nothing more than the call for clean socks.

One night, when the baby was restless and prevented my sleeping, light broke in upon my mind. Eureka! I was impatient for morning to dawn, and at the earliest convenient moment I sat down to make those socks "almost as good as new." I took strong cloth, new denim, hickory, drilling, or ducking, and cut out heels large enough to cover all the ragged portion of the sock-heel. All this ragged part I cut away, and put the new heels in double, the outer cloth being larger than the inner, in order that there might be no bungling place where the new heels joined on to the old socks. I turned in the edges of the outer heel and hemmed them down neatly, but the inner cloth I only cross-stitched on. It all took but little time, not one quarter so long as it would to knit in new heels, as some good knitters do, and I think the cloth heels will wear much longer, as none of these double cloth heels have worn out yet. I do not doubt that many and many a smart woman has made this discovery for herself long ago, but she failed to report it for the benefit of the sisterhood of stocking-darners—"hence these tears," and hence the delight I found in invention. MARMAR.

HEELING A STOCKING.

Home Topics.

BY FAITH ROCHESTER.

THE SCHOOL EXHIBITION.—Some of the best teachers and some of the wisest parents are opposed to school exhibitions. These are of two kinds—the public examination and rehearsal, and the regular exhibition with its foot-lights, stage scenery, and dramatic performances. Of the latter we will speak first. Intelligent teachers get up these exhibitions with a good deal of secret misgiving as to their utility. They know that the learning of parts in dialogues, and the attendance at rehearsals, and all that, interfere with the regular progress of the pupils, or overtask them. They see also how the public display cultivates jealousy, and vanity, and selfish ambition among the little men and women. The rehearsals take place in the evening, and children going to them without the company of their parents are liable to exposures of health, and perhaps of morals, from which careful parents would protect them. The exhibitions usually take place in the evening, and close late. Late hours and crowds are bad enough when children are only quiet spectators and auditors, but when they are the excited actors upon the stage, subjects of the criticism or applause of the crowd, it is very great abuse of innocent childhood. Flushed and heated by the close air and by excitement, the children expose themselves to cold

draughts of air, and become victims of disease, sometimes of speedy death. Little girls are in especial danger of catching cold, because more barbarously exposed by their insufficient clothing. One would suppose that the parents of these rate their children's lives very cheaply.

The reason most frequently urged in favor of putting children upon the public stage is that "it gives them confidence"! O dear! So it does! But does it seem to you that Young America suffers from excess of modesty? Human nature hardly needs cultivation in the way of self-confidence, love of display, desire for applause. Oratory is well in its way, but I think it is over-rated. I have a suspicion, too, that our children may be taught to read and speak with proper expression, and with a natural (or, if you please, *dramatic*) rendering of conversations, better in the regular reading-class than in the especial training for exhibitions and theatricals. That subject is too large for this page, and I want to take it up again.

The public examination is superseding the old-fashioned dramatic school exhibition, and it has many firm friends among professional educators. The pupils are examined in the presence of their parents and friends, so that all may see just what progress has been made by each, and give credit accordingly. The expectation of these periodical examinations is supposed to act as a stimulus with teachers and pupils alike. That is the *idea* of the public examination, and if I had not been interested as pupil, as teacher, and not exactly as parent, but as elder sister and children's friend, I suppose I might not feel so much like calling these examinations a *humbug*. The parents are deceived most; the children take another lesson in the arts of deception, and in the immense importance of being able to make a show; and the teachers feel how almost impossible it is to help this wretched state of things until the public mind learns the true idea of education.

The public examination is no true test of the advancement of the pupils, or of the teacher's ability as an educator. Children naturally quick and ready show to the best advantage, while slower ones are abashed and discouraged. Those who need stimulus most get the least help from the public exhibition. Those whom nature has gifted with quicker wits, get praise which nurtures their self-conceit, instead of encouraging their lagging faculties. The poorest educators often make the best show as exhibitors on examination-day. They can show you that the pupils have been trained to a certain dexterity and mechanical precision, and to concert action which is very effective with the unreflecting crowd; but no teacher can exhibit the best things a good teacher can do in the way of education. The illustrations which have brightened all the daily tasks; the bits of history and biography which have endeared to each pupil textbooks otherwise dry and dull; opportune suggestions as to methods of study; and, better still, sympathetic help toward the formation of noble character, toward the development of honest men and women with clear heads, and warm hearts, and helpful hands—can any public examination, yearly or monthly, make a true exhibit of these most precious works of an educator? Will it be likely to help or to hinder this larger education?

If you would satisfy yourself as to the faithfulness and ability of your children's teacher, go and see him or her at work two or three times at least every term, dropping in unexpected for fifteen minutes or a half-day, as you can find time. Let the teacher feel that your eye is on him and your heart in his work. If you talk with the children at home about their school work frequently, as well as visit them in school, it will do them a deal of good—provided all is done with true sympathy, and not in the character of a cool superior critic.

WARM FEET.—To go with cold feet is to undermine the constitution, and this half of the women and girls are doing. They have a habit of cold feet and an accompanying habit of ill-health. Thick, home-knit woolen stockings are not very fashionable. Once, no country girl was reckoned fit to be married until she had knit her pillow-case full of

stockings, but it is not so now. I do not regret that less hand-knitting is done now than formerly, but I hope we shall not give up warm woolen stockings for winter until we can replace them with something better. Merino, or the common "boughten" white wool stockings, are rather thin, but some of us supplement them with an additional pair of cotton stockings, wearing the cotton or the woolen pair next the feet, as individuals prefer. Cold feet are often caused, at least in part, by too tight elastics or bands at the tops of the stockings, or by tight shoes, or shoes tight in the ankles. These interfere with the circulation of the blood, and there can not be a comfortable degree of warmth without a good circulation and aeration of the blood. My last lesson in this matter came from baby's experience last September. Suddenly she contracted a habit of having cold feet, and when I warmed them the skin seemed hard and inactive, suggesting the need of a bath, when a bath did not seem necessary except for the feet. At length it occurred to me that her "ankle-tics" had been too loose, and just before we came home from our visit a young lady cousin had set the

Fig. 1.—OFFICE STOOL.

button back further, to make the little slippers stay on better. Ever since that change the slipper-straps had been too tight around her ankles, especially after I put on woolen stockings. I changed the buttons again, and her feet no longer got cold, except in consequence

Fig. 2.—STOOL FOR TABLE.

of the actual rigors of the climate. Some well-informed persons object to Congress gaiters, the elastics are usually so firm and close about the ankle. Only very loose garters are allowable, and these may not be necessary when the stockings are worn over under-drawers. Garters in the shape of straps buttoning to both waist and stockings are most sensible for women as well as children.

Many women are obliged to work in kitchens where the floors in winter are always cold. It helps matters to have a carpet down, but the kitchen carpet is objectionable on the score of cleanliness, especially where there are many children. A few large thick rugs are better. These can be shaken often, and will afford the kitchen occupants warm places to stand or sit at their work. There

are some very cold days when the mercury sinks from 10° to 30° below zero (in Minnesota), and then I wear my arctic overshoes all day, and the children also keep on overshoes. The floors of our houses are many degrees colder than the air about our heads.

One thing too little thought of in this connection is absolutely essential to healthy warmth of body. That is pure air. Men who work in the

Fig. 3.—LOW STOOL.

open air some every day have a great advantage over housekeepers. Their blood gets oxygenated, and so purified (as far as such a degree of air can do it) and prepared to warm and nourish the body, of which the blood is the constant up-builder. Everybody, male and female, old and young, ought to get out of doors some every day, and breathe freely *with the mouth closed*. The air of sleeping rooms and other living rooms should be purified each day.

Keep bricks or soapstones in the oven, to be wrapped up and put under your feet when you are obliged to sit for some time at a distance from the fire, especially if you are writing or studying.

HIGH SEATS AT TABLE FOR EX-BABIES.—There are nice large high-chairs, a little lower than regular baby high-chairs, to be found at some furniture stores, but many parents neglect to procure them when baby No. 1 is dethroned by baby No. 2. But no child of six or seven is large enough to sit comfortably and gracefully at table in a chair made to suit a grown person, especially if not allowed to put its feet upon the chair-rung. Its feet do not reach the floor, and are apt to swing about in a way to fret nervous people, and in a way that certainly is not graceful. And its elbows are not high enough to give it easy command of its plate and knife and fork. So, in teaching table manners, look first for the comfortable seating of your children. A cheap piano-stool does very well for an intermediate seat between high-chair and common dining-chair. Any man with tools can make one on a rainy day, if it seems too much to purchase a second high-chair.

A friend of ours purchased a high, yellow office-stool for a dollar. This was sawed off, to suit the needs of a child of six, above the lower rungs. A second very comfortable and useful seat was made of the part sawed off, by putting a square board atop, and cushioning it with gay woolen patchwork.

SKINNING SUN-FISH.—Mr. Rochester says that I was mistaken when I wrote that sun-fish are as easily skinned without scalding or sealing as with. It was found to be the best way to scale the fishes and wash them, also the hands, and then to strip off the skins, leaving the fishes all clean for cooking. In trying to skin the fishes without scalding, the whole got badly slimed. A small matter, perhaps, but having mentioned it, I had better get it right.

Toughening and Coddling.

BY RELL.

In certain minds there is a prejudice against protecting children much from the cold or from any hardships, for fear it will make them effeminate or unduly weak and dependent. One may be over-careful, it is true. There is such a thing as "coddling children" by a fussy, unwise tenderness, so that they develop no nerve, no power of endurance. There is also such a thing as false "toughening," a process that kills off the children of weaker constitutions. How steer clear of this Scylla without being drawn into that Charybdis?

To keep children close in warm rooms, never allowing them to feel a rough breath of air; to do everything for them, paying heed to every whimper "I can't" and "I don't want to;" to inquire anxiously after all their preferences and listen pityingly to all their whining; to teach them no tasks, and never to let them get wholesomely tired—all that comes under the name of "coddling," and I pity the children who are put through the weakening process.

The false toughening which is equally to be avoided, is on its face a compound of neglect and cruelty; but sometimes it is deliberately undertaken by parents of really kind hearts, from mistaken ideas of what Nature really needs. What she needs is a fair chance to do her work. She has wonderful power of adaptation, but she can not stand everything; and if her children be pinched with cold and starved for nourishment, she will surely tell the tale in her own time and way. She says that her little animals (and she makes no exceptions in favor of humans) must have regular

meals of simple, nourishing materials, and that their growing bones and muscles should have plenty. And then she insists upon plenty of warmth. If the surface of the body gets chilled, some harm to internal organs is sure to result, though not always in a perceptible degree, at the particular time. A succession of such chills, or a shivering, half-cold condition for any length of time, makes a serious drain upon the vitality, and weak constitutions break down under it, and the little victims of neglect fall an easy prey to the diseases of winter's cold or summer's heat. These "die a-toughening."

To be tough is to be "strong and able to endure hardships." Strength is born of struggle. Ability to endure hardships is the result of discipline in the way of endurance. Some children are born with "iron constitutions," apparently; or were in our grandfathers' day—and they bore a wonderful amount of knocking-about and deprivation of one kind or another. You may think they turned out well enough in spite of it; but I don't. I think that many of those foreparents of remarkable mention came out of the hard mill in which they were ground, pitifully stunted and deformed in more ways than one, and that, too, in spite of their iron constitutions—constitutions so used up by their hard early life that they could not bequeath one half their own native vigor to the sons and daughters born of them.

Yet I believe in toughening children, and in discipline. But these are consistent with perfect tenderness and unceasing care. Turn them out of doors—no, never turn them out, but let them go, or coax them out if they have morbid fears. But have them so well protected with warm overcoats (give sleeved sacks to girls, instead of bothersome pretenses, called shawls), over-socks, or over-shoes with leggings, mittens, and hoods, or caps with ear-taps, that they can run and coast and skate and slide and snow-ball without any discomfort from the north wind or the ice.

Teach children to wait upon themselves, and to take pleasure in helping others. Encourage them to bear necessary pain with as little fuss as possible. Give them good tools, and show an interest in their use of them. Show them *how* to work as you do, but *require* very little at first, letting them make things for friends, or do their tasks to "help" those they love, until they learn to feel an ambition about doing their work fast and thoroughly. Expect them to keep their engagements, and not allow them to back out of an undertaking as soon as the flush of novelty wears off. Therefore let them not attempt too much—unless to cure a habit of bragging. Give them long, warm night-clothes and bedding enough (too much will induce perspiration) to keep them warm in any position, and let them sleep in cool, ventilated rooms, and give them all the natural sleep they can take.

Devonshire Cream.

One of the noted luxuries of the London market is "Devonshire cream," or "clotted cream." The method of its preparation is as follows: From six to eight quarts of milk is strained into a thick earthenware pan or crock, which, when new, is prepared for use by being stood in clear cold water for several days, and then sealed three or four times with skimmed milk. Tin pans may be used if they are sealed in hot bran and left to stand with the bran in them for twenty-four hours. The milk being strained into the pan is stood in a cool room from nine to fourteen hours, according to the temperature. It is then carefully moved to the top of the stove or range, or placed over a bright fire (not too near it), and slowly heated—so that at the end of a half-hour the cream will have shrunk away from the sides of the pan and gathered into large wrinkles, the milk at the sides of the pan commencing to simmer. The pan is then carefully returned to the cool-room and left about ten hours, when the cream is skimmed off.

This cream is very delicious to use on fruit or preserves, and is esteemed a great luxury—selling for about the price per pound of the best butter.

BOYS & GIRLS' COLUMNS.

The Doctor Talks about Indian Relics.

Georgia is a queer place for the Doctor to write you from, but he finds himself here, and not liking to have the *Agriculturist* appear without a word to his boys and girls he writes from this far Southern State. One of our boys, Louis, lives here—where don't they live?—and he of course showed me his curiosities. Near his home he had found in the woods the place where had been some old Indian graves, and not many days ago he and another went and explored the spot. The graves were so old that about the only things to be found were stone imple-

ing them, and in trying to find out how they were made. This Mr. Evans, for that is the gentleman's name, has published a book which is full of fine engravings of the things that have been found in England and other parts of Europe. The puzzle as to how such things could be made out of flint and other hard stones without the aid of steel or iron he has solved by going to work and trying to make such things himself. He has found that by selecting the right kind of a stone, and using no other implement than another stone, he could make just as good arrow-heads and spear-heads as are found in the old graves and mounds. More than this, he discovered that by the use of a stick and sand he could drill just such holes as are in the ancient hammers and such things. To be sure, it required much patience and lots of "elbow-grease" to do it, but he proved that probably these early

thought at length that he had had enough of it. Then came the winding in of the string, which was almost as much fun as letting it out. Down, down came the kite, every now and then giving an angry toss as if it did not like to be taken away from its fine place up in the air, where it could look down upon everything. But Tommy kept on winding in the string, until at last, when quite near the earth, the saucy kite gave a toss of its tail, and came head foremost with a pitch to the ground. You may be sure that Tommy was over the fence in a minute to pick up his kite, and what was his surprise to see that it had come down in the midst of a flock of turkeys, and that the slack of the string was directly around the neck of the old gobbler! It was a very respectable gobbler, but not at all used to such tricks as this of the kite, so he immediately showed fight, and began to twist himself

TOMMY'S HOUR OF TROUBLE.

TOMMY'S HOUR OF TRIUMPH.

ments. You will think that implements are strange things to find in a grave, but you must know that almost all savages think that they can carry into the other world the things they have used in this. Believing this, the friends of an Indian bury with him his weapons, his ornaments, and his treasures, and some even kill a horse at his grave, so that the dead man may be mounted in the "happy hunting-grounds" to which he is going. Louis' collection contained various things that must have been buried with the occupants of the graves. There were large stone "arrow-heads," as they are called, but as these are over two inches long, and broad in proportion, I doubt if they were ever used upon arrows, as they are too heavy for this purpose. I have seen stone arrow-heads in use among the Indians of the present day, but these were slender, and not more than a tenth as heavy as those found in graves and mounds in various parts of the country. It looks more probable that these heavy so-called arrow-heads were used as spear or lance-heads, or they may have been fastened to a staff to be thrown by hand. I don't think any bow could carry an arrow with such a heavy weight at one end. Besides these war-like things, Louis found more or less perfect hammers or tomahawks, one of which had a neat hole bored through it, apparently to admit a handle. I am not sure that this particular piece was not a portion of a pipe. At any rate, there was a clean round hole in a solid stone an inch or more through. So far as we know, these early Indians—for these relics are so old that no one knows what tribes made and used them—had no hammers, drills, nor other tools of iron and steel, and how hard stone could be worked into these various shapes has always been a great puzzle.

Implements and other relics similar to those Louis and others have found in this country also occur in Europe, and an English gentleman has spent a lifetime in study-

inhabitants of England drilled their holes in stone in this slow and laborious manner. All relics like those my young friend Louis has collected are interesting, as they show us what were the habits of the people who inhabited the country long, long before our ancestors came here. We can now buy for a few dimes a hammer much better than one which the forgotten Indian spent weeks and perhaps months in making. It seems not so very strange that they desired to have these things, so precious on account of the labor expended on them, buried with them. There are but few places, even in what are called the "older States," where these Indian relics are not occasionally found, and in some of the Western and Southern States they are very abundant. Now, I would like to have those youngsters—whether boys or girls—to tell me about what things of this kind they find. It may be that something interesting will come of it.

Somewhere in Georgia, Oct. 26.

THE DOCTOR.

Tommy's Trouble and Triumph.

In there any story, needed with these two pictures—one showing the troubles which befell Tommy, and the other giving the scene when Tommy had the better of the cause of all his trouble? These pictures are intended for our little readers, and very young people like to have a little tale with the pictures, no matter how plainly they may tell their own story.

Once there was a boy whose name was Tommy—but there is no need to tell you that, for if there had been no boy Tommy, how could we have had any picture of him? Well, this boy Tommy had a kite; a new and a fine one, which his big brother John had made for him. Tommy went out one fine day to fly his kite. How that kite did fly, and what a happy boy was Tommy! It was great fun, to be sure, but after a while the best of fun, even that of flying a new kite, becomes tiresome, and Tommy

up worse and worse with the kite-string. Tommy made a hard struggle for his kite, but when he recovered it, it was not at all the beautiful new one that he had sent up that morning, but a poor, torn, dragged kite, that would have put its tail between its legs—only you see it had no legs. Tommy never liked that gobbler after the affray. Some months afterwards it came the gobbler's turn to furnish the family dinner, and when it appeared on the table Tommy looked mightily pleased. The rest of the family could not guess why Tommy's face wore such a broad grin, but he knew, and we think you do too.

Jenny's Dream.

Jenny had many good friends who sent her Christmas presents. Most of them, knowing her to be fond of reading, sent her story-books, and these, together with the books given by her parents, made a nice child's library. How pleased was Jenny, and how she did read! No sooner had she finished one story than she began another. She could hardly leave her books long enough to take her meals, but she read on and on until she was so tired she fell asleep. It was a very wrong thing for Jenny to do, but the books were so pretty, and the stories were so fine, that she thought she could not read them half fast enough. She had filled her head with so many fancies that when she fell asleep she dreamed and saw in her dreams all the things she had been reading about. Our artist has pictured the things Jenny saw in her dream. There are poor Cinderella and—but we will not tell you, because we wish you to have the fun of picking out the characters in the picture yourself, and then you will know what Jenny had been reading.

While the claims of the various organ-makers are so persistently urged, the purchaser has one sure resource: he can hear and judge for himself.

IT IS EASY TO INQUIRE and to be satisfied of the merits of the

AMERICAN ORGAN,

as it is sold by first-class dealers in all the principal cities and towns.

Ask for the

SAFE and PROFITABLE INVESTMENT.

THE

CHICAGO

AND

Canada Southern

First Mortgage Sinking Fund

THIRTY YEARS

7 PER CENT GOLD BONDS.

INTEREST PAYABLE APRIL AND OCTOBER. REGISTERED OR COUPON PAYABLE IN LONDON OR NEW YORK. AT 50 AND ACCRUED INTEREST IN CURRENCY.

THIS ROAD, WITH THE CANADA SOUTHERN, FORMS THE NEW TRUNK AIR-LINE FROM BUFFALO TO CHICAGO. IT IS UNDER THE SAME CONTROL AND MANAGEMENT, AND IS BEING BUILT BY THE SAME PARTIES WHO BUILT THE CANADA SOUTHERN: MILTON COURTRIGHT, JOHN F. TRACY, DAVID DOWS, WILLIAM L. SCOTT, HENRY FAIRNAM, R. A. FORSYTH, JOHN M. BURKE, M. L. STOKES, JR., ALL DIRECTORS BOTH IN THE CHICAGO AND NORTH-WEST AND THE CHICAGO AND ROCK ISLAND; GEORGE OPDYKE, OF THE NEW YORK MIDLAND; SIDNEY DILLON, DANIEL DREW, JOHN ROSS, DAVID STEWART, SAMUEL J. TILDEN, KENYON COX, AND OTHER PROMINENT RAILROAD MEN. THE ROAD IS BEING RAPIDLY BUILT IN THE BEST POSSIBLE MANNER, WITH SIXTY-POUND STEEL RAILS THROUGHOUT ITS ENTIRE LINE, AND WILL BE COMPLETED DURING THE COMING YEAR; NEARLY ONE HALF OF THE ROAD WILL BE COMPLETED AND IN RUNNING ORDER BY THE 1ST OF JANUARY NEXT, SO THAT THE ENTIRE LINE, FROM BUFFALO TO CHICAGO, WILL, WITHIN THAT TIME, BE IN SUCCESSFUL OPERATION. THE BUILDERS OF THIS ROAD CONTROL ENOUGH OF THE LEADING LINES RUNNING FROM CHICAGO TO INSURE AN ENORMOUS BUSINESS FROM THE START, TAKING INTO CONSIDERATION THE IMPORTANT FACT, PATENT TO ALL WHO STUDY THE STATISTICS OF TRADE, THAT THE PRESENT TRUNK LINES, NOW TAXED TO THEIR UTMOST CAPACITY, ARE NOT AFFORDING FACILITIES EQUAL TO THE GREAT AND CONSTANTLY-INCREASING DEMAND FOR TRANSPORTATION, AND THAT THIS ROAD, THROUGH ITS ENTIRE LENGTH, BEING PRACTICALLY STRAIGHT AND LEVEL, AND SHORTER BY THIRTY-FIVE MILES THAN BY ANY OTHER NOW BUILT, OR THAT CAN BE BUILT, IT MUST BE APPARENT THAT THIS LINE IS NOT ONLY NEEDED, BUT MUST BE A GREAT SUCCESS. THE PROCEEDS OF THESE BONDS WILL COMPLETE AND EQUIP THE ENTIRE ROAD, AND WE CONFIDENTLY RECOMMEND THEM AS A MOST SAFE AND PROFITABLE INVESTMENT.

FOR RENT.—The Bluffton Vineyards, bordering the Missouri River, in Montgomery Co., Mo., within one mile of the Pacific Railroad. About 1,500 acres, with 80 acres in vineyards, choice varieties, nearly all in full bearing condition, and trellised. These most valuable vineyards and lands, scarcely equalled in this country, with many buildings and other improvements, formerly the property of the Bluffton Wine Co., will be rented very low to a responsible party. For particulars, terms, etc., address ISIDOR BUSIL, St. Louis, Mo.

A CURIOSITY for old and young. Chain 14 inches long of running rings. Sample sent by mail, postage paid, for 25 cts. Circular sent free. Address WILCOX, CRITTENDEN & CO., Middletown, Ct.

The recent improvements on this machine make it one of the most perfect pieces of mechanism in the world. Every housekeeper in the country should see it, and judge for themselves, since it is now guaranteed to meet every need of the household. Any machine at this price that will knit 20,000 stitches, or 22 inches perfect work, per minute—either in flat web, hollow tube, or circular form, in any plain or fancy stitch that can be done by hand—will certainly be found more useful and convenient in a family than a sewing-machine can possibly be. It is very simple in its operation, and knits any kind of yarn, cotton, linen, silk, or woollen, in plain or fancy stitch of Knitted, Crochet, or Afghan work.

Agents wanted. Send for illustrated circular. Bickford Knitting Machine Co., DANA BICKFORD, Pres. and General Business Sup't, 689 Broadway, New York.

A GOOD PAYING BUSINESS

for Women as well as Men— Honorable and Useful.

Several persons of both sexes, in different parts of the country, devote their chief time to gathering subscribers to the American Agriculturist and to Hearth and Home, and to selling hooks on Agriculture, Horticulture, Gardening, Architecture, etc. (see list on second cover page, and notices of some of them in the advertising pages). For the subscribers obtained they take the Premium Articles offered on page 469, and sell them, as they are all very good, wanted generally, and are readily salable. These Premiums, obtained by the Publishers on special terms, are just as good as money, and give much better pay than could possibly be given in cash commissions. These canvassers, who work during the most favorable seasons, realize from \$300 to \$3,500 a year, according to their tact, experience, etc. Experience goes a great way. Some, who succeeded poorly at first, hardly paying their board, have by persevering practice come to be very successful. The success to be obtained is worthy of long practice. It is certainly quite as honorable and useful to engage in urging people to supply themselves with good reading and useful information, as it is to stand behind a counter and show up, and persuade people to buy, silks, laces, or other goods, or to engage in any other work or business.

BUILDING FELT. This water-proof material, resembling fine leather, is for outside work (no tar substances used) and inside, instead of plaster. Fit carpetings, etc. Send two stamps for circular and samples. C. J. FAY, Camden, N. J.

MOELLER & DAILEY, Landscape Gardeners. Will furnish Plans and Drawings in this line at the shortest notice. Also superintend the work if desired. Best of reference given. Address MOELLER & DAILEY, 170 Broadway, N. Y., Room 59.

Full Descriptions

of our Premiums are given in our last October number, which will be mailed free to applicants. We have room in this paper only for the following **Descriptive Notes**:

Nos. 1, 2, 3.—American Table Cutlery.—We are glad to be able to offer really good articles of American manufacture, such as are competing successfully with the best foreign make. Messrs. Patterson Bros., 27 Park Row, who supply us with these articles, are also importers of English goods. They recommend these Knives, manufactured by the **Meriden Cutlery Co.**, as equal to any Cutlery in the market, and their recommendation is a guarantee, wherever they are known. We offer two kinds of Knives, and three sizes of each kind. No. 1 have Rubber Handles, which are actually boiling-water proof, so that, if they were accidentally to remain in it for several minutes, or even hours, they would not be injured. The Blades are of the best steel, and warranted. Dessert size, with Forks, sold at \$15. For 24 subscribers at \$1.50, or \$0 at \$1, we will give either the medium size or the table size, sold at \$16.00. No. 2 have Ivory Handles, are selected with great care, have Steel Blades, and are beautiful goods. Dessert size, with Forks, sold at \$20.00. For 33 subscribers, at \$1.50, or 110 at \$1, we will send the medium size, sold at \$22.00. For 35 at \$1.50, or 116 at \$1, we will send the Table size, sold at \$23.00. The Forks, which accompany these Premiums, Nos. 1 and 2, are made of genuine Albata, and warranted double-plated with coin-silver. These Forks are furnished to us by Messrs. Patterson Bros. The Carving-Knife and Fork are made by **The Meriden Cutlery Co.**, with the best Ivory, balanced Handles.

Nos. 5, 6, 7, 8.—Pocket Knives.—HERE'S FOR THE BOYS AND GIRLS!—These Premiums are among the most pleasing and useful that we have ever offered. Every boy, and girl too, wants a pocket knife. We give them an opportunity to obtain a most valuable one for merely a little effort. These knives are furnished by the **Meriden Cutlery Co.**, 49 Chambers st., New York, whose work is equal to any done in this country or Europe. No. 5 is a neat, substantial Knife, with three blades and huck-horn handle. No. 6 is a still finer article, with four blades and pearl handle. No. 7 is an elegant Knife, with five blades and shell handle. No. 8 is a Lady's Pocket Knife, a beautiful article, with four blades and shell handle.

No. 9.—Mullum in Parvo Pocket Knife.—This is a most attractive as well as useful Premium, from the well-known manufacturers, **Miller Bros' Cutlery Co.**, West Meriden, Conn. It comprises, in one knife-handle, a large and a small blade, a screw-driver, a saw, a strong hook, a nut-cracker, a brad-awl, a gimlet, a corkscrew, a pointer, a slim punch, tweezers, and, in addition to this, it can be used for various other purposes which will at once suggest themselves to any smart boy or man. It is a pocketful of tools weighing but two ounces. The knives will be sent anywhere in our country, post-paid.

No. 10.—Cake Basket.—A new pattern, oval-shaped, or square, nicely chased—a very taking, useful, and beautiful table ornament. This, with other articles that follow, is made by the **Lucius Hart Manufacturing Co.**, of Nos. 4 and 6 Burling Slip, New York City, and is warranted to them to be of the best triple plate. Mr. Hart, "the veteran Sunday-school man," was engaged in the same place and business for nearly a quarter of a century. We have known him and his work for many years, and have taken pleasure in commending and guaranteeing its value to be as represented. We believe the Company which bears his name is fully sustaining his reputation. The amount of silver upon plated ware depends wholly upon the will and integrity of the manufacturer. We could give nearly as good-looking plated ware for less than half the money.

Nos. 19, 20, 21.—Gold Pens: with ever-pointed Pencils, in extension, coin-silver cases.—Premium No. 19 contains the best No. 4 Gold Pen; and No. 20 the best No. 6 Gold Pen, which is the same style, but larger. No. 21 contains No. 7 Gold Pen, in Gold-tipped Ebony Holder. Each pen will be sent in a neat leather case by mail, post-paid. These pens are made by **Geo. F. Hawkes**, No. 66 Nassau St., and have obtained an excellent reputation. We have known the maker and his goods for many years, and can recommend them.

Nos. 23, 24.—Paragon Patent Revolving Pencil.—This is a beautiful Pocket Pencil, which is extended or closed by pulling or pressing the head. They are made with great care, and every Pencil warranted to work perfectly. They are gold-plated, and will last for years. We offer two patterns, one for ladies, with ring for chain, at \$1.50 each, and one of heavier and firmer plate, at \$3.00. Same maker as No. 19.

No. 25.—Payson's Indelible Ink, and Briggs's Marking-Pen Combination.—Payson's Indelible Ink is too well known to need further commendation. It is almost indispensable in the family. Briggs's Marking-Pen has been before the public for fifteen years, and is justly celebrated for all kinds of marking, and particularly for writing upon coarse fabrics. The Pen and Ink are put up in a neat case, being thus portable, always ready for use, and protected from loss or injury by evaporation or breakage.

No. 27.—Steam-Engine.—This is a veritable steam-engine; one that will GO; and a capital, intensely interesting, and instructive article for boys, and grown-up people too. Our eleven-year-old boy ran his engine an average of an hour or more a day for six months; he exhibited it in motion to many of his playmates, hitched on various toy machinery, and it appeared to go just as well as when first started.

No. 34.—Doty's Improved Clothes Washer, with the Metropolitan Balance Weight. Over seventy-five thousand families in the United States are using the Doty Washing Machine, and we believe the improved machine has no superior. The "help" use it and like it. Send for descriptive circulars to **R. C. Browning**, 32 Cortlandt St., New York, or to **Metropolitan Washing Machine Co.**, Middlefield, Ct. It goes cheaply by freight or Ex.

No. 35.—Universal Clothes Wringer.—A very useful, time-saving, strength-saving, clothes-saving implement, that should be in every family. The wringing of clothes by hand is hard upon the hands, arms, and chest, and the twisting stretches and breaks the fibers with lever power. With the Wringer Machine, the garments are passed rapidly between elastic rollers, which press the water out better than hand wringing, and as fast as one can pick up the articles. We have given thousands of these premiums, with almost universal satisfaction. They are made by the **Metropolitan Washing Machine Co.**, Middlefield, Ct. **R. C. Browning**, 32 Cortlandt st., N. Y.

No. 40.—Ladies' Fine Gold Watch.—This elegant Premium will delight our friends who may receive it. Our arrangement with the **American Watch Co.** (see No. 39 above) includes these beautiful gold watches. They are full-jeweled, in 18-carat "hunting" cases, warranted to be made of the best materials, and possessing every requisite for a reliable Time-Keeper. Upon the movement of each Premium Watch will be engraved "AM. AGRICULTURIST. MADE BY THE AM. WATCH CO., WALTHAM, MASS."

No. 47.—Crandall's Improved Building Blocks furnish a most attractive amusement for children. Churches, Dwellings, Barns, Mills, Fences, Furniture, etc., in almost endless variety, can be built with them, and the structures remain so firm as to be carried about. For developing the ingenuity and taste of children they are unequalled. The Blocks are put up in neat boxes, accompanied by a large illustrated sheet giving various designs of buildings, etc. This is one of the most successful toys ever invented.

No. 48.—B. O. B.—The "Boy's Own Boat"—a Real Toy Steamboat, that will propel itself on the water for over half an hour. This beautiful toy is durably made, elegantly finished, and is just the thing for bath-tubs in winter and ponds and streams in summer. The boat is 18 inches long, and fitted with Ryder's Dollar Steam-Engine and Dodge's Propeller. The engine has a perfect-working safety-valve, whereby any excess of steam passes off. It is one of the most pleasing and instructive toys ever produced. Printed directions for management accompany each boat.

Nos. 76 to 87.—Good Libraries.—In these premiums, we offer a choice of Books for the **Farm, Garden, and Household.** The person entitled to any one of the premiums 76 to 87 may select any books desired from the list of our books published monthly in the *American Agriculturist*, to the amount of the premiums, and the books will be forwarded, Post or Express paid. Let the farmers of a neighborhood unite their efforts, and through these premiums get an agricultural library for general use. See Table List of Books in advertisiog columns.

No. 88.—General Book Premium.—Any one sending 25 or more names, may select books from our list to the amount of 10 cents for each subscriber sent at \$1; or 30 cents for each name sent at \$1.20; or 60 cents for each name at \$1.50. This offer is only for clubs of 25 or more. The books will be sent by mail or express, prepaid through, by us. See List as in No. 76.

No. 89.—Remington's Breech-loading, Single-Barrel Shot-Gun.—This gun has the best quality barrel, 32-in. gauge, No. 16, weight 6½ lbs., using "Draper's" patent brass shells, which can

be reloaded over and over again, and will last nearly as long as the gun. Ordinary gun-caps and wads used in loading. Breech system same as the celebrated Remington's military and sporting guns. This Premium includes gun, with varnished stock, one shell and loader. Price of cartridge shells, \$3.00 per dozen extra. These guns are manufactured by the noted firm of **E. Remington & Sons**, Nos. 281 and 283 Broadway, New York, whose reputation is world-wide, and who stand in the front rank of manufacturers of fire-arms.

A GREAT BOON.

A Good Cheap Sewing-Machine at Last.

We have been offering as a Premium, for some months past, the **Beckwith Sewing Machine**, which was fully described in the *American Agriculturist* for March and April, 1872. We have already given and sold some hundreds of these machines, and testimonials of satisfaction have come from every quarter.

We now offer the **Beckwith Sewing-Machine, Improved**, price \$12. A new and very simple braiding-foot has been made, by which a child can sew on braid without the least trouble, following any desired pattern with ease; also a new arm, spiral spring and lever for raising the presser-foot, all of which are now set in a position that leaves the needle free to be threaded. The joint is much enlarged, and the machine is otherwise greatly strengthened and improved. The use of the braider-foot alone will be valued more than the cost of the machine. This, with the other improvements, is considered so important, that the Beckwith Sewing Machine Company will make no more of the \$10 style. The improved machine is japanned and tastefully ornamented with gold; cloth-plate and trimmings are plated.

SPECIAL POINTS TO OBSERVE—(See "Directions" on inside of cover of each box.)

1. Tension-screw, spring, and discs. See "Directions" No. 6.
2. Thumb-screw that fastens the needle. Also to set needle for long or short stitch, as per "Directions" No. 8.
3. Rubber that goes on to the spindle, but must not touch the spool.
4. Cloth-plate with slot in it, and thumb-screw to fasten hemmer and guide.
5. Presser-foot arm, to which is attached the presser-foot with braider. Also a lever for raising foot. Within the upright portion of arm is a spiral spring that holds the foot firmly to the cloth. To sew on braid, pass the end of braid through the forward opening in presser-foot so it can reach the needle.

We have contracted with the Beckwith Sewing Machine Company for a large number of them to supply our own friends, and as Premiums. Each machine is put in a neat, compact box, with hemmer and guide, oil-can with oil, thread, different-sized needles, etc., with full Printed Directions for using, and delivered to any express office in this city, without extra charge above the \$12. As we buy the machines at wholesale price, we have decided to give our readers some advantage of this, and we therefore propose to make a present for himself or herself, or for any friend, of one copy of *Hearth and Home* for six months, or one copy of the *AMERICAN AGRICULTURIST* for one year, to those persons who send us \$12 for one of the machines while this offer is continued.

The New Sewing Machine as a PREMIUM without Money.

To enable those to get this machine who can not raise even the \$12 to buy it, we make the following offer:

We will send the Machine free to any one who will collect and forward EIGHT subscribers for HEARTH AND HOME one year at \$3 each; or SIXTEEN subscribers to AMERICAN AGRICULTURIST for one year, at \$1.50 each.

Almost any lady can readily secure this small number of subscribers and get a machine free; or some friend can thus obtain it for her, as a present.

Address

ORANGE JUDD & CO., 245 Broadway, N. Y.

JUST PUBLISHED. ROYAL QUARTO. PRICE **TWELVE DOLLARS**, POST-PAID.

THE NATIONAL BUILDER,

A COMPLETE, PRACTICAL, PLAIN, AND VALUABLE WORK ON

CONSTRUCTIVE CARPENTRY.

SHOWING THE SIMPLEST METHODS OF FINDING ALL JOINTS AND GEOMETRICAL FORMS.

INCLUDING

Stair-Building and Hand-Railing,

WHICH IS TREATED IN AN ENTIRELY ORIGINAL MANNER; TOGETHER WITH

DESIGNS FOR STAIRCASES, NEWELS, BALUSTERS, AND HAND-RAILS,

WITH FULL DETAILED EXPLANATIONS, ILLUSTRATED BY NOT LESS THAN

NINETY-TWO PLATES, WITH ONE THOUSAND FIGURES PRINTED IN COLORS, WITH A GLOSSARY,

FOR THE USE OF

ARCHITECTS, BUILDERS, CARPENTERS, AND STAIR-BUILDERS.

By JAMES H. MONCKTON,

AUTHOR OF "THE AMERICAN STAIR-BUILDER."

In the preparation of this work the Author has aimed at the most concise possible explanations. Carpenters have no time for extensive studies, and therefore require a careful selection of what to them will prove of the highest practical utility, the greatest amount of valuable information in the smallest compass. In my judgment, no one is qualified to prepare a really useful book in any department of instruction who does not know by actual labor and experience the practical needs of those whom he seeks to instruct. Many years' experience as a workman, a student, and as a teacher of the subjects treated, have taught the author what is required, and also the best manner of presenting each case so as to make it available to the learner with the least effort and time.

To impart exceedingly valuable information never before published, knowing by experience the need of a complete and practical book on Constructive Carpentry, embracing all modern improvements, is the principal reason that induced the author to undertake this work.

Each drawing has been made and every word written as if no other work of the kind had been published, and yet the author acknowledges, to some extent, his indebtedness, either directly or indirectly, to every original author or mechanic that has preceded him.

The large and simple reference letters, cast expressly for this work, also the two colors of ink used in the accompanying drawings—in this connection unique—can not fail to be appreciated by the student.

Before closing these prefatory remarks, the casual examiner, and more particularly the intelligent student, are requested to give special attention to the following examples and their treatment:

A method of drawing every form of face-mould without ordinates, in connection with which the solids introduced and made use of show an easy practical way of acquiring a knowledge of the principles of hand-railing.—Plates 3 to 8.

A second method, and an example of every kind of face-mould drawn by ordinates.—Plates **D, E, and F.**

The object, application, and use of face-moulds for squaring wreaths.—Plate 9.

Shaping the top and bottom of wreath-pieces by finding correct center lines to work from on the plumb sides of wreath.—Plate **A.**

The proper way to plan and arrange the treads of winding stairs, head-room, etc.—Plate 10.

How to lay out from its edge a string for winders having treads of different widths by the use of the mean tread.—Plate 12, FIG. 2.

Case of hand-rail showing how to make one instead of two wreath-pieces serve every practical purpose. Plate 15, Figs. 10 and 11.

Management of a steamboat stairs and hand-rail.—Plate 16.

Construction of stairs for wholesale stores having close strings, paneling, etc.—Plate 18.

Simple method of controlling and working a flat curved side-wreath mitering to newel-cap.—Plate 20.

Angle newel stairs, designs, plans, and elevations.—Plates 23 and 41.

Bending-strings, building-forms, saw-kerfing, laminated and solid mouldings.—Plate 26.

The true method of planning elliptic stairs.—Plate 32.

Designs for newels and balusters.—Plates **F, G, H, I, J, K, L, M, N, O, P, Q, R, S, T, U, V, W, X, Y, Z,** 39, 40, and 41.

Plans and management of close paneled curved strings with continued hand-rails.—Plates 33 to 36.

Twenty-two complete plans of stairs variously arranged, drawn to a scale, and all their dimensions figured.—Plates 37 and 38.

Design for wainscoting, thirteen forms for hand-rails.—Plate 39.

Design for a floral bower, etc.—Plate 42.

Door-making in detail, including the best hard-wood doors.—Plate 43.

How to make window-frames for brick and wood houses.—Plate 44.

Sash-making, glazing, and hanging.—Plate 45.

To find the form from any given moulding for the face-edge of a revolving cutting-iron.—Plate 57.

Splayed work, of great variety.—Plates 58 to 61.

Pitching planes, a preparatory study to roofing.—Plate 64.

Roofing, giving bevels and lengths of all timbers.—Plates 65 to 69.

French roofs, in detail.—Plates 70 and 71.

Balloon-framing.—Plates 80 to 83.

Without asking further special consideration of the value and uses of the remaining contents, and their manner of presentation, the Author would say in conclusion, that the most of the above features being new, and not before contained in any work on Carpentry, and many of them of very great value, the whole is respectfully submitted with the fullest confidence that the book will gain the approval of all who require the instruction it proffers.

UNIFORM WITH WOODWARD'S NATIONAL ARCHITECT.

ORANGE JUDD & CO., Publishers, 245 Broadway, New York.

Rare and Beautiful Flowers and Choice Vegetables

CAN ALWAYS BE OBTAINED BY SOWING

B. K. BLISS & SONS,
23 Park Place and 20 Murray St., N. Y.
IMPORTERS, GROWERS, AND DEALERS IN
GARDEN, FIELD, & FLOWER SEEDS,
SMALL FRUITS,
Agricultural and Horticultural
Implements,
Fertilizers, and Other Requisites for the
Farm and Garden.

The Nineteenth Annual Edition of their celebrated Seed Catalogue and Amateur's Guide to the Flower and Kitchen Garden will be ready for distribution early in January, and mailed to our customers of 1872 as rapidly as possible, and to all applicants upon receipt of 25 cents, an edition beautifully bound in cloth, 75 cents. This is without exception the largest and best Catalogue ever published in this or any other country. It will contain nearly 200 pages, including many finely executed engravings of favorite flowers and vegetables, and a beautifully colored chromo of a group of twenty of the most popular flowers in cultivation. Also a descriptive list of 2,500 species and varieties of flower and vegetable seeds, including all the novelties of the past season, with full directions for culture.
Address **B. K. BLISS & SONS,**
P. O. Box 5,712, New York City.

My business is to supply what every good farmer is anxious to get, the very best of vegetable seed. I grow a hundred and fifty kinds on my four seed farms, right under my own eye, making new vegetables a specialty, besides importing their choicest varieties from European growers. A fine selection of flower-seed, home-grown and imported, will also be found in my Catalogue. It will be ready by January, and sent free to all applicants. My customers of last year will receive it without writing for it.

FOR ALL KINDS OF

SEWING MACHINES.

Saves half the labor, can not turn the wrong way, consequently does not tangle the thread, break the needles, and damage the machine. A child can run any machine with Cowles's Treadle. It saves half the labor, and avoids the heel-and-toe motion which destroys the nervous system and is so injurious that physicians forbid its use to many. Makes the hardest machine run so easy that one is astonished. Gives complete control at fast or slow speed with the feet alone, so that both hands are free to hold the work, and no starting the wheel with hands. In 12 weeks this Treadle has gained a notoriety unparalleled, and the sales are immense. We have thousands of certificates, both from physicians and operators, testifying in the strongest terms. Send for circulars. Territory for sale.

HOLMES & CO., 7 Murray St., New York.

ORANGE JUDD & COMPANY, 245 BROADWAY, NEW YORK.

READ THE NEW BOOK
ON
Farm - Gardening
AND
SEED - GROWING.

BY FRANCIS BRILL.

NOTICES BY THE PRESS.

Orange Judd & Co. have added to their splendid catalogue of agricultural books "Farm-Gardening and Seed-Growing," by Francis Brill; it is practical, plain, complete, and satisfactory, so that for a small amount of money a great deal of desirable information can be obtained. If there is any firm anywhere which is to-day disseminating so much knowledge in regard to tilling of the soil as this same said firm of Orange Judd & Co., we will present a medal to our informer.—*Watchman and Reflector* (Boston).

The want occasionally expressed to us of a work on the cognate subjects above named (Farm-Gardening and Seed-Growing), is now met in a book under this title from the pen of Mr. Francis Brill, formerly a market-gardener and seed-grower at Newark, N. J., and at present engaged in raising seeds at Mattituek, L. I. Its directions are concise and practical, covering those points on which a beginner is most likely to require information.—*Country Gentleman*.

Mr. Brill has had large experience, and derived his knowledge wholly from the school of actual tests.—*Chicago Evening Journal*.

We have in this volume the results of a practical man's experience in raising root crops and other vegetables in the market-garden. Not only the professional seed-grower and trucker, but the amateur gardener who has a little patch in his suburban home, will find many a valuable hint and direction in this full and comprehensive manual.—*Sunday-School Times*.

It seems to be a very sensible, practical work by a practical man. Mr. Brill's father was a gardener; and he himself has had an extensive experience, and he talks about what he knows, which is more than can be said of many authors of industrial works.—*Moore's Rural New Yorker*.

There can be no question that this farm-gardening can be made in many districts of the Southern Atlantic States, especially near the coast, far more profitable than growing the ordinary staple crops. In connection with producing the vegetables, the growing and saving their seeds receive minute attention.—*American Farmer* (Baltimore).

A very useful hand-book, not merely for farmers and growers of seed on an extensive scale, but for all who, whether for recreation or for the purpose of supplying their own families with garden products, desire to know something about the adaptation of seed to soil and the mode of culture.—*Church Journal* (New York).

This industry is now occupying the attention of many persons who sell their products to the great seed-houses, and novices who have the facilities, and wish to enter upon the business, will find in this book just the hints needed.—*Springfield Republican*.

Mr. Brill has been a successful farm-gardener and seed-grower for a number of years, and gives in a clear and concise form the knowledge he has gained. . . . It gives the best method of manuring, planting, and cultivating every vegetable sold in markets—in short, everything required to be known, plainly and fully—and should be in the hands of every one who cultivates so much as a rod of land, for family use, pleasure, or profit.—*Suffolk* (L. I.) *Times*.

The seal of Orange Judd & Co. upon an agricultural publication is sufficient guarantee of its worth. Francis Brill's book, published by them, is a very complete work, giving plain, minute instructions as to raising, taking care of, and bringing to market those vegetables which are most in demand in the large cities, and those seeds which are being called for throughout the country.—*N. Y. Evening Mail*.

The work of showing how this can be accomplished has fallen in good hands, and it has been done well. The book will well repay perusal, and we hope soon to see its good effects in a more intelligent direction of farm industry, and accompanied by more satisfactory pecuniary results.—*The Signal* (L. I.)

To the market-gardener, or even the owner of a small piece of tillable land, this book will be of great value. Qualities of soil required for the growth of different vegetables, how to plant, how to cultivate, to harvest and preserve during winter.—*N. Y. Citizen and Round Table*.

Price, Post-paid, \$1.00.

The Prairie Farmer FOR 1872-'73!

THE PRAIRIE FARMER, now almost entering upon the thirty-third year of its usefulness, is the most popular and pre-eminently the best Western farm and fireside journal. It is **original, reliable, and comprehensive**, each number presenting a **rich variety** of instructive and entertaining matter. Issued **weekly**, its contents are always **fresh and seasonable**, and notwithstanding its present high standard of excellence, the publishers are warranted in promising that it shall be a **better paper** next year than ever before. Though designed especially to meet the wants of Western, North-western, and Southern farmers and industrial men, and their families, it is also **just what is needed** by the thousands of people at the East who contemplate "going West," and hence wish to know all about Western farming, fruit-growing, tree-planting, cost of land, improved and unimproved, character of soil and climate, mode of cultivation, average yield, etc., etc.

Now is the Time to Subscribe!

Because for the purpose of introducing **THE PRAIRIE FARMER** into households where it is not now taken we make the following **liberal offer**—viz.: To every new subscriber to **THE PRAIRIE FARMER**, for the year 1873, whose name, accompanied by **TWO DOLLARS**, is received after this date and prior to January next, we will send the paper the **remainder of 1872, gratis**. That is, subscriptions will date from the time received, and expire January 1st, '73! Therefore, if you subscribe **now**, you will receive **THE FARMER thirteen months** at the regular price for a year, and the **sooner you subscribe the more you will get for your money!**

Now is the Time to Get Subscribers!

Because you can reap the benefit of the foregoing offer of the rest of the year free to new subscribers for 1873, by presenting it as an inducement, and thereby be enabled to secure a larger club in less than **half the time** than if you waited until the close of the year. Besides, "**the early bird catches the worm**," and if you go to work **now** you will have a comparatively clear field, and readily secure many subscriptions which a few weeks later will, perhaps, have been given to some other journal. Therefore, we call upon all our old Agents and friends everywhere, as well as new ones, to begin the canvass **immediately and in earnest**, and let us have a lively, vigorous, and successful campaign.

You Don't Work for Nothing!

Remember that our **New Premium List**, now ready, in pamphlet form, embraces over **One Hundred Attractive and Useful Articles**, offered on most desirable terms, and also that Agents who prefer it, may retain, in remitting, a **Cash Commission of Twenty per Cent**. Sample copies of the paper, and other canvassing documents, are ready, and furnished **free** on application. Send for them and go to work. Address

THE PRAIRIE FARMER COMPANY, Chicago.

THE COMPANION aims to be a favorite in every family—looked for eagerly by the young folks, and read with interest by the older. Its purpose is to interest while it amuses; to be judicious, practical, sensible; and to have really permanent worth, while it attracts for the hour.

It is handsomely illustrated, and has for contributors some of the most attractive writers in the country. Among these are:

- Prof. James De Mille, Louise C. Moulton
- Louisa M. Alcott, "Sophie May,"
- Grace Greenwood, C. A. Stephens,
- Rebecca H. Davis, Ruth Chesterfield,
- C. W. Flanders, M. A. Denison,
- S. S. Robbins, Prof. H. Lincoln.

Its reading is adapted to the old and young, is very varied in its character; sprightly and entertaining. It gives

- Stories of Adventure, Stories of Home and
- Letters of Travel, School Life,
- Editorials upon Cur- Tales, Poetry,
- rent Topics, Selections for Decla-
- Historical Articles, mation,
- Biographical Sketches, Anecdotes, Puzzles,
- Religious Articles, Facts and Incidents.

Subscription Price, \$1.50. Specimen copies sent free. Address

PERRY MASON & CO.,
41 Temple Place, Boston, Mass.

THE NEW ILLUSTRATED PEOPLE'S WEEKLY, has in two weeks fixed itself firmly in public favor.

Its novel and striking features and splendid illustrations have helped to this result; but, in addition, the gift of the charming and remarkable oil chromo.

"JUST SO HIGH,"

has proved irresistible. Agents are having unheard-of success, one taking four hundred names in two weeks, another two hundred and eighty in some time, one one hundred and ten the first week, etc., etc.

All pronounce this great combination the best chance for money-making offered this winter. Lose no time in securing territory. Circulars and terms FREE.

DICK'S

Encyclopedia of **practical Receipts and Processes.**

CONTAINING OVER

6,400 RECEIPTS,

Embracing thorough information, in plain language, applicable to almost every possible industrial and domestic requirement.

By **WILLIAM B. DICK.**

607 pages, royal octavo, printed on fine-tinted, sized, and pressed paper. Bound in cloth, price \$5.00; sheep, \$6.00; arabesque, \$6.00; half-calf, extra, \$8.50.

This work is a comprehensive Book of Reference for the Merchant, Manufacturer, Artisan, Amateur, and Housekeeper, embracing valuable information in the Arts, Professions, Trades, Manufactures, including Medicine, Pharmacy, and Domestic Economy.

It would be difficult to find any one of the 6,422 paragraphs in this work (many of which contain several receipts) that is not worth at least the price of the book to the person desiring to apply it. A great number of them are original contributions prepared expressly for the Encyclopedia, or are to be found only in rare and costly works. Prominent among the immense mass of subjects treated of in the book are the following:

- Tanning. The Art of Dyeing. Alcohol and Alcolometry.
- Distillation. Metals and Alloys. Petroleum and Kerosene.
- Brewing. Patent Medicines. Bleaching and Cleaning.
- Syrups. Medical Receipts. Sauces, Catsups, and Pickles.
- Cements, etc. Imitation Liquors, Cid r and Vinegar. Receipts for the Garden.
- Waterproofing. Perfumery, Cosmetics. Pyrotechny and Explosives.
- Artificial Gems. Flavouring Essences, etc. Inks and Writing Fluids.
- Aufline Colors. Hair Dyes and Washes. Paints and Pigments.
- Lubricators. Tooth Powders, etc. Palating and Paper-hanging.
- Photography. * * * The above book is for sale everywhere, and will be sent by mail to any address, free of postage, upon the receipt of price. Send all orders to

DICK & FITZGERALD, Publishers, New York.

Wood's Household Magazine

Is an original, first-class, Dollar Monthly. It is fresh and sprightly, and will interest the entire household, including lovers and maidens, husbands and wives, parents and children. It suggests the importance of securing a union of hearts and purposes in life, before there shall be a union of hands. It believes that, while it is woman's privilege to purify and comfort and adorn, it should be man's pleasure to provide for, cherish, and protect. It would have children treated as feeling, thinking and growing creatures—perfectly created, but not full grown. Yet in advocating these doctrines, the Magazine does not employ doctrinal sermons—long and dreary disquisitions which do not interest and therefore do not impress the reader. On the contrary, it would rather preach as though it preached not—an interesting story, for instance, being made to serve the purpose of a long discourse by giving the reader something real, interesting and profitable to think about.

The worst as well as the best feature of the Magazine is its price. The idea of getting a really first-class Magazine at one dollar a year, seems absurd to most people. Yet it employs some of the best contributors in the country—including Gail Hamilton, its leading editor, who receives a salary of three thousand dollars, equivalent to about ten dollars per day. Each number contains nearly eight hundred dollars' worth of matter, which costs the subscriber about eight cents.

Hope and Joy—two beautifully tinted crayon portraits worth Four Dollars, will be mailed free to every subscriber to the Magazine at \$1.50 Specimens free. Agents wanted. Address S. S. WOOD & CO., Newburgh, N. Y.

Hope and Joy--Hope and Joy

United Voice of the Press.—Wood's Magazine is one of the monuments of business enterprise which mark the age.—Methodist Home Journal, Phila., Pa. ... As its title promises, it is devoted to the instruction and entertainment of the family circle, and in order to place it within the means of readers in moderate circumstances, it is furnished at a remarkably low rate in proportion to the interest of its contents.—N. Y. Tribune. ... It is essentially a home magazine, and is just the thing that one would most desire to place in the hands of his wife and little ones, or that a man of business would himself take up for the enjoyment of a leisure hour.—Post Wilmington, N. C. ... Were we out of our chair editorial, as a "private citizen," cut off from our exchange list and all that, one of the first magazines to which we should subscribe would be Wood's Household.—Register, Hartford, Ct. ... It is an intellectual and moral educator, highly prized by all who become acquainted with it.—Christian Advocate. ... If popular writers are, therefore, good writers, and if high prices prove the merit of literary wares, then Mr. Wood's magazine is a good one.—The Independent, New York. ... Its articles breathe a spirit of economy, morality and virtue which is highly refreshing in this age of fashionable folly and extravagance.—Sentine, Edina, Mo. ... It is undoubtedly one of the freshest, liveliest journals we have examined.—Record, Springfield, Tenn. ... The articles are short, piquant, and of such unquestioned excellence, that this periodical ought to be both familiar and welcome in very many households. Wood's is a marvel of cheapness and first-class quality combined.—New York Times.
